Install the UNIX and Linux backup-archive clients

This section provides instructions to install and set up IBM Spectrum Protect™ UNIX and Linux clients.

Note: You must log on as the root user to install the backup-archive client on a UNIX or Linux workstation.

The supported UNIX and Linux clients and the location of the installation instructions for each client are listed here.

- AIX Installing the AIX client
  You can install the AIX® backup-archive client from the product installation media.
- AIX Uninstalling the AIX client
  You can use the following procedures to uninstall the IBM Spectrum Protect AIX backup-archive client.
- Installing the HP-UX Itanium 2 API
  You can install the HP-UX Itanium 2 API from the product installation media.
- Uninstalling the HP-UX Itanium 2 API
  You can use the following procedures to uninstall the IBM Spectrum Protect HP-UX Itanium 2 API.
- Linux Installing the backup-archive client on Linux on Power Systems (Little Endian)
  You can install the backup-archive client from the product installation media.
- Linux Uninstalling the backup-archive client on Linux on Power Systems (Little Endian)
  You can uninstall the IBM Spectrum Protect client on Linux on Power Systems™ (Little Endian).
- Linux Installing the backup-archive client on Ubuntu Linux on Power Systems (Little Endian)
  You can install the backup-archive client from the product installation media.
- Linux Uninstalling the client on Ubuntu Linux on Power Systems (Little Endian)
  You can uninstall the IBM Spectrum Protect backup-archive client on Ubuntu Linux on Power Systems (Little Endian).
- Linux Installing the API on Linux on Power Systems (Big Endian)
  You can install the IBM Spectrum Protect API from the product installation media.
- Linux Uninstalling the API on Linux on Power Systems (Big Endian)
  You can uninstall the IBM Spectrum Protect API on IBM Spectrum Protect Linux on Power Systems (Big Endian).
- Linux Installing the Linux x86_64 client
  You can install the Linux x86_64 backup-archive client from the product installation media.
- Linux Uninstalling the Linux x86_64 client
  You can use the following procedure to uninstall the IBM Spectrum Protect Linux x86_64 client.
- Linux Installing the Ubuntu Linux x86_64 client
  You can install the Ubuntu Linux 64-bit backup-archive client from the product installation media.
- Linux Uninstalling the Ubuntu Linux x86_64 client
  Use the following procedure to uninstall the IBM Spectrum Protect Ubuntu Linux 64-bit client.
- Linux Installing the Linux on System z client
  You can install the Linux on System z® backup-archive client from the product installation media.
- Linux Uninstalling the Linux on System z client
  You can use the following procedures to uninstall the IBM Spectrum Protect Linux on System z client.
- Mac OS X Installing the Mac OS X client
  You can install the IBM Spectrum Protect Mac OS X backup-archive client from the product installation media.
- Mac OS X Uninstalling the Mac OS X client
  You can uninstall the IBM Spectrum Protect Mac OS X client if you no longer need it.
- Solaris Installing the Oracle Solaris x86_64 client
  You can install the IBM Spectrum Protect Oracle Solaris x86_64 backup-archive client from the product installation media.
- Solaris Uninstalling the Oracle Solaris x86_64 client
  You can uninstall all the packages that are related to IBM Spectrum Protect Oracle Solaris x86_64 client, including the command-line, GUI, web GUI, and administrative client components.
- Solaris Installing the Oracle SPARC API
  You can install the IBM Spectrum Protect Oracle Solaris SPARC API from the product installation media.
- Solaris Uninstalling the Oracle Solaris SPARC API
  You can uninstall all the packages that are related to IBM Spectrum Protect Oracle Solaris SPARC API.
- AIX Linux Mac OS X Solaris Software updates
  Software updates might periodically be made available by IBM® for download.

AIX

Installing the AIX client

You can install the AIX® backup-archive client from the product installation media.

About this task

In IBM Spectrum Protect™ Version 8.1.2, a 64-bit version of the AIX client is provided in the distribution libraries. You cannot upgrade a previously installed 32-bit AIX client to new the 64-bit AIX client. If you have a 32-bit client that is installed from a previous version of IBM Spectrum Protect, use SMIT to perform the following steps:

1. Uninstall the 32-bit client (tivoli.tsm.client.ba).
2. Uninstall any national language files that were previously installed.
3. Uninstall the API (tivoli.tsm.client.api.32bit).

Next, use SMIT to install the following packages in the IBM Spectrum Protect V8.1.2 distribution libraries, in the following order:

1. Install the 64-bit API (tivoli.tsm.client.api.64bit).
2. Install the 64-bit client (tivoli.tsm.client.ba.64bit).

If you already have a 64-bit IBM Spectrum Protect V6.3 (or newer) client installed, you can upgrade the client instead of uninstalling it and reinstalling it.

If you have a 64-bit client from an earlier version of IBM Spectrum Protect installed (for example, V6.1, or V6.2) you must uninstall the client, language packs, and API. Then, install the new IBM Spectrum Protect API and client.

All of the packages that are needed to install the client are in the AIX client package, and they overwrite any older runtime applications on your system during installation. The LibC (C Set ++) runtime library is required.

When you use the installp command to install this client, do not change the default field values for the following two choices:

- AUTOMATICALLY install requisite software?
- OVERWRITE same or newer versions?

Disabling or changing the values allows a lower-level client component to install over a currently higher installed component. Under such circumstances, function calls between components at different levels might not be valid any longer.

Install the following packages. They are all provided on the installation media. You need an Extended Edition license to use the NAS client.

The following files are listed in order of dependency. For example, the API is dependent on the Global Security Kit (GSKit). When you install all of them using SMIT, you can select them (F7) in any order.

GSKit8.gskcrypt64.ppc.rte and GSKit8.gskssl64.ppc.rte
: IBM® GSKit 64-bit (required by the 64-bit client API).

tivoli.tsm.client.api.64bit
: Installs the 64-bit API.

tivoli.tsm.client.ba.64bit
: Installs the following 64-bit client files:

  - Backup-archive Java™ client (GUI)
  - Backup-archive web client
  - NAS backup client

tivoli.tsm.filepath_aix
: Installs the file path kernel extension that is required for journal-based backup.

tivoli.tsm.client.jbb.64bit
: Installs the journal-based backup component.

Each package is installed in the following default installation directory:

- The backup-archive, web client, and administrative client (dsmadmc) 64-bit files are installed in the `/usr/tivoli/tsm/client/ba/bin64` directory.
- The IBM Spectrum Protect 64-bit API files are installed in the `/usr/tivoli/tsm/client/api/bin64` directory.
- The sample system-options file, dsm.sys.smp, is placed in the installation directory.

This installation procedure can be used to install new distributions or updates from downloaded installation media. The downloaded files that you use to install the client might be compressed. Depending on the package file format, either copy or extract the files to disk and use these instructions to install the components.

You can download the appropriate package file from one of the following websites:

- Download the client package from Passport Advantage or Fix Central.
- For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.

If you are copying the client files into a local directory first, a .toc file is automatically created by the installp command. You can create a .toc file manually by running /usr/sbin/inutoc in the local directory to which you copied the IBM Spectrum Protect image. From the AIX command line, enter:

```
/usr/sbin/inutoc /usr/sys/inst.images
```

A .toc file is created in that directory.

Procedure

1. Log in as the root user.
2. Mount the volume that you are installing from.
3. From the AIX command line, type `smitty install` and press Enter.
4. Select Install and Update Software and press Enter.
5. Select Install and Update From ALL Available Software and press Enter.
6. At the `INPUT device/directory for software` prompt, press the F4 key and specify the directory that contains the installation images, and press Enter.
7. At the `SOFTWARE to install` prompt, press the F4 key. Select the IBM Spectrum Protect file sets you want to install by pressing the F7 key. Then, press the Enter key.
8. On the Install and Update From ALL Available Software panel, press the F4 key to change any entry fields, or use the default fields. Press Enter twice to begin the installation.
9. After the installation completes, press F10 to exit.

Results

When file sets are installed, they are automatically committed on the system. The previous version of backup-archive client software is replaced by the newly installed version.

The backup-archive client files are installed in the /usr/tivoli/tsm/client/ba/bin64 directory. If you move the client files to another directory, you must perform the following steps:

1. Make sure that the permissions of the installed files have not changed.
2. Update the symbolic links for the installed files in the following directories:
   - The /usr/bin directory
   - The /usr/lib directory for IBM Spectrum Protect libraries
3. Ensure that every user of the backup-archive client sets the DSM_DIR environment variable to the newly installed directory.

What to do next

After the installation completes, see Configure the IBM Spectrum Protect client for required and optional tasks to complete before you use the backup-archive client.

Note:

- AIX workload partitions (WPAR) are supported as follows:
  - Supported in global environments
  - Supported with non-shared system WPARs
  - Supported with shared system WPARs (backup-archive client logs and configuration files must be defined to non-default locations)
  - No support for application WPARs
  - No support for image backup
  - No support for backup set restore from tape
- On AIX Version 6.1, if you are using encrypted file systems (EFS) with the backup-archive client, and if the EFS user keystore password is different from the user login password, the EFS keystore is not automatically opened when you log on. If the EFS keystore is not open when you log on, the client might not restore a non-EFS file into an EFS file system. You can prevent the EFS file system restore problem one of the following ways:
  - Start the backup-archive client by using the efskeymgr -o command. For example: efskeymgr -o ./dsmj
  - Synchronize the keystore password with the user login password by using the efskeymgr -n command. For example: efskeymgr -n

AIX

Uninstalling the AIX client

You can use the following procedures to uninstall the IBM Spectrum Protect™ AIX® backup-archive client.

Before you begin

IBM Spectrum Protect client modules and components are tightly integrated and installed file sets are automatically committed. There is no option for rollbacks of uninstalled components.

Procedure

1. Enter the following AIX command: smitty remove.
2. Press the ENTER key.
3. In the SOFTWARE name field, press F4 to list the IBM Spectrum Protect file sets that you want to uninstall; press the ENTER key.
4. Select the IBM Spectrum Protect file sets that you want to uninstall; press the ENTER key.
   Note: The journal-based backup feature is contained in two file sets. Select both tivoli.tsm.client.jbb.64bit and tivoli.tsm.filepath_aix. If you uninstall the file sets one at a time, uninstall the tivoli.tsm.client.jbb.64bit file set first.
5. In the PREVIEW only? field (the remove operation does not occur), select No; press the ENTER key.

Installing the HP-UX Itanium 2 API

You can install the HP-UX Itanium 2 API from the product installation media.

About this task

The following source packages are available on the installation media:

`tsmcli/hp11ia64/gskcrypt64-8.x.x.x.hpux.ia64.tar.Z` and `tsmcli/hp11ia64/gskssl64-8.x.x.x.hpux.ia64.tar.Z`
: Contains the GSKit. If you have a previous version of the GSKit, uninstall it before you install the new version.

`tsmcli/hp11ia64/TIVsmCapi64`
: In this package, the software selection name that is used by swlist for the top-level product name is `TIVsm64`. The component under `TIVsm64` is `TIVsm.CLIENT_API64`.

Default installation directories

Here are the default directories where some files are stored as part of the client installation:

- The IBM Spectrum Protect™ API files are installed in the `/opt/tivoli/tsm/client/api/bin64` directory.
- The sample system-options file, `dsm.sys.smp`, is placed in the installation directory.

To remove previous backup-archive client versions, log in as the root user and enter the following command:

```
/usr/sbin/swremove -x mount_all_filesystems=false -v TIVsm64
```

If you installed additional languages in a Version 7.1.2 or earlier client, run the following command to remove them:

```
/usr/sbin/swremove -x mount_all_filesystems=false -v TIVsm64.CLIENT_msg_lang
```

Replace *lang* with the appropriate language code from Table 1.

Table 1. HP-UX Itanium 2 client: Language codes for installation packages

Language	Language code
Simplified Chinese	ZH_CN
Traditional Chinese	ZH_TW
Czech	CS_CZ
French	FR_FR
German	DE_DE
Hungarian	HU_HU
Italian	IT_IT

Language	Language code
Japanese	JA_JP
Korean	KO_KR
Polish	PL_PL
Brazilian Portuguese	PT_BR
Russian	RU_RU
Spanish	ES_ES

This installation procedure can be used to install new distributions or updates from downloaded installation media. The downloaded files that you use to install the client might be compressed. Depending on the package file format, either copy or extract the files to disk and use these instructions to install the components.

You can download the appropriate package file from one of the following websites:

- Download the client package from Passport Advantage or Fix Central.
- For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.

Procedure

1. Log in as the root user.
2. Mount the volume that you are installing from.
3. To install GSKit: If you have a previous version of GSKit installed, remove it before you install the new version. Extract the contents of gskcrypt64-8.x.x.x.hpux.ia64.tar.Z and gskssl64-8.x.x.x.hpux.ia64.tar.Z to a directory on your hard disk. Enter the following commands to install the packages:

   ```
   /usr/sbin/swinstall -x mount_all_filesystems=false -v -s `pwd`
     /gskcrypt64 gskcrypt64
   /usr/sbin/swinstall -x mount_all_filesystems=false -v -s `pwd`
     /gskssl64 gskssl64
   ```

4. If you downloaded from FTP, go to the directory where the installable image is located. Enter the following command:

   ```
   /usr/sbin/swinstall -x mount_all_filesystems=false -v -s `pwd`/TIVsmCapi64 TIVsm64
   ```

   `pwd` can be used instead of the absolute name of the current directory.

- Increasing the default limit of the data segment size
  The default limit of the data segment size of a process in HP-UX 11i v2 is 64 MB. When backing up large file systems, the API might exceed this limit and run out of memory.

Related concepts:
Configure the IBM Spectrum Protect client

Uninstalling the HP-UX Itanium 2 API

You can use the following procedures to uninstall the IBM Spectrum Protect™ HP-UX Itanium 2 API.

Before you begin

Important: Make sure that you uninstall the packages in the order shown.

Procedure

1. To remove the CLIENT_API file set, enter the following command:

   ```
   /usr/sbin/swremove -x mount_all_filesystems=false -v TIVsm64
   ```

2. To remove the Global Security Kit (GSKit), enter the following commands:

   ```
   /usr/sbin/swremove -x mount_all_filesystems=false gskssl64
   /usr/sbin/swremoveswremove -x mount_all_filesystems=false gskcrypt64
   ```

What to do next

After you uninstall the HP-UX API, several empty directories remain in the file system, such as the following directories:

- The license directory (/opt/tivoli/tsm/license)
- One or more language directories (/opt/tivoli/tsm/client/ba/bin/xx_XX), where xx_XX represents one of the following language codes: `cs_CZ, de_DE, es_ES, it_IT, fr_FR, hu_HU, ja_JP, ko_KR, pl_PL, pt_BR, ru_RU, zh_CN and zh_TW`
- /opt/tivoli/tsm/client/ba/bin/cit
- /opt/tivoli/tsm/client/ba/bin/images
- /opt/tivoli/tsm/client/ba/bin/plugin

If you want to remove these empty directories, you can manually remove them.

Linux

Installing the backup-archive client on Linux on Power Systems™ (Little Endian)

You can install the backup-archive client from the product installation media.

Before you begin

You must be logged in as root user to install the product.

This installation procedure can be used to install new distributions or updates from downloaded installation media. The downloaded files that you use to install the client might be compressed. Depending on the package file format, either copy or extract the files to disk and use these instructions to install the components.

You can download the appropriate package file from one of the following websites:

- Download the client package from Passport Advantage or Fix Central.
- For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.

About this task

The following installation options are available in uncompressed packages on the installation media.

Table 1. Package names, contents, and default directory

Package Name	Contents	Default directory
gskcrypt64-8.x.x.x.linux.ppcle.rpm gskssl64-8.x.x.x.linux.ppcle.rpm	64-bit Global Security Kit (GSKit) packages	/usr/local/ibm/gsk8
TIVsm-API64.ppc64le.rpm	Application programming interface (API), which contains the shared libraries and samples for the IBM Spectrum Protect™ API.	/opt/tivoli/tsm/client/api/bin64

Package Name	Contents	Default directory
TIVsm-BA.ppc64le.rpm	Backup-archive client (command-line and GUI), administrative client (dsmadmc), and the web client.	/opt/tivoli/tsm/client/ba/bin This directory is typically the default installation directory for many backup-archive client files. The sample system-options file (dsm.sys.smp) is written to this directory. If you do not set the DSM_DIR environment variable, the dsmc executable file, the resource files, and the dsm.sys file are stored in this directory. If you do not set the DSM_CONFIG environment variable, the client user-options file must be in this directory. If you do not set the DSM_LOG environment variable, the backup-archive client writes messages to the dsmerror.log and dsmsched.log files in the current working directory.
TIVsm-APIcit.ppc64le.rpm TIVsm-BAcit.ppc64le.rpm	These files provide the Common Inventory Technology components that you can use to obtain information about the number of client and server devices that are connected to the system, and the utilization of processor value units (PVUs) by server devices. These files are optional. For more information about PVUs, see Estimating processor value units in the IBM Spectrum Protect server documentation.	APIcit is installed in /opt/tivoli/tsm/client/api/bin64/cit BAcit is installed in /opt/tivoli/tsm/client/ba/bin/cit
TIVsm-filepath-source.tar.gz TIVsm-JBB.ppc64le.rpm	Files that are needed for journal-based backups.	The filepath and TIVsm-JBB packages are only required if you plan to use journal-based backups. Filepath is installed in /opt/filepath The TIVsm-JBB.ppc64le.rpm package is installed in /opt/tivoli/tsm/client/ba/bin.

Procedure

1. Mount the volume that you are installing the packages from.
2. Change to the directory where the installation packages are stored.
3. Install the 64-bit GSKit packages. In the following command example, the "8.x.x.x" characters represent the GSKit version:

   ```
   rpm -U gskcrypt64-8.x.x.x.linux.ppcle.rpm gskssl64-8.x.x.x.linux.ppcle.rpm
   ```

4. Install the IBM Spectrum Protect API, and optionally install the Common Inventory Technology package that is necessary to support processor value unit (PVU) calculations.
   a. Required: Install the API:

      ```
      rpm -ivh TIVsm-API64.ppc64le.rpm
      ```

b. Optional: Install the Common Inventory Technology package that is used by the API. This package depends on the API so it must be installed after the API package is installed.

```
rpm -ivh TIVsm-APIcit.ppc64le.rpm
```

Tip: If you are upgrading the API and the Common Inventory Technology package was previously installed, you must upgrade both the API and Common Inventory Technology packages. For example, you can run the following command:

```
rpm -U TIVsm-API64.ppc64le.rpm TIVsm-APIcit.ppc64le.rpm
```

If you need only the API installed, you can stop here. The rest of the steps in this procedure describe how to install the backup-archive client components and an optional client package that is needed only if you want the client to send PVU metrics to the server. Also described in subsequent steps are the installation of the packages that are needed if you want to perform journal-based backups.

5. Install the backup-archive client, and optionally install the Common Inventory Technology package that is necessary to support processor value unit (PVU) calculations.
   a. Install the backup-archive client components.

   ```
   rpm -ivh TIVsm-BA.ppc64le.rpm
   ```

   b. Optional: Install the Common Inventory Technology package the client uses to send PVU metrics to the server. This package depends on the client package so it must be installed after the client package is installed.

   ```
   rpm -ivh TIVsm-BAcit.ppc64le.rpm
   ```

6. Optional: If you want to use journal-based backups, install the packages that are needed for the filepath component and journal-based backups.
   a. Extract TIVsm-filepath-source.tar.gz and see the README file for compile and install instructions. The filepath kernel module is licensed pursuant to the terms of the GNU General Public License ("GPL").
   b. Install the journal-based backup package:

   ```
   rpm -ivh TIVsm-JBB.ppc64le.rpm
   ```

Related concepts:
Configure the IBM Spectrum Protect client

Linux

Uninstalling the backup-archive client on Linux on Power Systems (Little Endian)

You can uninstall the IBM Spectrum Protect™ Linux on Power Systems™ (Little Endian).

Before you begin

You must be logged in as root user to uninstall the product. You must uninstall the packages in the order that is shown, otherwise the uninstallation fails.

Procedure

To uninstall the backup-archive client, enter the following commands to remove the packages for journal-based backup, the filepath component, the backup-archive client, the API, and the IBM Global Security Kit (GSKit).

Tip: The version number of the packages is not required.

1. To uninstall the journal-based backup components only, remove both packages (journal-based backup and filepath). The TIVsm-JBB package is dependent on the filepath package. If you use two separate rpm -e commands to uninstall the components one at a time, uninstall the TIVsm-JBB package first.

   ```
   rpm -e TIVsm-JBB TIVsm-filepath
   ```

2. Uninstall the backup-archive client package:

   ```
   rpm -e TIVsm-BA
   ```

3. Uninstall the backup-archive client packages:

a. If you installed the client common inventory package (TIVsmBAcit), uninstall it:

```
rpm -e TIVsm-BAcit
```

b. Uninstall the backup-archive client package:

```
rpm -e TIVsm-BA
```

4. Uninstall products that are dependent on the API, such as IBM Spectrum Protect for Databases and IBM Spectrum Protect for Mail. Any API-dependent products must be uninstalled before you uninstall the API package. If you uninstall an API-dependent product, you must reinstall it after you install a newer version of the backup-archive client and API packages. Follow the instructions of the API-dependent products to determine what you need to do to prevent data loss when you uninstall and reinstall the products.
5. Uninstall the API package by using the following command:

```
rpm -e TIVsm-API64
```

6. Uninstall the API packages:
   a. If you installed the API common inventory package (TIVsm-APIcit), uninstall it:

```
rpm -e TIVsm-APIcit
```

   b. Uninstall the API package by using the following command:

```
rpm -e TIVsm-API64
```

7. Uninstall GSKit by entering the following command:

```
rpm -e gskcrypt64 gskssl64
```

Installing the backup-archive client on Ubuntu Linux on Power Systems™ (Little Endian)

You can install the backup-archive client from the product installation media.

Before you begin

You must be logged in as the root user to install the product.

This installation procedure can be used to install new distributions or updates from downloaded installation media. The downloaded files that you use to install the client might be compressed. Depending on the package file format, either copy or extract the files to disk and use these instructions to install the components.

You can download the appropriate package file from one of the following websites:

- Download the client package from Passport Advantage or Fix Central.
- For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.

About this task

The following installation packages are available on the installation media.

Table 1. Package names, contents, and default directory

Package Name	Contents	Default directory
gskcrypt64_8.x.x.x.ppc64el.deb gskssl64_8.x.x.x.ppc64el.deb	64-bit Global Security Kit (GSKit) packages	/usr/local/ibm/gsk8

Package Name	Contents	Default directory
tivsm-api64.ppc64el.deb	Application programming interface (API), which contains the shared library and samples for the IBM Spectrum Protect™ API.	/opt/tivoli/tsm/client/api/bin64
tivsm-ba.ppc64el.deb	Backup-archive client (command-line and GUI), administrative client (dsmadmc), and the web client.	/opt/tivoli/tsm/client/ba/bin This directory is typically the default installation directory for many backup-archive client files. The sample system-options file (dsm.sys.smp) is written to this directory. If you do not set the DSM_DIR environment variable, the dsmc executable file, the resource files, and the dsm.sys file are stored in this directory. If you do not set the DSM_CONFIG environment variable, the client user-options file must be in this directory. If you do not set the DSM_LOG environment variable, the backup-archive writes messages to the dsmerror.log and dsmsched.log files in the current working directory.
TIVsm-filepath-source.tar.gz tivsm-jbb.ppc64el.deb	Files that are required for journal-based backups.	The TIVsm-filepath-source.tar.gz package is installed in the /opt/filepath directory. The tivsm-jbb.ppc64el.rpm package is installed in the /opt/tivoli/tsm/client/ba/bin directory.

Procedure

1. Mount the volume that you are installing the packages from.
2. Change to the directory where the installation packages are stored.
3. Install the 64-bit GSKit packages. In the following command example, the "8.x.x.x" characters represent the GSKit version:

   ```
   dpkg -i gskcrypt64_8.x.x.x.ppc64el.deb gskssl64_8.x.x.x.ppc64el.deb
   ```

4. Install the IBM Spectrum Protect API:

   ```
   dpkg -i tivsm-api64.ppc64el.deb
   ```

   If you need to install only the API, you can stop here. Use the following steps to install the backup-archive client and the packages that are required to run journal-based backups.

5. Install the backup-archive client:

   ```
   dpkg -i tivsm-ba.ppc64el.deb
   ```

6. Optional: If you want to use journal-based backups, install the following packages:
   a. Extract TIVsm-filepath-source.tar.gz and review the README file for instructions about how to compile and install the software. The Linux Filepath kernel module is licensed pursuant to the terms of the GNU General Public License ("GPL").
   b. Install the journal-based backup package:

      ```
      dpkg -i tivsm-jbb.ppc64el.deb
      ```

Uninstalling the client on Ubuntu Linux on Power Systems (Little Endian)

You can uninstall the IBM Spectrum Protect™ backup-archive client on Linux on Power Systems™ (Little Endian).

Before you begin

You must be logged in as the root user to uninstall the product.
Requirement: You must uninstall the packages in the order that is shown, otherwise the uninstallation fails.

Procedure

To uninstall the backup-archive client, enter the following commands to remove the packages for journal-based backup, the backup-archive client, the API, and the IBM Global Security Kit (GSKit). Instructions for uninstalling the filepath component are provided with the source code for filepath, when you obtain the software from IBM®.

Tip: The version number of the packages is not required.

1. To uninstall only the journal-based backup components, remove both the tivsm-jbb and filepath packages. The tivsm-jbb package depends on the filepath package. Uninstall the tivsm-jbb package first.
   a. `dpkg -r tivsm-jbb`
   b. `dpkg -r TIVsm-filepath`
2. Uninstall the backup-archive client package:

   ```
   dpkg -r tivsm-ba
   ```

3. Uninstall any products that depend on the API, such as IBM Spectrum Protect for Databases and IBM Spectrum Protect for Mail.

   If you uninstall an API-dependent product, you must reinstall it after you install a newer version of the backup-archive client and API packages. Follow the instructions of the API-dependent products to determine what you need to do to prevent data loss when you uninstall and reinstall the products.

4. Uninstall the API package by issuing the following command:

   ```
   dpkg -r tivsm-api64
   ```

5. Remove the GSKit packages:

   ```
   dpkg -r gskcrypt64 gskssl64
   ```

Related tasks:
Installing the backup-archive client on Ubuntu Linux on Power Systems (Little Endian)
Linux

Installing the API on Linux on Power Systems™ (Big Endian)

You can install the IBM Spectrum Protect™ API from the product installation media.

Before you begin

You must be logged in as root user to install the product.

About this task

If you have IBM Spectrum Protect Version 6.2 (or an earlier version) installed, remove it (rpm -e) and any other dependent software programs before you install a newer version.

If you have IBM Spectrum Protect V6.3 (or newer) installed, you can use the rpm upgrade option (rpm -U) or the rpm freshen option (rpm -F) to upgrade the existing software to a newer version. The rpm -U command can be used to install new packages or upgrade existing packages; rpm -F can update only packages that are already installed.

Stop any running client processes before you uninstall or upgrade the IBM Spectrum Protect API or backup-archive client. If you are running a V7.1.2 or earlier client, you must uninstall any language packages before you proceed with the upgrade.

Table 1 shows the installation options that are available in uncompressed packages on the installation media.

Table 1. Package names, contents, and default directory

Package Name	Contents	Default directory
gskcrypt64-8.x.x.x.linux.ppc.rpm gskssl64-8.x.x.x.linux.ppc.rpm	64-bit Global Security Kit (GSKit) packages	/usr/local/ibm/gsk8
TIVsm-API64.ppc64.rpm	Application programming interface (API), which contains the IBM Spectrum Protect API shared libraries and samples.	/opt/tivoli/tsm/client/api/bin64
TIVsm-APIcit.ppc64.rpm	Optional. These files provide the Common Inventory Technology components that you can use to obtain information about the number of client and server devices that are connected to the system, and the utilization of processor value units (PVUs) by server devices. For more information about PVUs, see Estimating processor value units in the IBM Spectrum Protect server documentation.	APIcit is installed in /opt/tivoli/tsm/client/api/bin64/cit

This installation procedure can be used to install new distributions or updates from downloaded installation media. The downloaded files that you use to install the client might be compressed. Depending on the package file format, either copy or extract the files to disk and use these instructions to install the components.

You can download the appropriate package file from one of the following websites:

- Download the client package from Passport Advantage or Fix Central.
- For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.

Procedure

1. Mount the volume that you are installing from.
2. Change to the directory where the installation packages are stored.
3. Install the 64-bit GSKit packages. In this example, the "8.x.x.x" characters represent the GSKit version:

   ```
   rpm -U gskcrypt64-8.x.x.x.linux.ppc.rpm gskssl64-8.x.x.x.linux.ppc.rpm
   ```

4. Install the IBM Spectrum Protect API, and optionally install the Common Inventory Technology package that is needed to support processor value unit (PVU) calculations.
   a. Required: Install the API:

      ```
      rpm -i TIVsm-API64.ppc64.rpm
      ```

   b. Optional: Install the Common Inventory Technology package that is used by the API. This package is dependent on the API so it must be installed after the API package is installed.

      ```
      rpm -i TIVsm-APIcit.ppc64.rpm
      ```

   Tip: If you are upgrading the API and the Common Inventory Technology package was previously installed, you must upgrade both the API and Common Inventory Technology packages. For example, you can run the following command:

```
rpm -U TIVsm-API64.ppc64.rpm TIVsm-APIcit.ppc64.rpm
```

Related concepts:
Configure the IBM Spectrum Protect client
Linux

Uninstalling the API on Linux on Power Systems (Big Endian)

You can uninstall the IBM Spectrum Protect™ API on IBM Spectrum Protect Linux on Power Systems™ (Big Endian).

Before you begin

You must be logged in as root to uninstall the product. Uninstall the packages in the order shown.

Procedure

To uninstall a previously installed IBM Spectrum Protect package, enter the following commands to remove the packages for journal-based backup, the filepath component, the backup-archive client (if applicable), the API, and the IBM Global Security Kit (GSKit).

Tip: The version number of the packages is not needed for uninstall.

1. Complete this step if a version 7.1 or earlier client was installed previously.

   To uninstall the journal-based backup components only, remove both packages (journal-based backup and filepath). The TIVsm-JBB package is dependent on the filepath package. If you use two separate rpm -e commands to uninstall the components one at a time, uninstall the TIVsm-JBB package first.

   ```
   rpm -e TIVsm-JBB TIVsm-filepath
   ```

2. If a version 7.1 or earlier client was installed previously, uninstall the backup-archive client packages.
   a. If you installed the optional TIVsmBAcit package, uninstall it by using the following command:

      ```
      rpm -e TIVsm-BAcit
      ```

   b. Uninstall the backup-archive client package:

      ```
      rpm -e TIVsm-BA
      ```

   Note: If language packages are installed in a Version 7.1.2 or earlier client, you must remove them before you remove the API package. Enter the following command, and replace *xx_xx* with the language code for each additional language that you installed. For a list of language code identifiers, see Table 1.

   ```
   rpm -e TIVsm-BA.msg.xx_xx
   ```

Table 1. Language pack identifiers

Language	Language identifier
Czech	CS_CZ
French	FR_FR
German	DE_DE
Hungarian	HU_HU
Italian	IT_IT
Japanese	JA_JP
Korean	KO_KR
Polish	PL_PL
Portuguese	PT_BR
Russian	RU_RU
Spanish	ES_ES

Language	Language identifier
Traditional Chinese (EUC)	ZH_CN
Traditional Chinese Big5	ZH_TW

3. Uninstall any products that are dependent on the API, such as IBM Spectrum Protect for Databases and IBM Spectrum Protect for Mail. Any API-dependent products must be uninstalled before you uninstall the API package. If you uninstall an API-dependent product, you must reinstall it after you install a newer version of the API package. Consult the documentation of the dependent product to determine what you need to do to prevent data loss when you uninstall and reinstall the products.
4. If you installed the optional API common inventory package (TIVsm-APIcit), use the following command to uninstall the package:

   ```
   rpm -e TIVsm-APIcit
   ```

5. Uninstall the API package by using the following command:

   ```
   rpm -e TIVsm-API64
   ```

6. Uninstall GSKit by using the following command:

   ```
   rpm -e gskcrypt64 gskssl64
   ```

Related tasks:
Installing the API on Linux on Power Systems (Big Endian)

Installing the Linux x86_64 client

You can install the Linux x86_64 backup-archive client from the product installation media.

Before you begin

- You must be logged in as root to install the product.
- If you have IBM Spectrum Protect™ Version 6.2 (or an earlier version) installed, remove it (rpm -e) and any other dependent software programs before you install a newer version.
- If you have IBM Spectrum Protect V6.3 (or later) installed, you can use the rpm upgrade option (rpm -U) or the rpm freshen option (rpm -F) to upgrade the existing software to a newer version. The rpm -U command can be used to install new packages or upgrade existing packages only if you did not previously install any language packages. The rpm -F command can update only packages that are already installed.
- Stop any running client processes before you uninstall or upgrade the IBM Spectrum Protect API or backup-archive client.
- If any language packages are installed, you must uninstall them before you install or upgrade the IBM Spectrum Protect API or backup-archive client.

About this task

The following installation options are available in uncompressed packages on the installation media.

Table 1. Package names, contents, and default directory

Package Name	Contents	Default directory
gskcrypt64-8.x.x.x.linux.x86_64.rpm gskssl64-8.x.x.x.linux.x86_64.rpm	64-bit Global Security Kit (GSKit) packages	/usr/local/ibm/gsk8
TIVsm-API64.x86_64.rpm	Application programming interface (API), which contains the IBM Spectrum Protect API shared libraries and samples.	/opt/tivoli/tsm/client/api/bin64

Package Name	Contents	Default directory
TIVsm-BA.x86_64.rpm	Backup-archive client (command-line and GUI), administrative client (dsmadmc), and the web client.	/opt/tivoli/tsm/client/ba/bin This directory is considered to be the default installation directory for many backup-archive client files. The sample system-options file (dsm.sys.smp) is written to this directory. If the DSM_DIR environment variable is not set, the dsmc executable file, the resource files, and the dsm.sys file are stored in this directory. If DSM_CONFIG is not set, the client user-options file must be in this directory. If you do not define DSM_LOG, writes messages to the dsmerror.log and dsmsched.log files in the current working directory.
TIVsm-APIcit.x86_64.rpm TIVsm-BAcit.x86_64.rpm	Optional. These files provide the Common Inventory Technology components that you can use to obtain information about the number of client and server devices that are connected to the system, and the utilization of processor value units (PVUs) by server devices. For more information about PVUs, see Estimating processor value units in the IBM Spectrum Protect server documentation.	APIcit is installed in /opt/tivoli/tsm/client/api/bin64/cit/ BAcit is installed in /opt/tivoli/tsm/client/ba/bin/cit/
TIVsm-filepath-source.tar.gz TIVsm-JBB.x86_64.rpm	Files needed to support journal-based backups.	Filepath is installed in /opt/filepath JBB is installed in /opt/tivoli/tsm/client/ba/bin
TIVsm_BAhdw.x86_64.rpm	Provides support for snapshot incremental backup for NetAPP and N-Series file servers.	/opt/tivoli/tsm/client/ba/bin/plugins

This installation procedure can be used to install new distributions or updates from downloaded installation media. The downloaded files that you use to install the client might be compressed. Depending on the package file format, either copy or extract the files to disk and use these instructions to install the components.

You can download the appropriate package file from one of the following websites:

- Download the client package from Passport Advantage or Fix Central.
- For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.

Procedure

To install the Linux x86_64 backup-archive client, complete the following steps:

1. Mount the volume that you are installing from.
2. Change to the directory where the installation packages are stored.
3. Install the 64-bit GSKit packages. In this example, the "8.x.x.x" characters represent the GSKit version:

```
rpm -U gskcrypt64-8.x.x.x.linux.x86_64.rpm gskssl64-8.x.x.x.linux.x86_64.rpm
```

4. Install the IBM Spectrum Protect API, and optionally install the Common Inventory Technology package that is necessary to support processor value unit (PVU) calculations.
    a. Required: Install the API:

    ```
    rpm -i TIVsm-API64.x86_64.rpm
    ```

    b. Optional: Install the Common Inventory Technology package that is used by the API. This package depends on the API so it must be installed after the API package is installed.

    ```
    rpm -i TIVsm-APIcit.x86_64.rpm
    ```

    Tip: If you are upgrading the API and the Common Inventory Technology package was previously installed, you must upgrade both the API and Common Inventory Technology packages. For example, you can run the following command:

    ```
    rpm -U TIVsm-API64.x86_64.rpm TIVsm-APIcit.x86_64.rpm
    ```

    If you need only the API installed, you can stop here. The rest of the steps in this procedure describe how to install the backup-archive client components and an optional client package that is needed only if you want the client to send PVU metrics to the server. Also described in subsequent steps are the installation of the packages that are needed if you want to perform journal-based backups.

5. Install the backup-archive client, and optionally install the Common Inventory Technology package that is necessary to support processor value unit (PVU) calculations.
    a. Install the backup-archive client components.

    ```
    rpm -i TIVsm-BA.x86_64.rpm
    ```

    b. Optional: Install the Common Inventory Technology package the client uses to send PVU metrics to the server. This package depends on the client package so it must be installed after the client package is installed.

    ```
    rpm -i TIVsm-BAcit.x86_64.rpm
    ```

6. Optional: If you want to use journal-based backups, you must compile and install the filepath component that matches the Linux kernel on your client computer. Extract TIVsm-filepath-source.tar.gz and see the README file for compile and install instructions. The Linux filepath kernel module is licensed pursuant to the terms of the GNU General Public License ("GPL").
7. Install the snapshot difference incremental backup support for NetApp and N-Series file servers by entering the following command:

    ```
    rpm -i TIVsm-BAhdw.x86_64.rpm
    ```

Uninstalling the Linux x86_64 client

You can use the following procedure to uninstall the IBM Spectrum Protect™ Linux x86_64 client.

Before you begin

You must be logged in as root to uninstall the product. Uninstall the packages in the order shown.

Procedure

To uninstall a previously installed IBM Spectrum Protect client package, enter the following commands to remove the packages for journal-based backup, the filepath component, the backup-archive client, the API, and the IBM Global Security Kit (GSKit).

Tip: The version number of the packages is not needed for uninstall.

1. To uninstall the journal-based backup components only, remove both packages (journal-based backup and filepath). The TIVsm-JBB package depends on the filepath package. If you use two separate rpm -e commands to uninstall the components one at a time, uninstall the TIVsm-JBB package first.

    ```
    rpm -e TIVsm-JBB TIVsm-filepath
    ```

2. Uninstall the backup-archive client packages:
    a. If you installed the optional TIVsm-BAcit package, uninstall it before you uninstall the client:

```
rpm -e TIVsm-BAcit
```

b. Uninstall the backup-archive client.

```
rpm -e TIVsm-BA
```

Note: If language packages are installed in a Version 7.1.2 or earlier client, you must remove them before you remove the API package. Enter the following command, and replace *xx_xx* with the language code for each additional language that you installed. For a list of language code identifiers, see Table 1.

```
rpm -e TIVsm-msg.xx_xx
```

Table 1. Language pack identifiers

Language	Language identifier

Installing the Ubuntu Linux x86_64 client

You can install the Ubuntu Linux 64-bit backup-archive client from the product installation media.

About this task

The following installation options are available in uncompressed packages on the installation media.

Table 1. Package names, contents, and default directory

Package Name	Contents	Default directory
gskcrypt64_8.0-50.40.linux.x86_64.deb gskssl64_8.0-50.40.linux.x86_64.deb	64-bit Global Security Kit (GSKit) packages	/usr/local/ibm/gsk8
tivsm-api64.amd64.deb	Application programming interface (API), which contains the IBM Spectrum Protect™ API shared libraries and samples.	/opt/tivoli/tsm/client/api/bin64
tivsm-ba.amd64.deb	Backup-archive client (command-line and GUI), administrative client (dsmadmc), and the web client.	/opt/tivoli/tsm/client/ba/bin This directory is considered to be the default installation directory for many backup-archive client files. The sample system-options file (dsm.sys.smp) is written to this directory. If the DSM_DIR environment variable is not set, the dsmc executable file, the resource files, and the dsm.sys file are stored in this directory. If DSM_CONFIG is not set, the client user-options file must be in this directory. If you do not define DSM_LOG, writes messages to the dsmerror.log and dsmsched.log files in the current working directory.
tivsm-apicit.amd64.deb tivsm-bacit.amd64.deb	Optional. These files provide the Common Inventory Technology components that you can use to obtain information about the number of client and server devices that are connected to the system, and the utilization of processor value units (PVUs) by server devices. For more information about PVUs, see Estimating processor value units in the IBM Spectrum Protect server documentation.	APIcit is installed in /opt/tivoli/tsm/client/api/bin64/cit BAcit is installed in /opt/tivoli/tsm/client/ba/bin/cit
tivsm-filepath-source.tar.gz tivsm-jbb.amd64.deb	Files needed to support journal-based backups.	The filepath and tivsm-jbb packages are only required if you plan to use journal-based backups. The tivsm-jbb.x86_64.deb package is installed in /opt/tivoli/tsm/client/ba/bin.
tivsm-bahdw.amd64.deb	Provides support for snapshot incremental backup for NetAPP and N-Series file servers.	/opt/tivoli/tsm/client/ba/bin/plugins

This installation procedure can be used to install new distributions or updates from downloaded installation media. The downloaded files that you use to install the client might be compressed. Depending on the package file format, either copy or extract the files to disk and use these instructions to install the components.

You can download the appropriate package file from one of the following websites:

- Download the client package from Passport Advantage or Fix Central.
- For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.

Procedure

To install the Ubuntu Linux x86_64 backup-archive client, complete the following steps.

1. Mount the volume that you are installing from.
2. Change to the directory where the installation packages are stored.
3. Install the 64-bit GSKit packages.

   ```
   sudo dpkg -i gskcrypt64_8.0-50.40.linux.x86_64.deb gskssl64_8.0-50.40.linux.x86_64.deb
   ```

4. Install the IBM Spectrum Protect API, and optionally install the Common Inventory Technology package that is necessary to support processor value unit (PVU) calculations.
   a. Required: Install the API:

      ```
      sudo dpkg -i tivsm-api64.amd64.deb
      ```

   b. Optional: Install the Common Inventory Technology package that is used by the API. This package depends on the API so it must be installed after the API package is installed.

      ```
      sudo dpkg -i tivsm-apicit.amd64.deb
      ```

   If you need only the API installed, you can stop here. The rest of the steps in this procedure describe how to install the backup-archive client components and an optional client package that is needed only if you want the client to send PVU metrics to the server. Also described in subsequent steps are the installation of the packages that are needed if you want to perform journal-based backups.

5. Install the backup-archive client, and optionally install the Common Inventory Technology package that is necessary to support processor value unit (PVU) calculations.
   a. Install the backup-archive client components.

      ```
      sudo dpkg -i tivsm-ba.amd64.deb
      ```

   b. Optional: Install the Common Inventory Technology package that the client uses to send PVU metrics to the server. This package depends on the client package so it must be installed after the client package is installed.

      ```
      sudo dpkg -i tivsm-bacit.amd64.deb
      ```

6. Optional: Complete this step only if you plan to use journal-based backups.
   a. Extract tivsm-filepath-source.tar.gz and see the README file for compile and install instructions. The filepath kernel module is licensed pursuant to the terms of the GNU General Public License ("GPL").
   b. Install the journal-based backup package: `dpkg -i tivsm-jbb.amd64.deb`.
7. Install the snapshot difference incremental backup support for NetApp and N-Series file servers by entering the following command:

   ```
   sudo dpkg -i tivsm-bahdw.amd64.deb
   ```

Configure the IBM Spectrum Protect client
Linux

Uninstalling the Ubuntu Linux x86_64 client

Use the following procedure to uninstall the IBM Spectrum Protect™ Linux 64-bit client.

Procedure

To uninstall a previously installed IBM Spectrum Protect client package, enter the following commands to remove the packages for journal-based backup, the backup-archive client, the API, and the IBM Global Security Kit (GSKit). Instructions to uninstall the filepath component are provided with the source code for filepath, when you obtain the software from IBM®.

1. To uninstall only the journal-based backup components, remove both the tivsm-jbb and the filepath component. The tivsm-jbb package depends on the filepath package. Uninstall the tivsm-jbb package first.
   a. `sudo dpkg -r tivsm-jbb`

b. `sudo dpkg -r tivsm-filepath`

2. Uninstall the backup-archive client packages:
   a. If you installed the optional tivsm-bacit package, uninstall it before you uninstall the client:

      ```
      sudo dpkg -r tivsm-bacit
      ```

   b. Uninstall the backup-archive client.

      ```
      sudo dpkg -r tivsm-ba
      ```

   Note: If language packages are installed in a Version 7.1.2 or earlier client, you must remove them before you remove the API package. Enter the following command, and replace *xx-xx* with the language code for each additional language that you installed. For a list of language code identifiers, see Table 1.

   ```
   dpkg -r tivsm-msg.xx-xx
   ```

   Table 1. Language pack identifiers

Language	Language identifier
Czech	cs-cz
French	fr-fr
German	de-de
Hungarian	hu-hu
Italian	it-it
Japanese	ja-jp
Korean	ko-kr
Polish	pl-pl
Portuguese	pt-br
Russian	ru-ru
Spanish	es-es
Traditional Chinese (EUC)	zh-cn
Traditional Chinese Big5	zh-tw

3. Uninstall any products that depend on the API, such as IBM Spectrum Protect Data Protection products. Any API-dependent products must be uninstalled before you uninstall the API package. If you uninstall an API-dependent product, you must reinstall it after you install a newer version of the backup-archive client and API packages. Consult the documentation of the dependent product to determine what you need to do to prevent data loss when you uninstall and reinstall the products.
   a. If you installed the optional API common inventory package (tivsm-apicit), uninstall it before you uninstall the API package. Use the following command to uninstall the package:

      ```
      sudo dpkg -r tivsm-apicit
      ```

   b. Uninstall the API package by using the following command:

      ```
      sudo dpkg -r tivsm-api64
      ```

4. To remove the GSKit 64-bit packages, enter the following command:

   ```
   sudo dpkg -r gskcrypt64 gskssl64
   ```

Related tasks:
Installing the Ubuntu Linux x86_64 client
Linux

Installing the Linux on System z client

You can install the Linux on System z® backup-archive client from the product installation media.

Before you begin

You must be logged in as root to install the product.

About this task

If you have IBM Spectrum Protect™ Version 6.2 (or an earlier version) installed, remove it (rpm -e) and any other dependent software programs before you install a newer version.

If you have IBM Spectrum Protect V6.3 (or newer) installed, you can use the rpm upgrade option (rpm -U) or the rpm freshen option (rpm -F) to upgrade the existing software to a newer version. The rpm -U command can be used to install new packages or upgrade existing packages; rpm -F can update only packages that are already installed.

Stop any running client processes before you uninstall or upgrade the IBM Spectrum Protect API or backup-archive client. If you are running a V7.1.2 or earlier client, you must uninstall any language packages before you proceed with the upgrade.

The following installation options are available in uncompressed packages on the installation media.

Table 1. Package names, contents, and default directory

Package Name	Contents	Default directory
gskcrypt64-8.x.x.x.linux.s390x.rpm gskssl64-8.x.x.x.linux.s390x.rpm	64-bit Global Security Kit (GSKit) packages	/usr/local/ibm/gsk8
TIVsm-API64.s390x.rpm	Application programming interface (API), which contains the IBM Spectrum Protect API shared libraries and samples.	/opt/tivoli/tsm/client/api/bin64
TIVsm-BA.s390x.rpm	Backup-archive client (command-line and GUI), administrative client (dsmadmc), and the web client.	/opt/tivoli/tsm/client/ba This directory is considered to be the default installation directory for many backup-archive client files. The sample system-options file (dsm.sys.smp) is written to this directory. If the DSM_DIR environment variable is not set, the dsmc executable file, the resource files, and the dsm.sys file are stored in this directory. If DSM_CONFIG is not set, the client user-options file must be in this directory. If you do not define DSM_LOG, the backup-archive client writes messages to the dsmerror.log and dsmsched.log files in the current working directory.

Package Name	Contents	Default directory
TIVsm-APIcit.s390x.rpm TIVsm-BAcit.s390x.rpm	Optional. These files provide the Common Inventory Technology components that you can use to obtain information about the number of client and server devices that are connected to the system, and the utilization of processor value units (PVUs) by server devices. For more information about PVUs, see Estimating processor value units in the IBM Spectrum Protect server documentation.	APIcit is installed in /opt/tivoli/tsm/client/api/bin64/cit BAcit is installed in /opt/tivoli/tsm/client/ba/bin/cit
TIVsm-filepath-source.tar.gz TIVsm-JBB.s390x.rpm	Files needed to support journal-based backups.	Filepath is installed in /opt/filepath JBB is installed in /opt/tivoli/tsm/client/ba/bin

This installation procedure can be used to install new distributions or updates from downloaded installation media. The downloaded files that you use to install the client might be compressed. Depending on the package file format, either copy or extract the files to disk and use these instructions to install the components.

You can download the appropriate package file from one of the following websites:

- Download the client package from Passport Advantage or Fix Central.
- For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.

Procedure

1. Mount the volume that you are installing from.
2. Change to the directory where the packages are stored.
3. Install the 64-bit GSKit packages. In this example, the "8.x.x.x" characters represent the GSKit version:

   ```
   rpm -U gskcrypt64-8.x.x.x.linux.s390x.rpm gskssl64-8.x.x.x.linux.s390x.rpm
   ```

4. Install the IBM Spectrum Protect API, and optionally install the Common Inventory Technology package that is needed to support processor value unit (PVU) calculations.
   a. Required: Install the API:

      ```
      rpm -i TIVsm-API64.s390x.rpm
      ```

   b. Optional: Install the Common Inventory Technology package that is used by the API. This package is dependent on the API so it must be installed after the API package is installed.

      ```
      rpm -i TIVsm-APIcit.s390x.rpm
      ```

   Tip: If you are upgrading the API and the Common Inventory Technology package was previously installed, you must upgrade both the API and Common Inventory Technology packages. For example, you can run the following command:

   ```
   rpm -U TIVsm-API64.s390x.rpm TIVsm-APIcit.s390x.rpm
   ```

   If you need only the API installed, you can stop here. The rest of the steps in this procedure describe how to install the backup-archive client components and an optional client package that is needed only if you want the client to send PVU metrics to the server. Also described in subsequent steps are the installation of the packages that are needed if you want to perform journal-based backups.

5. Install the backup-archive client, and optionally install the Common Inventory Technology package that is needed to support processor value unit (PVU) calculations.

a. Install the backup-archive client components.

```
rpm -i TIVsm-BA.s390x.rpm
```

b. Optional: Install the Common Inventory Technology package the client uses to send PVU metrics to the server. This package is dependent on the client package so it must be installed after the client package is installed.

```
rpm -i TIVsm-BAcit.s390x.rpm
```

6. Optional: If you want to use journal-based backups, you must compile and install the filepath component that matches the Linux kernel on your client computer. Extract TIVsm-filepath-source.tar.gz and see the README file for compile and install instructions. The Linux filepath kernel module is licensed pursuant to the terms of the GNU General Public License ("GPL").

Configure the IBM Spectrum Protect client

Linux

Uninstalling the Linux on System z client

You can use the following procedures to uninstall the IBM Spectrum Protect™ Linux on System z® client.

Before you begin

You must be logged in as root to install the product. Uninstall the packages in the order shown.

About this task

To uninstall a previously installed IBM Spectrum Protect client package, enter the following commands to remove the packages for journal-based backup, the filepath component, the backup-archive client, the API, and the IBM® Global Security Kit (GSKit).

Tip: The version number of the packages is not needed for uninstall.

Procedure

1. To uninstall the journal-based backup components only, remove both packages (journal-based backup and filepath). The TIVsm-JBB package is dependent on the filepath package. If you use two separate rpm -e commands to uninstall the components one at a time, uninstall the TIVsm-JBB package first.

```
rpm -e TIVsm-JBB TIVsm-filepath
```

2. Uninstall the backup-archive client packages:
   a. If you installed the optional TIVsm-BAcit package, uninstall it before you uninstall the client:

```
rpm -e TIVsm-BAcit
```

   b. Uninstall the backup-archive client.

```
rpm -e TIVsm-BA
```

   Note: If language packages are installed in a Version 7.1.2 or earlier client, you must remove them before you remove the API package. Enter the following command, and replace *xx_xx* with the language code for each additional language that you installed. For a list of language code identifiers, see Table 1.

```
rpm -e TIVsm-msg.xx_xx
```

Table 1. Language pack identifiers

Language	Language identifier
Czech	CS_CZ
French	FR_FR
German	DE_DE
Hungarian	HU_HU
Italian	IT_IT

Language	Language identifier
Japanese	JA_JP
Korean	KO_KR
Polish	PL_PL
Portuguese	PT_BR
Russian	RU_RU
Spanish	ES_ES
Traditional Chinese (EUC)	ZH_CN
Traditional Chinese Big5	ZH_TW

3. Uninstall any products that are dependent on the API, such as IBM Spectrum Protect for Databases and IBM Spectrum Protect for Mail. Any API-dependent products must be uninstalled before you uninstall the API package. If you uninstall an API-dependent product, you must reinstall it after you install a newer version of the backup-archive client and API packages. Consult the documentation of the dependent product to determine what you need to do to prevent data loss when you uninstall and reinstall the products.
    a. If you installed the optional API common inventory package (TIVsm-APIcit), uninstall it before you uninstall the API package. Use the following command to uninstall the package:

    ```
    rpm -e TIVsm-APIcit
    ```

    b. Uninstall the API package by using the following command:

    ```
    rpm -e TIVsm-API64
    ```

4. To remove the GSKit 64-bit package, enter the following command:

```
rpm -e gskcryp64 gskssl64
```

Related tasks:
Installing the Linux on System z client

Mac OS X

Installing the Mac OS X client

You can install the IBM Spectrum Protect™ Mac OS X backup-archive client from the product installation media.

Before you begin

You must be a system administrator to install the backup-archive client.

About this task

This installation procedure can be used to install new distributions or updates from downloaded installation media. The downloaded files that you use to install the client might be compressed. Depending on the package file format, either copy or extract the files to disk and use these instructions to install the components.

You can download the appropriate package file from one of the following websites:

- Download the client package from Passport Advantage or Fix Central.
- For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.

For MAC OS X clients, you can use an installation wizard that prompts you for information as the product is installed, or you can also install the client from the command line. When you install the client by using the command-line installation procedure, the installation runs without user interaction. The command-line procedure is useful if you want to script the installation and run it on many nodes, or if you must install the software on a system that does not have a monitor.

Procedure

Select an installation method and install the client. Use either the installation wizard method or install the client from the command line.

Installation method	Procedure
Installation wizard	a. Double-click the 8.1.2.0.0-TIV-TSMBAC-Mac.dmg file to mount the disk image. b. Double-click the IBM Spectrum Protect installation package icon and follow the prompts to complete the installation.
Command line	a. Change directories to where the IBM Spectrum Protect installer is located. b. Install the custom installation package with the following command: `/usr/sbin/installer -pkg "/Volumes/IBM Spectrum Protect/ IBM Spectrum Protect.pkg" -target /`

What to do next

A sample client system options file, called `dsm.sys.smp`, is created in the installation directory. You can copy this file and modify it to create the client systems options file for your node. The default name for the client systems option file is dsm.sys.

After you install the client, you might need to set environment variables before you use it. For more information about setting environment variables, see Set processing environment variables.

Mac OS X

Uninstalling the Mac OS X client

You can uninstall the IBM Spectrum Protect™ Mac OS X client if you no longer need it.

Before you begin

If the IBM Spectrum Protect scheduler is configured as a startup item, use the IBM Spectrum Protect Tools for Administrators function or the StopCad.sh shell script to stop and uninstall the scheduler before you begin this procedure.

About this task

You can use a shell script to uninstall the backup-archive client. The shell script name is uninstall.sh and it is in the default installation directory, which is /Library/Application Support/tivoli/tsm/client/ba/bin. Use the sudo command to run the script.

Alternately, you can complete the following steps instead of using the script:

Procedure

1. Move the following folders to the trash:
   - /Applications/IBM Spectrum Protect
   - /Library/Application Support/tivoli
2. Remove the following symbolic links:
   - /usr/bin/dsmc
   - /usr/bin/dsmcad
   - /usr/bin/dsmadmc
   - /usr/bin/dsmtrace
   - /usr/bin/dsmagent
   - /usr/lib/libxmlutil-6.2.0.dylib
   - /usr/lib/libtsm620xerces-c1_6_0.dylib
3. Optional: Remove the log files and options files if you do not want to preserve them. The uninstall process leaves them on disk so your settings are retained in case you reinstall the product later.

   The backup-archive client might have created log files in these locations:

   a. /Library/Logs/tivoli
   b. ~/Library/Logs/tivoli

   The client option files (dsm.opt and dsm.sys) are typically saved in the following locations:

a. /Library/Preferences/Tivoli Storage Manager
b. ~/Library/Preferences/Tivoli Storage Manager

Solaris

Installing the Oracle Solaris x86_64 client

You can install the IBM Spectrum Protect™ Oracle Solaris x86_64 backup-archive client from the product installation media.

Before you begin

Starting in IBM Spectrum Protect Version 8.1.0, the Oracle Solaris backup-archive client is available only on the Oracle Solaris x86_64 platform. The backup-archive client is no longer available on the Oracle Solaris SPARC platform; only the IBM Spectrum Protect API is available on Oracle Solaris SPARC. For information about how to install the Solaris SPARC API, see Installing the Oracle SPARC API.

About this task

If a previous version of the backup-archive client is installed, remove it before you install a new version. For information about removing previous Solaris client packages, see Uninstalling the Oracle Solaris x86_64 client.

The IBM Spectrum Protect installation administration file (tsmadmin) is used in place of the default administration file (/var/sadm/install/admin), so that you are not asked about `setuid`, `setgid`, or superuser permission during installation. If you want to use the default administration file, remove the -a ./tsmadmin option from the commands that are shown, and answer the questions about `setuid`, `setgid`, or superuser permission during installation with `Y`.

Table 1. Installation package names and descriptions

Package	Package Name	Package Description
IBM® Global Security Kit (GSKit) 64 bit	gsk8cry64.pkg and gsk8ssl64.pkg	Contains the IBM GSKit that provides Secure Sockets Layer (SSL) 64-bit data encryption between the IBM Spectrum Protect client and server.
IBM Spectrum Protect application programming interface (API)	TIVsmCapi.pkg	Contains the IBM Spectrum Protect 64-bit API shared library and samples.
Backup-archive client	TIVsmCba.pkg	Contains the following 64-bit components: • Backup-archive client (command-line and GUI) • Administrative client (command-line) • Web backup-archive client Note: 1. TCP/IP and Shared memory are supported as communication methods. 2. The web client is a part of the backup-archive client package and cannot be installed without it.

This installation procedure can be used to install new distributions or updates from downloaded installation media. The downloaded files that you use to install the client might be compressed. Depending on the package file format, either copy or extract the files to disk and use these instructions to install the components.

You can download the appropriate package file from one of the following websites:

- Download the client package from Passport Advantage or Fix Central.
- For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.

Install the packages in the order shown; some packages depend on the presence of others. For example, GSKit is a prerequisite of the API, and the API is a prerequisite of the backup-archive client package.

Procedure

1. Log in as the root user.
2. Mount the volume that you are installing from.
3. Change to the directory where the packages are stored.
4. The IBM GSKit; it is a prerequisite of the IBM Spectrum Protect API package. Install GSKit by using the following commands:

   ```
   pkgadd -n -a ./tsmadmin -d ./gsk8cry64.pkg gsk8cry64
   pkgadd -n -a ./tsmadmin -d ./gsk8ssl64.pkg gsk8ssl64
   ```

   Note: On Solaris 10, these commands install the 64-bit GSKit in the global zone and in all running non-global zones. To install the client in a sparse-root, non-global zone only, GSKit must first be installed in the global zone. On Solaris 11, the packages are only installed in the zone where these commands are run.
5. Use the following command to install the IBM Spectrum Protect API:

   ```
   pkgadd -n -a ./tsmadmin -d ./TIVsmCapi.pkg TIVsmCapi
   ```

   Note: On Solaris 10, this command installs the IBM Spectrum Protect 64-bit API in the global zone and in all running non-global zones. If you want to install it in the global zone only, use the -G parameter of the pkgadd command. On Solaris 11, the API is only installed in the zone where this command is run.
6. Use the following command to install the backup-archive client:

   ```
   pkgadd -n -a ./tsmadmin -d ./TIVsmCba.pkg TIVsmCba
   ```

   Note: On Solaris 10, this command installs the backup-archive client components in the global zone and in all running non-global zones. If you want to install them in the global zone only, use the -G parameter of the pkgadd command. On Solaris 11, the client components must are only installed in the zone where this command is run.

Results

Important: For a Solaris 10 sparse root non-global zone, the `/usr` file system is normally mounted as read-only (LOFS) from the global zone, and the following conditions apply:

- If the client is not installed in the global zone, a warning message appears at the end of the installation. The message asks the global administrator to create the required links that are provided as part of the warning messages.
- If the client is already installed in the global zone, creation of these links is not necessary. The links are already present and they are pointing to the correct executable files and libraries.

Related concepts:
Configure the IBM Spectrum Protect client
Solaris

Uninstalling the Oracle Solaris x86_64 client

You can uninstall all the packages that are related to IBM Spectrum Protect™ Oracle Solaris x86_64 client, including the command-line, GUI, web GUI, and administrative client components.

About this task

Important: Make sure that you uninstall the packages in the specified order.

The IBM Spectrum Protect installation administration file (`tsmadmin`) is used in place of the default administration file (`/var/sadm/install/admin`), so that you are not prompted for questions about `setuid`, `setgid`, or superuser permission during installation. If you want to use the default administration file, remove the `-a ./tsmadmin` option from the following commands and answer the questions about `setuid`, `setgid`, or superuser permission during installation with `y`.

Procedure

1. Enter the following command to uninstall the backup-archive client:

```
pkgrm -n -a ./tsmadmin TIVsmCba
```

This command uninstalls all of the components of the backup-archive client (command-line, GUI, web client, and the administrative client). You cannot uninstall individual components of this package (for example, the command-line client).

Note: If one or more language messages packages are installed in Version 7.1.2 or earlier clients, remove them before you remove the API package. Enter the following command as the root user:

```
pkgrm -n -a ./tsmadmin TIVsmClCs TIVsmClDe TIVsmClEs TIVsmClFr \
                       TIVsmClHu TIVsmClIt TIVsmClJa TIVsmClKo \
                       TIVsmClPl TIVsmClPt TIVsmClRu TIVsmClSc TIVsmClTc
```

2. Enter the following command to uninstall the IBM Spectrum Protect API:

```
pkgrm -n -a ./tsmadmin TIVsmCapi
```

The API cannot be removed if the backup-archive client is installed. The backup-archive client must be removed first.

3. Enter the following commands to uninstall the GSKit:

```
pkgrm -n -a ./tsmadmin gsk8ssl64
pkgrm -n -a ./tsmadmin gsk8cry64
```

Solaris

Installing the Oracle SPARC API

You can install the IBM Spectrum Protect™ Oracle Solaris SPARC API from the product installation media.

About this task

If a previous version of the API installed, remove it before you install a new version. For information about removing previous Solaris API packages, see Uninstalling the Oracle Solaris SPARC API.

The IBM Spectrum Protect installation administration file (tsmadmin) is used in place of the default administration file (/var/sadm/install/admin), so that you are not asked about `setuid`, `setgid`, or superuser permission during installation. If you want to use the default administration file, remove the -a ./tsmadmin option from the commands that are shown, and answer the questions about `setuid`, `setgid`, or superuser permission during installation with `Y`.

Table 1. Installation package names and descriptions

Package	Package Name	Package Description
IBM® Global Security Kit (GSKit) 64 bit	gsk8cry64.pkg and gsk8ssl64.pkg	Contains the IBM GSKit that provides Secure Sockets Layer (SSL) 64-bit data encryption between the IBM Spectrum Protect API and server.
IBM Spectrum Protect application programming interface (API)	TIVsmCapi.pkg	Contains the IBM Spectrum Protect 64-bit API shared library and samples.

This installation procedure can be used to install new distributions or updates from downloaded installation media. The downloaded files that you use to install the client might be compressed. Depending on the package file format, either copy or extract the files to disk and use these instructions to install the components.

You can download the appropriate package file from one of the following websites:

- Download the client package from Passport Advantage or Fix Central.
- For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.

Install the packages in the order shown.

Procedure

1. Log in as the root user.
2. Mount the volume that you are installing from.
3. Change to the directory where the packages are stored.

4. The IBM GSKit; it is a prerequisite of the IBM Spectrum Protect API package. Install GSKit by using the following commands:

   ```
   pkgadd -n -a ./tsmadmin -d ./gsk8cry64.pkg gsk8cry64
   pkgadd -n -a ./tsmadmin -d ./gsk8ssl64.pkg gsk8ssl64
   ```

   Note: On Solaris 10, these commands install the 64-bit GSKit in the global zone and in all running non-global zones. To install the API in a sparse-root, non-global zone only, GSKit must first be installed in the global zone. On Solaris 11, the packages are only installed in the zone where these commands are run.
5. Use the following command to install the IBM Spectrum Protect API:

   ```
   pkgadd -n -a ./tsmadmin -d ./TIVsmCapi.pkg TIVsmCapi
   ```

   Note: On Solaris 10, this command installs the IBM Spectrum Protect 64-bit API in the global zone and in all running non-global zones. If you want to install it in the global zone only, use the -G parameter of the pkgadd command. On Solaris 11, the API is only installed in the zone where this command is run.

Results

Important: For a Solaris 10 sparse root non-global zone, the `/usr` file system is normally mounted as read-only (LOFS) from the global zone, and the following conditions apply:

- If the API is not installed in the global zone, a warning message appears at the end of the installation. The message asks the global administrator to create the required links that are provided as part of the warning messages.
- If the API is already installed in the global zone, creation of these links is not necessary. The links are already present and they are pointing to the correct executable files and libraries.

Software updates

Software updates might periodically be made available by IBM® for download.

For the latest information, updates, and maintenance fixes, see the IBM Support Portal for IBM Spectrum Protect™.

Windows

Windows backup-archive client installation overview

You can install the IBM Spectrum Protect™ Windows backup-archive client from the installation media.

Before you begin

Before you begin a Windows client installation, ensure that the system that you want to install the client on meets the client requirements. Then, determine the type of installation that you need to perform, and follow the steps in the appropriate procedure.

For the hardware and software requirements for the Windows client, see technote 1197133.

- Windows Windows client installation might require a reboot
  As part of the Windows client installation process, one or more Microsoft C++ redistributable packages are installed, if they are not already installed on the Windows workstation. These packages can also be automatically updated by the Windows Update service. If the packages are updated, the update can cause the system to reboot when you start the Windows client installation program.
- Windows Installation procedures
  The procedure that you follow to install the IBM Spectrum Protect Windows backup-archive client depends on the type of installation that you want to perform.
- Windows Troubleshooting problems during installation (Windows)
  If you are upgrading from a previous version of the backup-archive client and there are client services running (for example, Client Acceptor or Scheduler), you might see an error during the installation.
- Windows Software updates
  Software updates might periodically be made available by IBM® for download.

Related concepts:

Windows

Windows client installation might require a reboot

As part of the Windows client installation process, one or more Microsoft C++ redistributable packages are installed, if they are not already installed on the Windows workstation. These packages can also be automatically updated by the Windows Update service. If the packages are updated, the update can cause the system to reboot when you start the Windows client installation program.

The reboot that is triggered if the C++ redistributable packages are updated can occur, even under any of the following conditions:

- An automatic client deployment pushes a client upgrade to a node, and the client or the scheduler sets the AUTODEPLOY=NOREBOOT option.
- A manual installation or upgrade of the client is started.
- A client silent installation is started, even if the options to suppress reboot prompts, and the client reboot itself, are set.

Additionally, because the Microsoft Visual Studio C++ redistributable package is a shared Windows component, other applications that have dependencies on the package might be stopped or restarted by Windows as part of the installation or upgrade of the C++ redistributable package. Schedule client installations and upgrades during a maintenance window when other applications will not be adversely affected if they are stopped or restarted when the C++ redistributable package is installed. Monitor other applications after the client is installed to see whether there are any applications that were stopped and not restarted.
Windows

Installation procedures

The procedure that you follow to install the IBM Spectrum Protect™ Windows backup-archive client depends on the type of installation that you want to perform.

Procedures are provided for each of the following installation types:

Installation type	Installation description

Installing the Windows client for the first time	Describes how to install the Windows backup-archive client for the first time. This procedure presumes that the Windows computer that you are installing the client on has never had a previous version of the client installed on it before.
Upgrading the Windows client	Describes how to upgrade an earlier version of the Windows backup-archive client to this latest version.
Reinstalling the Windows client	Describes how to reinstall the Windows backup-archive client, if you uninstalled it.
Silent installation	Describes how to install the Windows backup-archive client silently, without user interaction during the installation procedure.
Repairing, modifying, or uninstalling the Windows client	Describes how to add or remove features from an installed backup-archive client (modify), replace damaged files or missing registry keys (repair), or uninstall the Windows backup-archive client.

- Windows Installing the Windows client for the first time
  Complete this procedure to install the Windows backup-archive client for the first time.
- Windows Upgrading the Windows client
  You can upgrade an earlier version of the IBM Spectrum Protect Windows backup-archive client to Version 8.1.2. Your previous configuration settings are preserved, where it is possible to do so. However, enhancements that are in the latest version of the client can deprecate or prohibit the use of options that were available in earlier versions of the client.
- Windows Reinstalling the Windows client
  If you uninstall the Version 8.1.2 Windows client, you can reinstall it if you need to.
- Windows Silent installation
  The backup-archive client installation program supports silent, unattended installations.
- Windows Modifying, repairing, or uninstalling the Windows client
  You can modify, repair, or uninstall an existing Windows client.

Windows

Installing the Windows client for the first time

Complete this procedure to install the Windows backup-archive client for the first time.

Before you begin

If you have an earlier version of the Windows backup-archive client that is already installed on a node and you want to upgrade it to Version 8.1.2, see Upgrading the Windows client.

Important: You must know the host name or IP address of the IBM Spectrum Protect server, the port number that the server listens on for client communications, and the communications method to use when the client communicates with the server. Obtain this information from your IBM Spectrum Protect server administrator before you start this procedure.

Procedure

1. Download the appropriate package file from one of the following websites.
   - Download the client package from Passport Advantage or Fix Central.
   - For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.
2. Install the product by using the compressed installation file that you download from Passport Advantage®.
   a. Copy the downloaded compressed installation package to a local disk or to a network-accessible share. Be sure to extract the installation files to an empty directory.
   b. To extract the installation files to the same directory, double-click the compressed installation package.
   c. By default, the uncompressed files are stored in the current disk drive, in the *download_directory*\TSMClient directory. If the installation program detects files from another client installation attempt in this directory, you are prompted about whether to overwrite the old files. If you receive this prompt, enter `A` to overwrite the existing files; this selection ensures that only the files from the current installation are used.
   d. Double-click the spinstall.exe file to start the client installation program.
3. Select a language to use for this installation and click OK.
4. If the installation wizard indicates that one or more Microsoft C++ redistributable files must be installed, click Install. These files are needed to run the Windows client.
5. On the IBM Spectrum Protect client welcome screen, click Next to begin installing the client software.

6. Accept the default installation directory by clicking Next, or specify a different installation directory. The default installation directory is C:\Program Files\Tivoli\TSM.
7. Select the installation type: Typical or Custom.

Option	Description
Typical	A typical installation installs the following components: ○ The backup-archive client GUI files (needed to use the Java™ GUI) ○ The backup-archive client web files (needed to use the web client) ○ The client API files (as needed by your client and operating system)
Custom	A custom installation installs the same files as a typical installation. However, you can choose to install the following optional components: ○ The API SDK files (only needed if you are developing applications that work with the backup-archive client ○ The Administrative Client command-line files (required to remotely run administrator functions on the IBM Spectrum Protect server

8. Click Next, then click Install.
9. When the installer completes the installation, click Finish.
10. Verify the installation. Click Start > All Programs > IBM Spectrum Protect. The client components that you installed are shown in the list of IBM Spectrum Protect startable programs. The administrative command-line client, backup-archive command-line client, and the backup-archive GUI are the only components that are displayed in this list. The administrative command-line client is only shown if you perform a custom installation and you include the administrative command-line client. If you installed other components, such as the API Runtime and SDK, they are not shown in this list.
11. Click Backup-Archive GUI to start the client GUI. The Client Options File Configuration Wizard starts. Click Next to start the wizard.
12. On the Options File Task screen, select Create a new options file and click Next.
13. On the Client Node Name screen, specify a node name. A node name uniquely identifies your node to the IBM Spectrum Protect server. The default node name is the short host name of the Windows computer that you are installing the client on. Accept the default node name or specify a new node name. Click Next.
14. On the IBM Spectrum Protect Client/Server Communications screen, specify the communications method to use when the client communicates with the server and click Next. This information must be provided to you by your IBM Spectrum Protect server administrator. If you are not sure what to select, accept the default setting (TCP/IP). If the default setting does not work when the client attempts to connect to the server, contact the server administrator to determine which communications method to specify.
15. On the TCP/IP Options screen, specify the server address and port information that your IBM Spectrum Protect administrator provided to you. In the Server Address field, specify the IP address or fully qualified domain name of the IBM Spectrum Protect server. In the Port Number field, specify the port number that the server listens on for client communications. The default port number is 1500. Click Next.
16. The Recommended Include/Exclude List screen contains a list of system files and directories that are typically included, or excluded from client operations. The excluded files are typically not required to restore your system. You can select or clear all default selections. Alternatively, you can use the Shift and Ctrl keys to selectively include objects. To facilitate the installation process, click Select All; you can add or remove files from this list later, if you want to. Click Next.
17. The Common File Exclusion Selection screen provides a default list of file extensions that you can exclude from client operations. The file extensions that are provided in this list are typically large files, like graphics or multimedia extension. These files consume server disk space but they might not be required to restore critical data. Click Select All to exclude all of the default file extensions. Alternatively, you can use the Shift and Ctrl keys to selectively choose which extensions to exclude from client operations. Click Clear All to clear any extensions that you selected. You can modify these extensions later if you want to. Click Next.
18. The Domains for Backup screen specifies the default file systems and objects to include in client operations for incremental and image backups.
    a. To configure the default file systems for incremental backups, in the Backup Type field, select Incremental. By default, Back up all local file systems is selected. If you do not want to back up all local file systems as the default action during incremental backups, clear this option and individually select the file systems to include. You can override the default selection when you initiate an incremental backup operation.
    b. To configure the default file systems for image backups, in the Backup Type field, select Image. By default, Back up all local file systems is selected. If you do not want to back up all local file systems as the default action during image backups, clear this option and individually select the file systems to include. You can override the default selection when you initiate an image backup operation.
    c. Click Next.
19. On the Confirm and apply your configuration screen, click Apply. You might be prompted to enter a user ID and password to log on to the IBM Spectrum Protect server. The user ID defaults to the node name that you specified in step 13.

20. You can accept the default user ID or specify a different user ID. Specify the password that you will use when you log on to the server. Click Login. What happens next depends on whether the IBM Spectrum Protect server is configured for open or closed registration.

Option	Description
Server is configured for open registration (IBM Spectrum Protect server V8.1.1, V8.1.0, V7.1.7 or earlier)	The Register New Node screen prompts you for contact information and it prompts you again for the password. Adding text to the Contact Information field is optional, but suggested; specify your name. Re-enter your password, twice, in the two Password fields. If the password that you enter and confirm in these Password fields does not match what you previously specified in the Login into an IBM Spectrum Protect server screen, the password that you specify and confirm here becomes the password that is required to log on to the server. Click Register to register this node on the server. Click Finish. The graphical user interface opens and is ready for use. You can also start any of the other installed client components from the Start menu.
Server uses closed registration	Click Finish. Provide the information that you specified in the client configuration wizard to your IBM Spectrum Protect server administrator. Provide the administrator with the following information: ◦ The node name that you specified. ◦ The user ID and password that you entered. ◦ Your contact information, such as your name, email address, and phone number, so the administrator can contact you after your node and user information is registered on the server. After the administrator registers your node, you can start any of the installed client components from the Start menu.

Troubleshooting problems during installation (Windows)
Windows

Upgrading the Windows client

You can upgrade an earlier version of the IBM Spectrum Protect™ Windows backup-archive client to Version 8.1.2. Your previous configuration settings are preserved, where it is possible to do so. However, enhancements that are in the latest version of the client can deprecate or prohibit the use of options that were available in earlier versions of the client.

Before you begin

Wait for any in-progress backup-archive client tasks (backup, restore, archive, retrieve) to complete before you upgrade a client node.

About this task

To upgrade to the Version 8.1.2 Windows client, install the Version 8.1.2 Windows client; you do not need to uninstall previously installed client software first. The Version 8.1.2 client installation program preserves your current client options and settings (in dsm.opt), and it does not overwrite or delete the dsmerror.log, dsmsched.log, and dsmwebcl.log files, if you install the new client into the same directory that was used by the previous installation.

The Logical Volume Snapshot Agent (LVSA) component was deprecated in IBM Spectrum Protect Version 6.4. If you previously had LVSA configured as your snapshot provider, install the Version 8.1.2 client, and then configure it to use the Microsoft Volume Shadow Copy Service (VSS) as the snapshot provider in the new installation. If LVSA was installed, your client reboots after the upgrade installation completes, to allow for the removal of LVSA entries from the registry.

The installation program stops any client services that are running before it upgrades the client software. If you prefer, you can manually stop the services by using the control panel or command line. Table 1 shows the stoppable services, and the names to look for in the Control Panel > Administrative Tools > Services list, so you can stop them with the Control Panel. The table also provides the commands to stop them from a command prompt or a script.

Note: The service names that are shown in the table are the default names that are set by the installation program. You can change some of these service names when you configure the services by using one of the configuration wizards on the Utilities > Setup Wizard menus. If you change the service name, record the name that you specify and use that name to stop the services.

Table 1. Stoppable services

Control panel display name	Command-line procedure
TSM Journal Service	`net stop "tsm journal service"`
TSM Client Acceptor	`net stop "tsm client acceptor"`
TSM Client Scheduler	`net stop "tsm client scheduler"`
Remote Client Agent	`net stop "tsm remote client agent"`

Complete the following steps to upgrade an earlier version of the Windows backup-archive client to Version 8.1.2:

Procedure

1. Download the appropriate package file from one of the following websites.
   - Download the client package from Passport Advantage or Fix Central.
   - For the latest information, updates, and maintenance fixes, go to the IBM Support Portal.
2. Install the product by using the compressed installation file that you download from Passport Advantage®.
   a. Copy the downloaded compressed installation package to a local disk or to a network-accessible share. Be sure to extract the installation files to an empty directory.
   b. To extract the installation files to the same directory, double-click the compressed installation package.
   c. By default, the uncompressed files are stored in the current disk drive, in the *download_directory*\TSMClient directory. If the installation program detects files from another client installation attempt in this directory, you are prompted about whether to overwrite the old files. If you receive this prompt, enter `A` to overwrite the existing files; this selection ensures that only the files from the current installation are used.
   d. Double-click the spinstall.exe file to start the client installation program.
3. Select a language to use for this installation and click OK.
4. If you are prompted to install one, or more, Microsoft C++ redistributable files, the prompt indicates that your node does not have the C++ files that are required by the Windows backup-archive client. Click Install to install the files and continue with the client installation; or, click Cancel to end the installation process.
5. The backup-archive client installation program starts. On the Welcome screen, click Next to begin installing the new client software.
6. Accept or change the default installation directory.
7. Select the installation type: Typical or Custom.

Option	Description
Typical	A typical installation installs the following components: - The backup-archive client GUI files (required to use the Java™ GUI) - The backup-archive client web files (required to use the web client) - The client API files (as needed by your client and operating system)
Custom	A custom installation installs the same files as a typical installation. However, you can choose to install the following optional components: - The API SDK files. These files are only needed if you are developing applications that work with the backup-archive client. - The administrative client command line files. These files are needed if you want to run administrator functions on the IBM Spectrum Protect server.

8. Click Next, then click Install.
9. When the installer completes the installation, click Finish.
10. Verify the installation. Click Start > All Programs > IBM Spectrum Protect. The client components that you installed are shown in the list of IBM Spectrum Protect startable programs. This list includes only the administrative command-line client, backup-archive command-line client, or the backup-archive GUI. The other installable components (the API Runtime and SDK files) do not display in this list.
11. Click the Backup-Archive GUI entry in the startable programs list.
    a. When prompted, type your user ID and password and click Login.
    b. After the GUI starts, click Help > About IBM Spectrum Protect. Verify that the version shown is Version 8.1.2.

What to do next

Your previous configuration settings are preserved in the dsm.opt file. If you previously used LVSA as the snapshot provider, warning messages are displayed when the command-line client is started. The messages provide instructions to edit the dsm.opt file and remove the LVSA options. Removing the unused options is not required, but removing options that have no affect or are not used, can facilitate troubleshooting. If you are using the GUI, the messages are not displayed, but they are logged in the dsmerror.log file, which is in the client installation directory, in the baclient directory. Messages are issued when any of the following options are included in dsm.opt. Some of these options are valid for VSS, and if they are, the messages are displayed and logged only if they contain parameters that are specific to LVSA.

- snapshotcachelocation
- snapshotfsidleretries
- snapshotproviderimage
- snapshotproviderfs
- snapshotcachesize

You can set VSS options on the Snapshot tab in the Preferences Editor. They can also be set by running the online image support and open file support configuration wizards. To use the wizards, start the GUI and click Utilities > Setup Wizard. Select the wizards that you want to run, click Next, and follow the prompts to make your selections.

Troubleshooting problems during installation (Windows)

Windows

Reinstalling the Windows client

If you uninstall the Version 8.1.2 Windows client, you can reinstall it if you need to.

About this task

If you reinstall the Windows client into the same directory that it was installed in before, the previous configuration information is detected by the installation program. Because the previous configuration information is detected, the installation process is the same as an upgrade installation; follow the steps in Upgrading the Windows client to reinstall the Windows client.

If you do not want to preserve the old configuration information, you can remove it. For information about thoroughly removing client settings and files, see the IBM® developerWorks® article, .How to completely remove the Backup-Archive client from Microsoft Windows

If you do completely remove all configuration settings and later decide to reinstall the Windows client, follow the steps in Installing the Windows client for the first time. That procedure is the appropriate installation procedure to follow if you reinstall the software into a different directory, or if you reinstall the software on a system that contains no previous configuration information.

Windows

Silent installation

The backup-archive client installation program supports silent, unattended installations.

Note: The Microsoft Visual C++ 2010 and 2012 redistributable packages are required to use the backup-archive client. The graphical installation program installs these packages for you. If you are silently installing the client by using MSIEXEC, you must separately install the Microsoft Visual C++ 2010 and 2012 redistributable packages. The packages can be installed before or after the silent installation of the client is completed, but they must be installed before you use the backup-archive client.
Use the following executable files to install the C++ 2010 and 2012 redistributable packages. In the paths that are shown, the *dir* text string represents the drive and directory where you saved the files when you extracted them from the installation package.

Windows executable files for installing C++ redistributable packages

dir\ISSetupPrerequisites\{270b0954-35ca-4324-bbc6-ba5db9072dad} (contains MS 2010 x86 C++ Runtime - vcredist_x86.exe)
dir\ISSetupPrerequisites\{BF2F04CD-3D1F-444e-8960-D08EBD285C3F} (contains MS 2012 x86 C++ Runtime - vcredist_x86.exe)
dir\ISSetupPrerequisites\{7f66a156-bc3b-479d-9703-65db354235cc} (contains MS 2010 x64 C++ Runtime - vcredist_x64.exe)
dir\ISSetupPrerequisites\{3A3AF437-A9CD-472f-9BC9-8EEDD7505A02} (contains MS 2012 x64 C++ Runtime - vcredist_x64.exe)

To install a predefined (custom) dsm.opt file, use the following instructions before you begin the silent installation.

- Place the customized copy of the dsm.opt file in the ...\CONFIG directory that is located within the installation image, for example:
  - `C:\tsm_images\TSMClient\Program Files 64\Tivoli\TSM\config`

  The file must be named *dsm.opt*.
- The installation program copies the predefined dsm.opt file to the ..\BACLIENT directory when BOTH of the following conditions are met:
  - dsm.opt does NOT exist in the ..\BACLIENT directory. The installation program does not copy over an existing dsm.opt file.
  - dsm.opt exists in the ..\CONFIG directory of the installation image, as described earlier.

To silently install the C++ redistributables or the backup-archive client, you must turn off User Account Control (UAC).

To turn off UAC, use either the Windows Control Panel or the MSCONFIG utility.

- To turn off UAC by using the Control Panel, go to the Control Panel and find User Account Control settings, then set the notification level to Never Notify.
- To turn off UAC by using the MSCONFIG utility, open a command prompt window and enter msconfig. Select the User Account Control settings tool, and set the notification level to Never Notify.

After you install the C++ redistributables and the Windows client, remember to turn on UAC.

The C++ redistributables require elevated privileges to install them. Open a command prompt window as follows:

1. Click Start Menu > All Programs > Accessories > Command Prompt.
2. Right-click the Command Prompt icon to view the properties.
3. Click Run as administrator.
4. Click Continue in the permission window.
5. Start the product installation by using the command prompt window.

Silently installing C++ redistributables

Run the following command twice. Run it first from the directory where the C++ 2010 vcredist_x86.exe file is stored. Then, run it again from the directory where the C++ 2012 vcredist_x86.exe file is stored.

```
vcredist_x86.exe /install /quiet /norestart /log logfilename
```

For more information about the vcredist_x86.exe command, run the following command:

```
vcredist_x86.exe /?
```

Run the following command twice. Run it first from the directory where the C++ 2010 vcredist_x64.exe file is stored. Then, run it again from the directory where the C++ 2012 vcredist_x64.exe file is stored.

```
vcredist_x64.exe /install /quiet /norestart /log logfilename
```

For more information about the vcredist_x86.exe command, run the following command:

```
vcredist_x64.exe /?
```

Install the Windows backup-archive client. UAC must still be turned off. If it is not turned off, turn off UAC now. Open a command prompt that has elevated privileges.

1. Click Start Menu > All Programs > Accessories > Command Prompt.
2. Right-click the Command Prompt icon to view the properties.
3. Click Run as administrator.
4. Click Continue in the permission window.
5. Start the Windows backup-archive client silent installation by using the command prompt window. Use the following instructions to silently install the Windows client and API.

Silent installation of the Windows client

When you place a customized version of the msiexec command (which calls the Microsoft Software Installer) in a script or batch file, you can perform installations on multiple Windows systems. The following example is a sample command to install the backup-archive command-line client, client GUI, web client, API, and Administrative command-line client. You might need to customize this example to run correctly on your system. Although the command is physically spread across multiple lines in the following example, enter it on a single command line.

```
msiexec /i "Z:\tsm_images\TSMClient\IBM Tivoli Storage Manager Client.msi" RebootYesNo="No"
REBOOT="Suppress" ALLUSERS=1 INSTALLDIR="C:\Program Files\Tivoli\Tsm"
ADDLOCAL="BackupArchiveGUI,BackupArchiveWeb,Api64Runtime, AdministrativeCmd"
TRANSFORMS=1033.mst /qn /l*v "C:\log.txt"
```

The descriptions of the silent installation parameters are as follows:

msiexec
: Starts the Microsoft Software Installer (MSI) program.

/i
: Installs the specified source package (replace with `/x` to uninstall the package).

"*Z:*\tsm_images\TSMClient\IBM Tivoli Storage Manager Client.msi"
: Specifies the complete path to the source package. The Z drive is shown in this example. Specify the drive letter for the disk drive, in your configuration, that contains the installation image.

RebootYesNo="No" REBOOT="Suppress"
: Under certain conditions, a system reboot might be necessary for the installation to complete successfully. This option causes the installation program to not reboot the system if circumstances would otherwise cause the reboot to occur. While this option is convenient, use it with caution because suppressing the reboot might cause the program to behave in an unpredictable manner. The most common reason that a reboot is required is if the installation was an upgrade to an existing backup-archive client, and the installation was performed while the client programs were running. Therefore, shut down all backup-archive client programs and services before you begin the installation.

ALLUSERS=1
: Specifies that the package is for all users. This option is required.

INSTALLDIR="C:\Program Files\Tivoli\TSM"
: Specifies the destination path. If you already installed this product or a previous version of this product on your workstation, use the current installation directory as the destination path for this package.

ADDLOCAL="BackupArchiveGUI,BackupArchiveWeb,Api64Runtime"
: Specifies the features to install. Specify all the components on a single line within quotation marks, separated by commas, with no spaces before or after the commas. The installable client features are shown in the following table:

Windows client features	Feature description
BackupArchiveGUI	Graphical user interface
BackupArchiveWeb	Backup-archive web client
Api64Runtime	API Runtime
ApiSdk	API SDK
AdministrativeCmd	Administrative Command Line

TRANSFORMS=1033.mst
: Specifies which language transform to use. The following language transforms are available:

Transform	Language
1028.mst	CHT Traditional Chinese
1029.mst	CSY Czech
1031.mst	DEU German
1033.mst	ENG English
1034.mst	ESP Spanish
1036.mst	FRA French
1038.mst	HUN Hungarian
1040.mst	ITA Italian
1041.mst	JPN Japanese
1042.mst	KOR Korean
1045.mst	PLK Polish
1046.mst	PTB Portuguese
1049.mst	RUS Russian

Transform	Language
2052.mst	CHS Simplified Chinese

/qn
Specifies to install the product silently.

/l*v "C:\log.txt"
Specifies verbose logging and the name and location of the log file.

The installation process creates the IBM Spectrum Protect™ folder in the programs folder of the Windows Start menu. You can start the backup-archive client by clicking one of the icons in this folder.

Troubleshooting problems during installation (Windows)
Windows

Modifying, repairing, or uninstalling the Windows client

You can modify, repair, or uninstall an existing Windows client.

About this task

Use the Windows control panel to modify, repair, or uninstall the Windows client.

Procedure

1. Click Start > Control Panel > Uninstall a program.
2. Select IBM Spectrum Protect™ Client in the list of installed programs.
3. Select the function that you want to perform: Repair, Change, or Uninstall.

Option	Description
Repair	Wait for any in-progress backup-archive client tasks to completed before you repair the Windows client. This option repairs an existing Windows client installation. If you select Repair, the files installed by the installation program are examined to determine whether they have somehow become corrupted. If a file is determined to be corrupted, the repair option attempts to replace it from the saved installation image. The repair option also repairs missing program short cuts and icons, missing files, and registry keys.
Change	Wait for any in-progress backup-archive client tasks to completed before you modify the Windows client. This option modifies an existing installation. If you select Change, the next screen that is displayed shows Modify as the option for changing installed programs. If you already installed the client and you need to add or remove components, click Change, and select Modify. Choose the icon next to the feature that you want to install or remove and select the appropriate action from the drop-down list. For example, if you selected a typical installation when you installed the client, the administrative client command line interface files are not installed. If you decide that a node needs this interface, select the icon next to Administrative Client Command Line Files and click the This feature will be installed on local hard drive option. Note: This option achieves the same effect as upgrading the client. The difference is that you bypass the initial steps and the installation process begins with the last installation type that you selected. If you want to change the installation type, you can click Back, and select the new installation type; then complete the information as you are prompted for it. Use the information that is provided in Upgrading the Windows client (start at step 7) if you have questions about a prompt.

Option	Description
Uninstall	Wait for any in-progress backup-archive client tasks to completed before you uninstall the Windows client. This option uninstalls the Windows client program. It does not remove any client services. It also does not remove log files, or other items that were created when you configured or used the client. Most of these artifacts remain in the installation directory (Program Files\Tivoli\TSM directory), but they can exist anywhere on the disk, depending on what you chose for the installation directory and other options. This option also does not remove files that were copied to the local disk if you extracted the installation files from a compressed distribution file. Leaving these artifacts on disk is not a problem if you want to reinstall the client in the future. However, if you want to more thoroughly remove the client and related files and settings, see the wiki article How to completely remove the Backup-Archive client from Microsoft Windows. The installation program stops any client services that are running before it uninstalls the software. If you want to stop the services yourself, type the following commands at a command prompt window: • `net stop "tsm journal service"` • `net stop "tsm client acceptor"` • `net stop "tsm client scheduler"` • `net stop "tsm remote client agent"` You can also use the Control Panel to stop these services. Their display names match the name used on the command line. Note: The service names shown here are the default names that are set by the installation program. You can change some of these service names when you configure the services using one of the configuration wizards on the Utilities > Setup Wizard menus. If you change the service name, record the name that you specify and use that name to stop the services. If you want to remove any of these services without uninstalling the client, perform the following steps: a. Click Start > All Programs > IBM Spectrum Protect > Backup-Archive GUI. b. Click Utilities > Setup Wizard. c. Select and run the wizard for each service that you want to remove. The setup wizard options can also remove the configuration information for online image support and open file support.

Windows

Troubleshooting problems during installation (Windows)

If you are upgrading from a previous version of the backup-archive client and there are client services running (for example, Client Acceptor or Scheduler), you might see an error during the installation.

If there are other IBM Spectrum Protect™ client services running on any account (for example, Client Acceptor or Scheduler), you might see a request to reboot the system during installation. You must stop all instances of the IBM Spectrum Protect client on all accounts before starting the installation.

You might see the following error during installation:

```
Error 1303. The installer has insufficient privileges to access this directory:
(Install Drive):\Program Files\Tivoli\TSM\baclient\plugins. The installation
cannot continue. Log on as an administrator or contact your system administrator.
```

When this error occurs, you must stop the installation. After stopping the installation process, the previous version is no longer installed. Stop the client services and retry the installation process.

Windows

Software updates

Software updates might periodically be made available by IBM® for download.

For the latest information, updates, and maintenance fixes, see the IBM Support Portal for IBM Spectrum Protect™.

Linux | Windows

Installing the client management service to collect diagnostic information

You can install IBM Spectrum Protect™ client management services to collect diagnostic information about the backup-archive client. The client management service makes the information available to the IBM Spectrum Protect Operations Center for basic monitoring capability.

About this task

After you install the backup-archive client, install the client management service on the same computer so that the IBM Spectrum Protect server administrator can view diagnostic information from the Operations Center.

For installation instructions and more information about the client management service, see Collecting diagnostic information with IBM Spectrum Protect client management services.

Configuring backup-archive clients

You can configure the backup-archive client to use many of the available client features. Information for configuring the backup-archive client is provided.

- Configure the IBM Spectrum Protect client
  After installing the backup-archive client, you must configure it before performing any operations.
- Getting started
  Before you can use the IBM Spectrum Protect backup-archive client, you must learn how to start a GUI or command-line session, and how to start the client scheduler automatically. You can also learn about other commonly used tasks.

Related concepts:
Installing the IBM Spectrum Protect backup-archive clients (UNIX, Linux, and Windows)

Backup-archive client options and commands

Configure the IBM Spectrum Protect client

After installing the backup-archive client, you must configure it before performing any operations.

AIX | Linux | Solaris | Mac OS X If you are upgrading the backup-archive client, it is unnecessary to reconfigure the scheduler, web client, or other configuration settings. If the dsm.opt and dsm.sys files used by the previous client installation are available in the default installation directory or the directory or file pointed to by the DSM_CONFIG and DSM_DIR environment variables, the client accesses these files for configuration information.

Windows If you are upgrading the backup-archive client, it is unnecessary to reconfigure the scheduler, web client, or other configuration settings. If the dsm.opt file used by the previous client installation is available in the default installation directory or the directory or file pointed to by the DSM_CONFIG and DSM_DIR environment variables, the client accesses this file for configuration information.

Some configuration tasks are required, while other tasks are optional. The following configuration tasks are required:

- Mac OS X | AIX | Linux | Solaris Creating and modifying the client system-options file
- Windows Creating and modifying the client options file
- Register your workstation with a server

The following configuration tasks are optional:

- AIX | Linux | Solaris Creating a default client-user options file
- AIX | Linux | Solaris Creating a customized client user-options file

- AIX Linux Solaris Environment variables
- Windows Create a shared directory options file
- Windows Creating multiple client options files
- Windows Environment variables
- Windows Configuring the language for displaying the Java GUI
- Windows Configuring the web client on Windows systems
- AIX Linux Mac OS X Solaris Configuring the web client on AIX, Linux, Mac, and Solaris systems
- Configuring the scheduler
- Windows Configuring the journal engine service
- Windows Configuring online-image backup support
- Windows Configuring Open File Support
- Creating an include-exclude list
- Linux Windows Configuring parallel backups of VMware virtual machines. See Parallel backups of virtual machines
- Mac OS X AIX Linux Solaris UNIX and Linux client root and authorized user tasks
  An authorized user is any non-root user who has read and write access to the stored password (TSM.sth file), or anyone who knows the password and enters it interactively. Authorized users use the passworddir option to define the directory where their copy of the password file is saved.
- AIX Linux Mac OS X Solaris Enable non-root users to manage their own data
  To enable non-root users to use the backup-archive client to manage their own data, the system administrator must complete steps in addition to the normal configuration steps to setup first-time Authorized users for non-root users.
- Client options file overview
  You set (specify) client options and values in a client options file. Client options can also be set on the server in a *client option set*. Client options that are set on the server in a client option set override client options that are set in the client options file.
- Windows Environment variables
  Generally, setting the environment variables is an optional task. Setting them makes it more convenient for you to use the command line.
- Mac OS X AIX Linux Solaris Environment variables
  Generally, setting the environment variables is an optional task. Setting these variables makes it more convenient for you to use the command line.
- Windows Configuring the language for displaying the Java GUI
  You can select the language to use for displaying the backup-archive client Java GUI.
- Web client configuration overview
  The IBM Spectrum Protect web client provides remote management of a client node from a web browser. The procedures to configure the web client vary depending on which operating system is on the client node.
- Configuring the scheduler
  Your IBM Spectrum Protect administrator can schedule the client to perform tasks automatically. For scheduled events to occur on the client, you must configure the client scheduler to communicate with the IBM Spectrum Protect server.
- Mac OS X AIX Linux Solaris Start the client scheduler
  This task guides you through the steps to schedule events using the GUI and the command-line client.
- Windows Starting the client scheduler
  To start the client scheduler, use the Services Control Panel or the **net start** command.
- Configuring IBM Spectrum Protect client/server communication across a firewall
  In most cases, the IBM Spectrum Protect server and clients can work across a firewall.
- AIX Linux Solaris Windows Configuring IBM Spectrum Protect client/server communication with Secure Sockets Layer
  Secure Sockets Layer (SSL) allows industry standard SSL-based secure communications between the IBM Spectrum Protect client and server.
- AIX Windows Linux Configure your system for journal-based backup
  You must install and configure the journal daemon (Linux) or journal engine service (Windows) before you can perform journal-based backups.
- Client-side data deduplication
  Data deduplication is a method of reducing storage needs by eliminating redundant data.
- Automated client failover configuration and use
  The backup-archive client can automatically fail over to a secondary server for data recovery when the IBM Spectrum Protect server is unavailable. You can configure the client for automated failover or prevent the client from failing over. You can also determine the replication status of your data on the secondary server before you restore or retrieve the replicated data.
- Linux Windows Configuring the client to back up and archive Tivoli Storage Manager FastBack data
  Before you can back up or archive Tivoli® Storage Manager FastBack client data, you must complete configuration tasks.

- Windows Configuring the backup-archive client to protect FastBack client data
  You can configure the backup-archive client to protect FastBack client data by using the client configuration wizard.
- Mac OS X AIX Linux Solaris Cluster environment configuration and use
  The term *cluster* has different meanings in different environments. It can mean highly available, high performance, load balancing, grid computing, or some combination of all of these terms.
- Windows Configuring the backup-archive client in a cluster server environment
  You can install the backup-archive client software locally on each node of a Microsoft Cluster Server (MSCS) or Veritas Cluster Server (VCS) environment cluster.
- Windows Configuring online-image backup support
  If the online image feature is configured, the backup-archive client performs a snapshot-based image backup, during which the real volume is available to other system applications.
- Windows Configuring Open File Support
  You configure Open File Support (OFS) after you install the Window client.
- AIX AIX configuration considerations prior to performing snapshot-based file backups and archives
  If you are configuring your IBM Spectrum Protect AIX® client to perform snapshot-based file backups and archives, there are some items that you need to consider.
- Linux Windows Configuring NetApp and IBM Spectrum Protect for snapshot difference incremental backups
  You must configure the NetApp file server connection information to run the snapshot difference incremental backup command on the backup-archive client. You must also use the set password command to specify the file server host name, and the password and user name that is used to access the file server.
- Register your workstation with a server
  Before you can use IBM Spectrum Protect, you must set up a node name and password and your node must be registered with the server.
- Creating an include-exclude list
  If you do not create an include-exclude list, the backup-archive client considers all files for backup services and uses the default management class for backup and archive services.

Mac OS X AIX Linux Solaris

UNIX and Linux client root and authorized user tasks

An authorized user is any non-root user who has read and write access to the stored password (TSM.sth file), or anyone who knows the password and enters it interactively. Authorized users use the passworddir option to define the directory where their copy of the password file is saved.

Table 1 shows the tasks that can and cannot be performed by the root user, authorized users, and other users.

Table 1. Tasks for root users and authorized users

Task	Root user	Authorized user
Log on to the IBM Spectrum Protect™ server, using an LDAP server to authenticate credentials.	Yes	Yes
Register new nodes with the IBM Spectrum Protect server (if registration is set to open on the server).	Yes	Yes

Task	Root user	Authorized user
Set or re-create the IBM Spectrum Protect password for client workstations	Yes	Yes
Backup	Yes Note: The IBM Spectrum Protect administrator can specify an option on either the Register Node or Update Node commands to specify who is allowed to back up data for a node. Setting BACKUPINITiation to root restricts backups so that only root or authorized users can back up files on a node. Setting BACKUPINITiation to all allows any user to back up data on a node. For information about these commands and options, see the IBM Spectrum Protect server documentation.	Yes, if you have read permission, regardless of ownership
Restore	Yes; when restoring to a new location or the same location, file permission and ownership are preserved	Yes; however, the operating system prevents writing to the same location if the file has read only permission. When restoring to the same location, file permissions and ownership are preserved. When restoring to a different location, the permissions of the restored file are preserved but the ownership changed to the current user.
Archive	Yes	Yes, if you have read permission, regardless of ownership
Retrieve	Yes. When retrieving to a new location or to the same location, file permissions and ownership are preserved.	Yes. However, the operating system prevents writing to the same location if the file has read only permission. Ownership of all retrieved objects is changed to the current user.
Client scheduler	Yes	Yes, if not using the client acceptor daemon. You must be root to manage the client acceptor daemon. A non-root authorized user can use the scheduler (dsmc sched).
Grant user access to files on the IBM Spectrum Protect server	Yes	Yes
Delete IBM Spectrum Protect server file spaces	Yes, if the node is granted backup or archive delete authority by the IBM Spectrum Protect server administrator	Yes, if the node is granted backup or archive delete authority by the IBM Spectrum Protect server administrator

On Mac OS X systems, a system administrator is any user that is allowed to administer the system. You can check your account type using the System Preferences > Accounts tool. System Administrators have an account type of Admin.

Mac OS X The system administrator is responsible for configuring the backup-archive client so non-administrators can manage their own data. Non-administrators (or non-authorized users) meet the following criteria:

Mac OS X

- They do not have a user ID of 0. They are not the root user.
- They have a user account that has not been configured as a system administrator.

Mac OS X When a task requires additional authority to complete, you must use the authorization application to start the backup-archive client. This allows the client to run with sufficient system privileges to complete the task. The following table lists the authorization tools to use.

Table 2. Mac OS X authorization tools and associated IBM Spectrum Protect applications

Mac OS X authorization tool	Associated IBM Spectrum Protect application
IBM Spectrum Protect For Administrators	IBM Spectrum Protect StartCad.sh StopCad.sh
sudo	dsmc

AIX Linux Mac OS X Solaris

Enable non-root users to manage their own data

To enable non-root users to use the backup-archive client to manage their own data, the system administrator must complete steps in addition to the normal configuration steps to setup first-time Authorized users for non-root users.

In addition to the normal configuration steps, the system administrator must complete the following steps to setup Authorized users for non-root users:

1. Add a stanza in the client system-options file, dsm.sys, for the non-root user.
2. In this stanza, use the passworddir option to point to a directory that is owned by the non-root user. The non-root user can then create a file in this passworddir directory.
3. Assign the non-root user with a unique TSM node name.
4. Ensure that an earlier TSM.PWD file that is not owned by the non-root user, does not exist in the passworddir directory. If such a file exists, change ownership of this file to the non-root user or remove the file.
5. Ensure that TSM.KDB, TSM.IDX or TSM.sth files that are not owned by the non-root user, do not exist in the passworddir directory. If such files exist, remove them.

On completion of the steps by the system administrator, the non-root user must complete the following steps:

1. Create a client system-options file, dsm.opt, and use the servername option to specify the stanza name.
2. Ensure that the dsm.opt file can be read by default by the DSM_CONFIG environment variable. Issue the export DSM_CONFIG=<dsm.opt> command from a shell command window to check.
3. Run the dsmc q f command to use password files that are pointed to by the passworddir option. If no password files exist, the user is prompted.

- AIX Linux Mac OS X Solaris Enabling encryption for backup-archive client users
  If you configure the backup-archive client to encrypt data during backup and archive operations, and if you specify the option to store the encryption key password (encryptkey save), by default, only root and IBM Spectrum Protect™ authorized users can use the stored password to encrypt or decrypt files. Authorized users include any non-root users who have read and write access to the stored password (TSM.sth file), or users who know the password and enter it interactively.

Client options file overview

You set (specify) client options and values in a client options file. Client options can also be set on the server in a *client option set*. Client options that are set on the server in a client option set override client options that are set in the client options file.

Windows On Windows systems, the default client options file is named dsm.opt.

AIX Linux Mac OS X Solaris On AIX®, Linux, Mac, and Solaris systems, the default client options file is named dsm.opt. For these operating systems, two files contain backup-archive client options:

- The *client-user options* file. The default name for this file is dsm.opt. For brevity, this file is often called the *client options file*.
- The *client-system options* file. The default name for this file is dsm.sys. The client-system options file is an editable file that identifies the server and communication method, and provides the configuration for backup, archiving, hierarchical storage management, and scheduling. For brevity, this file is often called the *system options file*.

You can create multiple client options files. If your client options file is not named dsm.opt, or if dsm.opt is not in the default directory, use the OPTFILE client option to tell the backup-archive client which file to read the options and parameters from when the backup-archive client is started.

AIX Linux Mac OS X Solaris You cannot change the name of the client-system option file. It must be named dsm.sys.

You can use a text editor application to directly edit the client options file. You can also set options by using the backup-archive client GUI. In the GUI, select Edit > Preferences and use the Preferences Editor to set client options. Options that you set in the Preferences Editor are stored in the client options file. Not all client options can be set by using the Preferences Editor.

Mac OS X Restriction: For Mac OS X, the client-user options file and client-system options file must be plain text files, encoded as Unicode (UTF-8). By default, TextEdit does not save files as plain text. Select Format > Make Plain Text to save the files as plain text files. Select Unicode (UTF-8) in the Plain Text Encoding drop down list. Do not add the .txt extension when you save the file.

You can use the query options command to display all or part of your options and their current settings. This command accepts an argument to specify a subset of options. The default is to display all options.

Some options consist of only the option name, such as verbose and quiet. You can enter the entire option name, or its abbreviation. For example, you can specify the verbose option in either of the following ways:

```
verbose
ve
```

Follow these rules when you add options to your options files:

- You can annotate option settings by adding comments to the options file. Begin each comment with an asterisk (*) as the first character on the line.
- Do not specify options on a line that contains a comment.
- You can optionally indent options with spaces or tabs, to make it easier to view the options and values that you specify in the file.
- Enter each option on a separate line and enter all parameters for an option on the same line, as shown in the following examples:

  AIX Linux Mac OS X Solaris

  ```
  domain /home /mfg /planning /mrkting /mgmt
  domain / /Volumes/fs2 /Volumes/fs2 /Volumes/fs3 /Volumes/fs4
  ```

  Windows

  ```
  domain="c: d:"
  domain="ALL-LOCAL -c: -systemstate"
  ```

- To set an option in this file, enter the option name and one or more blank spaces, followed by the option value.
- Enter one or more blank spaces between parameters.
- The lengths of file and path names in the client options files cannot exceed the following limits:
  - AIX Linux Mac OS X Solaris On AIX, Mac OS, and Solaris, the maximum length for a file name is 255 bytes. The maximum combined length of the file name and path name is 1024 characters. The Unicode representation of a character can occupy several bytes, so the maximum number of characters that a file name might contain can vary.
  - Linux On Linux, the maximum length for a file name is 255 bytes. The maximum combined length of the file name and path name is 4096 bytes. This matches the PATH_MAX that is supported by the operating system. The Unicode representation of a character can occupy several bytes, so the maximum number of characters that comprises a path and file name can vary. The limitation is the number of bytes in the path and file components, which might or might not correspond to an equal number of characters.
  - Windows On Windows, a file name cannot exceed 255 bytes. Directory names, including the directory delimiter, are also limited to 255 bytes. The maximum combined length for a file name and path name is 5192 bytes. The Unicode representation of a character can occupy several bytes, so the maximum number of characters that a file name might contain can vary.

    File path and file name limits are shown in Table 1.

  - For archive or retrieve operations, the maximum length that you can specify for a path and file name, combined, is 1024 bytes.

Windows

Table 1. File path and name limits

MBCS encoding	Path name length limits	File name length limits

MBCS encoding	Path name length limits	File name length limits
1	5192 bytes	255 bytes
2	4092 bytes	127 bytes
3	2728 bytes	85 bytes

Windows In the table, MBCS encoding has these meanings:

Basic Latin
: Standard US English characters, numbers, symbols, and control characters that are traditionally represented in 7-bit ASCII have a 1:1 ratio of bytes to characters.

Latin extensions
: Latin characters that have tildes, grave or acute accents, and so on, as well as Greek, Coptic, Cyrillic, Armenian, Hebrew, and Arabic characters, typically have a 2:1 ratio of bytes to characters.

Chinese, Japanese, Korean, Vietnamese
: These characters and other East Asian language characters typically have a 3:1 ratio of bytes to characters.

Windows If you update the client options file while a session is active, you must restart the session to pick up the changes. If you use the client GUI setup wizard to make changes, the changes are effective immediately. If you are not using the client acceptor to manage the scheduler, you must also restart the scheduler.

Mac OS X AIX Linux Solaris If you update the client-user options file while a session is active, you must restart the session to pick up the changes.

- Mac OS X AIX Linux Solaris Creating and modifying the client system-options file
  The client system-options file is an editable file that identifies the server and communication method, and provides the configuration for backup, archiving, hierarchical storage management, and scheduling.
- Windows Creating and modifying the client options file
  The client options file is an editable text file that contains configuration information for the backup-archive client.
- Mac OS X AIX Linux Solaris Creating a default client-user options file
  A client-user options file stores the backup-archive client processing options. The backup-archive installation program places a sample client-user options file on disk when you install the backup-archive client. A system administrator or root can edit this file to create a default client options file, and makes the file accessible to workstation users who use the backup-archive client. Individual users can create and use their own client options file.
- Mac OS X AIX Linux Solaris Creating a customized client user-options file
  If you want to use different options than those specified in the default client user-options file (dsm.opt), you can create your own client user-options file.
- Windows Create a shared directory options file
  The IBM Spectrum Protect™ server administrator can generate client options files in a shared directory.
- Windows Creating multiple client options files
  You can create multiple client options files if you must work with multiple servers, or find that you need multiple sets of parameters to do back up or archive tasks.

Query Options
Mac OS X AIX Linux Solaris

Creating and modifying the client system-options file

The client system-options file is an editable file that identifies the server and communication method, and provides the configuration for backup, archiving, hierarchical storage management, and scheduling.

About this task

Creating and modifying the client system-options file (dsm.sys) is a required task.

The backup-archive client GUI provides a Configuration Wizard that can be used to create basic configuration files and test the connection to the IBM Spectrum Protect™ server. The Configuration Wizard starts automatically if the configuration files are not found when the GUI starts. If you want to modify the configuration files after they are created, click on Setup Wizard from the Tools menu of the GUI.

If you do not use the Configuration Wizard, you can create and modify the client options file manually.

Mac OS X For Mac OS X, copy the dsm.sys.smp file to dsm.sys in one of the following locations. The default locations are listed in the order that they are searched.

1. A location identified by the DSM_DIR environment variable
2. `/Library/Application Support/tivoli/tsm/client/ba/bin/`
3. `/Library/Preferences/Tivoli Storage Manager/`

   The client uses the first options file that is found. You must use the name dsm.sys for this file. The dsm.sys file is controlled by the system administrator.

Solaris For Oracle Solaris systems, copying dsm.sys.smp to dsm.sys is not required. The client options files (dsm.opt and dsm.sys) are automatically created in /usr/bin, if they do not already exist, and they are linked to the client installation directory when you install the client. Note that the files are not removed if you uninstall the client, so you can reuse your settings if you upgrade or reinstall the client.

Mac OS X AIX Linux For the other platforms, as the root user, copy the dsm.sys.smp file to dsm.sys and then edit that file to configure your settings. The client looks for dsm.sys in the directory specified by the DSM_DIR environment variable (if it is set and exported), and then in the installation directory.

Important: If you are reinstalling and you want to keep your existing dsm.sys file intact, do not copy the dsm.sys.smp file to dsm.sys.

Use the dsm.sys file to specify one or more servers to contact for services, and communications options for each server. This file can also include authorization options, backup and archive processing options, and scheduling options.

Edit dsm.sys to include the server or servers to which you want to connect. The following is an example of a client system-options file stanza which contains the required options for a server you want users to contact. You can specify options for more than one server:

```
Servername                server_a
COMMMethod                TCPip
TCPPort                   1500
TCPServeraddress          node.domain.company.com
```

Important: If you want to use the web client, you must also specify the passwordaccess=generate option, and log in with the client to save the password.

As the default, your client node contacts the first server identified in the dsm.sys file. You can specify a different server to contact by entering the servername option in your own client user-options file (dsm.opt), or by entering that option with a command.

AIX Linux Solaris You can also specify a default server and a migration server (if you have the HSM client installed on your workstation) in your dsm.sys file.

The dsm.sys file can also contain the following option categories:

- Communication options
- Backup and archive processing options
- Restore and retrieve processing options
- Scheduling options
- Authorization options
- Error processing options
- Transaction processing option
- Web client options

You can modify your dsm.sys file using one of the following methods:

- From the client Java™ GUI main window, select Edit > Client Preferences.
- Use your favorite text editor.

Mac OS X Important: For Mac OS X, the system-options file must be a plain text file, encoded as Unicode (UTF-8). By default, TextEdit does not save files as plain text. Select Format > Make PlainText to save the user-options file as a plain text file. Set the Plain Text Encoding: to `Unicode (UTF-8)`. Do not add the .txt extension.

If you update the dsm.sys file while the client is running, you must restart the process to pick up the changes.

Windows

Creating and modifying the client options file

The client options file is an editable text file that contains configuration information for the backup-archive client.

About this task

The first time that you start the Windows backup-archive client GUI, the installation program searches for an existing client options file, called dsm.opt. If this file is not detected, a client options file configuration wizard starts and prompts you to specify initial client configuration settings. When the wizard completes, it saves the information that you specified in the dsm.opt file. By default, the dsm.opt file is saved to C:\Program Files\Tivoli\TSM\baclient.

The options file must contain the following information to communicate with the server:

- The host name or IP address of the IBM Spectrum Protect™ server.
- The port number that the server listens on for client communications. A default port number is configured by the client options file configuration wizard. You do not need to override this default port number unless your server is configured to listen on a different port.
- Your client node name. The node name is a name that uniquely identifies your client node. The node name defaults to the short host name of the computer that the client is installed on.

Additional client options can be specified, as needed.
Note: Client options can also be set on the server in a *client option set*. Client options that are defined on the server in a client option set override client options that are set in the client options file.

A sample options file is copied to your disk when you install the backup-archive client. The file is called dsm.smp. By default, the dsm.smp file is copied to C:\Program Files\Tivoli\TSM\config\. You can view the contents of this file to see examples of different options and how they are specified. The file also contains comments that explain syntax conventions for include lists, exclude lists, and wildcard use. You can also use this file as a template for your client options file by editing it and saving it as dsm.opt in the C:\Program Files\Tivoli\TSM\baclient directory.

After the initial client options file is created, you can modify the client options by adding or changing the options as needed. You can modify the dsm.opt file in any of the following ways:

- By running the client options file configuration setup wizard
- By using the client preferences editor
- By editing the dsm.opt file with a text editor program, such as Notepad

Perform the following steps to modify the client options:

Procedure

1. Select a method to modify the file.

Option	Description
Setup wizard	a. Click Start > All Programs > IBM Spectrum Protect > Backup-Archive GUI. b. Select Utilities > Setup Wizard > Help me configure the Client Options File. On-screen text and online help is available to provide guidance as you navigate through the wizard panels. This client options file configuration wizard offers limited choices and configures only the most basic options.
Preferences editor	a. Click Start > All Programs > IBM Spectrum Protect > Backup-Archive GUI. b. Select Edit > Client Preferences. Select the tabs in the preferences editor to set client options. Specify the options in the dialog boxes, drop down lists, and other controls. Online help is provided. Click the question mark (?) icon to display the help topics for the online help for the tab that you are editing. You can set more options in the preferences editor than you can set in the setup wizard.

Option	Description
Edit the dsm.opt file	a. Edit the dsm.opt file by using a plain text editor. Each of the options is described in detail in the documentation in Client options reference. This method is the most versatile way to set client options because not all options can be set in the client options file configuration wizard or in the preferences editor. b. To comment out a setting, insert an asterisk (*) as the first character on the line that you want to comment out. Remove the asterisk to make the commented option active.

2. Save the changes.
    a. Changes made in the client options file configuration wizard and in the preferences editor are saved and recognized by the client when the wizard completes, or when you exit the preferences editor.
    b. If you edit the client options file with a text editor while the client is running, you must save the file and restart the client so the changes are detected.

Mac OS X | AIX | Linux | Solaris

Creating a default client-user options file

A client-user options file stores the backup-archive client processing options. The backup-archive installation program places a sample client-user options file on disk when you install the backup-archive client. A system administrator or root can edit this file to create a default client options file, and makes the file accessible to workstation users who use the backup-archive client. Individual users can create and use their own client options file.

Before you begin

You must be root or a system administrator to complete this procedure.

About this task

Creating a default client-user options file is an optional task.

By default, the client-user options file is named dsm.opt, and the file contains the following types of client options:

- Backup and archive processing options
- Restore and retrieve processing options
- Scheduling options
- Format options
- Command processing options
- Authorization options
- Error processing options
- Transaction processing option
- Web client options

For Mac clients, the client installation program places a sample client-user options file named dsm.opt.smp in /Libraries/Preferences/Tivoli Storage Manager/. This directory is the same directory that the installation program places a sample client-system option file (dsm.sys.smp) in.

For AIX® and Linux clients, the client installation program places a sample client-user options file named dsm.opt.smp in the default client installation directory. This directory is the same directory that the installation program places a sample client-system option file (dsm.sys.smp) in.

For Oracle Solaris clients, the installation program places an initial client-user options file named dsm.opt in the /usr/bin directory. This directory is the same directory that the installation program places a sample client-system option (dsm.sys) file in.

For all client operating systems, the following procedure instructs you to edit the sample client-user options file and save it with the default name, dsm.opt. You can save the file with a different name or path, if you want to, but if you change the file name or if you move the file from the default installation directory, you must use either of the following methods to specify the path and name of the client-user options file:

- Set the DSM_CONFIG environment variable to indicate the path and file name of the client-user option file (dsm.opt). Set the DSM_DIR environment variable to indicate the path and file name of the client-system option file (dsm.sys). For more information about the environment variables, see Set processing environment variables.
- Specify the backup-archive client optfile option to specify the path and file name of the client-user options file.

Note: All node users must have read access to the disk location where you store the client-user options file.

Procedure

1. Change to the directory that contains the sample client-user options file.
2. Copy the file to dsm.opt.
3. Add options for your node to the dsm.opt file. Use either of the following methods to set the client-user options:
   - Edit dsm.opt with a text editor to add the options that are needed in the node.
     Note: On Mac OS X, the dsm.opt file must be saved as a plain text file and use Unicode (UTF-8) as the encoding scheme. By default, TextEdit does not save files as plain text. To save dsm.opt, in TextEdit, select Format > Make Plain Text. In the Plain Text Encoding drop-down list, select Unicode (UTF-8). Do not add the .txt extension to the file name.
   - Set client options by using the preferences editior. In the backup-archive client GUI, select Edit > Client Preferences and select the options that you want to configure. The preferences editor updates the client configuration files, dsm.opt, and dsm.sys if you add, change, or remove options. If you update the dsm.opt file while the backup-archive client is running, you must restart the backup-archive client so the updates are recognized.

     The preferences editor uses the DSM_DIR environment variable to locate the client-system options file (dsm.sys) and the DSM_CONFIG environment variable to locate the client user-options file (dsm.opt). If you want dsm.opt to be in a non-default location, set DSM_CONFIG before you start backup-archive client and then use the preferences editor to set the options. The preferences editor queries the server for options on the server, but cannot change the server options file.

Creating and modifying the client system-options file

Mac OS X | AIX | Linux | Solaris

Creating a customized client user-options file

If you want to use different options than those specified in the default client user-options file (dsm.opt), you can create your own client user-options file.

About this task

You can set all of the options that can be set in the default user options file. Creating a customized client user-options file (dsm.opt) is an optional task. To create or modify a client user-options file, use the following method:

Procedure

1. Contact the IBM Spectrum Protect™ administrator on your workstation to determine the location of the sample client user-options file dsm.opt.smp, and to get the TCP/IP address of the backup server you are connecting to and the port it listens on.
2. Copy dsm.opt.smp to your home directory as dsm.opt, or a new file name of your choice. Store your client user-options file in any directory to which you have write access.
3. Set the DSM_CONFIG environment variable to point to your new client user-options file.
4. Edit your dsm.opt file as appropriate for your system or use the Preferences Editor by selecting Edit > Client Preferences from the backup-archive client GUI.

Results

Once you have created an options file, you can use the following steps to edit your options file from the GUI.

1. Open the Edit menu and select Client Preferences.
2. Make any necessary changes, then click OK to save those changes.

Mac OS X Important: For Mac OS X, the system-options file must be a plain text file, encoded as Unicode (UTF-8). By default, TextEdit does not save files as plain text. Select Format > Make PlainText to save the user-options file as a plain text file. Set the Plain Text Encoding drop-down list selection to `Unicode (UTF-8)`. Do not add the .txt extension.

Environment variables
Client options file overview
Windows

Create a shared directory options file

The IBM Spectrum Protect™ server administrator can generate client options files in a shared directory.

Windows clients can access the shared directory, and use the files there to create their own client options file.

Creating a shared directory options file is an optional root user or authorized user task.

Windows

Creating multiple client options files

You can create multiple client options files if you must work with multiple servers, or find that you need multiple sets of parameters to do back up or archive tasks.

About this task

Suppose you want to back up your files to one server (`server a`), and archive files to another (`server b`). Instead of editing the dsm.opt file each time you want to connect to a different server, create two options files. For example, create the options files a.opt for `server a`, and b.opt for `server b`.

Procedure

Use one of the following methods to specify or use a different client options file:

- Replace the dsm.opt file with the appropriate options file before you start the backup-archive client.
  For example, issue the following commands to copy the a.opt file to dsm.opt and then start the backup-archive client GUI:

  ```
  copy a.opt dsm.opt
  dsm
  ```

- Start the backup-archive client from the command line and use the optfile option to specify the options file that you want to use.
  For example:

  ```
  dsm -optfile=b.opt
  ```

- Define the DSM_CONFIG environment variable to specify the options file to use before you start a backup-archive client session.
  For example:

  ```
  SET DSM_CONFIG=C:\Program Files\Tivoli\TSM\baclient\b.opt
  ```

What to do next

If you are running the backup-achive client from the command line, the DSM_DIR and DSM_LOG environment variables might also need to be configured as follows:

- Define the DSM_DIR environment variable to point to the directory where all other executable files reside:

  ```
  SET DSM_DIR=C:\Program Files\Tivoli\TSM\baclient
  ```

- Define the DSM_LOG environment variable to point to the directory where `dsmerror.log` resides:

  ```
  SET DSM_LOG=C:\Program Files\Tivoli\TSM\baclient
  ```

Note: The directory path where the client executable files are located must be included in the PATH environment variable or you must enter a fully qualified path.
Windows

Environment variables

Generally, setting the environment variables is an optional task. Setting them makes it more convenient for you to use the command line.

About this task

You must set the environment variables if you need to run in either of the following environments:

- You want to invoke the backup-archive client from a directory other than the directory where the backup-archive client is installed.
- You want to specify a different options file for the backup-archive client, the administrative client, or both.

Note: You can also specify an alternate client options file for the command-line client (not the administrative client) using the ***optfile*** option.
You need to set four environment variables:

PATH
: This is the default search path the operating system uses to locate executable files. Set this to include the fully qualified paths of the client installation directories.

DSM_CONFIG
: Set this environment variable to the fully qualified path and file name of the client options file.

DSM_DIR
: Set this environment variable to the directory where the client message file dsc*.txt is located.

DSM_LOG
: Set this environment variable to the directory where the log files should reside.

Ensure that the environment variables meet the following guidelines:

- Include the directory where the executable files (for example, dsm.exe) reside in the current PATH environment variable. If you accepted the default installation directory using the C: drive, you can set this from a command prompt by typing:

  ```
  SET PATH=C:\Program Files\Tivoli\TSM\baclient
  ```

- Specify the fully-qualified path name of your client options file (dsm.opt) using the DSM_CONFIG environment variable:

  ```
  SET DSM_CONFIG=C:\Program Files\Tivoli\TSM\baclient\dsm.opt
  ```

- Define the DSM_DIR environment variable to point to the directory where the client message file dsc*.txt is located:

  ```
  SET DSM_DIR=C:\Program Files\Tivoli\TSM\baclient
  ```

Related reference:
Optfile
AIX Linux Mac OS X Solaris

Environment variables

Generally, setting the environment variables is an optional task. Setting these variables makes it more convenient for you to use the command line.

- Mac OS X AIX Linux Solaris Set language environment variables
  The backup-archive client automatically detects the language of the system locale and displays in that language.
- Mac OS X AIX Linux Solaris Set processing environment variables
  Some circumstances require you to set environment variables to ensure that IBM Spectrum Protect™ applications can locate the files that are needed to perform client operations, and that applications can create log files that record events and errors that occur during client operations.
- Mac OS X AIX Linux Solaris Set Bourne and Korn shell variables
  Enter the environment variables in the `.profile` file (Korn shell) or `.bash_profile` file (Bourne shell) in your `$HOME` directory.
- Mac OS X AIX Linux Solaris Set C shell variables
  For the C shell, add the DSM_CONFIG, DSM_LOG and DSM_DIR variables to the `.cshrc` file in your `$HOME` directory.
- Mac OS X AIX Linux Solaris Set API environment variables
  If you installed the IBM Spectrum Protect API, set the following environment variables.

AIX Linux Solaris

Set language environment variables

The backup-archive client automatically detects the language of the system locale and displays in that language.

For example, a French operating system displays the backup-archive client in French by default. If the backup-archive client cannot load the French message catalog, it defaults to the English (United States) language. For example, if the client is running in an unsupported language and locale combination, such as French/Canada or Spanish/Mexico, the client defaults to English (United States).

You can use the LANG environment variable to specify the language for the UNIX and Linux clients.

Note: The operating system locale, the terminal character set, and the file name character set encoding must match in order for files names to be displayed or entered correctly.
To set the LANG environment variable to French, type the following statement:

```
export LANG=fr_FR
```

Note:

- This task does not apply to Mac OS X.
- To display the IBM Spectrum Protect™ help browser menus in the language of your current locale, ensure that the NLSPATH environment variable in the `/etc/profile` file contains the following path:

  ```
  NLSPATH=/usr/dt/lib/nls/msg/%L/%N.cat:$NLSPATH
  export NLSPATH
  ```

If the locale of the backup-archive client is the same as the character encoding of the file names, all of those files are backed up or restored correctly. If you are running in any single-byte character set (SBCS), then all file names are valid and are backed up or restored by the backup-archive client.

If you are running in a DBCS or UTF-8 locale, file names that are composed of characters that are not valid in the DBCS or UTF-8 locale cannot be entered on the backup-archive client command line. The files might be skipped when you run a backup where a wildcard ("*") specification is used. If files are skipped, here is an example of the error message that is issued:

```
ANS4042E Object name '/testData/en_US_files/file3?'
contains one or more unrecognized characters and is not valid.
```

If all directories and files are not created with the same locale, then run your scheduled backups by using a single-byte character set locale. This action ensures that files are not skipped because the file names contain characters that are not defined in the current locale. When you restore files, run in the same locale that matches the locale encoding of the file name.

For example, file names that consist of Japanese characters might contain invalid multibyte characters if they are displayed in a Chinese locale. These files are not backed up and are not shown by the graphical user interface. If such files are found during backup, the dsmerror.log file lists the skipped files.

Tip: When you use the backup-archive client scheduling mode to back up a whole system, set the LANG environment variable to `en_US` (or some other SBCS language) to avoid skipped files.

Mac OS X | AIX | Linux | Solaris

Set processing environment variables

Some circumstances require you to set environment variables to ensure that IBM Spectrum Protect™ applications can locate the files that are needed to perform client operations, and that applications can create log files that record events and errors that occur during client operations.

You must set the environment variables in any of the following circumstances:

- You want to invoke the backup-archive client from a directory other than the directory where the backup-archive client is installed
- You want to specify a different options file for the backup-archive client, the administrative client, or both.
- You do not want log files to be written to the default installation directory.

Tip: You can also specify an alternate client options file for the command-line client (not the administrative client) using the optfile option.

There are four environment variables you can set which affect backup-archive client processing:

PATH
: Includes the directory where the executable file for the client executables (dsmc, dsmadmc, dsmj) resides.

DSM_DIR
: Specifies the directory where the executable file for the client executables (`dsmc`, dsmadmc, dsmj) the resource files, and the dsm.sys file reside. You cannot specify the root (/) directory for DSM_DIR.

  Refer to the installation section for your operating system to find the default installation directory information.

  Mac OS X | AIX | Linux | Solaris When you request an image backup, image restore, snapshot-based file backup, NAS backup, or NAS restore, the client uses the DSM_DIR environment variable to locate the corresponding plug-in library. If DSM_DIR is not set, the client looks for the plug-in library in the following directories:

  AIX®
  : /usr/tivoli/tsm/client/ba/bin/plugins

  Oracle Solaris and all Linux clients
  : /opt/tivoli/tsm/client/ba/bin/plugins

DSM_CONFIG
: Specifies the fully-qualified path and file name of the client user options file for users who create their own personalized options file. If DSM_CONFIG is not set, or the client optfile option is not used, the client user options file is expected to satisfy these requirements:

  1. The options file must be named `dsm.opt`.
  2. For UNIX clients other than Mac OS X, if DSM_DIR is *not* set, then the file must reside in the default installation directory. If DSM_DIR *is* set, then the file must reside in the directory specified by DSM_DIR.
  3. Mac OS X For Mac OS X, the file can reside in any of the following locations. These directories are searched in order, and the first option file found is used. `~/Library Preferences/Tivoli Storage Manager`, `/Library Preferences/Tivoli Storage Manager`, or `/Library/Application Support/tivoli/tsm/client/ba/bin`.

  Refer to the installation section for your operating system to find the default installation directory information.

DSM_LOG
: Points to the directory where you want the IBM Spectrum Protect log files to reside. You cannot specify the root (/) directory for DSM_LOG. The log files contain information about errors and events that occur during processing. The client creates the logs to help the technical support team diagnose severe errors.

  Refer to the installation section for your operating system to find the default installation directory information.

  Important: Set the DSM_LOG environment variable to name a directory where read-write permissions allow the required write access for the user to create and write to the log file. This prevents log write failures and process termination. Use the chmod or setacl commands to give the files permissions that allow all client user IDs to read and write them. If the log names are the default names, just set the DSM_LOG environment variable to point to the directory where they reside. When the client cannot write to the log file, an error message is written to stderror and to the syslog daemon. The syslog daemon must be running and configured to process messages with a priority of LOG_ERR for the error message to appear in the system log. Starting and configuring the syslog daemon is system specific. Use man syslogd command for information about starting the syslog daemon. Use man syslog.conf for information about configuring the syslog daemon.
  Note:

  1. The errorlogname and schedlogname options override DSM_LOG. If you specify the errorlogname client option, the file is stored in the directory specified by the errorlogname option and not in the location specified by DSM_LOG. If you specify the schedlogname client option, it is written to the directory specified by the schedlogname option and not in the location specified by DSM_LOG.
  2. The log files cannot be symbolic links. The client detects any such links, delete the links, then exits the operation. This action prevents the client from overwriting protected data. The affected logs are created as files in a subsequent operation.

To use the backup-archive client Java™ GUI program, you must export the directory where you installed the java binary file. For example, enter the following command:

```
export PATH=$PATH:java_bin_dir
```

where: *java_bin_dir* is the path to the runnable Java binary file in your file system.

Related reference:
Optfile

Mac OS X | AIX | Linux | Solaris

Set Bourne and Korn shell variables

Enter the environment variables in the `.profile` file (Korn shell) or `.bash_profile` file (Bourne shell) in your `$HOME` directory.

The following is an example, where `/home/davehil/dsm.opt` is the path and file name for your client user-options file, and the `/home/davehil` directory is where you want to store the `dsmerror.log` file, executable file, resource files, and dsm.sys file.

```
DSM_DIR=/home/davehil
DSM_CONFIG=/home/davehil/dsm.opt
DSM_LOG=/home/davehil
export DSM_DIR DSM_CONFIG DSM_LOG
```

Mac OS X | AIX | Linux | Solaris

Set C shell variables

For the C shell, add the DSM_CONFIG, DSM_LOG and DSM_DIR variables to the `.cshrc` file in your `$HOME` directory.

The following is an example, where `/home/davehil/dsm.opt` is the path and file name for your client user-options file, and the `/home/davehil` directory is where you want to store the `dsmerror.log` file, executable file, resource files, and dsm.sys file.

```
setenv DSM_DIR /home/davehil
setenv DSM_CONFIG /home/davehil/dsm.opt
setenv DSM_LOG /home/davehil
```

Mac OS X | AIX | Linux | Solaris

Set API environment variables

If you installed the IBM Spectrum Protect™ API, set the following environment variables.

DSMI_DIR
: Points to your installation directory. The file dsm.sys must reside in the directory pointed to by DSMI_DIR. This environment variable must be present.

DSMI_CONFIG
: Full path name of your own client user-options file (dsm.opt).

DSMI_LOG
: Path for dsierror.log (this path cannot be a symbolic link).

Note: End users of applications that are developed with the API can consult the installation directions for that application for special path names or guidelines for options.

For more information about the environment variables, see Set processing environment variables.

For more information about the IBM Spectrum Protect API, see Developing solutions with the application programming interface.

Windows

Configuring the language for displaying the Java GUI

You can select the language to use for displaying the backup-archive client Java™ GUI.

About this task

The language that is displayed by the backup-archive client Java GUI is defined by the Windows display locale and not the Windows system locale. For example, if the Windows system and input locale is French, but the display locale is Russian, the language that is displayed by the Java GUI is Russian by default, if the language option is not used.

If you want to display the Java GUI in US English or another language, you can override the default display language by specifying the language option.

Tip: The language option does not affect the web client. The web client displays in the language that is associated with the locale of the browser. If the browser is running in a locale that client does not support, the web client is displayed in US English.

Procedure

Use one of the following methods to configure the language for displaying the Java GUI:

- Add the `language` *`language`* option to the client options file (dsm.opt). For example, to set the display language to US English, add the following statement:

  ```
  language enu
  ```

- Complete the following steps in the backup-archive client Java GUI:
  1. In the main window of the Java GUI, click Edit > Client Preferences.
  2. Click the Regional Settings tab.
  3. Click the Language drop-down list and select a language.
  4. Click OK.

Language

Web client configuration overview

The IBM Spectrum Protect™ web client provides remote management of a client node from a web browser. The procedures to configure the web client vary depending on which operating system is on the client node.

Beginning with IBM Spectrum Protect Version 8.1.2, you can no longer use the web client to connect to the IBM Spectrum Protect V8.1.2 or later server. However, you can still use the web client to connect to IBM Spectrum Protect V8.1.1, V8.1.0, or V7.1.7 and earlier servers. For more information, see Using the web client in the new security environment.

Backup-archive client options are used to configure web client settings. These options include httpport, managedservices, webports, and revokeremoteaccess.

Windows On Windows client nodes, a web client setup wizard is provided in the backup-archive client GUI. You can use the setup wizard to configure the web client. The options that you select in the wizard are copied to the client-user options file (dsm.opt). You can also add the options directly to the dsm.opt file by editing the file and adding the web client options to it.

AIX Linux Mac OS X Solaris On AIX®, Linux, Mac, and Solaris client nodes, you add the web client options to the client-systems option file (dsm.sys).

To use the web client from the IBM Spectrum Protect Operations Center interface, specify the web client address in the URL parameter of the REGISTER NODE or UPDATE NODE command. The web address must include the DNS name or IP address of the node, and the port number that the web client uses. For example, `http://node.example.com:1581`. Replace this example host name with the IP address or host name of your client node. When you access the web client by using a web browser, enter the same URL syntax in the browser address bar.

All web client messages are written to the web client log file, which is named dsmwebcl.log. By default, the dsmwebcl.log file and the backup-archive client error log file (dsmerror.log) are created in the client installation directory. You can use the DSM_LOG environment variable to override the default locations for the error logs. If you do set the DSM_LOG environment variable, do not specify the root directory as location for the error logs. You can also use the backup-archive client errorlogname option, to change the location of the error log files. If you specify this option, it overrides the DSM_LOG environment variable setting.

- AIX Linux Mac OS X Solaris Configuring the web client on AIX, Linux, Mac, and Solaris systems
  To configure the web client, edit the client-system options file (dsm.sys) to specify the required options, and then start the client acceptor daemon.
- Windows Configuring the web client on Windows systems
  On Windows systems, you can configure and start the web client by using a wizard that is available in the backup-archive client GUI, or by using both IBM Spectrum Protect and Windows commands.

Configuring the web client on AIX®, Linux, Mac, and Solaris systems

To configure the web client, edit the client-system options file (dsm.sys) to specify the required options, and then start the client acceptor daemon.

Procedure

1. Set the following options in the dsm.sys file: managedservices webclient schedule and passwordaccess generate.
2. Generate the IBM Spectrum Protect™ password. Enter `dsmc query session`. When you are prompted for credentials, enter the IBM Spectrum Protect user name and password.

   Mac OS X On Mac OS X systems, you can also generate the password by using the IBM Spectrum Protect Tools for Administrators application. In the application, select IBM Spectrum Protect to start the client.

3. Start the client acceptor daemon. Enter `dsmcad`.

   Mac OS X On Mac OS X, you can also start the client acceptor daemon with the IBM Spectrum Protect Tools for Administrators application. In the application, select Start the Client Acceptor Daemon.

4. To access the web client from a browser, specify the host name or IP address of the client node in the browser address bar, followed by the web client port number. The default port number is 1581. For example, to access the web client on the node that is named myserver.example.com, specify: `http://myserver.example.com:1581`

   If you must change the default web client port number, use the backup-archive client httpport option to assign a different port number.

What to do next

After you configure the web client, you can use the IBM Spectrum Protect Operations Center or a browser to backup or restore, or archive or retrieve, data on a node.

Windows

Configuring the web client on Windows systems

On Windows systems, you can configure and start the web client by using a wizard that is available in the backup-archive client GUI, or by using both IBM Spectrum Protect™ and Windows commands.

Procedure

Choose one of the following methods to configure the Windows web client:

Setup method	Procedure
Setup wizard	a. Start the backup-archive client GUI. b. Click Utilities > Setup Wizard. c. Select the Help me configure the Web Client check box. d. Click NEXT and follow the wizard instructions to configure the web client options.

Setup method	Procedure
Command prompt	a. Set the following options in the dsm.opt file: managedservices webclient schedule and passwordaccess generate. b. Install the client acceptor service by entering the following command: `dsmcutil install cad /name:"TSM CAD" /node:nodename /password:password /autostart:yes` where: *TSM CAD* a name for the service. The default name is TSM Client Acceptor. *nodename* is the name of the client node. *password* is the IBM Spectrum Protect password. `/autostart:yes` indicates that the client acceptor service is started when the operating system starts. Start the service by using the Windows net start command. c. Install the IBM Spectrum Protect remote-client-agent service by entering the following command: `dsmcutil install remoteagent /name:"TSM AGENT" /node:nodename /password:password /partnername:"TSM CAD"` where: ○ *TSM AGENT* is a name for the remote-client-agent service. The default service name is TSM Remote Client Agent. ○ *nodename* is the name of the client node. ○ *password* is the IBM Spectrum Protect password. ○ *TSM CAD* is the service-partner name. This name must match the service name that you specified when you installed the client acceptor service. The default name is TSM Client Acceptor. Do not start the TSM Remote Client Agent service from the Control Panel > Administrative Tools > Services view, or by using the net start command. The client acceptor service starts the remote client agent when it is needed.

What to do next

After you configure the web client, you can use the IBM Spectrum Protect Operations Center or a browser to backup or restore, or archive or retrieve, data on a node.

Configuring the scheduler

Your IBM Spectrum Protect™ administrator can schedule the client to perform tasks automatically. For scheduled events to occur on the client, you must configure the client scheduler to communicate with the IBM Spectrum Protect server.

About this task

For example, you can automatically back up files at the end of each day or archive some of your files every Friday. This procedure, which is known as central scheduling, is a cooperative effort between the server and your client node. Your administrator associates clients with one or more schedules that are part of the policy domain that is maintained in the server database. The IBM Spectrum Protect administrator defines central scheduling on the server and you start the client scheduler on your workstation. After you start the client scheduler, no further intervention is required.

With client scheduling, you can perform the following tasks:

- Display information about available schedules.
- Display information about work that the schedule completed.
- Windows Modify scheduling options in the client options file (dsm.opt).
- Mac OS X AIX Linux Solaris Modify scheduling options in the dsm.sys file.

The most effective way to manage the client scheduler is to use the client acceptor service. You can read about a comparison between using the client acceptor and traditional scheduler services to manage the scheduler. You can also learn how to configure the client to use the client acceptor to manage the scheduler.

- Comparison between client acceptor-managed services and traditional scheduler services
  You can use either the client acceptor service or the traditional scheduler service to manage the IBM Spectrum Protect scheduler. A comparison of these methods is provided.
- Configuring the client to use the client acceptor service to manage the scheduler
  One of the most effective ways of managing the client scheduler is to use the client acceptor. You must configure the client to use the client acceptor to manage the scheduler.

Comparison between client acceptor-managed services and traditional scheduler services

You can use either the client acceptor service or the traditional scheduler service to manage the IBM Spectrum Protect™ scheduler. A comparison of these methods is provided.

The following table shows the differences between the client acceptor-managed services and the default traditional scheduler services methods.

Table 1. Client acceptor-managed services versus traditional scheduler services

Client acceptor-managed services	**IBM Spectrum Protect traditional scheduler services**
Defined by using the `managedservices schedule` option and started with client acceptor services. AIX Linux Mac OS X Solaris The client acceptor daemon is started with the dsmcad command Windows The client acceptor service is started as a Windows service	Started with command dsmc sched command.
The client acceptor service starts and stops the scheduler process as needed for each scheduled action.	Remains active, even after scheduled backup is complete.
Requires fewer system resources when idle.	Requires higher use of system resources when idle.
Client options and IBM Spectrum Protect server override options are refreshed each time the client acceptor services start a scheduled backup.	Client options and IBM Spectrum Protect server override options are only processed after dsmc sched is started.
Cannot be used with `SESSIONINITiation=SERVEROnly` backups.	You must restart the scheduler process for updated client options to take effect. Important: If you run the client scheduler on the command line, the scheduler does not run as a background service. Tip: Restart the traditional scheduler periodically to free system resources previously used by system calls.

Configuring the client to use the client acceptor service to manage the scheduler

One of the most effective ways of managing the client scheduler is to use the client acceptor. You must configure the client to use the client acceptor to manage the scheduler.

Before you begin

- If you include files for encryption, ensure that the encryptkey option is set to save in the options file. This option is set by selecting Save Encryption Key Password Locally on the Authorization tab in the preference editor. Setting this option enables unattended scheduled services. If the encryption key was not previously saved, you must run an attended backup of at least one file so that you get the encryption prompt to save the key.
- You cannot use the client acceptor for scheduling when the sessioninitiation option is set to serveronly.

About this task

The client acceptor serves as an external timer for the scheduler. When the scheduler is started, it queries the server for the next scheduled event. The event is either run immediately or the scheduler exits. The client acceptor restarts the scheduler when it is time to run the scheduled event. This action reduces the number of background processes on your workstation and resolves memory retention problems that can occur when the scheduler is run without client acceptor management.

The client acceptor service is also known as the client acceptor daemon.

Procedure

- AIX | Linux | Mac OS X | Solaris Complete the following steps to use the client acceptor to manage the client scheduler:
  1. From the backup-archive client GUI, select Edit > Preferences.
  2. Click the Web Client tab.
  3. In the Managed Services Options field, click Schedule. If you also want the client acceptor to manage the web client, click Both option.
  4. Start the client acceptor daemon by running the following command on the command line:

     ```
     dsmcad
     ```

  Tip:
  - You can also use the managedservices option in the client system-options file (dsm.sys) to specify whether the client acceptor manages the scheduler.
  - If you need the client acceptor to manage the scheduler in polling mode without opening a listening port, use the cadlistenonport option in the dsm.sys file.
- Windows Complete the following steps to use the client acceptor to manage the scheduler on the Windows client:
  1. In the backup-archive client GUI, click Utilities > Setup Wizard > Help me configure the Client Scheduler and click Next.
  2. Read the information in the Scheduler Wizard page and click Next.
  3. In the Scheduler Task page, select Install a new or additional scheduler and click Next.
  4. In the Scheduler Name and Location page, specify a name for the client acceptor service that you want to manage the scheduler. Then, select Use the client acceptor to manage the scheduler and click Next.
  5. If the client acceptor is already installed for use by the web client, select that name of the client acceptor from the drop-down list in the Web Service Name page. Otherwise, type the name that you want to assign to this client acceptor. The default name is TSM Client Acceptor. Click Next.
  6. Follow the instructions on the remaining screens to complete the configuration.

     Use the following information to help you complete the wizard pages:

     - If the sessioninitiation option is set to serveronly in the client options file (dsm.opt), the client configuration wizard and scheduler service might be unable to initiate authentication with the IBM Spectrum Protect™ server. To avoid this problem, ensure that the Contact the IBM Spectrum Protect Server to validate password check box on the IBM Spectrum Protect Authentication page is cleared.
     - For the client acceptor-managed scheduler, select Manually when I explicitly start the service in the Service login options page.
  7. Start the client acceptor service from the Services Control Panel, but do not start the scheduler service. The scheduler service is started and stopped automatically by the client acceptor service as needed.

  Tip:
  - You can also use the managedservices option in the client options file (dsm.opt) to specify whether the client acceptor manages the scheduler.

- If you need the client acceptor to manage the scheduler in polling mode without opening a listening port, use the cadlistenonport option in the dsm.opt file.
- If you do not use the client acceptor to manage the scheduler, select Automatically when Windows boots in the Service login options window. This setting starts the service automatically when Windows starts so that your schedules are run automatically. Alternatively, you can use the Services Control Panel or the net start command to start the Scheduler service.
- You can also use the Scheduler Service Configuration utility (dsmcutil.exe) to configure the scheduler. The Scheduler Service Configuration utility must be run from an account that belongs to the Administrator/Domain Administrator group. You can start multiple client scheduler services on your system.

Configuring IBM Spectrum Protect client/server communication across a firewall

In most cases, the IBM Spectrum Protect™ server and clients can work across a firewall.

About this task

Every firewall is different, so the firewall administrator might need to consult the instructions for the firewall software or hardware in use.

There are two methods for enabling client and server operations through a firewall:

Method 1:

To allow clients to communicate with a server across a firewall, the following ports must be opened in the firewall by the firewall administrator:

TCP/IP port

To enable the backup-archive client, command-line admin client, and the scheduler to run outside a firewall, the port specified by the server option ***tcpport*** (default 1500) must be opened by the firewall administrator. This port is set on the client and the server using the ***tcpport*** option. The setting must be the same on the client and server. This allows IBM Spectrum Protect scheduler communications in both *polling* and *prompted* mode, client acceptor-managed schedulers, and regular backup-archive client operations.

Note: The client cannot use the port specified by the ***tcpadminport*** option (on the server) for a client session. That port can be used for administrative sessions only.

HTTP port

To allow the web client to communicate with remote workstations across a firewall, the HTTP port for the remote workstation must be opened. Use the ***httpport*** option in the remote workstation client options file to specify this port. The default HTTP port is 1581.

TCP/IP ports for the remote workstation

The two TCP/IP ports for the remote workstation client must be opened. Use the ***webports*** option in the remote workstation client options file to specify these ports. If you do not specify the values for the ***webports*** option, the default zero (0) causes TCP/IP to randomly assign two free port numbers.

TCP/IP port for administrative sessions

Specifies a separate TCP/IP port number on which the server is waiting for requests for administrative client sessions, allowing secure administrative sessions within a private network.

Method 2:

For the client scheduler in prompted mode, it is unnecessary to open *any* ports on the firewall. If you set the ***sessioninitiation*** option to *serveronly*, the client will not attempt to contact the server. *All sessions are initiated by server prompted scheduling* on the port defined on the client with the ***tcpclientport*** option. The ***sessioninitiation*** option only affects the behavior of the client scheduler running in the prompted mode.

The IBM Spectrum Protect server must set the SESSIONINITiation parameter on the **register node** and **update node** commands for each node. If the server specifies SESSIONINITiation=*clientorserver*, the default, the client can decide which method to use. If the server specifies SESSIONINITiation=*serveronly*, all sessions are initiated by the server.

Note:

1. If ***sessioninitiation*** is set to *serveronly*, the value for the ***tcpclientaddress*** client option must be the same as the value for the ***HLAddress*** option of the **update node** or **register node** server command. The value for the ***tcpclientport*** client option must be the same as the value for the ***LLAddress*** option of the **update node** or **register node** server command.
2. AIX | Linux | Mac OS X | Solaris If you set the ***sessioninitiation*** option to *serveronly*, with the exception of client acceptor-managed schedulers, the command-line client, backup-archive client Java™ GUI, and web client GUI still attempts to initiate sessions, but are blocked by the IBM Spectrum Protect server for nodes that have the ***sessioninitiation*** option set to *serveronly*.
3. Windows If you set the ***sessioninitiation*** option to *serveronly*, with the exception of client acceptor-managed schedulers, the command-line client, backup-archive client GUI, and web client GUI still attempts to initiate sessions, but are blocked by the IBM Spectrum Protect server for nodes that have the ***sessioninitiation*** option set to *serveronly*.
4. Windows When installing the scheduler using the setup wizard or dsmcutil, and the IBM Spectrum Protect server is behind a firewall, the node password will not get stored on the client workstation. As a result, the scheduler service might be unable to authenticate to the server when the server contacts the client to run a schedule. In this case, you can run the scheduler from the command line (dsmc schedule), wait until a scheduled operation starts, and enter the password for your node when prompted. After you enter the password for your node, restart the scheduler service. You can also use the following **dsmcutil** command to save the password:

   ```
   dsmcutil updatepw /node:nnn /password:ppp /validate:no
   ```

   If ***sessioninitiation*** option is set to *serveronly* in your client options file (dsm.opt), the client setup wizard and scheduler service is unable to initiate authentication with the IBM Spectrum Protect server. To avoid this problem, when configuring the client scheduler using the setup wizard, ensure that the Contact the IBM Spectrum Protect Server to validate password check box on the IBM Spectrum Protect Authentication page is unchecked.

A similar problem can occur if an encryption key is required for backup operations. In this case, you can run the scheduler from the command line (dsmc schedule), wait until a scheduled backup starts, and enter the encryption key when prompted. After the password and encryption key are updated, you must restart the scheduler.

5. When configuring the scheduler on a client workstation for the first time, the scheduler service might be unable to authenticate to the server when the server contacts the client scheduler to run a schedule. This can happen when the ***passwordaccess*** is set to generate and the IBM Spectrum Protect server is behind a firewall and the encrypted password cannot be locally stored before the scheduler is started. To correct this problem, you need to run the scheduler from the command line (dsmc schedule), wait until a scheduled operation starts, and enter the password for your node when prompted.
6. The client cannot prompt for the encryption key password in scheduler mode. If you are using IBM Spectrum Protect data encryption, you must run an initial interactive backup once to set up the encryption key by opening the TCP/IP connection from the client workstation to the server workstation. See **Method 1** for more information about setting up this communication. After the encryption key is set, you can use server-initiated sessions to back up the files using encryption.

If you set the ***sessioninitiation*** option to *client*, the client initiates sessions with the server (**Method 1**) by communicating on the TCP/IP port defined with the *server* option ***tcpport***. This is the default. Server prompted scheduling can be used to prompt the client to connect to the server.

When using IBM Spectrum Protect across a firewall in *prompted* mode, the IBM Spectrum Protect server needs to contact the client. In order to complete this action, some software might need to be installed on the IBM Spectrum Protect server to route the request through the firewall. This software routes the server request through a socks port on the firewall. This method is typically called *socksifying* a system. Proxies are not supported, because they only route a few types of communication protocols (HTTP, FTP, GOPHER). IBM Spectrum Protect communications are not routed by proxies. It is important to note that the client creates a new connection to the IBM Spectrum Protect server when prompted. This means that the firewall configuration discussed above must be in place.

Configuring IBM Spectrum Protect client/server communication with Secure Sockets Layer

Secure Sockets Layer (SSL) allows industry standard SSL-based secure communications between the IBM Spectrum Protect™ client and server.

About this task

The following client components support SSL:

- Command-line client
- Administrative command-line client
- Client GUI
- Client API

Only outgoing client/server connections support SSL. A V8.1.2 client communicating with a down-level servers supports SSL. A V8.1.2 client communicating with a V8.1.2 server must use SSL. Incoming connections (for example, client acceptor, server-initiated schedule connections) do not support SSL. Client-to-client communications do support SSL. Web GUI does not support SSL. The Web GUI is no longer supported when communicating with a V8.1.2 server.

Each IBM Spectrum Protect server that is enabled for SSL must have a unique certificate. The certificate can be one of the following types:

- A certificate that is self-signed by IBM Spectrum Protect.
- A certificate that is issued by a certificate authority (CA). The CA can be from a company such as VeriSign or Thawte, or an internal CA, maintained within your company.

Follow these steps to enable SSL communication with a self-signed certificate:

1. Obtain the IBM Spectrum Protect server self-signed certificate (cert256.arm) Use the cert.arm certificate file when the server is not setup to use Transport Layer Security (TLS) 1.2; otherwise, use the cert256.arm file. The client certificate file must be the same as the certificate file that the server uses.
2. Configure the clients. To use SSL, each client must import the self-signed server certificate.

   Use the dsmcert utility to import the certificate.

3. For a disaster recovery of the IBM Spectrum Protect server, if the certificate has been lost, a new one is automatically generated by the server. Each client must obtain and import the new certificate.

For fast path details for communication between a V8.1.2 client and a V8.1.2 server, you can use the SSLACCEPTCERTFROMSERV option to automatically accept a self-signed certificate. See Default security settings for the client (fast path) for details.

Follow these steps to enable SSL communication with a CA-signed certificate:

1. Obtain the CA root certificate.
2. Configure the clients. To use SSL, each client must import the self-signed server certificate.

   Use the dsmcert utility to import the certificate.

   Tip: After you complete this step, if the server gets a new certificate that is signed by the same CA, the client does not need to import the root certificate again.
3. If you are recovering the backup-archive client as part of disaster recovery, you must install the SSL certificate on the server again. If the certificate was lost, you must get a new one. You do not need to reconfigure the client if the new certificate has been signed by a CA.

Windows The dsmcert utility is provided by the backup-archive client and automatically installs it in `C:\Program Files\Tivoli\TSM\baclient`.

Windows Before you set up the server certificate on the client, follow these steps:

1. Open a command prompt and change the directory to the backup-archive client directory, for example: cd `"C:\Program Files\Tivoli\TSM\baclient"`
2. Append the GSKit binary path and library path to the `PATH` environment variable, for example:

   ```
   set PATH=C:\Program Files\Common Files\Tivoli\TSM\api64\gsk8\bin\;
    C:\Program Files\Common Files\Tivoli\TSM\api64\gsk8\lib64;%PATH%
   ```

   See Creating a symbolic link to access the latest GSKit library and IBM Global Security Kit return codes for details on GSkit libraries.

Next, you must import the server certificate, or the CA root certificate.

If you use a self-signed certificate

AIX Linux Mac OS X Solaris Each IBM Spectrum Protect server generates its own certificate. The certificate has a fixed file name of either cert.arm or cert256.arm. The certificate file is stored on the server workstation in the server instance directory, for example, /opt/tivoli/tsm/server/bin/cert256.arm. If the certificate file does not exist and you specify the SSLTCPPORT or SSLTCPADMINPORT server option, the certificate file is created when you restart the server with these options set. IBM Spectrum Protect V6.3 servers (and newer versions) generate files named cert256.arm and cert.arm. IBM Spectrum Protect servers older than V6.3 generate only certificate files named cert.arm. You must choose the certificate that is set as the default on the server.

Windows Each IBM Spectrum Protect server generates its own certificate. The certificate has a fixed file name of either cert.arm or cert256.arm. The certificate file is stored on the server workstation in the server instance directory, for example, C:\Program Files\tivoli\tsm\server1\cert256.arm. If the certificate file does not exist and you specify the SSLTCPPORT or SSLTCPADMINPORT server option, the certificate file is created when you restart the server with these options set. IBM Spectrum Protect V6.3 servers (and newer versions) generate files named cert256.arm and cert.arm. IBM Spectrum Protect servers older than V6.3 generate only certificate files named cert.arm. You must choose the certificate that is set as the default on the server.

AIX Linux Mac OS X Solaris Windows Follow these steps to set up the SSL connection to a server:

1. Obtain the certificate from the server administrator.
2. Import the certificate into the client key database by using the following command:

   ```
   dsmcert -add -server <servername> -file <path_to_cert256.arm>
   ```

If you use a certificate from a certificate authority

If the certificate was issued by a certificate authority (CA) such as VeriSign or Thawte, the client is ready for SSL and you can skip the following steps.

For the list of preinstalled root certificates from external certificate authorities, see Certificate Authorities root certificates.

If the certificate was not issued by one of the well-known certificate authorities, follow these steps:

1. Obtain the root certificate of the signing CA.
2. Import the certificate into the client key database by using the following command:

```
dsmcert -add -server <servername> -file <path_to_cert256.arm>
```

Important:

1. A pseudo random password is used to encrypt the key database. The password is automatically stored encrypted in the stash file (`dsmcert.sth`). The stash file is used by the backup-archive client to retrieve the key database password.
2. More than one server certificate can be added to the client key database file so that the client can connect to different servers. Also, more than one CA root certificate can be added to the client key database.
3. AIX Linux Mac OS X Solaris If you do not run the preceding commands from the backup-archive client directory, you must copy `dsmcert.kdb` and `dsmcert.sth` into that directory.
4. AIX Linux Mac OS X Solaris By default, local key database files have root ownership and permissions and cannot be read by other users. If you plan to run the client as a non-root user, you must update the permissions. For example, to grant read access to all users and groups, run the following command:

   ```
   # chmod go+r dsmcert.*
   ```

5. Windows If you do not run the preceding commands from the backup-archive client directory, you must copy `dsmcert.kdb` and `dsmcert.sth` into that directory.
6. For performance reasons, use SSL only for sessions where it is needed. A V8.1.2 client communicating with a V8.1.2 server must use SSL. SSL No (the default value) indicates that encryption is not used when data is transferred between the client and a server earlier than V8.1.2. When the client connects to a V8.1.2 or later server, the default value No indicates that object data is not encrypted. All other information is encrypted, when the client communicates with the server. When the client connects to a V8.1.2 or later server, the value Yes indicates that SSL is used to encrypt all information, including object data, when the client communicates with the server. Consider adding more processor resources on the IBM Spectrum Protect server system to manage the increased requirements.
7. In order for a client to connect to a server that is using Transport Layer Security (TLS) Version 1.2, the certificate's signature algorithm must be SHA-1 or stronger. If you are using a self-signed certificate, you must use the cert256.arm certificate. Your IBM Spectrum Protect administrator might need to change the default certificate on the IBM Spectrum Protect server.

Additional details for a V8.1.2 client communicating with a server V8.1.1 and earlier V8 levels, and V7.1.7 and earlier levels.

After the server certificate is added to the client key database, add the SSL Yes option to the client options file, and update the value of the TCPPORT option. It is important to understand that the server is normally set up for SSL connections on a different port. In other words, two ports are opened on the server:

1. One port accepts regular non-SSL client connections
2. Another port accepts SSL connections only

You cannot connect to a non-SSL port with an SSL-enabled client, and vice versa.

If the value of tcpport is incorrect, the client cannot connect to the server. Specify the correct port number on the tcpport option.

To disable security protocols that are less secure than TLS 1.2, add the SSLDISABLELEGACYtls yes option to the client options file, or within the Java™ GUI select the Require TLS 1.2 or above checkbox on the Communication tab of the Preferences editor. Requiring TLS 1.2 or above helps prevent attacks by malicious programs.

- AIX Linux Solaris Windows Creating a symbolic link to access the latest GSKit library

  You can create a symbolic link to point the directory where the older version of GSKit is installed to the location of the latest GSKit libraries on the system.

Creating a symbolic link to access the latest GSKit library

You can create a symbolic link to point the directory where the older version of GSKit is installed to the location of the latest GSKit libraries on the system.

About this task

When you install DB2 for Linux, UNIX, and Windows, on UNIX and Linux, local GSKit libraries are also installed. Those libraries are stored in <db2_install_path>/lib64/gskit_db2 or <db2_install_path>/lib32/gskit_db2. On Windows, the default location is C:\Program Files\ibm\gsk8.

During the installation of other IBM products, such as IBM Spectrum Protect™, another copy of the GSKit libraries might be installed. Depending on the product, these libraries might be either local GSKit libraries or global GSKit libraries. When DB2 for Linux, UNIX, and Windows and another IBM product that includes GSKit libraries are both installed on the same system, some interoperability issues might arise. These interoperability issues might occur because GSKit allows only libraries from a single GSKit source to exist in any single process. The interoperability issues might lead to unpredictable behavior and runtime errors.

To ensure that a single source of GSKit libraries is used, the symbolic link approach can be used. During an initial DB2 for Linux, UNIX, and Windows installation, the installer creates a symbolic link <db2_install_path>/lib64/gskit or <db2_install_path>/lib32/gskit to <db2_install_path>/lib64/gskit_db2 or <db2_install_path>/lib32/gskit_db2. These symbolic links are the default locations from where GSKit libraries are loaded. Products that bundle DB2 for Linux, UNIX, and Windows, and change the symbolic link from the default directory to the library directory of another copy of GSKit must ensure that the newly installed GSKit is at the same or a newer level. This restriction applies whether the libraries are global or local. During an upgrade or update of DB2 for Linux, UNIX, and Windows, the symbolic link is preserved. If the newly installed copy has a symbolic link to the default location, the symbolic link that is associated with the older installation copy is preserved. If the newly installed copy does not have a symbolic link to the default location, the symbolic link that is associated with the newer installation copy is preserved.

Some limitations exist since the symbolic link <db2_install_path>/lib64/gskit or <db2_install_path>/lib32/gskit is in the path of the DB2 for Linux, UNIX, and Windows installation copy. For example, if two or more instances are created for any DB2 copy, the symbolic link changes affect all the instances.

You can also modify a Domino Server GSKit in a similar manner. A Domino server does not have a GSKit folder, but it has folders C and N, and a library libgsk8iccs_64.so. You can first create soft links for these folders, and files to point to the corresponding folders on the GSKit package, where the IBM Spectrum Protect backup-archive client V8.1.2 is installed, as follows:

- ln -s /usr/local/ibm/gsk8_64/lib64/C /opt/ibm/lotus/notes/90010/zlinux
- ln -s /usr/local/ibm/gsk8_64/lib64/N /opt/ibm/lotus/notes/90010/zlinux
- ln -s /usr/local/ibm/gsk8_64/lib64/libgsk8iccs_64.so /opt/ibm/lotus/notes/90010/zlinux

Next, change the DPD node's password to domdsmc CHANGEADSMPwd tvt1054_domnote2 tvt1054_domnote2 tvt1054_domnote2. Finally, run domdsmc query adsm.

Procedure

1. Create a symbolic link on Windows, if you have administrator privileges. Rename the DB2 GSKit copy of the lib64 directory that is located in the default location, C:\Program Files\ibm\gsk8. Start a DOS shell, navigate to the DB2 GSKit location, and rename the directory as follows:

   ```
   cd C:\Program Files\ibm\gsk8

   rename lib64 lib64-db2
   ```

2. Create a symbolic link in the location of the DB2 GSKit copy and point to the location of the TSM GSKit copy by running the following commands in the DOS shell. Navigate to the location of the DB2 GSKit copy and then create the symbolic link as follows:

   ```
   cd C:\Program Files\ibm\gsk8

   mklink /d lib64 "c:\Program Files\Common Files\Tivoli\TSM\api64\gsk8\lib64"
   ```

3. Restart DB2 for changes to take effect. On startup, DB2 loads GSKit from the new location, which points to the IBM Spectrum Protect copy of GSKit. In the DB2 command prompt, enter these commands as follows:

   ```
   db2stop
   ```

```
db2start
```

AIX | Linux | Solaris | Windows

Certificate Authorities root certificates

The backup-archive client includes a list of root certificates for a number of common Certificate Authorities.

The following is a list of root certificates for a number of common Certificate Authorities that are delivered with the client:

- Entrust.net Global Secure Server Certification Authority
- Entrust.net Global Client Certification Authority
- Entrust.net Client Certification Authority
- Entrust.net Certification Authority (2048)
- Entrust.net Secure Server Certification Authority
- VeriSign Class 3 Public Primary Certification Authority
- VeriSign Class 2 Public Primary Certification Authority
- VeriSign Class 1 Public Primary Certification Authority
- VeriSign Class 4 Public Primary Certification Authority - G2
- VeriSign Class 3 Public Primary Certification Authority - G2
- VeriSign Class 2 Public Primary Certification Authority - G2
- VeriSign Class 1 Public Primary Certification Authority - G2
- VeriSign Class 4 Public Primary Certification Authority - G3
- VeriSign Class 3 Public Primary Certification Authority - G3
- VeriSign Class 2 Public Primary Certification Authority - G3
- VeriSign Class 1 Public Primary Certification Authority - G3
- Thawte Personal Premium CA
- Thawte Personal Freemail CA
- Thawte Personal Basic CA
- Thawte Premium Server CA
- Thawte Server CA
- RSA Secure Server Certification Authority

To use certificates issued by any other Certificate Authority you must install the root certificate of the Certificate Authority on all clients as part of the client configuration.

AIX | Windows | Linux

Configure your system for journal-based backup

You must install and configure the journal daemon (Linux) or journal engine service (Windows) before you can perform journal-based backups.

- Windows Configuring the journal engine service
  Journal-based backup can be used for all Windows clients. If you install the journal engine service and it is running, then by default the incremental command automatically performs a journal-based backup on selected file systems that are being monitored by the journal engine service.
- AIX | Linux Journal daemon configuration
  Journal-based backup is enabled by installing and configuring the IBM Spectrum Protect™ journal daemon.

Windows

Configuring the journal engine service

Journal-based backup can be used for all Windows clients. If you install the journal engine service and it is running, then by default the incremental command automatically performs a journal-based backup on selected file systems that are being monitored by the journal engine service.

About this task

Journal-based backup is enabled by installing and configuring the IBM Spectrum Protect™ journal service. You can install the journal service with the GUI Setup wizard or with the dsmcutil command. Basic journal service configuration can be done with the

GUI Setup wizard, more advanced configuration can be done by editing the journal service configuration file, tsmjbbd.ini.
Tip: The default location for journal service configuration file is C:\Program Files\Tivoli\TSM\baclient\tsmjbbd.ini. If this is the first time you are configuring the journal engine service and a copy of tsmjbbd.ini does not already exist, copy the sample file C:\Program Files\Tivoli\TSM\config\tsmjbbd.ini.smp to C:\Program Files\Tivoli\TSM\baclient\tsmjbbd.ini.

To install and configure this service using the client Java™ GUI setup wizard, perform the following steps:

Procedure

1. From the main window, open the Utilities menu and select Setup Wizard.
2. Select the Help me configure the Journal Engine check box.
3. Select the task you want to perform. You can install a new journal engine, update a previously installed journal engine, or remove a previously installed journal engine from your system.
4. Complete each panel in the wizard and click the Next button to continue. To return to a previous panel, click the Back button. To display help information for a panel, click the Help button.

Results

Journal service configuration settings are stored in the journal configuration file tsmjbbd.ini. This file can be installed and configured with the GUI setup wizard or be manually edited.

Follow these steps to set up multiple journal services:

1. Create and set up a separate journal configuration file (tsmjbbd.ini) for each journal service to be installed. Each configuration file must specify a different JournalPipe value, and must also specify different drives to journal, so that the two services do not interfere with each other. Multiple journal services journaling the same drive causes problems. The different services attempts to write to the same journal database unless this is specifically overridden by specifying different journal directories in the different configuration files.
2. Install the multiple journal services using the dsmcutil.exe tool. Use distinct names for each service, and specify the /JBBCONFIGFILE option to identify the tsmjbbd.ini to be used for that particular journal instance. For example:

   ```
   dsmcutil install journal /name:"TSM Journal Service 1"
   /JBBCONFIGFILE:c:\journalconfig\tsmjbbd1.ini

   dsmcutil install journal /name:"TSM Journal Service 2"
   /JBBCONFIGFILE:d:\journalconfig\tsmjbbd2.ini
   ```

   Note: In Uniform Naming Convention (UNC) format, the jbbconfigfile path must contain a drive letter. In the following UNC format example, the path contains the drive letter D$: \\computer7\D$\journalconfig\tsmjbbd1.ini
3. Different backup clients (based on the distinct dsm.opt file used) can now connect to the desired journal service by specifying the appropriate JournalPipe option in the appropriate dsm.opt, which corresponds to the JournalPipe journal service setting.

Note:

1. Each journal service instance is associated to only one backup-archive client node name. Changing the association requires a restart of the journal service to recognize the new association.
2. You cannot use network and removable file systems.

Configuration settings that you apply when the journal service is started and any changes you make while the journal service is running are applied without having to restart the service. This also applies to the journal exclude list. However, some settings for journaled file systems do not take effect until the file system is brought offline and then back online.

File systems can be taken online (added) or offline (removed) without stopping and restarting the journal service. You can bring a file system offline by removing it from the list of journaled file systems in the journal configuration file `tsmjbbd.ini`, or by shutting down the journal service. You can bring a file system back online by adding it to the list of journaled file systems in the journal configuration file `tsmjbbd.ini` or by starting (restarting) the journal service.

Attention: If you take a file system offline without setting the PreserveDbOnExit value of 1, the journaled file system journal database is deleted. PreserveDbOnExit=1 specifies that the journaled file system journal database is not deleted when the journal file system goes offline. The database is also valid when the journal file system comes back online.
The following is the syntax for stanza and stanza settings:

Syntax for stanzas:
    [*StanzaName*]

Syntax for stanza settings:
stanzaSetting=*value*

Note:

1. You can specify comments in the file by beginning the line with a semicolon.
2. Stanza and value names are not case sensitive.
3. Numeric values can be specified in hexadecimal by preceding the value with `0x` otherwise they are interpreted as decimal.
4. There is no correlation between these settings and any settings in the backup-archive client options file. The journal service is a completely independent process and does not process backup-archive client options.

- Windows JournalSettings stanza (Windows)
  Settings under this stanza are global and apply to the entire journal service.
- Windows JournalExcludeList stanza
  This list of exclude statements filters changes from being recorded in the journal database. Changes to objects which match statements in this stanza are ignored and are not recorded in the journal database.
- Windows JournaledFileSystemSettings stanza
  Settings under this stanza apply to each specified journaled file system unless they are overridden for individual file systems in an override stanza.
- Windows Overriding stanzas
  Any setting in the ***JournaledFileSystemSettings*** stanza, except for the buffer sizes, can be overridden for a particular journaled file system by creating an override stanza.

Related concepts:
Journal-based backup
Windows

JournalSettings stanza (Windows)

Settings under this stanza are global and apply to the entire journal service.

The following is the syntax for the `JournalSettings` stanza:

Syntax for `JournalSettings` stanza:
`[JournalSettings]`
Syntax for stanza settings:
JournalSettings=*value*

You can specify the following `JournalSettings` values:

JournalPipe=*pipename*
Specifies the pipe name of the journal service session manager to which backup clients initially connect, when establishing a journal-based backup session. This setting is used in conjunction with the backup client option of the same name. The default pipe name is `\\.\pipe\jnlSessionMgr1`. For example, in dsm.opt:

```
JournalPipe \\.\pipe\jnlSessionMgr1
```

Under `tsmjbbd.ini` [JournalSettings] stanza:

```
JournalPipe=\\.\pipe\jnlSessionMgr1
```

Note: The same pipe name must be specified by the client using the `JournalPipe` option.

`NlsRepos`
Specifies the National Language Support repository the journal service uses for generating messages. Since the journal service is non-interactive, this only applies to messages written to the journal error log. The default value is `dscameng.txt`. For example:

```
NlsRepos=dscenu.txt
```

`ErrorLog`
Specifies the log file where detailed error messages generated by the journal service are written. Note that less detailed error and informational messages are written to the Windows application event log as well. The default value is `jbberror.log`. For example:

```
ErrorLog=jbberror.log
```

In Uniform Naming Convention (UNC) format, the path must contain a drive letter. In the following UNC format example, the path contains the drive letter D$: \\computer7\D$\temp\jbberror.log.

`JournalDir`
: Specifies the directory where journal database files are stored and written. The default directory is the journal service installation directory. You can specify different journal locations for each file system being journaled. This is useful when running in a clustered environment because the location of the journal must be accessible by each workstation in the cluster running the journal service. Typically the journal for local resources being journaled resides in the same location and the journal for shared cluster resources (which can move from workstation to workstation) is located on the shared resource to ensure that it is accessible to both workstations.

  By default, this setting applies to all journaled file systems but can be overridden by an override stanza for each journal file system. If the default value is a fully qualified path (for example c:\tsmjournal), all journal database files are written to the specified directory. If the default value does not specify a drive letter, (for example \tsmjournal) the journal database files for each journal file system are written to the specified directory on each journal file system.

  In Uniform Naming Convention (UNC) format, the path must contain a drive letter. In the following UNC format example, the path contains the drive letter D$: \\computer7\D$\temp\tsmjournal.

  The following is an example configuration stanza:

```
[JournalSettings]
;
; Store all resources in one location unless overridden
; by an override stanza
;
JournalDir=c:\tsmjournal
;
;
[JournaledFileSystemSettings.D:\]
;
; Journal for d: only is in location specified below
;
JournalDir=d:\tsmjournal
```

  Note: Changes to this setting do not take effect until the journaled file systems are brought online.

Windows

JournalExcludeList stanza

This list of exclude statements filters changes from being recorded in the journal database. Changes to objects which match statements in this stanza are ignored and are not recorded in the journal database.

Note:

1. Excluding files from the journal has no bearing on those files being excluded by the backup client, other than preventing the files from being sent to the backup client to be processed during journal-based backup. A file that is not excluded from the journal should still be excluded by the backup-archive client, if there is a matching exclude statement in the client options file.
2. The journal service only provides a subset of the INCLUDE/EXCLUDE function provided by the backup-archive client. The journal service does not support INCLUDE statements and it does not support the *exclude.dir* option.

There is no correlation between the journal exclude list and the backup-archive client exclude list.

The following are examples of equivalent journal exclude statements:

```
dsm.opt: tsmjbbd.ini

EXCLUDE c:\testdir\...\* c:\testdir\*
EXCLUDE.DIR c:\testdir\test* c:\testdir\test*\*
```

The following pattern matching meta characters are supported:

`%`
: Matches exactly one character.

`*`
: Matches zero or more characters.

%EnvVar%
Expands environment variable.

The following is an exclude statement syntax example:

```
[JournalExcludeList]
%SystemRoot%\System32\Config\*
C:\Program Files\Tivoli\TSM\baclient\adsm.sys\*
%TEMP%\*
%TMP%\*
c:\excludedir\*
c:\dir1\excludefile
*.:\*.tmp
```

Note: The `c:\excludedir\*` statement matches the entire tree including subdirectories and files.
Windows

JournaledFileSystemSettings stanza

Settings under this stanza apply to each specified journaled file system unless they are overridden for individual file systems in an override stanza.

The following is the syntax for the JournaledFileSystemSettings stanza:

Syntax for ***JournaledFileSystemSettings*** stanza:
[*JournaledFileSystemSettings*]
Syntax for stanza settings:
JournaledFileSystemSetting=*value*

You can specify the following ***JournaledFileSystemSettings*** values:

DirNotifyBufferSize
Specifies the size of the buffer to record change notifications for a particular journal file system. You might need to increase this value for journaled file systems that generate a very large volume of change activity. The buffer size is limited by memory. The default value is 16 KB.
JournaledFileSystems
Specifies a space delimited list of file systems to journal. Full file system specifications and Windows junctions are supported. There is no default value. You must specify at least one journaled file system for the journal service to run. Journaled file systems can be added or removed online without having to restart the service. For example:

```
JournaledFileSystems=c: d:
```

JournalDbSize
Specifies the maximum size the journal database can grow. The journal database size is expressed in bytes. A value of zero (0) indicates that the database size is limited only by the capacity of the file system containing the journal database. The default is `0` (unlimited). For example:

```
JournalDBSize=0x10000000
```

NotifyBufferSize
Specifies the size of the memory buffer receiving file system change notifications for a particular journal file system. You might need to increase this value for journaled file systems that generate a very large volume of change activity. The buffer size is limited by memory. The default value is 32 KB. For example:

```
NotifyBufferSize=0x00008000
```

NotifyFilter
Specifies what file system change actions generate notifications to the journal service. ***NotifyFilter*** applies to file changes and directory modifications. Directory name changes, such as deletions and creations, are always tracked regardless of the filter value. Multiple actions can be monitored by combining (adding) values together. The default value is `0x11F` (File and Dir Name, Attrib, Size, Last Write, and security Changes). You can also use the IBM Spectrum Protect™ Journal Engine Wizard to specify that any or all of these actions are monitored. Supported values are:

Value type	Decimal	Hex
File Name	1	0x001
Dir Name	2	0x002

Value type	Decimal	Hex
Attribute	4	0x004
File size*	8	0x008
Last Write Time*	16	0x010
Last Access Time	32	0x020
Create Time	64	0x040
Security (ACL)	256	0x100

The asterisk (*) indicates that notification might be deferred until disk write cache is flushed. Name changes are object creations, deletions, or renames.

Example:

```
NotifyFilter=0x107
```

PreserveDbOnExit setting

This setting allows a journal to remain valid when a journaled file system goes offline and comes back online. This is useful for preserving the journal during system reboots, cluster failovers, and resource movement.

File systems go offline when the journal service stops or when the file system is removed from the configuration file. File systems come back online when the journal service is started or when the file system is added to the configuration file.

This setting allows a journal-based backup to continue processing when the service is restarted (or the file system comes back online) without performing a full incremental backup.

Note: Any change activity which occurs while the journal service is not running (or the file system is offline) is not recorded in the journal.

In a clustered environment, shared resources can move to different workstations in the cluster. The journal service running on each workstation in the cluster must include these shared resources in the list of journaled file systems. The journal service running on the workstation which currently owns the resource actively journals the shared resource while other journal services on workstations in the cluster which do not own the resource must defer journaling until the resource becomes available (or is moved to that workstation). The configuration settings *deferFSMonStart*, *deferRetryInterval*, and *logFSErrors* allows deferment for a file system until the file system is available and accessible.

A value of 1 specifies that the journaled file system journal database is not deleted when the journal file system goes offline. The database is also valid when the journal file system comes back online. This value should be used with caution because any file system change activity which occurs while the journaled file system is offline is not reflected in the journal database. The default setting of 0 deletes the journaled file system journal database.

Note: The journal is only preserved when a journaled file system comes offline normally or is brought offline when the resource is no longer available and you specify the deferFsMonStart setting. If a file system comes offline due to an error such as a notification buffer overrun, the journal is not preserved.
An example for not deleting the journal database upon exit is:

```
[JournaledFileSystemSettings.D:\]
;
; Do not delete the journal when D:\ goes offline
;
PreserveDbOnExit=1
```

deferFSMonStart setting

This setting defers an attempt to begin monitoring a file system in the following cases:

- When the specified journaled file system is not valid or available
- The journal directory for the specified journaled file system cannot be accessed or created

Resources are checked at the interval you specify using the *deferRetryInterval* setting.

The *deferFSMonStart* setting is most commonly used in a cluster environment where shared resources might move to different workstations in the cluster.

A value of 1 indicates that the setting is on. A value of 0 indicates that the setting is off. The default value is off (set to 0) .

deferRetryInterval setting

This setting specifies the value in seconds that a deferred file systems with the *deferRetryInterval* setting enabled are checked for availability and brought online. The default value is 1 second.

logFSErrors setting

This setting specifies whether errors encountered while accessing a journaled file system or journal directory are logged in the `jbberror.log`and the event log.

Use the *logFSErrors* setting with the *deferFSMonStart* setting to prevent excessive *File System unavailable* messages from being logged when bringing a journaled file system online is deferred. The first error which causes the file system to be deferred is logged. Subsequent errors are not logged. A value of 1 indicates that the setting is on. A value of 0 indicates that the setting is off.

An example to defer journaling until the file system journal directories are valid is:

```
[JournalSettings]
;
; Place journal files in directory on each journaled file system
;
journalDir=\tsmjournal

[JournaledFileSystemSettings]
;
;journal c:, d:, and f:
;
JournaledFileSystems=c: d: d:\mountpoint f:
;
; Override stanza to defer starting journaling for f:\
; until it is a valid file system

[JournalFileSystemSettings.f:\]
;
; Keep database valid if file system goes offline
;
PreserveDBOnExit=1
;
; Defer journaling until file system and journal directory
; are valid
;
deferFSMonStart=1
;
; Attempt to start journaling every 120 seconds when deferred
;
deferRetryInterval=120
;
;Do not log excessive resource unavailable messages
;
logFsErrors=0
```

Overriding stanzas

Windows

Overriding stanzas

Any setting in the ***JournaledFileSystemSettings*** stanza, except for the buffer sizes, can be overridden for a particular journaled file system by creating an override stanza.

The following is the syntax for the ***JournaledFileSystemSettings*** stanza:

Syntax for JournaledFileSystemSettings stanza:

[***JournaledFileSystemSettings***.*fs*]

Syntax for stanza settings:

JournaledFileSystemSetting=*override value*

Example:

```
[JournalFileSystemSettings.C:\]
NotifyBuffer=0x0020000
NotifyFilter=0x107
```

AIX Linux

Journal daemon configuration

Journal-based backup is enabled by installing and configuring the IBM Spectrum Protect™ journal daemon.

Configure the journal daemon by editing the journal daemon configuration sample file, tsmjbbd.ini.smp, and saving it as tsmjbbd.ini. Both files should be in the default installation directory.

After you configured the tsmjbbd.ini file, start the journal daemon by starting the tsmjbbd executable file.

AIX To start the journal daemon after you restart your system on AIX®, run the jbbinittab script file to add an entry to the /etc/inittab file. The tsmjbbd executable file and the jbbinittab script file should be in the default installation directory.

AIX To stop the journal daemon on AIX, issue the `kill nnnn` command, where *nnnn* is the process ID of tsmjbbd. Before the journal daemon process (tsmjbbd) shuts down, it notifies the filepath kernel extension to stop buffering file changes. Important: Do not use the `kill -9 nnnn` command, because the `kill -9` command immediately ends the process without notifying filepath to stop buffering file changes.
Linux On Linux, the installer creates the tsmjbbd service in /etc/init.d. To control the service, run the following command as root to stop, start, or restart the service, or to check its status:

```
>>-service tsmjbbd--+-start---+--------------------------------><
                    +-stop----+
                    +-restart-+
                    '-status--'
```

If the Linux operating system runs the `systemd` initialization service, complete the following steps to start the journal daemon:

1. Copy the provided `systemd` unit file /opt/tivoli/tsm/client/ba/bin/tsmjbbd.service to the /etc/systemd/system/ directory.
2. Run the following command to refresh the `systemd` unit list:

   ```
   systemctl daemon-reload
   ```

3. Run the following command to start the journal daemon at system boot time:

   ```
   systemctl enable tsmjbbd.service
   ```

4. Run the following command to start the journal daemon:

   ```
   systemctl start tsmjbbd.service
   ```

Note:

1. Network and removable file systems are not supported.
2. Periodic full incremental backups should be performed to complement daily journal-based backups. Full progressive incremental backups can take longer to run than a journal-based backup. Take this information into account when you schedule them, perhaps scheduling the incremental backups during off-peak times. Balance these two backup techniques according to your business needs. For example, you might decide to schedule nightly journal-based backups and also schedule a weekly full progressive incremental backup.
3. Journal-based backup uses the filepath kernel extension to monitor file system changes. To improve the performance of journal-based backups, directories that do not contain user files are not monitored for changes and are not included in journal-based backups. The following lists the directories that are not included in journal-based backups on AIX and Linux systems. Changes to these directories are processed if you perform periodic full incremental backups by using the incremental command with the -nojournal option.

AIX	Linux
/bin /dev /etc /lib /usr/bin /usr/lib /usr/share	/bin /boot /dev /etc /lib /proc /sbin /sys /usr/bin /usr/lib

	/usr/share /var

The journal daemon configuration file is periodically checked for updates to the list of journaled file systems. You can add or remove file systems from the list of monitored file systems without stopping the journal daemon.

Attention: If you bring a file system that is being monitored by the journal daemon offline, the journal database for that file system is deleted. To preserve the database, set `PreserveDbOnExit=1` in the journaled file systems settings stanza. This setting preserves the journal database when it is taken offline and ensures that the journal database is valid when the file system comes back online. For more information, see JournaledFileSystemSettings stanza.
The syntax for stanza and stanza settings is as follows:

Syntax for stanzas:
[*StanzaName*]
Syntax for stanza settings:
stanzaSetting=`value`

Note:

1. You can specify comments in the file by beginning the line with a semicolon.
2. Stanza and value names are not case-sensitive.
3. Numeric values can be specified in hexadecimal by preceding the value with `0x`; otherwise, they are interpreted as decimal.
4. These journaled file system settings do not correlate to any settings in the client options file. The journal daemon is an independent process; it does not process any options in the client options file.

- AIX Linux JournalSettings stanza
  Settings under this stanza are global and apply to the entire journal daemon.
- AIX Linux JournalExcludeList stanza
  This list of exclude statements filters changes from being recorded in the journal database.
- AIX Linux JournaledFileSystemSettings stanza
  Settings under this stanza apply to each specified journaled file system unless they are overridden for individual file systems in an override stanza.
- AIX Linux Overriding stanzas
  Any setting in the JournaledFileSystemSettings stanza, except for the buffer sizes, can be overridden for a particular journaled file system by creating an override stanza.

AIX Linux

JournalSettings stanza

Settings under this stanza are global and apply to the entire journal daemon.

The following is the syntax for the `JournalSettings` stanza:

Syntax for `JournalSettings` stanza:
`[JournalSettings]`
Syntax for stanza settings:
JournalSettings=*value*

You can specify the following `JournalSettings` values:

ErrorLog
Specifies the log file where detailed error messages generated by the journal daemon are written. The default value is `jbberror.log` in the directory of the daemon executable. For example:

```
ErrorLog=/logs/jbberror.log
```

JournalDir
Directory where journal database files are stored and written.

If the path given is an absolute (for example, it begins with a `dir` delimiter) `pathname`, this is the directory used. If the path given is a relative directory name, then this path is appended to each file system name and the resulting path name is used.

The default is a directory named `.tSm_JoUrNaL` (used within each file system being journaled).

The advantage of having the journal database on the file system being monitored is that the database stays with the file system. The disadvantage is that the updates to the database must be processed and discarded.
Important: Directing the database to a non-journaled file system, unless this file system is shared in a cluster environment.

This setting applies to all journaled file systems but can be overridden with an override stanza for each journal file system.

AIX

JournalExcludeList stanza

This list of exclude statements filters changes from being recorded in the journal database.

Changes to objects which match statements in this stanza are ignored and are not recorded in the journal database.

Note:

1. Excluding files from the journal has no bearing on those files being excluded by the backup client, other than preventing the file names from being sent to the backup client to be processed during journal-based backup. A file that is not excluded from the journal should still be excluded by the backup-archive client, if there is a matching exclude statement in the client options file.
2. The journal daemon only provides a subset of the INCLUDE/EXCLUDE function provided by the backup-archive client. The journal daemon does not support INCLUDE statements and it does not support the *exclude.dir* option.

There is no correlation between the journal exclude list and the backup-archive client exclude list.

The following pattern matching meta characters are supported:

%
: Matches exactly one character.

*
: Matches zero or more characters.

%EnvVar%
: Expands environment variable.

The following is an exclude statement syntax example:

```
[JournalExcludeList]
*.jbb.jbbdb
*.jbbInc.jbbdb
```

AIX Linux

JournaledFileSystemSettings stanza

Settings under this stanza apply to each specified journaled file system unless they are overridden for individual file systems in an override stanza.

File systems that you specify in the JournalFileSystems.Extended stanza override any file systems specified in the list of journaled file systems that you might have previously specified in the JournaledFileSystemSettings stanza. Any other options that you have specified in the JournaledFileSystemsSettings stanza are preserved.

The syntax for the JournaledFileSystemSettings stanza is as follows:

Syntax for ***JournaledFileSystemSettings*** stanza:
: **[*JournaledFileSystemSettings*]**

Syntax for stanza settings:
: ***JournaledFileSystemSetting***=*value*

You can specify the following ***JournaledFileSystemSettings*** values:

JournaledFileSystems
: Specifies a space delimited list of file systems to journal. Full file system specifications and Windows junctions are supported. There is no default value. You must specify at least one journaled file system for the journal daemon to run. Journaled file systems can be added or removed online without having to restart the daemon. For example:

```
JournaledFileSystems=/home /other
```

Important: The journal selects object names based strictly on a string match. The implication for the user is that care must be taken when selecting file systems to journal. For example, suppose you have a file system `/jbb` and another file system called `/jbb/mnt1`. If you ask the journal to monitor just `/jbb`, then all the changes for `/jbb/mnt1` also match this string and are entered in the database. When, however, you do a back up on the client, it parses the name based on file systems, realizes the journal is not monitoring this file system and then tells the journal to remove the `/jbb/mnt1` files from the database. The solution is to either monitor both or use the JournalExcludeList. The same is true for the virtual mount point options. You must be consistent with this list. For example, if you specify `/home/student1` as a virtual mount point in your dsm.sys option file and you want to journal `/home`, then you must specify `JournaledFileSystems=/home /home/student1`. In this case, two separate databases are created.

JournalDbSize

Specifies the maximum size the journal database can grow. The journal database size is expressed in bytes. A value of zero (0) indicates that the database size is limited only by the capacity of the file system containing the journal database. The default is `0` (unlimited). For example:

```
JournalDBSize=0x10000000
```

NotifyBufferSize, *DirNotifyBufferSize*

Specify change notification buffer sizes for a journaled file system. A large amount of change activity on a journaled file system might require this to be increased. The default is `0x00020000` (128 k) for files and `0x00010000` (64 k) for directories.

```
NotifyBufferSize=0x00200000
```

PreserveDbOnExit setting

This setting allows a journal to remain valid when a journaled file system goes offline and comes back online. This is useful for preserving the journal during system reboots, and resource movement.

This setting allows a journal-based backup to continue processing when the daemon is restarted (or the file system comes back online) without performing a full incremental backup.

Note: Any change activity which occurs while the journal daemon is not running (or the file system is offline) is not recorded in the journal.

A value of 1 specifies that the journaled file system journal database is not deleted when the journal file system goes offline. The database is also valid when the journal file system comes back online. This value should be used with caution because any file system change activity which occurs while the journaled file system is offline is not reflected in the journal database. The default setting of 0 deletes the journaled file system journal database.

Note: The journal is only preserved when a journaled file system comes offline normally or is brought offline when the resource is no longer available and you specify the deferFsMonStart setting. If a file system comes offline due to an error such as a notification buffer overrun, the journal is not preserved.
Note: Set PreserveDBonExit only when you can ensure that there is a controlled shutdown of the journal service. The scope of "controlled shutdown" includes stopping the journal service in order to reboot the system, failing over a cluster resource, or moving a cluster resource. The journal database can become corrupted if the shutdown is not controlled. Therefore, perform the following steps if the journal service was not shut down in a controlled manner or if the journal database was otherwise taken offline in an uncontrolled manner.

1. Stop the journal service (if it is running)
2. Delete the corrupted journal databases
3. Restart the journal service
4. Perform an incremental backup

An example for not deleting the journal database upon exit is:

```
preserveDBOnExit=1
```

deferFSMonStart setting

This setting defers an attempt to begin monitoring a file system in the following cases:

- When the specified journaled file system is not valid or available
- The journal directory for the specified journaled file system cannot be accessed or created

Resources are checked at the interval you specify using the *deferRetryInterval* setting.

A value of 1 indicates that the setting is on. A value of 0 indicates that the setting is off. The default value is off (set to 0) .

deferRetryInterval setting
This setting specifies the value in seconds that deferred file systems with the *deferRetryInterval* setting enabled are checked for availability and brought online. The default value is 5 seconds.

logFSErrors setting
A value of 1 indicates that all errors encountered accessing a journaled file system or journal directory should be logged. A value of zero indicates that logging of errors encountered while checking deferred file systems and journal directories is suppressed. This is usually used in conjunction with the *deferFSMonStart* setting to eliminate excessive `File System Unavailable` messages from being written to the logs when bringing a journaled file system online is deferred. The default value is 1 (log all errors).

- Linux | AIX JournaledFileSystems.Extended stanza
  The JournaledFileSystems.Extended stanza overrides any file systems that are included in the JournaledFileSystems stanza. It also removes the 1023 character limitation imposed by the JournaledFileSystem stanza.

Related concepts:
Overriding stanzas
JournaledFileSystems.Extended stanza
AIX | Linux

Overriding stanzas

Any setting in the JournaledFileSystemSettings stanza, except for the buffer sizes, can be overridden for a particular journaled file system by creating an override stanza.

HookFileName
In order for the journal to begin monitoring a file system, it must know the name of an existing file in that file system. This setting specifies an existing file. Access to this file is then used as a test of whether or not this file system is online. (The system definition of mounted cannot be used because we allow the use of virtual mount points in the backup-archive client. This means that the backup-archive client system can treat a directory as a (virtual) file system).

Therefore, if this file system can be mounted and unmounted, a HookFileName needs to be provided.

If a HookFileName is not entered, the journal daemon attempts to create a temporary file in the highest directory, use it to begin monitoring, and then delete it.

The following is the syntax for the JournaledFileSystemSettings stanza:

Syntax for JournaledFileSystemSettings stanza:
[*JournaledFileSystemSettings*.*fs*]
Syntax for stanza settings:
JournaledFileSystemSetting=*override value*

For example, the override stanza name for `/home` would be:

```
JournaledFileSystemSettings./home
HookFileName=/home/doNotDeleteThisFile
```

Client-side data deduplication

Data deduplication is a method of reducing storage needs by eliminating redundant data.

Overview

Two types of data deduplication are available: *client-side data deduplication* and *server-side data deduplication*.

Client-side data deduplication is a data deduplication technique that is used on the backup-archive client to remove redundant data during backup and archive processing before the data is transferred to the IBM Spectrum Protect™ server. Using client-side data deduplication can reduce the amount of data that is sent over a local area network.

Server-side data deduplication is a data deduplication technique that is done by the server. The IBM Spectrum Protect administrator can specify the data deduplication location (client or server) to use with the DEDUP parameter on the REGISTER NODE or UPDATE NODE server command.

Enhancements

With client-side data deduplication, you can:

- Exclude specific files on a client from data deduplication.
- Enable a data deduplication cache that reduces network traffic between the client and the server. The cache contains extents that were sent to the server in previous incremental backup operations. Instead of querying the server for the existence of an extent, the client queries its cache.

  Specify a size and location for a client cache. If an inconsistency between the server and the local cache is detected, the local cache is removed and repopulated.

  Note: For applications that use the IBM Spectrum Protect API, the data deduplication cache must not be used because of the potential for backup failures caused by the cache being out of sync with the IBM Spectrum Protect server. If multiple, concurrent backup-archive client sessions are configured, there must be a separate cache configured for each session.
- Enable both client-side data deduplication and compression to reduce the amount of data that is stored by the server. Each extent is compressed before it is sent to the server. The trade-off is between storage savings and the processing power that is required to compress client data. In general, if you compress and deduplicate data on the client system, you are using approximately twice as much processing power as data deduplication alone.

  The server can work with deduplicated, compressed data. In addition, backup-archive clients earlier than V6.2 can restore deduplicated, compressed data.

Client-side data deduplication uses the following process:

- The client creates extents. *Extents* are parts of files that are compared with other file extents to identify duplicates.
- The client and server work together to identify duplicate extents. The client sends non-duplicate extents to the server.
- Subsequent client data-deduplication operations create new extents. Some or all of those extents might match the extents that were created in previous data-deduplication operations and sent to the server. Matching extents are not sent to the server again.

Benefits

Client-side data deduplication provides several advantages:

- It can reduce the amount of data that is sent over the local area network (LAN).
- The processing power that is required to identify duplicate data is offloaded from the server to client nodes. Server-side data deduplication is always enabled for deduplication-enabled storage pools. However, files that are in the deduplication-enabled storage pools and that were deduplicated by the client, do not require additional processing.
- The processing power that is required to remove duplicate data on the server is eliminated, allowing space savings on the server to occur immediately.

Client-side data deduplication has a possible disadvantage. The server does not have whole copies of client files *until* you back up the primary storage pools that contain client extents to a non-deduplicated copy storage pool. (*Extents* are parts of a file that are created during the data-deduplication process.) During storage pool backup to a non-deduplicated storage pool, client extents are reassembled into contiguous files.

By default, primary sequential-access storage pools that are set up for data deduplication must be backed up to non-deduplicated copy storage pools before they can be reclaimed and before duplicate data can be removed. The default ensures that the server has copies of whole files at all times, in either a primary storage pool or a copy storage pool.

Important: For further data reduction, you can enable client-side data deduplication and compression together. Each extent is compressed before it is sent to the server. Compression saves space, but it increases the processing time on the client workstation.

In a data deduplication-enabled storage pool (file pool) only one instance of a data extent is retained. Other instances of the same data extent are replaced with a pointer to the retained instance.

When client-side data deduplication is enabled, and the server has run out of storage in the destination pool, but there is a next pool defined, the server will stop the transaction. The backup-archive client retries the transaction without client-side data deduplication. To recover, the IBM Spectrum Protect administrator must add more scratch volumes to the original file pool, or retry the operation with deduplication disabled.

For client-side data deduplication, the IBM Spectrum Protect server must be Version 6.2 or higher.

Prerequisites

When configuring client-side data deduplication, the following requirements must be met:

- The client and server must be at version 6.2.0 or later. The latest maintenance version should always be used.
- When a client backs up or archives a file, the data is written to the primary storage pool that is specified by the copy group of the management class that is bound to the data. To deduplicate the client data, the primary storage pool must be a sequential-access disk (FILE) storage pool that is enabled for data deduplication.
- The value of the DEDUPLICATION option on the client must be set to YES. You can set the DEDUPLICATION option in the client options file, in the preference editor of the backup-archive client GUI, or in the client option set on the IBM Spectrum Protect server. Use the DEFINE CLIENTOPT command to set the DEDUPLICATION option in a client option set. To prevent the client from overriding the value in the client option set, specify FORCE=YES.
- Client-side data deduplication must be enabled on the server. To enable client-side data deduplication, use the DEDUPLICATION parameter on the REGISTER NODE or UPDATE NODE server command. Set the value of the parameter to CLIENTORSERVER.
- Ensure files on the client are not excluded from client-side data deduplication processing. By default, all files are included. You can optionally exclude specific files from client-side data deduplication with the exclude.dedup client option.
- Files on the client must not be encrypted. Encrypted files and files from encrypted file systems cannot be deduplicated.
- Files must be larger than 2 KB and transactions must be below the value that is specified by the CLIENTDEDUPTXNLIMIT option. Files that are 2 KB or smaller are not deduplicated.

The server can limit the maximum transaction size for data deduplication by setting the CLIENTDEDUPTXNLIMIT option on the server. For more information about this option, see the IBM Spectrum Protect server documentation.

The following operations take precedence over client-side data deduplication:

- LAN-free data movement
- Simultaneous-write operations
- Data encryption

Important: Do not schedule or enable any of those operations during client-side data deduplication. If any of those operations occur during client-side data deduplication, client-side data deduplication is turned off, and a message is written to the error log.

The setting on the server ultimately determines whether client-side data deduplication is enabled. See Table 1.

Table 1. Data deduplication settings: Client and server

Value of the client DEDUPLICATION option	**Setting on the server**	**Data deduplication location**
Yes	On either the server or the client	Client
Yes	On the server only	Server
No	On either the server or the client	Server
No	On the server only	Server

Encrypted files

The IBM Spectrum Protect server and the backup-archive client cannot deduplicate encrypted files. If an encrypted file is encountered during data deduplication processing, the file is not deduplicated, and a message is logged.
Tip: You do not have to process encrypted files separately from files that are eligible for client-side data deduplication. Both types of files can be processed in the same operation. However, they are sent to the server in different transactions.
As a security precaution, you can take one or more of the following steps:

- Enable storage-device encryption together with client-side data deduplication.
- Use client-side data deduplication only for nodes that are secure.
- If you are uncertain about network security, enable Secure Sockets Layer (SSL).
- If you do not want certain objects (for example, image objects) to be processed by client-side data deduplication, you can exclude them on the client. If an object is excluded from client-side data deduplication and it is sent to a storage pool that is set up for data deduplication, the object is deduplicated on server.
- Use the SET DEDUPVERIFICATIONLEVEL command to detect possible security attacks on the server during client-side data deduplication. Using this command, you can specify a percentage of client extents for the server to verify. If the server detects a possible security attack, a message is displayed.

- Configuring the client for data deduplication
  Configure the client so that you can use data deduplication to back up or archive your files.
- Excluding files from data deduplication
  You can exclude a file from data deduplication during backup or archive processing.

Configuring the client for data deduplication

Configure the client so that you can use data deduplication to back up or archive your files.

Before you begin

Before you configure your client to use data deduplication, ensure that the requirements listed in Client-side data deduplication are met:

- The server must enable the client for client-side data deduplication with the DEDUP=CLIENTORSERVER parameter on either the REGISTER NODE or UPDATE NODE command.
- The storage pool destination for the data must be a data deduplication-enabled storage pool.
- Ensure that your files are bound to the correct management class.
- Files must be larger than 2 KB.

A file can be excluded from client-side data deduplication processing. By default, all files are included. Refer to the exclude.dedup option for details.

The server can limit the maximum transaction size for data deduplication by setting the CLIENTDEDUPTXNLIMIT option on the server.

Procedure

Use one of the following methods to enable data deduplication on the client:

Option	Description
Edit the client options file	• AIX Linux Mac OS X Solaris Add the `deduplication yes` option to the dsm.sys file. • Windows Add the `deduplication yes` option to the dsm.opt file.
Preferences editor	a. From the IBM Spectrum Protect™ window, click Edit > Client Preferences. b. Click Deduplication. c. Select the Enable Deduplication check box. d. Click OK to save your selections and close the Preferences Editor.

Results

After you have configured the client for data deduplication, start a backup or archive operation. When the operation completes, the backup or archive report shows the amount of data that was deduplicated in this operation, and how many files were processed by client-side data deduplication.

If you do not have enough disk space for the backup or archive operation, you can enable client-side data deduplication without local data deduplication cache on the client by using these steps:

1. Add the `deduplication yes` option to the client options file.

- AIX Linux Mac OS X Solaris Add the `deduplication yes` option to the dsm.sys file. You can also set this option in the GUI.
- Windows Add the `deduplication yes` option to the dsm.opt file. You can also set this option in the GUI.

2. Turn off the local data deduplication cache by completing one of the following steps:
   - AIX Linux Mac OS X Solaris Add the `ENABLEDEDUPCACHE NO` option to the dsm.sys file.
   - Windows Add the `ENABLEDEDUPCACHE NO` option to the dsm.opt file.

   You can also set this option in the backup-archive client preferences editor by clearing the Enable Deduplication Cache check box.

Example

The following example uses the query session command to show the type of data that was processed for data deduplication:

```
Protect> q sess
IBM Spectrum Protect Server Connection Information

Server Name.............: SERVER1
Server Type.............: Windows
Archive Retain Protect..: "No"
Server Version..........: Ver. 6, Rel. 2, Lev. 0.0
Last Access Date........: 08/25/2009 13:38:18
Delete Backup Files.....: "No"
Delete Archive Files....: "Yes"
Deduplication...........: "Client Or Server"

Node Name...............: AVI
User Name...............:
```

The following example uses the query management class command to show the type of data that was processed for data deduplication:

```
Protect> q mgmt -det
Domain Name : DEDUP
Activated Policy Set Name : DEDUP
Activation date/time : 08/24/2009 07:26:09
Default Mgmt Class Name : DEDUP
Grace Period Backup Retn. : 30 day(s)
Grace Period Archive Retn.: 365 day(s)

MgmtClass Name : DEDUP
Description : dedup - values like standard
Space Management Technique : None
Auto Migrate on Non-Usage : 0
Backup Required Before Migration: YES
Destination for Migrated Files : SPACEMGPOOL
Copy Group
Copy Group Name.........: STANDARD
Copy Type...............: Backup
Copy Frequency..........: 0 day(s)
Versions Data Exists....: 2 version(s)
Versions Data Deleted...: 1 version(s)

Excluding files from data deduplication

You can exclude a file from data deduplication during backup or archive processing.

About this task

AIX Linux Mac OS X Solaris You can exclude only files for archive data deduplication. You can exclude files and images (where applicable) for backup data deduplication.

Windows You can exclude only files for archive data deduplication. You can exclude files, images, system state objects, and ASR for backup data deduplication.

Procedure

If you do not want certain files to be processed by client-side data deduplication, you can exclude files from data deduplication processing using the GUI:

1. Click Edit > Client Preferences.
2. Click the Include-Exclude tab.
3. Click Add to open the Define Include-Exclude Options window.
4. Select a category for processing.
   - To exclude a file from data deduplication during archive processing, select Archive in the Category list.
   - To exclude a file from data deduplication during backup processing, select Backup in the Category list.
5. Select Exclude.Dedup in the Type list.
6. Select an item from the Object Type list.
   - For archive processing, only the File object type is available.
   - For backup processing, select one of the following object types:
     - File
     - Image
     - Windows System state
     - Windows ASR
7. Specify a file or pattern in the File or Pattern field. You can use wildcard characters. If you do not want to type a file or pattern, click Browse to open a selection window and select a file. For mounted file spaces, you can choose the directory mount point from the selection window.
   Windows For ASR and system state, this field is filled out automatically. When you specify the image object type, the drive letter must be followed by :** . For example, to exclude drive E:, enter the following pattern:

   ```
   E:\*\*
   ```

8. Click OK to close the Define Include-Exclude Options window. The exclude options that you defined are in an exclude statement at the bottom of the Statements list box in the Include-Exclude Preferences tab.
9. Click OK to save your selections and close the Preferences Editor.

What to do next

AIX Linux Mac OS X Solaris You can also exclude files from data deduplication processing by editing the dsm.sys file:

1. Add the `deduplication yes` option.
2. Exclude the files in a directory from data deduplication. For example, to exclude the files in the /Users/Administrator/Documents/Taxes/ directory, add the following statement: `EXCLUDE.dedup`

```
/Users/Administrator/Documents/Taxes/.../*
```

3. Exclude client-side data deduplication for image backup of a file system. For example, to exclude the /home file system, add the following statement: `EXCLUDE.DEDUP /home/*/* IEOBJTYPE=Image`.

Windows You can also exclude files from data deduplication processing by editing the dsm.opt file:

1. Add the `deduplication yes` option
2. Exclude client-side data deduplication for image backup of drive. For example, to exclude drive E:, add the following statement: `EXCLUDE.DEDUP E:\*\* IEOBJTYPE=Image` to dsm.opt.

Important: If an object is sent to a data deduplication pool, data deduplication occurs on the server, even if the object is excluded from client-side data deduplication.

Automated client failover configuration and use

The backup-archive client can automatically fail over to a secondary server for data recovery when the IBM Spectrum Protect™ server is unavailable. You can configure the client for automated failover or prevent the client from failing over. You can also determine the replication status of your data on the secondary server before you restore or retrieve the replicated data.

- Automated client failover overview
  When there is an outage on the IBM Spectrum Protect server, the backup-archive client can automatically fail over to a secondary server for data recovery.
- Configuring the client for automated failover
  You can manually configure the client to automatically fail over to the secondary server.
- Determining the status of replicated client data
  You can verify whether the most recent backup of the client was replicated to the secondary server before you restore or retrieve client data from the secondary server.
- Preventing automated client failover
  You can configure the client to prevent automated client failover to the secondary server.

Automated client failover overview

When there is an outage on the IBM Spectrum Protect™ server, the backup-archive client can automatically fail over to a secondary server for data recovery.

The IBM Spectrum Protect server that the client connects to during normal production processes is called the *primary server*. When the primary server and client nodes are set up for node replication, that server is also known as the *source replication server*. The client data on the source replication server can be replicated to another IBM Spectrum Protect server, which is the *target replication server*. This server is also known as the *secondary server*, and is the server that the client automatically fails over to when the primary server fails.

For the client to automatically fail over to the secondary server, the connection information for the secondary server must be made available to the client. During normal operations, the connection information for the secondary server is automatically sent to the client from the primary server during the logon process. The secondary server information is automatically saved to the client options file. No manual intervention is required by you to add the information for the secondary server.

Each time the client logs on to the IBM Spectrum Protect server, the client attempts to contact the primary server. If the primary server is unavailable, the client automatically fails over to the secondary server, according to the secondary server information in the client options file. In this failover mode, you can restore or retrieve any replicated client data. When the primary server is online again, the client automatically fails back to the primary server the next time the client is started.

Windows For example, the following sample text is the connection information about the secondary server that is sent to the client and saved to the client options file (dsm.opt):

```
*** These options should not be changed manually
REPLSERVERNAME          TARGET
   REPLTCPSERVERADDRESS 192.0.2.9
   REPLTCPPORT          1501
   REPLSSLPORT          1502
   REPLSERVERGUID       60.4a.c3.e1.85.ba.11.e2.af.ce.00.0c.29.2f.07.d3

MYREPLICATIONServer TARGET
MYPRIMARYServer SERVER1
*** end of automatically updated options
```

AIX Linux Mac OS X Solaris For example, the following sample text is the connection information that secondary server is sent to the client and saved to the client system options file (dsm.sys):

```
*** These options should not be changed manually
REPLSERVERNAME          TARGET
   REPLTCPSERVERADDRESS 192.0.2.9
   REPLTCPPORT          1501
   REPLSSLPORT          1502
   REPLSERVERGUID       60.4a.c3.e1.85.ba.11.e2.af.ce.00.0c.29.2f.07.d3

MYREPLICATIONServer TARGET
*** end of automatically updated options
```

- Requirements for automated client failover
  Before you configure or use the client for automated client failover, the backup-archive client and IBM Spectrum Protect server must meet several requirements.
- Restrictions for automated client failover
  Review the following information to better understand the process and the restrictions that apply to automated client failover.
- Failover capabilities of IBM Spectrum Protect components
  IBM Spectrum Protect components and products rely on the backup-archive client or API to back up data to the primary IBM Spectrum Protect server. When the primary server becomes unavailable, some of these products and components can fail over to the secondary server, while others are not capable of failover.

Requirements for automated client failover

Before you configure or use the client for automated client failover, the backup-archive client and IBM Spectrum Protect™ server must meet several requirements.

Ensure that the client meets the following requirements for automated client failover:

- The primary server, secondary server, and backup-archive client must be running IBM Spectrum Protect Verson 7.1, or a later version.
- The primary and secondary servers must be set up for node replication.
- The client node must be configured for node replication on the source replication server by using the `REGISTER NODE REPLSTATE=ENABLED` or `UPDATE NODE REPLSTATE=ENABLED` server commands.
- By default, the client is enabled for automated client failover. However, if the `usereplicationfailover no` option is specified in the client options file, either change the value to yes, or remove the option.
- Valid connection information for the secondary server must exist in the client options file. During normal operations, this information is automatically sent to the client from the primary server.
- To save the secondary server connection information that is sent from the primary server, the client must have write access to the dsm.opt file on Windows clients, and the dsm.sys file on AIX®, Linux, Mac OS X, and Oracle Solaris clients. If the client does not have write access to these files, the secondary server information is not saved to the client options file, and an error is added to the error log.
- Non-root users cannot use the default location for the node replication table. You must specify a different location by adding the nrtablepath option to the dsm.sys file. For more information, see Nrtablepath.
- The following processes must occur before the connection information for the secondary server is sent to the options file:
  - The client must be backed up to the source replication server at least one time.
  - The client node must be replicated to the target replication server at least one time.
- Failover occurs for client nodes that are backed up with client-node proxy support when both the target and agent nodes are configured for replication to the target replication server. When the target node is explicitly replicated, the agent node is implicitly replicated to the target replication server as well, along with the proxy relationship.

For example, Node_B is granted authority to perform client operations on behalf of Node_A with the following server command:

```
grant proxynode target=Node_A agent=Node_B
```

If both nodes are configured for replication with the `replstate=enabled` option in the node definition, when Node_A is replicated, Node_B and the proxy relationship are replicated as well.

Restrictions for automated client failover

Review the following information to better understand the process and the restrictions that apply to automated client failover.

The following restrictions apply for automated client failover:

- When the client is in failover mode, you cannot use any functions that require data to be stored on the secondary server, such as backup or archive operations. You can use only data recovery functions, such as restore, retrieve, or query operations. You can also edit client options and change the IBM Spectrum Protect™ client password.
- Schedules are not replicated to the secondary server. Therefore, schedules are not run while the primary server server is unavailable.
- After the client connects to the secondary server in failover mode, it does not attempt to connect to the primary server until the next initial logon to the server. The client attempts to fail over to the secondary server only when the initial connection to the primary server fails. The initial connection is the first connection that the client makes with the server.

  If the primary server becomes unavailable during a client operation, the client does not fail over to the secondary server, and the operation fails. You must restart the client so that it can fail over to the secondary server, and then run the client operation again.

  Restore operations that are interrupted when the primary server goes down cannot be restarted after the client fails over. You must run the whole restore operation again after the client fails over to the secondary server.

- If the IBM Spectrum Protect password is changed before the client node is replicated, the password will not be synchronized between the primary and secondary servers. If a failover occurs during this time, you must manually reset the password on the secondary server and the client. When the primary server is online again, the password must be reset for the client to connect to the primary server.

  If the password is reset while the client is connected to the secondary server, the password must be reset on the primary server before the client can log on to the primary server. This restriction is true if the passwordaccess option is set to generate or if the password is manually reset.

- If you backed up or archived client data, but the primary server goes down before it replicates the client node, the most recent backup or archive data is not replicated to the secondary server. The replication status of the file space is not current. If you attempt to restore or retrieve the data in failover mode and the replication status is not current, a message is displayed that indicates that the data you are about to recover is out-of-date. You can decide whether to proceed with the recovery or wait until the primary server comes back online.
- If an administrative user ID with client owner authority exists on the source replication server, and the user ID has the same name as the client node, the administrative user ID is replicated during the node replication process on the server. If such a user ID does not exist on the source replication server, the replication process does not create this administrator definition on the target replication server.

  If other administrative user IDs are assigned to the node, the IBM Spectrum Protect administrator must manually configure the administrative user IDs on the target replication server. Otherwise, the administrative user cannot connect to the target replication server (secondary server) with the IBM Spectrum Protect web client.

- If you restore a file from the IBM Spectrum Protect, and the file system is managed by IBM Spectrum Protect for Space Management, you must not restore the file as a stub file. You must restore the complete file. Use the `restoremigstate=no` option to restore the complete file. If you restore the file as a stub from the target server, the following consequences can occur:
  - You cannot recall the file from the IBM Spectrum Protect source server by using the IBM Spectrum Protect for Space Management client.
  - The IBM Spectrum Protect for Space Management reconciliation process that runs against the IBM Spectrum Protect source server expires the file. If the file is expired by a reconciliation process, you can restore the complete file with the backup-archive client and the `restoremigstate=no` option.

Failover capabilities of IBM Spectrum Protect components

IBM Spectrum Protect™ components and products rely on the backup-archive client or API to back up data to the primary IBM Spectrum Protect server. When the primary server becomes unavailable, some of these products and components can fail over to the secondary server, while others are not capable of failover.

To learn more about the failover capabilities of IBM Spectrum Protect components and products, see technote 1649484.

Related tasks:
Determining the status of replicated client data

Configuring the client for automated failover

You can manually configure the client to automatically fail over to the secondary server.

Before you begin

Before you begin the configuration:

- Ensure that the client node participates in node replication on the primary server.
- Ensure that the client meets the requirements for automated client failover.
- Use this procedure only if the connection information for the secondary server is not current or if it is not in the client options file.

About this task

You might manually configure the client for automated failover in the following situations:

- The secondary server configuration was changed and the primary server is down before the client logs on to the server. When you manually add the connection information, the client is enabled for failover to the secondary server.
- You accidentally erased some or all of the secondary server connection information in the client options file.
  Tip: Instead of manually configuring the client options file, you can run the dsmc q session command, which prompts you to log on to the primary server. The connection information for the secondary server is sent automatically to the client options file.

Procedure

To manually configure the client for automated failover, complete the following steps:

1. Ensure that the client is enabled for automated client failover by verifying that the `usereplicationfailover` option is either not in the client options file or is set to `yes`. By default, the client is enabled for automated client failover so the `usereplicationfailover` is not required in the client options file.
2. Obtain the connection information about the secondary server from the IBM Spectrum Protect server administrator and add the information to the beginning of the client options file. Group the statements into a stanza under the replservername statement.
   AIX | Linux | Mac OS X | Solaris For example, add the following statements to the dsm.sys file:

```
REPLSERVERNAME          TARGET
   REPLTCPSERVERADDRESS 192.0.2.9
   REPLTCPPORT          1501
   REPLSSLPORT          1502
   REPLSERVERGUID       60.4a.c3.e1.85.ba.11.e2.af.ce.00.0c.29.2f.07.d3

SErvername     server_a
   COMMMethod                TCPip
   TCPPort                   1500
   TCPServeraddress          server_hostname1.example.com
   PASSWORDAccess            prompt
   MYREPLICATIONServer       TARGET
```

   Windows For example, add the following statements to the dsm.opt file:

```
REPLSERVERNAME          TARGET
   REPLTCPSERVERADDRESS 192.0.2.9
```

```
   REPLTCPPORT          1501
   REPLSSLPORT          1502
   REPLSERVERGUID       60.4a.c3.e1.85.ba.11.e2.af.ce.00.0c.29.2f.07.d3

MYREPLICATIONServer TARGET
MYPRIMARYSERVERNAME SERVER1
```

3. AIX | Linux | Mac OS X | Solaris Non-root users must specify a location for the node replication table by adding the nrtablepath option to the dsm.sys file. The backup-archive client uses this table to store information about each backup or archive operation to the IBM Spectrum Protect server.
   You must specify a location that your user ID has write access to. For example:

   ```
   nrtablepath /Volumes/nrtbl
   ```

   Restriction: Do not specify the root directory (/) for the location of the node replication table.
4. Save and close the client options file.
5. Restart the backup-archive client GUI or log on to the IBM Spectrum Protect server from the command-line interface. The client is connected to the secondary server.

Example

After you configured the client for automated client failover, and the client attempts to log on to the server, the following sample command output is displayed:

```
IBM Spectrum Protect
Command Line Backup-Archive Client Interface
  Client Version 8, Release 1, Level 0.0
  Client date/time: 12/16/2016 12:05:35
(c) Copyright by IBM Corporation and other(s) 1990, 2016. All Rights Reserved.

Node Name: MY_NODE_NAME
ANS2106I Connection to primary IBM Spectrum Protect server 192.0.2.1 failed

ANS2107I Attempting to connect to secondary server TARGET at 192.0.2.9 : 1501

Node Name: MY_NODE_NAME
Session established with server TARGET: Windows
  Server Version 8, Release 1, Level 0.0
  Server date/time: 12/16/2016 12:05:35  Last access: 12/15/2016 09:55:56

  Session established in failover mode to secondary server
ANS2108I Connected to secondary server TARGET.
```

What to do next

You can restore or retrieve any replicated data in failover mode.

Related concepts:
Automated client failover overview

Determining the status of replicated client data

You can verify whether the most recent backup of the client was replicated to the secondary server before you restore or retrieve client data from the secondary server.

About this task

You can obtain the status of replicated client data to determine whether the most recent client backup was replicated to the secondary server.

If the time stamp of the most recent backup operation on the client matches the time stamp of the backup on the secondary server, the replication status is current.

If the time stamp of the most recent backup operation is different from the time stamp of the backup on the secondary server, the replication status is not current. This situation can occur if you backed up the client, but before the client node can be replicated, the primary server goes down.

Procedure

To determine the status of replicated client data, issue the following command at the command prompt:

```
dsmc query filespace -detail
```

The following sample output shows that the time stamps on the server and the client match, therefore the replication status is current:

```
#      Last Incr Date         Type        fsID  Unicode  Replication  File Space Name
---    --------------         -------     ----  -------  -----------  ---------------
  1    00/00/0000 00:00:00    HFS            9  Yes      Current          /

        Last Store Date     Server                 Local
        ---------------     ------                 -----
           Backup Data :    04/22/2013 19:39:17    04/22/2013 19:39:17
         Archive Data :     No Date Available      No Date Available
```

The following sample output shows that time stamps on the server and the client do not match, therefore the replication status is not current:

```
#      Last Incr Date         Type        fsID  Unicode  Replication  File Space Name
---    --------------         -------     ----  -------  -----------  ---------------
  1    00/00/0000 00:00:00    HFS            9  Yes      Not Current  /

        Last Store Date     Server                 Local
        ---------------     ------                 -----
           Backup Data :    04/22/2013 19:39:17    04/24/2013 19:35:41
         Archive Data :     No Date Available      No Date Available
```

What to do next

If you attempt to restore the data in failover mode and the replication status is not current, a message is displayed that indicates that the data you are about to restore is old. You can decide whether to proceed with the restore or wait until the primary server is online.

Related tasks:
Restoring or retrieving data during a failover

Nrtablepath

Preventing automated client failover

You can configure the client to prevent automated client failover to the secondary server.

About this task

You might want to prevent automated client failover, for example, if you know that the data on the client node was not replicated to the secondary server before the primary server went offline. In this case, you do not want to recover any replicated data from the secondary server that might be old.

Procedure

To prevent the client node from failing over to the secondary server, add the following statement to the client options file:

```
usereplicationfailover no
```

This setting overrides the configuration that is provided by the IBM Spectrum Protect™ server administrator on the primary server.

Results

The client node does not automatically fail over to the secondary server the next time it tries to connect to the offline primary server.

Related tasks:
Determining the status of replicated client data
Related reference:
Usereplicationfailover

Forcing the client to fail over

The client can immediately fail over to the secondary server even if the primary server is operational. For example, you can use this technique to verify that the client is failing over to the expected secondary server.

Procedure

To force the client to immediately fail over to the secondary server, complete the following steps:

1. AIX | Linux | Mac OS X | Solaris Add the forcefailover yes option in the client-system options file (dsm.sys).
2. Windows Add the forcefailover yes option in the client options file (dsm.opt).
3. Connect to the secondary server by restarting the backup-archive client GUI or by starting a command session with the dsmc command.
4. Optional: Instead of updating the options file, you can establish a connection with the secondary server by specifying the `-forcefailover=yes` option with a command. For example:

   ```
   dsmc q sess -forcefailover=yes
   ```

What to do next

You can verify that you are connected to the secondary server with one of the following methods:

- Check the Secondary Server Information field in the Connection Information window in the backup-archive client GUI.
- Check the command output when you start a command session. The status of the secondary server is displayed in the output.

Linux | Windows

Configuring the client to back up and archive Tivoli Storage Manager FastBack data

Before you can back up or archive Tivoli® Storage Manager FastBack client data, you must complete configuration tasks.

First ensure that you have configured the backup-archive client and that you installed the Tivoli Storage Manager FastBack client.

Install the FastBack client by using the information at Tivoli Storage Manager FastBack.

Linux After you install the FastBack client, complete the following tasks:

Windows After you install the FastBack client, complete the following tasks. You can also use the Client Configuration wizard for Tivoli Storage Manager FastBack.

1. Register a node for each FastBack client where data is backed up or archived. The node name must be the short host name of the FastBack client.

This is a one-time configuration performed once for each FastBack client whose volumes need to be backed up or archived.

This registration step must be performed manually only when the backup-archive client is used as a stand-alone application.

The Administration Center does this node registration automatically when the user creates schedules for archiving or backing up FastBack data using the Administration Center. Starting with Version 7.1, the Administration Center component is no longer included in Tivoli Storage Manager or IBM Spectrum Protect™ distributions. FastBack users who have an Administration Center from a previous server release can continue to use it to create and modify FastBack schedules. If you do not already have an Administration Center installed, you can download the previously-released version from ftp://public.dhe.ibm.com/storage/tivoli-storage-management/maintenance/admincenter/v6r3/. If you do not have an Administration Center installed, you must create and modify FastBack schedules on the IBM Spectrum Protect server. For information about creating schedules on the server, see the IBM Spectrum Protect server documentation.

2. Use the server GRANT PROXY command to grant proxy authority to your current backup-archive client node on each node representing the FastBack client created in step 1. The FastBack node should be the target, and the current client node should be the proxy.

   This is a one-time configuration, and is performed by the Administration Center if the backup or archive is initiated by the Administration Center.

3. Run the set password command to store the credentials of the FastBack repositories where the backup-archive client connects. Run the `set password -type=fastback` command once for each repository where the backup-archive client is expected to connect.
   The credentials that are stored depends on these configurations:
   - Backup-archive client on the FastBack server
   - Backup-archive client on the FastBack Disaster Recovery Hub
   - Backup-archive client on a dedicated proxy workstation

For information about integrating IBM Spectrum Protect and Tivoli Storage Manager FastBack, see Integrating Tivoli Storage Manager FastBack and IBM Spectrum Protect.

Windows

Configuring the backup-archive client to protect FastBack client data

You can configure the backup-archive client to protect FastBack client data by using the client configuration wizard.

Before you can use the IBM Spectrum Protect™ Client Configuration wizard for FastBack, you must complete the following tasks:

- Ensure that either the FastBack server, or the FastBack Disaster Recovery Hub, is installed and configured for short-term data retention.
- Also ensure that at least one snapshot has been taken.
- Ensure that the backup-archive client is properly configured with the IBM Spectrum Protect server. Also make sure that the client acceptor service (dsmcad.exe) is running. You can use the IBM Spectrum Protect Client Configuration wizard in the backup-archive client GUI, after you install the backup-archive client.
- Complete a one-time post-installation setup for these purposes:
  - To specify the FastBack user name and password to be used by the wizard, to query and mount volumes from the FastBack repository
  - To run IBM Spectrum Protect scheduler scripts
- Set up the FastBack credentials file. The user ID that you specify must have Tivoli® Storage Manager FastBack administrative authority.
  1. Configure the user ID and password. Run the following command on the workstation where the backup-archive client and FastBack server or Disaster Recovery Hub are installed:

     ```
     cd <TSM_FastBack_install_location>\FastBack\shell
     ```

where <TSM_FastBack_install_location> is the directory location where the Tivoli Storage Manager FastBack client is installed.

2. If it does not exist, create a folder called FastbackTSMScripts under the system drive of the workstation, using the following command:

   ```
   mkdir <machine_system_drive>:\FastbackTSMScripts
   ```

3. Run the fastbackshell command:

   ```
   FastBackShell -c encrypt -u userName -d domain -p password -f
   <machine_system_drive>:\FastbackTSMScripts\credential.txt
   ```

   The following options are used in the preceding command example:

   - -u specifies the Tivoli Storage Manager FastBack administrator user name.
   - -p specifies the Tivoli Storage Manager FastBack administrator password.
   - -d specifies the Tivoli Storage Manager FastBack domain for the user name.
   - -f specifies the output file where the encrypted credentials are to be written.

Important: The credentials file must be generated with the name "credential.txt". The credentials file must also be located in the FastbackTSMScripts directory of the system drive of the workstation, for the wizard to function properly.

You can use the client configuration wizard in the backup-archive client Java™ GUI or the backup-archive web client.

Follow these steps to use the client configuration wizard in the Java GUI:

1. Ensure that the backup-archive client is properly configured with the IBM Spectrum Protect server.
2. The configuration wizard starts automatically to create the configuration file.
3. Follow the instructions on the panel to complete the wizard.
4. From the backup-archive client GUI main window, select Utilities > Setup Wizard.
5. From the welcome page, select Help me configure the client to protect FastBack client data and click Next.
6. Use the wizard to complete the configuration process.

Follow these steps to start the client configuration wizard in the web client:

1. Ensure that the web client is properly configured with the IBM Spectrum Protect server, and that the IBM Spectrum Protect client acceptor service is running.

   To configure the web client, follow these steps:

   a. From the backup-archive client GUI main window in the Java GUI, click Utilities > Setup Wizard.
   b. From the welcome page, select Help me configure the Web Client and click Next. Follow the instructions on the panel to complete the wizard.
2. Start the web client. In your web browser, specify the client node name and port number where the client acceptor service is running.

   For example: `http://<machine_name_or_ip_address>:1585`

3. From the backup-archive client GUI main window, click Utilities > Setup Wizard.
4. From the welcome page, select Help me configure the client to protect FastBack client data, and click Next.
5. Use the wizard to complete the configuration process.

Cluster environment configuration and use

The term *cluster* has different meanings in different environments. It can mean highly available, high performance, load balancing, grid computing, or some combination of all of these terms.

There are currently several clustering products available for UNIX and Linux, and this section defines those aspects of a clustering environment that need to exist in order for this backup methodology to work correctly. A basic understanding of how your cluster software functions is needed. Cluster software related activities such as the development of application start and stop scripts are not described in this section.

A cluster environment refers to a UNIX or a Linux environment which exhibits the following characteristics:

- Disks are shared between physical workstations, either in an exclusive fashion (only one host has access to the logical disk at any one time) or in a concurrent fashion.
- Disks appear as local disks to the host and not as network resources.
  Important: Mount the file systems locally to the system, not through a LAN-based file share protocol such as network file system (NFS).
- Mount points of local disks are identical on each physical host in the environment (if file system `/group1_disk1` fails from `NodeA to NodeB`, it is mounted on `NodeB` as `/group1_disk1`).

AIX | Linux | Solaris | Mac OS X

Overview of cluster environments

Cluster environments can be set up in many different configurations. This section describes the most popular cluster configurations.

- Mac OS X | AIX | Linux | Solaris Active/Active: Pool cluster resources
  In an active/active configuration, each node is actively managing at least one resource and is configured as a backup for one or more resources in the cluster. Active/active is the most common form of a cluster environment.
- Mac OS X | AIX | Linux | Solaris Active/Passive: Fault tolerant
  In an active/passive configuration, one node actively manages the resource.
- Mac OS X | AIX | Linux | Solaris Concurrent access
  In a concurrent configuration, more than one node manages a resource. When a fault occurs, the resource continues to be managed by the other nodes.

AIX | Linux | Solaris | Mac OS X

Active/Active: Pool cluster resources

In an active/active configuration, each node is actively managing at least one resource and is configured as a backup for one or more resources in the cluster. Active/active is the most common form of a cluster environment.

AIX | Linux | Solaris | Mac OS X

Active/Passive: Fault tolerant

In an active/passive configuration, one node actively manages the resource.

The other node is only used if the primary node experiences a fault and the resource needs to failover. An active/passive cluster is a subtype of an active/active cluster.

AIX | Linux | Solaris | Mac OS X

Concurrent access

In a concurrent configuration, more than one node manages a resource. When a fault occurs, the resource continues to be managed by the other nodes.

AIX | Linux | Solaris | Mac OS X

Configuring the backup-archive client in a cluster environment

The backup-archive client is designed to manage the backup of cluster drives by placing the backup-archive client within the context of the cluster's resource groups.

About this task

This gives the advantage of backing up data from local resources (as opposed to accessing the data across the network) to maximize the performance of the backup operation and to manage the backup data relative to the resource group. Therefore, the backup-archive client can always back up data on cluster resources as if the data were local data and maximize backup performance. This ensures that critical data is getting backed up across system failures.

For example, an active/active cluster environment has three physical hosts in the cluster named `NodeA`, `NodeB`, and `NodeC`.

The nodes have the following qualities:

- `NodeA` owns the cluster resource with file systems `/A1` and `/A2`
- `NodeB` owns the cluster resources with file systems `/B1` and `/B2`
- `NodeC` owns the cluster resources with file systems `/C1` and `/C2`

Note: `NodeA` might also have two non-clustered volumes, `/fs1` and `/fs2`, that must be backed up.

For best backup performance, you might want all nodes in the cluster to perform the backups of the shared file systems that they own. When a node failover occurs, the backup tasks of the failed node shift to the node to which the failover occurred. For example, when `NodeA` fails over to `NodeB`, the backup of `/A1` and `/A2` moves to `NodeB`.

The following are prerequisites before configuring the backup-archive client to back up cluster and non-cluster volumes:

- A separate backup-archive client scheduler process must be run for each resource group being protected. In normal conditions, each node would have two scheduler processes: one for the cluster resources, and one for the local file systems. After a failure, additional scheduler processes are started on a node in order to protect the resources that have moved over from another node.
- The backup-archive client password files must be stored on cluster disks so that after a failure, the generated backup-archive client password is available to the takeover node.
- The file systems to be protected as part of a resource group are defined using the backup-archive client domain option. The domain option is specified in the `dsm.sys` file, which should also be stored on a cluster disk so that it can be accessed by the takeover node.

Follow the steps below to configure the backup-archive client in a cluster environment.

Procedure

1. Register backup-archive client node definitions on the IBM Spectrum Protect™ server. All nodes in the cluster must be defined on the IBM Spectrum Protect server. If you are defining multiple cluster resources in a cluster environment to failover independently, then unique node names must be defined per resource group. For the above sample three-way active/active cluster configuration, define three nodes (one per resource), as follows: (1) `Protect: IBM>register node nodeA nodeApw domain=standard`, (2) `Protect: IBM>register node nodeB nodeBpw domain=standard`, (3) `Protect: IBM>register node nodeC nodeCpw domain=standard`.
2. Configure the backup-archive client system-options file. Each node in the cluster must have separate server stanzas for each cluster resource group in order to be backed up in each respective `dsm.sys` file. You must ensure that the server stanzas are identical in the system option files on each node. Alternatively, you can place the `dsm.sys` file on a shared cluster location. The server stanzas defined to back up clustered volumes must have the following special characteristics:
    - The nodename option must refer to the client node name registered on the IBM Spectrum Protect server. If the client node name is not defined, the node name defaults to the host name of the node, which might conflict with other node names used for the same client system.
      Important: Use the nodename option to explicitly define the client node.
    - The tcpclientaddress option must refer to the service IP address of the cluster node.
    - The passworddir option must refer to a directory on the shared volumes that are part of the cluster resource group.
    - The errorlogname and schedlogname options must refer to files on the shared volumes that are part of the cluster resource group to maintain a single continuous log file.
    - All include exclude statements must refer to files on the shared volumes that are part of the cluster resource group.
    - If you use the inclexcl option, it must refer to a file path on the shared volumes that are part of the cluster group.
    - The stanza names identified with the servername option must be identical on all systems.

3. Other backup-archive client options can be set as needed. In the following example, all three nodes, `NodeA`, `NodeB`, and `NodeC`, must have the following three server stanzas in their `dsm.sys` file:

```
Servername        server1_nodeA
nodename          NodeA
commmethod        tcpip
tcpport           1500
tcpserveraddress  server1.example.com
tcpclientaddres   nodeA.example.com
passwordaccess    generate
passworddir       /A1/tsm/pwd
managedservices   schedule
schedlogname      /A1/tsm/dsmsched.log
errorlogname      /A1/tsm/errorlog.log

Servername        server1_nodeB
nodename          NodeB
commmethod        tcpip
tcpport           1500
tcpserveraddress  server1.example.com
tcpclientaddres   nodeB.example.com
passwordaccess    generate
passworddir       /B1/tsm/pwd
managedservices   schedule
schedlogname      /B1/tsm/dsmsched.log
errorlogname      /B1/tsm/errorlog.log

Servername        server1_nodeC
nodename          NodeC
commmethod        tcpip
tcpport           1500
tcpserveraddress  server1.example.com
tcpclientaddres   nodeC.example.com
passwordaccess    generate
passworddir       /C1/tsm/pwd
managedservices   schedule
schedlogname      /C1/tsm/dsmsched.log
errorlogname      /C1/tsm/errorlog.log
```

4. Configure the backup-archive client user-options file. The options file (`dsm.opt`) must reside on the shared volumes in the cluster resource group. Define the `DSM_CONFIG` environment variable to refer to this file. Ensure that the `dsm.opt` file contains the following settings:
   - The value of the servername option must be the server stanza in the `dsm.sys` file which defines parameters for backing up clustered volumes.
   - Define the clustered file systems to be backed up with the domain option.
     Note: Ensure that you define the domain option in the `dsm.opt` file or specify the option in the schedule or on the backup-archive client command line. This is to restrict clustered operations to cluster resources and non-clustered operations to non-clustered resources.

   In the example, nodes `NodeA`, `NodeB`, and `NodeC` set up their corresponding `dsm.opt` file and `DSM_CONFIG` environment variable as follows:

   NodeA:

```
1) Set up the /A1/tsm/dsm.opt file:

servername server1_nodeA
domain     /A1 /A2

2) Issue the following command or include it in your user profile:

export DSM_CONFIG=/A1/tsm/dsm.opt
```

   NodeB:

```
1) Set up the /B1/tsm/dsm.opt file:

servername server1_nodeB
domain     /B1 /B2

2) Issue the following command or include it in your user profile:
```

```
export DSM_CONFIG=/B1/tsm/dsm.opt
```

NodeC:

```
1) Set up the /C1/tsm/dsm.opt file:

servername server1_nodeC
domain     /C1 /C2

2) Issue the following command or include it in your user profile:

export DSM_CONFIG=/C1/tsm/dsm.opt
```

5. Set up the schedule definitions for each cluster resource group. After the basic setup is completed, define the automated schedules to back up cluster resources to meet the backup requirements. The procedure illustrates the schedule setup by using the built-in IBM Spectrum Protect scheduler. If you are using a vendor-acquired scheduler, refer to the documentation provided by the scheduler vendor.
   - Define a schedule in the policy domain where cluster nodes are defined. Ensure that the schedule's startup window is large enough to restart the schedule on the failover node in case of a failure and fallback event. This means that the schedule's duration must be set to longer than the time it takes to complete the backup of the cluster data for that node, under normal conditions.

     If the reconnection occurs within the start window for that event, the scheduled command is restarted. This scheduled incremental backup reexamines files sent to the server before the failover. The backup then "catches up" to where it stopped before the failover situation.

     In the following example, the `clus_backup` schedule is defined in the standard domain to start the backup at 12:30 A.M. every day with the duration set to two hours (which is the normal backup time for each node's data).

     ```
     Protect: IBM>define schedule standard clus_backup action=incr
     starttime=00:30 startdate=TODAY  Duration=2
     ```

   - Associate the schedule with the all of the backup-archive client nodes defined to backup cluster resources, as follows: `(1) Protect: IBM>define association standard clus_backup nodeA`, (2) `Protect: IBM>define association standard clus_backup nodeB`, (3) `Protect: IBM>define association standard clus_backup nodeC`.
6. Set up the scheduler service for backup. On each client node, a scheduler service must be configured for each resource that the node is responsible for backing up, under normal conditions. The `DSM_CONFIG` environment variable for each resource scheduler service must be set to refer to the corresponding `dsm.opt` file for that resource. For the sample configuration, the following shell scripts must be created to allow `dsmcad` processes to be started, as needed, from any node in the cluster.

   ```
   NodeA: /A1/tsm/startsched
   #!/bin/ksh
   export DSM_CONFIG=/A1/tsm/dsm.opt
   dsmcad
   NodeB: /B1/tsm/startsched
   #!/bin/ksh
   export DSM_CONFIG=/B1/tsm/dsm.opt
   dsmcad
   NodeC: /C1/tsm/startsched
   #!/bin/ksh
   export DSM_CONFIG=/C1/tsm/dsm.opt
   dsmcad
   ```

7. Define the backup-archive client to the cluster application. To continue the backup of the failed resource after a failover condition, the IBM Spectrum Protect scheduler service (for each cluster client node) must be defined as a resource to the cluster application in order to participate in the failover processing. This is required in order to continue the backup of the failed resources from the node that takes over the resource. Failure to do so would result in the incomplete backup of the failed resource. The sample scripts in step 5 can be associated with the cluster resources to ensure that they are started on nodes in the cluster while the disk resources being protected move from one node to another. The actual steps required to set up the scheduler service as a cluster resource are specific to the cluster software. Refer to your cluster application documentation for additional information.
8. Ensure that the password for each node is generated and cached correctly in the location specified using the passworddir option. This can be validated by performing the following steps:
   a. Validate that each node can connect to the IBM Spectrum Protect server without the password prompt. You can do this by running the backup-archive client command line interface and issuing the following command on each node:

```
#dsmc query session
```

If you are prompted to submit your password, enter the password to run the command successfully and rerun the command. The second time, the command should run without the prompt for the password. If you get prompted for the password, check your configuration.

b. Validate that the other nodes in the cluster can start sessions to the IBM Spectrum Protect server for the failed-over node. This can be done by running the same commands, as described in the step above, on the backup nodes. For example, to validate if `NodeB` and `NodeC` can start a session as `NodeA` in the failover event without prompting for the password, perform the following commands on `NodeB` and `NodeC`

```
#export DSM_CONFIG=/A1/tsm/dsm.opt
#dsmc query session
```

The prompt for the password might appear at this time, but this is unlikely. If you are prompted, the password was not stored in the shared location correctly. Check the passwordir option setting used for `NodeA` and follow the configuration steps again.

c. Ensure that the schedules are run correctly by each node. You can trigger a schedule by setting the schedule's start time to `now`. Remember to reset the start time after testing is complete.

```
Protect: IBM>update sched standard clus_backup starttime=now
```

d. Failover and fallback between `nodeA` and `nodeB`, while `nodeA` is in the middle of the backup and the schedule's start window, is still valid. Verify that the incremental backup continues to run and finish successfully after failover and fallback.

e. Issue the command below to cause a node's (`nodeA`) password to expire. Ensure that backup continues normally under normal cluster operations, as well as failover and fallback:

```
Protect: IBM>update node nodeA forcep=yes
```

9. Configure the backup-archive client to back up local resources.

a. Define client nodes on the IBM Spectrum Protect server. Local resources should never be backed up or archived using node names defined to back up cluster data. If local volumes that are not defined as cluster resources are backed up, separate node names (and separate client instances) must be used for both non-clustered and clustered volumes.

In the following example, assume that only `NodeA` has local file systems `/fs1` and `/fs2` to be backed up. In order to manage the local resources, register a node `NodeA_local` on the IBM Spectrum Protect server: `Protect: IBM>register node nodeA_local nodeA_localpw domain=standard`.

b. Add a separate stanza in each node's system options file `dsm.sys` that must back up local resources with the following special characteristics:

- The value of the tcpclientaddress option must be the local host name or IP address. This is the IP address used for primary traffic to and from the node.
- If the client backs up and restores non-clustered volumes without being connected to the cluster, the value of the tcpclientaddress option must be the boot IP address. This is the IP address used to start the system (node) before it rejoins the cluster:

```
Example stanza for NodeA_local:

Servername        server1_nodeA_local
nodename          nodeA_local
commmethod        tcpip
tcpport           1500
tcpserveraddress  server1.example.com
tcpclientaddres   nodeA_host.example.com
passwordaccess    generate
managedservices   schedule
```

c. Define the user options file `dsm.opt` in a path that is on a non-clustered resource.

- The value of the servername option must be the server stanza in the dsm.sys file which defines parameters for backing up non-clustered volumes.
- Use the domain option to define the non-clustered file systems to be backed up.

Note: Ensure that you define the domain option in the `dsm.opt` file or specify the option in the schedule or on the backup-archive client command line, in order to restrict the backup-archive operations to non-clustered volumes.

In the following example, `nodeA` uses the following `/home/admin/dsm.opt` file and sets up the `DSM_CONFIG` environment to refer to `/home/admin/A1.dsm.opt`.

Contents of `/home/admin/A1.dsm.opt`

```
servername ibm_nodeA_local
domain     /fs1 /fs2

export DSM_CONFIG=/home/admin/A1.dsm.opt
```

d. Define and set up a schedule to perform the incremental backup for non-clustered file systems.

```
Protect: IBM>define schedule standard local_backup action=incr
starttime=00:30 startdate=TODAY  Duration=2
```

Associate the schedule with all of the backup-archive client nodes that are defined to backup non-clustered resources.

```
Protect: IBM>define association standard nodeA_local
```

10. Restore cluster file system data. All volumes in a cluster resource are backed up under the target node defined for that cluster resource. If you need to restore the data that resides on a cluster volume, it can be restored from the client node that owns the cluster resource at the time of the restore. The backup-archive client must use the same user options file (`dsm.opt`) that was used during the backup to restore the data. There are no additional setup requirements necessary to restore data on cluster volumes.
11. Restore local file system data. The non-clustered volumes are backed up under the separate node name setup for non-clustered operations. In order to restore this data, the backup-archive client must use the same user options file `dsm.opt` that was used during the backup. In the example, set environment variable `DSM_CONFIG` to refer to `/home/admin/A1.dsm.opt` prior to performing a client restore for the local node `nodeA_local`.

AIX | Linux | Solaris | Mac OS X

Enabling web client access in a Cluster Environment

If IBM Spectrum Protect™ web client access is needed during a failover condition, you must configure the web client acceptor daemon that is associated with the cluster to failover along with the cluster resource.

Before you begin

Beginning with IBM Spectrum Protect Version 8.1.2, you can no longer use the web client to connect to the IBM Spectrum Protect V8.1.2 or later server. However, you can still use the web client to connect to IBM Spectrum Protect V8.1.1, V8.1.0, or V7.1.7 and earlier servers. For more information, see Using the web client in the new security environment.

About this task

After you have completed the configuration steps described in the *Configuring the backup-archive client in a cluster environment* section, perform the additional steps described below to complete the web client access setup:

Procedure

1. Set up the client acceptor daemon to manage the web client and scheduler. The client acceptor daemon should be set up to manage schedulers as well as web client access. This reduces the number of daemons that need to be configured as cluster applications and thus simplifies the configuration and administration. When a failover occurs, the client acceptor starts on the node that is managing the takeover.
2. Update the managedservices option in the system-options file `dsm.sys` on each node for each server stanza, as shown below for `NodeA`

```
Servername          server1_NodeA
nodename            NodeA
commmethod          tcpip
tcpp                1500
tcps                server1.example.com
tcpclientaddres     nodeA.example.com
```

```
passwordaccess    generate
passworddir       /A1/tsm/pwd
schedlogn         /A1/tsm/dsmsched.log
errorlogname      /A1/tsm/errorlog.log
managedservices   webclient schedule
```

3. Set up the client acceptor daemon to use a known HTTP port. By default, the client acceptor daemon uses HTTP port 1581, when available, for the web client access. If this port is not available, the client acceptor finds the first available port, starting with 1581. In a failover condition of an active-active cluster configuration, a failover cluster host system is probably running multiple instances of the client acceptor. If default settings are used for the HTTP port, the failover node uses any available port for the client acceptor being failed over, since the default port is probably in use by the current client acceptor processes of the failover host. This causes problems for the web client associated with the client acceptor that failed over, as the new HTTP port is not known to the web client users. You might use the httpport option to specify the specific ports for the web client access for each resource. This allows you to always use the same port when connecting from a web browser, independent of the node serving the cluster resource. Add the httpport option in the system-options file (`dsm.sys`) on each node for each server stanza as follows, making sure that each stanza uses a unique value:

```
Servername        server1_NodeA
nodename          NodeA
commmethod        tcpip
tcpp              1500
tcps              server1.example.com
tcpclientaddres   nodeA.example.com
passwordaccess    generate
passworddir       /A1/tsm/pwd
managedservices   webclient schedule
schedlogn         /A1/tsm/dsmsched.log
errorlogname      /A1/tsm/errorlog.log
httpport          1510

Servername        server1_NodeB
nodename          NodeB
commmethod        tcpip
tcpp              1500
tcps              server1.example.com
tcpclientaddres   nodeB.example.com
passwordaccess    generate
passworddir       /B1/tsm/pwd
managedservices   webclient schedule
schedlogn         /B1/tsm/dsmsched.log
errorlogname      /B1/tsm/errorlog.log
httpport          1511

Servername        server1_NodeC
nodename          NodeC
commmethod        tcpip
tcpp              1500
tcps              server1.example.com
tcpclientaddres   nodeC.example.com
passwordaccess    generate
passworddir       /C1/tsm/pwd
managedservices   webclient schedule
schedlogn         /C1/tsm/dsmsched.log
errorlogname      /C1/tsm/errorlog.log
httpport          1512
```

AIX

Migrating legacy AIX®IBM PowerHA SystemMirror setups

If you are currently using the backup-archive client in an IBM® PowerHA® SystemMirror® environment using the clusternode option, you must update your current configurations. The clusternode option is no longer supported.

About this task

Perform the following steps to update your current configurations:

Procedure

1. Update the backup-archive client system-options file. As with the clusternode option, each node in the cluster must continue to have separate server stanzas for each cluster resource group to be backed up in each respective `dsm.sys` file. The existing `dsm.sys` file for `NodeA` might appear as follows:

```
Servername          server1_nodeA
commmethod          tcpip
tcpp                1500
tcps                server1.example.com
tcpclientaddres     nodeA.example.com
passwordaccess      generate
passworddir         /A1
clusternode         yes
managedservices     schedule
schedlogn           /A1/dsmsched.log
errorlogname        /A1/errorlog.log
```

2. Notice that no nodename option is used in this sample. Make the following changes to the existing `dsm.sys` file for `NodeA`.
   - Remove the clusternode option.
   - Specify a nodename option if you do not have one already specified.
3. The new `dsm.sys` file for `NodeA` should appear as follows:

```
Servername          server1_nodeA
commmethod          tcpip
nodename            myclus (myclus is the existing cluster name )
tcpp                1500
tcps                server1.example.com
tcpclientaddres     nodeA.example.com
passwordaccess      generate
passworddir         /A1
managedservices     schedule
schedlogn           /A1/dsmsched.log
errorlogname        /A1/errorlog.log
```

4. Register backup-archive client nodes on the IBM Spectrum Protect™ server. If new backup-archive client nodes are added in the first step to replace the current default value of the cluster node name, register those nodes on the IBM Spectrum Protect server.
5. Update schedule definitions. If new backup-archive client nodes are added in the previous step, ensure that the backup schedule definitions used earlier to back up this node's data are now associated with the new client node names.
6. Validate the setup. For more information, see Configuring the backup-archive client in a cluster environment

Windows

Configuring the backup-archive client in a cluster server environment

You can install the backup-archive client software locally on each node of a Microsoft Cluster Server (MSCS) or Veritas Cluster Server (VCS) environment cluster.

You can use the backup-archive client in a VCS environment on the supported Windows Server platforms.

You can also install and configure the Scheduler Service for each cluster node to manage all local disks and each cluster group containing physical disk resources.

For example, MSCS cluster mscs-cluster contains two nodes: node-1 and node-2, and two cluster groups containing physical disk resources: group-a and group-b. In this case, an instance of the IBM Spectrum Protect™ Backup-Archive Scheduler Service should be installed for node-1, node-2, group-a, and group-b. This ensures that proper resources are available to the Backup-Archive client when disks move (or fail) between cluster nodes.

The clusternode option ensures that the client manages backup data logically, regardless of which cluster node backs up a cluster disk resource. Use this option for client nodes that process cluster disk resources, and not local resources.

Note: You must set the clusternode: option to `yes` for all IBM Spectrum Protect-managed cluster operations. Inconsistent use of the clusternode option for a given IBM Spectrum Protect cluster node name can cause the client to invalidate the cluster node name encrypted password, and prompt the user to reenter the password during the next backup-archive client program invocation.

Use the optfile option to properly call the correct (cluster) dsm.opt for all client programs to ensure proper functionality for cluster related operations.

How you install and configure the backup-archive client in a cluster environment depends on the cluster server technology used (MSCS or VCS) and the operating system being used by the nodes in the cluster.

- Windows Protecting data in MSCS clusters (Windows Server clients)
  A client configuration wizard is used on nodes in an MSCS cluster environment to automate and simplify the configuration of the backup-archive client to protect cluster disk groups. The wizard can only be used on nodes that run supported Windows Server clients as their operating system.
- Windows Configure the web client in a cluster environment
  To use the web client in a cluster environment, you must configure the backup-archive client GUI to run in a cluster environment.

Protecting data in MSCS clusters (Windows Server clients)

A client configuration wizard is used on nodes in an MSCS cluster environment to automate and simplify the configuration of the backup-archive client to protect cluster disk groups. The wizard can only be used on nodes that run supported Windows Server clients as their operating system.

- Windows Configuring cluster protection (Windows Server clients)
  Use the IBM Spectrum Protect™ cluster wizard to configure the backup-archive client to protect cluster resources. The wizard gathers the information that is needed so the backup-archive client can protect cluster resources, and log on to the server.

Windows

Configure the web client in a cluster environment

To use the web client in a cluster environment, you must configure the backup-archive client GUI to run in a cluster environment.

Beginning with IBM Spectrum Protect™ Version 8.1.2, you can no longer use the web client to connect to the IBM Spectrum Protect V8.1.2 or later server. However, you can still use the web client to connect to IBM Spectrum Protect V8.1.1, V8.1.0, or V7.1.7 and earlier servers. For more information, see Using the web client in the new security environment.

See Windows Configuring cluster protection (Windows Server clients) for detailed information about installing and configuring the backup-archive client in a MSCS or VCS environment.

- Windows Configure the web client to process cluster disk resources
  After installing and configuring the backup-archive client in a MSCS or VCS environment, there are some steps you must perform to process cluster disk resources.

Windows

Frequently asked questions

This section contains some frequently asked questions and answers about using cluster services.

About this task

Q: How do you configure a shortcut for the backup-archive client GUI in a cluster environment?
A: To configure a backup-archive client GUI icon (for example on the Windows desktop) that you can use to manage operations for a cluster resource group on a Windows cluster, perform the following steps:

Procedure

1. Right-click on the desktop and select New > Shortcut.
2. In the window that appears, find the path to the dsm.exe executable (located by default in directory `C:\program files\tivoli\tsm\baclient\`). If you type the path in, instead of using the Browse button, the path should be enclosed in double quotation marks. For example: "C:\Program Files\tivoli\tsm\baclient\dsm.exe"
3. After you enter the path and executable in the text field, add the following information after the closing double quotation marks (add a space between the double quotation marks and the following): `–optfile="x:\path\to\cluster\dsm.opt"`. This identifies the proper IBM Spectrum Protect™ cluster options file you want to use. This example assumes that the cluster options file is located in the folder "x:\path\to\cluster\" and has the file name dsm.opt.
4. The complete line in the text field now should look similar to the following: `"C:\Program Files\tivoli\tsm\baclient\dsm.exe" -optfile="x:\path\to\cluster\ dsm.opt"`.
5. Click Next and give this shortcut a meaningful name, such as Backup-Archive GUI: Cluster Group X.
6. Click Finish. A desktop icon should now be available. The properties of this icon shows the following correct Target, as noted in step 4: `"C:\Program Files\tivoli\tsm\baclient\dsm.exe" -optfile="x:\path\to\cluster\ dsm.opt"`.

Results

Q: How do you verify that a scheduler service setup in a cluster environment works?

A: Setting up a scheduler service for a Microsoft clustered resource group can be time consuming, and can be lengthened by mistakes and errors in the syntax of the commands used to set them up. Carefully entering the commands and recording important information about the cluster setup can minimize setup time. To successfully set up a scheduler service for Microsoft cluster environments:

1. Carefully read the information in this appendix for correct syntax on setting up a scheduler service for a cluster group.
2. Ensure that the proper dsm.opt file(s) are used for the cluster. In a typical normal workstation, only one dsm.opt file is used. In a clustered environment, additional dsm.opt files are required. Each cluster group that is backed up must have its own dsm.opt file. A cluster group is any group listed under the GROUPS folder of the cluster tree within the Microsoft Cluster Administrator utility or VCS Configuration Editor.
3. Understand what the following dsmcutil.exe options mean, and when to use them. (1) /clustername:*clustername* - Specifies the name of the Microsoft cluster, where *clustername* is the name at the top level of the tree within the Microsoft Cluster Administrator utility or VCS Configuration Editor. Use this option with dsmcutil.exe, only when installing a scheduler service for a cluster group. Do not specify a clustername of more than 64 characters. If you specify more than 256 characters and you are using Veritas Storage Foundation with High Availability or a Microsoft Cluster Server configuration, you might not be able to install or start the IBM Spectrum Protect scheduler service, and (2) /clusternode:yes - Specifies that you want to enable support for cluster resources. Use this option in the dsm.opt file for each cluster group, and with dsmcutil.exe when installing a scheduler service for a cluster group.
4. Common mistakes are made in typing the syntax of the dsmcutil.exe command. An easy way to prevent such syntax problems is to create a temporary text file which is accessible to the cluster group (for instance, place it on a cluster drive belonging to that cluster group), and type the syntax into this file. When needed, cut and paste this syntax from the file to the DOS prompt and press the Enter key. It guarantees the consistency of the command syntax regardless of which computer you enter it on.
5. If the scheduler service is failing to restart after a failover of the cluster group occurs (using the MOVE GROUP option in Cluster Administrator, for example), there might be potential password synchronization problems between the two cluster workstations. To verify that the passwords are the same, browse to this registry key on each workstation and compare the encrypted password value: HKEY_LOCAL_MACHINE\SOFTWARE\IBM\ADSM\CurrentVersion\Nodes*nodename**servername*.

   If the encrypted keys for this node do not match between the two cluster workstations, there is a password mismatch on one or both of the two workstations. To correct this problem, use the dsmc.exe program to update the password manually on both workstations.

   For example, assume that the Y: drive is part of the cluster group that is experiencing problems being backed up with a scheduler service. The Y:\tsm directory contains the dsm.opt file for this cluster group in the Y:\tsm directory. To update the password manually, enter the following command on both workstations: `dsmc –optfile=Y:\tsm\dsm.opt –clusternode=yes`, and enter the following command to receive the prompt for the node name and password: dsmc q se -optfile=Y:\tsm\dsm.opt -clusternode=yes.

   Verify that the passwords are synchronized, and restart the scheduler service to verify if the password remains consistent. If password mismatching continues, it might be due to a syntax error in the original dsmcutil.exe command that was used to install the scheduler service. In this case, uninstall the scheduler service (using the

`dsmcutil remove /name:`*`schedule_name`* command) and reinstall the scheduler service again (using the shared text file syntax as shown previously).

Q: How do you add a cluster drive to an existing cluster scheduler service resource for backup?

A: To add an additional cluster drive resource to an existing backup-archive client cluster scheduler service, the following components must be modified or updated to properly reflect this change:

1. The cluster drive resource, and any related resource shares, must exist and reside within the designated cluster group as defined in the Microsoft Cluster Administrator utility or VCS Configuration Editor. The designated cluster group must already contain the cluster scheduler service resource for which this new drive is added.
2. The dsm.opt file used by the designated cluster scheduler service resource must be modified to include the additional cluster drive resource on the domain option statement. For example, if you want to add the `R:\` drive, and the domain statement currently identifies cluster drives `Q:` and `S:`, update the domain statement in your dsm.opt file as follows: `domain Q: S: R:`.
3. You must modify the cluster scheduler service resource properties to include this file in the list of dependent resources needed to bring this resource online. This ensures that the cluster drive resource being added is included in the new backups, and for backups which run after a failover occurs.

After the changes above are made, bring the cluster scheduler service resource offline, and back online. The schedule should now process this additional resource for backups.

Q: The client acceptor service has been removed and now the generic service resource for the cluster group is failing. How can this be corrected?

A: The client acceptor can be used to control the scheduler, the web client, or both for a cluster environment. If the client acceptor is removed without updating the generic cluster resource, the resource fails. To correct this:

1. Verify which scheduler service was controlled by the client acceptor.
2. Using the Microsoft Cluster Administrator utility or VCS Configuration Editor, go to the properties window of the service resource, select the Parameters tab, and enter the name of the correct scheduler service to use.
3. Repeat steps one and two for each cluster group that was managed by the specific client acceptor.
4. To test the updated service resource, initiate a failure of the resource. If the resource comes back online with no failures, the update has worked properly.

Note: To fully disable the client acceptor service, remove the managedservices option from the cluster group dsm.opt file or comment it out.

Windows

Configuring online-image backup support

If the online image feature is configured, the backup-archive client performs a snapshot-based image backup, during which the real volume is available to other system applications.

About this task

A consistent image of the volume is maintained during the online image backup.

To configure online image backup, perform the following steps:

Procedure

1. Select Utilities > Setup Wizard from the backup-archive client GUI main window. The Client Configuration Wizard panel appears.
2. Select Help me configure Online Image Support and click Next. The Online Image Support Wizard panel appears.
3. Click Volume Shadowcopy Services (VSS) and then click Next. To disable online image support, click None (Disable online image support).
4. Click Finish button to complete the setup.
5. Complete each panel in the wizard and click the Next to continue. To return to a previous panel, click the Back. To display help information for a panel, click the help icon.

Results

To set preferences for open file support, use the Include-Exclude tab on the IBM Spectrum Protect™ Preferences editor. You can set these options for all volumes or for individual volumes using the include.fs option: snapshotproviderfs, presnapshotcmd, postsnapshotcmd.

Windows

Configuring Open File Support

You configure Open File Support (OFS) after you install the Window client.

About this task

If the Open File Support feature is configured, the backup-archive client performs a snapshot-based, file-level operation, during which the real volume is available to other system applications. A consistent image of the volume is maintained during the operation.

To configure OFS, perform the following steps:

Procedure

1. Start the Windows client Java GUI (run dsm.exe).
2. Select Utilities > Setup Wizard.
3. Select Help me configure Online Image Support and click Next.
4. Click Next again.
5. Select the VSS snapshot provider to enable Open File Support or select None to perform normal (non-snapshot) backups of the files on your volume; then click Next.
6. Click Apply and then click Finish.

Results

To set preferences for open file support, use the Include-Exclude tab on the Preferences editor. You can set these options for all volumes or for individual volumes using the include.fs option: snapshotproviderfs, presnapshotcmd, postsnapshotcmd

AIX

AIX configuration considerations prior to performing snapshot-based file backups and archives

If you are configuring your IBM Spectrum Protect™ AIX® client to perform snapshot-based file backups and archives, there are some items that you need to consider.

- Ensure that the volume group containing the file system to be snapshot has sufficient disk space to allow JFS2 external snapshots to be created for the file system.
- The client uses a default size of 100 percent of the file system size for the snapshot size. This value was found to be most appropriate for file systems with even moderate file system activity. If you need to lower this value based on your experience with your own file system activity, you can use the snapshotcachesize option to fine-tune this value.
- Do not enable internal snapshots when creating new JFS2 file systems on AIX 6.1 or later for all file systems managed by IBM Spectrum Protect. The client uses external snapshots and JFS2 does not allow the creation of external and internal snapshots concurrently for the same file system.

Snapshotcachesize
Linux | Windows

Configuring NetApp and IBM Spectrum Protect for snapshot difference incremental backups

You must configure the NetApp file server connection information to run the snapshot difference incremental backup command on the backup-archive client. You must also use the set password command to specify the file server host name, and the password and user name that is used to access the file server.

Procedure

1. Establish a console session on the NetApp filer and define a new user on the file server by using the following steps:
   a. Add the user ID to a group that permits users to log in to the file server with http and running API commands.
   b. From the file server, enter the following command to list the user ID to verify the settings and verify that the output is similar:

      ```
      useradmin user list snapdiff_user

      Name: snapdiff_user
      Info:
      Rid: 131077
      Groups: snapdiff_group
      Full Name:
      ```

      For 7-mode NetApp filers:

      ```
      Allowed Capabilities: login-http-admin,api-*
      ```

      For clustered-data ONTAP NetApp filers, the only capability that is required is `ontapapi` with the `admin` role.

   c. If the security.passwd.firstlogin.enable option for the user ID on the NetApp server is set to on, ensure that all groups have the login-telnet and cli–passwd* capabilities.
      Tip: When security.passwd.firstlogin.enable option is enabled, the user ID is set to expired when created. The user cannot run any commands, including snapshot differential incremental, until their password is changed. Users in groups that do not have these capabilities cannot log in to the storage system. For information about defining a user ID and a password on the NetApp file server, see the NetApp documentation.
2. Configure the NetApp Data ONTAP built-in HTTP server to allow remote administrative sessions to the NetApp filer.
   a. If you plan to use a plain HTTP connection for snapshot differential backups, turn on the httpd.admin.enable option on the NetApp filer.
   b. If you plan to use a secure HTTPS connection for snapshot differential backups (by specifying the -snapdiffhttps option), turn on the httpd.admin.ssl.enable option on the NetApp filer.
   c. From the IBM Spectrum Protect™ client node, test the connection between the IBM Spectrum Protect client computer and the NetApp ONTAP server to ensure that firewalls or other NetApp configuration options do not prevent you from connecting to the NetApp server.
      Tip: See the NetApp ONTAP documentation for instructions on how to test the connection.
3. Windows Export the NetApp volumes and consider the following settings:
   Tip: See the NetApp documentation for details on exporting the NetApp volumes for use with Windows.
   - Map the NetApp volumes by using CIFS.
   - Ensure the NetApp volumes have the NTFS security setting.
4. Linux Export the NetApp volumes and consider the following settings:
   Tip: See the NetApp documentation for details on exporting the NetApp volumes for use with Linux hosts.
   - Map the NetApp volumes by using an NFS mount.
   - Ensure the NetApp volumes have the UNIX security setting
5. Set the user ID, and password on the backup-archive client for the user ID that you created in step 1 using the following steps:
   a. Linux Log in as the root user ID.
   b. Windows Log on as the user with read/write access to the CIFS share.
   c. From the backup-archive client command line, enter the following command:

      ```
      dsmc set password -type=filer my_file_server snapdiff_user newPassword
      ```

      Substitute the following values:

      my_file_server
      This value is the fully qualified host name of your NetApp file server.
      snapdiff_user

This value is the user ID that you created in step 1.

newPassword
This value is the password for the user ID that you created in step 1.

- Linux Windows Protecting clustered-data ONTAP NetApp file server volumes
  You can create a snapshot differential incremental backup of a volume on a NetApp file server that is part of a clustered-data ONTAP configuration (c-mode file server).
- Linux Windows SnapMirror support for NetApp snapshot-assisted progressive incremental backup (snapdiff)
  You can use NetApp's SnapDiff backup processing in conjunction with NetApp's SnapMirror replication to back up NetApp source or destination filer volumes.

Linux Windows

Protecting clustered-data ONTAP NetApp file server volumes

You can create a snapshot differential incremental backup of a volume on a NetApp file server that is part of a clustered-data ONTAP configuration (c-mode file server).

Before you begin

- Complete the procedure in Configuring NetApp and IBM Spectrum Protect for snapshot difference incremental backups.
- Ensure that the clustered-data ONTAP environment is correctly set up by the NetApp storage virtual machine administrator.

Restriction: IBM Spectrum Protect™ support for snapshot differential incremental backups of clustered-data ONTAP volumes is supported only on NetApp ONTAP 8.2.1 and later versions.

About this task

In a clustered-data ONTAP environment, storage virtual machines (also referred to as data vServers) contain data volumes that can be protected by the backup-archive client.

A storage virtual machine consists of a single infinite volume or one or more flex volumes. Volumes are accessed remotely using file sharing (CIFS on Windows operating systems, NFS on Linux operating systems).

The storage virtual machines are managed by the cluster management filer, which is the physical filer (the c-mode filer) on which the storage virtual machines reside. The backup client is installed on the remote machine that accesses the volumes.

The backup-archive client must be configured with credentials for the NetApp c-mode filers that are being accessed for backup operations.

Requirements:

- The following information is required for this procedure:
  - The host name or IP address of the cluster management filer.
  - The host name or IP address of the storage virtual machine.
  - The storage virtual machine name.
  - The cluster management filer credentials (user name and password).
- The cluster management filer user that is configured by the client must be assigned the `ontapapi` capability with the role of `admin`.

  The `ontapapi` capability does not allow interactive access to the filer with methods such as `telnet`, `ssh`, or `http/https`. No other user capabilities are required to run snapshot differential incremental backups.

Procedure

Complete the following steps on the remote machine where the backup-archive client is installed:

1. Configure the backup-archive client with the cluster management filer credentials. Use the dsmc set password command to store the credentials of the management filer that is associated with the storage virtual machine. For example, enter the following command:

   ```
   dsmc set password -type=filer management_filer_hostname
      management_filer_username management_filer_password
   ```

   Where:

   management_filer_hostname
   : The host name or IP address of the cluster management filer.

   management_filer_username
   : The user name of the cluster management filer.

   management_filer_password
   : The password for user of the management filer.

   Tip: The cluster management filer password is encrypted when it is stored by the backup-archive client.
2. Associate each storage virtual machine with the management filer with the dsmc set netappsvm command. For example, enter the following command:

   ```
   dsmc set netappsvm storage_virtual_machine_hostname
   management_filer_hostname storage_virtual_machine_name
   ```

   Where:

   storage_virtual_machine_hostname
   : The host name or IP address of the storage virtual machine that is used to mount volumes to back up.

   management_filer_hostname
   : The host name or IP address of the cluster management filer.

   storage_virtual_machine_name
   : The name of the storage virtual machine.

   Note: The host name or IP address of the storage virtual machine that is used to mount volumes must be consistent with what is specified in the dsmc set commands. For example, if the volumes are mounted with a storage virtual machine IP address, the IP address (not the host name) must be used in the dsmc set commands. Otherwise, client authentication with the cluster management filer fails.

   You need only to specify the dsmc set netappsvm command once for each storage virtual machine. If the storage virtual machine is moved to a different cluster management filer, you must use the command to update the associated cluster management filer host name.
3. Windows Map the volumes to drive letters. For example, enter the following command for each storage virtual machine:

   ```
   net use y: \\storage_virtual_machine_hostname domain_name\CIFS_share_name
   ```

   Where:

   `y:`
   : The drive to map the volume to.

   storage_virtual_machine_hostname
   : The host name or IP address of the storage virtual machine.

   domain_name\CIFS_share_name
   : The CIFS share that is defined on the filer on the volume being backed up.
4. Linux Mount the remote storage virtual machine to a local file system. For example, enter the following command for each storage virtual machine:

   ```
   mount storage_virtual_machine_hostname /tmp/fs1
   ```

   Where:

   storage_virtual_machine_hostname
   : The host name or IP address of the storage virtual machine.

   /tmp/fs1
   : An example of a file system to mount the storage virtual machine volume to.
5. Start a full progressive incremental backup of a flex or infinite volume.

By default, HTTP access to the NetApp file server is not enabled. If you did not configure your file server to allow access by using HTTP, use the backup-archive client snapdiffhttps option to enable access to the cluster management server with the HTTPS protocol.

Windows For example, on Windows clients, enter the following command:

```
dsmc incr y: -snapdiff -snapdiffhttps
```

Linux For example, on Linux clients, enter the following command:

```
dsmc incr /tmp/fs1 -snapdiff -snapdiffhttps
```

Tip: You need only to run the full progressive incremental backup once. After this backup is successfully completed, run differential backups in future backup operations.

6. Start a snapshot differential backup of the flex or infinite volume.
   Windows For example, on Windows clients, enter the following command:

```
dsmc incr y: -snapdiff -snapdiffhttps
```

   Linux For example, on Linux clients, enter the following command:

```
dsmc incr /tmp/fs1 -snapdiff -snapdiffhttps
```

Example

A backup-archive client user wants to complete a snapshot differential incremental backup of the volumes on a c-mode file server. The user is using a Windows backup-archive client to complete the backup and the volumes are mounted as CIFS shares. The c-mode filer configuration is as follows:

ONTAP 8.31 management filer

```
Hostname: netapp1mgmt.example.com
User: netapp1mgmt_user
Password: pass4netapp1mgmt
CIFS Domain Controller: WINDC
Domain User: domainuser
```

Flex volume storage virtual machine

```
Hostname: netapp1-v1.example.com
Storage virtual machine name: netapp1-client1
CIFS share: demovol
Volume name: demovol
```

Infinite volume storage virtual machine

```
Hostname: netapp1-v4.example.com
Storage virtual machine name: netapp1-infiniteVolume1
CIFS Share: InfiniteVol
```

The user completes the following steps on the backup-archive client:

1. Configure the client with the management filer credentials by issuing the following command:

```
dsmc set password -type=filer netapp1mgmt.example.com netapp1mgmt_user pass4netapp1mgmt
```

2. Define storage virtual machine associations for each storage virtual machine with the following commands:

```
dsmc set netappsvm netapp1-v1.example.com netapp1mgmt.example.com netapp1-client1

dsmc set netappsvm netapp1-v4.example.com netapp1mgmt.example.com netapp1-infiniteVolume1
```

3. Map remote volumes to drive letters for each storage virtual machine:

```
net use y: \\netapp1-v1.example.com\demovol WINDC\domainuser

net use z: \\netapp1-v4.example.com\InfiniteVol WINDC\domainuser
```

4. Run a full progressive incremental backup of the flex volume and infinite volume:

```
dsmc incr y: -snapdiff -snapdiffhttps
```

```
dsmc incr z: -snapdiff -snapdiffhttps
```

You need only to run the full progressive incremental backup once. After this backup is successfully completed, run differential backups in future backup operations.

5. Run a snapshot differential backup of the flex volume and infinite volume:

```
dsmc incr y: -snapdiff -snapdiffhttps

dsmc incr z: -snapdiff -snapdiffhttps
```

Linux | Windows

SnapMirror support for NetApp snapshot-assisted progressive incremental backup (snapdiff)

You can use NetApp's SnapDiff backup processing in conjunction with NetApp's SnapMirror replication to back up NetApp source or destination filer volumes.

In a NetApp SnapMirror environment, data that is on volumes attached to the primary data center are mirrored to volumes attached to a remote server at a disaster recovery site. The NetApp filer in the primary data center is called the source filer; the NetApp filer at the disaster recovery site is called the destination filer. You can use the backup-archive client to create snapshot differential backups of the source or destination filer volumes.

Scenario: Back up data on a source filer volume

Linux You can configure the backup archive client to back up data from the source filer volumes. This scenario requires you to configure a backup-archive client node such that it has access to the NetApp source filer volumes by using NFS-exported shares to mount the filer volumes.

Windows You can configure the backup archive client to back up data from the source filer volumes. This scenario requires you to configure a backup-archive client node such that it has access to the NetApp source filer volumes by using CIFS shares to mount the filer volumes.

Linux For example, assume a configuration where the source filer is named ProdFiler. Assume that a volume named UserDataVol exists on ProdFiler filer and that the volume is accessible by using NFS from a backup-archive client node. Assume that the share is mounted as UserDataVol_Share.

Windows For example, assume a configuration where the source filer is named ProdFiler. Assume that a volume named UserDataVol exists on ProdFiler filer and that the volume is accessible by using CIFS from a backup-archive client node. Assume that the share is mounted as UserDataVol_Share.

When you initiate a snapshot differential backup, the NetApp filer creates a new differential snapshot on the volume that is being backed up. That differential snapshot is compared with the base (previous) snapshot. The base snapshot name was registered on the IBM Spectrum Protect™ server when the previous backup was completed. The contents of that base snapshot are compared to the differential snapshot that is created on the source filer volume. Differences between the two snapshots are backed up to the server.

The following command is used to initiate the snapshot differential backup. The command is entered on the console of a client node that is configured to access and protect the source filer volumes. Because this command is issued to back up volumes on a source filer, a new snapshot (the differential snapshot) is created and the snapshot registered on the IBM Spectrum Protect server is used as the base snapshot. Creating both the differential and base snapshots is the default behavior; the `–diffsnapshot=create` option is a default value, and it does not need to be explicitly specified on this command.

```
dsmc incr \\ProdFiler\UserDataVol_Share -snapdiff -diffsnapshot=create
```

Back up data on a destination filer

A more typical configuration is to offload the backups from the source filer by creating backups of the source volumes by using the replicated volume snapshots stored on the destination filer. Ordinarily, backing up a destination filer presents a problem because creating a snapshot differential backup requires that a new snapshot must be created on the volume that you are backing up. The destination filer volumes that mirror the contents of the source volumes are read only volumes, so snapshots cannot be created on them.

To overcome this read-only restriction, client configuration options are provided to allow you to use the existing base and differential snapshots on the read-only destination volume to back up changes to the IBM Spectrum Protect server.

AIX Linux Like in the source filer scenario, the destination filer volumes are accessed by using NFS-exported shares.

Windows Like in the source filer scenario, the destination filer volumes are accessed by using CIFS shares.

Snapshot differential options summary

The useexistingbase option causes the most recent snapshot on the volume to be used as the base snapshot, when a base snapshot must be established. A new base snapshot is established when any of the following conditions are true:

- When this backup is the initial backup.
- When `createnewbase=yes` is specified.
- When the base snapshot that was registered by a previous differential snapshot no longer exists, and an existing snapshot that is older than the missing base snapshot does not exist.

If this option is not specified, a new snapshot is created on the volume that is being backed up. Because destination filer volumes are read-only volumes, useexistingbase must be specified when creating snapshot differential backups of destination filer volumes. If useexistingbase is not specified, snapshot differential backups of a destination filer volume fail because the new snapshot cannot be created on the read-only volume.

When backing up destination filer volumes, use both the useexistingbase option and the diffsnapshot=latest option to ensure that the most recent base and most recent differential snapshots are used during the volume backup.

You use the basesnapshotname option to specify which snapshot, on the destination filer volume, to use as the base snapshot. If you do not specify this option, the most recent snapshot on the destination filer volume is used as the base snapshot. You can use wildcards to specify the name of the base snapshot.

You use the diffsnapshotname option to specify which differential snapshot, on the destination filer volume, to use during a snapshot differential backup. This option is only specified if you also specify diffsnapshot=latest. You can use wildcards to specify the name of the differential snapshot.

The diffsnapshot=latest option specifies that you want to use the latest snapshot that is found on the file server as the source snapshot.

Additional information about each of these options is provided in the Client options reference topics.

Snapshot differential backup command examples

In the examples that follow, assume that volumes on a source filer are replicated, by using NetApp's SnapMirror technology, to a disaster recovery filer (host name is DRFiler). Because the DRFiler volumes are read only, you use the options to specify which of the replicated snapshots that you want to use as the base snapshot, and which of the snapshots you want to use as the differential snapshot. By specifying the snapshots to use when creating a snapshot differential backup of a destination filer, no attempt is made to create a snapshot on the read-only volumes.

The following commands are used to initiate snapshot differential backups. Most of these commands create snapshot differential backups by using snapshots stored on the destination filer volumes. When backing up from a destination filer volume, be sure to include the -useexistingbase option, because that option prevents attempts to create a new snapshot on the read-only destination filer volumes.

Example 1: Back up a destination filer by using default nightly backups that were created by the NetApp snapshot scheduler

```
dsmc incr \\DRFiler\UserDataVol_Share -snapdiff -useexistingbase
  -diffsnappshot=latest -basesnapshotname="nightly.?"
```

You can use a question mark (?) to match a single character. In this example, -basesnapshotname=nightly.? uses the latest base snapshot that is named "nightly.", followed by a single character (for example: nightly.0, nightly.1, and so on).

Example 2. Back up a destination filer volume by using snapshots created manually (not created by the NetApp snapshot scheduler)

```
dsmc incr \\DRFiler\UserDataVol_Share -snapdiff -useexistingbase
  -diffsnapshot=latest -basesnapshotname="share_vol_base?"
  -diffsnapshotname="share_vol_diff?"
```

This example also uses the question mark (?) wildcard to illustrate the syntax if the base and differential snapshot names have different numbers as part of the name.

Example 3. Back up a destination filer volume, and specify which snapshots to use for the base and differential snapshots

```
dsmc incr \\DRFiler\UserDataVol_Share -snapdiff -useexistingbase
  -diffsnapshot=latest -basesnapshotname="share_vol_base"
  -diffsnapshotname="share_vol_diff_snap"
```

Example 4: Back up script-generated snapshots that use a naming convention

In this example, a script that is running on the NetApp filer adds a date and time stamp to the snapshot names. For example, a snapshot created on November 3, 2012 at 11:36:33 PM is named UserDataVol_20121103233633_snapshot. You can use wildcards with the options to select the most recent base and differential snapshots. For example:

```
dsmc incr \\DRFiler\UserDataVol_Share -snapdiff -useexistingbase
  -basesnapshotname="UserDataVol_Share_*_snapshot" -diffsnapshot=latest
  -diffnsnapshotname="UserDataVol_Share_*snapshot
```

-useexistingbase selects the most recent base snapshot. Adding an asterisk (*) wildcard to -basesnapshotname selects the most recent base snapshot that follows the script-naming convention. The -diffsnapshot=latest option suppresses the creating of a new differential snapshot and -diffsnapshotname= selects the most recent existing differential snapshot that follows the script-naming convention. (The asterisks wildcards match any string).

Example 5: Perform a snapshot differential backup by using an existing differential snapshot that exists on the source filer

To use an existing differential snapshot that exists on the source filer, use the -diffsnapshot=latest to prevent the creation of a new differential snapshot. Also use the -diffsnapshotname option to specify which existing differential snapshot to use. The snapshot you specify is compared to the base snapshot, which was registered in the IBM Spectrum Protect server database when the last backup was created. For example:

```
dsmc incr \\ProdFiler\UserDataVol_Share -snapdiff -diffsnapshot=latest
  -diffsnapshotname="share_vol_diff_snap"
```

Register your workstation with a server

Before you can use IBM Spectrum Protect™, you must set up a node name and password and your node must be registered with the server.

The process of setting up a node name and password is called *registration*. Two types of registration are available, *open* and *closed*.

Your IBM Spectrum Protect server administrator chooses the type of registration for your site.

Restriction: Beginning with the IBM Spectrum Protect Version 8.1.2 server, open registration is no longer available. You must use closed registration. Open registration is available only for the IBM Spectrum Protect V8.1.1, V8.1.0, V7.1.7 or earlier server.

AIX | Linux | Mac OS X | Solaris You must be a root user or authorized user to perform this required task.

If you plan to use the web client, you must have an administrative user ID with system privilege, policy privilege, client access authority, or client owner authority. When a new node is registered, the server administrator must create an administrative user ID that matches the node name. By default, this node has client owner authority.

The IBM Spectrum Protect server administrator must specify the userid parameter with the REGISTER NODE server command:

```
REGISTER NODE node_name password userid=user_id
```

where the node name and the administrative user ID must be the same. For example:

```
REGISTER NODE node_a mypassw0rd userid=node_a
```

- Closed registration
  With closed registration, the IBM Spectrum Protect administrator must register your workstation as a client node with the server. If your enterprise uses closed registration, you must provide some information to your IBM Spectrum Protect administrator.
- Open registration
  With open registration, a system administrator can register your workstation as a client node with the IBM Spectrum Protect Version 8.1.1, V8.1.0, V7.1.7 or earlier server.

Closed registration

With closed registration, the IBM Spectrum Protect™ administrator must register your workstation as a client node with the server. If your enterprise uses closed registration, you must provide some information to your IBM Spectrum Protect administrator.

About this task

You must provide the following items to your IBM Spectrum Protect administrator:

- Your node name (the value returned by the **hostname** command, the name of your workstation, or the node name you specified with the ***nodename*** option). If you do not specify a node name with the ***nodename*** option, the default login ID is the name that the **hostname** command returns.
- The initial password you want to use, if required.
- Contact information, such as your name, user ID, and phone number.

Your IBM Spectrum Protect administrator defines the following for you:

- The policy domain to which your client node belongs. A policy domain contains policy sets and management classes that control how IBM Spectrum Protect manages the files you back up and archive.
- Whether you can compress files before sending them to the server.
- Whether you can delete backup and archive data from server storage.

Open registration

With open registration, a system administrator can register your workstation as a client node with the IBM Spectrum Protect™ Version 8.1.1, V8.1.0, V7.1.7 or earlier server.

About this task

The first time you start a session, you are prompted for information necessary to register your workstation with the IBM Spectrum Protect server that is identified in your client options file. You need to supply your node name, a password, and contact information.

When you use open registration:

- Your client node is assigned to a policy domain named **standard**.
- You can delete archived copies of files from server storage, but not backup versions of files.

If necessary, your IBM Spectrum Protect administrator can change these defaults later.

Creating an include-exclude list

If you do not create an include-exclude list, the backup-archive client considers all files for backup services and uses the default management class for backup and archive services.

About this task

This is an optional task, but an important one.

You can create an include-exclude list to exclude a specific file or groups of files from backup services, and to assign specific management classes to files. The client backs up any file that is not explicitly excluded. You should exclude IBM Spectrum Protect™ client directories from backup services. You can use the query inclexcl command to display a list of include and exclude statements in the order they are examined when determining whether an object is to be included.

Windows Specify your include-exclude list in your client options file (dsm.opt). The include-exclude list can also go into a separate file, which is referred to by the inclexcl option. The include-exclude statements are not case-sensitive.

Windows The client options file, dsm.opt, must be in a non-Unicode format. However, if you are using a separate include-exclude file, it can be in Unicode or non-Unicode format.

AIX Linux Solaris Mac OS X Specify the include-exclude list in your dsm.sys file. If you define more than one server in your dsm.sys file, each server must have its own include-exclude list. This list can also contain include-exclude statements obtained from the include-exclude files you specify with the inclexcl option.

Windows When the client processes include-exclude statements, the include-exclude statements within the include-exclude file are placed at the position occupied by the inclexcl option in dsm.opt, in the same order, and processed accordingly.

AIX Linux Solaris Mac OS X When the client processes include-exclude statements, the include-exclude statements within the include-exclude file are placed at the position occupied by the inclexcl option in dsm.sys, in the same order, and processed accordingly.

Procedure

You can use the following methods to create an include-exclude list or specify an include-exclude file:

- You can add include-exclude statements in the backup-archive client GUI or web client directory tree. The online help provides detailed instructions.
    1. Open the Edit menu and select Client Preferences. In the Preferences dialog, select the Include/Exclude tab. You can specify an INCLEXCL file using the Preferences editor. However, you cannot create the INCLEXCL file using the Preferences editor.
    2. Create the include-exclude list manually, following the steps listed.
- You can create an include-exclude list manually by performing the following steps:
    1. Determine your include and exclude requirements.
    2. Windows Locate the client options file
    3. AIX Linux Mac OS X Solaris Locate the server stanza in your dsm.sys file. Each server stanza must have its own include-exclude list.
    4. Windows **Important:** Group your include-exclude options together in your client options file.
    5. AIX Linux Mac OS X Solaris Enter your include and exclude statements. The client evaluates all exclude.fs and exclude.dir statements *first* (regardless of their position within the include-exclude list), and removes the excluded file spaces, directories, and files from the list of objects available for processing. All other include-exclude statements are processed from the bottom of the list up. Therefore, it is important to enter all your include-exclude statements in the proper order. For example, in the following include-exclude list the `includefile.cpp` file *is not* backed up:

        ```
        include /Users/user01/Documents/includefile.cpp
        exclude /Users/user01/Documents/.../*
        ```

        However, in the following include-exclude list the `includefile.cpp` file is backed up:

        ```
        exclude /Users/user01/Documents/.../*
        include /Users/user01/Documents/includefile.cpp
        ```

    6. Windows Enter your include and exclude statements. The client evaluates all exclude.dir statements *first* (regardless of their position within the include-exclude list), and removes the excluded directories and files from the list of objects available for processing. All other include-exclude statements are processed from the bottom of the list up. Therefore, it is important to enter all your include-exclude statements in the proper order. For example, in the following include-exclude list the `includefile.txt` file *is not* backed up:

        ```
        include c:\test\includefile.txt
        exclude c:\test\...\*
        ```

        However, in the following include-exclude list the `includefile.txt` file *is* backed up:

        ```
        exclude c:\test\...\*
        include c:\test\includefile.txt
        ```

    7. Save the file and close it.

        Mac OS X For Mac OS X, ensure that you save the file as plain text encoded as Unicode (UTF-8 or UTF-16). Do not add the `.txt` extension.

    8. Windows Restart the client and the scheduler and client acceptor services to enable your include-exclude list.
    9. AIX Linux Mac OS X Solaris Restart the client to enable your include-exclude list.

- Include-exclude options
  This topic provides brief descriptions of the include and exclude options that you can specify in your client options file, a minimum include-exclude list that excludes system files, a list of supported wildcard characters, and examples of how you might use wildcard characters with include and exclude patterns.
- Mac OS X AIX Linux Solaris Symbolic link and alias processing
  The backup-archive client evaluates all exclude.fs and exclude.dir statements and removes the excluded file spaces and

directories.

- Determine compression and encryption processing
  The backup-archive client evaluates exclude.dir and any other include-exclude options controlling backup and archive processing, and then determines which files undergo compression and encryption processing.
- Preview include-exclude list files
  You can preview the list of objects to be backed up or archived according to the include-exclude list, prior to sending any data to the server.
- Include and exclude option processing
  The IBM Spectrum Protect server can define include-exclude options using the inclexcl parameter in a client option set.
- Windows Processing rules when using UNC names
  When processing files with UNC names, there are rules that must be followed.

Include-exclude options

This topic provides brief descriptions of the include and exclude options that you can specify in your client options file, a minimum include-exclude list that excludes system files, a list of supported wildcard characters, and examples of how you might use wildcard characters with include and exclude patterns.

- Exclude file spaces and directories
  Use exclude.dir statements to exclude all files and subdirectories in the specified directory from processing.
- Windows Include-exclude statements for networked file systems
  Include-exclude statements that involve networked file systems (remote drives) must be written in the UNC format.
- AIX Windows Exclude files and directories from a journal-based backup
  There are two methods of excluding files and directories from a journal-based backup.
- Control processing with exclude statements
  After the client evaluates all exclude statements, the following options are evaluated against the remaining list of objects available for processing.
- System files to exclude
  There are some system files that should be placed in the client options file so that they are excluded.
- Windows Exclude files with UNC names
  You can exclude remotely accessed files by specifying their universal naming convention (UNC) names in your exclude statement.
- Include and exclude files that contain wildcard characters
  You must use special escape characters when including or excluding files and directories that contain wildcard characters.
- Include and exclude groups of files with wildcard characters
  You can use wildcard characters to include or exclude groups of files.
- Examples using wildcards with include and exclude patterns
  The backup-archive client accepts the exclude.dir option, which can be used to exclude directory entries. However, the include and exclude.dir options cannot be used together.

Exclude file spaces and directories

Use exclude.dir statements to exclude all files and subdirectories in the specified directory from processing.

The backup-archive client evaluates all exclude.dir statements *first* (regardless of their position within the include-exclude list), and removes the excluded directories and files from the list of objects available for processing. The exclude.dir statements override all include statements that match the pattern.

Table 1 lists the options you can use to exclude file spaces and directories from processing.

Table 1. Options for excluding file spaces and directories

Option	Description

Option	Description
AIX Linux Solaris Mac OS X exclude.fs Exclude options	AIX Linux Solaris Mac OS X Excludes file spaces matching the pattern. The client does not consider the specified file space for processing and the usual deleted-file expiration process cannot occur. If you exclude a file space that was previously included, existing backup versions remain on the server subject to retention rules specified in the associated management class definition.
Mac OS X AIX Linux Solaris exclude.dir Exclude options	Mac OS X AIX Linux Solaris Excludes a directory, its files, and all its subdirectories and their files from backup processing. For example, the statement `exclude.dir /test/dan/data1` excludes the `/test/dan/data1` directory, its files, and all its subdirectories and their files. Using the exclude.dir option is preferable over the standard exclude option to exclude large directories containing many files that you do not want to back up. You cannot use include options to override an exclude.dir statement. Only use exclude.dir when excluding an entire directory branch. • Use the following statements to exclude volumes `/Volumes/disk2` altogether from backup processing. Note that the volume `(/Volumes/disk2)` is backed up, but all other directories on `/Volumes/disk2` is excluded. `exclude /Volumes/disk2/*` `exclude.dir /Volumes/disk2/*` • An alternative method for excluding an entire volume from domain incremental backup is to use a domain statement to exclude the volume. For example: `domain "-/Volumes/disk2"` This alternative still permits selective backup processing of files on `/Volumes/disk2`.

Option	Description
Windows exclude.dir Exclude options	Windows Excludes a directory, its files, and all its subdirectories and their files from backup processing. For example, the statement `exclude.dir c:\test\dan\data1` excludes the `c:\test\dan\data1` directory, its files, and all its subdirectories and their files. Using the exclude.dir option is preferable over the standard exclude option to exclude large directories containing many files that you do not want to back up. You cannot use include options to override an exclude.dir statement. Only use exclude.dir when excluding an entire directory branch. If you define an exclude statement without using a drive letter, such as `exclude.dir dirname`, this excludes from processing any directory named `dirname` on any drive. • The following examples illustrate valid `exclude.dir` statements: Exclude directory `C:\MyPrograms\Traverse` and its files and subdirectories: `exclude.dir c:\MyPrograms\Traverse` Exclude all directories below `c:\MyPrograms\Traverse`. Note that directory `C:\MyPrograms\Traverse` and the files immediately below `C:\MyPrograms\Traverse` is eligible for backup. `exclude.dir c:\MyPrograms\Traverse\*` Exclude all directories whose names begin with `temp`, and are located within directory `x:\documents and settings` and its subdirectories, where *x:* is any drive. `exclude.dir "*:\documents and settings\...\temp*"` Exclude all directories whose names begin with `temp`, regardless of the drive or directory in which they reside: `exclude.dir temp*` The following example is invalid because it ends with a directory delimiter: `exclude.dir c:\MyPrograms\Traverse\` • Use the following statements to exclude drive `x:` altogether from backup processing. Note that the drive root `(x:\)` is backed up, but all other files and directories on `x:` is excluded. `exclude x:\*` `exclude.dir x:\*` • An alternative method for excluding an entire drive from domain incremental backup is to use a domain statement to exclude the drive. For example: `domain -x:` This alternative still permits selective and explicit incremental backup processing of files on `x:`. For example: `dsmc s x:\ -subdir=yes` `dsmc i x:` `dsmc i x:\MyPrograms\ -subdir=yes`

Windows

Include-exclude statements for networked file systems

Include-exclude statements that involve networked file systems (remote drives) must be written in the UNC format.

In the following example `Z:` is a mapped drive to a remote file system on `vista.example.com`.

The old format would be to exclude `\dir\dir2` on the remote file system, as in this example:

```
EXCLUDE.DIR "Z:\dir1\dir2"
```

Here is an example of the new format using UNC:

```
EXCLUDE.DIR "\\vista.example.com\d$\dir1\dir2"
```

The include-exclude statements written in the old format will not be recognized by the client.

AIX Windows Linux

Exclude files and directories from a journal-based backup

There are two methods of excluding files and directories from a journal-based backup.

AIX Linux

- On AIX® and Linux, one method is to add exclude statements to the client options file to prevent the files or directories from being backed up during backup processing.
- On AIX and Linux the other method is to add exclude statements to the journal configuration file `tsmjbbd.ini`, to prevent journal entries from being added for the files or directories, which prevents them from being processed during a journal-based backup.

  AIX If you are running AIX Version 6.1 or later, add an `exclude .snapshot` statement to the `tsmjbbd.ini` file to prevent JFS2 internal snapshot directories from being monitored by the journal-based backup daemon.

Windows

- One method is to add exclude statements to the client options file to prevent the files or directories from being backed up during backup processing.
- The other method is to add exclude statements to the journal configuration file `tsmjbbd.ini`, to prevent journal entries from being added for the files or directories, which prevents them from being processed during a journal-based backup.

Note: There is no correlation between the two exclude statements. The preferred place for exclude statements in `tsmjbbd.ini` to prevent them from entering the journal database and being processed during a journal-based backup.

Control processing with exclude statements

After the client evaluates all exclude statements, the following options are evaluated against the remaining list of objects available for processing.

Table 1 lists the options that you can use to control processing with include and exclude statements.

Table 1. Options for controlling processing using include and exclude statements

Option	Description	Page
Back up processing		
exclude exclude.backup exclude.file exclude.file.backup	*These options are equivalent*. Use these options to exclude a file or group of files from backup services and space management services (if the HSM client is installed). The exclude.backup option only excludes files from normal backup, but not from HSM.	Exclude options
include include.backup include.file	Use these options to include files or assign management classes for backup processing.	Include options
AIX Linux Solaris Mac OS X include.fs	AIX Linux Solaris Mac OS X Controls how the client processes your file space for incremental backups.	AIX Linux Solaris Mac OS X Include options
Windows include.fs	Windows Use this option to set options on a file space-by-file space basis.	Windows Include options
Archive processing		
exclude.archive	Excludes a file or group of files from archive services.	Exclude options

Option	Description	Page
include include.archive	*These options are equivalent*. Use these options to include files or assign management classes for archive processing.	Include options
	AIX Linux Solaris Windows **Image processing**	
AIX Solaris exclude.fs.nas	AIX Solaris Excludes file systems on the NAS file server from an image backup when used with the backup nas command. If you do not specify a NAS node name, the file system identified applies to all NAS file servers. The backup nas command ignores all other exclude statements including exclude.fs and exclude.dir statements. This option is for AIX® and Solaris clients *only*.	AIX Solaris Exclude options
Windows exclude.fs.nas	Windows Excludes file systems on the NAS file server from an image backup when used with the backup nas command. If you do not specify a NAS node name, the file system identified applies to all NAS file servers. The backup nas command ignores all other exclude statements including exclude.dir statements. This option is for all Windows clients.	Windows Exclude options
AIX Linux Solaris exclude.image	AIX Linux Solaris Excludes mounted file systems and raw logical volumes that match the specified pattern from full image backup operations. Incremental image backup operations are unaffected by exclude.image. This option is valid for AIX, Solaris, and all Linux clients.	AIX Linux Solaris Exclude options
Windows exclude.image	Windows Excludes mounted file systems and raw logical volumes that match the specified pattern from full image backup operations. Incremental image backup operations are unaffected by exclude.image. This option is valid for all Windows clients.	Windows Exclude options
AIX Solaris include.fs.nas	AIX Solaris Use the include.fs.nas option to bind a management class to Network Attached Storage (NAS) file systems. To specify whether the client saves Table of Contents (TOC) information during a NAS file system image backup, use the toc option with the include.fs.nas option in your dsm.sys file. For more information, see Toc. This option is valid only for AIX and Solaris clients.	AIX Solaris Include options
Windows include.fs.nas	Windows Use the include.fs.nas option to bind a management class to Network Attached Storage (NAS) file systems. To specify whether the client saves Table of Contents (TOC) information during a NAS file system image backup, use the toc option with the include.fs.nas option in your client options file (dsm.opt). See Toc for more information. This option is valid for all Windows clients.	Windows Include options
AIX Linux Solaris include.image	AIX Linux Solaris Includes a file space or logical volume, assigns a management class, or allows you to assign one of several image backup processing options to a specific logical volume when used with the backup image command. The backup image command ignores all other include options. This option is valid for AIX, Solaris, Linux x86_64, and Linux on POWER® only.	AIX Linux Solaris Include options
Windows include.image	Windows Includes a file space or logical volume, assigns a management class, or allows you to assign one of several image backup processing options to a specific logical volume when used with the backup image command. The backup image command ignores all other include options. This option is valid for all Windows clients.	Windows Include options
	Windows **System state processing**	
Windows include.systemstate	Windows Assigns management classes for backup of the Windows system state. The default is to bind the system state object to the default management class.	Windows Include options

Mac OS X Windows

System files to exclude

There are some system files that should be placed in the client options file so that they are excluded.

Attention: These system files are either locked by the operating system or they can cause problems during restore. These are system files that cannot be recovered without the possibility of corrupting the operating system, or temporary files with data that you can easily recreate.

The implicitly generated statements can be seen in the lines of output of the query inclexcl command with the source "operating system".

Windows Use the sample include-exclude list in the dsm.smp file as a starting point for your include-exclude list. This is the minimum include-exclude list that you should have. The dsm.smp file is located in the config folder in the installation directory. If you accepted the defaults, the path to this file is `C:\Program Files\Tivoli\TSM\config\dsm.smp`

Windows There are exclude statements generated from a list defined by the Windows operating system in the Windows Registry. Those implicitly generated statements can be seen in the lines of output of the query inclexcl command with the source "operating system".

Mac OS X The backup-archive client adds the following exclude statements to the include-exclude list from your dsm.sys file. Do not include any of these statements in the dsm.sys file, or duplicate entries occurs.

```
EXCLUDE.ARCHIVE "/.../Desktop DB"
EXCLUDE.BACKUP "/.../Desktop DB"
EXCLUDE.ARCHIVE "/.../Desktop DF"
EXCLUDE.BACKUP "/.../Desktop DF"
EXCLUDE.ARCHIVE /.vol
EXCLUDE.BACKUP /.vol
EXCLUDE.ARCHIVE /automount
EXCLUDE.BACKUP /automount
EXCLUDE.ARCHIVE /Network
EXCLUDE.BACKUP /Network
EXCLUDE.ARCHIVE /dev
EXCLUDE.BACKUP /dev
EXCLUDE.BACKUP /.vol/.../*
EXCLUDE.ARCHIVE /.vol/.../*
EXCLUDE.BACKUP /automount/.../*
EXCLUDE.ARCHIVE /automount/.../*
EXCLUDE.BACKUP /Network/.../*
EXCLUDE.ARCHIVE /Network/.../*
EXCLUDE.BACKUP /dev/.../*
EXCLUDE.ARCHIVE /dev/.../*
EXCLUDE.DIR /.vol
EXCLUDE.DIR /automount
EXCLUDE.DIR /Network
EXCLUDE.DIR /dev
```

Mac OS X Note:

1. Do not specify volumes with periods in the name (...). The backup-archive client uses the sequence of periods as part of include-exclude processing. The client reports an invalid include-exclude statement if a volume has a sequence of periods in the name. The volume *must* be renamed.
2. Objects that have a type of rhap and a creator of lcmt are excluded from processing. Generally, these are special file-system objects that can also be created with the mknod command or are UNIX mount points. The objects or mount points must be manually recreated as part of a full system restore.

Mac OS X You should have the following minimum include-exclude list in your include-exclude options file:

```
EXCLUDE   /.../dsmsched.log
EXCLUDE   /.../dsmprune.log
EXCLUDE   /.../dsmj.log
EXCLUDE   /.../dsmerror.log
EXCLUDE   /.../.hotfiles.bTree

EXCLUDE.DIR  /private/tmp
EXCLUDE.DIR  /private/var/vm
EXCLUDE.DIR  /private/var/tmp
EXCLUDE.DIR  /private/var/db/netinfo/local.nidb

EXCLUDE.DIR  /.../.Trashes
EXCLUDE.DIR  /.../.Spotlight-*
EXCLUDE.DIR  /.../Library/Caches
EXCLUDE.DIR  /.../.fseventsd
```

Windows

Exclude files with UNC names

You can exclude remotely accessed files by specifying their universal naming convention (UNC) names in your exclude statement.

The following example assumes that local drive letter `g` is mapped to the remote share point:

```
\\remote\books
```

You would like to exclude from backups all files at the root of this share point that have an extension of `.txt`. You could use either of the following commands:

```
exclude g:\*.txt
exclude \\remote\books\*.txt
```

You cannot specify UNC names for removable drives such as DVD, ZIP, or diskette. For example, the following command is *not valid*:

```
exclude \\ocean\a$\winnt\system32\...\*
```

Include and exclude files that contain wildcard characters

You must use special escape characters when including or excluding files and directories that contain wildcard characters.

The backup-archive client treats wildcard characters in different ways on different platforms.

The names of directories and files can contain different symbols. The types of symbols that are allowed depend on the operating system.

AIX | Linux | Mac OS X | Solaris For example, on AIX®, the names of directories or files can contain:

```
* ? : [ ]
```

Windows For example, on Windows, the names of directories and files should not contain the following symbols:

```
? * < > " / \ : |
```

Windows However, they can contain the following symbols:

```
[ ]
```

To specify files and directories in include and exclude statements, you must use the escape character "`\`" to specify the wildcards. However, the escape character can only be used inside the character classes "`[]`".

The following examples illustrate how to specify files and directories that contain wildcard characters using the escape character and character classes in include-exclude statements.

AIX | Linux | Mac OS X | Solaris To exclude the single directory /usr1/[dir2] from backup processing, enter the following in the dsm.sys file or the include-exclude file:

```
exclude.dir "/usr1/[\[]dir2[\]]"
```

AIX | Linux | Mac OS X | Solaris To exclude the single file /usr1/fi*le1 from backup processing, enter the following statement in the dsm.sys file or the include-exclude file:

```
exclude "/usr1/fi[\*]le1"
```

AIX | Linux | Mac OS X | Solaris Tip: If you use the Preferences Editor to include or exclude a single file or directory that contains wildcard characters, you must manually edit the include or exclude statement to escape the wildcard characters. The Preferences Editor does not automatically escape the wildcard characters. Follow the previous examples to edit the include or exclude statements in the dsm.sys file or the include-exclude file.

Windows To exclude the single directory `C:\[dir2]` from backup processing, enter the following in the dsm.opt file:

```
exclude.dir "C:\[\[]dir2[\]]"
```

Windows To exclude the single file `C:\file[.txt` from backup processing, enter the following in the dsm.opt file:

```
exclude.dir "C:\file[\[].txt"
```

Windows Tip: If you use the Preferences Editor to include or exclude a single file or directory that contains wildcard characters, you must manually edit the include or exclude statement to escape the wildcard characters. The Preferences Editor does not automatically escape the wildcard characters. Follow the previous examples to edit the include or exclude statements in the dsm.opt file or the include-exclude file.

Related concepts:
Wildcard characters

Include and exclude groups of files with wildcard characters

You can use wildcard characters to include or exclude groups of files.

To specify groups of files that you want to include or exclude, use the wildcard characters listed in the following table. This table applies to include and exclude statements *only*.

A very large include-exclude list can decrease backup performance. Use wildcards and eliminate unnecessary include statements to keep the list as short as possible.

Table 1. Wildcard and other special characters

Character	Function
?	The match one character matches any single character *except* the directory separator; it does not match the end of the string. For example: • The **pattern** ab?, **matches** abc, but **does not match** ab, abab, or abzzz. • The **pattern** ab?rs, **matches** abfrs, but **does not match** abrs, or abllrs. • The **pattern** ab?ef?rs, **matches** abdefjrs, but **does not match** abefrs, abdefrs, or abefjrs. • The **pattern** ab??rs, **matches** abcdrs, abzzrs, but **does not match** abrs, abjrs, or abkkkrs.
*****	The match-all character. For example: • The **pattern** ab*, **matches** ab, abb, abxxx, but **does not match** a, b, aa, bb. • The **pattern** ab*rs, **matches** abrs, abtrs, abrsrs, but **does not match** ars, or aabrs, abrss. • The **pattern** ab*ef*rs, **matches** abefrs, abefghrs, but **does not match** abefr, abers. • The **pattern** abcd.*, **matches** abcd.c, abcd.txt, but **does not match** abcd, abcdc, or abcdtxt.
Windows **\...**	Windows The match-n character matches zero or more directories. The following pattern specifies all files in the root directory of the C drive: `c:\*` The following pattern specifies all files and all directories on the C drive: `c:\...\*`
AIX Linux Solaris Mac OS X **/...**	AIX Linux Solaris Mac OS X The match-n character matches zero or more directories.
[	The open character-class character begins the enumeration of a character class. For example: `xxx[abc] matches xxxa, xxxb, or xxxc.`
–	The character-class range includes characters from the first character to the last character specified. For example: `xxx[a-z] matches xxxa, xxxb, xxxc, ... xxxz.` Windows This format should not be used to specify remote drives in an ***exclude*** statement.
AIX Linux Solaris Mac OS X Windows ****	AIX Linux Solaris Mac OS X Windows The literal escape character. When used within a character class, it treats the next character literally. When used outside of a character class, it is not treated in this way. For example, if you want to include the ']' in a character class, enter [...\]...]. The escape character removes the usual meaning of ']' as the close character-class character.
]	The close character-class character ends the enumeration of a character class.

Character	Function
Windows **:**	Windows The drive separator character separates a file specification. The character *before* the colon identifies a drive letter. The characters *after* the colon identify file specification or pattern. For example: `d:\direct\file.nam`

Windows Note: Because a drive specification can consist of only one letter, you should not use more than one wildcard or a combination of a wildcards with a letter to designate a drive specification. The following patterns are not allowed, and if specified in the client options file (dsm.opt), stops the client program immediately after it starts:
Windows

- ?*:\test.txt
- *?:\...\pagefile.sys
- H*:\test.*
- *H:\test.txt
- myvolume*:\
- myvolume?*:\

Windows If you are using UNC names, Table 2 shows how to correctly specify shared drives.

Table 2. Specifying a drive specification using wildcards

Incorrect	Correct
\\remote*:\...*.*	\\remote*$\...*.*
\\remote\?:\...*.*	\\remote\?$\...*.*
\\remote*:\...\pagefile.sys	\\remote*$\...\pagefile.sys

Related concepts:
Wildcard characters

Examples using wildcards with include and exclude patterns

The backup-archive client accepts the exclude.dir option, which can be used to exclude directory entries. However, the include and exclude.dir options cannot be used together.

Mac OS X AIX Linux Solaris Mac OS X Note: In the dsm.sys file, the include and exclude options do not work with symbolic links to directories. For example, do not use `/u` in your include or exclude statements because `/u` is a symbolic link to the `/home` directory. Instead of entering:

```
include /u/tmp/save.fil
```

enter:

```
include /home/tmp/save.fil
```

AIX Linux Solaris Mac OS X However, the exclude option does work with symbolic links to directories when you enter a backup command with the absolute path that contains the symbolic link.

Table 1 shows how to use wildcard characters to include or exclude files.

Table 1. Using wildcard characters with include and exclude patterns

Task	Pattern
AIX Linux Solaris Mac OS X Exclude all files that end with `.doc`, except those found in the home directory of aleko, `Documents` directory.	AIX Linux Solaris Mac OS X `EXCLUDE /.../*.doc` `INCLUDE "/home/aleko/Documents/ *.doc"`
AIX Linux Solaris Mac OS X Exclude all files during backup with an extension of *bak*, except those found on the /usr file system in the `dev` directory.	AIX Linux Solaris Mac OS X `exclude /.../*.bak` `include /usr/dev/*.bak`
Windows Exclude all files during backup with an extension of *bak*, except those found on the `d:` drive in the `dev` directory.	Windows `exclude ?:\*.bak` `include d:\dev\*.bak`

Task	Pattern
AIX Linux Solaris Mac OS X Exclude all files and directories under any `Documents` directory that might exist, *except* for the `Current` file of user `aleko`.	AIX Linux Solaris Mac OS X `EXCLUDE /.../Documents/.../*` `INCLUDE "/home/aleko/Documents/ Current"`
AIX Linux Solaris Mac OS X Exclude all files in any directory named "tmp" and its subdirectories, *except* for the file `/home/tmp/save.fil`.	AIX Linux Solaris Mac OS X `exclude /.../tmp/.../*` `include /home/tmp/save.fil`
Windows Exclude all files in any directory named "tmp" and its subdirectories, *except* for the file `d:\tmp\save.fil`.	Windows `exclude ?:\...\tmp\...\*` `include d:\tmp\save.fil`
Mac OS X AIX Linux Solaris Mac OS X Exclude any `.cpp` file in any directory on the `Vol1`, `Vol2`, `Vol3`, and `Vol4` volumes.	Mac OS X AIX Linux Solaris Mac OS X `EXCLUDE /Volumes/Vol[1-4]/.../*.cpp`
Mac OS X Exclude any `.cpp` file in any directory on the `Vol1`, `Vol2`, `Vol3`, and `Vol4` volumes.	Mac OS X `EXCLUDE /Volumes/Vol[1-4]/.../*.cpp`
AIX Linux Solaris Mac OS X Exclude any `.cpp` file in any directory on the `/fs1`, `/fs2`, `/fs3` and `/fs4` file systems.	AIX Linux Solaris Mac OS X `EXCLUDE /fs[1-4]/.../*.cpp`
AIX Linux Solaris Mac OS X Exclude the `.cpp` files found in the `/fs2/source` directory.	AIX Linux Solaris Mac OS X `EXCLUDE /fs2/source/*.cpp`
Windows Exclude any `.obj` file for backup in any directory on the `c:` `e:` `f:` and `g:` drives.	Windows `exclude [ce-g]:\...\*.obj` The `c:` `e:` `f:` and `g:` drives are local or removable.
AIX Linux Solaris Mac OS X Exclude any `.o` file in any directory on the `/usr1`, `/usr2`, and `/usr3` file systems.	AIX Linux Solaris Mac OS X `exclude /usr[1-3]/.../*.o`
AIX Linux Solaris Mac OS X Exclude the `.o` files found in the root directory in the `usr2` file system *only*.	AIX Linux Solaris Mac OS X `exclude /usr2/*.o`
Windows Exclude the `.obj` files found in the root directory in the `d:` drive *only*.	Windows `exclude d:\*.obj`
AIX Linux Solaris Mac OS X Exclude any file that resides under the `tmp` directory found in any file system.	AIX Linux Solaris Mac OS X `exclude /.../tmp/.../*`
Windows Exclude any file that resides under the `tmp` directory found on any drive.	Windows `exclude ?:\tmp\...\*`
AIX Linux Solaris Mac OS X Exclude the entire directory structure `/var/spool` from all processing.	AIX Linux Solaris Mac OS X `exclude.dir /var/spool`
AIX Linux Solaris Mac OS X Exclude a single file system from backup processing.	AIX Linux Solaris Mac OS X `exclude.fs /fs1` `exclude.fs home:`
AIX Linux Solaris Mac OS X Exclude all file systems mounted anywhere in the `/test/myfs/fs01` and `/test/myfs/fs02` directory tree from backup processing.	AIX Linux Solaris Mac OS X `exclude.fs /test/myfs/fs01/.../*` `exclude.fs /test/myfs/fs02/*`
AIX Linux Solaris Mac OS X Exclude the `/home/mydir/test1` directory and any files and subdirectories under it.	AIX Linux Solaris Mac OS X `exclude.dir /home/mydir/test1`
Windows Exclude the `c:\mydir\test1` directory and any files and subdirectories under it.	Windows `exclude.dir c:\mydir\test1`

Task	Pattern
AIX Linux Solaris Mac OS X Exclude all directories under the `/home/mydir` directory with names beginning with `test`.	AIX Linux Solaris Mac OS X `exclude.dir /home/mydir/test*`
Windows Exclude all directories under the `\mydir` directory with names beginning with `test`.	Windows `exclude.dir c:\mydir\test*`
AIX Linux Solaris Mac OS X Exclude all directories directly under the `/mydir` directory with names beginning with `test`, on any file system.	AIX Linux Solaris Mac OS X `exclude.dir /.../mydir/test*`
Windows Exclude all directories directly under the `\mydir` directory with names beginning with `test`, on any drive.	Windows `exclude.dir ?:\mydir\test*`
AIX Linux Solaris Exclude the raw logical volume from image backup.	AIX Linux Solaris `exclude.image /dev/hd0`
Windows Exclude the raw logical volume from image backup.	Windows `exclude.image c:\*`
AIX Linux Solaris Mac OS X Mac OS X Exclude all symbolic links or aliases (aliases apply to Mac OS X) from backup processing, except for the `Docs` directory for `user1`.	AIX Linux Solaris Mac OS X Mac OS X `EXCLUDE.ATTRIBUTE.SYMLINK /.../*` `INCLUDE.ATTRIBUTE.SYMLINK /Users/ user1/Docs/*`
Windows Exclude all directories and files on the local drives, except the **c:** drive.	Windows `exclude [abd-z]:\...\*` `exclude.dir [abd-z]:\...\*`

Exclude options
Mac OS X AIX Linux Solaris

Symbolic link and alias processing

The backup-archive client evaluates all exclude.fs and exclude.dir statements and removes the excluded file spaces and directories.

After this initial evaluation, the client evaluates any include-exclude statements for controlling symbolic link and alias processing (exclude.attribute.symlink and include.attribute.symlink) against the remaining list of objects available for processing.

Alias processing applies to Mac OS X.

Table 1 defines options for controlling symbolic link and alias processing.

Table 1. Options for controlling symbolic link and alias processing

Option	Description	Page
exclude.attribute.symlink	Excludes a file or a group of files that are symbolic links or aliases from backup processing only.	Exclude options
include.attribute.symlink	Includes a file or a group of files that are symbolic links or aliases within broad group of excluded files for backup processing only.	Include options

Determine compression and encryption processing

The backup-archive client evaluates exclude.dir and any other include-exclude options controlling backup and archive processing, and then determines which files undergo compression and encryption processing.

The following options determine which files undergo compression and encryption processing.

Windows

Table 1. Options for controlling compression and encryption processing

Option	Description	Page
Compression processing		
exclude.compression	Excludes files from compression processing if compression=*yes* is specified. This option applies to backups and archives.	Exclude options
include.compression	Includes files for compression processing if compression=*yes* is specified. This option applies to backups and archives.	Include options
Encryption processing		
exclude.encrypt	Excludes files from encryption processing.	Exclude options
include.encrypt	Includes files for encryption processing. The data that you include is stored in encrypted form, and encryption does not affect the amount of data sent or received. **Important:** The include.encrypt option is the only way to enable encryption on the Backup-Archive client. If no include.encrypt statements are used encryption will not occur.	Include options

AIX Linux Solaris

Table 2. Options for controlling compression and encryption

Option	Description	Page
Compression processing		
exclude.compression	Excludes files from compression processing if compression=*yes* is specified. This option applies to backups and archives.	Exclude options
include.compression	Includes files for compression processing if compression=*yes* is specified. This option applies to backups and archives.	Include options
Encryption processing		
exclude.encrypt	Excludes files from encryption processing.	Exclude options
include.encrypt	Includes files for encryption processing. The data that you include is stored in encrypted form, and encryption does not affect the amount of data sent or received. **Important:** The include.encrypt option is the only way to enable encryption on the Backup-Archive client. If no include.encrypt statements are used encryption will not occur.	Include options

Preview include-exclude list files

You can preview the list of objects to be backed up or archived according to the include-exclude list, prior to sending any data to the server.

The backup-archive client GUI directory tree shows detailed information of included and excluded objects. The directory tree windows in the backup-archive client GUI allow you to select files and directories to include or exclude. You should use this preview command to make sure that you include and exclude the correct files. The following is a sample scenario for using the include-exclude preview function.

For example, follow these steps to back up the files on your `/Users/home` file space:

1. Start the backup-archive client GUI and open the Backup tree. You can see all of the directories and files that have been excluded by your options file and other sources.
2. Scroll down the tree and notice that all of the `*.o` files in your `/Volumes/home/mary/myobjdir` are backed up.
3. You do not want to back up all of the `*.o` files, so you right click a `.o` file, and choose "View File Details" from the popup menu.

4. The dialog shows that these files are included, so click the "Advanced" button and create a rule to exclude all `.o` files from the `DATA:\home` file space.
5. A rule is created at the bottom of your options file. The current directory is refreshed in the Backup tree, and the `.o` files have the red `'X'`, meaning they are excluded.
6. When you look at other directories, they show the new excludes that you have added. Press "Backup" and back up the files on your `/home` file space.

Include and exclude option processing

The IBM Spectrum Protect™ server can define include-exclude options using the inclexcl parameter in a client option set.

The include-exclude statements specified by the server are evaluated along with those in the client options file. The server include-exclude statements are always enforced and placed at the bottom of the include-exclude list and evaluated before the client include-exclude statements.

Windows If the client options file include-exclude list contains one or more inclexcl options that specify include-exclude files, the include-exclude statements in these files are placed in the list position occupied by the inclexcl option and processed accordingly.

AIX Linux Solaris Mac OS X If the dsm.sys file include-exclude list contains one or more inclexcl options that specify include-exclude files, the include-exclude statements in these files are placed in the list position occupied by the inclexcl option and processed accordingly.

A very large include-exclude list can decrease backup performance. Use wildcards and eliminate unnecessary include statements to keep the list as short as possible.

Windows When performing an incremental backup, the client evaluates all exclude.dir statements first, and removes the excluded directories and files from the list of objects available for processing.

AIX Linux Solaris Mac OS X When performing an incremental backup, the client evaluates all exclude.fs and exclude.dir statements first, and removes the excluded file spaces, directories, and files from the list of objects available for processing.

Windows After evaluating all exclude.dir statements, the client evaluates the include-exclude list from the bottom up and stops when it finds an include or exclude statement that matches the file it is processing. The order in which the include and exclude options are entered therefore affects which files are included and excluded.

AIX Linux Solaris Mac OS X After evaluating all exclude.fs and exclude.dir statements, the client evaluates the include-exclude statements for controlling symbolic link or alias processing (exclude.attribute.symlink and include.attribute.symlink) from the bottom up and stops if it finds an include or exclude statement that matches the file it is processing. After the include-exclude statements for controlling symbolic link or alias processing are processed, the client evaluates the remaining include-exclude list from the bottom up and stops when it finds an include or exclude statement that matches the file it is processing. The order in which the include and exclude options are entered therefore affects which files are included and excluded.

To display a list of all include-exclude statements in effect on your client workstation in the actual order they are processed, use the query inclexcl command.

The client program processes the list of include-exclude statements according to the following rules:

1. Files are checked; directories are only checked if the exclude.dir option is specified.
2. File names are compared to the patterns in the include-exclude list from the bottom up. When a match is found, the processing stops and checks whether the option is include or exclude. If the option is include, the file is backed up. If the option is exclude, the file is not backed up.
   Note: If a match is not found, files are implicitly included and backed up.
3. When a file is backed up, it is bound to the default management class unless it matched an include statement that specified a different management class name, in which case the file is bound to that management class.

The following examples demonstrate bottom up processing. Mac OS X AIX Linux Solaris

Example 1
Assume that `La Pomme` is not the startup disk.

```
EXCLUDE /.../*.cpp
INCLUDE "/Volumes/La Pomme/Foo/.../*.cpp"
EXCLUDE "/Volumes/La Pomme/Foo/Junk/*.cpp"
```

The file being processed is: `/Volumes/La Pomme/Foo/Dev/test.cpp`. Processing follows these steps:

1. Rule 3 (the last include or exclude statement defined) is checked first because of bottom-up processing. The pattern `/Volumes/La Pomme/Foo/Junk/*.cpp` does not match the file name that is being processed.
2. Processing moves to Rule 2 and checks. This time, pattern `/Volumes/La Pomme/Foo/.../*.cpp` matches the file name that is being processed. Processing stops, the option is checked, and it is included.
3. File `/Volumes/La Pomme/Foo/Dev/test.cpp` is backed up.

Example 2

Assume that `La Pomme` is not the startup disk.

```
EXCLUDE /.../*.cpp
INCLUDE "/Volumes/La Pomme/Foo/.../*.cpp"
EXCLUDE "/Volumes/La Pomme/Foo/Junk/*.cpp"
```

The file being processed is: `/Volumes/La Pomme/Widget/Sample File`. Processing follows these steps:

1. Rule 3 is checked and finds no match.
2. Rule 2 is checked and finds no match.
3. Rule 1 is checked and finds no match.
4. Because a match is not found, `Volumes/La Pomme/Widget/Sample File` is implicitly included and is backed up.

Example 3

Assume that you defined the following statements for the include and exclude options:

```
exclude *.o
include /home/foo/.../*.o
exclude /home/foo/junk/*.o
```

The file being processed is: `/home/foo/dev/test.o`. Processing follows these steps:

1. Rule 3 (the last statement defined) is checked first because of bottom-up processing. The pattern `/home/foo/junk/*.o` does not match the file name that is being processed.
2. Processing moves to Rule 2 and checks. This time, pattern `/home/foo/.../*.o` matches the file name that is being processed. Processing stops, the option is checked, and it is include.
3. File `/home/foo/dev/test.o` is backed up.

Example 4

Assume that you defined the following statements for the include and exclude options:

```
exclude *.obj
include /home/foo/.../*.o
exclude /home/foo/junk/*.o
```

The file being processed is: `/home/widg/copyit.txt .` Processing follows these steps:

1. Rule 3 is checked and finds no match.
2. Rule 2 is checked and finds no match.
3. Rule 1 is checked and finds no match.
4. Because a match is not found, file `/home/widg/copyit.txt` is implicitly included and backed up.

Example 5

Assume that you defined the following statements for the include and exclude options:

```
exclude /.../*.o
include /home/foo/.../*.o
exclude /home/foo/junk/*.o
```

The current file being processed is: `/home/lib/objs/printf.o`. Processing follows these steps:

1. Rule 3 is checked and finds no match.
2. Rule 2 is checked and finds no match.
3. Rule 1 is checked and a match is found.
4. Processing stops, the option is checked, and it is excluded.
5. File `/home/lib/objs/printf.o` is not backed up.

Example 6

Assume that you defined the following statements for the include and exclude options:

```
exclude.attribute.symlink /.../*
exclude /.../*.o
include /home/foo/.../*.o
exclude /home/foo/junk/*.o
```

The current file being processed is: /home/lib/objs/printf.o. Processing follows these steps:

1. The exclude.attribute.symlink statement is checked first. If the printf.o file is a symbolic link it is excluded, otherwise proceed to the next step. Note that the exclude.attribute.symlink statements are always processed before the other include-exclude statements, regardless of their position in the include-exclude list.
2. Rule 3 is checked and finds no match.
3. Rule 2 is checked and finds no match.
4. Rule 1 is checked and a match is found.
5. Processing stops, the option is checked, and it is excluded.
6. File /home/lib/objs/printf.o is not backed up.

Windows

Example 1

Assume that you defined the following statements for the include and exclude options:

```
exclude ?:\*.obj
include c:\foo\...\*.obj
exclude c:\foo\junk\*.obj
```

The file being processed is: `c:\foo\dev\test.obj`. Processing follows these steps:

1. Rule 3 (the last statement defined) is checked first because of bottom-up processing. The pattern `c:\foo\junk\*.obj` does not match the file name that is being processed.
2. Processing moves to Rule 2 and checks. This time, pattern `c:\foo\...\*.obj` matches the file name that is being processed. Processing stops, the option is checked, and it is included.
3. File `c:\foo\dev\test.obj` is backed up.

Example 2

Assume that you defined the following statements for the include and exclude options:

```
exclude ?:\*.obj
include c:\foo\...\*.obj
exclude c:\foo\junk\*.obj
```

The file being processed is: `c:\widg\copyit.bat`. Processing follows these steps:

1. Rule 3 is checked and finds no match.
2. Rule 2 is checked and finds no match.
3. Rule 1 is checked and finds no match.
4. Because a match is not found, file `c:\widg\copyit.bat` is implicitly included and backed up.

Example 3

Assume that you defined the following statements for the include and exclude options:

```
exclude ?:\...\*.obj
include c:\foo\...\*.obj
exclude c:\foo\junk\*.obj
```

The current file being processed is: `c:\lib\objs\printf.obj`. Processing follows these steps:

1. Rule 3 is checked and finds no match.
2. Rule 2 is checked and finds no match.
3. Rule 1 is checked and a match is found.
4. Processing stops, the option is checked, and it is excluded.
5. File `c:\lib\objs\printf.obj` is not backed up.

Windows

Processing rules when using UNC names

When processing files with UNC names, there are rules that must be followed.

The backup-archive client uses the rules that are described in Include and exclude option processing. The rules in Explicit use of UNC names for remote drives also apply.

- Windows Explicit use of UNC names for remote drives
  The backup-archive client recognizes explicit use of UNC names for remote drives.
- Windows Conversion of DOS pathnames for fixed and remote drives
  The backup-archive client converts DOS path names that are mapped to remote share points.
- Windows Character-class matching examples
  This topic shows examples of valid matches using character class.

Windows

Explicit use of UNC names for remote drives

The backup-archive client recognizes explicit use of UNC names for remote drives.

For example, as shown in Table 1, the UNC name pattern can be substituted for the DOS pattern.

Assume local drive letter `r:` is mapped to remote share point `\\remote\c$`, `s:` is mapped to `\\remote\share4`, and `t:` is mapped to `\\remote\share2`.

Table 1. UNC name patterns and DOS patterns

UNC name pattern	DOS pattern
`\\remote\c$\include\file.out`	`r:\include\file.out`
`\\remote\c$\...\file.out`	`r:\...\file.out`
`\\remote\share4\exclude\*`	`s:\exclude\*`
`\\remote\share2\...\?.out`	`t:\...\?.out`

Windows

Conversion of DOS pathnames for fixed and remote drives

The backup-archive client converts DOS path names that are mapped to remote share points.

For example, a remote share point that is mapped from `r:\test\...\exclude.out` to `\\remote\share\test\...\exclude.out` is converted. Remote share points that are not mapped are not converted. Files on removable media are not converted.

Windows

Character-class matching examples

This topic shows examples of valid matches using character class.

```
\\remote[a-z]\share\file.txt
matches    \\remotea\share\file.txt
 \\remote\share[a-z]\file.txt
matches     \\remote\sharex\file.txt
 \\remote\share\file[a-z].txt
matches     \\remote\share\fileg.txt
```

Getting started

Before you can use the IBM Spectrum Protect™ backup-archive client, you must learn how to start a GUI or command-line session, and how to start the client scheduler automatically. You can also learn about other commonly used tasks.

Before you use the backup-archive client, complete the following tasks:

- Starting a Java GUI session
- Starting a command-line session
- Starting a web client session
- Start the client scheduler automatically
- Changing your password

You can also complete the following tasks:

- Sorting file lists using the backup-archive client GUI
- Displaying online help
- Ending a session

- Configuring the client security settings to connect to the IBM Spectrum Protect server version 8.1.2 and later
  There are several configuration options that pertain to the IBM Spectrum Protect client security settings when connecting to the IBM Spectrum Protect server version 8.1.2 and later. Accepting the default values for those options transparently configures the client for enhanced security, and is recommended for most use cases.
- Secure password storage
  Beginning in IBM Spectrum Protect Version 8.1.2, the location of the IBM Spectrum Protect password is changed.
- Windows Backup-archive client operations and security rights
  This section explains the types of IBM Spectrum Protect backup-archive client operations that can be performed and the security rights that are needed.
- Windows Permissions required to restore files that use adaptive subfile backup
  Adaptive subfile backup is deprecated, but you can still restore subfile backup data that was created with the version 7.1 or earlier client. To restore files that were processed using adaptive subfile backup, you must either be the owner of the file or have read access.
- Windows Permissions required to back up, archive, restore or retrieve files on cluster resources
  To back up, restore, archive, or retrieve data residing on Microsoft Cluster Server (MSCS) or Veritas Cluster Server cluster resources, your Windows account must belong to the Administrators or Domain Administrators group or Backup Operators group.
- IBM Spectrum Protect client authentication
  When using the graphical user interface or command line interface of the IBM Spectrum Protect client, you can log on using a node name and password *or* administrative user ID and password.
- Windows User account control
  User Account Control (UAC) is a Windows security feature that helps prevent malware from compromising the operating system. UAC restricts programs to standard user privileges.
- Starting a Java GUI session
  The steps that are used to start the backup-archive client graphical interface (GUI) program depend on the operating system.
- Starting a command-line session
  You can start a command-line session by invoking the dsmc command.
- Specifying input strings that contain blank spaces or quotation marks
  You must follow certain rules when you specify an input string that has blanks or quotation marks.
- Mac OS X AIX Linux Solaris Starting: Additional considerations
  You can include options as arguments to **dsmj** and **dsmc** commands. For example, you can use options to modify the format that displays dates, times, and numbers, or to include your password so that the backup-archive client does not prompt for it.
- Using the web client in the new security environment
  Beginning with IBM Spectrum Protect Version 8.1.2, you can no longer use the web client to connect to the IBM Spectrum Protect V8.1.2 or later server.
- Mac OS X AIX Linux Solaris Windows Start the client scheduler automatically
  You can start the client scheduler automatically when you start your workstation.
- Changing your password
  Your IBM Spectrum Protect administrator can require you to use a password to connect to the server.
- Sorting file lists using the backup-archive client GUI
  You can use the backup-archive client GUI to display, sort, or select files.
- Displaying online help
  You can display online help in any of the following ways: On the backup-archive client GUI, from the web client, or from the dsmc command line.

- Ending a session
  You can end a client session from the backup-archive client GUI or from the dsmc command line.
- Online forums
  To participate in user discussions of IBM Spectrum Protect products, you can subscribe to the ADSM-L list server.

Configuring the client security settings to connect to the IBM Spectrum Protect server version 8.1.2 and later

There are several configuration options that pertain to the IBM Spectrum Protect™ client security settings when connecting to the IBM Spectrum Protect server version 8.1.2 and later. Accepting the default values for those options transparently configures the client for enhanced security, and is recommended for most use cases.

- Default security settings for the client (fast path)
  Fast path details the configuration options that impact the security of the client connection to the server and the behavior for various use cases when default values are accepted. This scenario minimizes the steps in the configuration process at endpoints. It automatically obtains certificates from the server when the client connects the first time, assuming that the IBM Spectrum Protect server 'SESSIONSECURITY' parameter is set to 'TRANSITIONAL', which is the default and recommended value. You can follow this scenario whether you first upgrade the IBM Spectrum Protect server to version 8.1.2 and then upgrade the client to version 8.1.2 or vice versa.
- Configuring the client without automatic certificate distribution
  This scenario details the configuration options that impact the security of the client when automatic distribution of certificates from the server is not acceptable. Automatic distribution of certificates from the server is not acceptable if the server is configured to use LDAP authentication or it is necessary that certificates are signed by a certificate authority.

Default security settings for the client (fast path)

Fast path details the configuration options that impact the security of the client connection to the server and the behavior for various use cases when default values are accepted. This scenario minimizes the steps in the configuration process at endpoints. It automatically obtains certificates from the server when the client connects the first time, assuming that the IBM Spectrum Protect™ server 'SESSIONSECURITY' parameter is set to 'TRANSITIONAL', which is the default and recommended value. You can follow this scenario whether you first upgrade the IBM Spectrum Protect server to version 8.1.2 and then upgrade the client to version 8.1.2 or vice versa.

Attention: This scenario cannot be used if the IBM Spectrum Protect server is configured for LDAP authentication. If LDAP is used, you can manually import the certificates necessary by using the dsmcert utility. See Configuring IBM Spectrum Protect client/server communication with Secure Sockets Layer for details.

Client options that affect session security

1. SSLREQUIRED. The default value Default enables existing session-security connections to servers earlier than V8.1.2, and automatically configures the client to securely connect to a V8.1.2 or newer server by using TLS for authentication.
2. SSLACCEPTCERTFROMSERV. The default value Yes enables the client to automatically accept a self-signed public certificate from the server, and to automatically configure the client to use that certificate when the client connects to a V8.1.2 or later server.
3. SSL. The default value No indicates that encryption is not used when data is transferred between the client and a server earlier than V8.1.2. When the client connects to a V8.1.2 or later server, the default value No indicates that object data is not encrypted. All other information is encrypted, when the client communicates with the server. When the client connects to a V8.1.2 or later server, the value Yes indicates that SSL is used to encrypt all information, including object data, when the client communicates with the server.
4. SSLFIPSMODE. The default value No indicates that a Federal Information Processing Standards (FIPS) certified SSL library is not needed.

In addition, the following options apply only when the client uses SSL connections to a server earlier than V8.1.2. They are ignored when the client connects to a V8.1.2 or later server.

1. SSLDISABLELEGACYTLS. The default value No indicates that connections at TLS 1.1 and lower SSL protocols are allowed when the client communicates with a server V8.1.1 and earlier V8 levels, and V7.1.7 and earlier levels.
2. LANFREESSL. Specifies whether the client uses SSL communication with the Storage Agent when LAN-free data transfer is configured.

3. REPLSSLPORT. Specifies the TCP/IP port address that is enabled for SSL when the client communicates with the replication target server.

Uses cases for default security settings for the client (fast path)

1. First, the server is upgraded to V8.1.2. Then, the client is upgraded. The existing client is not using SSL communications:
    - No changes are needed to the client security options.
    - The client configuration is automatically updated to use TLS when the client authenticates with the server.
2. First, the server is upgraded to V8.1.2. Then, the client is upgraded. The existing client is using SSL communications:
    - No changes are needed to the client security options.
    - SSL communication with existing server public certificate continues to be used.
    - SSL communication is automatically enhanced to use the TLS level that is needed by the server.
3. First, the client is upgraded to V8.1.2. Then, the server is upgraded later. The existing client is not using SSL communications:
    - No changes are needed to the client security options.
    - Existing authentication protocol continues to be used to servers at levels earlier than V8.1.2.
    - The client configuration is automatically updated to use TLS when the client authenticates with the server after the server is updated to V8.1.2 or later.
4. First, the client is upgraded to V8.1.2. Then, the server is upgraded later. The existing client is using SSL communications:
    - No changes are needed to the client security options.
    - SSL communication with existing server public certificate continues to be used with servers at levels earlier than V8.1.2.
    - SSL communication is automatically enhanced to use the TLS level that is needed by the server after the server is updated to V8.1.2 or later.
5. First, the client is upgraded to V8.1.2. Then, the client connects to multiple servers. The servers are upgraded to V8.1.2 at different times:
    - No changes are needed to the client security options.
    - The client uses existing authentication and session security protocol to servers at versions earlier than V8.1.2, and automatically upgrades to use TLS authentication when initially connecting to a server at V8.1.2 or later. Session security is managed per server.
6. New client installation, server is at V8.1.2 or later:
    - Configure the client according to a new client installation.
    - Default values for the client security options automatically configure the client for TLS-encrypted session authentication.
    - Set the SSL parameter to the Yes value if encryption of all data transfers between the client and the server is needed.
7. New client installation, server is at a version earlier than V8.1.2:
    - Configure the client according to a new client installation.
    - Accept the default values for client session-security parameters if SSL encryption of all data transfers is not needed.
        - Non-SSL authentication protocol is used until the server is upgraded to V8.1.2 or later.
    - Set the SSL parameter to the Yes value if encryption of all data transfers between the client and the server is needed, and proceed with the manual client configuration for SSL.
        - See Configuring IBM Spectrum Protect client/server communication with Secure Sockets Layer for details.
        - SSL communication is automatically enhanced to use the TLS level that is needed by the server after the server is updated to V8.1.2 or later.

Configuring the client without automatic certificate distribution

This scenario details the configuration options that impact the security of the client when automatic distribution of certificates from the server is not acceptable. Automatic distribution of certificates from the server is not acceptable if the server is configured to use LDAP authentication or it is necessary that certificates are signed by a certificate authority.

Note: In this scenario, you can accept the default values for most of the session-security options, except for the SSLACCEPTCERTFROMSERV option.

Client options that affect session security

1. SSLREQUIRED. The default value Default enables existing session-security connections to servers earlier than V8.1.2, and automatically configures the client to securely connect to a V8.1.2 or newer server by using TLS for authentication.
2. SSLACCEPTCERTFROMSERV. Set this value to No to ensure that the client does not automatically accept a self-signed public certificate from the server when the client first connects to a V8.1.2 or later server.
3. SSL. The default value No indicates that encryption is not used when data is transferred between the client and a server earlier than V8.1.2. When the client connects to a V8.1.2 or later server, the default value No indicates that object data is not encrypted. All other information is encrypted, when the client communicates with the server. When the client connects to a V8.1.2 or later server, the value Yes indicates that SSL is used to encrypt all information, including object data, when the client communicates with the server.
4. SSLFIPSMODE. The default value No indicates that a Federal Information Processing Standards (FIPS) certified SSL library is not needed.

In addition, the following options apply only when the client uses SSL connections to a server earlier than V8.1.2. They are ignored when the client connects to a V8.1.2 or later server.

1. SSLDISABLELEGACYTLS. The default value No indicates that connections at TLS 1.1 and lower SSL protocols are allowed when the client communicates with a server V8.1.1 and earlier V8 levels, and V7.1.7 and earlier levels.
2. LANFREESSL. Specifies whether the client uses SSL communication with the Storage Agent when LAN-free data transfer is configured.
3. REPLSSLPORT. Specifies the TCP/IP port address that is enabled for SSL when the client communicates with the replication target server.

Uses cases for configuring the client without automatic certificate distribution

1. First, the server is upgraded to V8.1.2. Then, the client is upgraded. The existing client is not using SSL communications:
    - Use the client configuration wizard to set the SSLACCEPTCERTFROMSERV option with the value No.
    - Obtain the necessary certificate from a trusted source.
    - Use the dsmcert utility to import the certificate for client use. See Configuring IBM Spectrum Protect client/server communication with Secure Sockets Layer for details.
2. First, the server is upgraded to V8.1.2. Then, the client is upgraded. The existing client is using SSL communications:
    - No changes are needed to the client security options. If the client already has a server certificate for SSL communication, the SSLACCEPTCERTFROMSERV option does not apply.
    - SSL communication with existing server public certificate continues to be used.
    - SSL communication is automatically enhanced to use the TLS level that is needed by the server.
3. First, the client is upgraded to V8.1.2. Then, the server is upgraded later. The existing client is not using SSL communications:
    - Use the client configuration wizard to set the SSLACCEPTCERTFROMSERV option with the value No.
    - Existing authentication protocol continues to be used to servers at levels earlier than V8.1.2.
    - Before the client connects to an 8.1.2 or later server:
        - Obtain the necessary certificate from a trusted source.
        - Use the dsmcert utility to import the certificate for client use. See Configuring IBM Spectrum Protect client/server communication with Secure Sockets Layer for details.
4. First, the client is upgraded to V8.1.2. Then, the server is upgraded later. The existing client is using SSL communications:
    - No changes are needed to the client security options. If the client already has a server certificate for SSL communication, the SSLACCEPTCERTFROMSERV option does not apply.
    - SSL communication with existing server public certificate continues to be used with servers at levels earlier than V8.1.2.
    - SSL communication is automatically enhanced to use the TLS level that is needed by the server after the server is updated to V8.1.2 or later.
5. First, the client is upgraded to V8.1.2. Then, the client connects to multiple servers. The servers are upgraded to V8.1.2 at different times:
    - Use the client configuration wizard to set the SSLACCEPTCERTFROMSERV option with the value No.
    - Existing authentication protocol continues to be used to servers at levels earlier than V8.1.2.
    - Before the client connects to an 8.1.2 or later server, or when SSL communication is needed at any server level:
        - Obtain the necessary certificate for the target server from a trusted source.
        - Use the dsmcert utility to import the certificate for client use. See Configuring IBM Spectrum Protect client/server communication with Secure Sockets Layer for details.

- The client uses existing authentication and session security protocol to servers at versions earlier than V8.1.2, and automatically upgrades to use TLS authentication when initially connecting to a server at V8.1.2 or later. Session security is managed per server.

6. New client installation, server is at V8.1.2 or later:
   - Configure the client according to a new client installation.
   - Use the client configuration wizard to set the SSLACCEPTCERTFROMSERV option with the value No.
   - Obtain the necessary certificate from a trusted source.
   - Use the dsmcert utility to import the certificate for client use. See Configuring IBM Spectrum Protect client/server communication with Secure Sockets Layer for details.
   - Set the SSL parameter to the Yes value if encryption of all data transfers between the client and the server is needed.
7. New client installation, server is at a version earlier than V8.1.2, SSL-encrypted sessions are needed:
   - Configure the client according to a new client installation.
   - Set the SSL parameter to the Yes value.
   - Obtain the necessary certificate from a trusted source.
   - Use the dsmcert utility to import the certificate for client use. See Configuring IBM Spectrum Protect client/server communication with Secure Sockets Layer for details.
8. New client installation, server is at a version earlier than V8.1.2, SSL-encrypted sessions are not needed:
   - Configure the client according to a new client installation.
   - Use the client configuration wizard to set the SSLACCEPTCERTFROMSERV option with the value No.
     - Non-SSL authentication protocol is used until the server is upgraded to V8.1.2 or later.
   - Before the client connects to an 8.1.2 or later server:
     - Obtain the necessary certificate from a trusted source.
     - Use the dsmcert utility to import the certificate for client use. See Configuring IBM Spectrum Protect client/server communication with Secure Sockets Layer for details.

Secure password storage

Beginning in IBM Spectrum Protect™ Version 8.1.2, the location of the IBM Spectrum Protect password is changed.

In V8.1.0 and V7.1.6 and earlier clients, the IBM Spectrum Protect password was stored in the Windows registry for Windows clients, and stored in the TSM.PWD file on UNIX and Linux clients.

Beginning in V8.1.2, the IBM® Global Security Kit (GSKit) keystores are used to store all IBM Spectrum Protect passwords. The process of importing server certificates is simplified. For information about importing server certificates, see Configuring IBM Spectrum Protect client/server communication with Secure Sockets Layer.

When you upgrade to IBM Spectrum Protect V8.1.2 backup-archive client, the existing passwords are migrated to the following files in the new password store:

TSM.KDB
: The file that stores the encrypted passwords.

TSM.sth
: The file that stores the random encryption key that is used to encrypt passwords in the TSM.KDB file. This file is protected by the file system. This file is needed for automated operations.

TSM.IDX
: An index file that is used to track the passwords in the TSM.KDB file.

Linux Windows For Data Protection for VMware clients, the Data Protection for VMware GUI server administration password is migrated to a keystore.

Windows

Password locations on Windows clients

On Windows clients, the passwords in the SOFTWARE\IBM\ADSM\CurrentVersion\BackupClient\Nodes registry key and the SOFTWARE\IBM\ADSM\CurrentVersion\Nodes registry key are migrated to the new password store.

The password entries in these registry keys are deleted after the migration.

The migrated server and encryption passwords are stored in the password stores in separate subdirectories of the C:\ProgramData\Tivoli\TSM\baclient directory (a hidden directory). Separating the server passwords this way allows an administrator to grant a non-administrative user access to individual passwords without giving that user access to all the other passwords. The following directories are examples of password file locations:

- C:\ProgramData\Tivoli\TSM\BAClient\NodeName\ServerName
- C:\ProgramData\Tivoli\TSM\BAClient\(VCB)\ServerName
- C:\ProgramData\Tivoli\TSM\BAClient\(DOMAIN)\ServerName
- C:\ProgramData\Tivoli\TSM\BAClient\(FILER)\ServerName

Access to the password stash files (TSM.sth) is restricted to the creator of the keystore, Administrators, and System. A utility (dsmcutil addace) is available to allow Windows users to easily modify password file access control lists. For more information, see ADDACE and DELETEACE.

AIX | Linux | Mac OS X | Solaris

Password locations on UNIX and Linux clients

On UNIX and Linux clients, the existing passwords in the TSM.PWD files are migrated to the new password store in the same location. For root users, the default location for the password store is /etc/adsm. For non-root users, the location of the password store is specified by the passworddir option.

The TSM.PWD file is deleted after the migration.

AIX | Linux | Mac OS X | Solaris

The trusted communications agent is no longer available

The trusted communications agent (TCA), previously used by non-root users in V8.1.0 and V7.1.6 and older clients, is no longer available. Root users can use the following methods to allow non-root users to manage their files:

Help desk method
: With the help desk method, the root user runs all backup and restore operations. The non-root user must contact the root user to request certain files to be backed up or restored.

Authorized user method
: With the authorized user method, a non-root user is given read/write access to the password store by using the passworddir option to point to a password location that is readable and writable by the non-root user. This method allows non-root users to back up and restore their own files, use encryption, and manage their passwords with the passwordaccess generate option.

  For more information, see Enable non-root users to manage their own data.

If neither of these methods are satisfactory, you must use the earlier clients that included the TCA.

Windows

Password locations in cluster environments

If you are operating the client in a cluster environment (CLUSTERNODE YES in the client options file), the password files are stored in a subdirectory of the client options file location. The subdirectory name is:

`NODES\NodeName\ServerName`

In a cluster configuration, the options file is stored on a cluster disk so that it can be accessed by the takeover node. The password files must also be stored on a cluster disk so that after a failure, the generated backup-archive client password is available to the takeover node.
For example, if the dsm.opt file is in the c:\ClusterStorage\Volume1\SPData directory, the node name is `Cluster-B`, and the server name is `Bigdata`, the location for password files is:

```
C:\ClusterStorage\Volume1\SPdata\Nodes\Cluster-B\Bigdata
```

Windows

Backup-archive client operations and security rights

This section explains the types of IBM Spectrum Protect™ backup-archive client operations that can be performed and the security rights that are needed.

You must have local or domain administrator privileges to install and configure IBM Spectrum Protect client services.

Table 1 summarizes the user security rights needed for backup and restore operations. The information in the table assumes that the default privileges for the Microsoft Windows Administrators group, Backup Operators group, and Users group have not been altered.

Table 1. Required user security rights for IBM Spectrum Protect backup and restore services

Operating system	Account	What can I back up and restore?
Windows Clients	Member of Administrators group	• Back up and restore all file and directory objects • Back up and restore system state • System state data (Backup Operators group cannot back up ASR writer data and cannot restore system state data)
Windows Clients	Member of Backup Operators group	• Back up and restore all file and directory objects • Back up system state, except for ASR Writer Note: Backup Operator group members cannot restore system state.
Windows Clients	Member of Users or other group	• Back up and restore all file and directory objects Attention: Users must have the following Microsoft Windows security privileges in order to back up and restore files and directories: ◦ Back up files and directories ◦ Restore files and directories These privileges represent a potential security risk since they allow the user to back up any file, or restore any file for which a backup copy exists. The privileges should be granted only to trusted users. For more information about these privileges, see the Microsoft Windows documentation. Note: System state cannot be backed up or restored.

By default, IBM Spectrum Protect client services run under the local system account. However, the local system account does not have access to network mapped drives and does not have the same permissions and logon properties as a user that is logged in to the system. If you experience discrepancies between a user initiated backup and a scheduled backup using the local system account, consider changing the services to run under the user account.

Tip: In addition to the appropriate user security rights, the IBM Spectrum Protect backup-archive client requires that the user has read permission to the root of any drive that needs to be backed up or restored. If you are using the system account to logon for the IBM Spectrum Protect scheduler service, ensure that you grant the system account (SYSTEM) read access to the root of the drive. It is not sufficient to grant Everyone read access to the root of the drive.

Domain resources, such as network drives, can only be accessed by services configured to run under a domain authorized account using dsmcutil or the Service Control Panel Application.

Beginning with IBM Spectrum Protect Version 8.1.2, stricter access control is enforced for the IBM Spectrum Protect password storage on Windows operating systems. By default, only the Administrator, SYSTEM, or LocalSystem account has access to the password store and SSL certificates.

You can use the dsmcutil addace command to modify the access control list to allow additional users, such as non-administrative users, or processes such as the IBM Spectrum Protect Data Protection client processes to access the password store and SSL certificates.

You can use the dsmcutil deleteace command to modify the access control list to remove access to the password store and client certificates for users, such as non-administrative users or processes such as the IBM Spectrum Protect Data Protection client processes.

For more information, see ADDACE and DELETEACE.

- Windows Backup Operators group operations
  The Backup Operators group allows users to back up and restore files regardless of whether they have read or write access to the files.
- Windows Considerations before you start using a Backup Operators group account
  There are some items that you need to consider before you use a Backup Operators group account to back up, archive, restore, or retrieve your data.

Windows

Backup Operators group operations

The Backup Operators group allows users to back up and restore files regardless of whether they have read or write access to the files.

This group has a limited set of user rights, so some functions are not available to members of the Backup Operators group.

The following list contains the backup-archive client operations that a member of the Backup Operators can do:

- Back up and restore files (see Table 1)
- Back up system state

  You must be a member of the Administrators group to back up ASR writer data.

- Start the scheduler service

The following list contains the backup-archive client operations that a member of the Backup Operators cannot do:

- Start any other services (client acceptor, remote client agent, and journal service)
- Install and configure client services
- Use open file support (OFS)
- Back up and restore images
- Back up and restore Windows file shares

Windows

Considerations before you start using a Backup Operators group account

There are some items that you need to consider before you use a Backup Operators group account to back up, archive, restore, or retrieve your data.

Consider these items before using a Backup Operators group account to back up, archive, restore, or retrieve your data:

- If you have already been using the backup-archive client with an Administrators group account you might not be able to launch the client because you cannot open the log files (for example `dsmerror.log`). To alleviate this problem, you can grant the Backup Operators group Read and Write permissions to the log files or the directories containing these log files.
- If you have existing backups from a version 5.2 or earlier backup-archive client and you attempt an incremental backup of an existing file space with a member of the Backup Operators group, all of the data appears as changed and it is resent to the IBM Spectrum Protect™ Server.

- Members of the Backup Operators group might not be able to back up or restore file data that was encrypted by an Administrator account using the Windows encrypting file system (EFS).
- Members of the Backup Operators group do not have the proper authority to update the last access time for files that is encrypted with the Windows encrypting file system (EFS). If EFS files are restored by a member of the Backup Operators group, the last access time will not be preserved.

Windows

Permissions required to restore files that use adaptive subfile backup

Adaptive subfile backup is deprecated, but you can still restore subfile backup data that was created with the version 7.1 or earlier client. To restore files that were processed using adaptive subfile backup, you must either be the owner of the file or have read access.

These permissions are in addition to those required to perform a normal restore.

For information about adaptive subfile backup, see Performing a backup with limited bandwidth in the version 7.1 backup-archive client documentation.

Windows

Permissions required to back up, archive, restore or retrieve files on cluster resources

To back up, restore, archive, or retrieve data residing on Microsoft Cluster Server (MSCS) or Veritas Cluster Server cluster resources, your Windows account must belong to the Administrators or Domain Administrators group or Backup Operators group.

By default, Backup Operators do not have the user rights necessary to perform these tasks on a cluster node. However, Backup Operators can perform this procedure if that group is added to the security descriptor for the Cluster service. You can do that using Cluster Administrator or cluster.exe.

IBM Spectrum Protect client authentication

When using the graphical user interface or command line interface of the IBM Spectrum Protect™ client, you can log on using a node name and password *or* administrative user ID and password.

The client prompts for your user ID and compares it to the configured node name. If they match, the client attempts to authenticate the user ID as a node name. If the authentication fails or if the user ID does not match the configured node name, the client attempts to authenticate the user ID as an administrative user ID.

To use an administrative user ID with any of the backup-archive clients, the user ID must have one of the following authorities:

System privilege
: Authority over the entire system. An administrator with system privilege can perform any administrative task.

Policy privilege
: Authority over the node policy domain. Allows an administrator to manage policy objects, register client nodes, and schedule client operations for client nodes.

Client owner
: Authority over the registered IBM Spectrum Protect client node. You can access the client through the web client or backup-archive client. You own the data and have a right to physically gain access to the data remotely. You can back up and restore files on the same or different system, and you can delete file spaces or archive data.

Client access
: To use the web client to back up and restore files on a remote client system, you must have an administrative user ID with client access authority over the node name for the remote client system. If you do not want IBM Spectrum Protect administrators with client access authority over your node name to be able to back up and restore files on your system, specify the revokeremoteaccess option in your client options file.

  Client access authority only allows IBM Spectrum Protect administrators to back up and restore files on remote systems. They do not have physical access to the data. That is, they cannot restore the data belonging to the remote system to their own systems. To restore data belonging to a remote system to your own system, you must possess at least client owner authority.

To determine what authority you have, you can use either of the following methods:

- From the main IBM Spectrum Protect GUI window, select **File** → **Connection Information**.
- Use the IBM Spectrum Protect server QUERY ADMIN command from the administrative command-line client.

Related reference:
Revokeremoteaccess
QUERY ADMIN command
Windows

User account control

User Account Control (UAC) is a Windows security feature that helps prevent malware from compromising the operating system. UAC restricts programs to standard user privileges.

When UAC is enabled, programs that require elevated privileges cannot run without your permission.

The backup-archive client requires elevated privileges. If UAC is enabled when you run the client, a User Account Control dialog box is displayed. The dialog asks if you want to allow the program to run. If you are not logged in as an administrator, the dialog also asks for your account credentials.

- Windows Enabling client access to network shares when UAC is enabled
  When Windows User Account Control (UAC) is enabled, the backup-archive client cannot access existing network share mappings. The solution is to map the network shares from an elevated command prompt before you start the client.

Starting a Java GUI session

The steps that are used to start the backup-archive client graphical interface (GUI) program depend on the operating system.

Procedure

Complete the procedure that is appropriate for your operating system to start the Java™ GUI.

Operating System	Procedure
Mac OS X **Mac OS X**	Mac OS X • Double-click the IBM Spectrum Protect™ application to start the backup-archive client without system administrator privileges. When you run the client without system administrator privileges, you can manage files that are owned by the current user. • Double-click IBM Spectrum Protect for Administrators and select IBM Spectrum Protect. After you enter a system administrator user name and password, the client starts with system administrator privileges. When you run the client with system administrator privileges, you can manage files that are owned by all users on the system. • You can also start the backup-archive client by using the dsmj command. You can run the client as either a foreground or background process. The dsmj script is installed in /Library/Application Support/tivoli/tsm/client/ba/bin.
AIX Linux Solaris **AIX®, Linux, Solaris**	AIX Linux Solaris On UNIX systems other than Mac OS X, the backup-archive client GUI must be run from the X Window System. If you see the IBM Spectrum Protect icon on your desktop, the client is already running. Double-click the icon to open the IBM Spectrum Protect window. If the IBM Spectrum Protect icon is not displayed on your desktop, start the backup-archive client graphical interface by using the dsmj command. You can run the client as either a foreground or background process.

Operating System	Procedure
Windows **Windows**	Windows To start the backup-archive client GUI on a Windows system, use one of the following methods: • Click Start > Programs > IBM Spectrum Protect > Backup-Archive GUI. • Click Start > Run and enter the full path to the backup client dsm.exe file. • On the command line, change directory to the backup-archive client installation directory and enter dsm. On Windows operating systems that have the User Account Control feature enabled, you might be prompted to allow the dsm.exe program to run. To allow the program to continue and start the backup-archive client GUI, provide administrative credentials.

Windows The backup-archive client locates and uses the options that are specified in the client options file (dsm.opt).

AIX Linux Mac OS X Solaris The backup-archive client locates and uses the options that are specified in the client system options file (dsm.sys) and the client options files (dsm.opt).

- IBM Spectrum Protect password
  Your IBM Spectrum Protect administrator can require you to use a password to connect to the server.
- Setup wizard
  When the client GUI starts, it checks to see whether a client options file exists.

Related tasks:
Windows Configuring the language for displaying the Java GUI

IBM Spectrum Protect password

Your IBM Spectrum Protect™ administrator can require you to use a password to connect to the server.

The IBM Spectrum Protect client prompts you for the password if one is required. Contact your IBM Spectrum Protect administrator if you do not know your password.

Related tasks:
Changing your password

Setup wizard

When the client GUI starts, it checks to see whether a client options file exists.

If the client options file does not exist (which usually happens after you have installed the client for the first time on your system), the setup wizard automatically starts and guides you through the configuration process.

Mac OS X AIX Linux Solaris The client options file is dsm.sys.

Windows You can launch the setup wizard at any time to modify your client options file.

Windows The client options file is dsm.opt.

Starting a command-line session

You can start a command-line session by invoking the dsmc command.

AIX Linux Solaris Mac OS X Note: If the `/usr/bin` directory contains a symbolic link to the IBM Spectrum Protect™ executable, and all DSM environment variables are set, you can enter the dsmc command from any directory. Otherwise, enter the fully qualified path of the command.
Mac OS X Note: On Mac OS X, system administrators can use the sudo command to gain additional authority so the backup-archive client can access files for all users on the system.

Mac OS X AIX Linux Solaris On the command line enter dsmc followed by the command *(batch mode)*. If the `/usr/bin` or `opt/bin` directory contains a symbolic link to the IBM Spectrum Protect installation directory, you can enter the dsmc command from any directory. Otherwise you can enter the fully qualified name.

Windows Note: If the PATH environment variable is set to the client installation directory, you can enter the dsmc command from any directory; otherwise, enter the fully qualified path.

One can start client with "dsmc" command only in case PATH environment variable is updates with path to the client location.

Windows You can open the Windows Start menu and select Programs > IBM Spectrum Protect > Backup-Archive Command Line.

Your IBM Spectrum Protect administrator can require you to use a password to connect to the server. The client prompts you for a password, if it is required. Contact your administrator if you do not know your password.

- Using batch mode
  Use *batch* mode to enter a single client command. When you use batch mode, you must precede the command with **dsmc**.
- Issuing a series of commands by using interactive mode
  Use *interactive* mode when you want to issue a series of commands.
- Windows Displaying Euro characters in a command-line prompt
  This topic explains how to display the Euro character in the Windows command-line prompt (console window).
- Windows Use options on the DSMC command
  This topic shows some examples of how to use options on the dsmc command.

Mac OS X UNIX and Linux client root and authorized user tasks
Using commands

Using batch mode

Use *batch* mode to enter a single client command. When you use batch mode, you must precede the command with **dsmc**.

About this task

For example, to issue the incremental command, enter the following at the command prompt:

```
dsmc incremental
```

Some commands require one or more arguments. For example, to archive a file:

AIX Linux Solaris Mac OS X

```
dsmc archive /home/proj1/file1.txt
```

Windows

```
dsmc archive c:\myfiles\file1.dat
```

Depending upon the current setting of your passwordaccess option, the client might prompt you for your password before the command is processed in a batch mode session.

When you enter your password, the password is not displayed on your screen.

Related reference:
Passwordaccess

Issuing a series of commands by using interactive mode

Use *interactive* mode when you want to issue a series of commands.

About this task

The connection to the server is established only once for interactive mode, so you can process a series of commands more quickly in interactive mode than in batch mode.

To start a client command session in interactive mode, enter either of the following commands:

- `dsmc`
- `dsmc loop`

The following prompt is displayed on your screen:

```
Protect>
```

Windows When you log on with an administrator ID, you can complete standard user tasks.. If you are not logged on before you begin a task from a command-prompt window, you are prompted to do so..

When you are in interactive mode, do not precede commands with dsmc. For example, instead of typing dsmc archive to archive a file, type only **archive**.

For example, to archive a file, enter the command with the file specification:

AIX Linux Solaris Mac OS X

```
archive /home/proj1/file1.txt
```

Windows

```
archive c:\myfiles\file1.dat
```

Depending upon the current setting of the passwordaccess option, the client might prompt you for your password before you are allowed to enter a command in an interactive session.

When you enter your password, the password is not displayed on your screen.

Windows

Displaying Euro characters in a command-line prompt

This topic explains how to display the Euro character in the Windows command-line prompt (console window).

Procedure

1. Contact your Microsoft Representative for the 858 code page (the file name is `c_858.nls`). Copy the file into your Windows system32 directory (for example, `C:\WINNT\system32`).
2. Edit the Windows Registry key, using this command: `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Nls\CodePage\850`, and set it to value `c_858.nls`. **Any changes that you make to the Windows Registry editor cannot be undone**. Errors made in editing the Windows Registry can cause your system to malfunction, and you might not even be able to restart your system. **Be very careful** when editing the Windows Registry. If you are unfamiliar with using the Windows Registry editor, then ask someone else who is familiar with the Windows Registry editor to help you.
3. In your Regional Settings, select a Western European country (Germany, France, Italy, etc.) as your locale setting.
4. Exit and reboot the system.

Results

Ensure that the console window font that you use supports the Euro symbol (such as Lucida Console).

Windows

Use options on the DSMC command

This topic shows some examples of how to use options on the dsmc command.

About this task

For example, suppose you have one workstation with node name `galaxy1`, and another workstation with node name `galaxy2`, and you want to restore the data from `galaxy1` to the `galaxy2` system. To recover a file from one workstation (`galaxy1`) while at the other workstation (`galaxy2`), you must access `galaxy1`. Use the set access command to gain access.

For example, assume the file to be recovered on `galaxy1` is `c:\universe\saturn.planet`. The owner of `galaxy1` enters the following command:

```
dsmc set access archive c:\universe\saturn.planet galaxy2
```

When access is granted, you would retrieve the file by entering the following command:

```
dsmc retrieve -fromnode=galaxy1 \\galaxy1\universe\saturn.planet c:\
```

Note: Access to the files of another user can also be granted and gained using the GUI.
If you have more than one backup server in your organization, you can easily switch between them using a command-line option. To override the server specified in dsm.opt, you could use a command such as this:

```
dsmc -tcpserveraddress=myserver -node=mynode -tcpport=1599
```

Related reference:
Fromnode
Set Access

Specifying input strings that contain blank spaces or quotation marks

You must follow certain rules when you specify an input string that has blanks or quotation marks.

Follow these rules when you specify an input string that has blank spaces or quotation marks:

- If the input string has one or more spaces, enclose the string with either single or double quotation marks. You can use single or double quotation marks, as long as they match.
- If the input string has a single quotation mark, enclose the string within double quotation marks, as in this example:

  ```
  -description="Annual backup of the accounting department's monthly reports"
  ```

- If the input string has a double quotation mark, enclose the string within single quotation marks, as in this example:

  ```
  -description='New translations of "The Odyssey" and "The Iliad"'
  ```

- If the input string has spaces and quotation marks, enclose the string in quotation marks. The outer quotation marks must not be the same as the quotation marks within the string.

Restriction: An input string that has single and double quotation marks is not a valid input string.

The following rules apply to these types of data:

- Fully qualified names
- The description that you specify in the archive command
- Any value for an option value where the character string can include spaces or quotation marks

Important: You cannot use escape characters in input strings. Escape characters are treated the same as any other characters. Here are some examples where escape characters are not recognized:

- If the character string is in an option file
- If the character string is in a list file
- If the character string is entered in interactive mode

Mac OS X | AIX | Linux | Solaris

Starting: Additional considerations

You can include options as arguments to **dsmj** and **dsmc** commands. For example, you can use options to modify the format that displays dates, times, and numbers, or to include your password so that the backup-archive client does not prompt for it.

About this task

In addition, if you have more than one server defined in dsm.sys and you want to contact a different server for backup-archive services (other than the one specified in your client user-options file dsm.opt), specify the server with the servername option.

For example:

```
dsmj -servername=server_b
```

AIX Linux Solaris Mac OS X The Java™ GUI (dsmj) accepts command-line parameters, such as the Java -X options. Because of this, you can also now modify the Java Heap Size. For example:

AIX Linux Solaris Mac OS X

```
dsmj -Xmx512M
```

Using the web client in the new security environment

Beginning with IBM Spectrum Protect™ Version 8.1.2, you can no longer use the web client to connect to the IBM Spectrum Protect V8.1.2 or later server or the V7.1.8 or later V7 server.

However, you can still use the web client to connect to IBM Spectrum Protect V8.1.1, V8.1.0, or V7.1.7 or earlier servers.

If you are connected to the IBM Spectrum Protect V8.1.2 or later V8 server or the V7.1.8 or later V7 server, use the following alternatives to the web client:

- To restore data that was backed up with the backup-archive client, use the backup-archive client Java GUI (dsmj) or the command-line client (dsmc). For more information, see:
  - Backing up your data
  - Restoring your data
- AIX Solaris Windows To back up and restore NAS file servers using Network Data Management Protocol (NDMP), use the IBM Spectrum Protect server commands on the administrative command-line client (dsmadmc).
  For more information, see the following server documentation:
  - Protecting NAS file servers
  - Backing up and restoring NAS file servers using NDMP
  - File-level backup and restore for NDMP operations

Tip: If you already upgraded the backup-archive client to V8.1.2 or later, you can uninstall it and reinstall the V8.1.0 client to continue to use the web client. The IBM Spectrum Protect server administrator needs to set the SESSIONSECURITY parameter on the node back to TRANSITIONAL. For more information, see UPDATE NODE (Update node attributes).

- Starting a web client session
  The web client is a Java™ Web Start application that can be started and managed independent of web browser software. After you install and configure the web client on your workstation, you can use the web client for remote access to remotely back up, restore, archive, or retrieve data on the client node. The web client facilitates the use of assistive devices for users with disabilities and contains improved keyboard navigation.

Mac OS X AIX Linux Solaris Windows

Start the client scheduler automatically

You can start the client scheduler automatically when you start your workstation.

If the IBM Spectrum Protect™ administrator has defined schedules for your node, starting the client scheduler permits you to automatically back up your workstation (or perform other scheduled actions).

You can also use the IBM Spectrum Protect Client Acceptor service to manage the scheduler.

Windows IBM Spectrum Protect supports remote network connections to the server. With a remote network connection, mobile users no longer need to dial-in to their company network when a backup is scheduled to run. IBM Spectrum Protect automatically establishes a connection before the scheduled backup occurs. If the connection fails, IBM Spectrum Protect reestablishes the connection before attempting the backup.

Related tasks:
Setting the client scheduler process to run as a background task and start automatically at startup

Changing your password

Your IBM Spectrum Protect™ administrator can require you to use a password to connect to the server.

About this task

The backup-archive client prompts you for the password if one is required. Contact your IBM Spectrum Protect administrator if you do not know your password.

Important: The password discussed in this topic is different than the password used for encrypting files.

To change your password from the GUI:

Procedure

1. Mac OS X On Mac OS X clients, start the backup-archive client with IBM Spectrum Protect Tools for Administrators.
2. AIX Linux Solaris Mac OS X Windows From the main window, open the **Utilities** menu and select **Change password**.
3. Enter your current and new passwords, and enter your new password again in the **Verify password** field.
4. Click **Change**.

Results

To change your password from the command-line client, enter this command:

AIX Linux Solaris Mac OS X Windows For UNIX, Linux, and Windows clients:

```
dsmc set password
```

Mac OS X For Mac OS X clients, enter this command to change your password from the command-line client:

```
sudo dsmc set password
```

Then, enter your old and new passwords when prompted.

Passwords can be up to 63 character in length. Password constraints vary, depending on where the passwords are stored and managed, and depending on the version of the IBM Spectrum Protect server that your client connects to.

If your IBM Spectrum Protect server is at version 6.3.3 or later, and if you use an LDAP directory server to authenticate passwords

Use any of the following characters to create a password:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9 . ! @ # $ % ^ & * _ - + = ` ( )
| { } [ ] : ; < > , ? / ~
```

Passwords are case-sensitive and are subject to more restrictions that can be imposed by LDAP policies.

If your IBM Spectrum Protect server is at version 6.3.3 or later, and if you do not use an LDAP directory server to authenticate passwords

Use any of the following characters to create a password:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9 . ! @ # $ % ^ & * _ - + = ` ( )
| { } [ ] : ; < > , ? / ~
```

Passwords are stored in the IBM Spectrum Protect server database and are not case-sensitive.

If your IBM Spectrum Protect server is earlier than version 6.3.3

Use any of the following characters to create a password:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9
_ - & + .
```

Passwords are stored in the IBM Spectrum Protect server database and are not case-sensitive.

AIX Linux Mac OS X Solaris Windows Remember:

On the command line, enclose all parameters that contain one or more special characters in quotation marks. Without quotation marks, the special characters can be interpreted as shell escape characters, file redirection characters, or other characters that have significance to the operating system.

Windows

On Windows systems:

Enclose the command parameters in quotation marks (").

Command line example:

```
dsmc set password "t67@#$%^&" "pass2><w0rd"
```

AIX | Linux | Solaris

On AIX®, Linux, and Solaris systems:

Enclose the command parameters in single quotation marks (').

Command line example:

```
dsmc set password -type=vmguest 'Win 2012 SQL' 'tsml2dag\administrator' '7@#$%^&7'
```

Quotation marks are not required when you type a password with special characters in an options file.

Sorting file lists using the backup-archive client GUI

You can use the backup-archive client GUI to display, sort, or select files.

About this task

Table 1. Working with your files using the backup-archive client GUI

Task	Procedure
Displaying files	To display files in a directory, click the folder icon next to the directory name. The files appear in the File List box on the right.
Sorting the file list	• Click the appropriate column heading in the File List box.
Display active and inactive backup versions	• Click the Display Active/Inactive Files option from the View menu. • Click the Display both active and inactive files tool on the tool bar.
Display only active backup versions	Click the Display active files only option from the View menu.
Selecting files to restore or retrieve.	• Click the selection box next to the directory or file name that you want to restore or retrieve. • Highlight the files that you want to restore or retrieve and click the Select Items tool on the tool bar. • Highlight the files that you want to restore or retrieve and click the Select Items option from the Edit menu.
Deselecting files	• Click the checked selection box next to the directory or file name. • Highlight the files that you want to deselect and click the Deselect Items tool on the tool bar. • Highlight the files that you want to deselect and click the Deselect Items option from the Edit menu.
Displaying file information	• Highlight the file name, and click the View File Details button on the tool bar. • Highlight the file name, and select File Details from the View menu.

Note:

1. Unless otherwise noted, the tasks and procedures in the above table apply to all client GUIs.

2. Using the client GUIs, you can sort a list of files by various attributes, such as name, directory, size, or modification date. Sorting files by the last backup date can be useful in determining what date and time to use for the point-in-time function.
3. An *active* file is the most recent backup version of a file that existed on your workstation when you ran your last backup. All other backup versions of that file are *inactive*. Only active backup versions of files are displayed, unless you select the Display active/inactive files menu option. If you delete the file from your workstation, the active version becomes inactive the next time you run an incremental backup.

   On the command-line client, you can use query commands with the inactive option to display both active and inactive objects. You can use restore commands with the pick and inactive options to produce the list of active and inactive backups to choose from.

Inactive
Pick

Displaying online help

You can display online help in any of the following ways: On the backup-archive client GUI, from the web client, or from the dsmc command line.

About this task

- On the backup-archive client GUI:
  - Open the help menu. Click Help or press F1.
  - Click the Help button in the current window.
  - Mac OS X On Mac systems, click the GUI question mark (?) icon, which displays online information about the current operation.
- From the dsmc command line: Enter the help command. The complete table of contents for the available help text is displayed.

Related reference:
Help

Ending a session

You can end a client session from the backup-archive client GUI or from the dsmc command line.

About this task

AIX Linux Solaris Mac OS X

- From the backup-archive client GUI:
  - Mac OS X Open the File menu and select Quit.
  - Mac OS X Press Command+Q.
  - AIX Linux Solaris Mac OS X Windows Open the File menu and select Exit.
  - Windows Click the X icon in the upper right corner.
  - AIX Linux Solaris Mac OS X Windows Open the System menu and select Close.
  - Windows Press `Alt+F4`.
  - AIX Linux Solaris Mac OS X Windows For the web client: Open a different URL or close the browser.
- From the DSMC command line:
  - In batch mode, each dsmc command you enter is a complete session. The client ends the session when it finishes processing the command.
  - To end an interactive session, enter quit at the `Protect>` prompt.
  - To interrupt a dsmc command before the client has finished processing, enter `QQ` on the IBM Spectrum Protect™ console. In many cases but not all, this interrupts the command. If the command cannot be interrupted, use the UNIX kill -9 command from an available command prompt. Do not press Ctrl-C or use the UNIX kill -15 command because it can lead to unexpected results.

Windows

- From the backup-archive client GUI main window:
  - Click File > Exit.

    - Press `Alt-X`.
    - For the web client: Open a different URL or close the browser.
- From the DSMC command line:
    - In batch mode, each dsmc command you enter is a complete session. The client ends the session when it finishes processing the command.
    - To end an interactive session, enter `quit` at the `protect>` prompt.
    - To interrupt a dsmc command before the client has finished processing, enter `QQ` on the IBM Spectrum Protect console. In many cases but not all, this interrupts the command. If the command cannot be interrupted, use the Windows Task Manager to end the dsmc process. Do not press Ctrl-C because, while it ends the session, it can lead to unexpected results.

Online forums

To participate in user discussions of IBM Spectrum Protect™ products, you can subscribe to the ADSM-L list server.

About this task

This is a user forum maintained by Marist College. While not officially supported by IBM®, product developers and other IBM support staff also participate on an informal, best-effort basis. Because this is not an official IBM support channel, you should contact IBM Technical Support if you require a response specifically from IBM. Otherwise there is no guarantee that IBM will respond to your question on the list server.

You can subscribe by sending a note to the following e-mail address:

```
listserv@vm.marist.edu
```

The body of the message must contain the following:

```
SUBSCRIBE ADSM-L yourfirstname yourlastname
```

The list server will send you a response asking you to confirm the subscription request. Once you confirm your subscription request, the list server will send you further instructions. You will then be able to post messages to the list server by sending e-mail to:

```
ADSM-L@vm.marist.edu
```

If at a later time you want to unsubscribe from ADSM-L, you can send a note to the following e-mail address:

```
listserv@vm.marist.edu
```

The body of the message must contain the following:

```
SIGNOFF ADSM-L
```

You can also read and search the ADSM-L archives, join discussion forums, and access other resources at the following URL:

```
http://www.adsm.org
```

Back up and restore data with backup-archive clients

If you want to save a copy of a file from your computer to the IBM Spectrum Protect™ server, use the *backup* function. If the original file is ever damaged or lost, you can *restore* the backup version from the server.

- Backing up your data
  Use the backup-archive client to store backup versions of your files on the IBM Spectrum Protect server. You can restore these backup versions if the original files are lost or damaged.
- Restoring your data
  Use IBM Spectrum Protect to restore backup versions of specific files, a group of files with similar names, or entire directories.

Backing up your data

Use the backup-archive client to store backup versions of your files on the IBM Spectrum Protect™ server. You can restore these backup versions if the original files are lost or damaged.

AIX Linux Mac OS X Solaris All client backup and restore procedures also apply to the web client.
Restriction: The web client does not provide a Preferences Editor for setting client options.
Windows All client backup and restore procedures also apply to the web client.
Restriction: The web client does not provide a Preferences Editor for setting client options. The web client does not offer a Setup wizard, which is available in the backup-archive client GUI on Windows clients. The web client cannot browse network resources.

Windows Unless otherwise specified, references to Windows refer to all supported Windows operating systems.

Windows The client provides backup and archive services for all files on the following file systems: File Allocation Table (FAT), FAT 32, NTFS, and ReFS.

The following is a list of primary backup tasks.

- Windows Planning your backups (Windows)
- Mac OS X AIX Linux Solaris Planning your backups
- Windows Pre-backup considerations (Windows)
- Mac OS X AIX Linux Solaris Pre-backup considerations (UNIX and Linux)
- Windows Incremental, selective, or incremental-by-date backups (Windows)
- Mac OS X AIX Linux Solaris Performing an incremental, selective, or incremental-by-date backup (UNIX and Linux)
- Windows Deleting backup data
- Mac OS X AIX Linux Solaris Deleting backup data
- Windows Backing up files from one or more file spaces for a group backup (Windows)
- Mac OS X AIX Linux Solaris Backing up files from one or more file spaces for a group backup (UNIX and Linux)
- Windows Backing up Windows system state
- Windows Backing up Automated System Recovery files
- AIX Linux Solaris Windows Image backup
- Back up NAS file systems using Network Data Management Protocol
- Windows Preparing the environment for full backups of VMware virtual machines
- Windows Back up virtual machines on a Hyper-V system
- Windows Backing up Net Appliance CIFS share definitions

- Windows Planning your backups (Windows)
  If you are a first-time user, or if you only back up files occasionally, you can use the table in this topic as a checklist of preliminary steps to consider before performing a backup.
- Mac OS X AIX Linux Solaris Planning your backups
  If you are a first-time user, or if you only back up files occasionally, you can use the table in this topic as a checklist of preliminary steps to consider before backing up data.
- Which files are backed up
  When you request a backup, the client backs up a file if certain requirements are met.
- Windows Open file support for backup operations
  The VSS snapshot provider is used for open file support.
- Windows Backing up data using the GUI
  You can use the backup-archive client GUI to back up specific files, a group of files with similar names, or entire directories.
- Windows Backing up data using the command line
  You can use the incremental or selective commands to perform backups. The following table shows examples of using commands to perform different tasks.
- Windows Deleting backup data
  If your administrator has given you authority, you can delete individual backup copies from the IBM Spectrum Protect server without deleting the entire file space.
- When to back up and when to archive files
  When the backup-archive client backs up or archives a file, it sends a copy of the file and its associated attributes to the server; however, backup and archive operations have different results.
- Windows Pre-backup considerations (Windows)
  Various factors in your system or environment can affect the way the backup-archive client processes data. Review these considerations before you back up your data.
- Mac OS X AIX Linux Solaris Pre-backup considerations (UNIX and Linux)
  Various factors in your system or environment can affect the way the backup-archive client processes data. Review these considerations before you back up your data.

- Windows Incremental, selective, or incremental-by-date backups (Windows)
  Your administrator might set up schedules to automatically back up files. This section contains information about how to back up files without a schedule.
- AIX Linux Mac OS X Solaris Performing an incremental, selective, or incremental-by-date backup (UNIX and Linux)
  Your administrator might have set up schedules to automatically back up files on your workstation. The following sections discuss how to back up files without using a schedule.
- Windows Backing up files from one or more file spaces for a group backup (Windows)
  Use the backup group command to create and back up a group from a list of files from one or more file space origins to a virtual file space on the IBM Spectrum Protect server.
- Mac OS X AIX Linux Solaris Backing up files from one or more file spaces for a group backup (UNIX and Linux)
  You can use the backup group command to create and back up a group containing a list of files from one or more file space origins to a virtual file space on the IBM Spectrum Protect server.
- Windows Backing up data with client-node proxy support (Windows)
  Backups of multiple nodes that share storage can be consolidated to a common target node name on the IBM Spectrum Protect server.
- Mac OS X AIX Linux Solaris Backing up data with client-node proxy support (UNIX and Linux)
  Backups of multiple nodes that share storage can be consolidated to a common target node name on the IBM Spectrum Protect server.
- Windows Associate a local snapshot with a server file space (Windows)
  Use the snapshotroot option with the incremental and selective commands in conjunction with a vendor-supplied application that provides a snapshot of a logical volume, to associate the data on the local snapshot with the real file space data that is stored on the IBM Spectrum Protect server.
- Mac OS X AIX Linux Solaris Associate a local snapshot with a server file space (UNIX and Linux)
  Use the snapshotroot option with the incremental and selective commands in conjunction with an independent software vendor application that provides a snapshot of a logical volume, to associate the data on the local snapshot with the real file space data that is stored on the IBM Spectrum Protect server.
- Windows Backing up Windows system state
  The backup-archive client uses VSS to back up all system state components as a single object, to provide a consistent point-in-time snapshot of the system state. System state consists of all bootable system state and system services components.
- Windows Backing up Automated System Recovery files
  You can back up Automated System Recovery (ASR) files in preparation for recovering the Windows disk configuration information and system state in case a catastrophic system or hardware failure occurs.
- Windows Preparation for Automated System Recovery
  Specific backups and media are required for Windows Automated System Recovery (ASR).
- AIX Linux Solaris Windows Image backup
  From your local workstation, you can back up a logical volume as a single object (image backup) on your system.
- AIX Snapshot-based file backup and archive and snapshot-based image backup
  For backup-archive clients running on AIX 5.3 or later JFS2 file systems as root user, snapshot-based image backup is created using snapshots by default.
- Linux Protecting Btrfs file systems
  Btrfs file systems can be included as file specifications for backup and restore commands, archive and retrieve commands, and on backup image and restore image commands. You can also specify Btrfs subvolumes as file specification to the backup and restore, and archive and retrieve functions. You cannot use the backup-archive client image backup or image restore commands on a Btrfs subvolume.
- AIX Solaris Windows Back up NAS file systems using Network Data Management Protocol
  Windows, AIX, and Solaris backup-archive clients can use Network Data Management Protocol (NDMP) to efficiently back up and restore network attached storage (NAS) file system images. The file system images can be backed up to, or be restored from, automated tape drives or libraries that are locally attached to Network Appliance or EMC Celerra NAS file servers, or to or from tape drives or libraries that are locally attached to the IBM Spectrum Protect server.
- Windows Support for CDP Persistent Storage Manager
  Persistent Storage Manager (PSM) is the snapshot technology that is included with a number of Microsoft Server Appliance Kit-based NAS boxes that include the IBM® TotalStorage NAS 200, 300, and 300G.
- Mac OS X AIX Linux Solaris Backup network file systems
  You can configure the backup-archive client to protect files that are accessed with either Network File System (NFS) or Common Internet File System (CIFS) protocols.
- AIX Back up AIX workload partition file systems
  Using the backup-archive client on AIX, you can back up and restore local partition file data within the global partition by using the local partition name space available within the global partition.
- Solaris Backing up Solaris Zettabyte file systems
  On Solaris SPARC and Solaris x86 systems, you can backup Zettabyte file systems (ZFS), by using ZFS snapshots. The

advantage of this approach, over an ordinary incremental or selective backup, is that the files and folders in a snapshot are always in a read-only state, so they cannot be changed during a backup.

- AIX AIX JFS2 encrypted file system backup
  Use AIX JFS2 Encrypted File System (EFS) to back up files either in clear text or raw format. With clear text format, the file is decrypted by EFS as it is read. With raw format, the data is not decrypted. The default is raw format, but when you set the efsdecrypt option to yes, you get clear text backups.
- AIX Back up AIX JFS2 extended attributes
  AIX Enhanced Journal File System (JFS2) provides backup processing for named extended attributes for all file systems that support named extended attributes.
- Linux Windows Backing up VMware virtual machines
  You can use the backup-archive client to back up and restore a VMware virtual machine (VM). Full backups of the virtual machine operate at a disk image level. Incremental backups copy only the data that is changed since the previous full backup.
- Windows Back up virtual machines on a Hyper-V system
  You can use the backup-archive client to backup virtual machines that are managed by a Microsoft Hyper-V server.
- Linux Windows Back up and archive Tivoli Storage Manager FastBack data
  Use Tivoli® Storage Manager FastBack to back up and archive the latest snapshots for short-term retention.
- Windows Backing up Net Appliance CIFS share definitions
  Network Appliance (NetApp) CIFS share definitions include share permissions that are set on the file server.
- Display backup processing status
  During a backup, by default the backup-archive client displays the status of each file it attempts to back up.
- Windows Backup (Windows): Additional considerations
  This section discusses additional information to consider when backing up data.
- Mac OS X AIX Linux Solaris Backup (UNIX and Linux): Additional considerations
  There are some special situations that you need to consider before you back up your data.

Windows

Planning your backups (Windows)

If you are a first-time user, or if you only back up files occasionally, you can use the table in this topic as a checklist of preliminary steps to consider before performing a backup.

Read the tasks listed in this table to determine whether you are ready to back up your data.

Table 1. Planning your backups

☐	Decide whether you want to back up or archive files. See When to back up and when to archive files for more information.
☐	See Pre-backup considerations (Windows) for important migration information, and how you might increase performance before backing up files and directories.
☐	Create an include-exclude list to specify files and directories you want to exclude from backup services. See Control processing with an include-exclude list for more information.
☐	Decide what type of backup you want according to your needs. See the following sections for more information: • Incremental, selective, or incremental-by-date backups (Windows) • Backing up files from one or more file spaces for a group backup (Windows) • Backing up Windows system state • Backing up Automated System Recovery files • Image backup • Back up NAS file systems using Network Data Management Protocol • Parallel backups of virtual machines
☐	For additional backup considerations, see Backup (Windows): Additional considerations.

Mac OS X AIX Linux Solaris

Planning your backups

If you are a first-time user, or if you only back up files occasionally, you can use the table in this topic as a checklist of preliminary steps to consider before backing up data.

Read the list of tasks to determine whether you are ready to back up your data.

- Decide whether you want to back up files or archive them. See When to back up and when to archive files for more information.
- See Pre-backup considerations (UNIX and Linux) for important considerations before you back up your files and directories.
- Do you need to exclude files from backup services? See Include-exclude options to control processing for more information.

Related concepts:
Installing the IBM Spectrum Protect backup-archive clients (UNIX, Linux, and Windows)
Related tasks:
Configuring backup-archive clients

Which files are backed up

When you request a backup, the client backs up a file if certain requirements are met.

To back up a file, the client must meet the following are the requirements:

- The selected management class contains a backup copy group.
- The file meets the serialization requirements that are defined in the backup copy group. If the copy group serialization parameter is static or shrstatic, and the file changes during backup, the file is not backed up.
- The file meets the mode requirements that are defined in the backup copy group. If the copy group mode parameter is modified, the file must have changed since the last backup. If the mode is absolute, the file can be backed up even if it does not change.
- The file meets the frequency requirements that are defined in the backup copy group. The specified minimum number of days since the last backup must elapse before a file is backed up.
- The file is not excluded from backup by an exclude statement.
- The file is not excluded from backup by the operating system. These excluded files can be found in registry subkey HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\BackupRestore\FilesNotToBackup.

Files that are part of the Windows system state are eligible for backup only when the system state is backed up. You can back up the system state only as a single entity because of dependencies among the system state components. You cannot back up or restore the files individually. For example, because C:\windows\system32\ntoskrnl.exe is part of the Windows system state, it is not backed up during an incremental or selective backup of the C:\ drive.

Windows

Open file support for backup operations

The VSS snapshot provider is used for open file support.

VSS is the snapshot provider for Windows.

Some applications can create files and open these files in a way that denies access to all other processes on a Microsoft Windows operating system. Although this is not a common practice, it is sometimes used by database vendors or other applications that might want to limit access to certain files. By restricting access to these files, backup products are prevented from backing up the data. These locked files are not the same as files that are open, or in use. The backup-archive client, running without the open file support (OFS) feature, can back up open, or in use files, including files that are open for reading or writing, files that are changing during the backup, executable and dll files that are running, log files that are being appended to, and so on.

You can create OFS or online image backups on workstations with a single NTFS-based, or ReFS-based, `C:\` drive.

The following is the error message that is seen in the `dsmerror.log` when the client encounters one of these locked files without OFS support enabled:

```
ANS4987E Error processing '\\machine1\d$\dir1\lockedfile.xyz': the object is in use
by another process
```

```
ANS1228E Sending of object '\\machine1\d$\dir1\lockedfile.xyz' failed
```

Do not use OFS for backing up locked Windows system files, such as the Windows system state. The client has advanced features for backing up data that is contained within these files. The backup of the system data that is contained in these files requires extra processing and must be backed up in a group to allow for a successful restore. These files are excluded from IBM Spectrum Protect™ file level backup.

For database applications that use certain files for transactional consistency (for example, a recovery log file), it might not be possible to back up and restore these files without database coordination. In these situations, do not back up these database files with the normal file level backup. You can exclude these files from backup processing by using an exclude or exclude.dir statement. A number of data protection clients (IBM Spectrum Protect for Databases, IBM Spectrum Protect for Mail, and so on) are available to provide this database coordination and backup along with other advanced database backup features. For a current list of data protection clients go to this website: http://www.ibm.com/systems/storage/spectrum/protect/.

For private applications or other database products where a Data Protection client is not available, you can use the preschedulecmd option to signal the database or application to do one of the following actions:

- Take the steps necessary to move these files to a consistent and unopen state.
- Bring down the database before the file level backup is started.
- Program or script another method to back up this data and exclude these files from the file level backup. In these cases the OFS feature is not necessary since these files are no longer unavailable or locked by the application. After the file level backup completes, use the postschedulecmd option to bring the database back online or restart the application.

If the time it takes to complete the file level backup is too long to have the open files offline (for example, having the database offline or holding up transactions), use the OFS feature to create a point-in-time snapshot of the volume. In this case, use the presnapshotcmd and postsnapshotcmd options to signal the database or application to coordinate with the backup of these open files. The snapshot, which occurs between the pre-snapshot command and post-snapshot command, generally takes only a few seconds to create. This allows the database or application to resume operations quickly while still allowing the client to perform a full incremental backup of the volume, including the locked files. There are other situations where these application-locked files can be safely backed up and restored on a file-by-file basis. In these situations, you can enable the OFS feature for that volume where the open files exist. The client then has access to these files and back them up using file level backup and archive operations.

For information about Open File Support restrictions and issues, see technote 1248971.

If open file support has been configured, the client performs a snapshot backup or archive of files that are locked (or "in use") by other applications. The snapshot allows the backup to be taken from a point-in-time copy that matches the file system at the time the snapshot is taken. Subsequent changes to the file system are not included in the backup. You can set the snapshotproviderfs parameter of the include.fs option to none to specify which drives do not use open file support.

To control an open file support operation, you can specify these additional options in your dsm.opt file or as values of the include.fs option: snapshotproviderfs, and presnapshotcmd and postsnapshotcmd.

Note:

1. You can use the include.fs option to set snapshot options on a per file system basis.
2. Open file support is provided for both backup and archive. For backup, this includes incremental, incremental by date, selective, incremental image, and journal-based backup.
3. Open file support is only available for local fixed volumes (mounted to either drive letters or volume mount points) formatted with FAT, FAT32, NTFS, or ReFS file systems. This support includes SAN-attached volumes that meet these requirements.
4. To enable OFS support in a cluster environment, all workstations in the cluster must have OFS configured. Set VSS as the snapshot provider on the snapshotproviderfs option.

Windows

Backing up data using the GUI

You can use the backup-archive client GUI to back up specific files, a group of files with similar names, or entire directories.

About this task

You can locate the files that you want to back up by searching or filtering. Filtering displays only the files that match the filter criteria for your backup. Files that do not match the filter criteria do not display.

To perform a GUI backup, use the following steps:

Procedure

1. Click Backup from the GUI main window. The Backup window appears.
2. Expand the directory tree by clicking the plus sign +. To display files in a folder, click the Folder icon. To search or filter files, click the Search icon from the toolbar.
3. Click the selection box for the objects that you want to back up.
4. Select the type of backup from the pull-down menu:
    a. To run an incremental backup, select Incremental (complete).
    b. To run an incremental backup by date, select Incremental (date only).
    c. To run a selective backup, select Always backup.
    d. To run an incremental backup without using the journal database, select Incremental (without journal). If you installed the journal engine service and it is running, then by default the Incremental command automatically performs a journal-based backup on selected file systems that are being monitored by the journal engine service. This option performs a traditional full incremental backup, instead of the default journal-based backup.
5. Click Backup. The Backup Task List window displays the backup processing status. When processing completes, the Backup Report window displays processing details.

Results

The following are some items to consider when you use the GUI to back up your data.

- IBM Spectrum Protect™ uses management classes to determine how to manage your backups on the server. Every time you back up a file, the file is assigned a management class. The management class that is used is either a default that is selected for you, or one that you assign to the file using an include option in the include-exclude options list. Select Utilities → View Policy Information from the backup-archive client or web client GUI to view the backup policies that are defined by the IBM Spectrum Protect server for your client node. Select Edit → Client Preferences from the backup-archive client or web client GUI and select the Include-Exclude tab in the Preferences editor to display your include-exclude list.
- To modify specific backup options, click the Options button. Any options that you change are effective during the current session only.
- To perform subsequent incremental backups, from the IBM Spectrum Protect main window, open the Actions menu and select Backup Domain.
- The web client GUI cannot browse network resources to perform a backup. No shares are listed if you expand the Network branch. It is possible to backup a network resource from the web client as long as the entire file is processed. To do this, the filesystem is specified using the domain option in `dsm.opt`. E.g. `domain all-local \\server\share`. To complete the backup, select Backup Domain from the Action menu. This processes all the filesystems that are specified with the domain option. Alternatively, you can use the GUI Client to perform the backup.

- Windows Specifying drives in your domain
  When you start the client, it sets your default domain to the drives you specify with the domain option in the dsm.opt file.

Backing up data using the command line

You can use the incremental or selective commands to perform backups. The following table shows examples of using commands to perform different tasks.

About this task

Table 1. Command line backup examples

Task	Command	Considerations
Incremental backups		
Perform an incremental backup of your client domain.	dsmc incremental	See Incremental for more information about the incremental command. See Full and partial incremental backup for detailed information about incremental backups.
Back up the `g:` and `h:` drives in addition to the `c:`, `d:`, and `e:` drives defined in your client domain.	`dsmc incremental -domain="g: h:"`	See Domain for more information about the domain option.
Back up all local volumes defined in your client domain *except* for the `c:` drive and systemobject domain.	`dsmc incremental -domain="all-local -c: -systemobject"`	You cannot use the (-) operator in front of the domain keyword all-local. See Domain for more information. For Windows clients you can also exclude the systemstate domain from backup processing in this way.
Back up all local volumes defined in your client domain *except* for the `c:` drive and systemstate domain.	`dsmc incremental -domain="all-local -c: -systemstate"`	You cannot use the (-) operator in front of the domain keyword all-local. See Domain for more information.
Back up *only* the `g:` and `h:` drives.	`dsmc incremental g: h:`	None
Back up all files in the `c:\Accounting` directory and all its subdirectories.	`dsmc incremental c:\Accounting\* -sub=yes`	See Subdir for more information about the subdir option.
Assuming that you initiated a snapshot of the `C:` drive and mounted the snapshot as the logical volume `\\florence\c$\snapshots\snapshot.0`, run an incremental backup of all files and directories under the local snapshot and manage them on the IBM Spectrum Protect™ server under the file space name `C:`.	`dsmc incremental c: -snapshot=\\florence\c$\snapshots\snapshot.0`	See Snapshotroot for more information.
Incremental-by-date backup		
Perform an incremental-by-date backup of your default client domain.	`dsmc incremental -incrbydate`	Use the incrbydate option with the incremental command to back up new and changed files with a modification date later than the last incremental backup stored at the server. See Incrbydate for more information about the incrbydate option.
Selective backups		

Task	Command	Considerations
Back up all files in the `d:\proj` directory.	`dsmc selective d:\proj\`	Use the selective command to back up specific files, a group of files with similar names, or empty directories and their attributes regardless of whether those files or directories were backed up during your last incremental backup and without affecting the last incremental backup count from the backup server. You can use wildcards to back up multiple files at once. See Selective for more information about the selective command.
Back up the `d:\proj` directory and all its subdirectories.	`dsmc selective d:\proj\ -subdir=yes`	See Subdir for more information about the subdir option.
Back up the `d:\h1.doc` and `d:\test.doc` files.	`dsmc selective d:\h1.doc d:\test.doc`	You can specify as many file specifications as available resources or other operating system limits permit. Separate file specifications with a space. You can also use the filelist option to process a list of files. The backup-archive client opens the file you specify with this option and processes the list of files within according to the specific command. See Filelist for more information.
Back up a list of files in the `c:` drive.	`dsmc selective -filelist=c:\filelist.txt`	Use the filelist option to process a list of files. See Filelist for more information.
Assuming that you initiated a snapshot of the `C:` drive and mounted the snapshot as the logical volume `\\florence\c$\snapshots\snapshot.0`, run a selective backup of the `c:\dir1\sub1` directory tree from the local snapshot and manage it on the IBM Spectrum Protect server under the file space name `C:`.	`dsmc selective c:\dir1\sub1\* -subdir=yes snapshot=\\florence\c$\snapshots\snapshot.0`	See Snapshotroot for more information.

Deleting backup data

If your administrator has given you authority, you can delete individual backup copies from the IBM Spectrum Protect™ server without deleting the entire file space.

About this task

For example, you might need to delete sensitive data that was backed up (intentionally or unintentionally), and now needs to be removed from the server. Or you might need to delete files that were backed up, but were later found to contain viruses. To determine if you have the authority to delete individual backup copies from the IBM Spectrum Protect server without deleting the entire file space, select **File** → **Connection Information** from the backup-archive client GUI or web client main menu. Your authority status is provided in the Delete Backup Files field.

Important: When you delete backup files, ***you cannot restore them.*** Verify that the backup files are no longer needed before you delete them. IBM Spectrum Protect prompts whether you want to continue with the delete. If you specify *yes*, the specified backup files are immediately deleted and removed from IBM Spectrum Protect server storage.

To delete backup copies using the IBM Spectrum Protect GUI or web client:

Procedure

1. Select **Delete Backup Data** from the **Utilities** menu. The Backup Delete window appears.
2. Expand the Directory tree by clicking the plus sign **(+)** or folder icon next to the object you want to expand.
3. Select an item from the drop-down list near the top of the **Backup Delete** window to specify the type of backup delete to perform. You can delete active backup versions, inactive backup versions, or all objects that you have selected in the tree. A directory is deleted only if you select **Delete All Objects**.

Results

To delete backup copies using the IBM Spectrum Protect command line client, use the delete backup command.

Delete Backup

When to back up and when to archive files

When the backup-archive client backs up or archives a file, it sends a copy of the file and its associated attributes to the server; however, backup and archive operations have different results.

Use backups to protect against unforeseen damage to your files, and use archives for maintaining more permanent versions of your files.

Backup data is managed by version by using predetermined policy-based rules. Using these rules, the IBM Spectrum Protect™ administrator can control the following processes:

- The number of versions that are maintained on the IBM Spectrum Protect server
- The number of days each additional backup copy is kept
- What happens to backup versions when the file is deleted on the client system

Each copy of the file that is stored on the server is considered to be a separate and unique version of the file.

Archive is a powerful and flexible mechanism for storing long-term data. Archive data, called archive copies, are kept for a specified number of days. The archive function has no concept or support for versions. The user or administrator is responsible for determining what files get added to an archive.

Tip: If a file is archived multiple times by using the same archive description, a new copy of the file is added to the archive each time that archive is operation run. To simplify the retrieve operation, store only one copy of a file in each archive.

Backups protect against file damage or loss that can occur through accidental deletion, corruption, or disk crashes. The server maintains one or more backup versions for each file that you back up. Older versions are deleted as newer versions are made. The number of backup versions the server maintains is set by your administrator.

AIX Linux Solaris Mac OS X Windows Archive copies are saved for long-term storage. Your administrator can limit how long archive copies are kept. The server can store an unlimited number of archive versions of a file. Archives are useful if you must go back to a particular version of your files, or you want to delete a file from your workstation and retrieve it later, if necessary. For example, you might want to save spreadsheets for tax purposes, but because you are not using them, you do not want to leave them on your workstation.

Restore data from a backup set
Windows

Pre-backup considerations (Windows)

Various factors in your system or environment can affect the way the backup-archive client processes data. Review these considerations before you back up your data.

- Windows LAN-free data movement
  LAN-free data movement shifts the movement of client data from the communications network to a storage area network

(SAN). This decreases the load on the IBM Spectrum Protect server.

- Windows Unicode file spaces (Windows)
  The Windows client is Unicode-enabled. However, client versions before Version 4.2 were not enabled for Unicode.
- Windows Incremental backups on memory-constrained systems
  Incremental backup performance suffers if the system has a low amount of memory available before starting the backup.
- Windows Incremental backups on systems with a large number of files
  The client can use large amounts of memory to run incremental backup operations, especially on file systems that contain large numbers of files.
- Windows Control processing with an include-exclude list
  There might be files on your system that you do not want to back up. These files might be operating system or application files that you can easily recover by reinstalling the program, or any other file that you can easily rebuild.
- Windows Data encryption during backup or archive operations
  For the strongest possible encryption, use 256-bit Advanced Encryption Standard (AES) data encryption, with the encryptiontype option. AES 128-bit encryption is currently the default.
- Windows Maximum file size for operations
  The maximum file sizes for backup and restore, and archive and retrieve operations depends on the Windows file system that is used.
- Windows How the client handles long user and group names
  The backup-archive client can handle user and group names that are up to 64 characters without any issues. However, names longer than 64 characters require special handling.

AIX Linux Solaris Windows

LAN-free data movement

LAN-free data movement shifts the movement of client data from the communications network to a storage area network (SAN). This decreases the load on the IBM Spectrum Protect™ server.

The SAN provides a path that allows you to back up, restore, archive, and retrieve data to and from a SAN-attached storage device. Client data moves over the SAN to the storage device using the IBM Spectrum Protect Storage Agent. The Storage Agent must be installed on the same system as the client.

AIX Linux Solaris AIX®, Linux, and Solaris clients support LAN-free data movement.

Windows All Windows clients support LAN-free data movement.

- Windows LAN-free prerequisites
  To enable LAN-free support, you must install and configure the IBM Spectrum Protect for SAN storage agent on the client workstation.
- Windows LAN-free data movement options
  To enable LAN-free data movement, you can use several client options. You must first install and configure the IBM Spectrum Protect for SAN storage agent on the client workstation.

AIX Linux Solaris Windows

LAN-free prerequisites

To enable LAN-free support, you must install and configure the IBM Spectrum Protect™ for SAN storage agent on the client workstation.

IBM Spectrum Protect for SAN is a separate product.

For more information about installing and configuring the storage agent, see the documentation for IBM Spectrum Protect for SAN.

AIX Linux Solaris Windows

LAN-free data movement options

To enable LAN-free data movement, you can use several client options. You must first install and configure the IBM Spectrum Protect™ for SAN storage agent on the client workstation.

Use the following options to enable LAN-free data movement:

enablelanfree
Specifies whether to enable an available LAN-free path to a SAN-attached storage device.
lanfreecommmethod
Specifies a communication protocol between the client and the Storage Agent.
lanfreeshmport
Specifies the unique number that is used by the client and the storage agent to identify shared memory area used for communications.
lanfreetcpport
Specifies the TCP/IP port number where the Storage Agent is listening.
lanfreetcpserveraddress
Specifies the TCP/IP address for the storage agent.

Windows

Unicode file spaces (Windows)

The Windows client is Unicode-enabled. However, client versions before Version 4.2 were not enabled for Unicode.

If you are backing up a system that had at one time used a client version older than Version 4.2, and the file spaces have not yet been migrated to Unicode, then you need to plan for the migration of file spaces to Unicode. This involves renaming your file spaces on the server and creating new Unicode-enabled file spaces on the server using the autofsrename option.

Mac OS X | AIX | Linux | Solaris | Windows

Incremental backups on memory-constrained systems

Incremental backup performance suffers if the system has a low amount of memory available before starting the backup.

If your system is memory constrained, specify the memoryefficientbackup *yes* option in your client options file. This option causes the backup-archive client to process only one directory at a time, which reduces memory consumption but increases backup time. When you specify *yes*, the client analyzes only one directory at a time for backup consideration. If performance remains poor, check your communication buffer settings and the communication link between your system and the IBM Spectrum Protect™ server. If your system is not memory constrained, setting the memoryefficientbackup option to *yes* degrades your backup performance.

Related reference:
Memoryefficientbackup

Incremental backups on systems with a large number of files

The client can use large amounts of memory to run incremental backup operations, especially on file systems that contain large numbers of files.

The term *memory* as used here is the addressable memory available to the client process. Addressable memory is a combination of physical RAM and virtual memory.

On average, the client uses approximately 300 bytes of memory per object (file or directory). Thus for a file system with one million files and directories, the client requires, on average, approximately 300 MB of memory. The exact amount of memory that is used per object varies, depending on the length of the object path and name length, or the nesting depth of directories. The number of bytes of data is not an important factor in determining the backup-archive client memory requirement.

The maximum number of files can be determined by dividing the maximum amount of memory available to a process by the average amount of memory that is needed per object.

The total memory requirement can be reduced by any of the following methods:

- Use the client option memoryefficientbackup diskcachemethod. This choice reduces the use of memory to a minimum at the expense of performance and a significant increase in disk space that is required for the backup. The file description data from the server is stored in a disk-resident temporary database, not in memory. As directories on the workstation are scanned, the database is consulted to determine whether to back up, update, or expire each object. At the completion of the backup, the database file is deleted.
- Use the client option memoryefficientbackup yes. The average memory that is used by the client then becomes 300 bytes times the number of directories plus 300 bytes per file in the directory that is being processed. For file systems with large numbers (millions) of directories, the client still might not be able to allocate enough memory to perform incremental backup with memoryefficientbackup yes.
- AIX Linux Solaris UNIX and Linux clients might be able to use the virtualmountpoint client option to define multiple virtual mount points within a single file system, each of which can be backed up independently by the client.
- If the client option resourceutilization is set to a value greater than 4, and multiple file systems are being backed up, then reducing resourceutilization to 4 or lower limits the process to incremental backup of a single file system at a time. This setting reduces the memory requirement. If the backup of multiple file systems in parallel is required for performance reasons, and the combined memory requirements exceed the process limits, then multiple instances of the backup client can be used to back up multiple file systems in parallel. For example, if you want to back up two file systems at the same time but their memory requirements exceed the limits of a single process, then start one instance of the client to back up one of the file systems, and start a second instance of the client to back up the other file system.
- Use the - incrbydate client option to perform an "incremental-by-date" backup.
- Use the exclude.dirclient option to prevent the client from traversing and backing up directories that do not need to be backed up.
- AIX Linux Solaris Except for Mac OS X, use the client image backup function to back up the entire volume. An image backup might actually use less system resources and run faster than incremental backup of some file systems with a large number of small files.
- Reduce the number of files per file system by spreading the data across multiple file systems.

Control processing with an include-exclude list

There might be files on your system that you do not want to back up. These files might be operating system or application files that you can easily recover by reinstalling the program, or any other file that you can easily rebuild.

Use the include and exclude options in the client options file (dsm.opt) to define which files to include or exclude from incremental or selective backup processing. A file is eligible for backup unless excluded by an exclude option. It is not necessary to use an include option to include specific files for backup unless those files are in a directory that contains other files that you want to exclude.

The include-exclude list might contain items that are specified by the server. To view the contents of your include-exclude list, use the query inclexcl command.

IBM Spectrum Protect™ uses *management classes* to determine how to manage your backups on the server. Every time you back up a file, the file is assigned a management class. The management class is either a default that is chosen for you, or one you assign to the file by using the include option in the include-exclude list. If you assign a management class, it must contain a backup copy group for the file to be backed up.

You can also add include-exclude statements in the backup-archive client GUI directory tree. You can use the preview command to see the resultant effects of the currently defined include-exclude list without need of running an actual backup operation.

Windows

Data encryption during backup or archive operations

For the strongest possible encryption, use 256-bit Advanced Encryption Standard (AES) data encryption, with the encryptiontype option. AES 128-bit encryption is currently the default.

The data that you include is stored in encrypted form, and encryption does not affect the amount of data sent or received.

Attention: If the encryption key password is not saved in the Windows Registry, and you have forgotten the password, your data cannot be recovered.

The include.encrypt option is the only way to enable encryption on the Backup-Archive client. If no include.encrypt statements are used, encryption will not occur.

Encryption is not compatible with VMware virtual machine backups that use the incremental forever backup modes (MODE=IFIncremental and MODE=IFFull). If the client is configured for encryption, you cannot use incremental forever backup.

To encrypt file data, you must select an encryption key password, which the client uses to generate the encryption key for encrypting and decrypting the file data. You can specify whether to save the encryption key password in the Windows Registry by using the encryptkey option.

IBM Spectrum Protect™ client encryption allows you to enter a value of up to 63 characters in length. This encryption password needs to be confirmed when encrypting the file for backup, and also needs to be entered when performing restores of encrypted files.

While restoring an encrypted file, you are prompted for the key password to decrypt the file in the following cases:

- If the encryptkey option is set to `Prompt`.
- If the key supplied by the user does not match.
- If the encryptkey option is set to `Save` and the locally saved key password does not match the encrypted file.

Maximum file size for operations

The maximum file sizes for backup and restore, and archive and retrieve operations depends on the Windows file system that is used.

The following table shows the maximum file size, in bytes, for backing up, restoring, and retrieving data.

Table 1. Maximum file size

File system	Maximum file size (in bytes)
Windows FAT16	Windows 2 147 483 647 (2 GB)
Windows FAT32	Windows 4 294 967 295 (4 GB)
Windows NTFS and ReFS	Windows 17 592 185 978 880 (16 TB-64 K)

Windows

How the client handles long user and group names

The backup-archive client can handle user and group names that are up to 64 characters without any issues. However, names longer than 64 characters require special handling.

Restriction: Do not exceed the 64-character limit for user and group names. The client shortens the name to fall within this limit by using the following algorithm: Use the first 53 characters, append a forward slash (/), and then use the numeric ID as a character string.

An error message is logged that contains both the long name and the resulting shortened string. For most functions, you do not need to be aware of the shortened name. The exceptions are:

- The set access command
- The fromowner option
- The users and groups (authorization) options

In each of these cases, when you need to enter a name, you either have to find the error message containing the transformation, or construct the name using the rule outlined here.

AIX | Linux | Mac OS X | Solaris

Pre-backup considerations (UNIX and Linux)

Various factors in your system or environment can affect the way the backup-archive client processes data. Review these considerations before you back up your data.

- AIX | Linux | Solaris LAN-free data movement
  LAN-free data movement shifts the movement of client data from the communications network to a storage area network (SAN). This decreases the load on the IBM Spectrum Protect server.
- Mac OS X | AIX | Linux | Solaris Incremental backups on memory-constrained systems
  Incremental backup performance suffers if the system has a low amount of memory available before starting the backup.
- Mac OS X | AIX | Linux | Solaris Incremental backups on systems with a large number of files
  The client can use large amounts of memory to run incremental backup operations, especially on file systems that contain large numbers of files.
- Mac OS X | AIX | Linux | Solaris Include-exclude options to control processing
  You might have files in your file systems that you do not want to back up. These files might be core files, local caches of network file systems, operating system or application files that could be easily recovered by reinstalling the program, or any other files that you could easily rebuild.
- Mac OS X | AIX | Linux | Solaris Data encryption during backup or archive operations
  The way to ensure data security is by encrypting data. Use data encryption to protect data during a backup or archive operation. Advanced Encryption Standard (AES) 128-bit encryption is the default encryption option. For the highest level of data encryption, use 256-bit Advanced Encryption Standard (AES) data encryption by specifying the encryptiontype option.
- Mac OS X | AIX | Linux | Solaris File system and ACL support
  Special file systems contain dynamic information that is generated by the operating system; they contain no data or files. The UNIX and Linux clients ignore special file systems and their contents.
- Mac OS X | AIX | Linux | Solaris Maximum file size for operations
  The maximum file size depends on the type of a file system. The backup-archive client does not check any file size limit during backup, archive, restore, or retrieve operations.
- Mac OS X | AIX | Linux | Solaris | Windows Long user and group names
  The backup-archive client can handle user and group names that are up to 64 characters without any issues. However, names longer than 64 characters require special handling by IBM Spectrum Protect.
- Mac OS X Mac OS X volume names
  The backup-archive client backs up volumes based on their UNIX mount point name.
- Mac OS X Mac OS X Unicode enablement
  The Mac OS X client is Unicode enabled. New clients storing data on the server for the first time require no special set up.
- Mac OS X Mac OS X Time Machine backup disk
  Time Machine is the backup application available with Mac OS X.

LAN-free data movement

LAN-free data movement shifts the movement of client data from the communications network to a storage area network (SAN). This decreases the load on the IBM Spectrum Protect™ server.

The SAN provides a path that allows you to back up, restore, archive, and retrieve data to and from a SAN-attached storage device. Client data moves over the SAN to the storage device using the IBM Spectrum Protect Storage Agent. The Storage Agent must be installed on the same system as the client.

AIX Linux Solaris AIX®, Linux, and Solaris clients support LAN-free data movement.

Windows All Windows clients support LAN-free data movement.

- AIX Linux Solaris LAN-free prerequisites
  To enable LAN-free support, you must install and configure the IBM Spectrum Protect for SAN storage agent on the client workstation.
- AIX Linux Solaris LAN-free data movement options
  To enable LAN-free data movement, you can use several client options. You must first install and configure the IBM Spectrum Protect for SAN storage agent on the client workstation.

AIX Linux Solaris Windows

LAN-free prerequisites

To enable LAN-free support, you must install and configure the IBM Spectrum Protect™ for SAN storage agent on the client workstation.

IBM Spectrum Protect for SAN is a separate product.

For more information about installing and configuring the storage agent, see the documentation for IBM Spectrum Protect for SAN.

AIX Linux Solaris Windows

LAN-free data movement options

To enable LAN-free data movement, you can use several client options. You must first install and configure the IBM Spectrum Protect™ for SAN storage agent on the client workstation.

Use the following options to enable LAN-free data movement:

enablelanfree
: Specifies whether to enable an available LAN-free path to a SAN-attached storage device.

lanfreecommmethod
: Specifies a communication protocol between the client and the Storage Agent.

lanfreeshmport
: Specifies the unique number that is used by the client and the storage agent to identify shared memory area used for communications.

lanfreetcpport
: Specifies the TCP/IP port number where the Storage Agent is listening.

lanfreetcpserveraddress
: Specifies the TCP/IP address for the storage agent.

Incremental backups on memory-constrained systems

Incremental backup performance suffers if the system has a low amount of memory available before starting the backup.

If your system is memory constrained, specify the memoryefficientbackup *yes* option in your client options file. This option causes the backup-archive client to process only one directory at a time, which reduces memory consumption but increases backup time. When you specify *yes*, the client analyzes only one directory at a time for backup consideration. If performance remains poor, check your communication buffer settings and the communication link between your system and the IBM Spectrum Protect™ server. If your system is not memory constrained, setting the memoryefficientbackup option to *yes* degrades your backup performance.

Related reference:
Memoryefficientbackup

Incremental backups on systems with a large number of files

The client can use large amounts of memory to run incremental backup operations, especially on file systems that contain large numbers of files.

The term *memory* as used here is the addressable memory available to the client process. Addressable memory is a combination of physical RAM and virtual memory.

On average, the client uses approximately 300 bytes of memory per object (file or directory). Thus for a file system with one million files and directories, the client requires, on average, approximately 300 MB of memory. The exact amount of memory that is used per object varies, depending on the length of the object path and name length, or the nesting depth of directories. The number of bytes of data is not an important factor in determining the backup-archive client memory requirement.

The maximum number of files can be determined by dividing the maximum amount of memory available to a process by the average amount of memory that is needed per object.

The total memory requirement can be reduced by any of the following methods:

- Use the client option memoryefficientbackup diskcachemethod. This choice reduces the use of memory to a minimum at the expense of performance and a significant increase in disk space that is required for the backup. The file description data from the server is stored in a disk-resident temporary database, not in memory. As directories on the workstation are scanned, the database is consulted to determine whether to back up, update, or expire each object. At the completion of the backup, the database file is deleted.
- Use the client option memoryefficientbackup yes. The average memory that is used by the client then becomes 300 bytes times the number of directories plus 300 bytes per file in the directory that is being processed. For file systems with large numbers (millions) of directories, the client still might not be able to allocate enough memory to perform incremental backup with memoryefficientbackup yes.
- AIX Linux Solaris UNIX and Linux clients might be able to use the virtualmountpoint client option to define multiple virtual mount points within a single file system, each of which can be backed up independently by the client.
- If the client option resourceutilization is set to a value greater than 4, and multiple file systems are being backed up, then reducing resourceutilization to 4 or lower limits the process to incremental backup of a single file system at a time. This setting reduces the memory requirement. If the backup of multiple file systems in parallel is required for performance reasons, and the combined memory requirements exceed the process limits, then multiple instances of the backup client can be used to back up multiple file systems in parallel. For example, if you want to back up two file systems at the same time but their memory requirements exceed the limits of a single process, then start one instance of the client to back up one of the file systems, and start a second instance of the client to back up the other file system.
- Use the - incrbydate client option to perform an "incremental-by-date" backup.
- Use the exclude.dirclient option to prevent the client from traversing and backing up directories that do not need to be backed up.
- AIX Linux Solaris Except for Mac OS X, use the client image backup function to back up the entire volume. An image backup might actually use less system resources and run faster than incremental backup of some file systems with a large number of small files.
- Reduce the number of files per file system by spreading the data across multiple file systems.

Include-exclude options to control processing

You might have files in your file systems that you do not want to back up. These files might be core files, local caches of network file systems, operating system or application files that could be easily recovered by reinstalling the program, or any other files that you could easily rebuild.

You can use the exclude and include options in your include-exclude options list to specify which files to exclude from backup processing.

Use the include and exclude options in dsm.sys to define which files to include or exclude from incremental or selective backup processing. A file is eligible for backup unless excluded by an exclude option. It is not necessary to use an include option to include specific files for backup unless those files are in a directory containing other files you want to exclude.

IBM Spectrum Protect™ uses management classes to determine how to manage your backups on the server. Every time you back up a file, the file is assigned a management class. The management class is either a default chosen for you, or one you assign to the file using the include option in the include-exclude list. If you assign a management class, it must contain a backup copy group for the file to be backed up.

Data encryption during backup or archive operations

The way to ensure data security is by encrypting data. Use data encryption to protect data during a backup or archive operation. Advanced Encryption Standard (AES) 128-bit encryption is the default encryption option. For the highest level of data encryption, use 256-bit Advanced Encryption Standard (AES) data encryption by specifying the encryptiontype option.

The data that you include is stored in encrypted form, and encryption does not affect the amount of data that is sent or received.

The include.encrypt option is the only way to enable encryption on the backup-archive client. If no include.encrypt statements are used encryption cannot occur.

Linux Encryption is not compatible with VMware virtual machine backups that use the incremental forever backup modes (MODE=IFIncremental and MODE=IFFull). If the client is configured for encryption, you cannot use incremental forever backup.

Use the include and exclude options in dsm.sys to define which files to include or exclude from incremental or selective backup processing. A file is eligible for backup unless excluded by an exclude option. It is not necessary to use an include option to include specific files for backup unless those files are in a directory that contains other files that you want to exclude.

To encrypt file data, you must select an encryption key password, which the client uses to generate the encryption key for encrypting and decrypting the file data. Store the encryption key password for later use. You can specify whether to save the encryption key password in a file that is named TSM.sth by using the encryptkey option.

IBM Spectrum Protect™ client encryption allows you to enter a value of up to 63 characters in length. This encryption password needs to be confirmed when encrypting the file for backup, and also needs to be entered when performing restores of encrypted files.

While restoring the encrypted file, the client prompts you for the key password to decrypt the file in the following cases:

- The encryptkey option is set to `Prompt`.
- The key supplied by the user in the previous case does not match.
- The encryptkey option is set to `Save` and the locally saved key password does not match the encrypted file.

File system and ACL support

Special file systems contain dynamic information that is generated by the operating system; they contain no data or files. The UNIX and Linux clients ignore special file systems and their contents.

Special file systems include the following types:

- The `/proc` file system on most of the UNIX platforms
- The `/dev/fd` file system on Solaris
- The `/dev/pts` on Linux

The backup-archive client can work on specific file system types that are commonly used. contains For a list of supported file system types, see Table 1.
Restriction: The table shows full support for NFS on AIX®, including preservation of ACLs and extended attributes. On other operating systems, NFS backups are supported, but the backups include only standard POSIX metadata (access permissions, creation date, and so on). For more information about backing up NFS file systems, see Backup network file systems.

Table 1. Supported file systems and ACL support

Platform	File System	ACL Support
AIX	GPFS™	Yes
	JFS	Yes
	JFS2	Yes
	JFS2 NFSV4	Yes
	VxFX	Yes
Linux x86_64	Btrfs	Yes
	XFS	Yes
	EXT2	Yes
	EXT3	Yes
	EXT4	Yes
	ReiserFS	Yes
	GPFS	Yes
	JFS	No
	VxFS	No
	NSS	Yes
Linux on Power Systems™ Servers	Btrfs	Yes
	XFS	Yes
	EXT2	Yes
	EXT3	Yes
	EXT4	Yes
	ReiserFS	Yes
	JFS	No
	GPFS	Yes
Linux on z Systems®	Btrfs	Yes
	EXT2	Yes
	EXT3	Yes
	EXT4	Yes
	ReiserFS	Yes
	JFS	No
	GPFS	Yes

Platform	File System	ACL Support
macOS	HFS Standard (HFS)	Yes
	HFS Extended (HFS+)	Yes
	HFS Extended case-sensitive (HFSX)	Yes
	Xsan (XSAN)	Yes
	Universal disk format (UDF)	Yes
	ISO9660	Yes
	Apple File System (APFS)	Yes
Solaris	UFS	Yes
	VxFS	Yes
	QFS	No
	ZFS	Yes

AIX Solaris With file systems where NFS V4 ACLs are defined and used (Solaris ZFS and AIX JFS2 V2), even if only the standard UNIX permissions or ACLs have changed (such as with the CHMOD command), the file or directory is fully backed up again. With other file systems, this type of change causes only an attribute update on the IBM Spectrum Protect™ server.

AIX Linux Solaris To process all other file systems, use the virtualmountpoint option to enable support for the following items:

- To back up, restore, archive, and retrieve file data
- For basic UNIX and Linux permissions
- For change, access, and modification time stamps, and the directory tree structure

No other file system specific attributes, such as the ACL, are valid. The file system type for such file systems is set to "UNKNOWN".

AIX Linux Solaris For example, if the `/media/abc/DATA1` file system is not supported by the client, add the following statement to dsm.sys to back up or archive the data in this file system:

```
VIRTUALMOUNTPOINT /media/abc/DATA1
```

This support is only available if the file system can use basic POSIX system calls, such as read or write processing on your system. Cross-platform backup and restore are not supported. For example, data backed up by an AIX client is not available for restore by a Windows client and vice versa.
Mac OS X Note: Data that is backed up or archived by the Mac OS X client cannot be restored by any other client. Additionally, the Mac OS X client cannot restore or retrieve data from any other client.

You can use the cross-file system type restore or retrieve method for ACL information if both the original file system and the destination file system support compatible ACLs. For example, on Solaris, the ACL information that is backed up from a VxFS file system is restored to a UFS file system because these file systems support compatible ACLs. The ACL information is not restored during cross-file system restore or retrieve operations if the original file system and the destination file system do not support ACLs,

The stand-alone package LSCqfs 3.5.0 is the only supported version of QFS. In addition, the following restrictions also apply to the QFS file system:

- AIX Linux Solaris Image backup is not supported on QFS file systems.
- The Solaris backup-archive client does not support the combination of QFS and SAM needed to archive files onto tertiary background storage, such as tapes. Instead, it recalls files from tape to disk automatically if it finds migrated files during a backup.
- A QFS file system contains two hidden system files and a system directory that cannot be backed up; and this is acceptable because a backup of these files is not needed. They contain internal data to manage the file system. The internal data is automatically excluded from a backup and is re-created automatically by the file system itself, if a restore of files in that file system is completed.

Incremental, selective, filelist back up, archive, restore, and retrieve processing of the Veritas file system and its ACLs on AIX are supported. Restore of a Veritas volume on a Logical Volume Manager volume (and vice versa) is allowed, provided both have the same file system type.

Mac OS X The following information pertains only to Mac OS X systems:

- On Mac OS X systems, the UFS and HFSX file systems are case-sensitive whereas the HFS+ file system is not case-sensitive but is case-preserving. Files that you back up from a UFS or HFSX file system (case-sensitive) might not be restored properly to an HFS+ file system (not case-sensitive) file system. For example, on a UFS file system, files `Afile` and `afile` are seen as different files. However, on an HFS+ file system the two files are seen as identical.
- On Mac OS X, if case-sensitive HFS+ or UFS file systems are used, it is important that the data from the HFSX or UFS file system is not backed up to an HFS+ file system on the IBM Spectrum Protect server. Either a new name must be used on the system or the existing file space on the IBM Spectrum Protect server must be renamed. For example, consider a system that has a file system named `/Volumes/fs2` and this system is repartitioned with a case-sensitive HFS+ file system. Either the `/Volumes/fs2` file system on the IBM Spectrum Protect server must be renamed, or a new name must be used on the local system. If this renaming is not done, the HFSX case-sensitive data is mixed with the HFS+ case-insensitive data that is already stored on the IBM Spectrum Protect server.
- On Mac OS X, aliases and symbolic links are backed up. However, the client does not back up the data to which the symbolic links point.
- On Mac OS X, when files that are backed up from an HFS volume are restored to a UFS volume, the resource forks are not assigned to the correct owner. Correct this problem by using the chown command on the resource fork file to change the owner. The resource fork file stores structured data in a file.

Linux On Linux on POWER® and Linux on System z®, you must install libacl.so for the client to back up ACLs.

AIX Linux Important: If you are running GPFS for AIX, GPFS for Linux x86_64, or GPFS for Linux on z Systems in a multinode cluster, and all nodes share a mounted GPFS file system, the client processes this file system as a local file system. The client backs up the file system on each node during an incremental backup. To avoid this, you can do one of the following things:

- Explicitly configure the domain statement in the client user-options file (dsm.opt) to list the file systems you want that node to back up.
- Set the exclude.fs option in the dsm.sys file to exclude the GPFS file system from backup services.

If the GPFS cluster contains different platforms, you must use backup-archive clients on only one platform to protect a single file system. Do not use backup-archive clients on more than one platform to protect a GPFS file system that is shared among more than one platform

For example, assume that a cluster contains nodes on AIX, Linux x86, and Linux zSeries systems. You can protect file system A with AIX backup-archive clients and protect file system B with Linux zSeries backup-archive clients. Or you can protect file system A and file system B with AIX backup-archive clients. If you protect file system A with an AIX backup-archive client, you must not protect file system A with a backup-archive client on any platform other than AIX.

Support for cross operating system recovery for files stored in IBM Spectrum Scale file systems

In an IBM Spectrum Scale™ cluster with multiple operating system types, a file that holds ACL or extended attribute metadata and was backed up on a source operating system, can be restored on a target operating system. The ACL or extended attribute metadata is correctly restored correctly if both operating system types on the source and the target use the same version of IBM Spectrum Scale.

The following are the supported source-operating-systems types:

- AIX
- Linux for IBM System Power big endian (pBE)
- Linux x86
- Linux for IBM System z

The following are the supported target-operating-system types:

- Linux for IBM System Power little endian (pLE)
- Linux x86
- Linux for IBM System z

The security settings for affected users and groups must match on both the source and the target systems.

Do not mix operating system types for backup activity. Choose only one operating system type available in your IBM Spectrum Scale cluster, and use it for all backup operations.

Mac OS X AIX Linux Solaris

Maximum file size for operations

The maximum file size depends on the type of a file system. The backup-archive client does not check any file size limit during backup, archive, restore, or retrieve operations.

If the file system allows creation of the file, the client backs up or archives the file.

The following table specifies the maximum file sizes for the native file systems on UNIX and Linux client platforms.

Table 1. Maximum file size

Platform	Max file size (in bytes)
AIX AIX® 6.1 (JFS2) size limitations	AIX Maximum JFS2 file system size: 32 TB Maximum JFS2 file size: 16 TB Minimum JFS2 file system size: 16 MB
Linux All Linux clients	Linux 9 223 372 036 854 775 807 (8 EB-1)
Mac OS X Mac OS X	Mac OS X HFS - 2 147 485 648 (2GB) HFS+, HFSX, XSAN, and UFS - 9 223 372 036 854 775 808 (8EB)
Solaris Solaris	Solaris 1 099 511 627 775 (1 TB-1)
Solaris Solaris (ZFS)	Solaris 18 446 744 073 709 551 616 (16 EB)

Mac OS X | AIX | Linux | Solaris | Windows

Long user and group names

The backup-archive client can handle user and group names that are up to 64 characters without any issues. However, names longer than 64 characters require special handling by IBM Spectrum Protect™.

Important: Do not exceed the 64 character limit for user and group names. If you do, the client shortens the name to fall within this limit by using the following transformation: Take the first 53 characters, append a forward slash (/), and then the numeric ID as a character string.

An error message is logged that contains both the long name and the resulting shortened string. For most functions, you do not need to be aware of the shortened name. The exceptions are:

- The set access command
- The fromowner option
- The users and groups (authorization) options

In each of these cases, when you need to enter a name, you either have to find the error message containing the transformation, or construct the name using the rule outlined here.

Mac OS X

Mac OS X volume names

The backup-archive client backs up volumes based on their UNIX mount point name.

IBM Spectrum Protect™ maintains each volume name as a separate restore or retrieve volume. These volume names become the names of file spaces on the server.

If you change the name of a volume you have already backed up, the client sees it as a new volume and does not relate it to the previous one. Any backup of the volume backs up the files under the new name. A mismatch might occur if you rename your volumes, or if you access IBM Spectrum Protect from a different workstation than the one from which you backed up the files.

- Mac OS X Mac OS X volume naming precautions
  IBM Spectrum Protect creates all new file spaces on the server with the UNIX mount point of the volume.

- Mac OS X Mac OS X volume naming precautions on dual boot systems
  If you have more than one version of Mac OS X that you switch between, it is critical that you understand how the client uses the UNIX mount paths for file space names on the IBM Spectrum Protect server.

Mac OS X

Mac OS X volume naming precautions

IBM Spectrum Protect™ creates all new file spaces on the server with the UNIX mount point of the volume.

If there are two volumes with the names such as "`La Pomme`" and "`la pomme`", two unique UNIX mount points are created.

The following examples show the two mount points that are created:

```
/Volumes/La Pomme
/Volumes/la pomme
```

If duplicate volumes exist on your desktop, it is possible for the UNIX mount points to be different than the last time the client did a backup. The client might not back up the data to the correct file system on the IBM Spectrum Protect server.

You can check the file system where the client backs up the data:

1. In the Backup window, select a file system.
2. Click **File** → **Show Info**.

The UNIX mount point is in the Information dialog.

The best way to avoid any potential naming problems is to ensure that the volume names are unique.

Important:

- The client continues to use the existing file space names on the IBM Spectrum Protect Server. Only new file spaces use the UNIX mount point for the name.
- Do not specify volumes with periods in the name (...). The client uses the sequence of periods as part of include-exclude processing. The client reports an invalid include-exclude statement if a volume has a sequence of periods in the name. The volume *must* be renamed.

Mac OS X

Mac OS X volume naming precautions on dual boot systems

If you have more than one version of Mac OS X that you switch between, it is critical that you understand how the client uses the UNIX mount paths for file space names on the IBM Spectrum Protect™ server.

For example, consider a dual-boot system that has two volumes, `El Capitan` and `Sierra`. The finder and the backup-archive client GUI displays these as `El Capitan` and `Sierra`. However, the UNIX mount points depend upon which version of Mac OS is running. If El Capitan is the startup disk, the UNIX paths are:

```
/
/Volumes/Sierra
```

If Sierra is the startup disk, the UNIX paths are:

```
/
/Volumes/El Capitan
```

When a backup or archive operation is run, the file space names also depend on which version of Mac OS X is running.

Both versions of Mac OS X back up to the `/` file system on the IBM Spectrum Protect server. When this happens, the system files are intermixed.

To avoid potential problems on dual-boot systems, complete one of these tasks:

1. Select one version of Mac OS X on which to install and run IBM Spectrum Protect. This ensures that the UNIX mount points are the same each time the client does a backup.
2. Configure each version of Mac OS X with a unique IBM Spectrum Protect node name. Then exclude the other version of Mac OS X from backup processing with a domain statement in the system options file. For example, if the volume Sierra is the

startup disk, add this option to the system options file:

```
DOMAIN -/Volumes/El Capitan
```

If the volume El Capitan is the startup disk, add this to the system options file:

```
DOMAIN -/Volumes/Sierra
```

Mac OS X

Mac OS X Unicode enablement

The Mac OS X client is Unicode enabled. New clients storing data on the server for the first time require no special set up.

The server automatically stores files and directories as Unicode enabled. However, if you are upgrading to the Unicode-enabled client, you need to plan the migration of existing file spaces so they can support Unicode.

Any file spaces that are already on the server must be renamed so Unicode-enabled file spaces can be created. Use the autofsrename option rename existing file spaces.

Related reference:
Autofsrename
Mac OS X

Mac OS X Time Machine backup disk

Time Machine is the backup application available with Mac OS X.

IBM Spectrum Protect™ can be used at the same time as Mac OS X Time Machine application. However, due to the unique nature of how the Mac OS X Time Machine application backs up data, consider the following items before using the backup-archive client to back up the Mac OS X Time Machine data:

- The Mac OS X Time Machine backup disk makes extensive use of both file and directory hard links to minimize disk usage. For example, if the disk backed up with the Mac OS X Time Machine application is 5 GB, the first backup copies 5 GBs of data to the Mac OS X Time Machine backup disk.

  Subsequent backups only copy the files that have changed since the previous backup. All files and directories that have not changed are hard-linked with the version that was copied during the previous backup.

  The Finder shows each backup as 5 GB, for a total size of 10 GB. However, because of the use of hard links, the total disk usage is only slightly larger than 5 GB.

  All hard-linked objects that are not already on the IBM Spectrum Protect server are backed up.

  For example, 10 GB of data would be sent to the IBM Spectrum Protect server.

- When files that are restored are hard-linked, the client recreates the original hard link. Recreating the original hard link can only be done if *all* files that are hard-linked are restored at the same time. Restoring all the hard-linked files at the same time is not a practical method for a large backup disk that uses the Mac OS X Time Machine application.
- When the Mac OS X Time Machine application copies files to the backup disk, ACLs are added to the files to protect them from deletion. the backup-archive can back up and restore files with ACLs. However, any files that are restored must have these restrictive ACLs in place.

Tip: For best results, exclude the Time Machine application backup data. All Time Machine application data is in a directory named `Backups.backupdb`.

System files to exclude
Windows

Incremental, selective, or incremental-by-date backups (Windows)

Your administrator might set up schedules to automatically back up files. This section contains information about how to back up files without a schedule.

There are three types of incremental backup: *full*, *partial*, and *incremental-by-date*.

If you migrate files with IBM Spectrum Protect™ HSM for Windows, there can be consequences for backup operations.

- Windows Full and partial incremental backup
  An incremental backup backs up only new and changed files. The type of incremental backup depends on what objects you select to be backed up.
- Windows Incremental-by-date backup
  For a file system to be eligible for incremental-by-date backups, you must have performed at least one full incremental backup of that file system. Running an incremental backup of only a directory branch or individual file will not make the file system eligible for incremental-by-date backups.
- Windows Comparing incremental-by-date, journal-based, and NetApp snapshot difference to full incremental and partial incremental backups
  Incremental-by-date, journal-based, and NetApp snapshot difference are alternatives to full incremental and partial incremental back methods.
- Windows Snapshot differential backup with an HTTPS connection
  You can use a secure HTTPS connection for the backup-archive client to communicate with a NetApp filer during a snapshot differential backup.
- Windows Selective backup
  Use a selective backup when you want to back up specific files or directories regardless of whether a current copy of those files exists on the server.

Related concepts:
Windows Backup and restore of migrated files
Related tasks:
Setting the client scheduler process to run as a background task and start automatically at startup

Full and partial incremental backup

An incremental backup backs up only new and changed files. The type of incremental backup depends on what objects you select to be backed up.

Mac OS X AIX Linux Solaris If you select entire file systems, the backup is a full incremental backup. If you select a directory tree or individual files, the backup is a partial incremental backup.

Windows If you select entire drives, the backup is a full incremental backup. If you select a directory tree or individual files, the backup is a partial incremental backup.

The first time that you run a full incremental backup, the backup-archive client backs up all the files and directories that you specify. The backup operation can take a long time if the number of files is large, or if one or more large files must be backed up. Subsequent full incremental backups only back up new and changed files. The backup server maintains current versions of your files without having to waste time or space by backing up files that exist in IBM Spectrum Protect™ server storage.

Mac OS X AIX Linux Solaris Windows Depending on your storage management policies, the IBM Spectrum Protect server might keep more than one version of your files in storage. The most recently backed up files are active backup versions. Older copies of your backed up files are inactive versions. However, if you delete a file from your workstation, the next full incremental backup causes the active backup version of the file to become inactive. You can restore an inactive version of a file. The number of inactive versions that are maintained by the server and how long they are retained is governed by the management policies that are defined by your IBM Spectrum Protect server administrator. The active versions represent the files that existed on your file system at the time of the last backup.

Mac OS X AIX Linux Solaris Windows To start a full or partial incremental backup by using the client GUI, select Backup, and then select the Incremental (complete) option. From the command line, use the incremental command and specify file systems, directory trees, or individual files to include in the backup.

Mac OS X AIX Linux Solaris Windows During an incremental backup, the client queries the server or the journal database to determine the exact state of your files since the last incremental backup. The client uses this information for the following tasks:

- Back up new files.
- Back up files whose contents changed since the last backup.
  Windows Files are backed up when any of the following attributes change:
  - File size

- Date or time of last modification
- Extended Attributes
- Access Control List
- Sparse, reparse point or encrypted file attributes.
- NTFS or ReFS file security descriptors:Owner Security Identifier (SID), Group SID, Discretionary Access Control List (ACL), and System ACL.
- Directory attributes

If only the following attributes change, the attributes are updated on the IBM Spectrum Protect server, but the file is not backed up:

- Read-only or read/write
- Hidden or not hidden
- Compressed or not compressed

The archive attribute is not examined by IBM Spectrum Protect in determining changed files.

Mac OS X | AIX | Linux | Solaris Files are backed up when any of the following attributes change:

- File size
- Date or time of last modification
- Extended Attributes
- Access Control List

If only the following attributes change, the attributes are updated on the IBM Spectrum Protect server, but the file is not backed up:

- File owner
- File permissions
- Inode
- Group ID
- AIX | Linux Change time (`ctime`) attribute (for objects in GPFS file systems only and if the updatectime option is set to yes). For more details, see the updatectime option.
- Icon location (Mac OS X only)
- Type or creator (Mac OS X only)

- Back up directories.
  A directory is backed up in any of the following circumstances:
  - The directory was not previously backed up.
  - The directory permissions changed since the last backup.
  - The directory Access Control List changed since the last backup.
  - The directory Extended Attributes changed since the last backup.
  - AIX | Linux The change time (`ctime`) attribute is updated since the last backup (for GPFS file systems only). For more details, see the updatectime option.

  Mac OS X | AIX | Linux | Solaris | Windows Directories are counted in the number of objects that are backed up. To exclude directories and their contents from backup, use the exclude.dir option.

- Mac OS X | AIX | Linux | Solaris | Windows Expire backup versions of files on the server that do not have corresponding files on the workstation. The result is that files that no longer exist on your workstation do not have active backup versions on the server. However, inactive versions are retained according to rules defined by the IBM Spectrum Protect administrator.
- Rebind backup versions if management class assignments change. Only objects that have active backup versions are bound again. Objects for which only inactive backup versions exist are not bound again.
  During a partial incremental backup operation, objects are rebound or expired as follows:

  If the file specification matches all files in a path:
  Rebinding and expiration occurs for all eligible backup versions that match the file specification. This is the case for an incremental command like `dsmc incr c:\mydir\* -subdir=yes`.
  If the file specification does not match all files in a path:
  Rebinding and expiration occurs for all eligible backup versions that match the file specification. However, eligible backup versions are not expired or rebound if they were in a directory that no longer exists on the client file system.

  Consider an incremental command like `dsmc incr c:\mydir\*.txt -subdir=yes`. Assume that some files in c:\mydir\ do not have the txt file type. Rebinding and expiration occurs only for files that match the *.txt specification and whose directories still exist on the client file system.

Mac OS X | AIX | Linux | Solaris | Windows You can use the preservelastaccessdate option to specify whether to modify the last access date after a backup or archive operation. By default, the access date changes after a backup or archive operation.

- Windows Journal-based backup
  Journal-based backup is an alternate method of backup that uses a change journal maintained by the IBM Spectrum Protect journal service process.

Incremental-by-date backup

For a file system to be eligible for incremental-by-date backups, you must have performed at least one full incremental backup of that file system. Running an incremental backup of only a directory branch or individual file will not make the file system eligible for incremental-by-date backups.

Windows To perform an incremental-by-date backup using the GUI, select the incremental (date only) option from the *type of backup* pull-down menu or use the incrbydate option with the incremental command.

The client backs up only those files whose modification date and time is later than the date and time of the last incremental backup of the file system on which the file resides. Files added by the client after the last incremental backup, but with a modification date earlier than the last incremental backup, are not backed up.

Files that were renamed after the last incremental backup, but otherwise remain unchanged, will not be backed up. Renaming a file does not change the modification date and time of the file. However, renaming a file does change the modification date of the directory in which it is located. In this case, the directory is backed up, but not the files it contains.

If you run an incremental-by-date backup of the whole file system, the server updates the date and time of the last incremental backup. If you perform an incremental-by-date backup on only part of a file system, the server does not update the date of the last full incremental backup. In this case, the next incremental-by-date backup backs up these files again.

Note: Unlike incremental backups, incremental-by-date backups do not expire deleted files or rebind backup versions to a new management class if you change the management class.

Comparing incremental-by-date, journal-based, and NetApp snapshot difference to full incremental and partial incremental backups

Incremental-by-date, journal-based, and NetApp snapshot difference are alternatives to full incremental and partial incremental back methods.

Incremental-by-date backup
An incremental-by-date backup takes less time to process than a full incremental backup and requires less memory.

An incremental-by-date backup might not place exactly the same backup files into server storage because the incremental-by-date backup:

- Mac OS X AIX Linux Solaris Windows Does not expire backup versions of files that you delete from the workstation.
- Does not rebind backup versions to a new management class if you change the management class.
- Does not back up files with attributes that change, unless the modification dates and times also change.
- Mac OS X AIX Linux Solaris Windows Ignores the copy group frequency attribute of management classes (Journal-based backups also ignore this attribute).

Journal-based backup

AIX Linux Windows The memory requirements for an initial journaling environment are the same as the memory requirements for a full file space incremental, because journal-based backups must complete the full file space incremental in order to set the journal database as valid, and to establish the baseline for journaling.

AIX Linux Windows The memory requirements for subsequent journal-based backups are much less. Journal backup sessions run in parallel and are governed by the resourceutilization client option in the same manner as normal backup sessions. The size of the journal database file reverts to a minimal size (less than 1 KB) when the last entry has been deleted from the journal. Since entries are deleted from the journal as they are processed by the client, the disk size occupied by the journal should be minimal after a complete journal backup. A full incremental backup with journaling active takes less time to process than an incremental-by-date backup.

AIX Linux On AIX and Linux, journal-based backup does have some limitations. See Journal-based backup on AIX and Linux for information.

NetApp snapshot difference

Linux Windows For NAS and N-Series file servers that are running ONTAP 7.3.0, or later, you can use the snapdiff option to invoke the snapshot difference backup from NetApp when running a full-volume incremental backup. Using this option reduces memory usage and is faster.

Linux Windows Consider the following restrictions when running a full-volume incremental backup using the snapdiff option, to ensure that data is backed up when it should be.

- A file is excluded due to an exclude rule in the include-exclude file. The client runs a backup of the current snapshot with that exclude rule in effect. This happens when you have not made changes to the file, but you have removed the rule that excluded the file. NetApp will not detect this include-exclude change because it only detects file changes between two snapshots.
- If you added an include statement to the option file, that include option does not take effect unless NetApp detects that the file has changed. The client does not inspect every file on the volume during backup.
- If you used the dsmc delete backup command to explicitly delete a file from the IBM Spectrum Protect inventory, NetApp cannot detect that a file was manually deleted from IBM Spectrum Protect storage. Therefore, the file remains unprotected in IBM Spectrum Protect storage until it is changed on the volume and the change is detected by NetApp, which signals the client to back it up again.
- Policy changes such as changing the policy from mode=modified to mode=absolute are not detected.
- The entire file space is deleted from the IBM Spectrum Protect inventory. This action causes the snapdiff option to create a new snapshot to use as the source, and a full incremental backup to be run.

The NetApp software determines what is a changed object, not IBM Spectrum Protect.

Linux If you run a full volume backup of an NFS-mounted NetApp or N-Series volume, all the snapshots under the snapshot directory might also be backed up.

To avoid backing up all snapshots under the snapshot directory, do one of the following actions:

- Run NDMP backups
- Run backups using the snapshotroot option
- Run incremental backups using the snapdiff option
  Tip: If you run an incremental backup using the snapdiff option and you schedule periodic incremental backups, use the createnewbase=yes option with the snapdiff option to create a base snapshot and use it as a source to run an incremental backup.
- Exclude the snapshot directory from backups.
  Linux On Linux systems, the snapshot directory is in .snapshot.
  Note: The .snapshot directory is not backed up for some versions of Red Hat Linux, so you are not required to exclude it.

  Windows On Windows systems, the snapshot directory is in ~snapshot.

Windows

Snapshot differential backup with an HTTPS connection

You can use a secure HTTPS connection for the backup-archive client to communicate with a NetApp filer during a snapshot differential backup.

The HTTPS protocol is enabled on NetApp filers by default and cannot be disabled.

When you run a snapshot differential backup, the backup-archive client establishes an administrative session with a NetApp filer. The filer credentials, such as the filer host name or IP address, the user name that is used to connect to the filer, and the filer password, are stored locally on the backup-archive client. This information must be transmitted to the filer to establish the

authenticated administrative session. It is important to use a secure connection because authenticating the administrative filer session requires the client to transmit the filer password in clear text.

To establish a secure connection by using the HTTPS communication protocol, you must use the snapdiffhttps option whenever you run a snapshot differential backup. Without the snapdiffhttps option, the backup-archive client can establish filer sessions only with the HTTP protocol, which would require HTTP administrative access to be enabled on the filer. With the snapdiffhttps option, you can establish a secure administrative session with the NetApp filer regardless of whether HTTP administrative access is enabled on the NetApp filer.

Restrictions:

The following restrictions apply to snapshot differential backups with HTTPS:

- The HTTPS connection is used only to securely transmit data over the administrative session between the backup-archive client and the NetApp filer. The administrative session data includes information such as filer credentials, snapshot information, and file names and attributes that are generated by the snapshot differencing process. The HTTPS connection is not used to transmit normal file data that is accessed on the filer by the client through file sharing. The HTTPS connection also does not apply to normal file data transmitted by the client to the IBM Spectrum Protect™ server through the normal IBM Spectrum Protect client/server protocol.
- The snapdiffhttps option does not apply to vFilers because the HTTPS protocol is not supported on the NetApp vFiler.
- The snapdiffhttps option is available only by using the command-line interface. It is not available for use with the backup-archive client GUI.

- Windows Running a snapshot differential backup with an HTTPS connection
  When you run a snapshot differential backup, you can use the snapdiffhttps option to create a secure HTTPS connection between the backup-archive client and the NetApp filer.

Selective backup

Use a selective backup when you want to back up specific files or directories regardless of whether a current copy of those files exists on the server.

Incremental backups are generally part of an automated system to back up entire file systems. In contrast, selective backups allow you to manually select a set of files to back up regardless of whether they have changed since your last incremental backup.

Unlike incremental backups, a selective backup provides the following:

- Does not cause the server to update the date and time of the last incremental.
- Backs up directory and file entries even if their size, modification timestamp, or permissions have not changed.
- Does not expire deleted files.
- Does not rebind backup versions to a new management class if you change the management class.

Mac OS X AIX Linux Solaris

Performing an incremental, selective, or incremental-by-date backup (UNIX and Linux)

Your administrator might have set up schedules to automatically back up files on your workstation. The following sections discuss how to back up files without using a schedule.

There are two types of incremental backup: *full incremental* and *partial incremental*.

- AIX Linux Mac OS X Solaris Full and partial incremental backup
  An incremental backup backs up only new and changed files. The type of incremental backup depends on what objects you select to be backed up.
- AIX Linux Mac OS X Solaris Incremental-by-date backup
  For a file system to be eligible for incremental-by-date backups, you must have performed at least one full incremental backup of that file system. Running an incremental backup of only a directory branch or individual file will not make the file system eligible for incremental-by-date backups.
- AIX Linux Mac OS X Solaris Comparing incremental-by-date, journal-based, and NetApp snapshot difference to full incremental and partial incremental backups
  Incremental-by-date, journal-based, and NetApp snapshot difference are alternatives to full incremental and partial incremental back methods.
- AIX Linux Mac OS X Solaris Snapshot differential backup with an HTTPS connection
  You can use a secure HTTPS connection for the backup-archive client to communicate with a NetApp filer during a snapshot differential backup.
- AIX Linux Mac OS X Solaris Selective backup
  Use a selective backup when you want to back up specific files or directories regardless of whether a current copy of those files exists on the server.
- Solaris Solaris global zone and non-global zones backups
  For Solaris zones, perform incremental and selective backups of file systems within the zone where these file systems were created.
- Mac OS X AIX Linux Solaris Saving access permissions
  When you back up your files, the backup-archive client also saves standard UNIX access permissions assigned to the files.
- Mac OS X AIX Linux Solaris Setting a virtual mount point
  If you are an authorized user and you want to back up files beginning with a specific directory within a file system, you can define that directory as a virtual mount point.
- Mac OS X AIX Linux Solaris Backing up data using the Java GUI
  You can back up specific files, entire directories, or entire file systems from the directory tree.
- Mac OS X AIX Linux Solaris Backing up data using the command line
  You can use the incremental or selective commands to perform backups.
- Mac OS X AIX Linux Solaris Deleting backup data
  If your administrator has given you authority, you can delete individual backup copies from the IBM Spectrum Protect server without deleting the entire file space. To determine if you have this authority, select File > Connection Information from the backup-archive client GUI or web client main menu. Your authority status is provided in the Delete Backup Files field.
- AIX Linux Solaris Mac OS X Deleting file spaces
  If your IBM Spectrum Protect administrator gives you authority, you can delete entire file spaces from the server. When you delete a file space, you delete all the files and images, both backup versions and archive copies, that are contained within the file space. For example, if you delete the `/tmp` file space, you are deleting every backup for every file in that file system and every file you archived from that file system. Carefully consider whether you want to delete a file space.

Related tasks:
Setting the client scheduler process to run as a background task and start automatically at startup

Full and partial incremental backup

An incremental backup backs up only new and changed files. The type of incremental backup depends on what objects you select to be backed up.

Mac OS X AIX Linux Solaris If you select entire file systems, the backup is a full incremental backup. If you select a directory tree or individual files, the backup is a partial incremental backup.

Windows If you select entire drives, the backup is a full incremental backup. If you select a directory tree or individual files, the backup is a partial incremental backup.

The first time that you run a full incremental backup, the backup-archive client backs up all the files and directories that you specify. The backup operation can take a long time if the number of files is large, or if one or more large files must be backed up. Subsequent full incremental backups only back up new and changed files. The backup server maintains current versions of your files without having to waste time or space by backing up files that exist in IBM Spectrum Protect™ server storage.

Mac OS X | AIX | Linux | Solaris | Windows Depending on your storage management policies, the IBM Spectrum Protect server might keep more than one version of your files in storage. The most recently backed up files are active backup versions. Older copies of your backed up files are inactive versions. However, if you delete a file from your workstation, the next full incremental backup causes the active backup version of the file to become inactive. You can restore an inactive version of a file. The number of inactive versions that are maintained by the server and how long they are retained is governed by the management policies that are defined by your IBM Spectrum Protect server administrator. The active versions represent the files that existed on your file system at the time of the last backup.

Mac OS X | AIX | Linux | Solaris | Windows To start a full or partial incremental backup by using the client GUI, select Backup, and then select the Incremental (complete) option. From the command line, use the incremental command and specify file systems, directory trees, or individual files to include in the backup.

Mac OS X | AIX | Linux | Solaris | Windows During an incremental backup, the client queries the server or the journal database to determine the exact state of your files since the last incremental backup. The client uses this information for the following tasks:

- Back up new files.
- Back up files whose contents changed since the last backup.
  Windows Files are backed up when any of the following attributes change:
  - File size
  - Date or time of last modification
  - Extended Attributes
  - Access Control List
  - Sparse, reparse point or encrypted file attributes.
  - NTFS or ReFS file security descriptors:Owner Security Identifier (SID), Group SID, Discretionary Access Control List (ACL), and System ACL.
  - Directory attributes

  If only the following attributes change, the attributes are updated on the IBM Spectrum Protect server, but the file is not backed up:
  - Read-only or read/write
  - Hidden or not hidden
  - Compressed or not compressed

  The archive attribute is not examined by IBM Spectrum Protect in determining changed files.
  Mac OS X | AIX | Linux | Solaris Files are backed up when any of the following attributes change:
  - File size
  - Date or time of last modification
  - Extended Attributes
  - Access Control List

  If only the following attributes change, the attributes are updated on the IBM Spectrum Protect server, but the file is not backed up:
  - File owner
  - File permissions
  - Inode
  - Group ID
  - AIX | Linux Change time (`ctime`) attribute (for objects in GPFS file systems only and if the updatectime option is set to yes). For more details, see the updatectime option.
  - Icon location (Mac OS X only)
  - Type or creator (Mac OS X only)
- Back up directories.
  A directory is backed up in any of the following circumstances:
  - The directory was not previously backed up.
  - The directory permissions changed since the last backup.
  - The directory Access Control List changed since the last backup.
  - The directory Extended Attributes changed since the last backup.
  - AIX | Linux The change time (`ctime`) attribute is updated since the last backup (for GPFS file systems only). For more details, see the updatectime option.

  Mac OS X | AIX | Linux | Solaris | Windows Directories are counted in the number of objects that are backed up. To exclude directories and their contents from backup, use the exclude.dir option.

- Mac OS X | AIX | Linux | Solaris | Windows Expire backup versions of files on the server that do not have corresponding files on the workstation. The result is that files that no longer exist on your workstation do not have active

backup versions on the server. However, inactive versions are retained according to rules defined by the IBM Spectrum Protect administrator.

- Rebind backup versions if management class assignments change. Only objects that have active backup versions are bound again. Objects for which only inactive backup versions exist are not bound again.
  During a partial incremental backup operation, objects are rebound or expired as follows:

  If the file specification matches all files in a path:
  Rebinding and expiration occurs for all eligible backup versions that match the file specification. This is the case for an incremental command like `dsmc incr c:\mydir\* -subdir=yes`.
  If the file specification does not match all files in a path:
  Rebinding and expiration occurs for all eligible backup versions that match the file specification. However, eligible backup versions are not expired or rebound if they were in a directory that no longer exists on the client file system.

  Consider an incremental command like `dsmc incr c:\mydir\*.txt -subdir=yes`. Assume that some files in c:\mydir\ do not have the txt file type. Rebinding and expiration occurs only for files that match the *.txt specification and whose directories still exist on the client file system.

Mac OS X | AIX | Linux | Solaris | Windows You can use the preservelastaccessdate option to specify whether to modify the last access date after a backup or archive operation. By default, the access date changes after a backup or archive operation.

- AIX Journal-based backup on AIX and Linux
  Journal-based backup is an alternate method of backup that uses a change journal maintained by the IBM Spectrum Protect journal daemon process.

Incremental-by-date backup

For a file system to be eligible for incremental-by-date backups, you must have performed at least one full incremental backup of that file system. Running an incremental backup of only a directory branch or individual file will not make the file system eligible for incremental-by-date backups.

Windows To perform an incremental-by-date backup using the GUI, select the incremental (date only) option from the *type of backup* pull-down menu or use the incrbydate option with the incremental command.

The client backs up only those files whose modification date and time is later than the date and time of the last incremental backup of the file system on which the file resides. Files added by the client after the last incremental backup, but with a modification date earlier than the last incremental backup, are not backed up.

Files that were renamed after the last incremental backup, but otherwise remain unchanged, will not be backed up. Renaming a file does not change the modification date and time of the file. However, renaming a file does change the modification date of the directory in which it is located. In this case, the directory is backed up, but not the files it contains.

If you run an incremental-by-date backup of the whole file system, the server updates the date and time of the last incremental backup. If you perform an incremental-by-date backup on only part of a file system, the server does not update the date of the last full incremental backup. In this case, the next incremental-by-date backup backs up these files again.

Note: Unlike incremental backups, incremental-by-date backups do not expire deleted files or rebind backup versions to a new management class if you change the management class.
Related tasks:
AIX | Linux | Mac OS X | Solaris Backing up data using the Java GUI
Windows | AIX | Linux

Comparing incremental-by-date, journal-based, and NetApp snapshot difference to full incremental and partial incremental backups

Incremental-by-date, journal-based, and NetApp snapshot difference are alternatives to full incremental and partial incremental back methods.

Incremental-by-date backup

An incremental-by-date backup takes less time to process than a full incremental backup and requires less memory.

An incremental-by-date backup might not place exactly the same backup files into server storage because the incremental-by-date backup:

- Mac OS X | AIX | Linux | Solaris | Windows Does not expire backup versions of files that you delete from the workstation.
- Does not rebind backup versions to a new management class if you change the management class.
- Does not back up files with attributes that change, unless the modification dates and times also change.
- Mac OS X | AIX | Linux | Solaris | Windows Ignores the copy group frequency attribute of management classes (Journal-based backups also ignore this attribute).

Journal-based backup

AIX | Linux | Windows The memory requirements for an initial journaling environment are the same as the memory requirements for a full file space incremental, because journal-based backups must complete the full file space incremental in order to set the journal database as valid, and to establish the baseline for journaling.

AIX | Linux | Windows The memory requirements for subsequent journal-based backups are much less. Journal backup sessions run in parallel and are governed by the resourceutilization client option in the same manner as normal backup sessions. The size of the journal database file reverts to a minimal size (less than 1 KB) when the last entry has been deleted from the journal. Since entries are deleted from the journal as they are processed by the client, the disk size occupied by the journal should be minimal after a complete journal backup. A full incremental backup with journaling active takes less time to process than an incremental-by-date backup.

AIX | Linux On AIX and Linux, journal-based backup does have some limitations. See Journal-based backup on AIX and Linux for information.

NetApp snapshot difference

Linux | Windows For NAS and N-Series file servers that are running ONTAP 7.3.0, or later, you can use the snapdiff option to invoke the snapshot difference backup from NetApp when running a full-volume incremental backup. Using this option reduces memory usage and is faster.

Linux | Windows Consider the following restrictions when running a full-volume incremental backup using the snapdiff option, to ensure that data is backed up when it should be.

- A file is excluded due to an exclude rule in the include-exclude file. The client runs a backup of the current snapshot with that exclude rule in effect. This happens when you have not made changes to the file, but you have removed the rule that excluded the file. NetApp will not detect this include-exclude change because it only detects file changes between two snapshots.
- If you added an include statement to the option file, that include option does not take effect unless NetApp detects that the file has changed. The client does not inspect every file on the volume during backup.
- If you used the dsmc delete backup command to explicitly delete a file from the IBM Spectrum Protect inventory, NetApp cannot detect that a file was manually deleted from IBM Spectrum Protect storage. Therefore, the file remains unprotected in IBM Spectrum Protect storage until it is changed on the volume and the change is detected by NetApp, which signals the client to back it up again.
- Policy changes such as changing the policy from mode=modified to mode=absolute are not detected.
- The entire file space is deleted from the IBM Spectrum Protect inventory. This action causes the snapdiff option to create a new snapshot to use as the source, and a full incremental backup to be run.

The NetApp software determines what is a changed object, not IBM Spectrum Protect.

Linux If you run a full volume backup of an NFS-mounted NetApp or N-Series volume, all the snapshots under the snapshot directory might also be backed up.

To avoid backing up all snapshots under the snapshot directory, do one of the following actions:

- Run NDMP backups
- Run backups using the snapshotroot option
- Run incremental backups using the snapdiff option

Tip: If you run an incremental backup using the snapdiff option and you schedule periodic incremental backups, use the createnewbase=yes option with the snapdiff option to create a base snapshot and use it as a source to run an incremental backup.

- Exclude the snapshot directory from backups.
  Linux On Linux systems, the snapshot directory is in .snapshot.
  Note: The .snapshot directory is not backed up for some versions of Red Hat Linux, so you are not required to exclude it.

  Windows On Windows systems, the snapshot directory is in ~snapshot.

Linux

Snapshot differential backup with an HTTPS connection

You can use a secure HTTPS connection for the backup-archive client to communicate with a NetApp filer during a snapshot differential backup.

The HTTPS protocol is enabled on NetApp filers by default and cannot be disabled.

When you run a snapshot differential backup, the backup-archive client establishes an administrative session with a NetApp filer. The filer credentials, such as the filer host name or IP address, the user name that is used to connect to the filer, and the filer password, are stored locally on the backup-archive client. This information must be transmitted to the filer to establish the authenticated administrative session. It is important to use a secure connection because authenticating the administrative filer session requires the client to transmit the filer password in clear text.

To establish a secure connection by using the HTTPS communication protocol, you must use the snapdiffhttps option whenever you run a snapshot differential backup. Without the snapdiffhttps option, the backup-archive client can establish filer sessions only with the HTTP protocol, which would require HTTP administrative access to be enabled on the filer. With the snapdiffhttps option, you can establish a secure administrative session with the NetApp filer regardless of whether HTTP administrative access is enabled on the NetApp filer.

Restrictions:

The following restrictions apply to snapshot differential backups with HTTPS:

- The HTTPS connection is used only to securely transmit data over the administrative session between the backup-archive client and the NetApp filer. The administrative session data includes information such as filer credentials, snapshot information, and file names and attributes that are generated by the snapshot differencing process. The HTTPS connection is not used to transmit normal file data that is accessed on the filer by the client through file sharing. The HTTPS connection also does not apply to normal file data transmitted by the client to the IBM Spectrum Protect™ server through the normal IBM Spectrum Protect client/server protocol.
- The snapdiffhttps option does not apply to vFilers because the HTTPS protocol is not supported on the NetApp vFiler.
- The snapdiffhttps option is available only by using the command-line interface. It is not available for use with the backup-archive client GUI.
- AIX | Linux | Mac OS X | Solaris Running a snapshot differential backup with an HTTPS connection
  When you run a snapshot differential backup, you can use the snapdiffhttps option to create a secure HTTPS connection between the backup-archive client and the NetApp filer.

Selective backup

Use a selective backup when you want to back up specific files or directories regardless of whether a current copy of those files exists on the server.

Incremental backups are generally part of an automated system to back up entire file systems. In contrast, selective backups allow you to manually select a set of files to back up regardless of whether they have changed since your last incremental backup.

Unlike incremental backups, a selective backup provides the following:

- Does not cause the server to update the date and time of the last incremental.
- Backs up directory and file entries even if their size, modification timestamp, or permissions have not changed.
- Does not expire deleted files.
- Does not rebind backup versions to a new management class if you change the management class.

Related tasks:
Windows Backing up data using the GUI
Mac OS X AIX Linux Solaris Backing up data using the Java GUI
Related reference:
Selective
Solaris

Solaris global zone and non-global zones backups

For Solaris zones, perform incremental and selective backups of file systems within the zone where these file systems were created.

Treat each non-global zone as a separate system that has its own IBM Spectrum Protect™ node name and run backups from within each of the zones.

If you run incremental or selective backups of non-global zones from the global zone, the global-zone administrator must decide which files in the non-global zone are included or excluded in backups. For example, device, system and kernel files of the non-global zones are not automatically excluded from backups, but they must not be backed up. Restoring such files can make a non-global zone unusable.

Mac OS X AIX Linux Solaris

Saving access permissions

When you back up your files, the backup-archive client also saves standard UNIX access permissions assigned to the files.

Depending on your operating system, it also saves extended permissions. For example, for files on an AIX® workstation, the client saves access control lists.

It is possible for an authorized user to back up files for another user, but this should not cause ownership conflicts. The backup server properly records that the file belongs to the original owner. The authorized user does not need to grant the original owner access to the backup versions.

Mac OS X AIX Linux Solaris

Setting a virtual mount point

If you are an authorized user and you want to back up files beginning with a specific directory within a file system, you can define that directory as a virtual mount point.

Defining a virtual mount point within a file system provides a direct path to the files you want to back up, saving processing time. It is more efficient than defining the file system with the domain option and then using an exclude option to exclude the files you do not want to back up. It also allows you to store backups and archives for specific directories in separate storage file spaces.

Backing up data using the Java GUI

You can back up specific files, entire directories, or entire file systems from the directory tree.

About this task

You can locate the files you want to back up by searching or filtering. Filtering displays only the files matching the filter criteria for your backup.

Use the backup-archive client Java™ GUI to back up your data as follows:

Procedure

1. Click **Backup** in the IBM Spectrum Protect™ window. The Backup window appears.
2. Expand the directory tree if necessary. Click on the selection boxes next to the object or objects you want to back up. To search or filter files, click the **Find** icon on the tool bar.
3. Enter your search criteria in the Find Files (Backup) window.
4. Click the **Search** button. The Matching Files (Backup) window appears.
5. Click the selection boxes next to the files you want to back up and close the Matching Files (Backup) window.
6. Enter your filter criteria in the Find Files (Backup) window.
7. Click the **Filter** button. The Backup window displays the filtered files.
8. Click the selection boxes next to the filtered files or directories you want to back up.
9. Select one of the following backup types from the pull-down menu: (1) To run an incremental backup, click **Incremental (complete)**, (2) To run an incremental-by-date backup, click **Incremental (date only)**, (3) To run a selective backup, click **Always backup**.
10. Click **Backup**. The Backup **Task List** window displays the backup processing status.

Results

Consider the following items when you back up your data using the Java GUI.

- To modify specific backup options, click the **Options** button. The options you select are effective during the current session *only*.
- IBM Spectrum Protect uses management classes to determine how to manage your backups on the server. Every time you back up a file, the file is assigned a management class. The management class used is either a default selected for you, or one that you assign to the file using an ***include*** option in the include-exclude options list. Select **Utilities** → **View Policy Information** from the backup-archive client Java GUI or web client GUI to view the backup policies defined by the IBM Spectrum Protect server for your client node.
- To perform an automatic incremental backup of your default domain, select **Actions** → **Backup Domain**. Your default domain is set with the ***domain*** option in your client user-options file (dsm.opt). If you do not have the ***domain*** option set, the default domain is *all local file systems*.
- You can use the Preferences editor to exclude file systems in your default domain from backup processing.

Mac OS X | AIX | Linux | Solaris

Backing up data using the command line

You can use the incremental or selective commands to perform backups.

The following table shows examples of using these commands to perform different tasks.

Table 1. Command-line backup examples

Task	Command	Considerations
Incremental backups		
Perform an incremental backup of your client domain.	`dsmc incremental`	See Incremental for more information about the incremental command.

Task	Command	Considerations
Back up the /fs1 and /fs2 file systems in addition to the /home, /usr, and /datasave file systems defined in your client domain.	`dsmc incremental -domain="/fs1 /fs2"`	See Domain for more information about the domain option.
Back up the /Volumes/fs1 and /Volumes/fs2 file systems in addition to the volumes defined in your client domain.	`dsmc incremental -domain="/Volumes/fs1 /Volumes/fs2"`	See Domain for more information about the domain option.
Back up all local file systems defined in your client domain except for the `/home` file system.	`dsmc incremental -domain="all-local -/home"`	You cannot use the (–) operator in front of the domain keyword all-local. See Domain for more information. For Windows clients, you can also exclude the system state domain from backup processing in this way.
Back up only the /fs1 and /fs2 file systems.	`dsmc incremental /fs1 /fs2`	None
Back up all files in the /home directory and all its subdirectories.	`dsmc incremental /home/ -subdir=yes`	See Subdir for more information about the subdir option.
Back up all files in the /Users directory and all its subdirectories.	`dsmc incremental /Users/ -subdir=yes`	See Subdir for more information about the subdir option.
Assuming that you initiated a snapshot of the /usr file system and mounted the snapshot as /snapshot/day1, run an incremental backup of all files and directories under the local snapshot and manage them on the IBM Spectrum Protect™ server under the file space name /usr.	`dsmc incremental /usr -snapshotroot=/snapshot/day1`	The backup-archive client considers the snapshotroot value as a file space name. See Snapshotroot for more information.
Incremental-by-date backup		
Perform an incremental-by-date backup of your default client domain.	`dsmc incremental -incrbydate`	Use the incrbydate option with the incremental command to back up new and changed files with a modification date later than the last incremental backup stored at the server. See Incrbydate for more information about the incrbydate option.
Selective backups		
Back up all files in the /home/proj or /Users/van/Documents directory.	`dsmc selective /home/proj/` or `dsmc selective /Users/van/Documents/`	Use the selective command to back up specific files or directories regardless of whether they have changed since your last incremental backup. You can use wildcards to back up multiple files at once. See Selective for more information about the selective command.

Task	Command	Considerations
Back up all files in the /home/proj directory and all its subdirectories.	`dsmc selective /home/proj/ -subdir=yes`	If you specify -subdir=*yes* when backing up a specific path and file, the client recursively backs up all subdirectories under that path, and any instances of the specified file that exist under any of those subdirectories. If a subdirectory is a mounted file system, the client does not back up the files in that subdirectory when you use the subdir=*yes* option. See Subdir for more information about the subdir option.
Back up all files in the /Users/van/Documents directory and all its subdirectories.	`dsmc selective /Users/van/Documents/ -subdir=yes`	If you specify -subdir=*yes* when backing up a specific path and file, the client recursively backs up all subdirectories under that path, and any instances of the specified file that exist under any of those subdirectories. If a subdirectory is a mounted file system, the client does not back up the files in that subdirectory when you use the subdir=*yes* option. See Subdir for more information about the subdir option.
Back up the /home/dir1/h1.doc and /home/dir1/test.doc files.	`dsmc selective /home/dir1/h1.doc /home/dir1/test.doc`	If you specify the removeoperandlimit option with the incremental or selective commands, the 20-operand limit is not enforced and is restricted only by available resources or other operating system limits. This allows you to specify more than 20 files on a single command. See Removeoperandlimit for more information about this option.
Back up the /Users/ann/Documents/ h1.doc and /Users/ann/Documents/ test.doc files.	`dsmc selective /Users/ann/Documents/h1.doc /Users/ann/Documents/test.doc`	If you specify the removeoperandlimit option with the incremental or selective commands, the 20-operand limit is not enforced and is restricted only by available resources or other operating system limits. This allows you to specify more than 20 files on a single command. See Removeoperandlimit for more information about this option.
Back up a list of files in the /home/filelist.txt file.	`selective -filelist=/home/filelist.txt`	Use the filelist option to process a list of files. See Filelist for more information.
Back up all files listed in the /Users/filelist.txt file.	`dsmc selective -filelist=/Users/filelist.txt`	Use the filelist option to process a list of files. See Filelist for more information.
Assuming that you initiated a snapshot of the /usr file system and mounted the snapshot as /snapshot/day1, run a selective backup of the /usr/dir1/sub1 directory tree from the local snapshot and manage it on the IBM Spectrum Protect server under the file space name /usr.	`dsmc selective /usr/dir1/sub1/ -subdir=yes -snapshotroot=/snapshot/day1`	The client considers the snapshotroot value as a file space name. See Snapshotroot for more information.

Selective

Mac OS X | AIX | Linux | Solaris

Deleting backup data

If your administrator has given you authority, you can delete individual backup copies from the IBM Spectrum Protect™ server without deleting the entire file space. To determine if you have this authority, select File > Connection Information from the backup-archive client GUI or web client main menu. Your authority status is provided in the Delete Backup Files field.

About this task

Important: When you delete backup files, ***you cannot restore them.*** Verify that the backup files are no longer needed before you delete them. The client prompts whether you want to continue with the delete. If you specify *yes*, the specified backup files are immediately deleted and removed from IBM Spectrum Protect server storage.

To delete backup copies using the backup-archive client GUI or web client:

Procedure

1. Select **Delete Backup Data** from the **Utilities** menu. The Backup Delete window appears.
2. Expand the Directory tree by clicking the plus sign **(+)** or folder icon next to the object you want to expand.
3. Click the selection boxes next to objects that you want to delete.
4. Select an item from the drop-down list near the top of the **Backup Delete** window to specify the type of backup delete to perform. You can delete active backup versions, inactive backup versions, or all objects that you have selected in the tree.

Results

Note:

1. A directory is deleted only if you select **Delete All Objects**.
2. To delete backup copies using the command line client, use the delete backup command.

Related reference:
Delete Backup
Mac OS X | AIX | Linux | Solaris

Deleting file spaces

If your IBM Spectrum Protect™ administrator gives you authority, you can delete entire file spaces from the server. When you delete a file space, you delete all the files and images, both backup versions and archive copies, that are contained within the file space. For example, if you delete the `/tmp` file space, you are deleting every backup for every file in that file system and every file you archived from that file system. Carefully consider whether you want to delete a file space.

About this task

You can also delete a file space using the delete filespace command. Use the class option with the delete filespace command to delete NAS file spaces.

You can delete individual backup versions by using the delete backup command.

You can delete file spaces using the backup-archive client GUI or command line clients. To delete NAS file spaces, use the web client or command line client.

To delete a file space using the GUI, perform the following steps:

Procedure

1. Select Utilities > Delete Filespaces from the main window.
2. Click the selection boxes next to the file spaces you want to delete.
3. Click the Delete button. The client prompts you for confirmation before deleting the file space.

Windows

Backing up files from one or more file spaces for a group backup (Windows)

Use the backup group command to create and back up a group from a list of files from one or more file space origins to a virtual file space on the IBM Spectrum Protect™ server.

About this task

A *group backup* creates a consistent point-in-time backup of a group of files that is managed as a single logical entity:

- All objects in the group are assigned to the same management class. Use the include option to bind a group to a management class.
- Existing exclude statements for any files in the group are ignored.
- All objects in the group are exported together.
- All objects in the group are expired together as specified in the management class. No objects in a group are expired until all other objects in the group are expired, even when another group they belong to gets expired.

A group backup can be added to a backup set.

You can perform a full or differential backup by using the mode option.

Procedure

Enter the backup group command to start a group backup.
For example, to perform a full backup of all the files in the `c:\dir1\filelist1` file to the virtual file space `\virtfs`, containing the group leader `c:\group1` file, enter the following command:

```
dsmc backup group -filelist=c:\dir1\filelist1 -groupname=group1 -virtualfsname=
\virtfs -mode=full
```

Mac OS X | AIX | Linux | Solaris

Backing up files from one or more file spaces for a group backup (UNIX and Linux)

You can use the backup group command to create and back up a group containing a list of files from one or more file space origins to a virtual file space on the IBM Spectrum Protect™ server.

Restriction: The backup group command does not apply to Mac OS X.

A *group backup* allows you to create a consistent point-in-time backup of a group of files that is managed as a single logical entity:

- All objects in the group are assigned to the same management class.
- Existing *exclude* statements for any files in the group are ignored.
- All objects in the group are exported together.
- All objects in the group are expired together as specified in the management class. No objects in a group are expired until all other objects in the group are expired, even when another group they belong to gets expired.

A group backup can be added to a backup set.

You can perform a full or differential backup using the mode option.

For example, to perform a full backup of all the files named in the `/home/dir1/filelist1` file to the virtual file space `/virtfs` containing the group leader `/home/group1` file, enter:

```
dsmc backup group -filelist=/home/dir1/filelist1 -groupname=group1 -virtualfsname=
/virtfs -mode=full
```

Windows

Backing up data with client-node proxy support (Windows)

Backups of multiple nodes that share storage can be consolidated to a common target node name on the IBM Spectrum Protect™ server.

Before you begin

The following considerations apply when you use a proxy node to back up or restore data on other nodes:

- A proxy operation uses the settings for the target node (such as maxnummp and deduplication) and schedules that are defined on the IBM Spectrum Protect server. The IBM Spectrum Protect server node settings and schedules for the agent node are ignored.
- You cannot use asnodename with the backup nas command.
- You cannot use asnodename with the fromnode option.
- If you use asnodename to backup and restore volumes that are in a cluster configuration, do not use clusternode yes.
- You cannot use asnodename to back up or restore system state.
- If an agent node restores data from a backup set, the system state object in the backup set is not restored.
- You can use asnodename with the backup image command, but you must specify the volume by UNC name. You cannot use the drive letter.
- If you use the same asnodename value to back up files from different machines, you need to keep track which files or volumes are backed up from each system so that you can restore them to the correct location.
- All agent nodes in a multiple node environment should be of the same platform type.
- Do not use target nodes as traditional nodes, especially if you encrypt your files before backing them up to the server.

About this task

An *agent node* is a client node which has been granted authority to perform client operations on behalf of a target node.

A *target node* is a client node which grants authority to one (or more) agent nodes to perform client operations on its behalf.

Using an agent node to backup target nodes is useful when the workstation responsible for performing the backup can change over time, such as with a cluster configuration.

The asnodename option allows data to be restored from a different system than the one which performed the backup.

Use the asnodename option with the appropriate command to back up, archive, restore, and retrieve data under the target node name on the IBM Spectrum Protect server. This support is only available with IBM Spectrum Protect Version 5.3 and higher server and client.

Procedure

To enable this option, follow these steps:

1. Install the backup-archive client on all nodes in a shared data environment.
2. Register each node with the IBM Spectrum Protect server, if it does not exist. Register the common target node name to be shared by each of the agent nodes used in your shared data environment.
3. Register each of the nodes in the shared data environment with the IBM Spectrum Protect server. This is the agent node name that is used for authentication purposes. Data will not be stored using the node name when the asnodename option is used.
4. Grant proxy authority to all nodes in the shared environment to access the target node name on the IBM Spectrum Protect server, using the GRANT PROXYNODE command (IBM Spectrum Protect administrator).

5. Use the QUERY PROXYNODE administrative client command to display the client nodes of the authorized user, granted by the GRANT PROXYNODE command.

Windows | Mac OS X | AIX | Linux | Solaris

Enabling multiple node operations from the GUI

To enable multinode operations in the GUI, use the Preferences editor to specify the name of the target node to which you have been granted proxy authority.

Procedure

1. Verify that the client node has proxy authority to a target node (or authorized to act as the target node) by using the QUERY PROXYNODE administrative client command.
2. Select Edit > Client Preferences to open the preferences window.
3. Select the General tab and fill in the As Node Name field with the name of the target node.
4. Click Apply and then OK to close the preferences window.

What to do next

Perform one of the following steps to verify that your client node is now accessing the server as the target node:

- Open the tree window and check that the target node name specified by the As Node Name field appears.
- Verify the target node name in the Accessing As Node field in the Connection Information window.

To return to single node operation, delete the As Node Name from the Accessing As Node field in the General > Preferences tab.

Windows

Setting up encryption

This topic lists the steps that you must follow to set up encryption with the encryptkey option.

Procedure

1. Specify `encryptkey=save` in the options file.
2. Back up at least one file with `asnode=ProxyNodeName` to create a local encryption key on each agent node in the multiple node environment.

Results

Follow these steps to set up encryption with the `encryptkey=prompt` option:

1. Specify `encryptkey=prompt` in the options file.
2. Ensure that users of the agent nodes in the multiple node environment are using the same encryption key.

Important:

- If you change the encryption key, you must repeat the previous steps.
- Use the same encryption key for all files backed up in the shared node environment.

Windows

Scheduling backups with client-node proxy support

Multiple nodes can be used to perform backup operations using the scheduler.

About this task

When you grant proxy authority to the agent nodes, they perform scheduled backup operation on behalf of the target node. Each agent node must use the asnodename option within their schedule to perform multiple node backup for the agent node.

Perform the following steps to enable scheduling of multiple nodes:

1. Ensure that all agent nodes must have proxy authority over the common target node
2. Ensure that all agent nodes must have a schedule defined on the server:

   ```
   def sched domain_name sched_name options='-asnode=target'
   ```

3. Ensure that each agent node must have its schedule associated with a node:

   ```
   def association domain_name schedule_name <agentnodename>
   ```

The following examples show the administrative client-server commands using the scheduler on multiple nodes.

- The administrator registers all the nodes to be used, by issuing the following commands:
  - `register node NODE-A`
  - `register node NODE-B`
  - `register node NODE-C`
- The administrator grants proxy authority to each agent node, by issuing the following commands:
  - `grant proxynode target=NODE-Z agent=NODE-A`
  - `grant proxynode target=NODE-Z agent=NODE-B`
  - `grant proxynode target=NODE-Z agent=NODE-C`
- The administrator defines the schedules, by issuing the following commands:
  - `define schedule standard proxy1 description="NODE-A proxy schedule" action=incremental options="-asnode=NODE-Z" objects=C: startdate=05/21/2005 starttime=01:00`
  - `define schedule standard proxy2 description="NODE-B proxy schedule" action=incremental options="-asnode=NODE-Z" objects=D: startdate=05/21/2005 starttime=01:00`
  - `define schedule standard proxy3 description="NODE-C proxy schedule" action=incremental options="-asnode=NODE-Z" objects=E: startdate=05/21/2005 starttime=01:00`

Note: Place the asnodename option in the schedule definition only. Do not place it in the client options file, on the command line, or in any other location.

Start the schedules by either configuring a scheduler service, or by using the following client command: `dsmc sched`

You can also use the client acceptor, with managedservices set to schedule in the systems options file.
Important:

- Each schedule can be started from a different workstation or LPAR.
- After running the schedules, any proxied client can query and restore all the backed up data.
- A proxy operation uses the settings for the target node (such as maxnummp and deduplication) and schedules that are defined on the IBM Spectrum Protect™ server. The IBM Spectrum Protect server node settings and schedules for the agent node are ignored.

Mac OS X | AIX | Linux | Solaris

Backing up data with client-node proxy support (UNIX and Linux)

Backups of multiple nodes that share storage can be consolidated to a common target node name on the IBM Spectrum Protect™ server.

About this task

Consolidating backups from multiple nodes to a common target node name on the server is helpful in configurations where the workstation that is responsible for performing the backups can change over time, such as within a cluster.

An agent node is a client node that is granted authority to perform client operations on behalf of a target node.

A target node is a client node that grants authority to one or more agent nodes to perform client operations on its behalf.

Use the asnodename option with the appropriate command to back up, archive, restore, and retrieve data under the target node name on the server.

The asnodename option also allows data to be restored from a different system than the one that performed the backup.

Consider the following features when you use a proxy node to back up or restore data on other nodes:.

- A proxy operation uses the settigns for the target node (such as maxnummp and deduplication) and schedules that are defined on the IBM Spectrum Protect server. The IBM Spectrum Protect server node settings and schedules for the agent node are ignored.
- All of the agent nodes in the multiple node environment must be running the same operating system type.
- Do not use target nodes as traditional nodes, especially if you encrypt your files before you back them up to the server.
- You cannot access another node (either from the GUI drop-down or by using the fromnode option).
- You cannot perform NAS backup or restore.

Procedure

1. Install the backup-archive client on all nodes in a shared data environment.
2. Register each node with the IBM Spectrum Protect server. Register the common target node name to be shared by each of the agent nodes that are used in your shared data environment.
3. Register each of the nodes in the shared data environment with the IBM Spectrum Protect server. Register the agent node name that is used for authentication purposes. Data is not stored on the server, under that node name, when the asnodename option is used.
4. The IBM Spectrum Protect server administrator must grant proxy authority to all nodes in the shared environment to access the target node name by using the GRANT PROXYNODE command.
5. Use the QUERY PROXYNODE administrative client command to display the client nodes of the authorized user that was granted by the GRANT PROXYNODE command.

Scheduling backups with client-node proxy support

Multiple nodes can be used to perform backup operations using the scheduler.

About this task

When you grant proxy authority to the agent nodes, they perform scheduled backup operations on behalf of the target node. Each agent node must use the asnodename option within their schedule to perform multiple node backup for the agent node.

Start the schedules using `dsmc sched` client command:

The following examples show the administrative client-server commands using the scheduler on multiple nodes.

- The administrator registers all of the nodes to be used by issuing the following commands:
  - `register node NODE-A`
  - `register node NODE-B`
  - `register node NODE-C`
- The administrator grants proxy authority to each agent node using the following commands:
  - `grant proxynode target=NODE-Z agent=NODE-A`
  - `grant proxynode target=NODE-Z agent=NODE-B`
  - `grant proxynode target=NODE-Z agent=NODE-C`
- Mac OS X | AIX | Linux | Solaris | Mac OS X The administrator defines the schedules using the following commands:
  - `define schedule standard proxy1 description="NODE-A proxy schedule" action=incremental options="-asnode=NODE-Z" objects=/Volumes/Xsan1 startdate=05/21/2005 starttime=01:00`
  - `define schedule standard proxy2 description="NODE-B proxy schedule" action=incremental options="-asnode=NODE-Z" objects=/Volumes/Xsan2 startdate=05/21/2005 starttime=01:00`
  - `define schedule standard proxy3 description="NODE-C proxy schedule" action=incremental options="-asnode=NODE-Z" objects=/Volumes/Xsan3 startdate=05/21/2005 starttime=01:00`

Note: Place the asnodename option in the schedule definition only. Do not place it in the client options file, on the command line, or in any other location.
You can also use the client acceptor daemon (dsmcad), with managedservices set to schedule in the systems options file.

Note:

- Each schedule can be started from a different workstation or LPAR.
- After running the schedules, any proxied client can query and restore all of the backed up data.
- A proxy operation uses the settings for the target node (such as maxnummp and deduplication) and schedules that are defined on the IBM Spectrum Protect™ server. The IBM Spectrum Protect server node settings and schedules for the agent node are ignored.

Session settings and schedules for a proxy operation
DEFINE SCHEDULE command
Mac OS X | AIX | Linux | Solaris

Examples of how to schedule a backup of an IBM PowerHA SystemMirror cluster

This section shows lists some examples of how to back up an IBM® PowerHA® SystemMirror cluster.

About this task

Perform the following steps to enable scheduling of multiple nodes:

1. Ensure that all agent nodes must have proxy authority over the common target node
2. Ensure that all agent nodes must have a schedule defined on the server:

   ```
   def sched domain_name sched_name options='-asnode=target'
   ```

3. Ensure that each agent node must have its schedule associated with a node:

   ```
   def association domain_name schedule_name <agentnodename>
   ```

In the following examples, IBM PowerHA SystemMirror is configured for two AIX® hosts, `host_a` and `host_b`. Along with their own local data, the hosts are sharing disk storage which has two file spaces: `/disk1` and `/disk2`.

The CLUSTERNODE example shows how the clusternode option is used in a current IBM PowerHA SystemMirror environment.

- The administrator defines 3 nodes on the IBM Spectrum Protect™ server: `host_a`, `host_b`, `cluster_group`, using the following commands: (1) `REGISTER NODE host_a mysecretpa5s`, (2) `REGISTER NODE host_b mysecretpa5s`, (3) `REGISTER NODE cluster_group mysecretpa5s`.
- The administrator defines a dsm.opt file on `host_a` and `host_b` (note that the opt files are different on each host), using the following commands: (1) `NODENAME host_a (option can be left as default)`, (2) `DOMAIN /home /usr ... etc.`.
- The administrator defines a dsm.opt file located somewhere on one of the cluster disk groups, for example, `/disk1/tsm/dsm.opt`, using the following commands: (1) `NODENAME cluster_group`, (2) `DOMAIN /disk1 /disk2`, (3) `CLUSTERNODE YES`.
- The administrator defines a schedule on the IBM Spectrum Protect server, using the following command: `DEFINE SCHEDULE STANDARD CLUSTER_BACKUP`.
- The administrator defines associations for each of the 3 nodes, using the following command: `DEFINE ASSOC STANDARD CLUSTER_BACKUP host_a,host_b,cluster_group`. At any one time, there are three instances of the backup-archive client schedule running (with the scheduler for `cluster_group` being part of the cluster resources that failover whenever the cluster group disk resources failover. Thus, it would be running on either `host_a` or `host_b` but not both simultaneously).
- All three node names contain data on the IBM Spectrum Protect server.

The ASNODE example shows a generic solution which could be applied to UNIX cluster solutions to which we do not have support, for example: Veritas Cluster Server for Solaris.

- The administrator defines 3 nodes on the IBM Spectrum Protect server `host_a`, `host_b`, `cluster_group`:

```
REGISTER NODE host_a mysecretpa5s
REGISTER NODE host_b mysecretpa5s
REGISTER NODE cluster_group mysecretpa5s
```

- The administrator defines a proxy node relationship between `host_a` and `host_b` to `hacmp_cluster`

```
GRANT PROXYNODE TARGET=cluster_group AGENT=host_a,host_b
```

- The administrator defines a dsm.opt file on `host_a` and `host_b` to handle the local file systems:

```
NODENAME        host_a (option can be left as default)
DOMAIN                  /home /usr ... etc.

NODENAME   host_b (option can be left as default)
DOMAIN                  /home /usr ... etc.
```

- The administrator defines a dsm.opt file on the cluster resource to handle the backup of the clustered resources, e.g. `/disk1/tsm/dsmcluster.opt` (the nodename is the default nodename, which is either `host_a` or `host_b`, depending on which workstation contains the cluster group at any given time):

```
DOMAIN          /disk1 /disk2
ASNODE    cluster_group
```

- The administrator defines a schedule on the IBM Spectrum Protect server:

```
DEFINE SCHEDULE STANDARD CLUSTER_BACKUP
```

- The administrator defines associations for each one of the 3 nodes.

```
DEFINE ASSOC STANDARD CLUSTER_BACKUP host_a,host_b,cluster_group
```

- At any one time, there are three instances of the backup-archive client schedule running with the scheduler for node `hacmp_cluster` running on either `host_a` or `host_b` but not both (it is included in the cluster resources that would failover). This scheduler would point to the `dsmcluster.opt` that is defined on each host. The three instances would be started as:

```
[host_a]                  dsmc sched
[host_b]                  dsmc sched
[cluster_group] dsmc sched -optfile=/disk/tsm/dsmcluster.opt
```

- All three node names contain data on the IBM Spectrum Protect server.

For more information about the server scheduler commands, see the server documentation.

AIX | Linux

Scheduling a backup of a GPFS file system

Use the scheduler and proxy relationships to back up a GPFS™ file system.

About this task

Assume that three nodes in a GPFS cluster participate in the backup operation. Nodes node_1, node_2, and node_3 are used for authentication only. The objects are backed up to file spaces that belong to node node_gpfs.

Procedure

1. Define four nodes on the IBM Spectrum Protect™ server.

```
REGISTER NODE node_1 mysecretpa5s

REGISTER NODE node_2 mysecretpa5s

REGISTER NODE node_3 mysecretpa5s

REGISTER NODE node_gpfs mysecretpa5s
```

2. Define a proxy relationship between the nodes.

```
GRANT PROXYNODE TARGET=node_gpfs AGENT=node_1, node_2, node_3
```

3. Define a schedule.

```
DEFINE SCHEDULE STANDARD GPFS_SCHEDULE ACTION=incremental
OBJECTS="/gpfs"

DEFINE ASSOCIATION STANDARD GPFS_SCHEDULE node_gpfs
```

4. Choose one of the GPFS systems to run the schedule. Specify the nodename and asnodename options in the dsm.sys options file on all systems in the GPFS cluster. The value for the asnodename option must be the same on all systems.

   Definitions in the dsm.sys options file on node 1:

   ```
   nodename node_1
   asnodename node_gpfs
   ```

   Definitions in the dsm.sys options file on node 2:

   ```
   nodename node_2
   asnodename node_gpfs
   ```

   Definitions in the dsm.sys options file on node 3:

   ```
   nodename node_3
   asnodename node_gpfs
   ```

5. Start the scheduler on the system that is chosen to run the schedule.

```
DSMC SCHED
```

Windows

Backing up Windows system state

The backup-archive client uses VSS to back up all system state components as a single object, to provide a consistent point-in-time snapshot of the system state. System state consists of all bootable system state and system services components.

About this task

The client supports the Microsoft volume shadow copy service (VSS) on the supported Windows clients.

System state is represented by several VSS writers of type "bootable system state" and "system service". Of these, the System Writer is the largest part of the system state in terms of number of files and size of data. By default, the System Writer backup is incremental. You can use the systemstatebackupmethod option to perform full backups of the System Writer. For more information, about this option, see Systemstatebackupmethod. The client always backs up all other writers in full.

The list of bootable system state and system services components are dynamic and can change depending on service pack and operating system features installed. The client allows for the dynamic discovery and back up of these components.

You must be a member of the Administrators or Backup Operators group to back up system state information.

To back up a system state object using the command line:

1. On the command line, use the **backup systemstate** command to back up all system state or system services components as a single object.
2. Use the **query systemstate** command to display information about a backup of the system state on the IBM Spectrum Protect™ server.

To back up a system state object using the GUI:

1. Click **Backup** from the GUI main window. The Backup window appears.
2. Expand the directory tree by clicking the plus sign (+). To display files in a folder, click the folder icon.
3. Locate the system state node in the directory tree. You can expand the system state node to display the components.
4. Click the selection box next to the system state node to back up the entire system state object. You can back up the system state node only as a single entity because of dependencies among the system state components. By default, all components are selected; you cannot back up individual system state components.
5. Click **Backup**. The Backup Task List window displays the backup processing status. When processing completes, the Backup Report window displays processing details.

System and boot files are backed up as a group only if one of the members of the group (one of the files) changes. If the files have not changed since the last backup, the system and boot files are not redundantly backed up.

By default, system state backups are bound to the default management class. To bind them to a different management class, use the include.systemstate option; specify all as the pattern, and specify the name of the new management class.

You can use the domain option to exclude the entire system state from domain incremental backup processing.

The system `dllcache` directory is now included in the boot partition backup of Windows systems. When the `dllcache` files are not available when you restore a Windows computer, system recovery might require availability of the operating system installation media. By backing up the `dllcache` directory, you can avoid the need for installation media during system restores.

If you do not want the `dllcache` directory included in the backup of your boot partition, and you understand the limitations of not backing up the `dllcache` directory, then you can use an exclude.dir statement to suppress backup of those files. For example:

```
exclude.dir c:\windows\system32\dllcache
```

On Windows clients, backup systemstate also backs up ASR data.

Backing up Automated System Recovery files

You can back up Automated System Recovery (ASR) files in preparation for recovering the Windows disk configuration information and system state in case a catastrophic system or hardware failure occurs.

About this task

The backup-archive client backs up ASR data when the backup-archive client backs up the Windows system state.

Procedure

To back up ASR files on Windows operating systems, use the backup systemstate command.

Results

The client generates the ASR files in the \adsm.sys\ASR staging directory on the system drive of your local workstation and stores these files in the ASR file space on the IBM Spectrum Protect™ server.

Preparation for Automated System Recovery

Specific backups and media are required for Windows Automated System Recovery (ASR).

- Windows Creating a client options file for Automated System Recovery
  Before you can recover a Windows computer by using Automated System Recovery (ASR), you must create an options file. The options file is unique for each computer.
- Windows Backing up the boot drive and system drive for Automated System Recovery
  Before you can recover your Windows computer by using Automated System Recovery (ASR), you must have a complete backup of the boot drive and system drive.

Windows

Creating a client options file for Automated System Recovery

Before you can recover a Windows computer by using Automated System Recovery (ASR), you must create an options file. The options file is unique for each computer.

About this task

This task assumes that you created a generic bootable WinPE CD or DVD. A generic bootable WinPE CD does not contain the client options file (dsm.opt) because the options file is unique for each computer. This task helps you create a computer-specific options file.

The Windows Preinstallation Environment (WinPE) requires particular options values.

Procedure

1. Find a copy of the client options file. You can find the file in several places:
   - There is an options file in the installation directory of an installed IBM Spectrum Protect™ client. The default installation location is C:\Program Files\Tivoli\TSM\baclient\dsm.opt. If you have the options file for the computer that you want to restore, this options file requires the fewest modifications.
   - There is a sample options file in the client installation package. The path in the package is TSM_BA_Client\program files\Tivoli\TSM\config\dsm.smp. Rename the file to dsm.opt.
2. Edit dsm.opt.
   a. Enter a writable location for the error log. The backup-archive client creates several log files. Use the option errorlogname to specify the log file location. For example, in the dsm.opt file, specify `errorlogname`

`x:\dsmerror.log`.
Note: This example uses x: because in WinPE mode, the default system drive is x:.

b. Enter the client node name with the nodename option.
c. Optional: If you plan to restore the system state from files that are stored on the IBM Spectrum Protect server, enter the server connection information. Enter appropriate values for the commmethod and tcpserveraddress options.
d. Optional: If you know the password for the node, enter the password with the password option.

3. Copy the dsm.opt file to media that the target computer can read during Automated System Recovery.
4. Optional: Copy IBM Spectrum Protect client registry information to media that the target computer can read during Automated System Recovery. Use the regedit.exe utility to export IBM Spectrum Protect client registry entries from the HKLM\SOFTWARE\IBM key. For example, from a command prompt window, run this command:

   ```
   regedit /e tsmregistry.out "HKEY_LOCAL_MACHINE\SOFTWARE\IBM"
   ```

   Copy the tsmregistry.out file to media that the target computer can read during ASR.
   During ASR, you can import the registry entries from the tsmregistry.out file. The backup-archive client can use the registry entries in the WinPE environment to access backup copies on the IBM Spectrum Protect server.
   Note: Saving registry entries is optional because there are other ways to get access to the password-protected IBM Spectrum Protect server. You can access the server with the following methods:
   - If you know the node password, you can type the password when prompted during recovery.
   - Request the IBM Spectrum Protect administrator to change the node password and provide you with the new password at the time of recovery.
   - Provide the password information in the dsm.opt file.

   If the files you want to restore are included in a backup set on tape or on a CD or DVD, then you do not need to access the IBM Spectrum Protect server.

Results

You created an options file that contains client configuration information that is unique for each computer. This information complements the generic bootable WinPE CD.

Related tasks:
Creating a bootable WinPE CD

Windows

Backing up the boot drive and system drive for Automated System Recovery

Before you can recover your Windows computer by using Automated System Recovery (ASR), you must have a complete backup of the boot drive and system drive.

Procedure

1. Perform a full incremental backup of your system and boot drives. Assuming that your system and boot files are on the c: drive, enter the following command:

   ```
   dsmc incremental c:
   ```

2. Back up the system state. To back up the system state, enter the following command:

   ```
   dsmc backup systemstate
   ```

   To verify that you backed up the system state, enter the following command:

   ```
   dsmc query systemstate
   ```

   You can specify `-showmembers=yes` to display file level detail.

AIX | Linux | Solaris | Windows

Image backup

From your local workstation, you can back up a logical volume as a single object (image backup) on your system.

The traditional static image backup prevents write access to the volume by other system applications during the operation.

AIX Linux Solaris You must be a root user to perform this task, and image backup does not apply to Mac OS X.

Windows These volumes can be formatted NTFS or ReFS, or unformatted RAW volumes. If a volume is NTFS-formatted, only those blocks that are used by the file system or smaller than the imagegapsize parameter are backed up.

Windows Normally you cannot restore an image backup of the system drive over itself since an exclusive lock of the system drive is not possible. However, in a Windows pre-installation environment (WinPE), an image restore of the system drive is possible. For information about restoring data in a WinPE environment, see technote 7005028.

Windows You cannot restore an image backup to the volume on which the client is running. Consider installing the backup-archive client on the system drive.

Windows Image backup does not guarantee consistency of system objects, such as the Active Directory. System objects can be spread out across multiple volumes, and should be backed up by using the backup systemstate command.

An image backup provides the following benefits:

- Backs up file systems that contain a large number of files faster than a full file system incremental backup.
- Improves the speed with which the client restores file systems that contain many small files.
- Conserves resources on the server during backups since only one entry is required for the image.
- Provides a point-in-time picture of your logical volume, which might be useful if your enterprise must recall that information.
- Restores a corrupted file system or raw logical volume. Data is restored to the same state it was when the last logical volume backup was performed.

AIX Linux Solaris The traditional static image backup prevents write access to the volume by other system applications during the operation. Use the dynamicimage option to back up the volume as is, without remounting it read-only. Corruption of the backup can occur if applications continue to write to the volume while the backup is running. Writing to a volume while an image backup is running can result in inconsistent data and data loss after a restore operation is run. The dynamicimage option overrides the copy serialization value in the management class to perform an image backup. After restoring an image backup taken with the dynamicimage option, always run the `chkdsk` utility.

Windows The traditional offline image backup prevents write access to the volume by other system applications during the operation. When you backup an image by using `snapshotproviderimage=none`, always run the fsck utility after you restore the data.

To restore an image backup of a volume, the backup-archive client must be able to obtain an exclusive lock on the volume that is being restored.

AIX Linux Solaris Restriction: Do not use dynamic image backups for file systems, because the file system might provide inconsistent data even when there is no write activity. Also, dynamic image backup might result in a fuzzy image, which might not be valid or complete when restored.

AIX Linux Solaris If the backup-archive client fails to mount the file system after it restores an image, run fsck. However, running fsck can affect the integrity of large amounts of data. Do not use dynamic image backup for AIX® JFS2 file systems. The client does not allow dynamic image backup for AIX JFS2 file systems. If you specify `dynamicimage=yes` for a JFS2 file system, the client performs a snapshot-based image backup. If the snapshot cannot be created for some reason, the client instead performs a static image backup.

AIX Linux Solaris Attention: To prevent data loss, avoid using the dynamicimage option, and ensure that there is no write activity on the volume while the backup is in progress.

AIX Linux Solaris For AIX JFS2 file systems, the amount of data that is backed up to the IBM Spectrum Protect™ server during static or snapshot image backup is reduced by backing up only those blocks used by the file system or smaller than the imagegapsize option. This method of backing up your data improves the performance of image backup. For more information, see Imagegapsize.

AIX For AIX clients only: By default, the client performs an online snapshot image backup of JFS2 file systems, during which the volume is available to other system applications.

Linux For Linux clients only: By default, the client performs a snapshot image backup of file systems that exist on a logical volume that is created by the Linux Logical Volume Manager. The volume is available to other system applications while the

snapshot image backup is performed.

Linux For Linux clients: Image backup of DASD devices with raw-track access mode on Linux on z Systems™ is not supported.

Windows If online image support is configured, the client performs an online image backup, during which the volume is available to other system applications. The snapshot provider, as specified by the snapshotproviderimage option, maintains a consistent image of a volume during online image backup.

Windows You can use the snapshotproviderimage option with the backup image command or the include.image option to specify whether to perform an offline or online image backup.

AIX Linux Solaris Attention: File systems that are managed by IBM Spectrum Protect for Space Management are not enabled for image backup.

AIX Linux Solaris Windows

Performing prerequisite tasks before creating an image backup

This topic lists some items to consider before you perform an image backup.

About this task

The following items are the image backup considerations.

- Windows *To perform an offline or online image backup you must have administrative authority on the system.*
- Windows You do not need more than one drive to perform an image backup.
- AIX Linux Solaris Ensure that no other application is using the volume when you run a static image backup. To ensure a consistent image during backup processing, if a file space is detected on the volume the client unmounts and remounts the volume as read only, so that no other applications can write to it. If the volume is in use when the client attempts to unmount, the backup fails. If the client cannot unmount and remount the volume as read only because it is in use, and snapshot image backup is not available, you can use the dynamicimage option to force the client to perform an image backup without unmounting and remounting the volume in read-only mode. Set the dynamicimage option in an include.image statement or from the command line. The backup can be corrupted if applications write to the volume while the backup is in progress. This can be corrected by running `fsck` after a restore to fix any corrupted blocks.

  If no file system is detected on the volume being backed up, ensure that all applications writing to the volumes are quiesced. The backup-archive client uses the file system table and mount table to detect the supported file systems.

  Do not include system files in an image backup because file systems being actively used cannot be unmounted.

  For AIX® and Linux only: If you perform an image backup of a mounted file system which is mounted to another mount point and specified in the file system table, then after completing the image backup, all mount options for this file system, except read or write state, is lost.

  Important: If a mounted file system has nested mount points, unmount them before attempting a backup. Otherwise, the client is unable to unmount the volume. The file system is rendered *busy* if it contains any mounts.

- Windows Ensure that no other application is using the volume when you run an offline image backup. To ensure a consistent image during backup processing, the client locks the volume, so that no other applications can write to it. If the

volume is in use when the client attempts to lock the volume, the backup fails. If the client cannot lock a volume because it is in use, you can perform an online image backup.

- Use the include.image option to assign a management class to the volume image. If you do not assign a management class, the default management class is used for the image.
  Windows Note: If the snapshotproviderimage option is set to *none*, then the copy serialization parameters set by the management class is used.
- You can exclude a volume from image backup using the exclude.image option.
- AIX Linux Solaris You must use the mount point for the file system volume on which you want to perform an image backup. The client will not back up a file system volume without the use of a mount point. Back up file systems using the mounted name. For example, if `/dev/lv01` is formatted as a file system mounted on `/home`, enter this command to perform an image backup of this volume:

  ```
  dsmc backup image /home
  ```

  Back up raw volumes using the device name. For example, if `/dev/lv02` is a raw volume, enter this command to perform an image backup of this volume:

  ```
  dsmc  backup image /dev/lv02
  ```

  If you back up a raw volume which is formatted as a file system, ensure that the file system is not mounted and does not have an entry in `/etc/filesystems`.

- Windows You must use the mount point or drive letter for the volume on which you want to perform an image backup. The client will not back up a volume without the use of a drive letter or mount point.
- Windows Do not include the system drive in an image backup because the client cannot have an exclusive lock of the system drive during the restore and the system drive image cannot be restored to the same location. Image backup does not guarantee consistency of system objects, such as the Active Directory. System objects can be spread out across multiple volumes, and should be backed up using the corresponding backup commands. Because you cannot restore an image backup to the volume from which the client is currently running (or any volume for which an exclusive lock cannot be obtained) you should install your client program on the system drive.
  Note: When using WinPE, an image restore of the system drive is possible. For more information, see IBM Spectrum Protect™ Recovery Techniques Using Windows Preinstallation Environment (Windows PE).
- Windows If bad disk sectors are detected on the source drive during a LAN-free or LAN-based image backup, data corruption can occur. In this case, bad sectors are skipped when sending image data to the IBM Spectrum Protect server. If bad disk sectors are detected during the image backup, a warning message is issued after the image backup completes.

Utilizing image backups to perform file system incremental backups

This topic lists the methods and steps to use image backups to perform efficient incremental backups of your file system.

These backup methods allow you to perform a point-in-time restore of your file systems and improve backup and restore performance. You can perform the backup only on formatted volumes; not on raw logical volumes.

You can use one of the following methods to perform image backups of volumes with mounted file systems.

- AIX Linux Solaris Windows Method 1: Using image backups with file system incremental backups
  This topic lists the steps to perform image backups with file system incremental backup.
- AIX Linux Solaris Windows Method 2: Using image backups with incremental-by-date image backups
  This topic lists the steps to perform image backups with incremental-by-date image backup.
- AIX Linux Solaris Windows Comparing methods 1 and 2
  This topic shows a comparison of methods 1 and 2: (1) Using image backup with file system incremental or (2) Using image backup with incremental-by-date image backup.

AIX Linux Solaris Windows

Method 1: Using image backups with file system incremental backups

This topic lists the steps to perform image backups with file system incremental backup.

About this task

Procedure

1. Perform a full incremental backup of the file system. This establishes a baseline for future incremental backups.
2. Perform an image backup of the same file system to make image restores possible.
3. Perform incremental backups of the file system periodically to ensure that the server records additions and deletions accurately.
4. Perform an image backup periodically to ensure faster restore.
5. Restore your data by performing an incremental restore. Ensure that you select the **Image plus incremental directories and files** and **Delete inactive files from local** options in the Restore Options window before beginning the restore. During the restore, the client does the following:

Results

- Restores the most recent image on the server.
- Deletes all of the files restored in the previous step which are inactive on the server. These are files which existed at the time of the image backup, but were subsequently deleted and recorded by a later incremental backup.
- Restores new and changed files from the incremental backups.

Note: If an incremental backup is performed several times after backing up an image, make sure that the backup copy group of the IBM Spectrum Protect™ server has enough versions for existing and deleted files on the server so that the subsequent restore image with incremental and deletefiles options can delete files correctly.

Related tasks:

Windows Backing up data using the GUI

Performing an image backup using the GUI

Restoring an image using the GUI

AIX | Linux | Solaris | Windows

Method 2: Using image backups with incremental-by-date image backups

This topic lists the steps to perform image backups with incremental-by-date image backup.

Procedure

1. Perform an image backup of the file system.
2. Perform an incremental-by-date image backup of the file system. This sends only those files that were added or changed since the last image backup to the server.
3. Periodically, perform full image backups.
4. Restore your volume by performing an incremental restore. Ensure that you select the **Image plus incremental directories and files** option in the Restore Options window before beginning the restore. This first restores the most recent image and then restores all of the incremental backups performed since that date.

Results

Note: You should perform full image backups periodically in the following cases:

- When a file system changes substantially (more than 40%), as indicated in step 4 of method 1 and step 3 of method 2. On restore, this would provide a file system image close to what existed at the time of the last incremental-by-date image backup and it also improves restore time.
- As appropriate for your environment.

This improves restore time because fewer changes are applied from incremental backups.

The following restrictions apply when using method 2:

- The file system can have no previous full incremental backups.
- Incremental-by-date image backup does not inactivate files on the server; therefore, when you restore an image with the incremental option, files deleted after the original image backup is present after the restore.
- If this is the first image backup for the file system, a full image backup is performed.
- If file systems are running at or near capacity, an out-of-space condition could result during the restore.

Related tasks:
Performing an image backup using the GUI

AIX Linux Solaris Windows

Comparing methods 1 and 2

This topic shows a comparison of methods 1 and 2: (1) Using image backup with file system incremental or (2) Using image backup with incremental-by-date image backup.

To help you decide which method is appropriate for your environment, the following table is a comparison of methods 1 and 2.

Table 1. Comparing incremental image backup methods

Method 1: Using image backup with file system incremental	**Method 2: Using image backup with incremental-by-date image backup**
Files are expired on the server when they are deleted from the file system. On restore, you have the option to delete files which are expired on server from image.	Files are not expired on server. After the image incremental restore completes, all of the files that are deleted on the file system after the image backup are present after the restore. If file systems are running at or near capacity, an out-of-space condition could result.
Incremental backup time is the same as regular incremental backups.	Incremental image backup is faster because the client does not query the server for each file that is copied.
Restore is much faster compared to a full incremental file system restore.	Restore is much faster compared to a full incremental file system restore.
Directories deleted from the file system after the last image backup are not expired.	Directories and files deleted from the file system after the last full image backup are not expired.

AIX Linux Solaris Windows

Performing an image backup using the GUI

If the image backup feature is configured, you can create an image backup where the real volume is available to other system applications.

About this task

A consistent image of the volume is maintained during the image backup.

Windows When you perform an image backup using the client GUI image backup option, the backup operation is run according to the snapshotproviderimage setting in your client options file (dsm.opt). If the online image support is configured, the client performs an online image backup, during which the volume is available to other system applications.

AIX Linux When you perform an image backup using the backup-archive client GUI image backup option, the backup operation is run according to the setting of the snapshotproviderimage option. The snapshotproviderimage option defaults to an AIX® JFS2 snapshot for AIX and a Linux LVM snapshot for Linux. You can override the default by using the Preferences editor Snapshot tab and the Image Snapshot Preferences.

Solaris For Solaris clients, selecting the image backup option performs a static image backup by default. For static image backup, the client unmounts and remounts the volume as read-only, so that no other applications can access it. You can override the default value by using the include.image option and selecting dynamicimage *yes*. For dynamic image backup, the client performs the image backup without making the file system read-only during the backup.

To create an image backup of your file system or raw logical volume, perform the following steps:

Procedure

1. Click on the **Backup** button in the IBM Spectrum Protect™ main window. The Backup window appears.
2. Expand the directory tree and select the objects you want to back up. To back up a raw logical volume, locate and expand the RAW directory tree object.
3. Click Backup. The Backup Task List window displays the backup processing status. The Backup Report window displays a detailed status report.

Results

- AIX Linux Solaris To perform a static image backup, select **Image Backup** from the drop-down list.
- Windows To perform an offline image backup, select **Image Backup** from the drop-down list.
- Windows To perform an online image backup, select **Snapshot Image Backup** from the drop-down list.
- AIX Linux For AIX and Linux clients *only*: To perform a snapshot image backup, use the snapshotproviderimage option.
- To perform an incremental-by-date image backup, select **Incremental image (date only)** from the drop-down list.

AIX Linux Solaris The following are some items to consider when you perform an snapshot-based image backup:

Windows The following are some items to consider when you perform an online image backup:

- To modify specific backup options, click the Options button. The options you select are effective only during the current session.
- Windows Because image backup allows you to back up only used blocks in a file system, the stored image size on the IBM Spectrum Protect server could be smaller than the volume size. For online image backups, the stored image can be larger than the file system based on the size of the cache files. To determine the actual stored image size, select View > File Details. The actual stored image size is noted in the Stored Size field.

- To modify specific backup options, click the Options button. The options you select are effective only during the current session.
- Windows Because image backup allows you to back up only used blocks in a file system, the stored image size on the IBM Spectrum Protect server could be smaller than the volume size. For online image backups, the stored image can be larger than the file system based on the size of the cache files. To determine the actual stored image size, select View > File Details. The actual stored image size is noted in the Stored Size field.

Linux Linux only: The IBM Spectrum Protect Version 5.4 (and newer) client will not recognize any LVM1 volumes for image operations. However, it allows prior image backups of LVM1 volumes to be restored on LVM2 volumes. Table 1 shows the combinations involving the old and new client levels handling LVM1 and LVM2 volumes for different image operations.

Linux

Table 1. LVM1 and LVM2 image operation comparisons

IBM Spectrum Protect client version	LVM1 Backup and Restore	LVM2 Backup and Restore	Mixed Volumes	
			Backup: LVM1, Restore: LVM2	Backup: LVM2, Restore: LVM1
V5.3 and prior	YES	Only static image for file system	NO	NO - raw volumes are not supported
V5.4 and beyond	NO Error msg ANS1090E displayed	YES	YES LVM1 vol must have been backed up using prior client	NO Restore to LVM1 vol fails

AIX Linux Solaris Windows

Performing an image backup using the command line

Use the backup image and restore image commands to perform image backup and restore operations on a single volume.

Windows You can use the snapshotproviderimage option with the backup image command or the include.image option in your dsm.opt file or on the command line to specify whether to perform an offline or online image backup.

Use the mode option with the backup image command to perform an incremental-by-date image backup that backs up only new and changed files after the last full image backup. However, this only backs up files with a changed date, not files with changed permissions.

AIX

Snapshot-based file backup and archive and snapshot-based image backup

For backup-archive clients running on AIX® 5.3 or later JFS2 file systems as root user, snapshot-based image backup is created using snapshots by default.

About this task

Optionally, you can enable snapshot-based file level backup and archive operations by specifying the snapshotproviderfs option. If for some reason a snapshot cannot be taken, the client attempts to perform a static image backup or regular file backup.

If you want to specify snapshot-based file backup and archive, set the option snapshotproviderfs to JFS2. This is applicable to all JFS2 file systems for that client.

Important: Use snapshot-based file backup and archive and snapshot-based image backup for all of your AIX JFS2 file systems.

For example, to turn *on* snapshot-based file backup and archive for all JFS2 file systems on the client, specify the following in the server stanza in the dsm.sys file:

```
snapshotproviderfs JFS2
```

To explicitly turn *off* snapshot-based file backup and archive for all JFS2 file systems on the client, specify the following in the server stanza in the dsm.sys file:

```
snapshotproviderfs   NONE
```

To turn *on* snapshot-based file backup and archive for only one specific JFS2 file system on the client, specify the following in the server stanza in the dsm.sys file:

```
snapshotproviderfs   NONE

include.fs   /kalafs1   snapshotproviderfs=JFS2
```

To turn *off* snapshot-based file backup and archive for only one specific JFS2 file system on the client, specify the following in the server stanza in the dsm.sys file:

```
snapshotproviderfs   JFS2

include.fs    /kalafs2    snapshotproviderfs=NONE
```

To turn *on* snapshot-based file backup and archive for only one specific operation on the client, specify the following on the command line:

```
dsmc incr   -snapshotproviderfs=JFS2  /kalafs1
```

To turn *off* snapshot-based file backup and archive for only one specific operation on the client, specify the following in the server stanza in the dsm.sys file:

```
 snapshotproviderfs   JFS2
```

Then perform the backup command. For example:

```
dsmc incr -snapshotproviderfs=NONE /kalafs2
```

Linux

Protecting Btrfs file systems

Btrfs file systems can be included as file specifications for backup and restore commands, archive and retrieve commands, and on backup image and restore image commands. You can also specify Btrfs subvolumes as file specification to the backup and restore, and archive and retrieve functions. You cannot use the backup-archive client image backup or image restore commands on a Btrfs subvolume.

Btrfs file systems are supported on SLES 11 SP2, or later, on IBM®System x, System p, and System z®.

If you want to create a static image backup of the entire Btrfs file system, you must unmount all the subvolumes so the backup-archive client can unmount or mount the Btrfs file system during the backup process. You can avoid the mounting and unmounting requirements if you perform a snapshot-based image backup of the Btrfs file system instead of a static image backup.

Image backup and image restore functionality is not available for Btrfs subvolumes. If you try to back up a subvolume by using the image backup, the following message is displayed:

```
ANS1162E Filesystem could not be mounted
```

You can mount a Btrfs subvolume by using either the subvolume name or the subvolume ID.

On Btrfs file systems, journal backup can be performed both at the file system and the subvolume level. If you perform journal-based backups on a Btrfs file system, the journal that is created is for the entire file system; there is not a separate journal for each subvolume.

Restriction: On Linux systems, some file systems such as ext2, ext3, ext4, btrfs, and xfs use a universally unique identifier (UUID) to identify themselves to the operating system. If you create an image backup of such a volume and you restore it to a different location, you might have two volumes with the same UUID. If you use UUID to define your file systems in /etc/fstab, be aware that the backup-archive client might be unable to correctly mount the restored file system because the UUIDs conflict. To avoid this situation, restore the image to its original location. If you must restore it to a different location, change the UUID of either the original or restored volume before you mount the restored file system. Refer to the Linux documentation for instructions on how to change a UUID. You might also need to manually edit the /etc/fstab file so the original volume, the restored volume, or both volumes can be mounted.

- Linux Backing up and restoring Btrfs file systems
  You can back up or restore, or archive and retrieve, Btrfs file systems by using the backup-archive client incremental, selective, restore, archive, and retrieve commands.
- Linux Backing up and restoring Btrfs subvolumes
  You can back up or restore, or archive and retrieve, Btrfs subvolumes by using the backup-archive client incremental, selective, restore, archive, and retrieve commands.

Linux

Backing up and restoring Btrfs file systems

You can back up or restore, or archive and retrieve, Btrfs file systems by using the backup-archive client incremental, selective, restore, archive, and retrieve commands.

About this task

If you used a version of the backup-archive client that is older than Version 7.1 to back up a Btrfs file system, the file system type was listed as `Unknown`, in the IBM Spectrum Protect™ server GUI and command output. The `Unknown` file system type is displayed because before IBM Spectrum Protect 7.1, Btrfs file systems were not formally supported. If you use a backup-archive V7.1 client (or newer) to back up that same Btrfs file system, all files that have Access Control Lists (ACLs) and extended attributes (XATTRs) are backed up again, even if their content has not changed since the last backup that was created by the older version of the client. Also, after a Btrfs file system is backed up by the V7.1 (or newer) client, the file system type is correctly shown as `Btrfs` in the IBM Spectrum Protect server GUI and command output.

Even with a V7.1 or newer client, copying a file on a Btrfs file system might cause the file to be included in the next backup operation. For example, if you copy a file by using the cp command with the -p or -preserve options (preserve mode, ownership, and time stamps), and if the file's attributes are changed, the access ACL extended attribute (system.posix_acl_access) is

changed. Because an extended attribute is changed, the client backs up the entire file, rather than just updating the attributes for the file.

Procedure

1. Mount the file system that you want to protect or recover. For example, use the following syntax to mount a file system:
   ```
   mount /dev/sdb1 on /btreefs1 type btrfs (rw)
   ```
2. Protect or recover the file system by performing one of the following operations:

Operation	Command
Back up the file system	`dsmc incr /btreefs1`
Restore the file system	`dsmc restore /btreefs1/ -subdir=yes -replace=yes`
Archive the file system	`dsmc archive /btreefs1/ -subdir=yes`
Retrieve the file system	`dsmc retrieve /btreefs1/ -subdir=yes -replace=yes`
Back up a file system snapshot	Create the file system snapshot. Use the btrfs subvolume snapshot command. The snapshot directory that is specified in this example is the btreefs1_snap directory on the file system named /btreefs1. `btrfs subvolume snapshot /btreefs1/ /btreefs1/btreefs1_snap` Issue the backup-archive client incremental command. Specify the snapshotroot option and the location of the Btrfs snapshot. `$DSM_DIR/dsmc incr /btreefs1 -snapshotroot=/btreefs1/btreefs1_snap`
Perform an image backup	All subvolumes must be unmounted before you create an image backup. `dsmc backup image /btreefs1 -snapshotproviderimage=none` To avoid having to unmount the subvolumes, create a snapshot-based image backup. `dsmc backup image /btreefs1`
Restore an image backup	All subvolumes must be unmounted before you restore an image backup. `dsmc restore image /btreefs1`

Linux

Backing up and restoring Btrfs subvolumes

You can back up or restore, or archive and retrieve, Btrfs subvolumes by using the backup-archive client incremental, selective, restore, archive, and retrieve commands.

Procedure

1. List the subvolumes and determine their IDs.
   ```
   btrfs subvolume list /btreefs1
    ID 256 top level 5 path @
    ID 262 top level 5 path @/btreefs1_sub1
   ```
2. Make the directory to use as the mount point for the subvolume.
   ```
   mkdir /btreefs1_sub1
   ```
3. Mount the subvolume. For example, to mount the subvolume on device sdb1 at /btreefs1_sub1, use the following syntax:
   ```
   mount -t btrfs -o subvolid=262 /dev/sdb1 /btreefs1_sub1
   ```
   Protect or recover the subvolume by using one or more of the following operations:

Operation	Command
Back up a subvolume	Both incremental and selective backups are supported. `dsmc incr /btreefs1_sub1` `dsmc sel /btreefs1_sub1/ -subdir=yes`
Restore a subvolume	`dsmc restore /btreefs1_sub1/` `-subdir=yes -replace=yes`
Archive a subvolume	`dsmc archive /btreefs1_sub1/` `-subdir=yes`
Retrieve a subvolume	`dsmc retrieve /btreefs1_sub1/` `-subdir=yes -replace=yes`
Back up a Btrfs subvolume snapshot	Create the subvolume snapshot. Use the btrfs subvolume snapshot command. The snapshot directory that is specified in this example is the /btreefs1/btreefs1_sub1_snap directory, for the subvolume named btreefs1_sub1. `btrfs subvolume snapshot` `/btreefs1/btreefs1_sub1` `/btreefs1/btreefs1_sub1_snap` Issue the backup-archive client incremental command. Specify the snapshot root option and the location of the Btrfs snapshot. `dsmc incr /btreefs1_sub1` `-snapshotroot=/btreefs1` `/btreefs1_sub1_snap`

AIX | Solaris | Windows

Back up NAS file systems using Network Data Management Protocol

Windows, AIX®, and Solaris backup-archive clients can use Network Data Management Protocol (NDMP) to efficiently back up and restore network attached storage (NAS) file system images. The file system images can be backed up to, or be restored from, automated tape drives or libraries that are locally attached to Network Appliance or EMC Celerra NAS file servers, or to or from tape drives or libraries that are locally attached to the IBM Spectrum Protect™ server.

NDMP support is available only on IBM Spectrum Protect Extended Edition.

For Linux x86_64 clients, incremental backup can also be used to back up NAS file system snapshots. See the incremental command and snapshotroot, snapdiff, createnewbase, and diffsnapshot options for more information.

After configuring NDMP support, the server connects to the NAS device and uses NDMP to initiate, control, and monitor each backup and restore operation. The NAS device performs outboard data transfer to and from the NAS file system to a locally attached library.

Filer to server data transfer is available for NAS devices that support NDMP Version 4.

The benefits of performing backups using NDMP include the following:

- LAN-free data transfer.
- High performance and scalable backups and restores.
- Backup to local tape devices without network traffic.

The following support is provided:

- Full file system image backup of all files within a NAS file system.
- Differential file system image backup of all files that have changed since the last full image backup.
- Parallel backup and restore operations when processing multiple NAS file systems.
- Choice of interfaces to initiate, monitor, or cancel backup and restore operations:
  - Web client (only for connections to IBM Spectrum Protect Version 8.1.1, V8.1.0, or V7.1.7 or earlier servers)
  - Backup-archive client command interface (only for connections to IBM Spectrum Protect Version 8.1.1, V8.1.0, or V7.1.7 or earlier servers)

    - Administrative client command line interface (backup and restore operations can be scheduled using the administrative command scheduler)
    - Administrative web client

The following functions are *not* supported:

- Archive and retrieve
- Client scheduling. Use server commands to schedule a NAS backup.
- Detection of damaged files.
- Data-transfer operations for NAS data stored by IBM Spectrum Protect:
    - Migration
    - Reclamation
    - Export
    - Backup set generation

- AIX Solaris Windows Backing up NAS file systems with the web client GUI using NDMP protocol
  For both the web client GUI and the client command line interface, you must specify passwordaccess=generate (which is a current web client restriction for the client node) and set authentication=on must be specified at the server.
- AIX Solaris Windows Back up NAS file systems using the command line
  You can use the command line to back up NAS file system images.
- Windows Methods for backing up and recovering data on NAS file servers accessed by CIFS protocol
  The backup-archive client can process network-attached storage (NAS) file-server data that is accessed by using the Common Internet File System (CIFS) protocol.

Snapshotroot
AIX Solaris Windows

Backing up NAS file systems with the web client GUI using NDMP protocol

For both the web client GUI and the client command line interface, you must specify passwordaccess=generate (which is a current web client restriction for the client node) and set authentication=on must be specified at the server.

You are always prompted for a user ID and password. To display NAS nodes and perform NAS functions, you must enter an authorized administrative user ID and password. The authorized administrative user ID should have at least client owner authority over both the NAS node and the client workstation node they are using either from command line or from the web.

You can use the toc option with the include.fs.nas option in the client options file to specify whether the client saves Table of Contents (TOC) information for each file system backup. If you save TOC information, you can use the Windows web client to examine the entire file system tree and select files and directories to restore. Creation of a TOC requires that you define the TOCDESTINATION attribute in the backup copy group for the management class to which this backup image is bound. Note that TOC creation requires additional processing, network resources, storage pool space, and possibly a mount point during the backup operation.

The web client interface is available only for connections to the IBM Spectrum Protect Version 8.1.1, V8.1.0, or V7.1.7 or earlier servers.

To back up NAS file systems using the web client GUI:

1. Click Backup from the main window. The Backup window is displayed.
2. Expand the directory tree if necessary.
   Note:
    a. The root node called Nodes is not selectable. This node only appears if a NAS plug-in is present on the client workstation.
    b. NAS nodes display on the same level as the client workstation node. Only nodes for which the administrator has authority appear.
    c. You can expand NAS nodes to reveal file spaces, but no further expansion is available (no file names).

3. Click the selection boxes next to the nodes or file systems you want to back up.
4. Click the type of backup you want to perform in the backup type pull-down menu. The NAS backup type list is active only when you first select NAS backup objects. Full backup backs up the entire file system. Differential backs up the changes since the most recent full backup.
5. Click Backup. The NAS Backup Task List window displays the backup processing status and progress bar. The number next to the progress bar indicates the number of bytes backed up so far. After the backup completes, the NAS Backup Report window displays processing details, including the actual size of the backup, including the total bytes backed up.
   Note: If it is necessary to close the web browser session, current NAS operations continue after disconnect. You can use the Dismiss button on the NAS Backup Task List window to quit monitoring processing without ending the current operation.
6. (Optional) To monitor processing of an operation from the GUI main window, open the Actions menu and select IBM Spectrum Protect™ Activities. During a backup, the status bar indicates processing status. A percentage estimate is not displayed for differential backups.

Here are some items to consider when you back up NAS file systems using the web client GUI:

- Workstation and remote (NAS) backups are mutually exclusive in a Backup window. After selecting an item for backup, the next item you select must be of the same type (either NAS or non NAS).
- Details will not appear in the right-frame of the Backup window for NAS nodes or file systems. To view information about objects in a NAS node, highlight the object and select View > File Details from the menu.
- To delete NAS file spaces, select Utilities > Delete Filespaces.
- Backup options do not apply to NAS file spaces and are ignored during a NAS backup operation.

AIX | Solaris | Windows

Back up NAS file systems using the command line

You can use the command line to back up NAS file system images.

You can use the command-line client only if you are connecting to the IBM Spectrum Protect™ Version 8.1.1, V8.1.0, and V7.1.7 or earlier servers. For IBM Spectrum Protect V8.1.2 or later servers, use server commands on the administrative command-line client (dsmadmc).

Table 1 lists the commands and options that you can use to back up NAS file system images from the command line.

Table 1. NAS options and commands

Option or command	Definition	Page
domain.nas	Use the domain.nas option to specify the volumes to include in your default domain for NAS backups.	Domain.nas
exclude.fs.nas	Use the exclude.fs.nas option to exclude file systems on the NAS file server from an image backup when used with the backup nas command. AIX Solaris This option is for AIX® and Solaris clients *only*. Windows This option is valid for all Windows clients.	Exclude options
include.fs.nas	Use the include.fs.nas option to bind a management class to Network Attached Storage (NAS) file systems. You can also specify whether Table of Contents (TOC) information is saved during a NAS file system image backup, using the ***toc*** option with the include.fs.nas option in your client options file.. AIX Solaris This option is for AIX and Solaris clients *only*. Windows This option is valid for all Windows clients.	Include options

Option or command	Definition	Page
query node	Use the query node command to display all the nodes for which a particular administrative user ID has authority to perform operations. The administrative user ID should have at least client owner authority over both the NAS node and the client workstation node they are using.	Query Node
backup nas	Use the backup nas command to create an image backup of one or more file systems that belong to a Network Attached Storage (NAS) file server.	Backup NAS
toc	Use the toc option with the backup nas command or the include.fs.nas option to specify whether Table of Contents (TOC) information is saved for each file system backup.	Toc
Mac OS X AIX Linux Solaris Windows monitor process	Mac OS X AIX Linux Solaris Windows Use the monitor process command to display current backup and restore processes for all NAS nodes for which an administrative user has authority. The administrative user can then select one process to monitor.	Mac OS X AIX Linux Solaris Windows Monitor Process
cancel process	Use the cancel process command to display current backup and restore processes for all NAS nodes for which an administrative user has authority. From the display, the administrative user can select one process to cancel.	Cancel Process
query backup	Use the query backup command with the class option to display information about file system images backed up for a NAS file server.	Query Backup
query filespace	Use the query filespace command with the class option to display a list of file spaces belonging to a NAS node.	Query Filespace
delete filespace	Use the delete filespace command with the class option to display a list of file spaces belonging to a NAS node so that you can choose one to delete.	Delete Filespace

Windows A NAS file system specification uses the following conventions:

- NAS nodes represent a new node type. The NAS node name uniquely identifies a NAS file server and its data to IBM Spectrum Protect. You can prefix the NAS node name to the file specification to specify the file server to which the include statement applies. If you do not specify a NAS node name, the file system you specify applies to all NAS file servers.
- Regardless of client platform, NAS file system specifications use the forward slash (/) separator, as in this example: `/vol/vol0`.
- Windows NAS file system designations on the command line require brace delimiters `{}` around the file system names, such as: `{/vol/vol0}`. Do not use brace delimiters in the option file.

Note: When you initiate a NAS backup operation by using the client command line interface, client GUI, or web client the server starts a process to initiate, control, and monitor the operation. It might take several moments before you notice progress at the client command line interface because the server must perform a mount operation, and other necessary tasks, before data movement occurs.

Windows

Methods for backing up and recovering data on NAS file servers accessed by CIFS protocol

The backup-archive client can process network-attached storage (NAS) file-server data that is accessed by using the Common Internet File System (CIFS) protocol.

You can use the following methods to back up and recover data on NAS devices:

- Use the backup-archive client to back up and restore data, by using CIFS to access files from the backup-archive client. Data can be stored on the IBM Spectrum Protect™ server with file-level granularity, by using the progressive-incremental backup method. The data is stored in the IBM Spectrum Protect storage hierarchy and can be migrated, reclaimed, and backed up to a copy storage pool.

  This method increases processor usage when the client accesses individual files. The method requires that the data to flow through the client. This method also requires that the data flows through the IBM Spectrum Protect server unless a LAN-free configuration is used.

- Use the snapdiff option to mitigate the performance problems of CIFS backup. This option stores data with file-level granularity by using progressive incremental backup for CIFS.
- Use a backup-archive client that is running on the NAS device, if you can use external programs with the NAS operating system.

  This method decreases processor usage of CIFS. Data can be stored on the IBM Spectrum Protect server with file-level granularity by using progressive-incremental backup. The data is stored in the IBM Spectrum Protect storage hierarchy and can be migrated, reclaimed, and backed up to a copy storage pool. This method requires that data flow through the backup-archive client. This method also requires that the data flows over a network and through the IBM Spectrum Protect server unless a LAN-free configuration is used.

- Use NDMP with the backup-archive client. File systems are backed up as full images (all files) or differential images (all files that changed since the last full backup). Backed up images are stored on a tape device that is accessed by the NAS file server. This method provides high performance because there is no data flow through a backup-archive client or IBM Spectrum Protect server. Data that is backed up to the server by using NDMP cannot be migrated, reclaimed, or backed up to a copy storage pool.

The following limitations exist for NAS file server data when it is accessed by using CIFS:

- File and directory security information might be inaccessible when the Windows account that is performing the backup is not a member of the Domain Administrators group of the domain the NAS file server is a trusted member of. It is also possible that these security access failures might prevent the entire file or directory from being backed up.
- Performance degradation occurs because data is being accessed remotely.
- The mapped drives appear to the client as NTFS file systems, but they might not have full NTFS functionality. For example, the encryption attribute of a file is set, but when the client backs up the file, the backup fails because the volume-level encryption setting indicates that encryption cannot be used for the volume. ReFS file systems also appear to the client as NTFS file systems.
  Tip: Use NDMP with the backup-archive client on a NAS file server to back up and restore volumes instead of backing up and restoring the volumes by using remote mapped drives.

Windows

Support for CDP Persistent Storage Manager

Persistent Storage Manager (PSM) is the snapshot technology that is included with a number of Microsoft Server Appliance Kit-based NAS boxes that include the IBM® TotalStorage NAS 200, 300, and 300G.

You can use the backup-archive client to back up the persistent images (PI) of a volume that is produced by PSM. You must first ensure that the volume has a label. You can then use PSM to schedule or create a persistent image with a specific image name, such as `snapshot.daily`, and set the number of images to save to 1. PSM overwrites the PI as needed and you can use the client to incrementally back up the PI. In this case, the client backs up only the files that changed between snapshots. One advantage of backing up a PSM PI rather than the actual volume, is that there are no open files in the PI.

Consider the following items before you use Persistent Storage Manager:

- By default, a PSM schedule uses a variable name (*snapshot.%i*) and keeps a number of images.
  Important: Do not use the client with PSM in this manner. The client considers each image as unique and makes a complete copy of each image.
- The client requires that the volume used to make the PI has a label. If the volume does not have a label, the client does not back up its PI.
- You use the image backup function to back up the original volume that is used to create the PI. However, you cannot use the backup image function to back up the PI.

- To avoid backing up unnecessary files when you back up PSM, include the following entries in your client option file (dsm.opt):

```
exclude.dir "Persistent Storage Manager State"
exclude.file "*.psm"
exclude.file "*.otm"
```

AIX | Linux | Mac OS X | Solaris

Backup network file systems

You can configure the backup-archive client to protect files that are accessed with either Network File System (NFS) or Common Internet File System (CIFS) protocols.

Backup performance is better when you install the backup-archive client where the file system physically exists. But sometimes it is necessary to access file systems by using NFS or CIFS to back up or recover data on remote shared drives. The backup-archive client on AIX®, Linux, Mac OS X, and Solaris operating systems can back up, archive, restore, and retrieve file data on an NFS or CIFS-mounted shared drive. The operations are valid on all versions of the NFS protocol, including NFS version 2, NFS version 3, and NFS version 4.

The backup-archive can back up and restore access control lists when it is configured to use NFS version 4.

The following restrictions apply when the backup-archive client protects data on network file system volumes:

- Backup-archive clients cannot complete image backups of network file system volumes.
- Backup-archive clients on AIX cannot complete snapshot-based file backups or archive files on network file system volumes.
- Backup-archive clients cannot complete journal-based backups of network file system volumes.
- Backup-archive clients might not be able to back up NetApp volume snapshots if they are accessed by using the NFS protocol. If the NetApp filer provides different device identifiers for its volume snapshots, these snapshots might be excluded from backups. The behavior depends on the OS version, the NetApp filer version, and the settings.
- Mac OS X | AIX | Linux | Solaris Back up NFS file systems with the global namespace feature
  NFS V4 clients can back up NFS file systems that are mounted by using the global namespace feature, which is called a *referral*. All file systems in the global namespace are backed up under a single file space.

AIX

Back up AIX workload partition file systems

Using the backup-archive client on AIX®, you can back up and restore local partition file data within the global partition by using the local partition name space available within the global partition.

Each workload partition (WPAR) has its own security domain, so only the global root user is guaranteed to have access to all of the data.

The WPARs are partitions that are created entirely in software within a single AIX system image, with the following attributes:

- Usually the WPAR appears to be a complete stand-alone AIX system
- There is no hardware assist or configuration

Workload partitions provide a secure and isolated environment for enterprise applications in terms of process, signal, and file system space. Software running within the context of a workload partition appears to have its own separate instance of AIX.

The following example shows a WPAR configuration from within the global WPAR:

Global partition:
    System name: `shimla`
    File system: `/home /opt`
WPAR #1 configuration:
    Name: `wpar1`
    File system: `/home; name in global WPAR: /wpars/wpar1/home`
WPAR #2 configuration:
    Name: `wpar2`
    File system: `/data; name in global WPAR: /wpars/wpar2/data`

There are two ways to back up WPAR data, as follows:

- Back up all WPAR file systems as the file spaces within the global partition. The file space name must be used to identify the WPAR to which it belongs. All of the data is managed on one node by using one schedule. Using the example configuration, here is a sample dsm.sys file with one server stanza for all file systems, both global and local:

```
SErvername  shimla
   TCPPort            1500
   TCPServeraddress   server.example.com
   nodename           shimla
   PasswordAccess     generate
   Domain             /wpars/wpar1/home /wpars/wpar2/data /home /opt
```

- Back up each WPAR file system under a different node name. This method provides file space name segregation for each WPAR. Each WPAR must have a separate node name and a scheduler that is running within the global partition. Also, three scheduler services must be set up, each using a different dsm.opt file corresponding to the server stanza name. This method allows each WPAR backup operation to be managed independently of the others. Using the example configuration, here is a sample dsm.sys file with three server stanzas: one for `wpar1`, one for `wpar2`, and one for global partition `shimla`:

```
SErvername  shimla_wpar1
   TCPPort            1500
   TCPServeraddress   server.example.com
   nodename           wpar1
   PasswordAccess     generate
   Domain             /wpars/wpar1/home

SErvername  shimla_wpar2
   TCPPort            1500
   TCPServeraddress   server.example.com
   nodename           wpar2
   PasswordAccess     generate
   Domain             /wpars/wpar2/data

SErvername  shimla
   TCPPort            1500
   TCPServeraddress   server.example.com
   nodename           shimla
   PasswordAccess     generate
   Domain             /home /opt
```

Solaris

Backing up Solaris Zettabyte file systems

On Solaris SPARC and Solaris x86 systems, you can backup Zettabyte file systems (ZFS), by using ZFS snapshots. The advantage of this approach, over an ordinary incremental or selective backup, is that the files and folders in a snapshot are always in a read-only state, so they cannot be changed during a backup.

About this task

You create a ZFS snapshot by using Oracle Solaris ZFS commands. For example:

```
zfs snapshot tank/myZFS@mySnapshot
```

In this example, the ZFS pool name is called tank and the ZFS file system name is myZFS. Files that belong to this ZFS snapshot are in the subdirectory named tank/myZFS/.zfs/snapshot/mySnapshot/.

Procedure

Use either of these two methods to backup a ZFS snapshot.

- Backup each file of the snapshot by using the snapshotroot option. For example:

  ```
  dsmc inc -snapshotroot=/tank/myZFS/.zfs/snapshot/mySnapshot /tank/myZFS
  ```

  This option allows the administrator to replace the current snapshot path with the ZFS file system path, so that the files and folders are backed up under the original file system.
- Backup the complete snapshot by using Oracle Solaris ZFS commands. For example:

```
zfs send tank/myZFS@mySnapshot > /tmpdir/mySnapshotFile
```

The advantage of backing up the complete snapshot is that the full file system can be restored, in a disaster recovery scenario.

AIX

AIX JFS2 encrypted file system backup

Use AIX® JFS2 Encrypted File System (EFS) to back up files either in clear text or raw format. With clear text format, the file is decrypted by EFS as it is read. With raw format, the data is not decrypted. The default is raw format, but when you set the efsdecrypt option to yes, you get clear text backups.

About this task

Important: Whenever you run a backup that includes any files encrypted on an EFS, you must ensure that you use the correct specification of the efsdecrypt option. If the efsdecrypt option value changes between two incremental backups, all encrypted files on EFS file systems are backed up again, even if they have not changed since the last backup. For example, if you are running an incremental backup of encrypted files that were previously backed up as raw, then ensure that efsdecrypt is specified as no. If you change efsdecrypt to yes, all of the files are backed up again in clear text even if they are unchanged, so ensure that you use this option carefully.

If you attempt to restore an encrypted file to either a work station that does not support EFS, or a file system where EFS is not active, an error message is written and the file is skipped.

Here are some reasons to back up EFS using clear text encryption:

- This type of decryption is useful if you want to use the IBM Spectrum Protect™ backup-archive client encryption or another type of hardware encryption (for tape systems, for example).
- You can use clear text for long term archival of data, because the data is stored independent of the platform or encryption scheme.

Here are some things to consider when backing up a file in clear text:

- The user who invoked the backup-archive client must be able to decrypt it
- The user can have read access to a file, but not have access to the key

In the following scenarios an error message is issued:

Procedure

1. The user is running in root guard mode, and EFS has the concept of two types of root. Root admin is the traditional mode. A root in guard mode will not have access to the unencrypted data, unless the user is the owner or a member of the file group.
2. The user is running with a non-root user ID and attempting an archive of a file to which they have read access, but the user is not the owner or member of the file group. EFS will not allow the data to be decrypted.

Results

Here are some considerations when backing up EFS raw data:

- The backup-archive client will not honor the client encryption setting, which prevents double encryption, but only at the client. The server has no knowledge that the data is encrypted so any encryption done by a tape drive, for example, still occurs.
- The client will not honor the compression setting, so the client will not even try to compress the data.
- The client does not automatically back up or restore the keystore files. When you are restoring encrypted files, you might also have to restore keystores in order to decrypt the data.

Tips:

1. To protect the keystore, make sure the contents of /var/efs are included in your periodic backups.

2. For the keystore data, use IBM Spectrum Protect storage policy with an unlimited number of versions.

- Encrypted file system (EFS) files backed up in raw mode (default) cannot be restored by a backup-archive client prior to V5.5, or by a client on another UNIX platform.

AIX

Back up AIX JFS2 extended attributes

AIX® Enhanced Journal File System (JFS2) provides backup processing for named extended attributes for all file systems that support named extended attributes.

These extended attributes are automatically backed up with each object that contains extended attributes data, and no additional action is required.

When the file system is defined with the v2 format, the only file system that supports named extended attributes is JFS2. You can use JFS2 for extended attributes for files and directories, but you cannot use JFS2 for extended attributes on symbolic links.

Linux | Windows

Backing up VMware virtual machines

You can use the backup-archive client to back up and restore a VMware virtual machine (VM). Full backups of the virtual machine operate at a disk image level. Incremental backups copy only the data that is changed since the previous full backup.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Linux Table 1 lists the backup and restore capabilities for VMware virtual machines that the backup-archive client can implement on Linux platforms.

Table 1. Backup and restore capabilities for VMware virtual machines on Linux platforms

Capability	Comment
Full VM incremental-forever backup:	A full VM backup is required before you can create incremental backups. If you schedule incremental-forever backups, this backup type is selected automatically for the first backup if a full backup was not already created. Data from incremental backups is combined with data from the full backup to create a synthetic full backup image. Subsequent full VM incremental-forever backups read all used blocks and copy those blocks to the IBM Spectrum Protect server. Each full VM incremental-forever backup reads and copies all of the used blocks, whether the blocks are changed or not since the previous backup. You can still schedule a full VM backup, although a full backup is no longer necessary. For example, you might run a full VM backup to create a backup to a different node name with different retention settings. You cannot use this backup mode to back up a VMware virtual machine if the client is configured to encrypt the backup data.

Capability	Comment
Incremental-forever-incremental VM backup:	Requires you to create a full VM backup one time only. The full VM backup copies all of the used disk blocks owned by a virtual machine to the IBM Spectrum Protect server. After the initial full backup is complete, all subsequent backups of the virtual machine are incremental-forever-incremental backups. Each incremental-forever-incremental backup copies only the blocks that are changed since the previous backup, irrespective of the type of the previous backup. The server uses a grouping technology that associates the changed blocks from the most recent backup with data already stored on the server from previous backups. A new full backup is then effectively created each time changed blocks are copied to the server by an incremental-forever-incremental backup. The incremental-forever-incremental backup mode provides the following benefits: • Improves the efficiency of backing up virtual machines. • Simplifies data restore operations. • Optimizes data restore operations. During a restore operation, you can specify options for point-in-time and point-in-date to recover data. The data is restored from the original full backup and all of the changed blocks that are associated with the data. You cannot use this backup mode to back up a VMware virtual machine if the client is configured to encrypt the backup data.
Item recovery for files and folders from a full backup of the virtual machine:	Provides the capability to recover files and folders from a full backup of a virtual machine. Item recovery is available only with the IBM Spectrum Protect recovery agent.
Full restore of the virtual machine:	Restores all of the file systems, virtual disks, and the virtual machine configuration.

Windows Table 2 lists the backup and restore operations for VMware virtual machines that the backup-archive client can implement on Windows platforms.
Restriction: You can complete VMware backup and restore operations with the backup-archive client only on 64-bit Windows operating systems.

Table 2. Backup and restore capabilities for VMware virtual machines on Windows platforms

Capability	Comment
Full VM incremental-forever backup:	Requires the IBM Spectrum Protect for Virtual Environments licensed product. A full VM backup is required before you can create incremental backups. If you schedule incremental-forever backups, this backup type is selected automatically for the first backup if a full backup was not already created. Data from incremental backups is combined with data from the full backup to create a synthetic full backup image. Subsequent full VM incremental-forever backups read all used blocks and copy those blocks to the IBM Spectrum Protect server. Each full VM incremental-forever backup reads and copies all of the used blocks, whether the blocks are changed or not since the previous backup. You can still schedule a full VM backup, although a full backup is no longer necessary. For example, you might run a full VM backup to create a backup to a different node name with different retention settings. You cannot use this backup mode to back up a VMware virtual machine if the client is configured to encrypt the backup data.

Item recovery for files and folders from a full backup of the virtual machine:	Requires the IBM Spectrum Protect for Virtual Environments licensed product. Provides the capability to recover files and folders from a full backup of a virtual machine. Item recovery is available only with the IBM Spectrum Protect recovery agent.
Full restore of the virtual machine:	Restores all of the file systems, virtual disks, and the virtual machine configuration.
File-level restore of the virtual machine:	The restore approach depends on the type of backup of the virtual machine: • If you have a license for IBM Spectrum Protect for Virtual Environments, you can restore files and directories from a full VM image backup. • Backup-archive client users can restore files and directories that are created file-level backups of a virtual machine. You use the restore command to restore individual files from a file-level backup of a virtual machine, not the restore vm command. Note: File-level backups were created with the version 7.1 or earlier backup-archive clients.

- Linux Windows Preparing the environment for full backups of VMware virtual machines
  Complete the following steps to prepare the VMware environment for backing up full VMware virtual machines. The vStorage backup server can run either a Windows or Linux client.
- Linux Windows Creating full backups for VMware virtual machines
  A full backup of a VMware virtual machine is a backup of an entire virtual machine, including the virtual disks and the virtual machine configuration file. This type of backup is similar to an image backup. To create the full backup, you configure the backup-archive client on the vStorage backup server. The vStorage backup server must run a Windows client or a Linux client.
- Linux Windows Parallel backups of virtual machines
  With parallel backup processing, you can use a single data mover node to back up multiple virtual machines (VMs) at the same time to optimize your backup performance.

Linux Windows

Preparing the environment for full backups of VMware virtual machines

Complete the following steps to prepare the VMware environment for backing up full VMware virtual machines. The vStorage backup server can run either a Windows or Linux client.

Before you begin

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Procedure

1. To configure the storage environment for backing up, complete the following steps:
   a. Configure your storage environment so that the vStorage backup server can access the storage volumes that are in your ESX server farm.
   b. If you are using network-attached storage (NAS) or direct-attach storage, ensure that the vStorage backup server is accessing the volumes with a network-based transport.
   c. Optional: For data access, make the following settings:
      - Create storage area network (SAN) zones that your vStorage backup server can use to access the storage logical units (LUNs) that host your VMware datastores.
      - Configure your disk subsystem host mappings so that all ESX servers and the backup proxy can access the same disk volumes.
2. To configure the vStorage backup server, complete the following steps:
   a. Linux Set and export the LD_LIBRARY_PATH environment variable to point to the client installation directory. For example:

      export LD_LIBRARY_PATH=/opt/tivoli/tsm/client/ba/bin

   b. Linux Add the client installation directory to the path of each account that uses backup-archive client commands, for example, dsmc, dsmcad, or dsmj.
   c. Windows When the backup-archive client runs on a vStorage backup server, this client configuration is called the IBM Spectrum Protect *data mover node*. A Windows system that is a data mover must have the 64-bit Windows client installed on it. A data mover node typically uses the SAN to back up and restore data. If you configure the data mover node to directly access the storage volumes, turn off automatic drive letter assignment. If you do not turn off letter assignments, the client on the data mover node might corrupt the Raw Data Mapping (RDM) of the virtual disks. If the RDM of the virtual disks is corrupted, backups fail. Consider the following conditions for restore configurations:

      The data mover node is on a Windows Server 2012 or Windows Server 2012 R2 system:
      If you plan to use the SAN to restore data, you must set the Windows SAN policy to OnlineAll. Run diskpart.exe and type the following commands to turn off automatic drive letter assignment and set the SAN policy to OnlineAll:

      ```
      diskpart
        automount disable
        automount scrub
        san policy OnlineAll
        exit
      ```

      The backup-archive client is installed in a virtual machine on a Windows Server 2012 or Windows Server 2012 R2 system:
      If you plan to use the `hotadd` transport to restore data from dynamically added disks, the SAN policy on that system must also be set to OnlineAll.
      Whether the client uses the SAN or `hotadd` transport, the Windows SAN policy must be set to OnlineAll. If the SAN policy is not set to OnlineAll, restore operations fail, and the following message is returned:

      ```
      ANS9365E VMware vStoragee API error.
      IBM Spectrum Protect function name: vddksdk Write
      IBM Spectrum Protect file : vmvddkdsk.cpp (2271)
      API return code : 1
      API error message : Unknown error
      ANS0361I DIAG: ANS1111I VmRestoreExtent(): VixDiskLib_Write
      FAILURE startSector=512 sectorSize=512 byteOffset=262144,
      rc=-1
      ```

      For a description of the vStorage transport settings and how you can override the defaults, see the following topic:

      Linux Windows Vmvstortransport

   d. Windows Install the backup-archive client on the vStorage backup server. At the custom setup page of the installation wizard, select VMware vStorage API runtime files.

Important: If you are moving the backup data by using backups that are not in a LAN, the SAN must have separate connections for tape and disk.

3. To modify IBM Spectrum Protect, complete the following steps:
   a. Access the administrative command line on the backup-archive client.
   b. From the backup-archive client on the vStorage backup server, run the following command to register the node:

      ```
      register node my_server_name my_password
      ```

      Where *my_server_name* is the full computer name of the vStorage backup server and *my_password* is the password to access the server.
      Windows Tip: On Windows systems, you can get the server full computer name by right-clicking on My Computer. Click the Computer Name tab and look at the name listed next to Full computer name.
   c. Windows From the backup-archive client on the vStorage backup server, run the following command to register the node:

      ```
      register node my_vm_name my_password
      ```

      Where *my_vm_name* is the full name of the virtual machine that you are backing up.
4. Windows If you back up a virtual machine where volumes are mounted to directories rather than drive letters, files might not be stored in the correct location. An error might be caused because the mount point does not correspond to the actual mount points of backed up files. An error is caused because the mount points for a virtual machine that is running Windows do not have a drive letter assignment. When you use the VMware vStorage APIs for Data Protection, a `filespace` name is created that includes a number assignment. The `filespace` names that are created for the mount point do not correspond to the actual mount points of the backed up file.

   To back up or restore files to their original location, use the following steps:

   a. To restore files to their original location, map the drive or assign a drive letter to the mount point from the virtual machine.
   b. If you restore a file that the vStorage API renamed, select a different restore location.
   c. When using mount points without drive letter assignments, use an include or exclude statement for that volume. See the following example of an exclude statement:

      ```
      exclude \\machine\3$\dir1\...\*.doc
      ```

Creating full backups for VMware virtual machines

A full backup of a VMware virtual machine is a backup of an entire virtual machine, including the virtual disks and the virtual machine configuration file. This type of backup is similar to an image backup. To create the full backup, you configure the backup-archive client on the vStorage backup server. The vStorage backup server must run a Windows client or a Linux client.

Before you begin

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Procedure

1. To prepare the environment, complete the steps in the following topic:

   Preparing the environment for full backups of VMware virtual machines

2. To configure the backup-archive client on the vStorage backup server, complete the following steps:
   a. From the welcome page of the backup-archive client GUI, click Edit > Client Preferences.
   b. Select the VM Backup tab.
   c. Select VMWare Full VM.
   d. In the Domain Backup Types list, select Domain Full VM.
   e. In the Host field, enter either the host name of each ESX server or the host name of the Virtual Center. If you specify the Virtual Center, you can back up virtual machines from any of the VMware servers that are managed by the Virtual Center.
   f. Enter the user ID and password information for the host that you specify in the Host field.
   g. Optional: If you want to override the default management class for full virtual machine backups, specify the management class that you want to use.
   h. In the Datastore Location field, enter the path to the directory where the files are stored.
   i. Click OK to save your changes.
3. To create a backup of one of the virtual machines, complete the following steps:
   a. At the command line of the vStorage backup server, run the following command:

      ```
      dsmc backup vm my_vm_name -mode=iffull -vmbackuptype=fullvm
      ```

      Where *my_vm_name* is the name of the virtual machine.
   b. Verify that the command is completed without errors. The following message indicates successful completion:

      ```
      Backup VM command complete
      Total number of virtual machines backed up successfully: 1
      virtual machine vmname backed up to nodename NODE
      Total number of virtual machines failed: 0
      Total number of virtual machines processed: 1
      ```

4. Linux To verify that you can restore the files for the virtual machine, complete the following steps:
   a. At the command-line interface of the vStorage backup server, run the following command:

      ```
      dsmc restore vm my_vm_name
      ```

   b. If errors occur in the restore processing, view the client error log for more information.
      Tip: The log file is saved to `/opt/ibm/Tivoli/TSM/baclient/dsmerror.log`
5. Windows To verify that you can restore the files for the virtual machine, complete the following steps:
   a. At the command-line interface of the vStorage backup server, run the following command:

      ```
      dsmc restore vm my_vm_name
      ```

      Windows The default location of the restore is in the following directory:
      c:\mnt\tsmvmbackup*my_vm_name*\fullvm\RESTORE_DATE_yyyy_mm_dd[hh_mm_ss].

   b. If errors occur in the restore processing, view the client error log for more information.
      Tip: The error log is saved to the following file:

      ```
      c:\Program Files\Tivoli\TSM\baclient\dsmerror.log
      ```

Windows

Backing up Net Appliance CIFS share definitions

Network Appliance (NetApp) CIFS share definitions include share permissions that are set on the file server.

About this task

The Windows client backs up the CIFS share definition under the root directory, the mapped CIFS share, or the UNC name. This support requires that the Net Appliance file server is running DATA ONTAP software, which presents CIFS shares to remote clients as ordinary remote NTFS shares.

The root directory of a CIFS share is backed up with a full progressive incremental backup of the mapped drive/UNC name. See the following two examples:

```
net use x: \\NetAppFiler\CifsShareName
dsmc incr x:

dsmc incr \\NetAppFiler\CifsShareName
```

The following output is displayed when the root directory (and share definition) is backed up:

```
Directory-->                    0 \\NetAppFiler\CifsShare\ [Sent]
```

Display backup processing status

During a backup, by default the backup-archive client displays the status of each file it attempts to back up.

The client reports the size, path, file name, total number of bytes transferred, and whether the backup attempt was successful for the file. These are also recorded in the `dsmsched.log` file for scheduled commands.

Mac OS X | AIX | Linux | Solaris The web client and backup-archive client Java™ GUI provide a Task List window that displays information about files during processing. When a task completes, a Backup Report window displays processing details. Click the Help button in the Backup Report window for context help.

Windows The web client and backup-archive client GUI provide a Task List window that displays information about files during processing. When a task completes, a Backup Report window displays processing details. Click the Help button in the Backup Report window for context help.

On the backup-archive command line, the name of each file is displayed after it is sent to the server. The progress indicator shows overall progress.

Table 1 lists some informational messages and meanings.

Table 1. Client command line informational messages

Informational message	Meaning
`Directory-->`	Indicates the directory that you back up.
Mac OS X | AIX | Linux | Solaris `Normal File-->.`	Mac OS X | AIX | Linux | Solaris Any file that is not a directory, symbolic link, or special file.
Mac OS X | AIX | Linux | Solaris `Special File-->`	Mac OS X | AIX | Linux | Solaris Special files define devices for the system or temporary files that are created by processes. There are three basic types of special files: FIFO (first-in, first-out), block, and character. FIFO files are also called pipes. Pipes are created by one process to temporarily allow communication with another process. These files cease to exist when the first process finishes. Block and character files define devices. The client processes only device and named pipe special files. Socket special files are not processed.
Mac OS X | AIX | Linux | Solaris `Symbolic Link-->`	Mac OS X | AIX | Linux | Solaris Indicates that the client backs up a symbolic link.
`Updating-->`	Indicates that only the file meta data is sent, not the data itself.
`Expiring-->`	Indicates an object (file or directory) on the server that no longer exists on the client is expired and made inactive on the server.
`Total number of objects inspected:`	As indicated. When using journal-based backup, the number of objects that are inspected might be less than the number of objects that are backed up. When you use the snapshot difference incremental backup, the number of objects that are inspected is zero. The number is zero because the client performs an incremental backup of the files that NetApp reported as changed. The client does not scan the volume looking for files that have changed.
`Total number of objects backed up:`	As indicated.
`Total number of objects encrypted:`	This is a count of the objects that were encrypted during backup or archive processing.
`Data encryption type:`	Specifies the encryption algorithm type (e.g 256-bit AES), if one or more objects are encrypted during backup or archive processing.
`Total number of objects updated:`	These are files whose attributes, such as file owner or file permissions, have changed.
`Total number of objects rebound:`	See Bind management classes to files for more information.
`Total number of objects deleted:`	This is a count of the objects that are deleted from the client workstation after being successfully archived on the server. The count is zero for all backup commands.
`Total number of objects expired:`	See the section about full and partial incremental backup for more information.

Informational message	Meaning
`Total number of objects failed:`	Objects can fail for several reasons. Check the `dsmerror.log` for details.
AIX Linux Windows `Total snapshot difference objects:`	AIX Linux Windows For snapshot difference incremental backups, this represents the total number of objects backed up and the total number of objects expired.
`Total objects deduplicated:`	Specifies the number of files that are deduplicated.
AIX Linux Mac OS X Solaris `Total number of bytes inspected:`	AIX Linux Mac OS X Solaris Specifies the sum of the sizes of the files that are selected for the operation. For example, the total number of bytes that are inspected for this command is the number of bytes that are used on the volume `/Volumes/BUILD:` `dsmc INCREMENTAL /Volumes/BUILD/* -SU=Yes`
`Total bytes before deduplication:`	Specifies the number of bytes to send to the IBM Spectrum Protect™ server if the client does not eliminate redundant data. Compare this amount with `Total bytes after deduplication`. Includes metadata size and might be greater than bytes inspected.
`Total bytes after deduplication:`	Specifies the number of bytes that are sent to the IBM Spectrum Protect server after deduplication of the files on the client computer. Includes metadata size and might be greater than bytes processed.
Windows `Total number of bytes inspected:`	Windows Specifies the sum of the sizes of the files that are selected for the operation. For example, the total number of bytes inspected for this command is the number of bytes used in the directory `C:\Users` `dsmc.exe INCREMENTAL C:\Users\* -su=yes`
`Total number of bytes processed:`	Specifies the sum of the sizes of the files that are processed for the operation.
`Data transfer time:`	The total time to transfer data across the network. Transfer statistics might not match the file statistics if the operation was retried due to a communications failure or session loss. The transfer statistics display the bytes attempted to be transferred across all command attempts.
`Network data transfer rate:`	The average rate at which the network transfers data between the client and the server. This is calculated by dividing the total number of bytes transferred by the time to transfer the data over the network. The time it takes to process objects is not included in the network transfer rate. Therefore, the network transfer rate is higher than the aggregate transfer rate.

Informational message	Meaning
`Aggregate data transfer rate:`	The average rate at which IBM Spectrum Protect and the network transfer data between the client and the server. This is calculated by dividing the total number of bytes transferred by the time that elapses from the beginning to the end of the process. Both IBM Spectrum Protect processing and network time are included in the aggregate transfer rate. Therefore, the aggregate transfer rate is lower than the network transfer rate. Windows **Note:** On occasion, the aggregate data transfer rate might be higher than the network data transfer rate. This is because the backup-archive client can have multiple simultaneous sessions with the backup server. If you set the resourceutilization option, the client attempts to improve performance and load balancing by using multiple sessions when it backs up a volume or other set of files. When multiple sessions are open during backup, the data transfer time represents the sum of the times reported by all sessions. In this case, aggregate data transfer time is incorrectly reported as higher. However, when running with a single session, the aggregate data transfer rate should always be reported as lower than the network data transfer rate. Mac OS X AIX Linux Solaris Note: On occasion, the aggregate data transfer rate might be higher than the network data transfer rate. This is because the backup-archive client can have multiple simultaneous sessions with the backup server. If you set the resourceutilization option, the client attempts to improve performance and load balancing by using multiple sessions when it backs up a file space or other set of files. When multiple sessions are open during backup, the data transfer time represents the sum of the times reported by all sessions. In this case, aggregate data transfer time is incorrectly reported as higher. However, when running with a single session, the aggregate data transfer rate should always be reported as lower than the network data transfer rate.
`Objects compressed by:`	Specifies the percentage of data sent over the network divided by the original size of the file on disk. For example, if the net data-bytes are 10K and the file is 100K, then Objects compressed by: == (1 - (10240/102400)) x 100 == 90%.
`Total number of objects grew:`	The total number of files that grew larger as a result of compression.
`Deduplication reduction:`	Specifies the size of the duplicate extents that were found, divided by the initial file or data size. For example, if the initial object size is 100 MB, after deduplication it is 25 MB. The reduction would be: (1 - 25/100) * 100 = 75%.
`Total data reduction ratio:`	Adds incremental and compression effects. For example, if the bytes inspected are 100 MB and the bytes sent are 10 MB, the reduction would be: (1 - 10/100) * 100 = 90%
`Elapsed processing time:`	The active processing time to complete a command. This is calculated by subtracting the starting time of a command process from the ending time of the completed command process.
`Total number of bytes transferred:`	As indicated.
AIX Linux Solaris Windows `LanFree bytes transferred:`	AIX Linux Solaris Windows The total number of data bytes transferred during a lan-free operation. If the enablelanfree option is set to *no*, this line will not appear.
`Total number of bytes inspected:`	A sum of sizes of files selected for the operation.
`Total number of retries:`	The total number of retries during a backup operation. Depending on the settings for the serialization attribute and the changingretries option, a file that is opened by another process might not be backed up on the first backup try. The backup-archive client might try to back up a file several times during a backup operation. This message indicates the total retries for all files that are included in the backup operation.

Windows

Backup (Windows): Additional considerations

This section discusses additional information to consider when backing up data.

- Windows Open files
  Some files on your system might be in use when you try to back them up. These are called *open files* because they are locked by an application for its exclusive use.
- Windows Ambiguous file space names in file specifications
  If you have two or more file spaces such that one file space name is the same as the beginning of another file space name, then an ambiguity exists when you try to restore, retrieve, query, or do another operation that requires the file space name as part of the file specification.
- Windows Management classes
  IBM Spectrum Protect uses management classes to determine how to manage your backups on the server.
- Windows Deleted file systems
  When a file system or drive has been deleted, or it is no longer backed up by the client, the existing backup versions for each file are managed according to the following policy attributes: Number of days to keep inactive backup versions, and number of days to keep the last backup version (if there is no active version).
- Windows Removable media backup
  The backup-archive client backs up your removable media (such as tapes, cartridges or diskettes) based on the drive label, not the drive letter.
- Windows Fixed drives
  The backup-archive client can back up your fixed drives even if they do not have a label, including drive aliases created with the DOS **subst** command. This applies to both the drive alias and the underlying physical drive, because the alias name and the physical drive label are the same.
- Windows NTFS and ReFS file spaces
  When you back up files on NTFS or ReFS partitions, the client also backs up file security information and file descriptors.
- Windows Universal Naming Convention names
  A Universal Naming Convention (UNC) name is a network resource name for a share point on a workstation.
- Windows Microsoft Dfs file protection methods
  There are some methods that you can use to protect the data in your Microsoft Dfs environment.

Windows

Open files

Some files on your system might be in use when you try to back them up. These are called *open files* because they are locked by an application for its exclusive use.

It is not very common for files to be opened in locked mode. An application can open a file in this way to avoid other applications or users from reading or accessing the file, but it can prevent backup programs from reading the file for backup.

You might not always want to use the open file feature to back up open or locked files. Sometimes an application opens a file or group of files in this locked mode to prevent the access of these files in an inconsistent state.

To avoid the increase of processor usage when you create a volume snapshot for each backup, and on platforms where the open file feature is not available or is not in use, consider the following points:

- If the file is unimportant or can be easily rebuilt (a temporary file for example), you might not care if the file is backed up, and might choose to exclude it.
- If the file is important:
  - Ensure the file is closed before backing it up. If backups are run according to a schedule, use the preschedulecmd option to enter a command that closes the file. For example, if the open file is a database, issue a command to close the database. You can use the postschedulecmd option to restart the application that uses the file after the backup completes. If you are not using a schedule for the backup, close the application that uses the file before you start the backup.
  - The client can back up the file even if it is open and changes during the backup. This is only useful if the file is usable even if it changes during backup. To back up these files, assign a management class with *dynamic* or *shared dynamic* serialization.

Note: If open file support is not configured: While the client attempts to back up open files, this is not always possible. Some files are open exclusively for the application that opened them. If the client encounters such a file, it cannot read it for backup purposes. If you are aware of such file types in your environment, you should exclude them from backup to avoid seeing error messages in the log file.

Select a management class for files
Windows

Ambiguous file space names in file specifications

If you have two or more file spaces such that one file space name is the same as the beginning of another file space name, then an ambiguity exists when you try to restore, retrieve, query, or do another operation that requires the file space name as part of the file specification.

For example, consider the following file spaces and the backup copies they contain:

File space name	File name
\\storman\home	amr\project1.doc
\\storman\home\amr	project2.doc

Notice that the name of the first file space, \\storman\home, matches the beginning of the name of the second file space, \\storman\home\amr. When you use the backup-archive command-line client interface to restore or query a file from either of these file spaces, by default the client matches the longest file space name in the file specification, \\storman\home\amr. To work with files in the file space with the shorter name, \\storman\home, use braces around the file space name portion of the file specification.

This means that the following query command finds project2.doc but does not find project1.doc:

```
dsmc query backup "\\storman\home\amr\*"
```

This is because the longer of the two file space names is \\storman\home\amr and that file space contains the backup for project2.doc.

To find project1.doc, enclose the file space name in braces. The following command finds project1.doc but does not find project2.doc:

```
dsmc query backup "{\\storman\home}\amr\*"
```

Similarly, the following command restores project1.doc but does not restore project2.doc:

```
dsmc restore {\\storman\home}\amr\project1.doc
```
Windows

Management classes

IBM Spectrum Protect™ uses management classes to determine how to manage your backups on the server.

Every time you back up a file, the file is assigned a management class. The management class used is either a default selected for you, or one that you assign to the file using an include option in the include-exclude options list. The selected management class must contain a backup copy group for the file to be backed up.

Select **Utilities** → **View Policy Information** from the backup-archive client or web client GUI to view the backup policies defined by the IBM Spectrum Protect server for your client node.

Related concepts:
Storage management policies
Related tasks:
Setting the client scheduler process to run as a background task and start automatically at startup
Windows

Deleted file systems

When a file system or drive has been deleted, or it is no longer backed up by the client, the existing backup versions for each file are managed according to the following policy attributes: Number of days to keep inactive backup versions, and number of days to keep the last backup version (if there is no active version).

If you do nothing else, active backup versions remain indefinitely. If you do not need to keep the active versions indefinitely, use the expire command to inactive the active versions.

You can also use the delete backup command to delete individual backup versions, or the delete filespace command to delete the entire file space. Your IBM Spectrum Protect™ server administrator must give you "delete backup" authority to use these commands. If the file space also contains archive versions, you must also have delete archive authority to use delete filespace.

Use the query session command to determine whether you have delete backup and delete archive authority. Alternatively, you can ask your IBM Spectrum Protect server administrator to delete the file space for you.

When you delete a file system, it has no effect on existing archive versions. However, if you no longer require the archive versions, you can use the delete archive or delete filespace commands to delete archives.

Related concepts:
Storage management policies
Windows

Removable media backup

The backup-archive client backs up your removable media (such as tapes, cartridges or diskettes) based on the drive label, not the drive letter.

If a drive has no label, the backup does not occur. This use of drive labels permits you to perform such tasks as backing up different diskettes from the `a:` drive.

For a restore or retrieve, a separate file space for each drive label is maintained. These labels become the file space names on the IBM Spectrum Protect™ server. If you change the label of a drive you already backed up, the client views it as a new drive and does not relate it to your previous drive.

Because the client uses the labels to manage backups and archives of your removable media, you occasionally need to use those labels to locate data when using commands. For example, if you try to restore a file on diskette or DVD–ROM using `d:\projx\file.exe` as a file name, IBM Spectrum Protect substitutes the current label of your `d:` drive for the `d:`. If the `d:` drive label is `d-disk`, `d:\projx\file.exe` becomes `{d-disk}\projx\file.exe`, and the label is enclosed in braces.

If the label of the `d:` drive does not match a file space name on the server, IBM Spectrum Protect cannot locate your files using the current `d:` drive label. However, the client can locate your files if you use the file space name based on the original drive label. A mismatch between a label and a file space name might occur if you label your drives again, or if you access IBM Spectrum Protect from a different workstation than the one from which you backed up the files. If you have not relabeled the drive, and you are at the same workstation where the file was backed up, then you can use the drive letter as a shorthand version of the file space name (drive label).

Windows

Fixed drives

The backup-archive client can back up your fixed drives even if they do not have a label, including drive aliases created with the DOS **subst** command. This applies to both the drive alias and the underlying physical drive, because the alias name and the physical drive label are the same.

Windows

NTFS and ReFS file spaces

When you back up files on NTFS or ReFS partitions, the client also backs up file security information and file descriptors.

The following file descriptors are backed up:

- Owner security information (SID)
- Primary group SID
- Discretionary access-control list
- System access-control list

You must specify a file space name that is mixed case or lowercase text, and enclosed in quotation marks and braces. For example, `{"NTFSDrive"}`. Single quotation marks or double quotation marks are valid in loop mode. For example: `{"NTFSDrive"}` and `{'NTFSDrive'}` are both valid. In batch mode, only single quotation marks are valid. The single quotation mark requirement is a restriction of the operating system.

Windows

Universal Naming Convention names

A Universal Naming Convention (UNC) name is a network resource name for a share point on a workstation.

The resource name includes the workstation name assigned to the workstation and a name you assign to a drive or directory so that it can be shared. The name you assign is also called a *share point name*.

- Windows Examples: UNC names in domain lists
  This topic shows some examples of using UNC names to specify a domain list.
- Windows Examples: UNC name backup
  You can back up shared files in a network through the use of a UNC name. Some examples of backing up UNC name files are shown.

Windows

Examples: UNC names in domain lists

This topic shows some examples of using UNC names to specify a domain list.

About this task

You must specify the following information:

- A drive letter for removable media
- Drive letters or UNC name for local fixed drives
- Drive letters or UNC names for remote mapped drives
- UNC names for remote unmapped drives

Example 1: To specify drive a: containing removable media, enter

```
domain a: \\local\c$
```

Example 2: To specify fixed drive c:, enter

```
domain c: \\remote\share1 \\remote\c$
```

Windows

Examples: UNC name backup

You can back up shared files in a network through the use of a UNC name. Some examples of backing up UNC name files are shown.

A UNC name is a network resource name for a share point on a workstation. The resource name includes the workstation name assigned to the workstation and a name you assign to a drive or directory so that it can be shared. The name you assign is also called a share point name.

Using a UNC name permits you to back up specific shared directories to a separate file space. This is useful if, for example, you or an administrator want to back up a small portion of data that you would otherwise be unable to access. Drives are not backed up to a separate file space.

Every local drive is accessible using a UNC name except for drives containing removable media (such as tapes, cartridges or diskettes). Access these drives by using a predefined administrative share name consisting of the workstation name and the local drive letter, followed by `$`. For example, to specify a UNC name on the `c:` drive for workstation `ocean`, enter:

```
\\ocean\c$
```

The `$` sign *must* be included with the drive letter.

To enter a UNC name for workstation `ocean` and share point `wave`, enter:

```
\\ocean\wave
```

When accessing files, you do not need to enter the letter of the drive except for drives containing removable media.

See the following table for examples showing selective backup of files using UNC names. In these examples, assume that:

- The workstation running **dsmc** is `major`.
- Share names `betarc` and `testdir` from workstation `alpha1` are mapped to drives r and t, respectively.

Table 1. UNC examples

Example	Comment
`dsmc sel \\alpha1\c$\`	name of remote file space is `\\alpha1\c$`
`dsmc sel \\major\c$\`	name of local, fixed file space is `\\major\c$`
`dsmc sel a:\`	name of local, removable file space is volume label of `a:`
`dsmc sel \\alpha1\betarc\`	name of remote file space is `\\alpha1\betarc`
`dsmc sel \\alpha1\testdir\`	name of remote file space is `\\alpha1\testdir`
`dsmc sel d:\`	name of local, fixed file space is `\\major\d$`
`dsmc sel c:\`	file space name is `\\major\c$`
`dsmc sel r:\`	file space name is `\\alpha1\betarc`

You can also specify UNC names for files in your include-exclude and domain lists.

Windows

Microsoft Dfs file protection methods

There are some methods that you can use to protect the data in your Microsoft Dfs environment.

About this task

Here are the methods you should use to protect your Microsoft Dfs data:

Procedure

1. Back up the Dfs link metadata and the actual data at the share target of each link from the workstation hosting the Dfs root. This method simplifies back up and restore by consolidating all of the IBM Spectrum Protect™ activities on a single workstation. This method has the disadvantage of requiring an additional network transfer during backup to access the data stored at link targets.
2. Back up only the Dfs link metadata that is local to the workstation hosting the Dfs root. Back up the data at the target of each link from the workstation(s) which the data is local too. This method increases back up and restore performance by eliminating the extra network transfer, but requires back up and restore operations to be coordinated among several workstations.

Results

Note:

1. See the product README file for current limitations of this feature.

Files contained on a Dfs server component are accessed using a standard UNC name, for example:

```
\\servername\dfsroot\
```

where servername is the name of the host computer and dfsroot is the name of the Dfs root.

If you set the dfsbackupmntpnt option to *yes* (the default), an incremental backup of a Dfs root does not traverse the Dfs junctions. Only the junction metadata is backed up. This is the setting you should use so that the client can be used to restore Dfs

links.

You can use the dfsbackupmntpnt option to specify whether the client sees a Dfs mount point as a Microsoft Dfs junction or as a directory.

Important: Restore the Dfs junction metadata first. This recreates the links. Then restore each junction and the data at each junction separately. If you do not restore the junction metadata first, the client creates a directory under the Dfs root using the same name as the junction point and restores the data in that directory.
The following example relates to method 1 above and illustrates how to use the client to back up and restore a Microsoft Dfs environment. Assume the existence of a domain Dfs environment hosted by the workstation `wkst1`:

Dfs root
    \\wkst1\abc64test
Dfs link1
    \\wkst1\abc64test\tools
Dfs link2
    \\wkst1\abc64test\trees

Backup procedure:

1. Set the dfsbackupmntpnt option to *yes* in your client options file (dsm.opt).
2. Enter the following command to back up link junction information:

   ```
   dsmc inc \\wkst1\abc64test
   ```

3. Enter the following command to back up data at the tools link:

   ```
   dsmc inc \\wkst1\abc64test\tools
   ```

4. Enter the following command to back up data at the trees link:

   ```
   dsmc inc \\wkst1\abc64test\trees
   ```

Note: DFS Replication uses staging folders to act as caches for new and changed files to be replicated from sending members to receiving members. If you do not want to backup these files, you can exclude them from your backup using the exclude.dir option.

```
exclude.dir x:\...\Dfsrprivate
```

Restore procedure:

1. Manually recreate shares at target workstations only if they no longer exist.
2. Manually recreate the Dfs root using the exact name as it existed at the time of back up.
3. Enter the following command to recover data from the tools link. This step is not necessary if the data still exists at the link target:

   ```
   dsmc restore \\wkst1\abc64test\tools\* -sub=yes
   ```

4. Enter the following command to recover data from the trees link. This step is not necessary if the data still exists at the link target:

   ```
   dsmc restore \\wkst1\abc64test\trees\* -sub=yes
   ```

5. Use the Distributed File System management console snap-in to reestablish replication for each link, if necessary.

The following limitations exist for restoring Microsoft Dfs data:

- The client does not restore root of Dfs. To recreate the Dfs tree, manually create the Dfs root first, then start restore to recreate the links.
- The client can back up the Dfs tree (both domain based Dfs and stand alone Dfs) hosted on local workstation only. You cannot back up Dfs if the Dfs host server is not your local workstation.
- The client cannot recreate shared folders on restore. For example, if you delete the junction and the shared folder the junction points to, restoring the Dfs root recreates the Dfs junction, but restoring a junction creates a local folder instead of creating the original backed up shared network folder.
- If a Dfs link is created with replica and the replica share is on a different server, the client does not display the replica data.

- If a Dfs root is added or modified, the client will not back it up. You must specify the Dfs root in the domain option in the client options file (dsm.opt) regardless of whether DOMAIN ALL-LOCAL is specified.

Mac OS X | AIX | Linux | Solaris

Backup (UNIX and Linux): Additional considerations

There are some special situations that you need to consider before you back up your data.

- Mac OS X | AIX | Linux | Solaris Stored files
  When you back up and archive files, IBM Spectrum Protect stores the backups and archives in a file space in storage that has the same name as the file system or virtual mount point from which the files originated.
- Mac OS X | AIX | Linux | Solaris Special file systems
  Special file systems contain dynamic information generated by the operating system; they contain no data or files. The backup-archive client ignores special file systems and their contents.
- Mac OS X | AIX | Linux | Solaris NFS or virtual mount points
  When files are backed up and archived from a file system or virtual mount point, the client does not follow the nested NFS or virtual mount points (if any are defined on a file system). The nested NFS or virtual mount points will not be backed up or archived.
- Mac OS X | AIX | Linux | Solaris Management classes
  IBM Spectrum Protect uses management classes to determine how to manage your backups on the server.
- Mac OS X | AIX | Linux | Solaris Back up symbolic links
  The backup-archive client backs up symbolic links differently than it does regular files and directories.
- Mac OS X | AIX | Linux | Solaris Hard links
  When you back up files that are hard-linked, the backup-archive client backs up each instance of the linked file.
- AIX | Linux | Solaris Sparse files
  Sparse files do not have disk space allocated for every block in the whole address space, leading to holes within the file. Holes are detected by their content, which is always zeros, and these zeros take up space.
- Mac OS X | AIX | Linux | Solaris NFS hard and soft mounts
  When the backup-archive client connects to an NFS file system, you can use either a hard mount or a soft mount.
- Mac OS X | AIX | Linux | Solaris Deleted file systems
  When a file system or drive has been deleted, or it is no longer backed up by the backup-archive client, the existing backup versions for each file are managed according to the following policy attributes: Number of days to keep inactive backup versions, and number of days to keep the last backup version (if there is no active version)
- Mac OS X | AIX | Linux | Solaris Opened files
  The backup-archive client looks for files that have changed between the start and the completion of the backup of the file.
- Mac OS X | AIX | Linux | Solaris Wildcard characters
  You can use the operating system wildcard characters in file specifications with the backup-archive client. These characters let you select groups of files that have similar names.

Mac OS X | Mac OS X | AIX | Linux | Solaris

Stored files

When you back up and archive files, IBM Spectrum Protect™ stores the backups and archives in a file space in storage that has the same name as the file system or virtual mount point from which the files originated.

For example, if you have a file system named `/home`, and you back up a file named `doc1` in the `/home/monnett` directory, IBM Spectrum Protect stores the file in a file space named `/home`. If you later define `/home/monnett` as a virtual mount point, any files you back up from the `/home/monnett` directory, such as `doc2`, are stored in a file space named `/home/monnett`. If you enter this command:

```
dsmc query backup "/home/monnett/*"
```

IBM Spectrum Protect looks for files in the `/home/monnett` file space. It always looks for a file in the file space with the longest name that matches the file specification you include in a command. It locates the file named `doc2` that was backed up after the virtual mount point was defined. However, it does not locate the file named `doc1` because that file was backed up before the virtual mount point was defined and the backup was stored in the `/home` file space.

To list or restore the `doc1` file using a command, you must explicitly specify the file space name by enclosing it in braces. For example:

```
dsmc query backup "{/home}/monnett/*"
dsmc restore {/home}/monnett/doc1
```

If you subsequently remove the `/home/monnett` virtual mount point, and you then back up additional files in the `/home/monnett` directory, the backups are once again stored in the `/home` file space. For example, if you now back up a file named `doc3` in the `/home/monnett` directory, it is stored in the `/home` file space. It is not stored in the existing `/home/monnett` file space.

However, because the `/home/monnett` file space already exists, when you try to query or restore the `doc3` file, IBM Spectrum Protect looks for the file in the `/home/monnett` file space unless you specify the correct file space name. For example:

```
dsmc query backup "{/home}/monnett/*"
dsmc restore {/home}/monnett/doc2
```

Note: You must explicitly specify the file space name only when there can be more than one resolution to the file specification.

For example, if the following file spaces exist in storage:

```
/home
/home/monnett
/home/monnett/project1
/home/monnett/project1/planning
```

then enter:

```
dsmc query backup "/home/monnett/project1/planning/*"
```

IBM Spectrum Protect looks for files only in the `/home/monnett/project1/planning` file space, even if one or more of the other file spaces contains a path with the same name. But, when you enter one of the following:

```
dsmc query backup "{/home}/monnett/project1/planning/*"
dsmc query backup "{/home/monnett}/project1/planning/*"
dsmc query backup "{/home/monnett/project1}/planning/*"
```

IBM Spectrum Protect looks for files only in the `/home` file space, the `/home/monnett` file space, or the `/home/monnett/project1` file space, depending on which form you use.

Mac OS X | AIX | Linux | Solaris

Special file systems

Special file systems contain dynamic information generated by the operating system; they contain no data or files. The backup-archive client ignores special file systems and their contents.

Special file systems include the following:

- the `/proc` file system on most of the UNIX platforms
- the `/dev/fd` file system on Solaris
- the `/dev/pts` on Linux

Mac OS X | AIX | Linux | Solaris

NFS or virtual mount points

When files are backed up and archived from a file system or virtual mount point, the client does not follow the nested NFS or virtual mount points (if any are defined on a file system). The nested NFS or virtual mount points will not be backed up or archived.

Mac OS X | AIX | Linux | Solaris

Management classes

IBM Spectrum Protect™ uses management classes to determine how to manage your backups on the server.

Every time you back up a file, the file is assigned a management class. The management class used is either a default selected for you, or one assigned to the file with an include option in the include-exclude options list. The selected management class must contain a backup copy group in order for the file to be backed up.

Select **Utilities** → **View Policy Information** from the Java™ or web client GUI to view the backup policies defined by the IBM Spectrum Protect server for your client node.

Related concepts:
Storage management policies
AIX | Linux | Solaris

Back up symbolic links

The backup-archive client backs up symbolic links differently than it does regular files and directories.

The way that the client backs up symbolic links depends on options settings, whether the target directory is accessible, and the way you specify objects.

A *UNIX symbolic link* is a file that contains a pointer to another file or directory. The object the symbolic link points to is called the target object.

A symbolic link can be backed up as path information to a target directory, or it can be backed up as a directory. If the symbolic link is backed up as a directory, the files and folders in the target directory can also be backed up.

Note: Symbolic link processing as described here does not apply to Mac OS X. Symbolic links are always backed up as files and are never followed.

- Mac OS X | AIX | Linux | Solaris Examples: Incremental or selective backup of symbolic links
  How the client backs up a symbolic link depends on whether the target of the symbolic link is a file or a directory, and how you specify the symbolic link on the incremental or selective backup command.
- Mac OS X | AIX | Linux | Solaris Incremental backup of a domain only
  The client backs up a symbolic link during an incremental backup of the domain, if the symbolic link is defined as a virtual mount point and the followsymbolic option is set to yes.

Related reference:
Archsymlinkasfile
Followsymbolic
Virtualmountpoint
Mac OS X | AIX | Linux | Solaris

Examples: Incremental or selective backup of symbolic links

How the client backs up a symbolic link depends on whether the target of the symbolic link is a file or a directory, and how you specify the symbolic link on the incremental or selective backup command.

If a symbolic link points to a file, the client only backs up the path information. The client does not back up a file that is the target of a symbolic link.

If a symbolic link points to a directory, the backup depends on how the directory is specified on the command.

If a directory is specified with a trailing slash on a selective or incremental backup command, the client saves the symbolic link as a directory, and backs up the contents of the target directory.

If the symbolic link is entered without a trailing slash, or if a symbolic link is not explicitly stated in a backup file specification, the client backs up only the path information to the target directory. The contents of the target directory are not backed up.

In the following examples, assume that `symdir` is a symbolic link to target directory `/fs1/guest/`. `/fs1/guest/` contains these objects:

- `/fs1/guest/file` (a file)
- `/fs1/guest/dir1` (a directory)
- `/fs1/guest/dir1/file1` (a file)

Example 1

```
dsmc incr /home/gillis/symdir/
```

In this example, the client backs up the symbolic link as a directory, and backs up the contents of the target directory `/fs1/guest/`. If you specify the subdir=yes option, the client backs up subdirectories of `/fs1/guest/`.

Example 2

```
dsmc incr /home/gillis/symdir/dir1
```

Example 3

```
dsmc incr /home/gillis/symdir/dir1/
```

In Example 2 and Example 3, the client backs up the symbolic link as a directory, and backs up the `/dir1/` subdirectory of the target directory. The trailing slash is relevant only for the symbolic link; it is not relevant for subdirectories of the symbolic link. If you specify the subdir=yes option, the client backs up subdirectories of the `/fs1/guest/dir1` directory. Backup copies that are stored on the IBM Spectrum Protect™ server have a path of `/home/gillis/symdir/dir1/file1`.

Example 4

```
dsmc incr /home/gillis/symdir
```

In Example 4, because there is no trailing slash after the symbolic link, the client backs up only the path to the target directory. The client does not back up the symbolic link as a directory, and does not back up files nor folders in the target directory.

Example 5

```
dsmc incr /home/gillis/
```

In Example 5, because the symbolic link is not explicitly stated in the backup file specification, the client backs up only the path to the target directory. As in example 3, the client does not back up the symbolic link as a directory, and does not back up files nor folders in the target directory.

Restriction: If you back up a symbolic link as a directory, a future incremental backup that does not back up that symbolic link as a directory expires that symbolic link as a directory, and expires the files and directories in that directory.

For example, assume that you first back up the symbolic link `symdir` as a directory, and back up the contents of the target directory. The command in example 1 does this. The client creates backup copies with a high-level path `/home/gillis/symdir/`. In this example, the client creates backup copies with these paths:

- `/home/gillis/symdir/`
- `/home/gillis/symdir/file`
- `/home/gillis/symdir/dir1`
- `/home/gillis/symdir/dir1/file1`

The contents of `/home/gillis` are backed up using the following command:

```
dsmc inc /home/gillis/ -subdir=yes
```

This command processes the value `symdir` as a symbolic link and does not process any objects that the symbolic link points to. Hence, the client expires backup copies in the `/home/gillis/symdir/` directory that were created in Example 1.

Mac OS X | AIX | Linux | Solaris

Incremental backup of a domain only

The client backs up a symbolic link during an incremental backup of the domain, if the symbolic link is defined as a virtual mount point and the followsymbolic option is set to yes.

The client backs up a symbolic link and the target directory when all of the following conditions are true:

- The client performs an incremental backup of the domain.
- AIX | Linux | Solaris The symbolic link is defined as a virtual mount point using the virtualmountpoint option.
- `followsymbolic=yes`

AIX | Linux | Solaris The virtualmountpoint and followsymbolic options add the symbolic link to the domain. The Incremental command backs up the domain, which includes the symbolic link target.

Followsymbolic
Virtualmountpoint

Mac OS X | AIX | Linux | Solaris

Hard links

When you back up files that are hard-linked, the backup-archive client backs up each instance of the linked file.

For example, if you back up two files that are hard-linked, the client backs up the file data twice.

When you restore hard-linked files, the client attempts to reestablish the links. For example, if you had a hard-linked pair of files, and only one of the hard-linked files is on your workstation, when you restore both files, they are hard-linked. The files are also hard-linked even if neither of the files exists at the time of restore, if both of the files are restored together in a single command. The one exception to this procedure occurs if you back up two files that are hard-linked and then break the connection between them on your workstation. If you restore the two files from the server using the standard (or classic) restore process, the client respects the current file system and does not re-establish the hard link.

Important: If you do not back up and restore all files that are hard-linked at the same time, problems occur. To ensure that hard-linked files remain synchronized, back up all hard links at the same time and restore those same files together.

AIX | Linux | Solaris

Sparse files

Sparse files do not have disk space allocated for every block in the whole address space, leading to holes within the file. Holes are detected by their content, which is always zeros, and these zeros take up space.

The default is to restore the sparse file without the holes, which would leave more free disk space. The backup-archive client detects sparse files during a backup operation and marks them as sparse on the IBM Spectrum Protect™ server.

Note: Sparse files do not apply to Mac OS X.

The backup-archive client backs up a sparse file as a regular file if client compression is off.

Compression
Makesparsefile

Mac OS X | Mac OS X | AIX | Linux | Solaris

NFS hard and soft mounts

When the backup-archive client connects to an NFS file system, you can use either a hard mount or a soft mount.

The client uses the nfstimeout option value to determine how long to wait for an NFS system call to respond before timing out; this setting applies to hard and soft mounts. The default is 0 seconds. This means that the client uses the default behavior of NFS system calls.

Be aware of the consequences of hard and soft mounts if the mount becomes stale (for example, if the server for the file system is not available).

Hard mount
: If the NFS file system is hard mounted, the NFS daemons try repeatedly to contact the server. The NFS daemon retries will not time out, they affect system performance, and you cannot interrupt them, but control returns to the client when the nfstimeout value is reached.

Soft mount
: If the NFS file system is soft mounted, NFS tries repeatedly to contact the server until either:

  - A connection is established
  - The NFS retry threshold is met
  - The nfstimeout value is reached

  When one of these events occurs, control returns to the calling program.

  Note: On UNIX and Linux systems, the nfstimeout option can fail if the NFS mount is hard. If a hang occurs, deactivate the nfstimeout option and mount the NFS file system soft mounted, as follows:

```
mount -o soft,timeo=5,retry=5 machine:/filesystem /mountpoint
```

  The parameters are defined as follows:

  soft
  : Generates a soft mount of the NFS file system. If an error occurs, the stat() function returns with an error. If the option hard is used, stat() does not return until the file system is available.

  timeo=n

Sets the timeout period for a soft mount error to *n* tenths of a second.

retry=n

Sets the number of times to try the mount, where *n* is an integer; the default is 10000.

Mac OS X | AIX | Linux | Solaris

Deleted file systems

When a file system or drive has been deleted, or it is no longer backed up by the backup-archive client, the existing backup versions for each file are managed according to the following policy attributes: Number of days to keep inactive backup versions, and number of days to keep the last backup version (if there is no active version)

If you do nothing else, active backup versions remain indefinitely. If you do not need to keep the active versions indefinitely, use the expire command to inactive the active versions.

If you do not need to keep any of the backup versions, use the delete backup command to delete all backup versions in the file space. Your IBM Spectrum Protect™ server administrator must give you the authority to use this command. Use the query session command to determine whether you have "delete backup" authority. Alternatively, you can ask your IBM Spectrum Protect server administrator to delete the file space for you.

Storage management policies

Mac OS X | AIX | Linux | Solaris

Opened files

The backup-archive client looks for files that have changed between the start and the completion of the backup of the file.

Some files on your system might be in use, or open, when you try to back them up. Because an open file can change, a backup action might not reflect the correct contents of the file at a given time.

Consider whether the file is important, and whether you can build the file again. If the file is not important, you might not want to back it up. Or, if the file is important, a root user on your workstation can ensure the file is closed before backup.

If your backups run on a schedule, a root user can use the preschedulecmd option to enter a command to close the file. For example, if the open file is a database, use the quiesce command of the database to shut down the database. A root user can use the postschedulecmd option to restart the application that uses the file after the backup completes. If you are not using a schedule for the backup, ensure that you close the application that uses the file before you start the backup.

The client can back up the file even if it is open and gets changed during the backup. This is only useful if the file is usable even if it changes during backup. To back up these files, assign the files a management class with the serialization *dynamic* or *shared dynamic*.

Mac OS X | AIX | Linux | Solaris

Wildcard characters

You can use the operating system wildcard characters in file specifications with the backup-archive client. These characters let you select groups of files that have similar names.

In a command, wildcard characters can only be used in the file name or extension. They cannot be used to specify destination files, file systems, or directories. When using wildcard characters in non-loop mode, as in `dsmc sel "/home/ledger.*"`, enclose the parameter containing the asterisk in quotation marks to ensure the system does not interpret the wildcard character and produce unexpected results. Wildcard character information is covered in the following table.

Important: Use an asterisk (*) instead of a question mark (?) as a wildcard character when trying to match a pattern on a multibyte code page, to avoid unexpected results.

This table shows some wildcard patterns and how to specify them.

* *(Asterisk)*	**Zero or more characters that match all files:**
***.cpp**	With a cpp extension
hm*.*	Starting with hm, regardless of extension, but must have the **'.'** character
hm*	Starting with hm, whether an extension exists or not
h*.	With an h somewhere in the file name, regardless of extension, but must have **.**

? *(Question mark)*	**One character that matches all files with:**
?.cpp	The extension cpp with one, and only one, character in the file name
hm?.cpp	Three-character names beginning with hm and that have the cpp extension

* ? *(Asterisk and question mark)*	**Asterisk and question mark combinations matching:**
??hm.*	All four-character file names ending in hm., no matter what extension they have

In a path name for a file specification, you cannot specify a directory whose name contains an asterisk (*) or a question mark (?). The client recognizes those characters only as wildcard characters.

Restoring your data

Use IBM Spectrum Protect™ to restore backup versions of specific files, a group of files with similar names, or entire directories.

You can restore these backup versions if the original files are lost or damaged. Select the files that you want to restore by using a file specification (file path, name, and extension), a directory list, or a subdirectory path to a directory and its subdirectories.

Windows Note: When you restore a directory, its modification date and time is set to the date and time of the restore operation, and not to the date and time the directory had when it was backed up. This is because IBM Spectrum Protect restores the directories first, then adds the files to the directories.

All client backup and restore procedures that are referenced by this topic also apply to the web client. However, the web client does not provide a Preferences Editor for setting client options.

AIX Linux Mac OS X Solaris Attention: Do not restore operating system files, like base system directories, kernel modules, or patches, to their original location while the file system is running. The operating system might hang or crash.

The following are the primary restore tasks:

- Windows Restoring files and directories
- Windows Restoring Windows system state
- Windows Restoring Automated System Recovery files
- Windows Microsoft Dfs tree and file restore
- AIX Linux Solaris Windows Restoring an image
- Mac OS X AIX Linux Solaris Mac OS X Restoring data using the GUI

- Restoring data to a point in time
- AIX Linux Solaris Mac OS X Windows Restore NAS file systems
- Windows Authorizing another user to restore or retrieve your files
- Mac OS X AIX Linux Solaris Mac OS X Authorizing another user to restore or retrieve your files
- Windows Restoring or retrieving files from another client node
- AIX Linux Solaris Mac OS X Restoring or retrieving files from another client node
- Windows Restoring or retrieving your files to another workstation
- Mac OS X AIX Linux Solaris Mac OS X Restore or retrieve files to another workstation
- Mac OS X AIX Linux Solaris Restoring a disk in case of disk loss
- Windows Deleting file spaces
- Mac OS X AIX Linux Solaris Mac OS X Deleting file spaces
- Windows Restoring data from a VMware backup

AIX Linux Solaris Mac OS X Refer to *IBM Spectrum Protect for Space Management for UNIX and Linux* for details about restoring migrated files and the restoremigstate option.

- Windows Duplicate file names
  If you attempt to restore or retrieve a file whose name is the same as the short name of an existing file, a file name collision occurs (existence of duplicate file names).
- Windows Universal Naming Convention names restore
  Using a Universal Naming Convention (UNC) name permits you to restore specific shared files to a separate file space. This is useful if, for example, you or an administrator want to restore a portion of data that you would otherwise be unable to access.
- Windows Active or inactive backup restore
  Your administrator determines how many backup versions IBM Spectrum Protect maintains for each file on your workstation. Having multiple versions of a file permits you to restore older versions if the most recent backup is damaged.
- Windows Restoring files and directories
  You can locate the files you want to restore by searching and filtering.
- Windows Restoring Windows system state
  The Microsoft Volume Shadowcopy Service (VSS) is supported on Windows backup-archive clients. The client uses VSS to restore the system state. The system state restore function is deprecated for online system state restore operations.
- Windows Restoring Automated System Recovery files
  You can restore Automated System Recovery (ASR) files to recover the Windows operating system volume configuration information and system state if a catastrophic system or hardware failure occurs.
- Windows Restoring the operating system when the computer is working
  If your computer is working, you can restore the operating system from backed up files.
- Recovering a computer when the Windows OS is not working
  If the computer has a catastrophic hardware or software failure, you can recover a Windows operating system with Automated System Recovery (ASR).
- Windows Microsoft Dfs tree and file restore
  To restore Dfs junctions and the data for each junction, restore the Dfs junction metadata first and then restore each junction separately.
- AIX Linux Solaris Windows Restoring an image
  There are some items to consider before you begin restoring images on your system.
- Restore data from a backup set
  Your IBM Spectrum Protect administrator can generate a backup set, which is a collection of your files that reside on the server, onto portable media created on a device using a format that is compatible with the client device.
- Windows Restore Net Appliance CIFS shares
  Restoring the share definition requires restoring the root directory of the share file space, which under most circumstances can be done as follows: `dsmc rest \\NetAppFiler\CifsShareName\ -dirsonly`.
- Windows Restoring data from a VMware backup
  You can use several methods for restoring data from backups to a VMware virtual machine. The restore method depends on the type of backup and on the version of the backup-archive client software that you use to run the restore.
- Windows Restore Windows individual Active Directory objects
  You can restore individual Active Directory objects to recover from accidental corruption or deletion of Active Directory objects without requiring a shutdown or restart of the Active Directory server.
- Restoring or retrieving data during a failover
  When the client fails over to the secondary server, you can restore or retrieve replicated data from the secondary server.
- Windows Authorizing another user to restore or retrieve your files
  You can authorize a user on another node to restore your backup versions or retrieve your archive copies. In this way, you can share files with other people or with other workstations that you use with a different node name.
- Windows Restoring or retrieving files from another client node
  After users grant you access to their files on the server, you can restore or retrieve those files to your local system.
- Windows Restoring or retrieving your files to another workstation
  When you are using a different workstation, you can restore or retrieve files you backed up from your own workstation.
- Windows Deleting file spaces
  If your IBM Spectrum Protect administrator grants you authority, you can delete entire file spaces from the server.
- AIX Linux Solaris Restore an image to file
  When you back up an image, the backup-archive client backs up the first sector of the volume, but when the data is restored, it skips the first sector to preserve the original logical volume control block of the destination volume.
- AIX Linux Manage GPFS file system data with storage pools
  With Global Parallel File Systems (GPFS™) technology, you can manage your data using storage pools. A storage pool is a collection of disks or RAIDs with similar properties that are managed together as a group.
- Restoring data to a point in time
  Use a *point-in-time* restore to restore files to the state that existed at a specific date and time.
- AIX Restore AIX encrypted files
  When files are backed up in raw format from an AIX® JFS2 Encrypted File System (EFS), you can only restore them to the same or another JFS2 EFS. They cannot be restored to any different file system, or on a different platform.

- AIX Restore AIX workload partition file systems
  All the files that are created by the local workload partition (WPAR), and backed up by the backup-archive client that is installed at the global WPAR, can be restored by the client installed at the global WPAR.
- AIX Solaris Windows Restore NAS file systems
  You restore NAS file system images using the web client or command line interface. The web client interface is available only for connections to the IBM Spectrum Protect Version 8.1.1, V8.1.0, or V7.1.7 or earlier servers.

Windows

Duplicate file names

If you attempt to restore or retrieve a file whose name is the same as the short name of an existing file, a file name collision occurs (existence of duplicate file names).

An example is when the file *abcdef**ghijk**.doc* has a short name of *abcdef~**1**.doc*, and you attempt to restore or retrieve a file explicitly named *abcdef~**1**.doc* into the same directory. In this case, a collision occurs because the name of the file you are restoring conflicts with the short name for *abcdef**ghijk**.doc*.

A collision can occur even if the files are restored or retrieved to an empty directory. For example, files *abcdef~**1**.doc* and *abcdef**ghijk**.doc* might originally have existed in the directory as *abcdef**ghijk**.doc* and *abcdef~**2**.doc*. During the restore, if *abcdef**ghijk**.doc* is restored first, it is assigned a short name of *abcdef~**1**.doc* by the Windows operating system. When you restore *abcdef~**1**.doc*, the duplicate file name situation occurs.

IBM Spectrum Protect™ handles these situations based on the value of the replace option. Use the replace option to specify whether to overwrite an existing file, or to prompt you for your selection when you restore or retrieve files.

If a file name collision occurs, you can do any of the following:

- Restore or retrieve the file with the short file name to a different location.
- Stop the restore or retrieve and change the name of the existing file.
- Disable short file name support on Windows.
- Do not use file names, such as *abcdef~**1**.doc*, that would conflict with the short file naming convention.

Replace
Windows

Universal Naming Convention names restore

Using a Universal Naming Convention (UNC) name permits you to restore specific shared files to a separate file space. This is useful if, for example, you or an administrator want to restore a portion of data that you would otherwise be unable to access.

Except for drives with removable media, every local drive letter is accessible using a local UNC name that includes the workstation name and a designation for the drive letter. For example, to enter a UNC name on drive `c:` for workstation `ocean`, enter:

```
\\ocean\c$
```

The $ sign *must* be included with the drive letter.

To enter a UNC name for workstation `ocean` and share point `wave`, enter:

```
\\ocean\wave
```

When accessing files, you do not need to enter the letter of the drive *except* for drives with removable media.
Windows

Active or inactive backup restore

Your administrator determines how many backup versions IBM Spectrum Protect™ maintains for each file on your workstation. Having multiple versions of a file permits you to restore older versions if the most recent backup is damaged.

The most recent backup version is the *active* version. Any other backup version is an *inactive* version. Every time IBM Spectrum Protect backs up your files, it marks the new backup version as the active backup, and the last active backup becomes an inactive backup. When the maximum number of inactive versions is reached, IBM Spectrum Protect deletes the oldest inactive version.

To restore a backup version that is inactive, you must display both active and inactive versions by clicking on the **View** menu → **Display active/inactive files** item. To display only the active versions (the default), click on the **View** menu → **Display active files only** item. If you try to restore both an active and inactive version of a file at the same time, only the active version is restored.

On the IBM Spectrum Protect command line, use the inactive option to display both active and inactive objects.

Related reference:
Inactive
Windows

Restoring files and directories

You can locate the files you want to restore by searching and filtering.

Filtering displays only the files that match the filter criteria for your restore operation. Files that do not match the filter criteria do not display. The filter process searches files in the specified directory but does not include subdirectories.

- Windows Restoring data by using the GUI
  You can use the client GUI to restore files and directories.
- Windows Examples for restoring data using the command line
  You can use the examples in this topic when you need to restore objects from IBM Spectrum Protectserver storage.

Windows

Restoring data by using the GUI

You can use the client GUI to restore files and directories.

About this task

Restriction: The web client GUI cannot browse network resources for a restore operation. No shares are listed if you expand the Network branch. You can restore to a network resource from the web client if the entire file is processed. Specify the shared file system in the domain option in the `dsm.opt` options file. For example, `domain all-local \\server\share`. To complete the restore operation, specify Network Share in the Restore Destination dialog. This processes all file systems that are specified by the domain option. Alternatively, you can use the GUI Client to complete the restore operation.

Procedure

1. Click Restore on the main window. The Restore window appears.
2. Expand the directory tree by clicking the plus (+) sign or the folder icon next to an object in the tree. Select the object that you want to restore. To search or filter files, click the Search icon from the toolbar.
3. Click the selection box for the objects that you want to restore.
4. To modify specific restore options, click the Options button. Any options that you change are effective during the current session only.
5. Click Restore. The Restore Destination window appears. Enter the appropriate information.
6. Click Restore. The Restore Task List window displays the processing status.

Backing up data using the GUI

Windows

Examples for restoring data using the command line

You can use the examples in this topic when you need to restore objects from IBM Spectrum Protect™server storage.

The following table shows how to use some restore commands to restore your objects from IBM Spectrum Protect server storage.

Table 1. Command-line restore examples

Task	Command	Considerations
Restore the most recent backup version of the `c:\doc\h1.doc` file, even if the backup is inactive.	`dsmc restore c:\doc\h1.doc -latest`	If the file you are restoring no longer resides on your workstation, and you have run an incremental backup since deleting the file, there is no active backup of the file on the server. In this case, use the latest option to restore the most recent backup version. IBM Spectrum Protect restores the latest backup version, whether it is active or inactive. See Latest for more information.
Display a list of active and inactive backup versions of files from which you can select versions to restore.	`dsmc restore c:\project\* -pick -inactive`	If you try to restore both an active and inactive version of a file at the same time, only the active version is restored. See Pick and Inactive for more information.
Restore all files with a file extension of .c from the c:\devel \projecta directory.	`dsmc restore c:\devel \projecta\*.c`	If you do not specify a destination, the files are restored to their original location.
Restore the c:\project\doc\h1.doc file to its original directory.	`dsmc restore c:\project\doc\h1.doc`	If you do not specify a destination, the files are restored to their original location.
Restore the `c:\project\doc\h1.doc` file under a new name and directory.	`dsmc restore c:\project\doc\h1.doc c:\project\newdoc\h2.doc`	None
Restore the files in the e: drive and all of its subdirectories.	`dsmc restore e:\ -subdir=yes`	You must use the subdir option to restore directory attributes/permissions. See Subdir for more information about the subdir option.
Restore all files in the c:\mydir directory to their state as of 1:00 PM on August 17, 2002.	`dsmc restore -pitd=8/17/2002 -pitt=13:00:00 c:\mydir\`	See Pitdate and Pittime for more information about the pitdate and pittime options.

Task	Command	Considerations
Restore the c:\doc\h2.doc file to its original directory on the workstation, named *star*.	`dsmc restore c:\doc\h2.doc \\star\c$\` To restore the file to "star" which has been renamed "meteor", enter: `dsmc restore \\star\c$\ doc\h2.doc \\meteor\c$\` You could also enter: `dsmc restore \\star\c$\ doc\h2.doc c:\` This example is valid because if the workstation name is not included in the specification, the local workstation is assumed ("meteor", in this case).	For the purposes of this manual, the workstation name is part of the file name. Therefore, if you back up files on one workstation and you want to restore them to another workstation, you must specify a destination. This is true even if you are restoring to the same physical workstation, but the workstation has a new name.
Restore a file that was originally backed up from the diskette labeled "workathome" in the a: drive, and restore it to a diskette in the a: drive labeled "extra".	`dsmc restore {workathome}\doc\h2.doc a:\doc\h2.doc`	If you are restoring a file to a disk with a different label than the disk from which the file was backed up, you must use the file space name (label) of the backup disk instead of the drive letter.
Restore files specified in the c:\filelist.txt file to the d:\dir directory.	`dsmc restore -filelist=c:\filelist.txt d:\dir\`	See Filelist for more information about restoring a list of files.
Restore all members of the `virtfs\group1` group backup stored on the IBM Spectrum Protect server.	`dsmc restore group {virtfs}\group1`	See Restore Group for more information.

- Windows Examples: Restoring large amounts of data
  If you need to restore a large number of files, you get faster performance using the command line interface rather than the GUI interface. In addition, you improve performance if you enter multiple restore commands at one time.
- Windows Standard query restore, no-query restore, and restartable restore
  This topic describes the standard (or classic) restore method, the no-query restore method, and the restartable restore method.

Related concepts:
Using commands
Related reference:
Restore
Windows

Examples: Restoring large amounts of data

If you need to restore a large number of files, you get faster performance using the command line interface rather than the GUI interface. In addition, you improve performance if you enter multiple restore commands at one time.

About this task

For example, to restore all the files in your `c:` file space, enter:

```
dsmc restore c:\* -subdir=yes -replace=all -tapeprompt=no
```

However, if you enter multiple commands for the root directories in your `c:` file space, you can restore the files faster. For example, enter these commands:

```
dsmc restore c:\users\ -subdir=yes -replace=all -tapeprompt=no
dsmc restore c:\data1\ -subdir=yes -replace=all -tapeprompt=no
dsmc restore c:\data2\ -subdir=yes -replace=all -tapeprompt=no
```

Or, if you need to restore files for multiple drives, enter these commands:

```
dsmc restore c:\* -subdir=yes -replace=all -tapeprompt=no
dsmc restore d:\* -subdir=yes -replace=all -tapeprompt=no
dsmc restore e:\* -subdir=yes -replace=all -tapeprompt=no
```

You can also use the quiet option with the restore command to save processing time. However, you will not receive informational messages for individual files.
Note: If you already have the appropriate values set for the subdir, replace, tapeprompt, and quiet options in your client options file, it is not necessary to include these options in the commands.

When you enter multiple commands to restore your files, you must specify a unique part of the file space in each restore command. Do not use any overlapping file specifications in the commands.

To display a list of the root directories in a file space, use the query backup command. For example:

```
dsmc query backup -dirsonly -subdir=no c:\
```

As a general rule, you can enter two to four restore commands at one time. The maximum number you can run at one time without degrading performance depends on factors such as network utilization and how much memory you have. For example, if `\users` and `\data1` are on the same tape, the restore for `\data1` must wait until the restore for `\users` is complete. However, if `\data2` is on a different tape, and there are at least two tape drives available, the restore for `\data2` can begin at the same time as the restore for `\users`.

The speed at which you can restore the files also depends upon how many tape drives are available and whether your administrator is using collocation to keep file spaces assigned to as few volumes as possible. If your administrator is using collocation, the number of sequential access media mounts required for restore operations is also reduced.

Standard query restore, no-query restore, and restartable restore

This topic describes the standard (or classic) restore method, the no-query restore method, and the restartable restore method.

- Windows Standard query restore process
  The standard query restore process is also known as classic restore. This topic explains how standard query restore works.
- Windows No-query restore process
  In the no-query restore process, a single restore request is sent to the server instead of querying the server for each object to be restored.
- Windows Restartable restore process
  If the restore process stops because of a power outage or network failure, the server records the point at which this occurred.

Standard query restore process

The standard query restore process is also known as classic restore. This topic explains how standard query restore works.

Here is how standard query restore works:

- The client queries the server for a list of files backed up for the client file space you want to restore.
- The server sends a list of backed up files that match the restore criteria. If you want to restore both active and inactive files, the server sends information about all backed up files to the client.
- The list of files returned from the server is sorted in client memory to determine the file restore order and to minimize tape mounts required to perform the restore.
- The client tells the server to restore file data and directory objects.
- The directories and files you want to restore are sent from the server to the client.

No-query restore process

In the no-query restore process, a single restore request is sent to the server instead of querying the server for each object to be restored.

1. The client tells the server that a no-query restore is going to be completed and provides the server with details about file spaces, directories, and files.
2. The server uses a separate table to track entries which guide the restore.
3. The data to be restored is sent to the client. File and directory objects that are stored on disk are sent immediately since sorting for such data is not required before the object is restored.
4. You can use multiple sessions to restore the data. If the data is on multiple tapes, there are multiple mount points available at the server. The combination of using the resourceutilization option and MAXNUMMP allows multiple sessions.

Windows When you enter an unrestricted wildcard source file specification on the restore command and do not specify any of the options: inactive, latest, pick, fromdate, or todate, the client uses a *no-query restore* method for restoring files and directories from the server. This method is called no-query restore because instead of querying the server for each object to be restored, a single restore request is sent to the server. In this case, the server returns the files and directories to the client without further action by the client. The client merely accepts the data that comes from the server and restores it to the destination named on the restore command.

Mac OS X AIX Linux Solaris When you enter an unrestricted wildcard source file specification on the restore command and do not specify any of the options: inactive, latest, pick, fromdate, todate, the client uses a *no-query restore* method for restoring files and directories from the server. This method is called no-query restore because instead of querying the server for each object to be restored, a single restore request is sent to the server. In this case, the server returns the files and directories to the client without further action by the client. The client merely accepts the data that comes from the server and restores it to the destination named on the restore command.

Mac OS X Using the IBM Spectrum Protect™ GUI client, an example of an unrestricted wildcard command would be to select a folder from the restore tree window. An example of a restricted wildcard command would be to select individual files from a folder.

Using the command-line client, an example of an unrestricted wildcard command would be:

Mac OS X

```
"/Users/user1/Documents/2004/*"
```

Mac OS X AIX Linux Solaris

```
/home/mydocs/2004/*
```

Windows

```
c:\mydocs\2004\*
```

An example of a restricted wildcard file specification would be:

Mac OS X

```
/Users/user1/Documents/2004/sales.*
```

Mac OS X AIX Linux Solaris

```
/home/mydocs/2004/sales.*
```

Windows

```
c:\mydocs\2004\sales.*
```

Restartable restore process

If the restore process stops because of a power outage or network failure, the server records the point at which this occurred.

This record is known to the client as a *restartable restore*. It is possible to have more than one restartable restore session. Use the query restore command or choose **restartable restores** from the Actions menu to find out if your client has any restartable restore sessions in the server database.

Windows You must complete a restartable restore before attempting further backups of the file system. If you attempt to repeat the restore that was interrupted or try to back up the destination file space, the attempt fails because you did not complete the original restore. You can restart the restore at the point of interruption by entering the restart restore command, or you can delete the restartable restore using the cancel restore command. If you restart the interrupted restore, it restarts with the first transaction, which might consist of one or more files, not completely restored when the interruption occurred. Because of this, you might receive some replace prompts for files from the interrupted transaction which were already restored.

Mac OS X AIX Linux Solaris You must complete a restartable restore before attempting further backups of the file system. If you attempt to repeat the restore that was interrupted or try to back up the destination file space, the attempt fails because you did not complete the original restore. You can restart the restore at the point of interruption by entering the restart restore command, or you can delete the restartable restore using the cancel restore command.

From the IBM Spectrum Protect™ GUI **Restartable restores** dialog box you can select the interrupted restore and delete it, or you can choose to restart the restore. If you restart the interrupted restore, it restarts with the first transaction, which might consist of one or more files, not completely restored when the interruption occurred. Because of this, you might receive some replace prompts for files from the interrupted transaction which were already restored.

Mac OS X AIX Linux Solaris Windows To perform restartable restores using the GUI, follow these steps:

1. Select **Actions –> Restartable restores** from the main panel.
2. Select the restartable restore session you want to complete.
3. Click the **Restart** button at the bottom of the panel.

Restoring Windows system state

The Microsoft Volume Shadowcopy Service (VSS) is supported on Windows backup-archive clients. The client uses VSS to restore the system state. The system state restore function is deprecated for online system state restore operations.

About this task

You can no longer restore the system state on a system that is still online. Instead, use the ASR-based recovery method to restore the system state in offline Windows PE mode. For more information, see the following IBM Spectrum Protect wiki articles:

- Best Practices for Recovering Windows Server 2012 and Windows 8
- Best Practices for Recovering Windows Server 2012 R2 and Windows 8.1

If you try to restore the system state with the dsmc restore systemstate command, from the backup-archive client GUI, or from the web client, the following message is displayed:

```
ANS5189E Online SystemState restore has been deprecated. Please use offline
    WinPE method for performing system state restore.
```

Restoring Automated System Recovery files

You can restore Automated System Recovery (ASR) files to recover the Windows operating system volume configuration information and system state if a catastrophic system or hardware failure occurs.

Before you begin

You must be a member of the Administrators or Backup Operators group to back up and restore ASR files.

About this task

The backup-archive client restores ASR data when the backup-archive client restores the Windows system state.

Procedure

To restore ASR files on Windows operating systems, use the restore systemstate command.

Related concepts:
Recovering a computer when the Windows OS is not working

Windows

Restoring the operating system when the computer is working

If your computer is working, you can restore the operating system from backed up files.

About this task

If Active Directory is installed, you must be in Active Directory restore mode. When performing an operating system recovery including the system state, use the following restore order. Do not restart the computer between each step, even though you are prompted to do so.

Procedure

1. Restore the system drive. For example: `dsmc restore c:\* -sub=yes -rep=all`.
2. Restore system state. For example: `dsmc restore systemstate`.

Windows

Recovering a computer when the Windows OS is not working

If the computer has a catastrophic hardware or software failure, you can recover a Windows operating system with Automated System Recovery (ASR).

AIX Linux Solaris Windows

Restoring an image

There are some items to consider before you begin restoring images on your system.

Before you restore an image (offline or online), you must have administrative authority on the system.

Here is a list of items to consider before you restore an image:

- Restoring the image of a volume restores the data to the same state that it was in when you performed your last image backup. Be absolutely sure that you need to restore an image, because it replaces your entire current file system or raw volume with the image on the server.
- Windows The image restore operation overwrites the volume label on the destination volume with the one that existed on the source volume.
- Ensure that the volume to which you are restoring the image is at least as large as the image that is being restored.
- Linux On Linux systems, some file systems such as ext2, ext3, ext4, btrfs, and xfs use a universally unique identifier (UUID) to identify themselves to the operating system. If you create an image backup of such a volume and you restore it to a different location, you might have two volumes with the same UUID. If you use UUID to define your file systems in /etc/fstab, be aware that the backup-archive client might be unable to correctly mount the restored file system because the UUIDs conflict. To avoid this situation, restore the image to its original location. If you must restore it to a different location, change the UUID of either the original or restored volume before you mount the restored file system. Refer to the Linux documentation for instructions on how to change a UUID. You might also need to manually edit the /etc/fstab file so the original volume, the restored volume, or both volumes can be mounted.
- AIX Linux Solaris The file system or volume you are restoring to must be the same type as the original.
- Windows The file system or volume you are restoring to does not have to be the same type as the original. The volume does not even have to be formatted. The image restore process creates the appropriately formatted file system for you.
- Ensure that the target volume of the restore is not in use. The client locks the volume before starting the restore. The client unlocks the volume after the restore completes. If the volume is in use when the client attempts to lock the file system, the restore fails.
- You cannot restore an image to where the IBM Spectrum Protect™ client program is installed.
- Windows If you created an image of the system drive, you cannot restore the image to the same location because the client cannot have an exclusive lock of the system drive. Also, because of different system component configurations, the system

image might not be consistent across components (such as Active Directory). Some of these components can be configured to use different volumes where parts are installed on the system drive and others to non-system volumes.

- If you have run progressive incremental backups *and* image backups of your file system, you can perform an incremental image restore of the file system. The process restores individual files after the complete image is restored. The individual files restored are those backed up after the original image. Optionally, if files were deleted after the original backup, the incremental restore can delete those files from the base image.

  Deletion of files is performed correctly if the backup copy group of the IBM Spectrum Protect server has enough versions for existing and deleted files. Incremental backups and restores can be performed only on mounted file systems, not on raw logical volumes.

- AIX Linux Solaris If for some reason a restored image is corrupted, you can use the `fsck` tool to attempt to repair the image.

  You can use the verifyimage option with the restore image command to specify that you want to enable detection of bad sectors on the destination target volume. If bad sectors are detected on the target volume, the client issues a warning message on the console and in the error log.

  If bad sectors are present on the target volume, you can use the imagetofile option with the restore image command to specify that you want to restore the source image to a file. Later, you can use a data copy utility of your choice to transfer the image from the file to a disk volume.

- Windows If for some reason a restored image is corrupted, you should run *chkdsk* to check for and repair any bad sectors (unless the restored volume is RAW).

  You can use the verifyimage option with the restore image command to specify that you want to enable detection of bad sectors on the destination target volume. If bad sectors are detected on the target volume, the client issues a warning message on the console and in the error log.

  If bad sectors present on the target volume, you can use the imagetofile option with the restore image command to specify that you want to restore the source image to a file. Later, you can use a data copy utility of your choice to transfer the image from the file to a disk volume.

AIX Linux Solaris Windows

Restoring an image using the GUI

You can use the GUI to restore an image of your file system or raw logical volume.

About this task

Follow these steps to restore an image of your file system or raw logical volume:

Procedure

1. Click **Restore** from the main window. The Restore window appears.
2. Expand the directory tree.
3. Locate the object in the tree named **Image** and expand it. Click the selection box next to the image you want to restore. You can obtain detailed information about the object by highlighting the object and selecting **View** → **File Details...** from the main window or click the **View File details** button.
4. **(Optional)** To perform an incremental image restore, click the **Options** button to open the Restore Options window and select the **Image plus incremental directories and files** option. If you want to delete inactive files from your local file system, select the **Delete inactive files from local** check box. Click the **OK** button.
5. AIX Linux Solaris Click **Restore**. The Restore Destination window appears. The image can be restored to the volume with the mount point from which it was originally backed up. Alternatively, a different volume can be chosen for the

restore location.

6. Windows Click **Restore**. The Restore Destination window appears. The image can be restored to the volume with the drive letter or mount point from which it was originally backed up. Alternatively, a different volume can be chosen for the restore location.
7. Click the **Restore** button to begin the restore. The **Task List** window appears showing the progress of the restore. The Restore Report window displays a detailed status report.

Results

The following are some items to consider when you perform an image restore using the GUI:

- You can select **View** → **File Details** from the main window or click the **View File details** button to display the following statistics about file system images backed up by the client:
  - Image Size - This is the volume size which was backed up.
  - AIX Linux Solaris Stored Size - This is the actual image size stored on the server. The stored image on the IBM Spectrum Protect™ server is the same size as the volume capacity.
  - Windows Stored Size - This is the actual image size stored on the server. Because image backup allows you to back up only used blocks in a file system, the stored image size on the IBM Spectrum Protect server could be smaller than the volume size. For online image backups, the stored image can be larger than the file system based on the size of the cache files.
  - File system type
  - Backup date and time
  - Management class assigned to image backup
  - Whether the image backup is an active or inactive copy
- To modify specific restore options, click the **Options** button. Any options you change are effective during the current session *only*.
- In the Restore Options window, you can choose to restore the image only or the image and incremental directories files. If you choose **Image Only**, you restore the image from your last image backup only. This is the default.

  If you ran incremental-by-date image backup on a volume or image backups on a volume with incrementals, you can choose the **Image plus incremental directories and files** option. If you choose **Image plus incremental directories and files**, you can also select **Delete inactive files from local** to delete the inactive files that are restored to your local file system. If incremental-by-date image backup was the only type of incremental backup you performed on the file system, deletion of files will not occur.

  Important: Be absolutely sure that you need to perform an incremental restore because it replaces your entire file system with the image from the server and then restore the files that you backed up using the incremental image backup operation.

AIX Linux Solaris Windows

Restoring an image using the command line

Use the restore image command to restore an image using the IBM Spectrum Protect™ command line client.

Windows You can use the verifyimage option with the restore image command to specify that you want to enable detection of bad sectors on the destination target volume. If bad sectors are detected on the target volume, IBM Spectrum Protect issues a warning message on the console and in the error log.

Windows If bad sectors are present on the target volume, you can use the imagetofile option with the restore image command to specify that you want to restore the source image to a file. Later, you can use a data copy utility of your choice to transfer the image from the file to a disk volume.

Restore data from a backup set

Your IBM Spectrum Protect™ administrator can generate a backup set, which is a collection of your files that reside on the server, onto portable media created on a device using a format that is compatible with the client device.

You can restore data from a backup set from the IBM Spectrum Protect server, or when the backup set is locally available as a file or on a tape device.

You can restore backup sets from the following locations:

- From the IBM Spectrum Protect server
- From portable media on a device attached to your client workstation
- From a backup set file on your client workstation

Backup sets can provide you with instant archive and rapid recovery capability as described in the following list.

Instant archive
: This capability allows an administrator to create an archive collection from backup versions already stored on the server.

Rapid recovery with local backup sets
: Typically, restores are performed from normal file backups that are stored on the IBM Spectrum Protect server outside of backup sets. This restore approach gives you the ability to restore the most recent backup version of every file. It is possible that a backup set does not contain the most recent backup version of your files.

  In some cases restoring data from a backup set can be a better option than restoring data from normal backup files on the IBM Spectrum Protect server. Restoring from a backup set can be a better option for the following reasons:

  - A backup set restore can provide for a faster recovery because all of the required files for restore are contained together within a smaller number of storage volumes.
  - A backup set provides a point-in-time collection of files. You can restore to a point in time rather than restoring what is currently available from a normal file-level restore from the server.
  - Windows You can perform an ASR restore using a backup set volume.

  Restoring a backup set from the IBM Spectrum Protect server provides a larger set of restore options than restoring from a local backup set. However, restoring from a local backup set can be preferable in some cases:

  - It is possible that you need to restore your data when a network connection to the IBM Spectrum Protect server is not available. This is possible in a disaster recovery situation.
  - The local restore may be faster than restoring over a network connection to your IBM Spectrum Protect server.

A backup set can be restored from the IBM Spectrum Protect server while the backup set volumes are available to the server, or they can be moved to the client system for a local backup set restore. A backup set can be generated with or without a table of contents (TOC), and can contain file data or image data.

Windows The backup set can contain system state data.

Your ability to restore data from backup sets is restricted by the location of the backup set and the type of data in the backup set. The command-line client can restore some data that the GUI cannot restore, but the GUI can allow you to browse and choose which objects to restore. Generally, backup sets from the server with a TOC allow more options when restoring. However, local backup sets provide options that are sometimes preferable to restoring from theIBM Spectrum Protect server.

The restrictions for restoring data from backup sets using the GUI are summarized in the following table. Each interior cell represents one combination of data type and backup set location. For each situation, the cell indicates if you can use the GUI to restore only the entire backup set, to select objects within the backup set, or if you cannot use the GUI to restore the backup set.

Table 1. Backup set GUI restore restrictions

	Backup set location		
Data type in the backup set	**Local (`location=file` or `location=tape`)**	**IBM Spectrum Protect Server (TOC available)**	**IBM Spectrum Protect Server (TOC not available)**
file	Restore entire backup set only.	Restore entire backup set, or selected objects in the backup set.	Restore entire backup set only.
image	Cannot be restored.	Restore entire backup set, or selected objects in the backup set.	Cannot be restored.
system state	Restore entire backup set only.	Restore entire backup set, or selected objects in the backup set.	Restore entire backup set only.

The restrictions for restoring data from backup sets using the command-line client are summarized in the following table. Each interior cell represents one combination of data type and backup set location. For each situation, the cell lists the restore commands you can use. Except as noted, you can restore specific objects within a backup set, as well as the entire backup set.

Table 2. Backup set command-line restore restrictions

Data type in the backup set	Backup set location		
	Local (`location=file` or `location=tape`)	**IBM Spectrum Protect Server (TOC available)**	**IBM Spectrum Protect Server (TOC not available)**
file	Commands: `restore` `restore backupset`	Commands: `restore` `restore backupset`	Commands: `restore backupset`
image	Cannot be restored	Command: `restore image`	Cannot be restored
system state	Command: `restore backupset`	Commands: `restore backupset` `restore systemstate`	Command: `restore backupset`

Restriction: When restoring system state data using the restore backupset command, you cannot specify individual objects. You can only restore the entire system state.

- Restore backup sets: considerations and restrictions
  This topic lists some considerations and restrictions that you must be aware of when restoring backup sets.
- Backup set restore
  IBM Spectrum Protect considers a backup set as one object containing the whole file structure. You can restore the entire backup set or, in some cases, you can select portions. The backup set media is self-describing and contains all the information required to perform a successful restore.
- Restoring backup sets using the GUI
  The client GUI can restore data from a backup set from the server, from a local file, or from a local tape device. You can use the GUI to restore individual files from a backup set from the IBM Spectrum Protect server with a TOC, but not from a local backup set nor from a backup set from the server without a TOC.
- Backup set restores using the client command-line interface
  The client command line interface can restore data from a backup set from the server, from a local file, or from a local tape device. You can use the client command line interface to restore individual files from local backup sets and from backup sets without a TOC.

Restore backup sets: considerations and restrictions

This topic lists some considerations and restrictions that you must be aware of when restoring backup sets.

Backup set restore considerations

Consider the following when restoring backup sets:

- If the object you want to restore was generated from a client node whose name is different from your current node, specify the original node name with the filespacename parameter on any of the restore commands.
- If you are unable to restore a backup set from portable media, check with your IBM Spectrum Protect™ administrator to ensure that the portable media was created on a device using a compatible format.
- If you use the restore backupset command on the initial command line with the parameter `-location=tape` or `-location=file`, the client does not attempt to contact the IBM Spectrum Protect server.

- When restoring a group from a backup set:

  - The entire group, or all groups, in the virtual file space are restored. You cannot restore a single group by specifying the group name, if there are several groups in the same virtual file space. You cannot restore a part of a group by

specifying a file path.

    - Specify a group by using the following values:
        - Specify the virtual file space name with the filespacename parameter.
        - Use the subdir option to include subdirectories.
- Limited support is provided for restoring backup sets from tape devices attached to the client system. A native device driver provided by the device manufacturer must always be used. The device driver provided by IBM to be used with the IBM Spectrum Protect server cannot be used on the client system for restoring local backup sets.
- Mac OS X | AIX | Linux | Solaris If a backup set contains files from several owners, the backup set itself is owned by the root user ID, and non-root user IDs cannot see the backup set. In this case, non-root user IDs can restore their files by obtaining the backup set name from the IBM Spectrum Protect administrator. Non-root users can restore only their own files.
- Mac OS X | AIX | Linux | Solaris | Windows To enable the client GUI to restore a backup set from a local device, without requiring a server connection, use the localbackupset option.

Backup set restore restrictions

Be aware of the following restrictions when restoring backup sets:

- A backup set data that was backed up with the API cannot be restored or used.
- AIX | Linux | Solaris | Windows You cannot restore image data from a backup set using the restore backupset command. You can restore image data from a backup set only with the restore image command.
- AIX | Linux | Solaris | Windows You cannot restore image data from a local backup set (`location=tape` or `location=file`). You can restore image data from a backup set only from the IBM Spectrum Protect server.

Backup set restore

IBM Spectrum Protect™ considers a backup set as one object containing the whole file structure. You can restore the entire backup set or, in some cases, you can select portions. The backup set media is self-describing and contains all the information required to perform a successful restore.

If you are connected to the Tivoli® Storage Manager Version 5.4 or later server, your server administrator can create backup sets that are stacked. Stacked backup sets can contain data from multiple client nodes, and they can contain different types of data for a particular client node. The types of data can be file data or image data.

Windows If you have upgraded from Tivoli Storage Manager Express®, some application data is also supported.

Restriction: Image data and application data restore processing is only available when restoring from the server. You cannot restore image data and application data from a client local backup set restore.

When a backup set is stacked, you can only restore data for your own node. Data for all other nodes is skipped. When restoring data from a stacked backup set on a local device, you can only restore file level data for your own client node. It is important that the nodename option is set to match the node name used to generate the backup set for one of the nodes in the stack.

Important: Due to the portability of local backup sets, you must take additional steps to secure your local backup sets on portable media. The backup set media should be physically secured because the backup set can be restored locally without authenticating with the server. Each user has access to all of the data on the stacked backup set, which means that the user has access to data that they do not own, by changing the node name or viewing the backup set in its raw format. Encryption or physical protection of the media are the only methods to ensure that the data is protected.

If you restore backup set data from the server, individual files, directories or entire backup set data can be restored in a single operation from the GUI or the command line. When you restore backup set data locally, the GUI can only display and restore an entire backup set. The command line can be used to restore individual files or directories stored in a backup set locally.

Restoring backup sets using the GUI

The client GUI can restore data from a backup set from the server, from a local file, or from a local tape device. You can use the GUI to restore individual files from a backup set from the IBM Spectrum Protect™ server with a TOC, but not from a local backup set nor from a backup set from the server without a TOC.

About this task

Important: Before you begin a restore operation, be aware that backup sets can contain data for multiple file spaces. If you specify a destination other than the original location, data from *all* file spaces are restored to the location you specify.

To restore a backup set from the GUI, perform the following steps:

1. Mac OS X AIX Linux Solaris Windows Click Restore from the GUI main window. The Restore window appears.
2. Locate the Backup Sets directory tree object and expand it by clicking the plus sign (+) beside it.
   - Mac OS X AIX Linux Solaris Windows To restore the backup set from a local device, expand the Local object and the Specify backup set location window is displayed. On the window, select File name: or Tape name: from the list and enter the tape or file name location. You can also click the Browse button to open a file selection window and select a backup set.
   - To restore data from backup set from the server, first expand the Server object and then either Filelevel or Image, depending on the type of restore requested.
3. Click the selection box next to the backup set or directory or file within the backup set that you want to restore.

   You can select files from within a backup set if that backup set is from the server and has a table of contents.

4. Click Restore. The Restore Destination window appears. Enter the appropriate information.
5. Click Restore. The Task List window displays the restore processing status.

Note:

- If the object you want to restore is part of a backup set generated on a node, and the node name is changed on the server, any backup set objects that were generated prior to the name change will not match the new node name. Ensure that the node name is the same as the node for which the backup set was generated.
- Mac OS X AIX Linux Solaris Windows The client can be used to restore a backup set on an attached device with or without a server connection. If the server connection fails, a prompt appears to continue for purposes of local backup set restore. Also, thelocalbackupset option can be used to tell the client not to attempt the connection to the server.
- Mac OS X AIX Linux Solaris Windows Certain local devices such as tape devices (tape devices do not apply to Mac OS X) require device drivers to be set up prior to performing a restore. See the device manual for assistance with this task. You also need to know the device address in order to perform the restore.
- Mac OS X AIX Linux Solaris Windows The following features of a backup set restore from the server are not available when restoring locally:
  1. Mac OS X AIX Linux Solaris Windows Image restore.
  2. Windows Restoring individual system state components.
  3. Mac OS X AIX Linux Solaris Windows The GUI display and restore of individual files and directories. The command line can be used to restore an individual directory or file from a local backup set.
  4. Windows Application data restore if the server was migrated from the Tivoli® Storage Manager Express® product.

Backup set restores using the client command-line interface

The client command line interface can restore data from a backup set from the server, from a local file, or from a local tape device. You can use the client command line interface to restore individual files from local backup sets and from backup sets without a TOC.

To restore a backup set from the client command line interface, use the query backupset command to display what backup set data is available, then use restore commands to restore the data.

You can use the following commands to restore data from backup sets:

- restore
- restore backupset
- restore image
- Windows restore systemstate

Use the appropriate command for the location of the backup set and the data in the backup set. For more information, see Table 2.

Restore Net Appliance CIFS shares

Restoring the share definition requires restoring the root directory of the share file space, which under most circumstances can be done as follows: `dsmc rest \\NetAppFiler\CifsShareName\ -dirsonly`.

The following output indicates that the root directory (and share definition has been restored):

```
Restoring               0 \\NetAppFiler\CifsShareName\ [Done]
```

If the CIFS share definition is deleted on the Net Appliance file server, the client is unable to directly restore the share definition because the share is no longer accessible.

The share definition can be restored indirectly by creating a temporary local share and restoring the share definition to the temporary share as follows:

```
md c:\tempdir  net share tempshare=c:\tempdir
  /remark:"Temporary Share for Restoring Deleted CIFS Share"
net use z: \\LocalMachineName\tempshare
dsmc res \\NetAppFiler\CifsShareName\ z:\ -dirsonly
```

This restores the original share definition (including permissions) on the file server.

Older versions of the IBM Spectrum Protect™ server might have a problem which prevents restoring the root directory and the CIFS share definition. If this problem occurs, it can be circumvented by using by one of the following methods:

1. Use the DISABLENQR testflag to restore the root directory as follows:

   ```
   dsmc res \\NetAppFiler\CifsShareName\ -test=disablenqr  -dirsonly
   ```

2. Use the command line client `-pick` option with a restore command and select the root directory:

   ```
   dsmc res \\NetAppFiler\CifsShareName\  -dirsonly -pick
   ```

Backing up Net Appliance CIFS share definitions
Linux Windows

Restoring data from a VMware backup

You can use several methods for restoring data from backups to a VMware virtual machine. The restore method depends on the type of backup and on the version of the backup-archive client software that you use to run the restore.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Linux Windows Full VM restore

Linux Windows Use the restore vm command to restore an entire virtual machine from a full VM backup. When you restore a full VM backup, the restored image replaces the virtual machine or a new virtual machine is created. In a full VM restore, you restore all of the VMware files and the system state on Windows systems. If you have access to IBM Spectrum Protect recovery agent, you can restore individual files.

Linux Windows Depending on the version of the backup-archive client that is running on the VMware client, use the appropriate method to restore a full VM backup:

Versions of the backup-archive earlier than 6.2.2:

Restore the full VM backup by using VMware Consolidated Backup. For more information, see the following topic:

Restoring full VM backups that were created with VMware Consolidated Backup

Versions of the backup-archive client at 6.2.2 or later:

Restore the full VM backup by using the vStorage API. The IBM Spectrum Protect V6.2.2 or later client can restore full VMware backups that were created with versions of the client that is earlier than V6.2.2. For more information, see the following topic:

Restoring full VM backups

Windows File-level restore

Windows Use the restore command to restore individual files from a file-level VM backup. Use this method when you cannot practically restore an entire VMware image. File-level backups were created with the version 7.1 or earlier backup-archive clients.
The following restrictions apply to file-level restores:

- You can use the file-level restore method only if a file-level backup of the virtual machine exists.
- You cannot restore an entire virtual machine from file-level backups because the restore command does not re-create Windows system states.
- You cannot use this method to restore individual files from a full VM backup of a virtual machine.

Windows Depending on the configuration of the virtual machine where you restore the files, use the appropriate method to restore files from a file-level backup:

The backup-archive client is not installed on the VM:
Restore the files from the vStorage backup server that backed up the virtual machine.
The backup-archive client is installed on the VM:
Restore the file from the backup-archive client that is installed on the virtual machine.

For more information, see the following topic:

Scenario: Restoring file-level VM backups

- Windows Restoring full VM backups
You can restore a full VMware backup to re-create all of the files for a VMware virtual machine (VM) directly to the VMware server. This method replaces the deprecated method of restoring backups that were created by using the VMware Consolidated Backup (VCB) tools. This restore method does not require you to use the VMware converter tool before you restore the backup to the VMware server. You cannot use this restore method to restore individual files from a full VM backup.
- Windows Scenarios for running full VM instant access and full VM instant restore from the backup-archive client command line
Full VM instant access and full VM instant restore operations require a license for IBM Spectrum Protect for Virtual Environments. You can perform either of these operations from the backup-archive client command line. Instant access and instant restore operations and options are supported only for VMware virtual machines that are hosted on VMware ESXi 5.1 servers, or later versions.
- Windows Scenario: Restoring file-level VM backups
On Microsoft Windows systems, you can restore specific files from a file-level backup of a VMware virtual machine. A file-level restore is useful for restoring individual files that might be lost or damaged. You cannot use this method to restore files that were part of a full VM backup. Before you can restore files from the off-host backup server onto the VMware virtual machine, the off-host backup server must be configured as a proxy server.
- Windows Restoring full VM backups that were created with VMware Consolidated Backup
You can restore a full VMware backup to re-create all of the files for a VMware virtual machine (VM). Complete these steps to restore full VM backups that were created by using VMware Consolidated Backup (VCB) running on IBM Spectrum Protect Version 6.2.0 or earlier.

Linux | Windows

Restoring full VM backups

You can restore a full VMware backup to re-create all of the files for a VMware virtual machine (VM) directly to the VMware server. This method replaces the deprecated method of restoring backups that were created by using the VMware Consolidated Backup (VCB) tools. This restore method does not require you to use the VMware converter tool before you restore the backup to the VMware server. You cannot use this restore method to restore individual files from a full VM backup.

Before you begin

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

To restore a full VMware backup that was created by using VCB tools in IBM Spectrum Protect Version 6.2.0 or earlier, see the topic "Restoring full VM backups that were created with VMware Consolidated Backup".

Procedure

1. Depending on the target location for the restore, complete the appropriate step:
   - If the restore of the full VM backup is going to overwrite the existing VMware virtual machine, delete the existing virtual machine.
   - If you restore the full VM backup to a new virtual machine, you do not need to delete the existing virtual machine. You can delete the existing virtual machine if you prefer, otherwise proceed to the next step.
2. Query the virtual machine for VMware backups, by completing the following steps:
   a. From the off-host backup server, run the following command:

      ```
      dsmc q vm *
      ```

      The command lists the available backups, for example:

      ```
       #        Backup Date       Mgmt Class           Type   A/I Virtual Machine
      ---     -----------       ----------          -----   --- ---------------
        1    12/03/2009 03:05:03   DEFAULT             VSTORFULL  A  vm_guest1
        2    09/02/2010 10:45:09   DEFAULT             VSTORFULL  A  vm_guest11
        3    09/02/2010 09:34:40   DEFAULT             VSTORFULL  A  vm_guest12
        4    09/02/2010 10:10:10   DEFAULT             VSTORFULL  A  vm_guest13
        5    12/04/2009 20:39:35   DEFAULT             VSTORFULL  A  vm_guest14
        6    09/02/2010 11:15:18   DEFAULT             VSTORFULL  A  vm_guest15
        7    09/02/2010 02:52:44   DEFAULT             VSTORFULL  A  vm_guest16
        8    08/05/2010 04:28:03   DEFAULT             VSTORFULL  A  vm_guest17
        9    08/05/2010 05:20:27   DEFAULT             VSTORFULL  A  vm_guest18
       10    08/12/2010 04:06:13   DEFAULT             VSTORFULL  A  vm_guest19
       11    09/02/2010 00:47:01   DEFAULT             VSTORFULL  A  vm_guest7
       12    09/02/2010 01:59:02   DEFAULT             VSTORFULL  A  vm_guest8
       13    09/02/2010 05:20:42   DEFAULT             VSTORFULL  A  vm_guest9
      ANS1900I Return code is 0.
      ANS1901I Highest return code was 0.
      ```

   b. From the results that are returned by the query command, identify a virtual machine to restore.
3. Restore the full VMware backup, by using the restore vm command. To restore the backup to a virtual machine with a new name, use the -vmname option. For example, in the following command the virtual machine is restored and a new name is specified for the restored virtual machine:

   ```
   dsmc restore vm my_old_vmname -vmname=new_vm_name -datastore=myPath
   ```

4. When the restore is complete, the virtual machine is powered off. Start the virtual machine from the VMware vCenter.

Windows

What to do next

If you are restoring application protection backups, see Shadow copy considerations for restoring an application protection backup from the data mover.

- Windows Shadow copy considerations for restoring an application protection backup from the data mover
  For Windows VMware virtual machines (VMs), if you attempt to restore an application protection backup from the data mover, be aware of shadow copy restrictions when you restore the application protection backup.

Scenarios for running full VM instant access and full VM instant restore from the backup-archive client command line

Full VM instant access and full VM instant restore operations require a license for IBM Spectrum Protect™ for Virtual Environments. You can perform either of these operations from the backup-archive client command line. Instant access and instant restore operations and options are supported only for VMware virtual machines that are hosted on VMware ESXi 5.1 servers, or later versions.

The following scenarios demonstrate the full VM instant access or full VM instant restore operations that you might perform. Before you can complete the operations that are described in the following text, you must configure at least one data mover node on the vStorage backup server so it can protect the virtual machines by starting off host backup and restore operations. The steps for setting up the data mover nodes are described in Setting up the data mover nodes in a vSphere environment.

Scenario: You want to perform a full VM instant access to verify the integrity of a backed up image of a VMware virtual machine, without actually restoring the virtual machine or disks to the ESXi host

The purpose of this goal is to verify that a backed up virtual machine image can be used to successfully restore a system if the virtual machine is deleted or its disks and data are corrupted or otherwise unusable.

For this scenario, assume that an ESX server has a virtual machine named Orion running on it. You want to verify that the backed up image that is stored by the IBM Spectrum Protect server can be used to restore this virtual machine if the current virtual machine fails.

You perform a VM instant access operation, you use the restore vm command with inventory location options specified to identify the location for the restored virtual machine. All inventory location options, such as vmname, datacenter, host, and datastore can be used in combination with the instant access option (`-VMRESToretype=INSTANTAccess`) to specify the location for the restored (instant access) virtual machine.

Because the Orion virtual machine does exist in the inventory and is running, you must provide a new name for a temporary virtual machine by adding the new name to the vmname option. You must also add the `-VMRESToretype=INSTANTAccess` option to the command line to indicate that this is an instant access restore operation.

Entering the following command prepares a virtual machine named "Orion_verify" so it is available for instant access. You can use this virtual machine to verify that the backed-up image can be restored.

```
dsmc restore vm Orion -vmname=Orion_verify  -Host=esxi.example.com
  -datacenter=mydataCenter -VMRESToretype=INSTANTAccess -VMAUTOSTARTvm=YES
```

The `-VMAUTOSTARTvm=YES` option indicates that the virtual machine is started when it is restored. By default, the new virtual machine is not automatically started. With this default setting, you can reconfigure the virtual machine before you start it.

You can also list the versions of a virtual machine that were backed up by using the inactive or pick options or the pittime or pitdate options to select an inactive or active backup, from a particular date or time. For example, to display a list of backed up versions of the Orion virtual machine, by using the following command:

```
dsmc restore vm Orion -pick
```

For a virtual machine that is restored by using the `-VMRESToretype=INSTANTAccess` option, temporary data that is created by this virtual machine is stored in a VMware snapshot.

After you restore the temporary virtual machine (Orion_verify), run verification tools on it to verify the integrity of the disks and data. Use a utility such as chkdsk, or a utility or application of your choosing, to verify the virtual disks and data. If the temporary virtual machine passes the integrity checks, you can remove the temporary resources that were created to support the instant access restore operation.

Scenario: You want to determine whether any temporary (instant access) virtual machines exist, so you can run a clean-up operation to free the resources associated with them

Use the query vm command with one of the following options that you specify on the command line:

```
-VMRESToretype=INSTANTAccess
-VMRESToretype=ALLtype
```

Where:

`-VMRESToretype=INSTANTAccess`
: Displays all temporary virtual machines that are running in instant access mode, created by a `restore vm -VMRESToretype=INSTANTAccess` operation.

`-VMRESToretype=ALLtype`
: Displays all virtual machines with active instant access or instant restore sessions that were started by a restore vm command that uses either the `-VMRESToretype=INSTANTAccess` or `VMRESToretype=-INSTANTRestore` options.

The following examples show the syntax for the various options:

```
query vm * -VMREST=INSTANTA
query vm * -VMREST=ALL
```

You can add a –Detail option to each of the query vm commands shown to display more information about each of the temporary virtual machines.

```
query vm vmname -VMREST=INSTANTA -Detail
```

To remove the resources that were created for a temporary virtual machine named "Orion_verify", run the following command:

```
dsmc restore vm Orion -vmname=Orion_verify -VMREStoretype=VMCLeanup
```

The –VMREStoretype=VMCLeanup option deletes the temporary virtual machine from the ESXi host, unmounts any iSCIS mounts that were mounted, and clears the iSCSI device list from the ESX host. All temporary data for the temporary virtual machine is deleted from the VMware snapshot.

Scenario: You want to start an instant restore operation to restore a failed virtual machine to an ESX host, from a backup image created by IBM Spectrum Protect

The advantage of a full VM instant restore, as opposed to a classic full VM restore, is that an instant restore operation makes the virtual machine ready for immediate use, as soon as it is started. You do not have to wait for all data to be restored before you can use the virtual machine. During an instant restore operation, the virtual machine uses iSCSI disks until its local disks are fully restored. When the local disks are restored, the virtual machine switches I/O from the iSCSI disks to the local disks, without noticeable interruption of service.

Restore a virtual machine named Orion by using the following command:

```
dsmc restore vm Orion -Host=esxi.example.com -datacenter=mydatacenter
  -VMTEMPDAtastore=temp_datastore -VMRESToretype=INSTANTRestore
  -datastore=mydatastore
```

This command specifies the name of the virtual machine to restore, the host and data center to restore it to, and the restore type (`-VMRESToretype=INSTANTRestore`). The VMTEMPDAtastore option is a mandatory parameter for instant restore operations.

The temporary datastore is used by vMotion to store the configuration of the restored virtual machine during the instant restore process. The name that you specify must be unique. It cannot match the name of any of the original datastores that were used by the virtual machine when it was backed up, and it cannot be the same as the name specified on the optional –datastore option. If the –datastore option is omitted, the virtual machine files are restored to the datastores that they used when the virtual machine was backed up.

By default, virtual machines that are instantly restored are provisioned with thick disks. You can change this behavior and provision thin disks by adding the `–VMDISKProvision=THIN` option to the command line, or in the client options file.

Important: For instant restore operations, ensure that both the temporary datastore that you specify with the vmtempdatastore option and the VMware datastore that is specified by the datastore option on the restore VM command have enough free storage to save the virtual machine that you are restoring, and the snapshot file that contains changes that were made to the data. If you are restoring a virtual machine and you specify thin or thick provisioning (-vmdiskprovision=thin or -vmdiskprovision=thick), the datastore that you restore the VM to must have enough free space to accommodate the total capacity of the VM disk, and not just the amount of disk that is used. For example, if a VM has 300 GB total capacity for its disk, you cannot restore that VM to a datastore that has less than 300 GB available, even if only a portion of the total capacity is being used.

- Windows Full VM instant restore cleanup and repair scenarios
  When an instant restore operation fails after the VM is powered on, manual cleanup and repair tasks are required.
- Windows Recovering from non-standard error conditions
  Problems with iSCSI devices can prevent you from performing an instant access or instant restore operation.

Windows

Full VM instant restore cleanup and repair scenarios

When an instant restore operation fails after the VM is powered on, manual cleanup and repair tasks are required.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

An instant restore operation that fails with storage vMotion running creates either of the following situations:

- The instant restore operation generates an error message.
- The instant restore operation suspends indefinitely and the VM is not responsive.

To determine the cause of the problem, perform a detailed query of the VM by using the following command:

```
dsmc q vm * -vmrestoretype=instantrestore -detail
```

In the output that is produced by this command, for each VM in the output, look for the line that contains `Action Needed`. Use the following *Action Needed* paragraphs to recover from failed instant restore operation, depending on the `Action Needed` status.

Action Needed: Cleanup

In the output of the `query vm * -vmrestoretype=instantrestore -detail` command, verify that the storage vMotion status is successful (`vMotion Status: Successful`) and that all VM disks are physical disks (`Disk Type: Physical`). This status confirms that the VM was restored and cleanup of orphaned components, such as iSCSI mounts, is needed.

This type of failure occurs as a result of either of the following situations:

- The instant restore failed and Storage vMotion is running. VMware vSphere continues the vMotion process.
- Storage vMotion finished successfully, but the automatic cleanup of the iSCSI mounts fails.

To clean up any orphaned components, run the restore vm command with the -VMRESToretype=VMCLeanup parameter. For example:

```
dsmc restore vm original_vmname -vmname=new_vm_name -VMRESToretype=VMCLeanup
```

Action Needed: Repair

In the output of the `query vm * -vmrestoretype=instantrestore -detail` command, verify that the iSCSI device that is attached to the VM is dead (status is `Disk Path: Dead`).

This type of failure occurs as a result of one of the following three situations:

- The VM that is used as a data mover or the physical data mover machine failed.
- A network failure occurred between the data mover and the ESX host or the data mover and the IBM Spectrum Protect server.
- The Data Protection for VMware Recovery Agent Service failed.

The iSCSI device must be returned to an active state before any other instant operation is attempted.
To attempt to recover from a data mover failure, complete the following steps:

1. Investigate that cause of the failure and restart the data mover machine if it does not start automatically. This action starts an automatic recovery of the mounted iSCSI disks.
2. In the output of the `query vm * -vmrestoretype=instantrestore -detail` command, verify that the VM disks are active (`Disk Path: Active`). This status means that the VM was restored and is available for use.
3. Restart storage vMotion in the vSphere client and monitor its progress in the vSphere client status bar.
4. If storage vMotion processing completed successfully, run the restore vm command with the -vmrestoretype=VMCLeanup parameter to clean up the iSCSI disks. For example:

   ```
   dsmc restore vm original_vmname -vmname=new_vm_name -VMRESToretype=VMCLeanup
   ```

To attempt recovery after a network failure, complete the following steps:

1. Repair the network issue so that communication between the data mover and the ESX host, and the data mover and the IBM Spectrum Protect server resumes.
2. In the output of the `query vm * -vmrestoretype=instantrestore -detail` command, verify that the VM disks are active (`Disk Path: Active`). This status means that the VM was restored and is available for use.
3. If the network failure did not cause storage vMotion to time out, no action is required.
4. If the network failure caused storage vMotion to time out, and the error message indicates that the source disk is not responding, restart storage vMotion in the vSphere client. When storage vMotion processing completes, run the restore vm command with the -vmrestoretype=VMCLeanup parameter to clean up the iSCSI disks. For example:

   ```
   dsmc restore vm original_vmname -vmname=new_vm_name -VMRESToretype=VMCLeanup
   ```

To attempt recovery after a Data Protection for VMware Recovery Agent service failure, complete the following steps:

1. Investigate that cause of the failure and restart the Data Protection for VMware Recovery Agent service if it does not start automatically. This action starts an automatic recovery of the mounted iSCSI disks.
2. In the output of the `query vm * -vmrestoretype=instantrestore -detail` command, verify that the VM disks are active (`Disk Path: Active`). This status means that the VM was restored and is available for use.
3. If the Data Protection for VMware Recovery Agent service failure did not cause storage vMotion to time out, no action is required.
4. If the Data Protection for VMware Recovery Agent service failure caused storage vMotion to time out, and the error message indicates that the source disk as not responding, restart storage vMotion in the vSphere client. When storage vMotion processing completes, run the restore vm command with the -vmrestoretype=VMCLeanup parameter to clean up the iSCSI disks. For example:

   ```
   dsmc restore vm original_vmname -vmname=new_vm_name -VMRESToretype=VMCLeanup
   ```

Full cleanup

If you are not able to recover from a failure and want to remove the VM and its components, run the restore vm with the -vmrestoretype=VMFULLCLeanup parameter. For example:

```
dsmc restore vm original_vmname -vmname=new_vm_name -VMRESToretype=VMFULLCLeanup
```

A VMFULLCLeanup operation forces removal of the VM and all of its components, regardless of the state of the virtual machine. Do not start a full clean up operation while vMotion is still migrating a virtual machine.

Windows

Recovering from non-standard error conditions

Problems with iSCSI devices can prevent you from performing an instant access or instant restore operation.

About this task

When an ESX server cannot access a datastore on an iSCSI disk, a VMware message is issued to indicate that a "permanent device loss" error occurred. You should be offered an option to either cancel or retry the iSCSI connection attempt. Choose the option to try the operation again to see whether the error is transient and if recovery is possible. If the retry is not successful, try the following troubleshooting steps. If they are successful, then try the instant restore or instant access operation again.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Procedure

1. Examine the ESX server Task and Event log for an All Paths Down (APD) error. It can take time for this error to display in the logs, but it must be present before you continue to the next steps. If you do not wait for the error before you attempt more troubleshooting, you might bring the ESX server down.
2. Power off the virtual machine.
3. Rescan the HBA. Rescanning the HBA on the ESX server might reactivate the failed device. If VMware kernel locks prevent you from rescanning the HBA, perform the following steps:
   a. In the vCenter interface, select the ESX host.
   b. Click Configuration.
   c. Right click iSCSI Software Adapter and select Properties.
   d. Click Static Discovery.
   e. Delete any static addresses and click Close.
   f. Rescan the HBA.

Windows

Scenario: Restoring file-level VM backups

On Microsoft Windows systems, you can restore specific files from a file-level backup of a VMware virtual machine. A file-level restore is useful for restoring individual files that might be lost or damaged. You cannot use this method to restore files that were

part of a full VM backup. Before you can restore files from the off-host backup server onto the VMware virtual machine, the off-host backup server must be configured as a proxy server.

Before you begin

File-level backups were created with the version 7.1 or earlier backup-archive clients.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Important: Use the restore command to run a file-level restore. Do not use the restore vm command.
The following assumptions are made for this scenario of a file-level restore:

- The goal is to restore files that were previously backed up to the IBM Spectrum Protect server.
- The files were previously backed up on a VMware virtual machine called Orion, with the host name orion. For this scenario, the Orion VM fails and some of the files must be restored.
- Files on Orion were backed up to file spaces that match the lowercase form of the computer host name. The file space names are expressed in Universal Naming Convention (UNC) format, for example:
  - Files that are backed up from the C: drive on Orion, are stored in the \\orion\c$ file space.
  - If Orion has a D: drive, files that are backed up from that drive are stored in the \\orion\d$ file space.
- In this scenario, the files are restored from the C:\mydocs directory that was on Orion to the C:\restore_temp directory on a different computer. The computer that you restore file to can be another VMware virtual machine or a physical computer.
- The computer that runs the restore has a different host name and node name than the virtual machine Orion. During the restore, you must specify the source file specification in the complete UNC format and use one of the following parameters to access Orion:

  -virtualnodename
  : Specifies the client node for which you are restoring a backup. Use this parameter if you are restoring files to the computer where you are currently logged on.

  -asnodename
  : Specifies the client node for which you are restoring a backup. Use this parameter if you are restoring files to a computer for which you have proxy authority.

Complete the following steps to run a file-level restore for the computer Orion:

Procedure

1. Query the IBM Spectrum Protect server to determine the file spaces that are registered for Orion:

   ```
   dsmc query filespace -virtualnode=orion
   ```

2. Restore files for the Orion file space, by running one of the following commands:

   Restore files to the computer where you are currently logged on:
   : Assume that you are currently logged on to the computer called Orion. Run one of the following commands:
     a. If you know the password for the node that you are restoring, use the -virtualnodename option in the restore command. For example, run the following command to restore the files to Orion:

        ```
        dsmc restore \\orion\c$\mydocs\ c:\restore_temp\ -sub=yes
        -virtualnodename=orion
        ```

     b. If you have proxy authority, you can restore files on behalf of the target node. Proxy authority must be granted from the agent node, in other words the node of the computer that the restore is run from. You must know the password for the agent node so that you can access the target node. For example, run the following command to restore the files to Orion:

        ```
        dsmc restore \\orion\c$\mydocs\ c:\restore_temp\ -sub=yes
        -asnodename=orion
        ```

Table 1. Components for the restore command when you restore files to the same computer

Command component	Description

Command component	Description
`\\orion\c$\mydocs\`	Source file specification on the IBM Spectrum Protect server. This location contains the backed up files that you are restoring. The files are backed up for the `orion` VM, so the file specification must be in UNC format.
`c:\restore_temp\`	Destination file specification on the computer where you are currently logged on. The files are restored to this location.
`-sub=yes`	Specifies that all subdirectories in the source file specification are included when you run the restore operation.
`-virtualnodename=orion`	Notifies the IBM Spectrum Protect server that the backup is running from the node `orion`.
`-asnodename=orion`	Notifies the IBM Spectrum Protect server that the backup is running from the node `orion`.

Restore files to a different computer:

To restore the files from the IBM Spectrum Protect server to a computer other than the one you are logged on to, run the following command. You can use this command only if you are logged in with authority to write to the remote computer as controlled by the operating system.

```
dsmc restore \\orion\c$\mydocs\ \\orion\c$\restore_temp\ -sub=yes
-virtualnode=orion
```

Table 2. Components for the restore command when you restore files to a different computer

Command component	Description
`\\orion\c$mydocs\`	Identifies the source file specification on the IBM Spectrum Protect server. This location contains the backed up files that you are restoring. The files are backed up for the `orion` VM, so the file specification must be in UNC format.
`\\orion\c$\restore_temp\`	Identifies the destination file specification on a computer other than the computer where you are logged on. The You are restoring the files to the `orion` VM over the network, by using a Microsoft feature that identifies network locations in UNC notation.
`-sub=yes`	Specifies that all subdirectories in the source file specification are included when you run the restore operation.
`-virtualnodename=orion`	Notifies the IBM Spectrum Protect server that the backup is running from the node `orion`.

Restoring full VM backups that were created with VMware Consolidated Backup

You can restore a full VMware backup to re-create all of the files for a VMware virtual machine (VM). Complete these steps to restore full VM backups that were created by using VMware Consolidated Backup (VCB) running on IBM Spectrum Protect™ Version 6.2.0 or earlier.

Before you begin

To restore a full VMware backup that was created by using IBM Spectrum Protect Version 6.2.2 or later, see the topic "Restoring full VM backups".

This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

Procedure

1. Depending on the target location for the restore, complete the appropriate step:
   - If the restore of the full VM backup is going to overwrite the existing VMware virtual machine, delete the existing virtual machine.
   - If you restore the full VM backup to a new virtual machine, you do not need to delete the existing virtual machine. You can delete the existing virtual machine, otherwise proceed to the next step.
2. Query the virtual machine for full VMware backups, by completing the following steps:
   a. From the off-host backup server, run the following command:

      ```
      dsmc q vm *
      ```

      The command lists the available backups, for example:

      ```
        #       Backup Date       Mgmt Class           Type   A/I Virtual Machine
      ---     -----------       ----------          ----   --- ---------------
        1   12/03/2009 03:05:03   DEFAULT             VMFULL  A  vm_guest1
        2   09/02/2010 10:45:09   DEFAULT             VMFULL  A  vm_guest11
        3   09/02/2010 09:34:40   DEFAULT             VMFULL  A  vm_guest12
        4   09/02/2010 10:10:10   DEFAULT             VMFULL  A  vm_guest13
        5   12/04/2009 20:39:35   DEFAULT             VMFULL  A  vm_guest14
        6   09/02/2010 11:15:18   DEFAULT             VMFULL  A  vm_guest15
        7   09/02/2010 02:52:44   DEFAULT             VMFULL  A  vm_guest16
        8   08/05/2010 04:28:03   DEFAULT             VMFULL  A  vm_guest17
        9   08/05/2010 05:20:27   DEFAULT             VMFULL  A  vm_guest18
       10   08/12/2010 04:06:13   DEFAULT             VMFULL  A  vm_guest19
       11   09/02/2010 00:47:01   DEFAULT             VMFULL  A  vm_guest7
       12   09/02/2010 01:59:02   DEFAULT             VMFULL  A  vm_guest8
       13   09/02/2010 05:20:42   DEFAULT             VMFULL  A  vm_guest9
      ANS1900I Return code is 0.
      ANS1901I Highest return code was 0.
      ```

   b. From the results that are returned by the query command, identify a virtual machine to restore.
3. Restore the full VMware backup, by using the restore vm command. To restore a virtual machine from a specific point in time, include the -pitdate and -pittime options, for example:

   ```
   dsmc restore vm my_vm_name destination -pitdate=date -pittime=hh:mm:ss
   ```

   Where:

   my_vm_name
   : Name of the virtual machine that you are restoring.

   destination
   : Directory location for the restored vmdk file.

   -pitdate
   : Date that the backup was created.

   -pittime
   : Time that the backup was created.

4. When the restore is completed, the following message is returned. Enter `Y`.

   ```
   Virtual Infrastructure Client or VMware Converter tool
   can be used to redefine virtual machine to the VMware Virtual Center Inventory.

   Would you like to launch VMware Converter now? (Yes (Y)/No (N))
   ```

   Tip: If you enter `N`, the command-line returns without opening the VMware Converter. However, you must convert the image before the image can be restored.
5. To convert the restored VCB image into a virtual machine on a VMware server by using the VMware vCenter Converter tool, complete following steps:

a. From the Windows Start menu, open the Converter tool.
b. From the Converter tool, click Convert Machine.
c. In the Virtual machine file field, enter the location of the restored .vmx file.
Tip: The .vmx file is restored to the directory specified by the vmbackdir option of the `restore vm` command.
d. Follow the remaining steps in the wizard to convert the full VM backup.

6. When the restore is complete, the virtual machine is powered off. Start the virtual machine from the VMware vCenter.

Windows

Restore Windows individual Active Directory objects

You can restore individual Active Directory objects to recover from accidental corruption or deletion of Active Directory objects without requiring a shutdown or restart of the Active Directory server.

On the Windows Server client, use the restore adobjects command to restore local, deleted Active Directory objects (tombstone objects). You can also restore individual Active Directory objects from system state backups on the IBM Spectrum Protect™ server.

- Windows Reanimate tombstone objects or restoring from a system state backup
  Tombstone reanimation is a process to restore an object that had been deleted from the Active Directory. When an object is deleted from Active Directory, it is not physically erased, but only marked as deleted. It is then possible to reanimate (restore) the object.
- Windows Restoring Active Directory objects using the GUI and command line
  To restore individual Active Directory objects, you must run the backup-archive client on a domain controller and your user account must be a member of the Administrators group. The Active Directory objects are not displayed in the directory tree if your user account is not a member of the Administrators group.
- Windows Restrictions and limitations when restoring Active Directory objects
  There are some restrictions and limitations to be aware of when restoring Active Directory objects.
- Windows Preserve attributes in tombstone objects
  To specify an attribute to be preserved in the tombstone object, first locate this attribute in the Active Directory schema, then update the *searchFlags* attribute of the schema object.
- Windows Modifying the client acceptor and agent services to use the web client
  You cannot restore individual Active Directory objects using the web client by default. The web client services (client acceptor and agent) run under the Local System account by default. The Local System account does not have enough privileges to restore Active Directory objects.

Windows

Reanimate tombstone objects or restoring from a system state backup

Tombstone reanimation is a process to restore an object that had been deleted from the Active Directory. When an object is deleted from Active Directory, it is not physically erased, but only marked as deleted. It is then possible to reanimate (restore) the object.

When an object is reanimated, not all object attributes are preserved. When an object becomes a tombstone object, many attributes are automatically stripped from it, and the stripped attributes are lost. It is possible, however, to change the Active Directory schema so that more attributes are preserved when the object is deleted.

User-group links are not preserved in tombstones. For example, when a user object is reanimated, the user account is not a member of any group. All of this information must be recreated manually by the Active Directory administrator.

When an Active Directory object is restored from a system state backup on the IBM Spectrum Protect™ server, virtually all of its attributes and its group membership are restored. This is the best restore option using a Windows Server domain controller. When an object is restored from the server:

- The Active Directory database is extracted from a system state backup and restored into a temporary location.
- The restored database is opened.
- Select which objects you want to restore. For each object:
  - A search for the matching tombstone is performed. The Globally Unique Identifier (GUID) of the restored object is used to search for the tombstone.
  - If the matching tombstone is found, it is reanimated. In this case, the restored object retains the original Globally Unique Identifier (GUID) and the Security Identifier (SID).
  - If the matching tombstone is not found, a new object is created in the database. In this case, the new object has a new GUID and a new SID that are different than the original object.
- Missing attributes are copied from the backup into the reanimated or recreated object. Existing attributes that have been changed since the backup was taken are updated to match the value in the backup. New attributes that have been added since the backup was taken are removed.
- Group membership is restored.

Although all attributes that can be set and the group links are recreated, the restored objects might not be immediately available after the restore operation. An Active Directory administrator might have to manually update the restored objects in order to make them available. Make sure to read Restrictions and limitations when restoring Active Directory objects before performing the restore.

Windows

Restoring Active Directory objects using the GUI and command line

To restore individual Active Directory objects, you must run the backup-archive client on a domain controller and your user account must be a member of the Administrators group. The Active Directory objects are not displayed in the directory tree if your user account is not a member of the Administrators group.

You can restore active directory objects or tombstone objects using either the GUI or the command line.

To restore individual objects from the GUI:

1. Click Restore in the IBM Spectrum Protect™ window. The Restore window opens.
2. Expand the directory tree if necessary. To expand an object in the tree, click the plus sign (+) next to the object.
3. Locate the Active Directory node in the directory tree. Expand it to reveal Local Deleted Objects. The Server object is also available.
   - To restore tombstone objects, expand Local Deleted Objects, navigate to the tombstone objects that you want to restore, and select the tombstone objects.
   - To restore Active Directory objects that are backed up to the IBM Spectrum Protect server:
     a. Expand the Server object. A window opens displaying a list of system state backups (with different time stamps) on the server.
     b. Select a system state backup from the list. The Active Directory database from that system state is restored in the background, and the tree is populated with Active Directory objects.
     c. Navigate to the Active Directory objects that you want to restore and select the Active Directory objects.

   Tip: To see the attributes for an Active Directory object, keep expanding each Active Directory object in the tree until you reach the one you want. The attributes for an object are displayed in the display area that is adjacent to the tree. You can search or filter the tree for an Active Directory object based on its name.
4. Click Restore to begin the restore operation. The Task List window opens and shows the progress of the restore operation.

On the command line, use the query adobjects command to query and the restore adobjects command to restore individual Active Directory objects.

Windows

Restrictions and limitations when restoring Active Directory objects

There are some restrictions and limitations to be aware of when restoring Active Directory objects.

Understand the following restrictions before restoring objects:

- Do not restore the Active Directory as part of a system-state restore operation, unless it is intended to be used for a disaster recovery-level restore operation of the full Active Directory. This type of restore operation requires the Active Directory Server to be stopped and restarted.
- You cannot perform a point-in-time restore of tombstone objects. You can perform a point-in-time restore of Active Directory objects that are backed up to the server.
- You cannot restore Active Directory objects from backup sets.

Understand the following limitations before restoring objects:

- Restoring Active Directory objects from the IBM Spectrum Protect™ server requires temporary space on your local hard disk drive. You can use the stagingdirectory option to specify a directory on your local hard disk for storing temporary data from the server. Depending on the size of the temporary data, network bandwidth, and both client and server performance, this operation can take anywhere from 20 seconds to over an hour. There might be a delay in refreshing the Restore window when displaying the Active Directory tree.
- User passwords cannot be restored by default. A restored user object is disabled until the administrator resets the password and re-enables the account. Also, if an account was deleted from the domain and is then restored by the backup-archive client, it must be manually joined to the domain after the restore operation. Otherwise, users on the target computer cannot log on to the domain.

  In order to have a user or a computer object fully operational after restore, you must modify schema attribute *Unicode-Pwd* as described in **Preserve attributes in tombstone objects**.

- The Active Directory schema is not recreated when the Active Directory object is restored. If the schema was modified after the backup, the restored object might no longer be compatible with the new schema, and some Active Directory object attributes might no longer be valid. The client issues a warning message if some attributes cannot be restored.
- Group Policy Objects and their links to organizational units (OU) cannot be restored.
- Local policies for restored Active Directory objects are not restored.
- When you restore an object from the IBM Spectrum Protect server, if the target object already exists in the Active Directory and you replace it with its backup version, the object is not deleted and recreated. The existing object is used as a base, and its attributes are overwritten by the backup version. Some attributes, such as the GUID and the SID, stay with the existing object and are not overwritten by the backup version.
- If there are multiple tombstone objects for the same container, reanimate them from the backup-archive client command line using the object GUID, in which case the command-line client only reanimates the container object and not its children. In the backup-archive client GUI, the entire container can be selected to reanimate.
- When you restore an object from the IBM Spectrum Protect server, if the live Active Directory object exists and has the *prevent deletion* bit on, the client can modify the attributes of the object. However, if there is a tombstone object of the same name but a different object GUID, the Directory Services returns the *access denied* error.
- When you restore an object from the IBM Spectrum Protect server and the container of the object has been renamed, the client recreates the container using the original name at the time of the backup. When restoring a tombstone object, the client restores it to the renamed container because the *lastKnownParent* attribute of the tombstone object has been updated to reflect the new container name.

Windows

Preserve attributes in tombstone objects

To specify an attribute to be preserved in the tombstone object, first locate this attribute in the Active Directory schema, then update the *searchFlags* attribute of the schema object.

There is vendor-acquired software (for example, ADSI Edit) that allows you to update the *searchFlags* attribute of the schema object.

Usually none of the bits in the *searchFlags* bit mask are set (the value is 0). Set *searchFlags* to 8 (0x00000008) if you want Active Directory to save the particular attribute in the tombstone object when the original object is deleted.

Windows

Modifying the client acceptor and agent services to use the web client

You cannot restore individual Active Directory objects using the web client by default. The web client services (client acceptor and agent) run under the Local System account by default. The Local System account does not have enough privileges to restore Active Directory objects.

To enable this restore operation in the web client, follow these steps:

1. Modify the client acceptor and agent services to use an administrative account such as *Administrator* when logging on to Windows.
2. You can edit the properties for the client acceptor and agent services (typically called TSM Client Acceptor and TSM Remote Client Agent) in the Control Panel.
3. Modify the client acceptor and the agent services in the Login Options page of the IBM Spectrum Protect™ configuration wizard when you set up the web client

If the web client is already set up, follow these steps:

1. Click Start.
2. Click Control Panel → Administrative Tools → Services.
3. Select the scheduler service from the list of Windows services.
4. Click the Log On tab.
5. Click This Account in the `Login As` section.
6. Enter an administrative account, or click Browse to locate the domain account.
7. Enter the password for the domain account.
8. Click OK and then click Start.

Restore Adobjects

Restoring or retrieving data during a failover

When the client fails over to the secondary server, you can restore or retrieve replicated data from the secondary server.

Before you begin

Before you begin to restore or retrieve data during a failover:

- Ensure that the client is configured for automated client failover.
- Ensure that you are connected to an IBM Spectrum Protect™ server that replicates client nodes. For more information about failover requirements, see Requirements for automated client failover.

Restriction: In failover mode, you cannot back up or archive data to the secondary server.

Procedure

To restore or retrieve data during a failover, complete the following steps:

1. Verify the replication status of the client data on the secondary server. The replication status indicates whether the most recent backup was replicated to the secondary server.
2. Restore or retrieve your data as you would normally do from the client GUI or from the command-line interface.
   Tip: Restartable restore operations function as expected when you are connected to the secondary server. However, restore operations that are interrupted when the primary server goes down cannot be restarted after the client fails over. You must run the whole restore operation again after the client fails over to the secondary server.

Results

If the replicated data on the secondary server is not current, you are prompted to continue or to stop the restore or retrieve operation.

For example, to restore the build.sh directory at the command-line interface, you issue the following command: AIX Linux Mac OS X Solaris

```
dsmc res /build.sh
```

Windows

```
dsmc res C:\build.sh
```

The following output is displayed:

```
IBM Spectrum Protect
Command Line Backup-Archive Client Interface
  Client Version 8, Release 1, Level 0.0
  Client date/time: 11/16/2016 12:05:35

Windows

Authorizing another user to restore or retrieve your files

You can authorize a user on another node to restore your backup versions or retrieve your archive copies. In this way, you can share files with other people or with other workstations that you use with a different node name.

About this task

You can also authorize other nodes to access the automated system recovery (ASR) file space.

Another node can be used to create the ASR diskette so that the workstation can be recovered using ASR and the backup-archive client. Use the other node if a problem occurs with the workstation and the ASR diskette of the workstation is not available.

To authorize another node to restore or retrieve your files:

Procedure

1. Click **Utilities** → **Node Access List** from the main window.
2. In the **Node Access List** window, click the **Add** button.
3. In the **Add Access Rule** window, select an item in the **Permit Access** field to specify the type of data that the other user can access. You can select either **Backed up Objects** or **Archived Objects**.
4. Type the node name of the user in the **Grant Access to Node** field. Type the node name of the host workstation of the user in the **Grant Access to Node** field.
5. Type the user ID on the host workstation in the **User** field.
6. In the **Filespace and Directory** field, select the file space and the directory that the user can access. You can select one file space and one directory at a time. If you want to give the user access to another file space or directory, you must create another access rule.
7. If you want to limit the user to specific files in the directory, type the name or pattern of the files on the server that the other user can access in the **Filename** field. You can make only one entry in the **Filename** field. It can either be a single file name or a pattern that matches one or more files. You can use a wildcard character as part of the pattern. Your entry must match files that have been stored on the server.
8. If you want to give access to all files that match the file name specification within the selected directory including its subdirectories, click **Include subdirectories**.
9. Click **OK** to save the access rule and close the **Add Access Rule** window.
10. The access rule that you created is displayed in the list box in the **Node Access List** window. When you have finished working with the **Node Access List** window, click **OK**. If you do not want to save your changes, click **Cancel** or close the window.

Results

For example, to give the node user2 access to all backup files and subdirectories under the `d:\user1` directory, create a rule with the following values:

```
Permit Access to: Backed up Objects
Grant Access to Node: user2
Filespace and Directory: d:\user1
Filename: *
Include subdirectories: Selected
```

The node you are authorizing must be registered with your IBM Spectrum Protect™ server.

On the command line of the client, use the set access command to authorize another node to restore or retrieve your files. You can also use the query access command to see your current list, and delete access to delete nodes from the list.

Related reference:
Delete Access
Query Access
Set Access
Windows

Restoring or retrieving files from another client node

After users grant you access to their files on the server, you can restore or retrieve those files to your local system.

About this task

You can display file spaces for another user on the server, restore the backup versions of files for another user, or retrieve the archive copies for another user to your local file system, by following these steps:

Procedure

1. Click **Utilities** from the main window.
2. Click **Access Another Node**.
3. Type the node name of the host workstation of the user in the **Node name** field and click **Set**.

Results

If you are using commands, use the fromnode option to indicate the node. You must also use the file space name, rather than the drive letter, to select the restore-retrieve drive that you want to access. Include the file space name in braces and specify it as you

would specify a drive letter. For example, to restore the files from the cougar node \projx directory on the d–disk file space to your own \projx directory, enter:

```
dsmc restore -fromnode=cougar  \\cougar\d$\projx\* d:\projx\
```

Use the query filespace command to display a list of file spaces. For example, to display a list of the file spaces of cougar, enter:

```
dsmc query filespace -fromnode=cougar
```

Important: The backup-archive client can use file space information when restoring files. The file space information can contain the name of the computer from which the files were backed up. If you restore files from another client node and do not specify a destination for the restored files, the client uses the file space information to restore the files. In this case, the client attempts to restore the files to the drive on the original computer. If the restoring computer has access to the drive of the original computer, you can restore files to the original drive. If the restoring computer cannot access the drive of the original computer, the client returns a network error message. If you want to restore the original directory structure but on a different computer, specify only the target drive when you restore the files. This is true when restoring files from another node and when retrieving files from another node.

Restore
Retrieve

Windows

Restoring or retrieving your files to another workstation

When you are using a different workstation, you can restore or retrieve files you backed up from your own workstation.

Your backup versions and archive copies are stored according to your node, not your specific workstation. Your IBM Spectrum Protect™ password protects your data.

To restore or retrieve files to another workstation, use the virtualnodename option to specify the node name of the workstation from which you backed up the files. You can use the virtualnodename option when starting IBM Spectrum Protect or place the option in your client options file, dsm.opt, on the workstation. If you are using a workstation other than your own, use the virtualnodename option with the dsm command. For example, if your node name is cougar, enter:

```
start dsm -virtualnodename=cougar
```

You can then restore or retrieve files as if you were working from your original workstation.
You can also use virtualnodename option on commands. For example, to restore your \projx files to your local c:\myfiles directory, enter:

```
dsmc restore -virtualnodename=cougar \\cougar\d$\projx\*.* c:\myfiles\
```

If you do not want to restore or retrieve the files to the same directory name on the alternate workstation, enter a different destination.

Restoring or retrieving files to another type of workstation

You can restore or retrieve files from one system type to another. This is called *cross-client restore*.

Restriction: You must have the appropriate permissions to access the file space of the other workstation.

NTFS and ReFS drives permit file and directory names that are longer than those permitted on FAT drives. If you are recovering files to a FAT drive with long file names, specify a destination file specification for each file.

When you use the Windows client to recover files with long names to an NTFS or ReFS file system, the long names are preserved, even if you are recovering the file to a different type of drive than the source drive.

Related tasks:
Authorizing another user to restore or retrieve your files
Restoring or retrieving files from another client node

Windows

Deleting file spaces

If your IBM Spectrum Protect™ administrator grants you authority, you can delete entire file spaces from the server.

About this task

You cannot delete individual backup copies that are kept on the server. When you delete a file space, you delete all the files, both backup copies and archive copies, that are contained within the file space. For example, if you delete the file space for your `C` drive, you are deleting every backup copy for every file on that disk and every file that you archived from that disk.

Attention: Carefully consider what you are doing before you delete a file space.

You can delete file spaces using the GUI or the command-line client. To delete network-attached storage (NAS) file spaces, use the web client or command-line client.

To delete a file space using the GUI client, perform the following steps:

Procedure

1. From the main window, click **Utilities** → **Delete Filespaces**.
2. Select the file spaces you want to delete.
3. Click **Delete**. The client prompts you for confirmation before deleting the file space.

Results

You can also delete a file space using the delete filespace command. Use the class option with the delete filespace command to delete NAS file spaces.

Delete Filespace
AIX | Linux | Solaris

Restore an image to file

When you back up an image, the backup-archive client backs up the first sector of the volume, but when the data is restored, it skips the first sector to preserve the original logical volume control block of the destination volume.

When you restore an image to file, entire volume contents, including the first sector, are restored to the file.

AIX® LVM volumes from original volume groups contain the Logical Volume Control Block (LVCB) on the first sector (512 bytes) of the volume. The LVCB contains volume specific meta-data that should be preserved by applications using the volume.

When you copy the file, containing the image, onto an LVM volume from the original volume group, you need to skip the LVCB from both the file and destination volume. The following dd command can be used for this purpose.

```
dd if=<filename> of=/dev/<vol> bs=512 skip=1 seek=1
```

The dd command sets the block size to 512 bytes, which makes copying very slow. It is better to use `bs=1m` or similar. Here is an alternative way to copy image data:

1. Save the original first sector to a file:

   ```
   dd if=/dev/<vol> of=firstblk.tmp bs=512 count=1
   ```

2. Copy the restored image:

   ```
   dd if=<filename> of=/dev/<vol> bs=1m
   ```

3. Restore the original first sector:

   ```
   dd if=firstblk.tmp of=/dev/<vol> bs=512 count=1
   ```

With the introduction of big and scalable volume group formats on AIX, it is possible that the first sector of the logical volume cannot contain LVCB and is available for the data. If you use big or scalable volume groups on your system, and need to restore the whole volume including the first sector, restore the volume to file and then copy it to a destination volume. The following **dd** command can be used for this purpose.

```
dd if=<filename> of=/dev/<vol> bs=1m
```

Manage GPFS file system data with storage pools

With Global Parallel File Systems (GPFS™) technology, you can manage your data using storage pools. A storage pool is a collection of disks or RAIDs with similar properties that are managed together as a group.

The group under which the storage pools are managed together is the file system. The automated placement and management of files on the storage pool level is done by policies. A policy is a set of rules that describes the life cycle of user data, based on the attributes of the file.

When a file is created, the placement policy determines the initial location of the data of the file and assigns the file to a storage pool. All data written to that file is placed in the assigned storage pool. The management policy determines file management operation, such as migration and deletion. The files within a GPFS file system are distributed over different storage pools, depending on the enabled placement and migration policies.

During restore, the files are placed on the correct storage pool. The IBM Spectrum Protect™ server is not aware of pool-to-pool migrations, so the files are placed on the storage pool from where the backup has taken place. The policy engine replaces the files based on migration policies.

If a storage pool ID is stored in the extended attributes of the file, and that storage pool is available, the file is always placed in that storage pool. If the storage pool is not available, the file is placed according to the placement policy. If the placement policy does not match the file, the file is placed in the system pool.

GPFS handles the placement of files after a restore as follows:

- The file is placed in the pool that can be selected by matching the saved file attributes to a RESTORE rule
- The file is placed in the pool that it was in when it was backed up
- The file is placed based on the current placement policy
- The file is placed in the system storage pool

The GPFS RESTORE rule allows you to match files against their saved attributes rather than the current file attributes. If the file attributes do not match, GPFS tries to restore the file in the sequence described above.

For more information about the GPFS RESTORE rule, read the GPFS documentation about policies and rules.

The following restrictions apply:

- The restore of stub files does not work with multiple storage pools, or with files that have ACLs
- Unlink of filesets are not allowed
- The ctime option of GPFS should be set to no (default), to prevent unwanted Backup-Archive backups of files after GPFS file migration from pool to pool

For information about using storage pools, see the IBM Spectrum Protect server documentation.

Restoring data to a point in time

Use a *point-in-time* restore to restore files to the state that existed at a specific date and time.

About this task

A point-in-time restore can eliminate the effect of data corruption by restoring data from a time prior to known corruption, or recover a basic configuration to a prior condition.

Mac OS X | AIX | Linux | Solaris You can perform a point-in-time restore of a file space, directory, or file.

AIX | Linux | Solaris You can also perform a point-in-time restore of image backups.

Windows You can perform a point-in-time restore of system state data, a file space, a directory, or a file. You can also perform a point-in-time restore of image backups.

Perform incremental backups to support a point-in-time restore. During an incremental backup, the backup-archive client notifies the server when files are deleted from a client file space or directory. Selective and incremental-by-date backups do not notify the server about deleted files. Run incremental backups at a frequency consistent with possible restore requirements.

If you request a point-in-time restore with a date and time that is before the oldest version maintained by the IBM Spectrum Protect™ server, the object is not restored to your system. Files that were deleted from your workstation before the point-in-time specified are not restored.

Note:

1. Your administrator must define copy group settings that maintain enough inactive versions of a file to guarantee that you can restore that file to a specific date and time. If enough versions are not maintained, the client might not be able to restore all objects to the point-in-time you specify.
2. If you delete a file or directory, the next time you run an incremental backup, the active backup version becomes inactive and the oldest versions that exceed the number specified by the *versions data deleted* attribute of the management class are deleted.

When you perform a point-in-time restore, consider the following information:

- The client restores file versions from the most recent backup before the specified point-in-time date. Ensure the point-in-time that you specify is not the same as the date and time this backup was performed.
- If the date and time you specify for the object you are trying to restore is earlier than the oldest version that exists on the server, the client cannot restore that object.
- Point-in-time restore restores files that were deleted from the client workstation after the point-in-time date but not files that were deleted before this date.
- The client cannot restore a file that was created after the point-in-time date and time. When a point-in-time restore runs, files that were created on the client after the point-in-time date are not deleted.

Procedure

To perform a point-in-time restore by using the client GUI, complete the following steps:

1. Click the Restore button in the main window. The Restore window appears.
2. Click the Point-in-Time button from the Restore window. The Point in Time Restore window appears.
3. Select the Use a Point-in-Time Date selection box. Select the date and time and click OK. The point in time that you specified appears in the Point in Time display field in the Restore window.
4. Display the objects that you want to restore. You can search for an object by name, filter the directory tree, or work with the directories in the directory tree.
5. Click the selection boxes next to the objects you want to restore.
6. Click the Restore button. The Restore Destination window is displayed. Enter the appropriate information.
7. Click the Restore button to start the restore. The Restore Task List window displays the restore processing status.

Results

Note: If there are no backup versions of a directory for the point-in-time you specify, files within that directory are not restorable from the GUI. However, you can restore these files from the command line.

You can start point-in-time restore from the command-line client by using the pitdate and pittime options with the query backup and restore commands. For example, when you use the pitdate and pittime options with the query backup command, you establish the point-in-time for which file information is returned. When you use pitdate and pittime with the restore command, the date and time values you specify establish the point-in-time for which files are returned. If you specify pitdate without a pittime value, pittime defaults to 23:59:59. If you specify pittime without a pitdate value, it is ignored.

Restore AIX encrypted files

When files are backed up in raw format from an AIX® JFS2 Encrypted File System (EFS), you can only restore them to the same or another JFS2 EFS. They cannot be restored to any different file system, or on a different platform.

When EFS files are backed up in clear text, then you can restore them anywhere. If you restore them to a JFS2 EFS, they are automatically re-encrypted only if the directory to which they are restored has the AIX "EFS inheritance" option set.

After restoring a file that was backed up in raw format, you might find that the file cannot be decrypted. The encryption key originally used for the file might no longer be available in the keystore of the user. In this case, you must restore the keystore used at the time of backup.

For information on backing up EFS data, refer to AIX JFS2 encrypted file system backup.

AIX

Restore AIX® workload partition file systems

All the files that are created by the local workload partition (WPAR), and backed up by the backup-archive client that is installed at the global WPAR, can be restored by the client installed at the global WPAR.

Here are some global partition and WPAR configuration examples:

```
Global partition:

   system name: shimla

   file system: /home /opt

WPAR #1 configuration:

   name: wpar1

   file system: /home; name in global WPAR: /wpars/wpar1/home

WPAR #2 configuration:

   name: wpar2

   file system: /data; name in global WPAR: /wpars/wpar2/data
```

There are two ways to restore WPAR data, depending on the method used to back up the WPAR data files:

- Restore all WPAR file systems as the file spaces within the global partition. The file space name must be used to identify the WPAR to which it belongs. All of the data is managed on one node using one schedule. Using the example configuration mentioned previously, here is a sample `dsm.sys` file with one server stanza for all file systems, both global and local:

  ```
  SErvername  shimla

     TCPPort           1500

     TCPServeraddress  server.example.com

     nodename          shimla

     PasswordAccess    generate

     Domain            /wpars/wpar1/home /wpars/wpar2/data /home /opt
  ```

  Use the following command to restore each file space:

  ```
  dsmc restore /wpars/wpar1/home/*
  dsmc restore /wpars/wpar2/data/*
  dsmc restore /home/*
  dsmc restore /opt/
  ```

- Restore each WPAR file system from a different node name, if it is backed up under a different node name. Each WPAR must have a separate node name and a scheduler running within the global partition. Also, three scheduler services must be set up, each using a different `dsm.opt` file corresponding to the server stanza name. This method allows each WPAR restore operation to be managed independent of the others. Using the example configuration mentioned previously, here is a sample `dsm.sys` file with three server stanzas: one for `wpar1`, one for `wpar2`, and one for global partition `shimla`:

```
SErvername  shimla_wpar1
  TCPPort                                 1500
  TCPServeraddress              server.example.com
  nodename                                wpar1
  PasswordAccess                generate
  Domain                                  /wpars/wpar1/home

SErvername  shimla_wpar2
  TCPPort                                 1500
  TCPServeraddress              server.example.com
  nodename                                wpar2
  PasswordAccess                generate
  Domain                                  /wpars/wpar2/data

SErvername  shimla
  TCPPort                                 1500
  TCPServeraddress              server.example.com
  nodename                                shimla
  PasswordAccess                generate
  Domain                                  /home /opt
```

Table 1. Sample WPAR restore commands with dsm.opt file

In dsm.opt file	Sample restore command
servername shimla_wpar1	dsmc restore /wpars/wpar1/home/*
servername shimla_wpar2	dsmc restore /wpars/wpar2/data/*
servername shimla	dsmc restore /home/* dsmc restore /opt/*

AIX Solaris Windows

Restore NAS file systems

You restore NAS file system images using the web client or command line interface. The web client interface is available only for connections to the IBM Spectrum Protect Version 8.1.1, V8.1.0, or V7.1.7 or earlier servers.

You can restore full or differential NAS file system images that were backed up previously. If you restore a differential image, IBM Spectrum Protect™ automatically restores the full backup image first, followed by the differential image. It is not necessary for a client node to mount a NAS file system to perform backup or restore operations on that file system.

- AIX Solaris Windows Restoring NAS file systems using the web client
  This section lists the steps to follow to restore NAS file systems using the web client GUI.
- Windows Restoring NAS files and directories using the web client
  You can use the toc option with the include.fs.nas option in your client options file to specify whether the client saves Table of Contents (TOC) information for each file system backup.
- AIX Solaris Windows Options and commands to restore NAS file systems from the command line
  This topic lists some examples of options and commands you can use to restore NAS file system images from the command line.

Related concepts:

AIX Solaris Windows

Restoring NAS file systems using the web client

This section lists the steps to follow to restore NAS file systems using the web client GUI.

Before you begin

The web client interface is available only for connections to the IBM Spectrum Protect Version 8.1.1, V8.1.0, or V7.1.7 or earlier servers.

Procedure

1. Click the **Restore** button from the main window. The Restore window appears.
2. Expand the directory tree if necessary. To expand a node in the tree, click the plus sign (+) next to an object in the tree. Nodes shown are those that have been backed up and to which your administrator has authority. The root node called **Nodes** is not selectable. This node only appears if a NAS plug-in is present on the client workstation. NAS nodes display on the same level as the node of the client workstation. Only nodes to which the administrator has authority appear.
3. Expand the NAS node to reveal the Image object.
4. Expand the Image object to display volumes that you can restore. You cannot expand Volume objects.
5. Click the selection boxes next to the volumes under the Image object that you want to restore. If you want to restore a NAS image that was backed up on a particular date, click the **Point In Time** button. After you select a date, the last object that was backed up on or prior to that date appears, including any inactive objects. If you want to display all images (including active images and inactive images), before you select them, select **View** → **Display active/inactive files** from the menu bar.
6. Click **Restore**. The Restore Destination window appears. Enter the information in the Restore Destination window. If you choose to restore to a different destination, you can only restore one volume at a time to a different destination. You can restore NAS file system images to any volume on the NAS file server from which they were backed up. You cannot restore images to another NAS file server.
7. Click **Restore**. The NAS Restore **Task List** window displays the restore processing status and progress bar. If there is a number next to the progress bar, it indicates the size of the restore, if known. After the restore completes, the NAS Restore Report window displays processing details. If you must close the web browser session, current NAS operations continue after you disconnect. You can use the **Dismiss** button on the NAS Restore **Task List** window to quit monitoring processes without ending the current operation.
8. (Optional) To monitor processing of an operation, select the Actions > IBM Spectrum Protect™ Activities from the main window.

Results

Considerations:

- Workstation and remote (NAS) backups are mutually exclusive in a Restore window. After selecting an item for restore, the next item you select must be of the same type (either NAS or non NAS).
- Details will not appear in the right-frame of the Restore window for NAS nodes or images. To view information about a NAS image, highlight the NAS image and select View > File Details from the menu.
- To delete NAS file spaces, select Utilities > Delete Filespaces. You can delete both workstation and remote objects.

Windows

Restoring NAS files and directories using the web client

You can use the toc option with the include.fs.nas option in your client options file to specify whether the client saves Table of Contents (TOC) information for each file system backup.

About this task

If you save TOC information, you can use web client to examine the entire file system tree and select files and directories to restore. Creation of a TOC requires that you define the TOCDESTINATION attribute in the backup copy group for the management class to which this backup image is bound. Note that TOC creation requires additional processing, network resources, storage pool space, and possibly a mount point during the backup operation. If you do not save TOC information, you can still restore individual files or directory trees using the RESTORE NODE server command, provided that you know the fully qualified name of each file or directory and the image in which that object was backed up.

To restore NAS files and directories:

Procedure

1. Click Restore from the main window. The Restore window appears.
2. Expand the directory tree if necessary. To expand a node in the tree, click the plus sign (+) next to an object in the tree. Nodes shown are those that have been backed up and to which your administrator has authority. The root node called

Nodes is not selectable. This node only appears if a NAS plug-in is present on the client workstation. NAS nodes appear on the same level as the node of the client workstation. Only nodes to which the administrator has authority appear.

3. Expand the NAS node to display the File Level object.
4. Expand the File Level object to display the volumes, directories, and files that were last backed up. When you expand the volume object, and complete TOC information is available on the server for the latest backup, the Load Table of Contents dialog appears. If complete TOC information is not available for the latest backup, no objects appear below the volume object. The next step explains how to display objects from backups other than the latest backup. Complete TOC information is provided if you performed either of the following operations: (1) A differential image backup with TOC information and its corresponding full image backup with TOC information, or (2) A full image backup with TOC information.
5. Click the selection boxes next to the directories or files that you want to restore.
    a. If you want to restore files from a NAS image that was backed up on a particular date or display files from several older versions, highlight the volume you want to restore and click the Point In Time button.
    b. If you select Use a Point in Time Date in the Point in Time Restore windows, files from the image backed up on that date, and if it is a differential image, files from its corresponding full image appear under the File Level object.
    c. If you click Use Selected Images in the Point in Time Restore window, the Selected Images window appears for you to select images. The contents of the selected images appear in the File Level object.
6. Click Restore. The Restore Destination window appears. Enter the information in the Restore Destination window. If you choose to restore to a different destination, you can only restore one volume at a time to a different destination.
7. Click Restore. The NAS Restore Task List window displays the restore processing status and progress bar. If there is a number next to the progress bar, it indicates the size of the restore, if known. After the restore completes, the NAS Restore Report window displays processing details. If you must close the web browser session, current NAS operations continue after you disconnect. You can use the Dismiss button on the NAS Restore Task List window to quit monitoring processes without ending the current operation.
8. (Optional) To monitor processing of an operation, select the Actions > IBM Spectrum Protect™ Activities from the main window.

Results

Considerations:

- Workstation and remote (NAS) backups are mutually exclusive in a Restore window. After selecting an item for restore, the next item you select must be of the same type either (either workstation or NAS).
- To view information about objects in a NAS node, highlight the object and select View > File Details from the menu.
- To delete NAS file spaces, select Utilities > Delete Filespaces. You can delete both workstation and remote objects.

Options and commands to restore NAS file systems from the command line

This topic lists some examples of options and commands you can use to restore NAS file system images from the command line.

Table 1. NAS options and commands

Option or command	Definition	Page
query node	Displays all the nodes for which a particular administrative user ID has authority to perform operations. The administrative user ID should have at least client owner authority over both the NAS node and the client workstation node they are using either from command line or from the web client.	Query Node
query backup	Use the query backup command with the class option to display information about file system images backed up for a NAS file server.	Query Backup
query filespace	Use the query filespace command with the ***class*** option to display a list of file spaces belonging to a NAS node.	Query Filespace
restore nas	Restores the image of a file system belonging to a Network Attached Storage (NAS) file server.	Restore NAS

Option or command	Definition	Page
AIX Solaris Windows monitor process	AIX Solaris Windows Displays current backup and restore processes for all NAS nodes for which an administrative user has authority. The administrative user can then select one process to monitor.	AIX Solaris Windows Monitor Process
cancel process	Displays current backup and restore processes for all NAS nodes for which an administrative user has authority. From the display, the administrative user can select one process to cancel.	Cancel Process
delete filespace	Use the delete filespace with the class option to display a list of file spaces belonging to a NAS node so that you can choose one to delete.	Delete Filespace

AIX Solaris Regardless of client platform, NAS file system specifications use the forward slash (/) separator, as in this example: `/vol/vol0`.

Windows A NAS file system specification uses the following conventions:

Windows

- Regardless of client platform, NAS file system specifications use the forward slash (/) separator, as in this example: `/vol/vol0`.
- NAS file system designations on the command line require brace delimiters `{}` around the file system names, such as: `{/vol/vol0}`.

Note: When you initiate a NAS restore operation using the command line client or the web client, the server starts a process to initiate, control, and monitor the operation. It might take several moments before you notice progress at the client command line interface because the server must perform a mount and other necessary tasks before data movement occurs. The IBM Spectrum Protect command line client might display an `Interrupted ...` message when the mount occurs. You can ignore this message.
Mac OS X Mac OS X AIX Linux Solaris

Restore active or inactive backups

Your administrator determines how many backup versions IBM Spectrum Protect™ maintains for each file on your workstation.

Having multiple versions of a file permits you to restore older versions if the most recent backup is damaged. The most recent backup version is the *active* version. Any other backup version is an *inactive* version.

Every time IBM Spectrum Protect backs up your files, it marks the new backup version as the active backup, and the last active backup becomes an inactive backup. When the maximum number of inactive versions is reached, IBM Spectrum Protect deletes the oldest inactive version.

To restore a backup version that is inactive, you must display both active and inactive versions by clicking on the **View** menu → **Display active/inactive files** item. To display only the active versions (the default), click on the **View** menu → **Display active files only** item. If you try to restore more than one version at a time, only the active version is restored.

On the IBM Spectrum Protect command line, use the inactive option to display both active and inactive objects.

Related reference:
Inactive
Mac OS X Mac OS X AIX Linux Solaris

Restoring data using the GUI

This section lists the steps to follow to restore backup versions of individual files or subdirectories.

Procedure

1. Click **Restore** from the main window. The Restore window appears.
2. Expand the directory tree. Select the selection boxes next to the files or directories you want to restore. To search or filter files, click the **Find** icon on the tool bar.
3. Enter your search criteria in the Find Files (Restore) window.

4. Click the **Search** button. The Matching Files (Restore) window appears.
5. Click the selection boxes next to the files you want to restore and close the Matching Files (Restore) window.
6. Enter your filter criteria in the Find Files (Restore) window.
7. Click the **Filter** button. The Restore window displays the filtered files.
8. Click the selection boxes next to the filtered files or directories you want to restore.
9. To modify specific restore options, click the **Options** button. Any options you change are effective during the current session *only*.
10. Click **Restore**. The Restore Destination window appears. Enter the information in the Restore Destination window.
11. Click **Restore**. The Restore **Task List** window displays the restore processing status.

Results

Note: On Mac OS X, consider the following items when restoring data using the GUI:

1. When IBM Spectrum Protect™ Tools for Administrators is used to start the client, the client is running with a UID of zero. This means that if you create a folder to restore your files to, that folder is owned by root. To access the files you must change the permissions of the folder. You can change the folder owner from a terminal window using the sudo **chown** command. See your operating system documentation for more information on how to accomplish this.
2. When restoring files with the replace option set to *no*, existing files will not be overwritten, but existing directories are overwritten. To leave existing directories intact during a restore operation, select the **Options** button ⇒ **All selected files and directories** dropdown menu ⇒ **Files only** option.
3. When folders are restored from a UFS or HFSX file system to a HFS file system and they differ only in case, the client restores the contents of both folders to one folder.

Mac OS X | Mac OS X | AIX | Linux | Solaris

Command line restore examples

This topic lists some examples of restore commands to use for specific tasks.

The following table shows examples of how to use the restore command to restore objects from IBM Spectrum Protect™ server storage.

Table 1. Command-line restore examples

Task	Command	Considerations
Restore the most recent backup version of the `/Users/monnett/Documents/h1.doc` file, even if the backup is inactive.	`dsmc restore /Users/monnett/Documents/h1.doc -latest`	If the file you are restoring no longer resides on your workstation, and you have run an incremental backup since deleting the file, there is no active backup of the file on the server. In this case, use the latest option to restore the most recent backup version. IBM Spectrum Protect restores the latest backup version, whether it is active or inactive. See Latest for more information.
Display a list of active and inactive backup versions of files from which you can select versions to restore.	`dsmc restore "/Users/monnett/Documents/*"-pick -inactive`	If you try to restore both an active and inactive version of a file at the same time, only the active version is restored. See Pick and Inactive for more information.
Restore the `/Users/monnett/Documents/h1.doc` file to its original directory.	`dsmc restore /Users/monnett/Documents/h1.doc`	If you do not specify a destination, the files are restored to their original location.
Restore the `/Users/monnett/Documents/h1.doc` file under a new name and directory.	`dsmc restore /Users/monnett/Documents/h1.doc /Users/gordon/Documents/h2.doc`	None
Restore the files in the `/Users` directory and all of its subdirectories.	`dsmc restore /Users/ -subdir=yes`	When restoring a specific path and file, IBM Spectrum Protect recursively restores *all* subdirectories under that path, and any instances of the specified file that exist under *any* of those subdirectories. See Subdir for more information about the ***subdir*** option.

Task	Command	Considerations
Restore all files in the `/Users/gordon/Documents` directory to their state as of 1:00 PM on August 17, 2003.	`dsmc restore -pitd=8/17/2003 -pitt=13:00:00 /Users/gordon/Documents/`	See Pitdate and Pittime for more information about the pitdate and pittime options.
Restore all files from the `/Users/mike/Documents` directory that end with `.bak` to the `/Users/mike/projectn/` directory.	`dsmc restore "/Users/mike/Documents/*.bak" /Users/mike/projectn/`	If the destination is a directory, specify the delimiter `(/)` as the last character of the destination. If you omit the delimiter and your specified source is a directory or a file spec with a wildcard, you receive an error. If the `projectn` directory does not exist, it is created.
Restore files specified in the `restorelist.txt` file to a different location.	`dsmc restore -filelist=/Users/user2/Documents/restorelist.txt /Users/NewRestoreLocation/`	See Filelist for more information about restoring a list of files.

- Mac OS X | AIX | Linux | Solaris Examples: Command line restores for large amounts of data
  If you need to restore a large number of files, you can get faster performance by using the restore command instead of the GUI. In addition, you can improve performance by entering multiple restore commands at one time.
- Mac OS X | AIX | Linux | Solaris Standard query restore, no-query restore, and restartable restore
  This topic describes the standard (or classic) restore method, the no-query restore method, and the restartable restore method.

Related reference:
Restore
Mac OS X | Mac OS X | AIX | Linux | Solaris

Examples: Command line restores for large amounts of data

If you need to restore a large number of files, you can get faster performance by using the restore command instead of the GUI. In addition, you can improve performance by entering multiple restore commands at one time.

For example, to restore all the files in your `/home` file system, enter:

```
dsmc restore /home/ -subdir=yes -replace=all -tapeprompt=no
```

However, if you enter multiple commands for the directories in the `/home` file space, you can restore the files faster.

For example, you could enter these commands:

```
dsmc restore /home/monnett/ -subdir=yes -replace=all -tapeprompt=no
dsmc restore /home/gillis/ -subdir=yes -replace=all -tapeprompt=no
dsmc restore /home/stewart/ -subdir=yes -replace=all -tapeprompt=no
```

You can also use the quiet option with the restore commands to save processing time. However, you will not receive informational messages for individual files.

Note: If you already have the appropriate values set for the subdir, replace, tapeprompt, and quiet options in your client user-options file, you do not need to include those options in the commands.

When you enter multiple commands to restore your files, you must specify a unique part of the file space in each restore command. Be sure you do not use any overlapping file specifications in the commands.

To display a list of the directories in a file space, use the query backup command. For example:

```
dsmc query backup -dirsonly -subdir=no /Users/
```

As a general rule, you can enter from two to four restore commands at one time. The maximum number you can run at one time without degrading performance depends on factors such as how much memory you have and network utilization.

The speed at which you can restore the files also depends on how many tape drives are available on the server, and whether your administrator is using collocation to keep file spaces assigned to as few volumes as possible.

For example, if `/Users/user1` and `/Users/user2` are on the same tape, the restore for `/Users/user2` must wait until the restore for `/Users/user1` is complete. However, if `/Users/user3` is on a different tape, and there are at least two tape drives available, the restore for `/Users/user3` can begin at the same time as the restore for `/Users/user1`.

Set the system ulimit values to unlimited (-1) if you are restoring very large (2 GB) files with HSM or the backup-archive client. The client can restore these large files with enough system resources. If the ulimits are set to lower values, there might be restore failures.

Standard query restore, no-query restore, and restartable restore

This topic describes the standard (or classic) restore method, the no-query restore method, and the restartable restore method.

- Mac OS X | AIX | Linux | Solaris Standard query restore process
  The standard query restore process is also known as classic restore. This topic explains how standard query restore works.
- Mac OS X | AIX | Linux | Solaris No-query restore process
  In the no-query restore process, a single restore request is sent to the server instead of querying the server for each object to be restored.
- Mac OS X | AIX | Linux | Solaris Restartable restore process
  If the restore process stops because of a power outage or network failure, the server records the point at which this occurred.

Standard query restore process

The standard query restore process is also known as classic restore. This topic explains how standard query restore works.

Here is how standard query restore works:

- The client queries the server for a list of files backed up for the client file space you want to restore.
- The server sends a list of backed up files that match the restore criteria. If you want to restore both active and inactive files, the server sends information about all backed up files to the client.
- The list of files returned from the server is sorted in client memory to determine the file restore order and to minimize tape mounts required to perform the restore.
- The client tells the server to restore file data and directory objects.
- The directories and files you want to restore are sent from the server to the client.

No-query restore process

In the no-query restore process, a single restore request is sent to the server instead of querying the server for each object to be restored.

1. The client tells the server that a no-query restore is going to be completed and provides the server with details about file spaces, directories, and files.
2. The server uses a separate table to track entries which guide the restore.
3. The data to be restored is sent to the client. File and directory objects that are stored on disk are sent immediately since sorting for such data is not required before the object is restored.
4. You can use multiple sessions to restore the data. If the data is on multiple tapes, there are multiple mount points available at the server. The combination of using the resourceutilization option and MAXNUMMP allows multiple sessions.

Windows When you enter an unrestricted wildcard source file specification on the restore command and do not specify any of the options: inactive, latest, pick, fromdate, or todate, the client uses a *no-query restore* method for restoring files and directories from the server. This method is called no-query restore because instead of querying the server for each object to be restored, a single restore request is sent to the server. In this case, the server returns the files and directories to the client without further action by the client. The client merely accepts the data that comes from the server and restores it to the destination named on the restore command.

Mac OS X | AIX | Linux | Solaris When you enter an unrestricted wildcard source file specification on the restore command and do not specify any of the options: inactive, latest, pick, fromdate, todate, the client uses a *no-query restore* method for restoring files and directories from the server. This method is called no-query restore because instead of querying the server for each object to be restored, a single restore request is sent to the server. In this case, the server returns the files and directories to the client without further action by the client. The client merely accepts the data that comes from the server and restores it to the destination named on the restore command.

Mac OS X Using the IBM Spectrum Protect™ GUI client, an example of an unrestricted wildcard command would be to select a folder from the restore tree window. An example of a restricted wildcard command would be to select individual files from a folder.

Using the command-line client, an example of an unrestricted wildcard command would be:

Mac OS X

```
"/Users/user1/Documents/2004/*"
```

Mac OS X AIX Linux Solaris

```
/home/mydocs/2004/*
```

Windows

```
c:\mydocs\2004\*
```

An example of a restricted wildcard file specification would be:

Mac OS X

```
/Users/user1/Documents/2004/sales.*
```

Mac OS X AIX Linux Solaris

```
/home/mydocs/2004/sales.*
```

Windows

```
c:\mydocs\2004\sales.*
```

Restartable restore process

If the restore process stops because of a power outage or network failure, the server records the point at which this occurred.

This record is known to the client as a *restartable restore*. It is possible to have more than one restartable restore session. Use the query restore command or choose **restartable restores** from the Actions menu to find out if your client has any restartable restore sessions in the server database.

Windows You must complete a restartable restore before attempting further backups of the file system. If you attempt to repeat the restore that was interrupted or try to back up the destination file space, the attempt fails because you did not complete the original restore. You can restart the restore at the point of interruption by entering the restart restore command, or you can delete the restartable restore using the cancel restore command. If you restart the interrupted restore, it restarts with the first transaction, which might consist of one or more files, not completely restored when the interruption occurred. Because of this, you might receive some replace prompts for files from the interrupted transaction which were already restored.

Mac OS X AIX Linux Solaris You must complete a restartable restore before attempting further backups of the file system. If you attempt to repeat the restore that was interrupted or try to back up the destination file space, the attempt fails because you did not complete the original restore. You can restart the restore at the point of interruption by entering the restart restore command, or you can delete the restartable restore using the cancel restore command.

From the IBM Spectrum Protect™ GUI **Restartable restores** dialog box you can select the interrupted restore and delete it, or you can choose to restart the restore. If you restart the interrupted restore, it restarts with the first transaction, which might consist of one or more files, not completely restored when the interruption occurred. Because of this, you might receive some replace prompts for files from the interrupted transaction which were already restored.

Mac OS X AIX Linux Solaris Windows To perform restartable restores using the GUI, follow these steps:

1. Select **Actions –> Restartable restores** from the main panel.
2. Select the restartable restore session you want to complete.
3. Click the **Restart** button at the bottom of the panel.

Solaris

Restoring Solaris Zettabyte (ZFS) file systems

Zettabyte File Systems (ZFS) use storage pools to manage physical storage.

How you restore a ZFS file system depends on how it was backed up.

- If you backed up all files and folders as separate objects, you can restore them by performing a file-level restore. For example:

  ```
  dsmc restore /tank/myZFS/ -subdir=yes -replace=all
  ```

  Do not perform a file-level restore operation in a disaster recovery scenario. Even though you successfully restore all system files and folders from a backup-archive client-created backup, the restored system might be unstable or fail.
- If you backed up an entire ZFS snapshot as a single file, you need to restore the snapshot file from the server into a temporary location. For example:

  ```
  dsmc restore /tmpdir/mySnapshotfile
  ```

  You can then restore the file system from the snapshot file by using the Oracle Solaris ZFS commands. For example:

  ```
  zfs receive tank/myZFS@mySnapshot < /tmpdir/mySnapshotFile
  ```

  The advantage of restoring ZFS from a snapshot file is that the full file system can be restored, in a disaster recovery scenario.

  For detailed information about restoring data on ZFS file systems, see the product documentation that is available from Oracle. If you are restoring a ZFS root pool, see the topics that describe how to re-create your root pool and recover root pool snapshots.

Additional restore tasks

This section discusses some advanced considerations for restoring data.

- Mac OS X | AIX | Linux | Solaris Authorizing another user to restore or retrieve your files
  You can authorize another user on the same workstation or a different workstation to restore backup versions or retrieve archive copies of your files.
- Mac OS X | AIX | Linux | Solaris Restoring or retrieving files from another client node
  After users grant you access to their files on the server, you can restore or retrieve those files to your local system.
- Mac OS X | AIX | Linux | Solaris Restore or retrieve files to another workstation
  From a different workstation, you can restore or retrieve files you have already backed up from your own workstation. You must know the IBM Spectrum Protect password assigned to your node.
- Mac OS X | AIX | Linux | Solaris Restoring a disk in case of disk loss
  You can only recover your files if you can run the client. If the disk that contains the client is lost (from theft or hardware failure, for example), you must reinstall the client before you can recover your files. If you also lose the disk that contains the operating system and communication software, you must recover them before you can connect to the IBM Spectrum Protect server.
- Mac OS X | AIX | Linux | Solaris Deleting file spaces
  If your IBM Spectrum Protect administrator gives you authority, you can delete entire file spaces from the server.
- Linux Enable SELinux to restore files on the Red Hat Enterprise Linux 5 client
  If you are a non-root user, and you are trying to restore files on the Red Hat Enterprise Linux 5 client, you must first enable SELinux.

Mac OS X | Mac OS X | AIX | Linux | Solaris

Authorizing another user to restore or retrieve your files

You can authorize another user on the same workstation or a different workstation to restore backup versions or retrieve archive copies of your files.

About this task

This permits you to share files with other people or with other workstations that you use with a different node name. To authorize a user on another workstation to restore or retrieve your files, the other workstation must be running one of the UNIX clients and must be registered with your server.

Mac OS X Note: Mac OS X can *only* restore Mac OS X nodes.

To authorize another user to restore or retrieve your files:

Procedure

1. Click **Utilities** → **Node Access List** from the main window. The Node Access List window appears.
2. Click the **Add** button. The Add Access Rule window appears.
3. In the Add Access Rule window, select an item in the Permit Access to field to specify the type of data that the other user can access. You can select either Backed up Objects or Archived Objects.
4. In the Grant Access to Node field, type the node name of the host workstation of the user that can access your data.
5. In the User field, type the name of the user on a node who can access your data.
6. In the Filespace and Directory field, select the file space and the directory that the user can access. You can select one file space and one directory at a time. If you want to give the user access to another file space or directory, you must create another access rule.
7. If you want to limit the user to specific files in the directory, type the name or pattern of the files on the server that the other user can access in the Filename field. You can make only one entry in the Filename field. It can either be a single file name or a pattern which matches one or more files. You can use a wildcard character as part of the pattern. Your entry must match files that have been stored on the server.
8. For the Java™ GUI: If you want to give access to all files that match the file name specification within the selected directory including its subdirectories, click **Include subdirectories**.
9. Click the **OK** button to save the access rule and close the Add Access Rule window.
10. The access rule that you created is displayed in the list box in the Node Access List window. When you have finished working with the Node Access List window, click the **OK** button. If you do not want to save your changes, click **Cancel** or close the window.

Results

In the client command line interface, use the set access command to authorize another node to restore or retrieve your files. You can also use the query access command to see your current list, and delete access to delete nodes from the list.

Query Access
Set Access

Mac OS X | AIX | Linux | Solaris

Restoring or retrieving files from another client node

After users grant you access to their files on the server, you can restore or retrieve those files to your local system.

About this task

You can display file spaces of another user on the server, restore the backup versions of another user, or retrieve the archive copies of another user to your local file system:

Procedure

1. Click **Utilities** from the main window.
2. Click **Access Another Node**. The Access Another Node window appears.
3. Type the node name of the host workstation of the user in the Node name field. Type the user name in the User name field.
4. Click the **Set** button.

Results

If you are using commands, use the fromnode and fromowner options to indicate the node name and the name of the user who owns the files.

For example, to restore files to one of your own file systems that were backed up from a workstation named `Node1` and owned by a user named `Ann`, enter:

```
dsmc restore -fromn=node1 -fromo=ann "/home/proj/*" /home/gillis/
```

Use the query filespace command to get a list of file spaces. For example, to get a list of file spaces owned by `Ann` on `Node1`, enter:

```
dsmc query filespace -fromn=node1 -fromo=ann
```

Restore
Retrieve

Mac OS X | Mac OS X | AIX | Linux | Solaris

Restore or retrieve files to another workstation

From a different workstation, you can restore or retrieve files you have already backed up from your own workstation. You must know the IBM Spectrum Protect™ password assigned to your node.

To restore or retrieve files to another workstation, use the virtualnodename option to specify the node name of the workstation from which you backed up the files. The virtualnodename option cannot be set to the hostname of the workstation. You can use the virtualnodename option when you start IBM Spectrum Protect or you can add the virtualnodename option to your client user options file dsm.opt. Use the virtualnodename option on the **dsmj** command if you are borrowing the workstation of another user and you do not want to update their client user-options file.

IBM Spectrum Protect prompts you for the password for your original node. After you enter the correct password, all file systems from your original workstation appear in the Restore or Retrieve window. You can restore or retrieve files as if you were working on your own workstation.

Important: When you use this method to access files, you have access to all files backed up and archived from your workstation. You are considered a virtual root user.

You can use the virtualnodename option in a command. For example, to restore your ***projx*** files, enter:

```
dsmc restore -virtualnodename=nodeone "/home/monnett/projx/*"
```

If you do not want to restore or retrieve the files to the same directory name on the alternate workstation, enter a different destination.

The considerations for retrieving files are the same as restoring files.

Mac OS X | AIX | Linux | Solaris

Restoring a disk in case of disk loss

You can only recover your files if you can run the client. If the disk that contains the client is lost (from theft or hardware failure, for example), you must reinstall the client before you can recover your files. If you also lose the disk that contains the operating system and communication software, you must recover them before you can connect to the IBM Spectrum Protect™ server.

About this task

To protect yourself against these kinds of losses, you need to put together a set of installation media that you can use to restore your system to a state that lets you contact the server and begin recovering data. The installation media should contain:

Procedure

1. A startable operating system that lets you perform basic functions.
2. A correctly configured communication program that lets you establish communications with the server.
3. A client with appropriate customized options files. You can use the client command line interface to complete this task.

Results

The communication package you use determines what files you need. Consult your operating system and communication software manuals to set up your installation media.

If you also have the IBM Spectrum Protect for Space Management installed on your workstation, your installation media should include the HSM command line client.

Note: Your administrator can schedule restore operations, which can be very useful when you need to restore a large number of files.

Deleting file spaces

If your IBM Spectrum Protect™ administrator gives you authority, you can delete entire file spaces from the server.

About this task

When you delete a file space, you delete all the files and images, both backup versions and archive copies, that are contained within the file space. For example, if you delete the file space for your `/home/monnet` file system, you are deleting every backup for every file in that file system and every file you archived from that file system. **Carefully consider whether you want to delete a file space**. You must be an authorized user to perform this task.

You can delete individual backup versions by using the delete backup command.

You can delete file spaces using the backup-archive client GUI or client command line interface. To delete NAS file spaces, use the web client or client command line interface.

To delete a file space using the GUI, perform the following steps:

Procedure

1. Select **Utilities→ Delete Filespaces** from the main window.
2. Click the selection boxes next to the file spaces you want to delete.
3. Click the **Delete** button. The client prompts you for confirmation before deleting the file space.

Results

You can also delete a file space using the delete filespace command. Use the ***class*** option with the delete filespace command to delete NAS file spaces.

Linux

Enable SELinux to restore files on the Red Hat Enterprise Linux 5 client

If you are a non-root user, and you are trying to restore files on the Red Hat Enterprise Linux 5 client, you must first enable SELinux.

If you do not enable SELinux, you will have problems if you restore files that have modified extended attributes.

Archive and retrieve data with backup-archive clients

If you want to save a copy of a file to long-term storage on the IBM Spectrum Protect™ server for archival purposes, use the *archive* function.

About this task

If the original file was ever damaged or lost, use the *retrieve* function to recover the archive copy from the server.

- Windows Archive and retrieve your data (Windows)
  You can archive infrequently used files to the IBM Spectrum Protect server and retrieve them when necessary. Archiving and retrieving files is similar to backing up and restoring files.
- Mac OS X AIX Linux Solaris Archive and retrieve your data (UNIX and Linux)
  You can archive infrequently used files to the IBM Spectrum Protect server and retrieve them when necessary. Archiving and retrieving files is similar to backing up and restoring files. Many of the windows and concepts are similar.

Windows

Archive and retrieve your data (Windows)

You can archive infrequently used files to the IBM Spectrum Protect™ server and retrieve them when necessary. Archiving and retrieving files is similar to backing up and restoring files.

Unless otherwise specified, references to Windows refer to all supported Windows operating systems.

All the primary archive and retrieve procedures also apply to the web client, except for the following functions:

- Preferences editor
- Setup wizard

You can complete the following primary archive and retrieve tasks:

- Archiving data with the GUI
- Archive data examples by using the command line
- Deleting archive data
- Retrieving archives with the GUI
- Retrieve archive copies by using the command line

- Windows Archive files
  To archive files, select the files that you want to archive. You can select the files by name or description, or select them from a directory tree.
- Windows Retrieve archives
  Select the Retrieve function to recover an archive copy of a file or a directory.

Related concepts:
When to back up and when to archive files
Related tasks:
Starting a web client session
Windows

Archive files

To archive files, select the files that you want to archive. You can select the files by name or description, or select them from a directory tree.

Your administrator might set up schedules to automatically archive certain files on your workstation. The following sections contain information about how to archive files without using a schedule.

You must assign an archive description for all archived files. An archive description identifies data through a meaningful description that you can use later to identify files and directories. You can enter as many as 254 characters to describe your archived data. If you do not enter a description, the following default archive description is assigned:

```
   Archive Date: mm/dd/yyyy
```

```
where mm/dd/yyyy is the current date.
```

When you select the archive function from the backup-archive GUI, a list of all previously used archive descriptions are displayed. You can assign these archive descriptions to future archives.

Incremental backup might recall migrated files, while selective backup and archive always recall migrated files, if you do not use the skipmigrated option.

- Windows Snapshot backup or archive with open file support
  If open file support has been configured, the backup-archive client runs a snapshot backup or archive of files that are locked (or "in use") by other applications.
- Windows Archiving data with the GUI
  You can archive specific files or entire directories from a directory tree. You can also assign a unique description for each group of files you archive (archive package).
- Windows Archive data examples by using the command line
  You can archive data when you want to preserve copies of files in their current state, either for later use or for historical or legal purposes.
- Windows Archiving data with client node proxy
  Archives of multiple nodes that share storage can be consolidated to a common target node name on the IBM Spectrum Protect server.
- Windows Deleting archive data
  You can delete individual archive objects from the IBM Spectrum Protect server, without having to delete the entire file space to which they belong.

Windows

Snapshot backup or archive with open file support

If open file support has been configured, the backup-archive client runs a snapshot backup or archive of files that are locked (or "in use") by other applications.

The snapshot allows the archive to be taken from a point-in-time copy that matches the file system at the time the snapshot is taken. Subsequent changes to the file system are not included in the archive. You can set the snapshotproviderfs parameter of the include.fs option to none to specify which drives do not use open file support.

Note:

1. You can use the include.fs option to set snapshot options on a per file system basis.
2. Open file support is only available for local fixed volumes (mounted to either drive letters or volume mount points) formatted with FAT, FAT32, NTFS, or ReFS file systems. This support includes SAN-attached volumes that meet these requirements.
3. If the client is unable to create a snapshot, failover to non-OFS backup occurs; the same backup support that would be done if the OFS feature was not installed.
4. To enable open file support in a cluster environment all workstations in the cluster should have the OFS feature configured.
5. When using the open file support feature with VSS, the client adds the snapshot volume name to the path of the objects being processed. The snapshot volume name can be up to 1024 bytes. The complete path (snapshot volume name plus object path) can be 8192 bytes or less.

For information about open file support restrictions and issues, search for *TSM Client Open File Support (OFS)* at the IBM® support website.

Configuring Open File Support
Windows

Archiving data with the GUI

You can archive specific files or entire directories from a directory tree. You can also assign a unique description for each group of files you archive (archive package).

About this task

To archive your files, complete the following steps:

Procedure

1. Click Archive in the GUI main window. The Archive window displays.
2. Expand the directory tree by clicking the plus sign (+) or a folder icon in the tree. To search or filter files, click the Search icon from the toolbar.
3. Enter a description, accept the default description, or select an existing description for your archive package in the Description field.
4. To modify specific archive options, click Options. Any options that you change are effective during the current session only.
5. Click Archive. The Archive Status window displays the progress of the archive operation.

Windows

Archive data examples by using the command line

You can archive data when you want to preserve copies of files in their current state, either for later use or for historical or legal purposes.

You can archive a single file, a group of files, or all the files in a directory or subdirectory. After you archive a file, you can delete the original file from your workstation. Use the archive command to archive files.

The following table shows examples of how to use the archive command to archive objects.

Table 1. Command-line archive examples

Task	Command	Considerations
Archive all files in the `c:\plan\proj1` directory with a file extension of `.txt`.	`dsmc archive c:\plan\proj1\*.txt`	Use wildcards to archive more than one file at a time.
Archive all files in the `c:\small\testdir` directory and delete the files on your workstation.	`dsmc archive c:\small\testdir\* -deletefiles`	Retrieve the archived files to your workstation whenever you need them again. For more information about the deletefiles option, see Deletefiles.
Archive the `c:\proj1\h1.doc` file and the `c:\proj2\h2.doc` file	`dsmc archive c:\proj1\h1.doc c:\proj2\h2.doc`	You can specify as many files to be archived as the resources and operating system limits permit. Separate the files to be archived with a space. For more information about the filelist option, see Filelist.
Archive a list of files in the `c:\filelist.txt` file.	`dsmc archive -filelist=c:\filelist.txt`	Use the filelist option to process a list of files. For more information about the filelist option, see Filelist.
Archive the `a:\ch1.doc` file and assign a description to the archive.	`dsmc archive a:\ch1.doc -description="Chapter 1, first version"`	If you do not specify a description with the archive command, the default is `Archive Date:x`, where *x* is the current system date. For more information about the description option, see Description.
Archive all the files in the `d:\proj` directory and its subdirectories.	`dsmc archive d:\proj\ -subdir=yes`	For more information about the subdir option, see Subdir.
Use the v2archive option with the archive command to archive only files in the `c:\relx\dir1` directory.	`dsmc archive c:\relx\dir1\ -v2archive`	IBM Spectrum Protect™ archives only files in the `c:\relx\dir1` directory. Directories that exist in the path are not processed. For more information about the v2archive option, see V2archive.
Use the archmc option with the archive command to specify the available management class for the policy domain to which you want to bind your archived files.	`dsmc archive -archmc=RET2YRS c:\plan \proj1\ budget.jan\*`	For more information about the archmc option, see Archmc. For more information about management classes, see Storage management policies .

Task	Command	Considerations
Assume that you initiated a snapshot of the `C:\` drive and mounted the snapshot as the logical volume `\\florence\c$\snapshots\snapshot.0`. You archive the `c:\dir1\sub1` directory tree from the local snapshot and manage it on the IBM Spectrum Protect server under the file space name `C:\`.	`dsmc archive c:\dir1\sub1\* -subdir=yes -snapshotroot=\\florence\c$\snapshots\snapshot.0`	For more information, see Snapshotroot.

- Windows Associate a local snapshot with a server file space (Windows)
  You can associate the data on the local snapshot with the real file space data that is stored on the IBM Spectrum Protect server.

Archive
Windows

Archiving data with client node proxy

Archives of multiple nodes that share storage can be consolidated to a common target node name on the IBM Spectrum Protect™ server.

About this task

This is useful when the workstation responsible for performing the archive can change over time, such as with a cluster. The asnodename option also allows data to be restored from a different system than the one that performed the backup. Use the asnodename option with the appropriate command to back up, archive, restore, and retrieve data under the target node name on the IBM Spectrum Protect server.

Tivoli® Storage Manager FastBack clients are also backed up using client node proxy.

To enable this option, follow these steps:

1. Install the backup-archive client on all nodes in a shared data environment.
2. Register each node with the IBM Spectrum Protect server, if it does not exist. Register the common target node name to be shared by each of the agent nodes used in your shared data environment.
3. Register each of the nodes in the shared data environment with the IBM Spectrum Protect server. This is the agent node name that is used for authentication purposes. Data is not stored using the node name when the asnodename option is used.
4. The IBM Spectrum Protect administrator must grant proxy authority to all nodes in the shared environment to access the target node name on the IBM Spectrum Protect server, using the GRANT PROXYNODE server command.
5. Use the QUERY PROXYNODE administrative client command to display the client nodes of the authorized user, granted by the GRANT PROXYNODE command.

Follow these steps to set up encryption with the encryptkey=save option:

Procedure

1. Specify encryptkey=save in the options file.
2. Back up at least one file with asnode=ProxyNodeName to create a local encryption key on each agent node in the multiple node environment.

Results

Follow these steps to set up encryption with the encryptkey=prompt option:

1. Specify encryptkey=prompt in the options file.
2. Ensure that users of the agent nodes in the multiple node environment are using the same encryption key.

- If you change the encryption key, you must repeat the previous steps.

- Use the same encryption key for all files backed up in the shared node environment.

Follow these steps to enable multinode operation from the GUI:

1. Verify that the client node has proxy authority to a target node (or authorized to act as the target node) using the QUERY PROXYNODE administrative client command.
2. Select Edit > Preferences to open the preferences window.
3. Select the General tab and fill in the As Node Name field with the name of the proxy authorized target node.
4. Click Apply and then OK to close the preferences window.

Follow these steps to verify that your client node is now accessing the server as the target node:

1. Open the tree window and check that the target node name specified by the As Node Name field appears, or
2. Verify the target node name in the Accessing As Node field in the Connection Information window.

To return to single node operation, delete the As Node Name from the Accessing As Node field in the General > Preferences tab.

Considerations for a proxied session:

- A proxy operation uses the settings for the target node (such as maxnummp and deduplication) and schedules that are defined on the IBM Spectrum Protect server. The IBM Spectrum Protect server node settings and schedules for the agent node are ignored.
- All agent nodes in the multiple node environment must be of the same platform type.
- Do not use target nodes as traditional nodes. Use them only for multiple node processing.
- You cannot perform a system object or system state backup or restore.
- You cannot access another node (either from GUI drop down or use of the fromnode option).
- You cannot use the clusternode option.
- You cannot perform NAS backup or restore.

Asnodename
Session settings and schedules for a proxy operation
Windows

Deleting archive data

You can delete individual archive objects from the IBM Spectrum Protect™ server, without having to delete the entire file space to which they belong.

Before you begin

Your IBM Spectrum Protect administrator must grant you the authority to delete archived objects. To determine whether you have this authority, select File > Connection Information from the backup-archive client GUI or from the main menu in the web client. Your archive delete authority status is listed in the `Delete Archive Files` field. If this field shows `No`, you cannot delete archived objects unless your administrator grants you the authority to delete them.

Procedure

To delete an archived object from the server, perform the following steps in the web client or GUI. As an alternative to using the web client or GUI, you can also delete archived objects from the command line by using the delete archive command.

1. Select Delete Archive Data from the Utilities menu.
2. In the Archive Delete window, expand the directory tree by clicking the plus sign (+) or folder icon next to the object you want to expand. Objects on the tree are grouped by archive package description.
3. Select the archived objects that you want to delete.
4. Click Delete. The client prompts you for confirmation before it starts to delete the selected objects. The Archive Delete Task List window shows the progress of the delete operation.

Delete Archive
Windows

Retrieve archives

Select the Retrieve function to recover an archive copy of a file or a directory.

Note: When you retrieve a directory, its modification date and time is set to the date and time of the retrieve, not to the date and time the directory had when it was archived. This is because a retrieve operation retrieves the directories first, and then adds the files to the directories.

You can also retrieve archive copies from the directory tree, filter the directory tree, and retrieve archive copies of files owned by someone else. To do any of these, click the Retrieve button on the main window of the backup-archive client GUI and follow the directions provided in the task help of the GUI.

Important: When you retrieve a file without any specifications, and more than one version of the archive copy exists on the server, all of the copies are retrieved. After the first copy is retrieved, the second copy is retrieved. If there is an existing copy on your client workstation, you are prompted to replace, skip, or cancel.

- Windows Retrieving archives with the GUI
  You can retrieve your archived files with the backup-archive client GUI.
- Windows Retrieve archive copies by using the command line
  You retrieve a file when you want to return an archive copy from the server to your workstation. Some examples of how to retrieve archived files by using the command line are shown.

Related concepts:
Duplicate file names
Windows

Retrieving archives with the GUI

You can retrieve your archived files with the backup-archive client GUI.

Procedure

1. Click Retrieve on the GUI main window. The Retrieve window displays.
2. Expand the directory tree by clicking the plus sign (+) or the folder icon next to an object you want to expand. To search or filter files, click the Search icon from the toolbar.
3. Enter your search criteria in the Find Files window.
4. Click Search. The Matching Files window displays.
5. Click the selection boxes of the files that you want to retrieve and close the Matching Files window.
6. Enter your filter criteria in the Find Files window.
7. Click Filter. The Retrieve window displays the filtered files.
8. Click the selection boxes of the filtered files or directories that you want to retrieve.
9. To modify specific retrieve options, click Options. Any options that you change are effective during the current session only.
10. Click Retrieve. The Retrieve Destination window displays. You can retrieve files to a directory or drive other than the one from where they were originally archived. You can also select how much of the parent directory structure is re-created at the retrieve location.
11. Click Retrieve. The Retrieve Status window displays the processing status.

Windows

Retrieve archive copies by using the command line

You retrieve a file when you want to return an archive copy from the server to your workstation. Some examples of how to retrieve archived files by using the command line are shown.

You can retrieve a single file, a group of files, or all the files in a directory or subdirectory. When you retrieve a file, the IBM Spectrum Protect™ server sends you a copy of that file. The archived file remains in storage.

Use the retrieve command to retrieve files. The following table shows examples of using the retrieve command.

Table 1. Command line examples of retrieving archives

Task	Command	Considerations
Retrieve the c:\doc\h2.doc file to its original directory.	`dsmc retrieve c:\doc\h2.doc`	If you do not specify a destination, the files are retrieved to their original location.

Task	Command	Considerations
Retrieve the c:\doc\h2.doc file under a new name and directory.	`dsmc retrieve c:\doc\h2.doc c:\proj2\h3.doc`	None
Retrieve all files that are archived with a specific description to a directory named retr1 at a new location	`dsmc retrieve c:\* d:\retr1\ -sub=yes -desc="My first archive"`	None
Retrieve all files from the c:\projecta directory that end with the characters .bak to the c:\projectn directory.	`dsmc retrieve c:\projecta\*.bak c:\projectn`	None
Use the pick option display a list of archives from which you can select files to retrieve.	`dsmc retrieve c:\project\* -pick`	For more information about the pick option, see Pick.
Retrieve a file that is originally archived from the diskette that is labeled *workathome* on the a: drive, to a diskette in the a: drive labeled *extra*.	`dsmc retrieve {workathome}\doc\h2.doc a:\doc\h2.doc`	If you are retrieving a file to a disk that has a different label other than the disk from which the file was archived, use the file space name (label) of the archive disk rather than the drive letter.
Retrieve the c:\doc\h2.doc file to its original directory on the workstation, named *star*.	`dsmc retrieve c:\doc\h2.doc \\star\c$\` To retrieve the file to *star*, which was renamed *meteor*, enter: `dsmc retrieve \\star\c$\ doc\h2.doc \\meteor\c$\` You can also enter: `dsmc retrieve \\star\c$\ doc\h2.doc c:\` This example is valid because if the workstation name is not included in the specification, the local workstation is assumed (*meteor*, in this case).	For the purposes of this manual, the workstation name is part of the file name. Therefore, if you archive files on one workstation and you want to retrieve them to another workstation, you must specify a destination. This requirement is true even if you are retrieving to the same physical workstation, but the workstation has a new name.

Archive and retrieve your data (UNIX and Linux)

You can archive infrequently used files to the IBM Spectrum Protect™ server and retrieve them when necessary. Archiving and retrieving files is similar to backing up and restoring files. Many of the windows and concepts are similar.

All the primary archive and retrieve procedures in this topic also apply to the web client, except for the Preferences editor procedures.

You can complete the following primary archive and retrieve tasks:

- Archiving data with the GUI
- Archive data examples by using the command line
- Deleting archive data
- Retrieving data with the GUI
- Retrieve data examples by using the command line

- Mac OS X | AIX | Linux | Solaris Archive files
  To archive files, you must specifically select the files to archive. You can select the files by using a file specification or by selecting them from a directory tree.
- Mac OS X | AIX | Linux | Solaris Retrieve archives
  Retrieve a file when you want to return an archive copy from the server to your workstation.

Related concepts:

Archive files

To archive files, you must specifically select the files to archive. You can select the files by using a file specification or by selecting them from a directory tree.

Your administrator might set up schedules to archive certain files on your workstation automatically. The following sections cover how to archive files without using a schedule.

- Mac OS X | AIX | Linux | Solaris Archiving data with the GUI
  You can archive a file or a group of files by using file names. You can select files that match your search criteria by using a directory tree.
- Mac OS X | AIX | Linux | Solaris Archive data examples by using the command line
  You request archive services when you want to preserve copies of files in their current state, either for later use or for historical or legal purposes. Examples of archiving data by using the command line are shown.
- Mac OS X | AIX | Linux | Solaris Archiving data with client node proxy
  Archives of multiple nodes that share storage can be consolidated to a common target node name on the IBM Spectrum Protect server.
- Mac OS X | AIX | Linux | Solaris Deleting archive data
  You can delete individual archive objects from the IBM Spectrum Protect server, without having to delete the entire file space to which they belong.
- Mac OS X | AIX | Linux | Solaris Advanced archive tasks
  Access permissions, symbolic links, and hard links are advanced functions to consider when you archive data.

Mac OS X | AIX | Linux | Solaris

Archiving data with the GUI

You can archive a file or a group of files by using file names. You can select files that match your search criteria by using a directory tree.

Procedure

Archive files with the following procedure.

1. Click Archive from the main window.
2. In the Archive window, expand the directory tree by clicking the plus sign (+) or the folder icon next to an object in the tree. To search or filter files, click the Search icon from the toolbar.
3. Enter your search criteria in the Find Files window.
4. Click Search.
5. In the Matching Files window, click the selection boxes next to the files you want to archive and close the Matching Files window.
6. Enter your filter criteria in the Find Files window.

7. Click Filter. The Archive window displays the filtered files.
8. Click the selection boxes next to the filtered files or directories that you want to archive.
9. Enter the description, accept the default description, or select an existing description for your archive package in the Description box. The maximum length of a description is 254 characters. When an existing archive description is used, the files or directories that are selected are added to the archive package. All archived packages with the same description are grouped for retrieves, queries, and deletions.
10. To modify specific archive options, click Options. Any options that you change are effective during the current session only.
11. Click Archive. The archive Task List window displays the archive processing status.

Mac OS X | AIX | Linux | Solaris

Archive data examples by using the command line

You request archive services when you want to preserve copies of files in their current state, either for later use or for historical or legal purposes. Examples of archiving data by using the command line are shown.

You can archive a single file, a group of files, or all the files in a directory or subdirectory. After you archive a file, you can choose to delete the original file from your workstation.

The following table shows examples of using the archive command to archive objects.

Table 1. Command line archive examples

Task	Command	Considerations
Archive all files in the `/home/proj1` directory with a file extension of `.txt`.	`dsmc archive "/home/proj1/*.txt"`	Use wildcards to archive more than one file at a time.
Archive all files in the `/home/jones/proj/` directory and delete the files on your workstation.	`dsmc archive /home/jones/proj/ -deletefiles`	Retrieve the archived files to your workstation whenever you need them again. For more information about the deletefiles option, see Deletefiles.
Archive the `/home/jones/h1.doc` and `/home/jones/test.doc` files.	`dsmc archive /home/jones/h1.doc /home/jones/test.doc`	If you specify the removeoperandlimit option with the archive command, the 20-operand limit is not enforced and is restricted only by available resources or other operating system limits. With this option, you can specify more than 20 files on a single command. For more information about this option, see Removeoperandlimit.
Archive a list of files in the `/home/avi/filelist.txt` file.	`dsmc archive -filelist=/home/avi/filelist.txt`	Use the filelist option to process a list of files. For more information, see Filelist.
Archive the `/home/jones/ch1.doc` file and assign a description to the archive.	`dsmc archive /home/jones/ch1.doc -description="Chapter 1, first version"`	If you do not specify a description with the archive command, the default is `Archive Date:x`, where `x` is the current system date. For more information about the description option, see Description.
Archive all of the files in the `/home/jones/proj/` directory and its subdirectories.	`dsmc archive /home/jones/proj/ -subdir=yes`	For more information about the subdir option, see Subdir.
Use the v2archive option with the archive command to archive only files in the `/home/relx/dir1` directory, but not the `relx` or `dir1` directories.	`dsmc archive "/home/relx/dir1/" -v2archive`	The backup-archive client archives only files in the `/home/relx/dir1` directory. Directories that exist in the path are not processed. For more information about the v2archive option, see V2archive.
Use the archmc option with the archive command to specify the available management class for your policy domain to which you want to bind your archived files.	`dsmc archive -archmc=ret2yrs /home/plan/proj1/budget.jan`	For more information about the archmc option, see Archmc. For more information about management classes, see Storage management policies.

Task	Command	Considerations
Assume that you initiated a snapshot of the `/usr` file system and mounted the snapshot as `/snapshot/day1`. You archive the `/usr/dir1/sub1` directory tree from the local snapshot and manage it on the IBM Spectrum Protect™ server under the file space name `/usr`.	`dsmc archive /usr/dir1/sub1/ -subdir=yes -snapshotroot=/snapshot/day1`	The client considers the snapshotroot value as a file space name. For more information, see Snapshotroot.

- Mac OS X | AIX | Linux | Solaris Associate a local snapshot with a server file space
  To associate data on the local snapshot with the real file space data that is stored on the IBM Spectrum Protect server, use the snapshotroot option.

Archiving data with client node proxy

Archives of multiple nodes that share storage can be consolidated to a common target node name on the IBM Spectrum Protect™ server.

Before you begin

All agent nodes in the multiple node environment should be of the same platform type. Do not use target nodes as traditional nodes. Use them only for multiple node processing.

Consider the following features of a proxied session:

- A proxy operation uses the settings for the target node (such as maxnummp and deduplication) and schedules that are defined on the IBM Spectrum Protect server. The IBM Spectrum Protect server node settings and schedules for the agent node are ignored.
- You cannot perform a system state or system services backup or restore.
- You cannot access another node (either from the GUI drop down or use of the fromnode option).
- You cannot perform a NAS backup or restore.

About this task

Consolidating archived files to a common target node name on the server is useful when the workstation responsible for performing the archive can change over time, such as with a Xsan or cluster. The asnodename option also allows data to be restored from a different system than the one which performed the backup. Use the asnodename option with the appropriate command to back up, archive, restore, and retrieve data under the target node name on the IBM Spectrum Protect server. This support is only available with IBM Spectrum Protect V5.3 and higher.

Linux Tivoli® Storage Manager FastBack clients are also backed up using client node proxy.

Configuring your environment for proxied operations is a multiple step procedure that involves setting options and commands on the backup-archive client and on the server.

Procedure

Perform steps 1 through 5 to install the client and grant proxy authority to the nodes that can perform archive procedures on behalf of another node.

1. Install the backup-archive client on all nodes in a shared data environment.
2. Register each node with the IBM Spectrum Protect server, if it does not exist. Register the common target node name to be shared by each of the agent nodes used in your shared data environment.
3. Register each of the nodes in the shared data environment with the IBM Spectrum Protect server. This is the agent node name that is used for authentication purposes. Data is not stored using the node name when the asnodename option is used.
4. Grant proxy authority to all nodes in the shared environment to access the target node name on the IBM Spectrum Protect server, using the GRANT PROXYNODE command (IBM Spectrum Protect administrator).

5. Use the QUERY PROXYNODE administrative client command to display the client nodes of the authorized user, granted by the GRANT PROXYNODE command.

Step 6 sets ensures that archived files are encrypted on the server.

6. Set the encryptkey option in the options file.

   Specify encryptkey=save in the options file to save the encryption key in the IBM Spectrum Protect password file. Back up at least one file with asnode=ProxyNodeName to create a local encryption key on each agent node in the multiple node environment.

   Specify encryptkey=prompt in the options file if you want the node users to manage the encryption key. Ensure that users of the agent nodes in the multiple node environment are using the same encryption key.

   Repeat this step if you change the encryption key. Use the same encryption key for all files that are backed up, in the shared environment.

Perform steps 7 to step 10 to enable multinode operation, from the GUI.

7. Verify that the client node has proxy authority to a target node (or authorized to act as the target node) using the QUERY PROXYNODE administrative client command.
8. Select Edit > Preferences to open the preferences window.
9. Select the General tab and fill in the As Node Name field with the name of the proxy authorized target node.
10. Click Apply and then OK to close the preferences window.

Perform step 11 to verify that your client node is now accessing the server as the target node.

11. Open the tree window and verify that the target node name specified by the As Node Name field is displayed. Alternatively, you can verify that the target node name shows in the Accessing As Node field in the Connection Information window.
12. Optional: To return to single node operation, delete the As Node Name from the Accessing As Node field in the General > Preferences tab.

Deleting archive data

You can delete individual archive objects from the IBM Spectrum Protect™ server, without having to delete the entire file space to which they belong.

Before you begin

Your IBM Spectrum Protect administrator must grant you the authority to delete archived objects. To determine whether you have this authority, select File > Connection Information from the backup-archive client GUI or from the main menu in the web client. Your archive delete authority status is listed in the `Delete Archive Files` field. If this field shows `No`, you cannot delete archived objects unless your administrator grants you the authority to delete them.

Procedure

To delete an archived object from the server, perform the following steps in the web client or GUI. As an alternative to using the web client or GUI, you can also delete archived objects from the command line by using the delete archive command.

1. Select Delete Archive Data from the Utilities menu.
2. In the Archive Delete window, expand the directory tree by clicking the plus sign (+) or folder icon next to the object you want to expand. Objects on the tree are grouped by archive package description.
3. Select the archived objects that you want to delete.
4. Click Delete. The client prompts you for confirmation before it starts to delete the selected objects. The Archive Delete Task List window shows the progress of the delete operation.

Mac OS X | AIX | Linux | Solaris

Advanced archive tasks

Access permissions, symbolic links, and hard links are advanced functions to consider when you archive data.

- Mac OS X | AIX | Linux | Solaris Access permissions
  When you archive a file, the client saves standard UNIX access permissions that are assigned to the file.
- Mac OS X | AIX | Linux | Solaris Archive and retrieve symbolic links
  The backup-archive client archives and retrieves symbolic links differently than it does regular files and directories.
- Mac OS X | AIX | Linux | Solaris Hard links
  When you archive files that are hard-linked, the backup-archive client archives each instance of the linked file.

Mac OS X | AIX | Linux | Solaris

Access permissions

When you archive a file, the client saves standard UNIX access permissions that are assigned to the file.

Depending on your operating system, it also saves extended permissions. For example, for files on an AIX® workstation, the client saves access control lists.

If you are a user, and you archive a file to which you have read access, you own the archived copy of the file. You are the only user who can retrieve the archived file unless you grant access to another user.

Mac OS X | AIX | Linux | Solaris

Archive and retrieve symbolic links

The backup-archive client archives and retrieves symbolic links differently than it does regular files and directories.

The way that the client archives and retrieves symbolic links depends on options settings, whether the target directory is accessible, and the way you specify objects.

A *UNIX symbolic link* is a file that contains a pointer to another file or directory. The object the symbolic link points to is called the *target object*.

A symbolic link can be backed up as path information to a target directory, or it can be backed up as a directory. If the symbolic link is backed up as a directory, the files and folders in the target directory can also be backed up.

What you restore depends on how the symbolic link was backed up, the scope of the restore, the setting of the followsymbolic option, and whether the target directory is accessible at the time of restore.

For more information on how symbolic links are handled during archive, see the archsymlinkasfile option.

Note: Symbolic link processing as described here does not apply to Mac OS X. Symbolic links are always archived as files and are never followed.

The following table shows symbolic link archive and retrieve functions and the action taken:

Table 1. Symbolic link management table for archive and retrieve

Function	Action taken
Archive of a file link.	Archives the file to which the symbolic link points.
Archive of a directory link.	Archives the directory and its contents.
Archive of a file with subdir=yes.	Archives the file, directory path and all like-named files in the subtree.
Archive of a directory with subdir=yes.	Archives the directory, its contents, and contents of subdirectories.
Archive of a symbolic link that points to a file or directory that does not exist.	Archives the symbolic link.
Retrieve a symbolic link that points to file; the file and link exist.	Replaces the file if replace=y is set.

Function	Action taken
Retrieve a symbolic link that points to file; the symbolic link no longer exists.	Retrieves the file replacing the file name with the symbolic link name and places it in the directory where the symbolic link resided.
Retrieve a symbolic link that points to a directory; the symbolic link and directory no longer exist.	A directory is created in the directory where the symbolic link resides, and all files and subdirectories are restored to that directory. The symbolic link name is used as the new directory name.
Retrieve a symbolic link that points to a directory; the symbolic link and directory still exist.	The directory is not retrieved as long as the symbolic link exists.

Related reference:
AIX Linux Solaris Archsymlinkasfile
Mac OS X AIX Linux Solaris

Hard links

When you archive files that are hard-linked, the backup-archive client archives each instance of the linked file.

For example, if you archive two files that are hard-linked, the client archives the file data twice.

When you retrieve hard-linked files, the client reestablishes the links. For example, if you had a hard-linked pair of files, and only one of the hard-linked files is on your workstation, when you retrieve both files, they are hard-linked. The only exception to this procedure occurs if you archive two files that are hard-linked and then break the connection between them on your workstation. If you retrieve the two files from the server, the client respects the current file system and does not retrieve the hard link.

Tip: If you do not archive and retrieve all files that are hard-linked at the same time, problems can occur. To ensure that hard-linked files remain synchronized, archive all hard links at the same time and retrieve those same files together.
Mac OS X AIX Linux Solaris

Retrieve archives

Retrieve a file when you want to return an archive copy from the server to your workstation.

Many of the advanced considerations for retrieving files are the same as for restoring files.

Important: When you retrieve a file without any specifications, and more than one version of the archive copy exists on the server, the client retrieves all of the copies. After the first copy is retrieved, the second copy is retrieved. If there is an existing copy on your client workstation, you are prompted to replace, skip, or cancel.

- Mac OS X AIX Linux Solaris Retrieving data with the GUI
  You can retrieve an archived file with the GUI.
- Mac OS X AIX Linux Solaris Retrieve data examples by using the command line
  You can retrieve a single file, a group of files, or all the files in a directory or subdirectory.
- Mac OS X AIX Linux Solaris Archive management classes
  The backup-archive client checks the include options in your include-exclude options list to determine which management class to assign to your archived files.

Retrieving data with the GUI

You can retrieve an archived file with the GUI.

Procedure

1. Click Retrieve from the client Java™ GUI main window. The Retrieve window displays.
2. Expand the directory tree by clicking the plus sign (+) or the folder icon next to an object that you want to expand. To search or filter files, click the Search icon from the toolbar.
3. Enter your search criteria in the Find Files window.
4. Click Search. The Matching Files window displays.
5. Click the selection boxes next to the files that you want to retrieve and close the Matching Files window.
6. Enter your filter criteria in the Find Files window.
7. Click Filter. The Retrieve window displays the filtered files.
8. Click the selection boxes of the filtered files or directories that you want to retrieve.
9. To modify specific retrieve options, click Options. Any options that you change are effective during the current session only.
10. Click Retrieve. The Retrieve Destination window displays. Enter the appropriate information in the Retrieve Destination window.
11. Click Retrieve. The Task List window displays the retrieve processing status.

Mac OS X | AIX | Linux | Solaris

Retrieve data examples by using the command line

You can retrieve a single file, a group of files, or all the files in a directory or subdirectory.

When you retrieve a file, a copy of that file is sent from the IBM Spectrum Protect™ server. The archived file remains in storage.

Use the retrieve command to retrieve files from storage to your workstation. The following table shows examples of using the retrieve command.

Table 1. Command line examples of retrieving archives

Task	Command	Considerations
Retrieve the `/home/jones/h1.doc` file to its original directory.	`dsmc retrieve /home/jones/h1.doc`	If you do not specify a destination, the files are retrieved to their original location.
Retrieve the `/home/jones/h1.doc` file with a new name and directory.	`dsmc retrieve /home/jones/h1.doc /home/smith/h2.doc`	None.
Retrieve all files from the `/home/jones` directory that end with the characters `.bak` to the `/home/smith` directory.	`dsmc retrieve "/home/jones/*.bak" /home/smith/`	None.
Retrieve the `/home/jones/ch1.doc` file and assign a description.	`dsmc retrieve /home/jones/ch1.doc -description="Chapter 1, first version"`	If you do not specify a description with the retrieve command, the default is `Retrieve Date:x`, where `x` is the current system date.
Use the pick option to display a list of archives from which you can select files to retrieve.	`dsmc retrieve "/home/jones/*" -pick`	None.
Retrieve a list of files that are specified in the retrievelist.txt file to their original directory.	`dsmc retrieve -filelist=/home/dir2/retrievelist.txt`	None.

Pick

Mac OS X | AIX | Linux | Solaris

Archive management classes

The backup-archive client checks the include options in your include-exclude options list to determine which management class to assign to your archived files.

If you do not assign a management class to a file with the include option, the client assigns the default management class to the file. The client can archive only a file if the selected management class contains an archive copy group.

You can override the default management class by using the archmc option, or by clicking Options in the Archive window in the GUI, clicking Override include/exclude list, and then selecting the management class.

You can also add include-exclude statements in the backup-archive client Java™ GUI or web client directory tree. Then, you can use the Utilities Preview Include-Exclude function to preview the include-exclude list before you send data to the server.

Schedule operations for backup-archive clients

You can schedule backup operations that protect client data to ensure that the operations run on a regular basis.

About this task

The client scheduler is available to interact with the IBM Spectrum Protect™ server's central scheduler to automatically back up your data.

- IBM Spectrum Protect scheduler overview
  The IBM Spectrum Protect central scheduler allows client operations to occur automatically at specified times.
- Client return codes
  The backup-archive command-line interface and the scheduler exit with return codes that accurately reflect the success or failure of the client operation.

IBM Spectrum Protect scheduler overview

The IBM Spectrum Protect™ central scheduler allows client operations to occur automatically at specified times.

To understand scheduling with IBM Spectrum Protect, several terms need to be defined:

schedule definition
: A schedule definition on the IBM Spectrum Protect server specifies critical properties of an automated activity, including the type of action, the time the action should take place, and how frequently the action takes place. Numerous other properties can be set for a schedule. For information about the DEFINE SCHEDULE, see the IBM Spectrum Protect server documentation.

schedule association
: A schedule association is an assignment to a specific schedule definition for a client node. Multiple schedule associations allow single schedule definitions to be used by many client nodes. Because schedule definitions are included with specific policy domains, it is only possible for nodes that are defined to a certain policy domain to be associated with schedules defined in that domain.

scheduled event
: A scheduled event is a specific occurrence of when a schedule is run for a node. The following conditions must be met before automatic scheduled events take place for a client:

  - A schedule definition must exist for a specific policy domain.
  - A schedule association must exist for the required node, which belongs to that policy domain.
  - The client scheduler process must be running on the client system.

AIX Linux Mac OS X Solaris When creating a schedule definition on the IBM Spectrum Protect server, schedule actions that you can take include incremental, selective, archive, restore, retrieve, image backup (does not apply to Mac OS X), image restore (does not apply to Mac OS X), command, and macro. The scheduled action that is most frequently used is incremental with the objects parameter left undefined. With this setting, the backup-archive client performs a domain incremental backup of all file systems defined by the client domain option. A schedule definition using the command action allows an operating system command or shell script to be executed. When automating tasks for IBM Spectrum Protect for Data Protection clients, you must use command action schedule definitions, which invoke the command-line utilities for those applications.

Windows When creating a schedule definition on the IBM Spectrum Protect server, schedule actions that you can take include incremental, selective, archive, restore, retrieve, imagebackup, imagerestore, command, and macro. The scheduled action that is

most frequently used is incremental with the objects parameter left undefined. With this setting, the IBM Spectrum Protect client performs a domain incremental backup of all drives defined by the client domain option. A schedule definition using the command action allows an operating system command or shell script to be executed. When automating tasks for IBM Spectrum Protect for Data Protection clients, you must use command action schedule definitions, which invoke the command-line utilities for those applications.

The schedule *startup window* indicates the acceptable time period for a scheduled event to start. The startup window is defined by these schedule definition parameters: startdate, starttime, durunits, and duration. The startdate and starttime options define the beginning of the startup window for the very first scheduled event. The beginning of the startup windows for subsequent scheduled events vary depending on the period and perunit values of the schedule definition. The duration and durunits parameters define the length of the startup window. The schedule action is required to start within the startup window. To illustrate, consider the results of the following schedule definition:

```
define schedule standard test1 action=incremental starttime=12:00:00 period=1
perunits=hour dur=30 duru=minutes
```

Event	Window start	Window end	Actual start (just an example, times vary)
1	12:00:00	12:30:00	12:05:33
2	13:00:00	13:30:00	13:15:02
3	14:00:00	14:30:00	14:02:00
and so on			

The variation in actual start times is a result of the randomization feature provided by the IBM Spectrum Protect central scheduler which helps to balance the load of scheduled sessions on the IBM Spectrum Protect server.

- Examples: Blank spaces in file names in schedule definitions
  When you define or update a schedule objects parameter or the schedule options parameter with file specifications that contain blank spaces, put quotation marks (") around each file specification that contains blanks, then add single quotes (') around the entire specification.
- Preferential start times for certain nodes
  Occasionally, you might want to ensure that a particular node begins its scheduled activity as close as possible to the defined start time of the schedule. The need for this typically arises when prompted mode scheduling is in use.
- Scheduler processing options
  Scheduler processing options determine what operations are performed when a scheduler job is started.
- Client-acceptor scheduler services versus the traditional scheduler services
  You can configure the IBM Spectrum Protect client to manage the scheduler process using the IBM Spectrum Protect client acceptor daemon.
- Setting the client scheduler process to run as a background task and start automatically at startup
  You can configure the IBM Spectrum Protect client scheduler to run as a background system task that starts automatically when your system is started.
- Examples: Display information about scheduled work
  Schedules can be classic or enhanced, depending on how the interval to the next execution is defined.
- Display information about completed work
  When you run the schedule command in the foreground, your screen displays output from the scheduled commands.
- Specify scheduling options
  You can modify scheduling options in the client options file or the graphical user interface (GUI).
- AIX Linux Solaris Mac OS X Scheduler options for commands
  The scheduler executes commands under a user ID of `0` (root); however, some commands might need to be executed under a user ID other than `0`.
- Enable or disable scheduled commands
  You can use the schedcmddisabled option to disable the scheduling of commands by the server.
- Windows Change processing options used by the scheduler service
  When you configure the IBM Spectrum Protect central-scheduling services (the scheduler, the client acceptor, or the remote client agent), some of the processing options that you specify are defined in the Windows registry.
- Manage multiple schedule requirements on one system
  In certain situations it is preferable to have more than one scheduled activity for each client system.

Examples: Blank spaces in file names in schedule definitions

When you define or update a schedule objects parameter or the schedule options parameter with file specifications that contain blank spaces, put quotation marks (") around each file specification that contains blanks, then add single quotes (') around the entire specification.

AIX Linux Mac OS X Solaris The following examples show how to delimit schedule object parameters when file specifications contain space characters:

```
objects='"/home/proj1/Some file.doc"'
objects='"/home/proj1/Some file.doc" "/home/Another file.txt" /home/noblanks.txt'
objects='"/home/My Directory With Blank Spaces/"'
objects='"/Users/user1/Documents/Some file.doc"'
objects='"/Users/user1/Documents/Some file.doc"
 "/Users/user5/Documents/Another file.txt" /Users/user3/Documents/noblanks.txt'
objects='"/Users/user1/My Directory With Blank Spaces/"'
```

This syntax ensures that a file specification containing a space, such as /home/proj1/Some file.doc, is treated as a single file name, and not as two separate files (/home/proj1/Some, and file.doc).

AIX Linux Mac OS X Solaris The following examples show how to delimit schedule options parameters when file specifications contain space characters:

```
options='-preschedulecmd="/home/me/my files/bin/myscript"
 -postschedulecmd="/home/me/my files/bin/mypostscript" -quiet'
options='-presched="/home/me/my files/bin/precmd" -postsched=finish'
```

Windows The following examples show how to delimit schedule object parameters when file specifications contain space characters:

```
objects='"c:\home\proj1\Some file.doc"'
objects='"c:\home\proj1\Some file.doc" "c:\home\Another file.txt"
 c:\home\noblanks.txt'
objects='"c:\home\My Directory With Blank Spaces\"'
objects='"c:\Users\user1\Documents\Some file.doc"'
objects='"c:\Users\user1\Documents\Some file.doc"
 "c:\Users\user5\Documents\ Another file.txt" c:\Users\user3\Documents\noblanks.txt'
objects='"c:\Users\user1\My Directory With Blank Spaces\"'
```

This syntax ensures that a file specification containing a space, such as c:\home\proj1\Some file.doc, is treated as a single file name, and not as two separate files (c:\home\proj1\Some, and file.doc)

Windows The following examples show how to delimit schedule options parameters when file specifications contain space characters:

```
options='-preschedulecmd="c:\home\me\my files\bin\myscript"
  -postschedulecmd="c:\home\me\my files\bin\mypostscript" -quiet'
options='-presched="c:\home\me\my files\bin\precmd" -postsched=finish'
```

You can also refer to the objects and options parameter information for the DEFINE SCHEDULE and UPDATE SCHEDULE commands. For descriptions of these commands and parameters, see the IBM Spectrum Protect™ server documentation..

Related concepts:
Specifying input strings that contain blank spaces or quotation marks

Preferential start times for certain nodes

Occasionally, you might want to ensure that a particular node begins its scheduled activity as close as possible to the defined start time of the schedule. The need for this typically arises when prompted mode scheduling is in use.

Depending on the number of client nodes associated with the schedule and where the node is in the prompting sequence, the node might be prompted significantly later than the start time for the schedule.

In this case, you can perform the following steps:

1. Copy the schedule to a new schedule with a different name (or define a new schedule with the preferred attributes).
2. Set the new schedule priority attribute so that it has a higher priority than the original schedule.
3. Delete the association for the node from the original schedule, then associate the node to the new schedule.

Now the IBM Spectrum Protect™ server processes the new schedule first.

Scheduler processing options

Scheduler processing options determine what operations are performed when a scheduler job is started.

You can define most of these scheduler processing options in the client options file. However, some of these options can be set on the IBM Spectrum Protect™ server, so they affect all clients.

The following table shows which options are defined by the client and server, and which options are overridden by the server. An *X* in a column indicates where the option can be specified.

Option	Client defined	Server defined	Server global override
managedservices	X		
maxcmdretries	X		SET MAXCMDRETRIES command
maxschedsessions		X	
postschedulecmd, postnschedulecmd	X		
preschedulecmd, prenschedulecmd	X		
queryschedperiod	X		SET QUERYSCHEDPERIOD command
randomize		X	
retryperiod	X		SET RETRYPERIOD command
schedcmddisabled	X		
schedlogname	X		
schedlogretention	X		
schedmode	X		SET SCHEDMODES command
sessioninitiation	X	X	UPDATE NODE command
tcpclientaddress	X	X (also defined on server when `sessioninit=serveronly` as part of the node definition)	
tcpclientport	X	X (also defined on server when `sessioninit=serveronly` as part of the node definition)	

Windows Client defined options are defined in the dsm.opt file. The IBM Spectrum Protect server can also define some options in a client options set, or as part of the options parameter of the schedule definition. The IBM Spectrum Protect server can also set some options globally for all clients. By default, the client setting for these options is honored. If the global override on the IBM Spectrum Protect server is set, the client setting for the option is ignored. Defining client options as part of the schedule definition is useful if you want to use specific options for a scheduled action that differ from the option settings normally used by the client node, or are different for each schedule the node executes.

AIX Linux Solaris Mac OS X Client defined options are defined in the dsm.sys or dsm.opt file, depending on the option and platform. The IBM Spectrum Protect server can also define some options in a client options set, or as part of the options parameter of the schedule definition. The IBM Spectrum Protect server can also set some options globally for all clients. By default, the client setting for these options is honored. If the global override on the IBM Spectrum Protect server is set, the client setting for the option is ignored. Defining client options as part of the schedule definition is useful if you want to use specific options for a scheduled action that differ from the option settings normally used by the client node, or are different for each schedule the node executes.

The schedmode option controls the communication interaction between the IBM Spectrum Protect client and server. There are two variations on the schedule mode: *client polling* and *server prompted*. These variations are explained in the IBM Spectrum

Protect server documentation.

- Evaluate schedule return codes in schedule scripts
  You can use environment variables to determine the current IBM Spectrum Protect return code before you run a script by using either the preschedulecmd or postschedulecmd client options.
- Return codes from preschedulecmd and postschedulecmd scripts
  The return codes that you might see when you use the preschedulecmd and postschedulecmd options are described.

Evaluate schedule return codes in schedule scripts

You can use environment variables to determine the current IBM Spectrum Protect™ return code before you run a script by using either the preschedulecmd or postschedulecmd client options.

AIX | Linux | Solaris | Mac OS X | Windows IBM Spectrum Protect provides the current value of the return code in the environment variable called *TSM_PRE_CMD_RC*. The *TSM_PRE_CMD_RC* variable is the current value of the IBM Spectrum Protect return code before you run a schedule script. The value of the *TSM_PRE_CMD_RC* variable is not necessarily the same as the return code issued by IBM Spectrum Protect following the execution of the schedule script. The *TSM_PRE_CMD_RC* variable can be used in schedule scripts to determine the current state of the schedule.

The *TSM_PRE_CMD_RC* variable is set on each of the following schedule options: preschedule, prenschedule, postschedule, and postnschedule. *TSM_PRE_CMD_RC* affects those schedules that have the ACTION=COMMAND option specified.

An example of the *TSM_PRE_CMD_RC* variable in use:

AIX | Linux | Solaris | Mac OS X | Windows

```
if [[ -n  ${TSM_PRE_CMD_RC} ]] ; then

   if [[ ${TSM_PRE_CMD_RC} == 0 ]] ; then
     echo "The TSM_PRE_CMD_RC is 0"

   elif [[ ${TSM_PRE_CMD_RC} == 4 ]] ; then
     echo "The TSM_PRE_CMD_RC is 4"

   elif [[ ${TSM_PRE_CMD_RC} == 8 ]] ; then
     echo "The TSM_PRE_CMD_RC is 8"

   elif [[ ${TSM_PRE_CMD_RC} == 12 ]] ; then
     echo "The TSM_PRE_CMD_RC is 12"
        else
     echo "The TSM_PRE_CMD_RC is an unexpected value: ${TSM_PRE_CMD_RC}"

   fi

else
   echo "The TSM_PRE_CMD_RC is not set"
fi
```

Return codes from preschedulecmd and postschedulecmd scripts

The return codes that you might see when you use the preschedulecmd and postschedulecmd options are described.

AIX | Linux | Solaris | Mac OS X | Windows

- If the command specified by the preschedulecmd option ends with a nonzero return code, IBM Spectrum Protect™ assumes that the command failed. In this case, the scheduled event and any postschedulecmd or postnschedulecmd command cannot run. The administrative query event command with format=detailed option shows that the event failed with return code 12.
- If the command specified by the postschedulecmd option ends with a nonzero return code, IBM Spectrum Protect considers the command to be failed. The administrative query event command with format=detailed option shows that the event completed with return code 8. The exception is if the scheduled operation completed with a higher return code, in which case the higher return code takes precedence. Therefore, if the scheduled operation completes with return code 0 or 4 and the postschedulecmd command fails, the administrative query event command shows that the event completed with return code 8. If the scheduled operation completes with return code 12, that return code takes precedence, and query event shows that the event failed with return code 12.

AIX Linux Solaris Mac OS X When you interpret the return code from a command, IBM Spectrum Protect considers 0 to mean success, and anything else to mean failure. While this behavior is widely accepted in the industry, it is not 100% guaranteed. For example, the developer of the widget command might exit with return code 3, if widget ran successfully. Therefore, it is possible that the preschedulecmd or postschedulecmd command might end with a nonzero return code and still be successful. To prevent IBM Spectrum Protect from treating such commands as failed, you can wrap these commands in a script, and code the script so that it interprets the command return codes correctly. The script exits with return code 0 if the command was successful; otherwise it exits with a nonzero return code. The logic for a script running widget might look like this example:

Windows When you interpret the return code from a command, IBM Spectrum Protect considers 0 to mean success, and anything else to mean failure. While this behavior is widely accepted in the industry, it is not 100% guaranteed. For example, the developer of the widget.exe command might exit with return code 3, if widget.exe ran successfully. Therefore, it is possible that the preschedulecmd or postschedulecmd command might end with a nonzero return code and still be successful. To prevent IBM Spectrum Protect from treating such commands as failed, you can wrap these commands in a script, and code the script so that it interprets the command return codes correctly. The script should exit with return code 0 if the command was successful; otherwise it should exit with a nonzero return code. The logic for a script that runs widget.exe might look like this example:

AIX Linux Solaris Mac OS X

```
run 'widget'
   if lastcc == 3
      exit 0
   else
      exit 1
```

Windows

```
run 'widget.exe'
   if lastcc == 3
      exit 0
   else
      exit 1
```

Client-acceptor scheduler services versus the traditional scheduler services

You can configure the IBM Spectrum Protect™ client to manage the scheduler process using the IBM Spectrum Protect client acceptor daemon.

The client acceptor daemon provides a light-weight timer which automatically starts and stops the scheduler process as needed. Alternatively, the traditional method keeps the IBM Spectrum Protect scheduler process running continuously. Generally, using the client acceptor daemon to manage the scheduler is the preferred method.

The following information is a comparison of the client acceptor daemon-managed services and the traditional scheduler services methods.

Client acceptor daemon-managed services

- Defined using the managedservices schedule option and started with client acceptor daemon services (dsmcad).
- The client acceptor daemon starts and stops the scheduler process as needed for each scheduled action.
- Requires fewer system resources when idle.
- IBM Spectrum Protect client options and IBM Spectrum Protect server override options are refreshed each time the client acceptor daemon services start a scheduled backup.
- Cannot be used with SESSIONINITiation=SERVEROnly backups.

IBM Spectrum Protect traditional scheduler services

- Started with command `dsmc sched` command.
- Remains active, even after scheduled backup is complete.
- Requires higher use of system resources when idle.
- IBM Spectrum Protect client options and IBM Spectrum Protect server override options are only processed once when `dsmc sched` is started; if you delete an option from a client options set, you must restart the scheduler so the scheduler is made aware of the deletion.

Tip: Restart the traditional scheduler periodically to free system resources previously used by system calls.

Setting the client scheduler process to run as a background task and start automatically at startup

You can configure the IBM Spectrum Protect™ client scheduler to run as a background system task that starts automatically when your system is started.

About this task

You can complete this task whether you use the client acceptor to manage the scheduler or whether you use the traditional method to start the scheduler client scheduler.

AIX Linux Solaris Mac OS X When you are running a client acceptor-managed schedule, set the client acceptor process to start automatically at startup time; not the scheduler process. For the traditional method, set the scheduler process to start automatically at startup time.

AIX Linux Solaris Mac OS X You can configure the client acceptor to run as a background system task that starts automatically when your system is started. To configure the client acceptor to manage scheduled backups, you use the managedservices option to specify whether the client acceptor manages only the scheduler, only the web client, or both the scheduler and web client. The method for setting up the client acceptor as a system task varies for each platform.

For the scheduler to start unattended, you must enable the client to store its password by setting the passwordaccess option to generate, and store the password by running a simple client command such as `dsmc query session`. For testing purposes, you can always start the scheduler in the foreground by running `dsmc sched` from a command prompt (without a `managedservices` stanza set).

AIX Linux Solaris Mac OS X To start the scheduler automatically at startup time, use either the client acceptor-managed method or the traditional method.

AIX Linux Solaris Mac OS X

Client acceptor-managed method

1. In your dsm.sys file, set the managedservices option to schedule or schedule webclient.
2. Start the client acceptor.
   a. AIX Solaris

      On AIX®and Solaris clients, add the following entry into the system startup file (/etc/inittab for most platforms):

      ```
      tsm::once:/usr/bin/dsmcad > /dev/null 2>&1 # TSM Client
      Acceptor Daemon
      ```

   b. Linux

      On Linux clients, the installation program creates a startup script for the client acceptor (dsmcad) in /etc/init.d. The client acceptor (dsmcad) must be started before it can manage scheduler tasks, or manage the web client. As root, use the following command to start, stop, or restart the client acceptor, or check its status:

      ```
      >>-service dsmcad--+-start---+---------------------------------><
                         +-stop----+
                         +-restart-+
                         '-status--'
      ```

      To enable the client acceptor to start automatically after a system restart, add the service as follows, at a shell prompt:

      ```
      # chkconfig --add dsmcad
      ```

      If the Linux operating system runs the `systemd` initialization service, complete the following steps to start the dsmcad and to run it at system start time:

      i. Copy the provided `systemd` unit file /opt/tivoli/tsm/client/ba/bin/dsmcad.service to the /etc/systemd/system/ directory.

ii. Run the following command to refresh the `systemd` unit list:

```
systemctl daemon-reload
```

iii. Run the following command to start the client acceptor at system start time:

```
systemctl enable dsmcad.service
```

iv. Run the following command to start the client acceptor:

```
systemctl start dsmcad.service
```

c. Mac OS X On Mac OS X, the client acceptor must be installed as a Startup Item. A system administrator must use the IBM Spectrum Protect Tools for Administrators to install and start the client acceptor. To start, stop, or restart the client acceptor, use the following command:

```
>>-sudo /sbin/SystemStarter--+-start---+--dsmcad--------------><
                             +-stop----+
                             '-restart-'
```

3. In your dsm.sys file, set the passwordaccess option to generate.
4. Run a command like `dsmc query sess` to store the node password.

AIX Linux Solaris Mac OS X Traditional method:

AIX Linux Solaris Mac OS X

1. Set the managedservices option.
   - AIX Linux Solaris On AIX, Linux, and Solaris clients, either remove the option entirely (it defaults to webclient) or set it to webclient.
   - Mac OS X On Mac OS X clients, set the managedservices option to either webclient or none. Do not set the option to schedule.
2. On AIX, Linux, and Solaris, add the following entry into the system startup file, for example, /etc/inittab, where it is supported:

   ```
   tsmsched::once:/usr/bin/dsmc sched > /dev/null 2>&1 # TSM scheduler
   ```

3. In your dsm.sys file, set the passwordaccess option to generate.
4. Run a command like `dsmc query sess` to store the node password.
5. To start the client scheduler on your client node and connect to the server schedule, enter the following command:

   ```
   dsmc schedule
   ```

   If the current directory is not in your PATH environment variable, enter the following command:

   ```
   ./dsmc schedule
   ```

   When you start the client scheduler, it runs continuously until you close the window, end the process, or log off your system.

   To run the schedule command in the background and to keep the client scheduler running, even if you log off your system, enter the following command:

   ```
   nohup dsmc schedule 2> /dev/null &
   ```

Windows On Windows platforms, the scheduler and the client acceptor run as services. You can create and manage these services by using either the setup wizard or the IBM Spectrum Protect Client Service Configuration Utility, dsmcutil.exe.

Windows

- To start the setup wizard, select Utilities > Setup Wizard in the backup-archive GUI and select a Help me configure option for the appropriate service. Follow the prompts to install, configure, and start the service.
- To start the Client Service Configuration Utility, open a command prompt window and issue the following command to change to the directory that contains dsmcutil.exe:

  ```
  cd /d "c:\program files\tivoli\tsm\baclient"
  ```

  Use dsmcutil to manage the client acceptor service or the scheduler service. Full documentation on how to use dsmcutil is available by entering `dsmcutil help`.

Windows The client scheduler can be managed by the client acceptor. When setting up scheduler services to run with client acceptor management, two services must be created: the scheduler service and the client acceptor service. When you install the client acceptor service with dsmcutil.exe, use the /cadschedname: parameter to identify which scheduler service the client acceptor manages. If you use the setup wizard to install the scheduler, you can select the Use the client acceptor to manage the scheduler check box, which automatically creates both services and associates them.

Windows Using the Client Service Configuration Utility, you can use either of the following methods:

Windows

Client acceptor-managed method

1. In your client options file (dsm.opt), either set the managedservices option to schedule or schedule webclient.
2. In your client options file (dsm.opt), set the passwordaccess option to generate.
3. Create the scheduler service:

```
dsmcutil inst /name:"TSM Client Scheduler" /node:tsmclient1
/password:secret /autostart:no /startnow:no
```

4. Create the client acceptor and associate scheduler service with the client acceptor:

```
dsmcutil inst CAD /name:"TSM Client Acceptor" /cadschedname:
"TSM Client Scheduler" /node:tsmclient1 /password:secret /autostart:yes
```

5. Manually start the client acceptor service:

```
net start "TSM Client Acceptor"
```

Traditional method

1. In your client options file (dsm.opt), either remove the managedservices entirely (it defaults to webclient) or set it to webclient.
2. In your client options file (dsm.opt), set the passwordaccess option to generate.
3. Create the scheduler service:

```
dsmcutil inst /name:"TSM Client Scheduler" /node:tsmclient1
/password:secret /autostart:yes
```

Windows To increase the reliability of the client scheduler service on Windows, set the services to automatically recover from a failure as follows:

Windows

- Start the Windows services management console (Start > Settings > Control Panel > Administrative Tools > Services)
- Right-click the TSM Client Scheduler service and select Properties.
- Click the Recovery tab.
- Define the recovery action as Restart the service for first, second, and subsequent failures.

Windows If you are using the client acceptor to manage the scheduler, you must set the recovery properties for the TSM Client Acceptor service, but leave the recovery settings for the TSM Client Scheduler service as Take No Action for the first, second, and subsequent failures. The same recovery settings can also be defined to increase the reliability of the TSM Journal Service.

Examples: Display information about scheduled work

Schedules can be classic or enhanced, depending on how the interval to the next execution is defined.

Classic schedules allow the period to be as small as an hour. Enhanced schedules allow actions to be executed on specific days.

To view schedules that are defined for your client node, enter: AIX Linux Solaris Mac OS X Windows

```
dsmc query schedule
```

The backup-archive client displays detailed information about all scheduled work for your client node. Table 1 displays sample classic query schedule output.

Table 1. Sample classic query schedule output

AIX Linux Solaris Mac OS X

```
 Schedule Name: DAILY_INC
   Description: Daily System-wide backup
Schedule Style: Classic
        Action: Incremental
       Options: QUIET
       Objects:
      Priority: 1
Next Execution: 30 minutes
      Duration: 4 Hours
        Period: 1 Day
   Day of Week: Any
         Month:
  Day of Month:
 Week of Month:
        Expire: Never

 Schedule Name: WEEKLY_INC
   Description: Weekly backup for project files
Schedule Style: Classic
        Action: Incremental
       Options: QUIET
       Objects: /proj
      Priority: 1
Next Execution: 60 minutes
      Duration: 8 Hours
        Period: 7 Days
   Day of Week: Friday
         Month:
  Day of Month:
 Week of Month:
        Expire: Never
```

Windows

```
 Schedule Name: DAILY_INC
   Description: Daily System-wide backup
Schedule Style: Classic
        Action: Incremental
       Options: QUIET
       Objects:
      Priority: 1
Next Execution: 30 minutes
      Duration: 4 Hours
        Period: 1 Day
   Day of Week: Any

       Options: QUIET
       Objects: e: f:
      Priority: 1
Next Execution: 60 minutes
      Duration: 8 Hours
        Period: 7 Days
   Day of Week: Friday
         Month:
  Day of Month:
 Week of Month:
        Expire: Never
```

AIX Linux Solaris Mac OS X The schedule name, **WEEKLY_INC**, starts a weekly incremental backup in the `/proj` file system.

Windows The schedule name, **WEEKLY_INC**, starts a weekly incremental backup on the `e:` and `f:` drives.

The schedule name, **DAILY_INC**, starts a daily incremental backup. The next incremental backup starts in 30 minutes. Because no objects are listed, the client runs the incremental backup on your default domain. The schedule has no expiration date.

To more accurately determine the status of scheduled events, the query schedule output for an enhanced schedule, on IBM Spectrum Protect™ Version 5.3 client and above, includes new fields. These fields are always displayed, even if it is a classic schedule or a version 5.3 client session with a pre-version 5.3 server, but the new fields are blank. Note that for a down-level (prior to verrsion 5.3) client, the server reports the period as indefinite and the day of week as an illegal day. Table 2 displays sample enhanced query schedule output.

Table 2. Sample enhanced query schedule output

AIX | Linux | Solaris | Mac OS X

```
Schedule Name: QUARTERLY_FULL
     Description: Quarterly full backup
  Schedule Style: Enhanced
          Action: Selective
         Options: subdir=yes
         Objects: /* /Volumes/fs2/*
         Priority: 5
  Next Execution: 1744 Hours and 26 Minutes
        Duration: 1 Day
          Period:
     Day of Week: Friday
           Month: March, June, September, December
    Day of Month: Any
   Week of Month: Last
          Expire: Never
```

Windows

```
Schedule Name: QUARTERLY_FULL
     Description: Quarterly full backup
  Schedule Style: Enhanced
          Action: Selective
         Options: subdir=yes
         Objects: \* \volumes\fs2\*
        Priority: 5
  Next Execution: 1744 Hours and 26 Minutes
        Duration: 1 Day
          Period:
     Day of Week: Friday
           Month: March, June, September, December
    Day of Month: Any
   Week of Month: Last
          Expire: Never
```

Display information about completed work

When you run the schedule command in the foreground, your screen displays output from the scheduled commands.

Output is also directed to the dsmsched.log file in the installation directory unless you change the directory and file name using the schedlogname option.

AIX | Linux | Solaris | Mac OS X When you run the schedule command in the background, output from scheduled commands is directed to the dsmsched.log file in the current directory, or to the path and file name that you specified. The dsmsched.log cannot be a symbolic link.

Mac OS X Note: On Mac OS X, by default the log can be found in one of these locations:

```
~/Library/Logs/tivoli/tsm
/Library/Logs/tivoli/tsm
```

Windows When you run the schedule command as a service, output from scheduled commands displays in the application event log. Output is also directed to the dsmsched.log file in the current directory unless you change the path and file name using the schedlogname option. The amount of detail is determined by whether *verbose* or *quiet* is set in the `dsm.opt` file. The scheduler service also posts messages to the Windows event log.

After scheduled work is performed, check the schedule log to verify that all work completed successfully.

When a scheduled command is processed the schedule log contains the following entry:

```
Scheduled event eventname completed successfully
```

If the scheduled event does not complete successfully, you receive a message similar to the following:

```
ANS1512E Scheduled event eventname failed. Return code = code.
```

The client indicates whether IBM Spectrum Protect™ successfully issued the scheduled command associated with the *eventname* (action=command). No attempt is made to determine the success or failure of the command. You can assess the status of the command by evaluating the return code from the scheduled command in the schedule log. The schedule log entry for the return code of the command is prefaced with the following text:

```
Finished command. Return code is:
```

The schedule log continues to grow unless you prune it using the schedlogretention option or specify a maximum size using the schedlogmax option.

- Examples: event logs
  The scheduler service logs information into the application event log and provides an event identification (event ID) number for each event in the log. This topic shows examples of events that are logged to the application event log.

Related concepts:
Specify scheduling options

Specify scheduling options

You can modify scheduling options in the client options file or the graphical user interface (GUI).

However, if your administrator specifies a value for these options, that value overrides the value in your client.

Related concepts:
Scheduling options

AIX | Linux | Solaris | Mac OS X

Scheduler options for commands

The scheduler executes commands under a user ID of `0` (root); however, some commands might need to be executed under a user ID other than `0`.

In this case, your IBM Spectrum Protect™ administrator can define schedules for commands that are executed under a user ID different from the scheduler user ID using the schedcmduser server option.

The schedcmduser option specifies the name of a valid user on the system where a scheduled command is executed. This option can only be defined by the IBM Spectrum Protect server administrator. If this option is specified, the command is executed with the authorization of the specified user. Otherwise, it is executed with the scheduler authorization.

```
>>-SCHEDCMDUser----user_name----------------------------------><
```

user_name
: Specifies the name of a valid user on the system where a scheduled command is executed.

Note: The schedcmduser option does *not* affect the user ID used for the pre-schedule and post-schedule commands. Pre-schedule and post-schedule always run as root (user ID 0).

Enable or disable scheduled commands

You can use the schedcmddisabled option to disable the scheduling of commands by the server.

Commands are scheduled by using the action=*command* option on the DEFINE SCHEDULE server command.

The schedcmddisabled option does not disable the preschedulecmd and postschedulecmd commands. However, you can specify preschedulecmd or postschedulecmd with a blank or a null string to disable the scheduling of these commands.

You can use the schedrestretrdisabled option to prevent the IBM Spectrum Protect™ server administrator from executing restore or retrieve schedule operations.

You can use the srvprepostscheddisabled option to prevent the IBM Spectrum Protect server administrator from executing pre-schedule and post-schedule commands when performing scheduled operations.

AIX Linux Solaris Mac OS X Windows You can use the srvprepostsnapdisabled option to prevent the IBM Spectrum Protect server administrator from executing pre-snapshot and post-snapshot commands when performing scheduled image snapshot backup operations.

Change processing options used by the scheduler service

When you configure the IBM Spectrum Protect™ central-scheduling services (the scheduler, the client acceptor, or the remote client agent), some of the processing options that you specify are defined in the Windows registry.

The following options can also be specified in the client options file (dsm.opt).

- nodename
- httpport
- tcpserveraddress
- tcpport
- webports

When the client scheduler runs as a foreground process using the dsmc sched command, the options in the client options file are used. However, when the scheduler runs as a Windows service, the options in the registry are used instead. If you are using the scheduler service and change an option in the dsm.opt file, you must update the corresponding value in the registry as well.

To update the Windows registry value:

Use the Setup wizard in the client GUI. For more information, see Configuring the scheduler.
Alternatively, you can use the dsmcutil utility to change the registry value. For example: `dsmcutil update scheduler /name: <service name> /node: <new node name> /password: <new node password>`.
Note: After updating the registry, you must restart the scheduler service for the changes to take effect. If you are using client acceptor daemon-managed scheduling this is not necessary because the scheduler is restarted by the client acceptor daemon for each backup.

Manage multiple schedule requirements on one system

In certain situations it is preferable to have more than one scheduled activity for each client system.

About this task

Normally, you can do this by associating a node with more than one schedule definition. This is the standard method of running multiple schedules on one system.

You must ensure that the schedule windows for each schedule do not overlap. A single client scheduler process is not capable of executing multiple scheduled actions simultaneously, so if there is overlap, the second schedule to start is missed if the first schedule does not complete before the end of the startup window of the second schedule.

AIX Linux Solaris Mac OS X Suppose that most of the file systems on your client system must be backed up daily, and that one file system containing critical data must be backed up hourly. In this case, you would need to define two schedules to handle this requirement. To avoid conflict between the hourly and daily backup schedule, the *starttime* of each schedule needs to be varied.

Windows Suppose that most of the drives on your client system must be backed up daily, and that one drive containing critical data must be backed up hourly. In this case, you would need to define two schedules to handle this requirement. To avoid conflict between the hourly and daily backup schedule, the *starttime* of each schedule needs to be varied.

In certain cases, it is necessary to run more than one scheduler process on a system. Multiple processes require a separate options file for each process and must contain the following information:

- Define a unique node name for each process
- Specify unique schedule and error logs for each process
- When running in prompted mode, you must use the tcpclientport option to specify a unique port for each process.

Windows Note: When the scheduler runs as a service, processing options specified in the Windows registry override the same options specified in the client options file.

The advantages of using multiple schedule processes:

- You can run more than one scheduled backup at the same time.
- You can specify different backup criteria for each schedule started, with the client option file or IBM Spectrum Protect™ server override options.

The disadvantages of using multiple schedule processes:

- A unique file space for each node name on the IBM Spectrum Protect server is created.
- When restoring the data, you must use the same node name associated with the backup.

AIX Linux Solaris Mac OS X Multiple schedule processes can run on UNIX and Linux platforms with either the client acceptor daemon-managed method, or the traditional method of running the scheduler. In either case, there are certain setup requirements:

AIX Linux Solaris Mac OS X

- Each process must run using a different node name.
- You must create multiple stanzas in the dsm.sys file for each scheduler process. In each stanza, you must define a unique node name, along with unique values for the options errorlogname and schedlogname. You might also choose to define customized domain, include, and exclude statements for each stanza.
- In your dsm.sys file, set the passwordaccess option to generate in each stanza. The password must be generated for each node name that is running a scheduler process, by running a command such as `dsmc query sess`.
- If running with the schedmode option set to *prompt*, you should set a unique tcpclientport value for each stanza.

AIX Linux Solaris Mac OS X You must start each `dsmc sched` command or instance with the -servername option to reference its unique stanza name in dsm.sys. For dsmcad, it is necessary to define the environment variable DSM_CONFIG for each instance of dsmcad to reference its unique option file.

AIX Linux Solaris Mac OS X The following is an example configuration of two schedule processes managed by the client acceptor daemon in the dsm.sys file. Note that you must use full paths for the log file names to avoid the files being written in the root directory):

```
servername tsm1_sched1
        nodename        aixsvt01_sched1
        tcpserv         firebat
        tcpclientport   1507
        passwordaccess  generate
        domain          /svt1
        schedmode       prompted
        schedlogname    /tsm/dsmsched1.log
        errorlogname    /tsm/dsmerror1.log
        managedservices schedule

servername tsm1_sched2
  nodename        aixsvt01_sched2
  tcpserv         firebat
  tcpclientport   1508
  passwordaccess  generate
  domain          /svt1
  schedmode       prompted
  schedlogname    /tsm/dsmsched2.log
  errorlogname    /tsm/dsmerror2.log
  managedservices schedule
```

AIX Linux Solaris Mac OS X Contents of /test/dsm.opt1:

AIX Linux Solaris Mac OS X

```
servername tsm1_sched1
```

AIX Linux Solaris Mac OS X Contents of /test/dsm.opt2:

AIX Linux Solaris Mac OS X

```
servername tsm1_sched2
```

Mac OS X Open two shell command windows:

Mac OS X

- In shell command window 1, enter:

  ```
  export DSM_CONFIG=/test/dsm.opt1
  sudo dsmcad
  ```

- In shell command window 2, enter:

  ```
  export DSM_CONFIG=/test/dsm.opt2
  sudo dsmcad
  ```

AIX Linux Solaris Mac OS X **Note:** You should enter these commands into a shell script if you intend to have the dsmcad processes started directly from /etc/inittab so that the proper DSM_CONFIG variable can be set prior to launching dsmcad.

Windows You must create a separate service for each schedule process. If you are using the client acceptor daemon to manage the scheduler, a client acceptor daemon service and schedule service are required for each schedule. The following is an example of setting up two schedule processes to be managed by the client acceptor daemon:

```
dsmcutil inst /name:"TSM Client Scheduler1"
/optfile:"c:\program files\tivoli\tsm\baclient\dsm.opt1"
/node:tsmcli_sched1 /password:secret /autostart:no /startnow:no

dsmcutil inst CAD /name:"TSM Client Acceptor1"
/optfile:"c:\program files\tivoli\tsm\baclient\dsm.opt1"
/cadschedname:"TSM Client Scheduler1" /node:tsmcli_sched1 /password:secret
/autostart:yes

dsmcutil inst /name:"TSM Client Scheduler2"
/optfile:"c:\program files\tivoli\tsm\baclient\dsm.opt2"
/node:tsmcli_sched2 /password:secret /autostart:no /startnow:no

dsmcutil inst CAD /name:"TSM Client Acceptor2"
/optfile:"c:\program files\tivoli\tsm\baclient\dsm.opt2"
/cadschedname:"TSM Client Scheduler2" /node:tsmcli_sched2 /password:secret
/autostart:yes
```

Windows Unique option files are required for each schedule instance, and must be identified at the time of service creation:

Option file #1 (c:\program files\tivoli\tsm\baclient\dsm.opt1)

```
tcps             tsmserv1.example.com
nodename         tsmcli_sched1
passwordaccess   generate
schedlogname     "c:\program files\tivoli\tsm\baclient\dsmsched1.log"
errorlogname     "c:\program files\tivoli\tsm\baclient\dsmerror1.log"
schedmode        prompted
tcpclientport    1507
domain           h:
managedservices  schedule
```

Option file #2 (c:\program files\tivoli\tsm\baclient\dsm.opt2)

```
tcps             tsmserv1.example.com
nodename         tsmcli_sched2
passwordaccess   generate
schedlogname     "c:\program files\tivoli\tsm\baclient\dsmsched2.log"
errorlogname     "c:\program files\tivoli\tsm\baclient\dsmerror2.log"
schedmode        prompted
tcpclientport    1508
domain           i:
managedservices  schedule
```

Client return codes

The backup-archive command-line interface and the scheduler exit with return codes that accurately reflect the success or failure of the client operation.

Scripts, batch files, and other automation facilities can use the return code from the command-line interface. For operations that use the IBM Spectrum Protect™ scheduler, the return codes are shown in the output of the QUERY EVENT administrative command.

In general, the return code is related to the highest severity message during the client operation.

- If the highest severity message is informational (ANSnnnnI), then the return code is 0.
- If the highest severity message is a warning (ANSnnnnW), then the return code is 8.
- If the highest severity message is an error (ANSnnnnE or ANSnnnnS), then the return code is 12.

An exception to these rules is made when warning or error messages indicate that individual files could not be processed. For files that cannot be processed, the return code is 4. Examine the dsmerror.log file to determine the cause of errors that occur during client operations. Errors that occur during scheduled events are recorded in the dsmsched.log file.

Table 1 describes the return codes and their meanings.

Table 1. Client return codes and their meanings

Code	Explanation
0	All operations completed successfully.
4	The operation completed successfully, but some files were not processed. There were no other errors or warnings. This return code is common. Files are not processed for various reasons; the following reasons are the most common. • The file satisfies an entry in an exclude list. Excluded files generate log entries only during selective backups. • The file was in use by another application and could not be accessed by the client. • The file changed during the operation to an extent prohibited by the copy serialization attribute. See Copy serialization attribute.
8	The operation completed with at least one warning message. For scheduled events, the status is `Completed`. Review the dsmerror.log file (and dsmsched.log for scheduled events) to determine what warning messages were issued and to assess their impact on the operation.
Windows 12	Windows The operation completed with at least one error message (except for error messages for skipped files). For scheduled events, the status is `Failed`. Review the dsmerror.log file (and dsmsched.log for scheduled events) to determine what error messages were issued and to assess their impact on the operation. Generally, this return code means that the error was severe enough to prevent the successful completion of the operation. For example, an error that prevents an entire drive from being processed yields return code 12.
AIX Linux Solaris Mac OS X 12	AIX Linux Solaris Mac OS X The operation completed with at least one error message (except for error messages for skipped files). For scheduled events, the status is `Failed`. Review the dsmerror.log file (and dsmsched.log for scheduled events) to determine what error messages were issued and to assess their impact on the operation. Generally, this return code means that the error was severe enough to prevent the successful completion of the operation. For example, an error that prevents an entire file system or file specification from being processed yields return code 12.
other	For scheduled operations where the scheduled action is COMMAND, the return code is the return code from the command that was run. If the return code is 0, the status of the scheduled operation is `Completed`. If the return code is nonzero, then the status is `Failed`. Some commands might issue a nonzero return code to indicate success. For these commands, you can avoid a `Failed` status by wrapping the command in a script that starts the command, interprets the results, and exits. The script should produce return code 0 if the command was successful, or a nonzero return code if the command failed. Then, ask your IBM Spectrum Protect server administrator to modify the schedule definition to run your script instead of the command.

The return code for a client macro is the highest return code that is issued among the individual commands that comprise the macro. For example, suppose a macro consists of these commands:

AIX Linux Solaris Mac OS X

```
selective "/home/devel/*" -subdir=yes
incremental "/home/devel/TestDriver/*" -subdir=yes
archive "/home/plan/proj1/*" -subdir=yes
```

Windows

```
selective c:\MyTools\* -subdir=yes
incremental c:\MyPrograms\TestDriver\* -subdir=yes
archive e:\TSM\* -subdir=yes
```

If the first command completes with return code 0, and the second command completes with return code 8, and the third command completed with return code 4, the return code for the macro is 8.

For more information about the QUERY EVENT command, see the IBM Spectrum Protect server documentation.

Storage management policies

Storage management policies are rules your administrator defines in order to manage your backups and archives on the server.

Your data is associated (or bound) to these policies; then when the data is backed up or archived, it is managed according to policy criteria. Policy criteria include a policy domain, a policy set, a management class, and a copy group.

Policies determine:

- Whether a file is eligible for backup or archive services.
- How many backup versions to keep.
- How long to keep inactive backup versions and archive copies.
- Where to place the copies in storage.
- For incremental backup, policies also determine:
  - How frequently a file can be backed up.
  - Whether a file must change before it is backed up again.

AIX Linux Solaris Mac OS X If you have the IBM Spectrum Protect™ for Space Management client installed, your administrator also defines rules that determine whether files are eligible for migration from your local file systems to storage.

This topic explains:

- Policy criteria (policy domains, policy sets, copy groups, and management classes).
- How to display policies.
- How your data is associated with policies.

- Policy domains and policy sets
  A *policy domain* is a group of clients with similar requirements for backing up and archiving data.
- Management classes and copy groups
  A *management class* is a collection of backup and archive copy groups that establishes and contains specific storage management requirements for backing up and archiving data.
- Display information about management classes and copy groups
  You can display policy information with the command-line interface or with a graphical user interface.
- Select a management class for files
  If the default management class meets the backup and archive requirements for all the files on your workstation, it is not necessary to take any action to associate your files with that management class. This is done automatically when you back up or archive your files.
- Assign a management class to files
  A management class defines when your files are included in a backup, how long they are kept on the server, and how many versions of the file the server should keep.
- Override the management class for archived files
  When you archive a file, you can override the assigned management class using the a graphical user interface (GUI), or by using the archmc option on the archive command.

- Select a management class for directories
  If the management class in your active policy set containing the longest "Retain only version" (RETONLY) setting meets your backup requirements for directories, it might not be necessary to take any action to associate directories with that management class. The management class association is done automatically when it backs up your directories.
- Bind management classes to files
  Binding associates a file with a management class.
- Rebind backup versions of files
  Rebinding associates a file or a logical volume image with a new management class.
- Retention grace period
  IBM Spectrum Protect also provides a *backup retention grace period* and an *archive retention grace period* to help protect your backup and archive data when it is unable to rebind a file to an appropriate management class.
- Event-based policy retention protection
  All management classes with an archive copy group must specify a retention period, for example, the number of days that an archived object is stored on the server before being deleted.

Policy domains and policy sets

A *policy domain* is a group of clients with similar requirements for backing up and archiving data.

Policy domains contain one or more policy sets. An administrator uses policy domains to manage a group of client nodes in a logical way.

For example, a policy domain might include:

- A department, such as Accounting.
- A physical location, such as a particular building or floor.
- A local area network, such as all clients associated with a particular file server.

IBM Spectrum Protect™ includes a default policy domain named *Standard*. At first, your client node might be associated with the default policy domain. However, your administrator can define additional policy domains if there are groups of users with unique backup and archive requirements.

A *policy set* is a group of one or more management classes. Each policy domain can hold many policy sets. The administrator uses a policy set to implement different management classes based on business and user needs. Only one of these policy sets can be active at a time. This is called the *active policy set*. Each policy set contains a *default management class* and any number of additional management classes.

Management classes and copy groups

A *management class* is a collection of backup and archive copy groups that establishes and contains specific storage management requirements for backing up and archiving data.

An administrator can establish separate management classes to meet the backup and archive requirements for different kinds of data, such as:

- System data that is critical for the business.
- Application data that changes frequently.
- Report data that Management reviews monthly.
- Legal information that must be retained indefinitely, requiring a large amount of disk space.

AIX Linux Solaris Mac OS X Note: If you have the IBM Spectrum Protect™ for Space Management installed, it can also contain specific requirements for migrating files to storage.

AIX Linux Solaris Mac OS X Windows Most of the work you do with storage management policies is with management classes. Each file and directory that you back up, and each file that you archive, is associated with (or *bound* to) a management class, as follows:

- If your data is not associated with a management class, IBM Spectrum Protect uses the default management class in the active policy set.
- When backing up directories, you can specify a management class with an *include* statement or the dirmc option. If you do not specify a management class, IBM Spectrum Protect uses the management class in the active policy set specifying the longest "Retain Only" retention period. If there are multiple management classes that meet this criteria, IBM Spectrum Protect uses the last one found, in alphabetical order.

- For archiving directories, you can specify a management class with an *include.archive* statement or the archmc option. If you do not specify a management class, the server assigns the default management class to the archived directory. If the default management class has no archive copy group, the server assigns the management class that currently has the archive copy group with the shortest retention time.

You can use *include* statements in your include-exclude list to associate files with management classes. In your client options file, you can associate directories with a management class, using the dirmc option.

Within a management class, the specific backup and archive requirements are in *copy groups*. Copy groups define the specific storage management attributes that describe how the server manages backed up or archived data. Copy groups include both *backup copy groups* and *archive copy groups*. A management class can have one backup copy group, one archive copy group, both, or neither.

A *backup copy group* contains attributes that are used during the backup process to determine:

- How many days must elapse before a file is backed up again.
- How a file is processed during a backup if it is in use.

It also contains attributes to manage the backup versions of your files on the server. These attributes control:

- On which media type the server stores backup versions of your files and directories.
- How many backup versions the server keeps of your files and directories.
- How long the server keeps backup versions of your files and directories.
- How long the server keeps inactive backup versions.
- How long the last remaining inactive version of a file is kept.

An *archive copy group* contains attributes that control:

- Whether a file is archived if it is in use
- On which media type the server stores archived copies of your files
- How long the server keeps archived copies of your files

Related concepts:
Select a management class for files
Retention grace period

Display information about management classes and copy groups

You can display policy information with the command-line interface or with a graphical user interface.

On a graphical user interface, click **View policy information** from the Utilities menu. The **Policy information** window displays the available management classes. On a command line, use the query mgmtclass command to view the available management classes. The detail option provides more information.

Table 1 shows the default values for the backup and archive copy groups in the standard management class.

Table 1. Default attribute values in the standard management class

Attribute	Backup default	Archive default
Copy group name	Standard	Standard
Copy type	Backup	Archive
Copy frequency	0 days	CMD (Command)
Versions data exists	Two versions	Does not apply
Versions data deleted	One version	Does not apply
Retain extra versions	30 days	Does not apply
Retain only version	60 days	Does not apply
Copy serialization	Shared static	Shared static
Copy mode	Modified	Absolute
Copy destination	Backuppool	Archivepool
Retain versions	Does not apply	365 days

Attribute	Backup default	Archive default
Lan free	Destination	No
Deduplication enabled	No	No

- Copy group name attribute
  The *copy group name* attribute is the name of the copy group. The default value for both backup and archive is *standard*.
- Copy type attribute
  The *copy type* attribute is the type of the copy group. The value for backup is always *backup*, and the value for archive is always *archive*.
- Copy frequency attribute
  The *copy frequency* attribute is the minimum number of days that must elapse between successive incremental backups. Use this attribute during a full incremental backup.
- Versions data exists attribute
  The *versions data exists* attribute specifies the maximum number of different backup versions retained for files and directories.
- Versions data deleted attribute
  The *versions data deleted* attribute specifies the maximum number of different backup versions retained for files and directories that you deleted.
- Retain extra versions attribute
  The *retain extra versions* attribute specifies how many days all but the most recent backup version is retained.
- Retain only version attribute
  The *retain only version* attribute specifies the number of days the last remaining inactive version of a file or directory is retained.
- Copy serialization attribute
  The copy serialization attribute determines whether a file can be in use during a backup or archive, and what to do if it is.
- Copy mode parameter
  The copy mode parameter determines whether a file or directory is considered for incremental backup regardless of whether it changed or not since the last backup.
- Copy destination attribute
  The *copy destination* attribute names the destination where backups or archives are stored.
- Retain versions attribute
  The *retain versions* attribute specifies the number of days an archived file remains in storage.
- Deduplicate data attribute
  The *deduplicate data* attribute specifies whether redundant data is transferred to the IBM Spectrum Protect™ server during backup and archive processing.

Copy group name attribute

The *copy group name* attribute is the name of the copy group. The default value for both backup and archive is *standard*.

Copy type attribute

The *copy type* attribute is the type of the copy group. The value for backup is always *backup*, and the value for archive is always *archive*.

Copy frequency attribute

The *copy frequency* attribute is the minimum number of days that must elapse between successive incremental backups. Use this attribute during a full incremental backup.

Copy frequency works with the mode parameter. For example, if `frequency=0` and `mode=modified`, a file or directory is backed up only if it changed since the last incremental backup. If `frequency=0` and `mode=absolute`, an object is backed up every time you run an incremental backup against it. If `frequency=0` and `mode=absolute`, changes and number of days since the last backup do not affect the current backup operation. The frequency attribute is not checked for selective backups.

For archive copy groups, copy frequency is always CMD (command). There is no restriction on how often you archive an object.

AIX | Windows Copy frequency is ignored during a journal-based backup.

Windows Journal-based incremental backup differs from the traditional full incremental backup because IBM Spectrum Protect™ does not enforce non-default copy frequencies (other than 0).

Versions data exists attribute

The *versions data exists* attribute specifies the maximum number of different backup versions retained for files and directories.

If you select a management class that permits more than one backup version, the most recent version is called the *active* version. All other versions are called *inactive* versions. If the maximum number of versions permitted is five, and you run a backup that creates a sixth version, the oldest version is deleted from server storage.

Versions data deleted attribute

The *versions data deleted* attribute specifies the maximum number of different backup versions retained for files and directories that you deleted.

This parameter is ignored until you delete the file or directory.

If you delete the file or directory, the next time you run an incremental backup, the active backup version is changed to inactive. The IBM Spectrum Protect™ server deletes the oldest versions in excess of the number specified by this parameter.

The expiration date for the remaining versions is based on the *retain extra versions* and *retain only version* parameters.

Retain extra versions attribute

The *retain extra versions* attribute specifies how many days all but the most recent backup version is retained.

The most recent version is the active version, and active versions are never erased. If *Nolimit* is specified, then extra versions are kept until the number of backup versions exceeds the *versions data exists* or *versions data deleted* parameter settings. In this case, the oldest extra version is deleted immediately.

Retain only version attribute

The *retain only version* attribute specifies the number of days the last remaining inactive version of a file or directory is retained.

If *Nolimit* is specified, the last version is retained indefinitely.

This parameter goes into effect during the next incremental backup after a file is deleted from the client system. Any subsequent updates to this parameter will not affect files that are already inactive. For example: If this parameter is set to 10 days when a file is inactivated during an incremental backup, the file is deleted from the server in 10 days.

Copy serialization attribute

The copy serialization attribute determines whether a file can be in use during a backup or archive, and what to do if it is.

The value for this attribute can be one of the following:

- Static. A file or directory must not be modified during a backup or archive. If the object is changed during a backup or archive attempt, it is not backed up or archived.
- Shared static. A file or directory must not be modified during backup or archive. The client attempts to perform a backup or archive as many as four additional times, depending on the value specified on the changingretries option in your options file. If the object is changed during every backup or archive attempt, it is not backed up or archived.
- Dynamic. A file or directory is backed up or archived on the first attempt regardless of whether it changes during a backup or archive.
- Shared dynamic. A file or directory is backed up or archived regardless of whether it changes during a backup or archive. The client attempts to back up or archive as many as four additional times. The number of attempts depend on the value that was specified on the changingretries option in your options file, without the file changing during the attempt. The file is backed up or archived on the last try even if it has changed.

  If you select a management class that permits a file to be backed up or archived while it is in use, the backup version or archived copy that is stored on the server might be a fuzzy copy. A *fuzzy copy* is a backup version or archived copy that does

not accurately reflect what is currently in the file. It might contain some, but not all, of the changes. If that is not acceptable, select a management class that creates a backup version or archive copy only if the file does not change during a backup or archive. When you use static serialization, applications cannot open a file for write access while the file is being backed up.

If you restore or retrieve a file that contains a fuzzy copy, the file might not be usable. Do not use dynamic or shared dynamic serialization to back up files unless you are certain that a fuzzy copy that is restored is usable.

Important: Be careful when you select a management class containing a copy group that specifies shared dynamic or serialization dynamic backup.

Snapshotproviderimage

Copy mode parameter

The copy mode parameter determines whether a file or directory is considered for incremental backup regardless of whether it changed or not since the last backup.

The client does not check the mode parameter when it runs selective backups.

The value for this parameter can be one of the following settings:

modified
The object is considered for incremental backup only if it has changed since the last backup. An object is considered changed if any of the following conditions are true:

- The date or time of the last modification is different.
- The size is different.
- Windows The attributes, except for the archive attribute, are different.
- If only the metadata changes (such as access permissions), the client might back up only the metadata.
- AIX Linux Solaris Mac OS X The owner is different.

absolute
The object is considered for incremental backup regardless of whether it changed since the last backup. For archive copy groups, the mode is always absolute, indicating that an object is archived regardless of whether it changed since the last archive request.

Copy destination attribute

The *copy destination* attribute names the destination where backups or archives are stored.

The destination can be either a storage pool of disk devices or a storage pool of devices that support removable media, such as tape.

Retain versions attribute

The *retain versions* attribute specifies the number of days an archived file remains in storage.

When the specified number of days elapse for an archived copy of a file, it is deleted from server storage.

Deduplicate data attribute

The *deduplicate data* attribute specifies whether redundant data is transferred to the IBM Spectrum Protect™ server during backup and archive processing.

Exclude options

Select a management class for files

If the default management class meets the backup and archive requirements for all the files on your workstation, it is not necessary to take any action to associate your files with that management class. This is done automatically when you back up or archive your files.

When selecting a different management class for your files, consider these questions:

- Does the management class contain a backup copy group?

  If you attempt to back up a file associated with a management class that does not contain a backup copy group, the file is not backed up.

- Does the management class contain an archive copy group?

  You cannot archive a file associated with a management class that does not contain an archive copy group.

- Does the backup copy group contain attributes that back up your files often enough?

  Mode and frequency work together to control how often a file is backed up when you use incremental backup. These attributes are not checked for selective backup.

- What serialization method does the copy group use?

  The serialization method determines how IBM Spectrum Protect™ functions when a file changes while it is being backed up.

- Does the backup copy group specify an adequate number of backup versions to keep, along with an adequate length of time to keep them?
- Does the archive copy group specify an adequate length of time to keep archived copies of files?

Related concepts:
Copy serialization attribute

Assign a management class to files

A management class defines when your files are included in a backup, how long they are kept on the server, and how many versions of the file the server should keep.

The server administrator selects a default management class. You can specify your own management class to override the default management class.

To assign a management class other than the default to directories, use the dirmc option in your options file.

You can assign a management class for a file or file group by using an include statement in your options file. You can also assign a management class by using an include statement in include-exclude file specified by the inclexcl option. Management class names are not case-sensitive.

Using the command-line client, to associate all files in the `costs` directory with the management class named `budget`, you would enter:

AIX | Linux | Solaris | Mac OS X

```
include /home/proj2/costs/* budget
```

Windows

```
include c:\adsm\proj2\costs\* budget
```

To specify a management class named `managall` to use for all files to which you do not explicitly assign a management class, enter the following:

AIX | Linux | Solaris | Mac OS X

```
include /.../* managall
```

Windows

```
include ?:\...\* managall
```

The following examples show how to assign a management class to files:

AIX Linux Solaris Mac OS X

```
exclude /.../*.sno
include /home/winter/.../*.ice      mcweekly
include /home/winter/december/*.ice mcdaily
include /home/winter/january/*.ice  mcmonthly
include /home/winter/february/white.sno
```

Windows

```
exclude ?:\...\*.sno
include c:\winter\...\*.ice      mcweekly
include c:\winter\december\*.ice mcdaily
include c:\winter\january\*.ice  mcmonthly
include c:\winter\february\white.sno
```

Processing follows these steps:

1. The file white.sno in the february directory in the winter directory is backed up following bottom-up processing rules. Because you did not specify a management class on this statement, the file is assigned to the default management class.
2. Any file with an extension of `ice` in the january directory is assigned to the management class named `mcmonthly`.
3. Any file with an extension of `ice` in the december directory is assigned to the management class named `mcdaily`.
4. Any other files with an extension of `ice` in any directory under the winter directory are assigned to the management class named `mcweekly`.
5. Any file with an extension of `sno` in any directory is excluded from backup. The exception to this rule is white.sno in the february directory, which is in the winter directory.

To specify your own default management class `mgmt_class_name` for files that are not explicitly included, put the following statement at the top of your include list:

AIX Linux Solaris Mac OS X

```
include /.../* mgmt_class_name
```

Windows

```
include ?:\...\* mgmt_class_name
```

AIX Linux Solaris Mac OS X When you archive a file using the graphical user interface, you can select a different management class to override the management class assigned to the file.

Related reference:
Dirmc
Include options

Override the management class for archived files

When you archive a file, you can override the assigned management class using the a graphical user interface (GUI), or by using the archmc option on the archive command.

Overriding the management class using the GUI is equivalent to using the archmc option on the archive command. To use the GUI, press the **Options** button on the archive tree to override the management class and select a different management class.

On the command line, to associate the file `budget.jan` with the management class **ret2yrs**, enter this command:

AIX Linux Solaris Mac OS X

```
dsmc archive -archmc=ret2yrs /home/jones/budget.jan
```

Windows

```
dsmc archive -archmc=ret2yrs c:\plan\proj1\budget.jan
```

Select a management class for directories

If the management class in your active policy set containing the longest "Retain only version" (RETONLY) setting meets your backup requirements for directories, it might not be necessary to take any action to associate directories with that management class. The management class association is done automatically when it backs up your directories.

If there is more than one management class with the longest RETONLY setting, the IBM Spectrum Protect™ client selects the management class whose name is last in alphabetical order.

If the default management class does not meet your requirements, select a management class with an adequate retention period specified by the retain only version parameter. For example, if the management class happens to back up data directly to tape, but you want your directory backups to go to disk, you must choose a different management class. You should keep directories at least as long as you keep the files associated with those directories.

For backup directories, use the dirmc option to specify the management class to which directories are bound.

For archive directories, use the archmc option with the archive command.

You can use these methods to view the available management classes and their attributes:

- GUI or web client: Select View Policy Information from the Utilities menu.
- Command-line client: Run `dsmc query mgmtclass -detail`.

Note: During expiration processing on the IBM Spectrum Protect server, if an archived directory is eligible for expiration, the server checks if any existing archived files require the archived directory to remain. If so, the archived directory is not expired and the backup-archive client updates the insert date on the archived directory to ensure that the directory is not expired before the files under it.

Bind management classes to files

Binding associates a file with a management class.

When you back up a file for the first time, IBM Spectrum Protect™ binds it to either the default management class or the management class specified in your include-exclude list.

If the backup copy group for the management class specifies keeping multiple backup versions of the file, and you request multiple backups, the server always has one active backup version (the current version) and one or more inactive backup versions of the file. All backup versions of a file are bound to the same management class and are managed based on the attributes in the backup copy group.

When you archive a file for the first time, IBM Spectrum Protect binds it to the default management class, to the management class specified in your include-exclude list, or to a management class you specify when modifying your archive options during an archive.

Archived files are never rebound to a different management class. If you change the management class for a file using an include.archive statement, the archmc option, or through the backup-archive client GUI, any previous copies of the file that you archived remain bound to the management class specified when you archived them.

If a file is deleted on the client system then that inactive objects of the file are not rebound.

For information about how to associate files and directories with management classes, see the IBM Spectrum Protect server documentation.

Rebind backup versions of files

Rebinding associates a file or a logical volume image with a new management class.

Backups of files are bound again to a different management class in the following conditions. In each condition, the files (active and inactive) are not bound again until the next backup.

- You specify a different management class in an Include statement to change the management class for the file. The backups are managed based on the old management class until you run another backup.

- Your administrator deletes the management class from your active policy set. The default management class is used to manage the backup versions when you back up the file again.
- Your administrator assigns your client node to a different policy domain and the active policy set in that domain does not have a management class with the same name. The default management class for the new policy domain is used to manage the backup versions.

For information about how to associate files and directories with management classes, see the IBM Spectrum Protect™ server documentation.

Retention grace period

IBM Spectrum Protect™ also provides a *backup retention grace period* and an *archive retention grace period* to help protect your backup and archive data when it is unable to rebind a file to an appropriate management class.

The backup retention grace period is in the following cases:

- You change the management class for a file, but neither the default management class nor the new management class contain a backup copy group.
- The management class to which a file is bound no longer exists, and the default management class does not contain a backup copy group.

The backup retention grace period, defined in your policy domain, starts when you run an incremental backup. The default is 30 days. However, your administrator can lengthen or shorten this period.

When the IBM Spectrum Protect server manages a file using the backup retention grace period, it does not create any new backup versions of the file. All existing backup versions of the file expire 30 days (or the number of days specified in your policy domain) from the day they are marked inactive.

Archive copies are never rebound because each archive operation creates a different archive copy. Archive copies remain bound to the management class name specified when the user archived them. If the management class to which an archive copy is bound no longer exists or no longer contains an archive copy group, the server uses the default management class. If you later change or replace the default management class, the server uses the updated default management class to manage the archive copy. If the default management class does not contain an archive copy group, the server uses the archive retention grace period specified for the policy domain.

Event-based policy retention protection

All management classes with an archive copy group must specify a retention period, for example, the number of days that an archived object is stored on the server before being deleted.

Event-based policy provides the option of beginning the retention period either at the time the object is archived or at a later date when an activation event is sent to the server for that object.

Setting the copy group value `RETINIT=CREATE` starts the data retention period when the file is archived. Using the copy group value `RETINIT=EVENT` starts the data retention period when the server is notified that the event has occurred.

The following example demonstrates this concept:

The user has two files, create.file and event.file. The user has available two management classes; CREATE, with `RETINIT=CREATE`, and EVENT, with `RETINIT=EVENT`. Both management classes have a 60-day retention period. The user, on the same day, archives both files:

```
dsmc archive create.file -archmc=CREATE
dsmc archive event.file -archmc=EVENT
```

Ten days later, the user issues the set event `-type=hold` command for the create.file file, so the file cannot be deleted. On the same day the user issues the set event `-type=activate` for the event.file file. At this time, create.file has 50 days left on its retention period, and event.file has 60 days. If no other action is taken, `create.file` remains on the server forever, and event.file is expired 70 days after it was created (60 days after its event occurred). However, if 20 days after the initial archive, the user issues set event *-type=release* for the create.file file. Thirty days of its retention period have passed, so the file is expired in 30 days (the hold does not extend the retention period).

For information about the RETINIT copy group value, see the IBM Spectrum Protect™ server documentation.

- Archive files on a data retention server
  Up to this point, there is no difference between archiving files on a normal server or a data retention server.

Archive and retrieve data with backup-archive clients

Reading syntax diagrams

To read a syntax diagram for entering a command, follow the path of the line. Read from left to right and from top to bottom.

- The ►►——— symbol indicates the beginning of a syntax diagram.
- The ———► symbol at the end of a line indicates that the syntax diagram continues on the next line.
- The ►——— symbol at the beginning of a line indicates that a syntax diagram continues from the previous line.
- The ———►◄ symbol indicates the end of a syntax diagram.

Syntax items, such as a keyword or a variable, can be:

- On the line (required element)
- Above the line (default element)
- Below the line (optional element)

Symbols

Enter these symbols *exactly* as they appear in the syntax diagram.

- * Asterisk
- *{ }* Braces
- *:* Colon
- , Comma
- = Equal Sign
- - Hyphen
- *()* Parentheses
- . Period
- Space
- " quotation mark

- 'single quotation mark

Variables

Italicized lowercase items such as *<var_name>* indicate variables. In this example, you can specify a *<var_name>* when you enter the **cmd_name** command.

```
>>-cmd_name--<var_name>-----------------------------------------><
```

Repetition

An arrow returning to the left means that the item can be repeated. A character within the arrow means that you must separate repeated items with that character.

```
   .-,------.
   V        |
>>---repeat-+-------------------------------------------------><
```

A footnote (1) by the arrow refers to a limit that tells how many times the item can be repeated.

```
   .-,------------.
   V  (1)         |
>>---------repeat-+-----------------------------------------><
```

Notes:

1. Specify repeat up to 5 times.

Required choices

When two or more items are in a stack and one of them is on the line, you *must* specify one item.

In this example, you must choose A, B, or C.

```
>>-cmd_name--+-A-+-----------------------------------------><
             +-B-+
             '-C-'
```

Optional choices

When an item is *below* the line, that item is optional. In the first example, you can select A or nothing at all.

```
>>-cmd_name--+---+-----------------------------------------><
             '-A-'
```

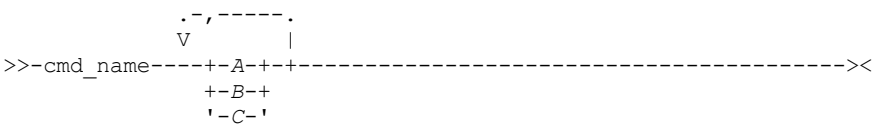
When two or more items are in a stack below the line, all of them are optional. In the second example, you can choose A, B, C, or nothing at all.

```
>>-cmd_name--+---+-----------------------------------------><
             +-A-+
             +-B-+
             '-C-'
```

Repeatable choices

A stack of items followed by an arrow returning to the left indicates that you can select more than one item, or in some cases, repeat a single item.

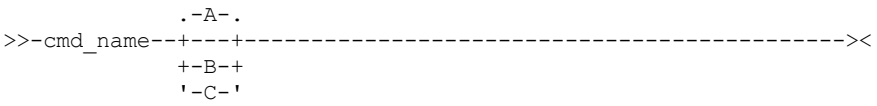
In this example, you can select any combination of A, B, or C.



Defaults

Defaults are above the line. The default is selected unless you override it, or you can select the default explicitly. To override the default, include an option from the stack below the line.

In this example, A is the default. Select either B or C to override A.



Processing options

You can use defaults for processing client options or you can tailor the processing options to meet your specific needs. Read about an overview of processing options and explore the options reference that provides detailed information about each option.

- Processing options overview

Processing options overview

IBM Spectrum Protect™ uses *processing options* to control communications, backup-archive processing, and other types of processing.

Windows You can specify processing options in the client options file (dsm.opt) or on the command line.

AIX Linux Solaris Mac OS X You can specify processing options in the client system-options file (dsm.sys), client user-options file (dsm.opt), or on the command line.

You can set the following types of options:

- Communication options
- Windows Node options
- AIX Linux Solaris Mac OS X Server and node options
- Backup and archive processing options
- Restore and retrieve processing options
- Scheduling options
- Windows Format and language options
- AIX Linux Solaris Mac OS X Format options
- Command processing options
- Authorization options
- Error processing options
- Transaction processing option
- Web client options
- Diagnostics options

The backup-archive client also includes a group of client command options that you can enter only on the command line with specific commands. You can override some of the options in your options file by entering them with appropriate backup-archive commands.

Windows Note: Some of the processing options that are used by the IBM Spectrum Protect central scheduler are defined in the Windows registry when the schedule services are configured. These options can also be specified in the client options file. When the scheduler runs as a service, processing options that are specified in the registry override the same options that are specified in the client options file.

Communication options

You use communication options to specify how your client node communicates with the IBM Spectrum Protect™ server. This topic provides information about the types of communication options you can use.

AIX Linux Mac OS X Solaris For UNIX and Linux use one of the following communication protocols:

- TCP/IP
- AIX Linux Shared memory (AIX®, Linux)

Windows For all Windows clients, use one of the following protocols:

Windows

- TCP/IP
- Named pipes
- Shared memory

AIX Linux Solaris Mac OS X Windows Use the commmethod option to specify the communication protocol.

Ask your IBM Spectrum Protect administrator for assistance in setting your communication options.

- TCP/IP options
  To use the TCP/IP communication protocol, you must include the tcpserveraddress option in your client options file.
- Windows Named Pipes option
  This topic provides information about the namedpipename communication option.
- AIX Linux Solaris Mac OS X Windows Shared memory options
  This topic provides information on the shared memory options that you can use.

Related reference:
Commmethod

TCP/IP options

To use the TCP/IP communication protocol, you must include the tcpserveraddress option in your client options file.

The other TCP/IP options have default values that you can modify if you want to change the default value. This topic provides information about the types of communication options you can use.

Table 1. TCP/IP options

Option	Description
httpport	Specifies a TCP/IP port address for the web client.
lanfreetcpport	Specifies the TCP/IP port number where the IBM Spectrum Protect™ storage agent is listening.
lanfreetcpserveraddress	Specifies the TCP/IP address for the IBM Spectrum Protect storage agent.
tcpbuffsize	Specifies the size, in kilobytes, of the internal TCP/IP communication buffer.
Windows tcpnodelay	Windows Specifies whether the server or client disables the delay of sending successive small packets on the network.
AIX Linux Solaris Mac OS X tcpnodelay	AIX Linux Solaris Mac OS X Specifies whether the server or client disables the delay of sending successive small packets on the network. This option is for all UNIX clients.
tcpadminport	Specifies a separate TCP/IP port number on which the server is waiting for requests for administrative client sessions, allowing secure administrative sessions within a private network.
tcpcadaddress	Specifies a TCP/IP address for dsmcad.
tcpport	Specifies the TCP/IP port address for an IBM Spectrum Protect server.
tcpserveraddress	Specifies the TCP/IP address for an IBM Spectrum Protect server.
tcpwindowsize	Specifies the size, in kilobytes, of the TCP/IP sliding window for your client node.
AIX Linux Solaris Mac OS X webports	AIX Linux Solaris Mac OS X Enables the use of the web client outside a firewall by specifying the TCP/IP port number used by the client acceptor daemon and the web client agent service (web client agent service does not apply to Mac OS X) for communications with the web GUI.
Windows webports	Windows Enables the use of the web client outside a firewall by specifying the TCP/IP port number used by the client acceptor service and the web client agent service for communications with the web GUI.

Windows

Named Pipes option

This topic provides information about the namedpipename communication option.

Table 1. Named Pipes communication option

Option	Description
namedpipename Namedpipename	Specifies the name of a named pipe to use for communications between a client and IBM Spectrum Protect™ server on the same Windows server domain.

AIX | Linux | Solaris | Mac OS X | Windows

Shared memory options

This topic provides information on the shared memory options that you can use.

Table 1. Shared memory communication options

Option	Description
lanfreeshmport Lanfreeshmport	Specifies the unique number that is used by the client and the storage agent to identify shared memory area used for communications.
lanfreeshmport Shmport	Specifies the unique number that is used by the client and the server to identify shared memory area used for communications.

AIX | Linux | Solaris | Mac OS X

Server options

Use the servername option in your dsm.sys file to begin a group of options (stanzas) used to connect to the IBM Spectrum Protect™ server.

You can set up multiple groups of stanzas in the dsm.sys file to connect to different servers. Each servername stanza must have listed below it all client option stanzas required to establish communication with a server. The stanza list can also contain other options for backup-archive operations.

If your client system-options file contains only one stanza - Your client node contacts the server you specify in that stanza for all services.

If your client system-options file contains more than one stanza - You can specify a default server with the defaultserver option. If you do not specify a default server, IBM Spectrum Protect contacts the server you specify in the first stanza of your dsm.sys file.

Place the defaultserver option at the beginning of your dsm.sys file before any server stanzas. See Defaultserver for more information.

Use the servername option in the client user-options file (dsm.opt) or on the command line to specify a server to contact for backup-archive services. This overrides the default server specified in your (`dsm.sys`) file.

Note: You cannot override the migration server specified in the client system-options file.

Table 1 shows a sample dsm.sys file.

Backup and archive processing options

You can specify client options to control some aspects of backup and archive processing.

Table 1. Backup and archive processing options

Option	Description
AIX Linux afmskipuncachedfiles	AIX Linux Use the afmskipuncachedfiles option to specify whether uncached and dirty files in General Parallel File System (GPFS™) Active File Management file sets are processed for backup, archive, and migration operations.
archmc	Use the archmc option with the archive command to specify the available management class for your policy domain to which you want to bind your archived files.
AIX Linux Solaris Mac OS X archsymlinkasfile	AIX Linux Solaris Mac OS X Specifies whether you want the client to follow a symbolic link and archive the file or directory to which it points, or archive the symbolic link only.
asnodename	Use the asnodename option to allow agent nodes to back up or restore data on behalf of another node (the target node). This option enables concurrent operations from multiple nodes to store data to the same target node and file space in parallel.
AIX Linux Solaris Mac OS X automount	AIX Linux Solaris Mac OS X Use this option with the domain option to specify all automounted file systems that the client tries to mount at the following points in time: • When the backup-archive client starts • When the backup is started • When the backup-archive client reaches an automounted file system during backup
autofsrename	Specifies whether to rename an existing file space on a Unicode-enabled server so a Unicode-enabled file space can be created for the current operation.
Windows backmc	Windows Specifies the management class to apply to the backup fastback subcommand for retention purposes.

Option	Description
changingretries	Specifies the number of times the client attempts to back up or archive a file that is in use.
Windows class	Windows Specifies whether to list the NAS or client Application Server objects during a query backup, query filespace, or delete filespace operation.
compressalways	The compressalways option specifies whether to continue compressing an object if it grows during compression. Use this option with the compression option.
compression	The compression option compresses files before you send them to the server. Compressing your files reduces data storage for backup versions and archive copies of your files.
AIX Linux Windows createnewbase Createnewbase	AIX Linux Windows The createnewbase option creates a base snapshot and uses it as a source to run a full incremental. Setting this option ensures the backup of any files that might have been skipped during the snapshot difference incremental.
deduplication Deduplication	Specifies whether to eliminate redundant data on the client side when the client transfers data to theIBM Spectrum Protect server during backup or archive processing.
dedupcachepath Dedupcachepath	Specifies the location where the client-side data deduplication cache database is created, if the enablededupcache=yes option is set during backup or archive processing.
dedupcachesize Dedupcachesize	Determines the maximum size of the data deduplication cache file.
enablededupcache Enablededupcache	Specifies whether you want to enable client-side data deduplication cache, so that the backup-archive client gets the changed data from the cache.
deletefiles	Use the deletefiles option with the archive command to delete files from your workstation after you archive them. AIX Linux Solaris Windows You can also use this option with the restore image command and the incremental option to delete files from the restored image if they were deleted after the image was created.
description	The description option assigns or specifies a description for files when the client performs archive, delete, retrieve, query archive, or query backupset operations.
detail	Use the detail option to list management class, file space, backup, and archive information, depending on the command with which it is used.
Linux AIX Windows diffsnapshot	Linux AIX Windows Use the diffsnapshot option to determine whether the client creates a differential snapshot.
dirmc	Specifies the management class to use for directories. If you do not specify this option, the client uses the management class in the active policy set of your policy domain with the longest retention period.

Option	Description
dirsonly	Backs up, restores, archives, retrieves, or queries directories only.
diskcachelocation	Specifies the location where the disk cache database is created if the option memoryefficient=diskcachemethod option is set during an incremental backup.
AIX Linux Solaris Mac OS X domain	AIX Linux Solaris Mac OS X Specifies the file systems to include in your default client domain for an incremental backup.
Windows domain	Windows Specifies the drives to include in your default client domain for an incremental backup.
AIX Linux Solaris domain.image	AIX Linux Solaris Specifies the mounted file systems and raw logical volumes that you want to include in your client domain for an image backup. This option is for AIX®, Linux x86_64, Linux on POWER®, and Solaris only.
Windows domain.image	Windows Specifies the file systems and raw logical volumes that you want to include in your client domain for an image backup. This option is valid for Windows clients.
AIX Solaris Windows domain.nas	AIX Solaris Windows Specifies the volumes to include in your default domain for NAS image backups.
Linux Windows domain.vmfull Domain.vmfull	Linux Windows Specifies the virtual machines to include in full image backups of VMware virtual machines.
AIX efsdecrypt	AIX Specifies whether files encrypted by an AIX Encrypted File System (EFS) are read in encrypted or decrypted format.
enablearchiveretentionprotection	Allows the client to connect to a data retention server.
AIX Linux Solaris Windows enablelanfree Enablelanfree	AIX Linux Solaris Windows Specifies whether to enable an available LAN-free path to a storage area network (SAN) attached storage device.
Windows exclude exclude.backup exclude.file exclude.file.backup	Windows Use these options to exclude a file or group of files from backup services.
AIX Linux Solaris Mac OS X exclude exclude.backup exclude.file exclude.file.backup	AIX Linux Solaris Mac OS X Use these options to exclude a file or group of files from backup services and space management services (if the HSM client is installed). The exclude.backup option excludes only files from normal backup, but not from HSM.
encryptiontype	Select AES-256 or AES-128 bit data encryption. AES 256-bit data encryption provides the highest level of data encryption.
encryptkey	Specifies whether to save the encryption key password locally when the client performs a backup-archive operation or whether to prompt for the encryption key password.

Option	Description
exclude.archive	Excludes a file or a group of files that match the pattern from archive services only.
AIX Linux Solaris Mac OS X exclude.attribute.symlink	AIX Linux Solaris Mac OS X Excludes a file or a group of files that are symbolic links or aliases (aliases apply to Mac OS X) from backup processing only.
exclude.compression	Excludes files from compression processing if you set the compression option to *yes*. This option applies to backups and archives.
exclude.dir	Excludes a directory, its files, and all its subdirectories and their files from backup processing.
exclude.encrypt	Excludes specified files from encryption processing.
AIX Linux Solaris Mac OS X exclude.fs	AIX Linux Solaris Mac OS X Excludes file spaces that match a pattern. This option is valid for all UNIX clients.
AIX Solaris exclude.fs.nas	AIX Solaris Excludes file systems on the NAS file server from an image backup when used with the backup nas command. This option is for AIX and Solaris clients only.
Windows exclude.fs.nas	Windows Excludes file systems on the NAS file server from an image backup when used with the backup nas command.
AIX Linux Solaris exclude.image	AIX Linux Solaris Excludes mounted file systems and raw logical volumes that match the specified pattern from full image backup operations. This option is valid only for AIX, Solaris, and all Linux clients.
Windows exclude.image	Windows Excludes mounted file systems and raw logical volumes that match the specified pattern from full image backup operations. Incremental image backup operations are unaffected by exclude.image.
Linux Windows fbbranch	Linux Windows Specifies the branch ID of the remote FastBack server to back up or archive.
Linux Windows fbclientname	Linux Windows Specifies the name of one or more FastBack clients to back up from the backup proxy.
Linux Windows fbpolicyname	Linux Windows Specifies the name of one or more Tivoli® Storage Manager FastBack policies that you want to back up from the backup proxy.
Linux Windows fbreposlocation	Linux Windows Specifies the location of the Tivoli Storage Manager FastBack repository for the IBM Spectrum Protect client proxy to connect to issue MOUNT DUMP, MOUNT ADD, and MOUNT DEL commands.
Linux Windows fbserver	Linux Windows Specifies host name of the FastBack server workstation or the FastBack Disaster Recovery Hub workstation that owns the repository that is specified by the fbreposlocation option.
Linux Windows fbvolumename	Linux Windows Specifies the name of one or more Tivoli Storage Manager FastBack volumes to back up from the backup proxy.

Option	Description
filelist	Specifies a list of files to be processed for the command. The client opens the designated file list and processes the files that are listed within according to the command.
filesonly	Backs up, restores, retrieves, or queries files only.
groupname	Use this option with the backup group command to specify the fully qualified name of the group leader for a group.
ieobjtype Ieobjtype	Specifies an object type for a client-side data deduplication operation. This option is used with the include.dedup and exclude.dedup options.
AIX imagegapsize	AIX Specifies the minimum size of empty regions on a volume that you want to skip during image backup. This option is valid for AIX JFS2 clients.
Windows imagegapsize	Windows Specifies the minimum size of empty regions on a volume that you want to skip during backup. This option is valid for all Windows clients.
inclexcl	Specifies the path and file name of an include-exclude options file.
include include.backup include.file	Use these options to include files or assign management classes for backup processing.
include.archive	Includes files or assigns management classes for archive processing.
AIX Linux Solaris Mac OS X include.attribute.symlink	AIX Linux Solaris Mac OS X Includes a file or a group of files that are symbolic links or aliases (aliases apply to Mac OS X) within broad group of excluded files for backup processing only.
include.compression	Includes files for compression processing if you set the compression option to *yes*. This option applies to backups and archives.
include.encrypt	Includes the specified files for encryption processing. By default, the client does not perform encryption processing.
AIX Linux Solaris Mac OS X include.fs	AIX Linux Solaris Mac OS X Use the include.fs option to control how the client processes your file space for incremental backup.
Windows include.fs	Windows Use the include.fs option to specify processing options for a file system. Use the include.fs option to specify which drives use open file support and to control how full file space incremental backups are processed.
AIX Solaris include.fs.nas	AIX Solaris Use the include.fs.nas option to bind a management class to Network Attached Storage (NAS) file systems. You can also specify whether the client saves Table of Contents (TOC) information during a NAS file system image backup by using the toc option with the include.fs.nas option in your dsm.sys file. For more information, see Toc. This option is valid for AIX and Solaris clients only.

Option	Description
Windows include.fs.nas	Windows Use the include.fs.nas option to bind a management class to Network Attached Storage (NAS) file systems. You can also specify whether the client saves Table of Contents (TOC) information during a NAS file system image backup, by using the toc option with the include.fs.nas option in your client options file (dsm.opt). For more information, see Toc.
AIX Linux Solaris include.image	AIX Linux Solaris Specifies a file system or logical volume to be included for image backup processing. This option also provides a way to specify an explicit management class assignment for a specified file system or logical volume. The backup image command ignores all other include options .This option is valid for AIX, Solaris, and all Linux clients.
Windows include.image	Windows Specifies a file system or logical volume to be included for image backup processing. This option also provides a way to specify an explicit management class assignment for a specified file system or logical volume. The backup image command ignores all other include options. Use the include.fs option to specify which drives use open file support and to control how full file space incremental backups are processed.
Windows include.systemstate	Windows Assigns management classes for backup of the Windows system state. The default is to bind the system object to the default management class.
incrbydate	Use with the incremental command to request an incremental backup by date.
AIX Linux Solaris incremental	AIX Linux Solaris Use with the restore image command to ensure that any changes that were made to the base image are also applied to the restored image. This option is valid for AIX, Solaris, and all Linux clients.
Windows incremental	Windows Use with the restore image command to ensure that any changes that were made to the base image are also applied to the restored image.
Windows incrthreshold	Windows The incrthreshold option specifies the threshold value for the number of directories in any journaled file space that might have active objects on the server, but no equivalent object on the workstation.
memoryefficientbackup	Specifies a memory-saving backup algorithm for incremental backups when used with the incremental command.

Option	Description
mode	Use the mode option with these commands, as follows: AIX Linux Solaris Windows backup image AIX Linux Solaris Windows To specify whether to perform a selective or incremental image backup of client file systems. AIX Solaris Windows backup nas AIX Solaris Windows To specify whether to perform a full or differential image backup of NAS file systems. backup group To specify whether to perform a full or differential group backup that contains a list of files from one or more file space origins. Linux backup vm Linux To specify whether to perform a selective or incremental backup of VMware systems. Windows backup vm Windows To specify whether to perform a full or incremental backup of a VMware virtual machine when vmbackuptype=fullvm, and when you have installed IBM Spectrum Protect for Virtual Environments.
AIX Solaris Windows monitor	AIX Solaris Windows Specifies whether you want to monitor an image backup of file systems that belong to a Network Attached Storage (NAS) file server.
Mac OS X noprompt	Mac OS X Suppresses the confirmation prompt that is presented by the delete group, delete archive, expire, and set event commands.
AIX Linux Solaris Windows noprompt	AIX Linux Solaris Windows Suppresses the confirmation prompt that is presented by the delete group, delete archive, expire, restore image, and set event commands.
AIX Linux nojournal	AIX Linux Use this option with the incremental command to specify that you want to perform the traditional full incremental backup, instead of the default journal-based backup.
Windows nojournal	Windows Use this option with the incremental command to specify that you want to perform the traditional full incremental backup, instead of the default journal-based backup.
Windows optfile	Windows Specifies the client options file you want to use when you start a backup-archive client session.
AIX Linux Solaris Mac OS X optfile	AIX Linux Solaris Mac OS X Specifies the client user-options file that you want to use when you start a backup-archive client session.
AIX Linux postsnapshotcmd	AIX Linux During a snapshot-based backup, this option allows you to manually open an application after the snapshot is created. This option is valid only for AIX JFS2 or Linux LVM snapshot-based operations.

Option	Description
Windows postsnapshotcmd	Windows During an online image backup or open file support operation, this option allows you to manually open an application after the snapshot provider starts a snapshot. This option is only valid if the OFS or online image support is enabled.
AIX Linux Solaris Windows preservelastaccessdate	AIX Linux Solaris Windows Use this option during a backup or archive operation to specify whether to reset the last access date of any specified files to their original value after a backup or archive operation. By default, the client does not reset the last access date of any backed up or archived files to their original value before the backup or archive operation.
AIX Linux presnapshotcmd	AIX Linux During a snapshot-based backup operation, this option allows you to manually quiesce an application before the snapshot is created. This option is valid only for AIX JFS2 or Linux LVM snapshot-based operations.
Windows presnapshotcmd	Windows During an online image backup or open file support operation, this option allows you to manually quiesce an application before the snapshot provider starts a snapshot. This option is only valid if the OFS or online image support is enabled.
AIX Linux Solaris Mac OS X removeoperandlimit	AIX Linux Solaris Mac OS X Specifies that the client removes the 20-operand limit. If you specify the removeoperandlimit option with the incremental, selective, or archive commands, the 20-operand limit is not enforced and is restricted only by available resources or other operating system limits.
Windows resetarchiveattribute	Windows Specifies whether the client resets the Windows archive attribute on files that are successfully backed up to the IBM Spectrum Protect server. This option is valid for all Windows clients.
AIX Linux Solaris Mac OS X skipacl	AIX Linux Solaris Mac OS X Specifies whether to skip ACL processing completely.
AIX Linux Solaris Mac OS X skipaclupdatecheck	AIX Linux Solaris Mac OS X Specifies whether to perform checksum and size comparisons before and after backup and during incremental processing.
Windows skipntpermissions	Windows Specifies whether to back up, archive, retrieve, or restore Windows security information.
Windows skipntsecuritycrc	Windows Specifies whether to compute the security CRC for permission comparison during subsequent backups. Use this option on all Windows clients.
AIX Linux Windows snapdiff	AIX Linux Windows Specifies an incremental backup of the files reported as changed by NetApp, instead of scanning the volume and looking for files that have changed. Use this option with a NAS full volume incremental backup.

Option	Description
AIX Linux snapshotcachesize	AIX Linux Linux and AIX only: Use this option to specify an appropriate snapshot size so that all original data blocks can be stored during file modification and deletion. A snapshot size of 100 percent ensures a valid snapshot. The default value is 100 percent.
AIX snapshotproviderfs	AIX Use the snapshotproviderfs option to enable snapshot-based file backup and archive operations, and to specify a snapshot provider. You must be a root user to perform a snapshot-based file backup or archive operation. If you are not a root user, the operation fails with an error message.
Windows snapshotproviderfs	Windows Use the snapshotproviderfs option to enable snapshot-based file backup and archive operations, and to specify a snapshot provider.
AIX Linux Solaris snapshotproviderimage	AIX Linux Solaris Use the snapshotproviderimage option to enable snapshot-based image backup, and to specify a snapshot provider. You must be a root user to perform a snapshot-based image backup operation. If you are not a root user, the operation fails with an error message.
Windows snapshotproviderimage	Windows Use the snapshotproviderimage option to enable snapshot-based online image backup, and to specify a snapshot provider.
Windows snapshotroot	Windows Use the snapshotroot option with the incremental, selective, or archive commands with an independent software vendor application that provides a snapshot of a logical volume, to associate the data on the local snapshot with the real file space data that is stored on the IBM Spectrum Protect server.
AIX Linux Solaris Mac OS X snapshotroot	AIX Linux Solaris Mac OS X Use the snapshotroot option with the incremental, selective, or archive commands with an independent software vendor application that provides a snapshot of a logical volume, to associate the data on the local snapshot with the real file space data that is stored on the IBM Spectrum Protect server. This option is valid for all UNIX and Linux clients.
subdir	Specifies whether to include subdirectories of a named directory.
tapeprompt	Specifies whether you want the client to wait for a tape mount if it is required for a backup, archive, restore, or retrieve process, or to be prompted for a choice.
AIX Solaris Windows toc	AIX Solaris Windows Use the toc option with the backup nas command or the include.fs.nas option to specify whether the client saves Table of Contents (TOC) information for each file system backup. If you save TOC information, you can use the QUERY TOC server command to determine the contents of a file system backup with the RESTORE NODE server command to restore individual files or directory trees. You can also use the web client to examine the entire file system tree and select files and directories to restore.

Option	Description
type	Use the type option with the query node command to specify the type of node to query.
v2archive	Use the v2archive option with the archive command to archive only files to the server. The client does not process directories that exist in the path of the source file specification.
virtualfsname (does not apply to Mac OS X)	Use this option with the backup group command to specify the name of the container for the group on which you want to perform the operation.
AIX Linux Solaris virtualmountpoint	AIX Linux Solaris Defines a virtual mount point for a file system if you want to consider files for backup that begin with a specific directory within that file system.
Linux Windows vmchost	Linux Windows Used with the backup VM, restore VM, or query VM commands to specify the host name of the VMware VirtualCenter or ESX server where the commands are directed.
Linux Windows vmcpw	Linux Windows Used with the backup VM, restore VM, or query VM commands to specify the password of the VirtualCenter or ESX user that is specified with the vmcuser option.
Linux Windows vmcuser	Linux Windows Used with the backup VM, restore VM, or query VM commands to specify the user name for the VMware VirtualCenter or ESX server where the commands are directed.
Linux Windows vmmaxvirtualdisks	Linux Windows Used with the backup VM command to specify the maximum size of the VMware virtual machine disks (VMDKs) to include in a backup operation.
Linux Windows vmskipmaxvirtualdisks	Linux Windows Used with the backup VM command to specify how the backup operation processes VMware virtual machine disks (VMDKs) that exceed the maximum disk size. In V7.1.3 and earlier, the vmskipmaxvirtualdisks option was named vmskipmaxvmdks.
Linux Windows	Linux Windows

Windows The following options are backup-archive client options that apply only to IBM Spectrum Protect HSM for Windows migrated files.

Windows

- Restorecheckstubaccess
- Restoremigstate
- Skipmigrated

Related concepts:
Windows Options for backing up migrated files: skipmigrated, checkreparsecontent, stagingdirectory
Windows Options for restoring migrated files: restorecheckstubaccess, restoremigstate

Restore and retrieve processing options

You can use client options to control some aspects of restore and retrieve processing.

Table 1 lists the restore and retrieve processing options that are available.

Table 1. Restore and retrieve processing options

Option	Description
Windows asrmode	Windows Use this option with the restore, and restore systemstate commands to specify whether to perform a restore operation in system ASR recovery mode. This option is used in the context of restore commands that are generated in the asr.sif file by the backup asr command only. Do not use this option outside the context of ASR recovery mode.
Windows backupsetname	Windows The backupsetname option specifies either the name of the backup set, or the name of the file or tape device that contains the backup set. This option is used with the location option.
dirsonly	Qualifies the operation (backup, archive, restore, retrieve) to process directories alone.
disablenqr	Specifies whether the backup-archive client can use the no-query restore method for restoring files and directories from the server.
filelist	Specifies a file that contains a list of files to be processed by the specified command.
filesonly	Qualifies the operation (backup, archive, restore, retrieve) to process files alone.
AIX Linux Solaris Mac OS X followsymbolic	AIX Linux Solaris Mac OS X Specifies whether you want to restore files to symbolic links or use a symbolic link as a virtual mount point.
fromdate	Use the fromdate option with the fromtime option to specify a date and time from which you want to search for backups or archives during a restore, retrieve, or query operation.
fromnode	Permits one node to perform commands for another node. A user on another node must use the set access command to give you permission to query, restore, or retrieve files or images for the other node.
AIX Linux Solaris Mac OS X fromowner	AIX Linux Solaris Mac OS X Displays file spaces for an alternative owner. Also specifies an alternative owner from which to restore or retrieve files.
fromtime	Use the fromtime option with the fromdate option to specify a beginning time from which you want to search for backups or archives during a restore, retrieve, or query operation.
ifnewer	Replaces an existing file with the latest backup version only if the backup version is newer than the existing file.
AIX Linux Solaris imagetofile	AIX Linux Solaris Use the imagetofile option with the restore image command to specify that you want to restore the source image to a file. You might need to restore the image to a file in the event of bad sectors present on the target volume, or if you want to do some manipulations with the image data. This option is valid for AIX®, Linux, and Solaris clients.
Windows imagetofile	Windows Use the imagetofile option with the restore image command to specify that you want to restore the source image to a file. You might need to restore the image to a file in the event of bad sectors present on the target volume, or if you want to do some manipulations with the image data.
inactive	Displays a list of active and inactive files when used with the pick option.
latest	Restores the most recent backup version of a file whether it is active or inactive.
localbackupset	Specifies whether the backup-archive client GUI bypasses initial logon with the server to restore a local backup set on a stand-alone workstation.

Option	Description
AIX Linux Solaris makesparsefile (does not apply to Mac OS X)	AIX Linux Solaris Use the makesparsefile option with the restore or retrieve commands to specify how sparse files are re-created.
AIX Linux Solaris Windows monitor	AIX Linux Solaris Windows Specifies whether you want to monitor an image restore of one or more file systems that belong to a network-attached storage (NAS) file server.
Mac OS X noprompt	Mac OS X suppresses the confirmation prompt that is presented by the delete group, delete archive, expire, and set event commands.
AIX Linux Solaris Windows noprompt	AIX Linux Solaris Windows suppresses the confirmation prompt that is presented by the delete group, delete archive, expire, restore image, and set event commands.
Windows optfile	Windows Specifies the client options file you want to use when you start a backup-archive client session.
AIX Linux Solaris Mac OS X optfile	AIX Linux Solaris Mac OS X Specifies the client user-options file that you want to use when you start a backup-archive client session.
pick	Creates a list of backup versions, images, or archive copies that match the file specification you enter. From the list, you can select the versions to process. Include the inactive option to view both active and inactive objects.
pitdate	Use the pitdate option with the pittime option to establish a point in time for which you want to display or restore the latest version of your backups.
pittime	Use the pittime option with the pitdate option to establish a point in time for which you want to display or restore the latest version of your backups.
preservepath	Specifies how much of the source path to reproduce as part of the target directory path when you restore or retrieve files to a new location.
replace	Specifies whether to overwrite an existing file, or to prompt you for your selection when you restore or retrieve files.
AIX Linux Solaris Windows showmembers (does not apply to Mac OS X)	AIX Linux Solaris Windows Displays all members of a group.
subdir	Specifies whether you want to include subdirectories of a named directory.
tapeprompt	Specifies whether you want the backup-archive client to wait for a tape that is required for a restore or retrieve to be mounted, or to prompt you for your choice.
todate	Use the todate option with the totime option to specify an ending date and time to which you want to search for backups or archives during a restore, retrieve, or query operation.
totime	Use the totime option with the todate option to specify an ending date and time to which you want to search for backups or archives during a restore, retrieve, or query operation.
type	Use the type option with the query node command to specify the type of node to query.
AIX Linux Solaris verifyimage	AIX Linux Solaris Use the verifyimage option with the restore image command to specify that you want to enable detection of bad sectors on the destination target volume. If bad sectors are detected on the target volume, the client issues a warning message on the console and in the error log.

Option	Description
Windows verifyimage	Windows Use the verifyimage option with the restore image command to specify that you want to enable detection of bad sectors on the destination target volume. If bad sectors are detected on the target volume, the client issues a warning message on the console and in the error log.

The following options are backup-archive client options that apply to IBM Spectrum Protect™ HSM for Windows migrated files. For more information about these options, see the IBM® Knowledge Center topics at http://www.ibm.com/support/knowledgecenter/SSERFH_8.1.2/hsmwin/welcome.html.

- Checkreparsecontent
- Restorecheckstubaccess
- Restoremigstate
- Skipmigrated

The following options are backup-archive client options that apply to IBM Spectrum Protect for Space Management migrated files. For more information about these options, see the IBM Knowledge Center topics at http://www.ibm.com/support/knowledgecenter/SSERBH_8.1.2/hsmul/welcome.html.

- Restoremigstate
- Skipmigrated

Scheduling options

This topic discusses the options that you can use to regulate central scheduling. The backup-archive client uses scheduling options only when the Scheduler is running.

Table 1 lists the scheduling options that are available.

Table 1. Scheduling options

Option	Description
cadlistenonport	Specifies whether to open listening ports for the client acceptor when the client acceptor is used to manage schedules in polling mode.
managedservices	Specifies whether the client acceptor manages the web client, the scheduler, or both.
maxcmdretries	Specifies the maximum number of times the client scheduler attempts to process a scheduled command that fails.
Mac OS X AIX Linux Solaris Mac OS X Windows postschedulecmd/postnschedulecmd	Mac OS X AIX Linux Solaris Mac OS X Windows Specifies a command to process after running a schedule.
Mac OS X AIX Linux Solaris Mac OS X Windows preschedulecmd/prenschedulecmd	Mac OS X AIX Linux Solaris Mac OS X Windows Specifies a command to process before running a schedule.
queryschedperiod	Specifies the number of hours the client scheduler waits between attempts to contact the server for scheduled work.
retryperiod	Specifies the number of minutes the client scheduler waits between attempts to process a scheduled command that fails or between unsuccessful attempts to report results to the server.
Windows runasservice	Windows Forces the client command process to continue running, even if the account that started the client logs off. Use this option on all Windows clients.
schedcmddisabled	Specifies whether to disable the scheduling of generic commands specified by your IBM Spectrum Protect™ administrator.

Option	Description
AIX Linux Solaris Mac OS X schedcmduser (server defined only)	AIX Linux Solaris Mac OS X The scheduler executes commands under a uid of 0, however, there might be some users who have a different user ID. In this case, your IBM Spectrum Protect administrator can define schedules and allow these schedules to be executed under a uid other than 0, using this option. The IBM Spectrum Protect Client API does not support this option.
schedlogmax Schedlogmax	Specifies the maximum size of the scheduler log and web client log, in megabytes.
schedlogname Schedlogname	Specifies the path and file name where you want to store schedule log information.
schedlogretention	Specifies the number of days to keep log file entries in the schedule log and the web client log, and whether to save pruned entries.
schedmode	Specifies which schedule mode to use, *polling* or *prompted*.
schedrestretrdisabled	Specifies whether to prevent the IBM Spectrum Protect Server administrator from executing restore or retrieve schedule operations.
sessioninitiation	Use the sessioninitiation option to control whether the server or client initiates sessions through a firewall. The default is that the client can initiate sessions.
srvprepostscheddisabled	Specifies whether to prevent the IBM Spectrum Protect Server administrator from executing pre-schedule and post-schedule commands when performing scheduled operations.
AIX Linux Solaris Windows srvprepostsnapdisabled	AIX Linux Solaris Windows Specifies whether to prevent the IBM Spectrum Protect Server administrator from executing pre-snapshot and post-snapshot commands when performing scheduled image snapshot backup operations.
tcpclientaddress	Specifies a TCP/IP address if your client node has more than one address, and you want the server to contact an address other than the one that was used to make the first server contact. The server uses this address when it begins the server prompted scheduled operation. See schedmode prompted (Schedmode) for details.
tcpclientport	Specifies a TCP/IP port number for the server to contact the client when the server begins the server prompted scheduled operation. See schedmode prompted (Schedmode) for details.

Format and language options

Format and language options allow you to select different formats for date, time and numbers for different languages.

AIX Linux Solaris Mac OS X Format options allow you to select different formats for date, time, and numbers.

Table 1. Format and language options

Option	Description
dateformat	Specifies the format for displaying dates.
Windows language	Windows Specifies the language used for messages.
numberformat	Specifies the format for displaying numbers.
timeformat	Specifies the format for displaying time.

Command processing options

This topic explains the options that you can use with the backup-archive client commands.

Command processing options allow you to control some of the formatting of data on your terminal screen.

Table 1. Command processing options

Option	Description
quiet	Limits the number of messages that are displayed on your screen during processing. This option can be overridden by the server.
scrolllines	Specifies the number of lines of information that are displayed on your screen at one time. Use this option only when scrollprompt is set to yes.
scrollprompt	Specifies whether you want the backup-archive client to stop and wait after displaying the number of lines of information you specified with the scrolllines option, or scroll through and stop at the end of the information list.
setwindowtitle	Specifies whether to display the IBM Spectrum Protect™ server name and host server name in the title of the administrative client command window.
verbose	Specifies that processing information should be displayed on your screen. The alternative is quiet. This option can be overridden by the server.

Authorization options

Authorization options control access to the IBM Spectrum Protect™ server.

Table 1 lists the authorization options that are available.

Table 1. Authorization options

Option	Description
AIX Linux Mac OS X Solaris Windows autodeploy	AIX Linux Mac OS X Solaris Windows Specifies whether you want to enable or disable an automatic deployment of the client if a restart is required.
AIX Linux Solaris Mac OS X groups	AIX Linux Solaris Mac OS X Specifies the groups on your workstation that you want to authorize to request IBM Spectrum Protect services from the server.
password	Specifies the IBM Spectrum Protect password.
passwordaccess	Specifies whether you want to use a generated password or be prompted for a password each time you start the client.
AIX Linux Solaris Mac OS X passworddir	AIX Linux Solaris Mac OS X Specifies the directory in which you want to store the automatically generated password for your client node. The encryption key and password are encrypted and stored in the TSM.sth file.
revokeremoteaccess	Restricts an administrator with client access privileges from accessing your workstation through the web client.
AIX Linux Solaris Mac OS X users	AIX Linux Solaris Mac OS X Authorizes specific users on your workstation to request services from a server.

Error processing options

Error processing options specify the name of the error log file and how the backup-archive client treats the entries in the log file.

Table 1 lists the error processing options that are available.

Table 1. Error processing options

Option	Description

Option	Description
errorlogmax	Specifies the maximum size of the error log, in megabytes.
errorlogname Errorlogname	Specifies the fully qualified path and file name of the file where you want to store information about errors that occur during processing.
errorlogretention	Specifies how many days to maintain error log entries before pruning, and whether to save the pruned entries.

Transaction processing options

Transaction processing options control how transactions are processed between the IBM Spectrum Protect™ client and server.

Table 1 lists the transaction processing options that are available.

Table 1. Transaction processing options

Option	Description
collocatebyfilespec	Specifies that you want the backup-archive client to use only one server session to send objects generated from one file specification. Setting the collocatebyfilespec option to *yes* eliminates interspersing of files from different file specifications, by limiting the client to one server session per file specification. Therefore, if you store the data to tape, files for each file specification are stored together on one tape (unless another tape is required for more capacity).
commrestartduration	Specifies the maximum number of minutes you want the client to try to reconnect to the IBM Spectrum Protect server after a communication error occurs.
commrestartinterval	Specifies the number of seconds you want the client to wait between attempts to reconnect to the IBM Spectrum Protect server after a communication error occurs.
diskbuffsize	Specifies the maximum disk I/O buffer size (in kilobytes) that the client can use when reading files.
AIX Linux Solaris Mac OS X Windows largecommbuffers	AIX Linux Solaris Mac OS X Windows This option has been replaced by the diskbuffsize option. At this time, largecommbuffers is still accepted by the backup-archive client in order to ease the transition to the new option. However, the value specified by largecommbuffers is ignored in favor of the diskbuffsize setting. Important: Discontinue the use of largecommbuffers because future releases of the client might not accept this option.
AIX Linux Solaris Mac OS X nfstimeout	AIX Linux Solaris Mac OS X Specifies the number of seconds the server waits for a status system call on an NFS file system before it times out.
Windows resourceutilization	Windows Use the resourceutilization option in your client options file dsm.opt to regulate the level of resources the IBM Spectrum Protect server and client can use during processing.
AIX Linux Solaris Mac OS X resourceutilization	AIX Linux Solaris Mac OS X Use the resourceutilization option in your dsm.sys file to regulate the level of resources the IBM Spectrum Protect server and client can use during processing.
txnbytelimit	Specifies the number of kilobytes the client program buffers before it sends a transaction to the server.
Windows usedirectory	Windows Provides a convenient way to simplify client communication configuration by overriding commmethod parameters set in the client options file and instead querying the Active Directory for the communication method and server with which to connect.

Web client options

Several backup-archive client options are used to configure the IBM Spectrum Protect™ web client.

Table 1 lists the web client options that are available.

Table 1. Web client options

Option	Description
httpport	Specifies a TCP/IP port address for the web client.
AIX Linux Solaris Mac OS X managedservices	AIX Linux Solaris Mac OS X Specifies whether the client acceptor daemon manages the web client, the scheduler, or both.
Windows managedservices	Windows Specifies whether the client acceptor service manages the web client, the scheduler, or both.
revokeremoteaccess	Restricts administrator access on a client workstation through the web client.
AIX Linux Solaris Mac OS X webports	AIX Linux Solaris Mac OS X Enables the use of the web client outside a firewall by specifying the TCP/IP port number used by the client acceptor daemon and the web Client Agent service for communications with the web client.
Windows webports	Windows Enables the use of the web client outside a firewall by specifying the TCP/IP port number used by the client acceptor service and the web Client Agent service for communications with the web client.

Using options with commands

You can override some of the options in your client options file (dsm.opt) file by entering them with appropriate backup-archive client commands.

AIX Linux Solaris Mac OS X You can override some of the options in your dsm.sys file or client user-options file (dsm.opt) by entering them with appropriate backup-archive client commands.

The client processes options in the following order (precedence):

1. Options defined on the server with server-enforced client options. The server overrides client values.
2. Options entered locally on the command line.
3. Options defined on the server for a schedule using the options parameters.
4. Options entered locally in the options file.
5. Options received from the server with client option sets not set as forced by the server. The server *does not* override client values if not forced.
6. Default option values.

- Entering options with a command
  You must follow the general rules for entering options with a command.
- Initial command-line-only options
  A subset of client options is valid on the initial command line only. Many of these options establish the runtime environment, such as the commmethod and optfile options. Options in this category are not valid in interactive, macro, or scheduler modes. They generate an error and cause processing to stop.
- Client options that can be set by the IBM Spectrum Protect server
  Some client options can be set by the IBM Spectrum Protect™ server.

Entering options with a command

You must follow the general rules for entering options with a command.

- Enter a command, a dash (–), the option name, an equal sign (=), and the option value or parameter. Do not include spaces on either side of the = sign.

  Here are examples of this syntax on different clients:

  AIX Linux Solaris Mac OS X

  ```
  dsmc archive -description="year end 1999" /home/
  ```

  Windows

  ```
  dsmc archive -description="Project A" c:\devel\proj1\*
  ```

- For options that do not include parameters, enter a command, a dash (–), and the option name. For example,

  ```
  dsmc incremental -quiet
  ```

  Note: Use a leading dash (-) to indicate that the following text is the name of an option. If an object name begins with a dash, you must surround it in either single quotation marks (') or quotation marks ("). Most operating system command line processors strip the quotation marks before the command-line arguments are submitted to the IBM Spectrum Protect™ client application. In such cases, by using escape characters or doubling the quotation marks allows the client to receive the quoted object name. In loop mode, surround such objects in either single quotation marks (') or quotation marks (").
- Enter either the option name, or an abbreviation for the option name. For example, to enter the latest option, enter either `-lat` or `-latest`. The capital letters in the syntax of each option indicate the minimum abbreviation for that option name.
- Enter options before or after command parameters. For example, you can enter the option before or after a file specification: AIX Linux Solaris Mac OS X

  ```
  dsmc selective -subdir=yes "/home/devel/proj1/*"
  dsmc selective "/home/devel/proj1/*" -subdir=yes
  ```

  Windows

  ```
  dsmc selective -subdir=yes c:\devel\proj1\*
  dsmc selective c:\devel\proj1\* -subdir=yes
  ```

- When you enter several options on a command, separate them with a blank space.
- Enclose the value in quotation marks (" ") if the option value that you enter contains a blank space. For example: AIX Linux Solaris Mac OS X

  ```
  dsmc archive -description="Project A" "/home/devel/proj1/*"
  ```

  Windows

  ```
  dsmc archive -description="Project A" c:\devel\proj1\*
  ```

- Most options that you enter on the command line override the value that is set in the preferences file. However, when you use the domain option with the incremental command, it adds to the domain specified in your client options file rather than overriding the current value.
- AIX Solaris Mac OS X On AIX®, Solaris, Linux on z, and Mac: The maximum number of characters for a file name is 255. The maximum combined length of the file name and path name is 1024 characters. The Unicode representation of a character can occupy several bytes, so the maximum number of characters that a file name might contain can vary.
- Linux On Linux: The maximum length for a file name is 255 bytes. The maximum combined length of both the file name and path name is 4096 bytes. This length matches the PATH_MAX that is supported by the operating system. The Unicode representation of a character can occupy several bytes, so the maximum number of characters that comprises a path and file name can vary. The actual limitation is the number of bytes in the path and file components, which might or might not correspond to an equal number of characters.

  Linux On Linux: For archive or retrieve operations, the maximum length that you can specify for a path and file name (combined) remains at 1024 bytes.

- Windows The maximum number of bytes for a file name and file path is 6255 combined. However, the file name itself cannot exceed 255 bytes and the path that leads to the file cannot exceed 6000 bytes. Furthermore, directory names (including the directory delimiter) within a path are limited to 255 bytes. The Unicode representation of a character can occupy several bytes, so the maximum number of characters that a file name might contain can vary.
- Mac OS X For Mac OS X, the maximum length of a file name is limited to 504 bytes (not characters). The Unicode representation of a character can occupy several bytes, so the maximum number of characters that a file name contains can vary.

Initial command-line-only options

A subset of client options is valid on the initial command line only. Many of these options establish the runtime environment, such as the commmethod and optfile options. Options in this category are not valid in interactive, macro, or scheduler modes. They generate an error and cause processing to stop.

Table 1 lists the options that are valid only on the initial command line.

Table 1. Options that are valid on the initial command line only

Options valid on the initial command line	

Options valid on the initial command line	
• Windows asrmode • Windows backupregistry • commmethod • Windows computername • deduplication • diskbuffsize • editor • enablededupcache • AIX Linux Solaris Windows enablelanfree • errorlogmax • errorlogname • errorlogretention • Windows incrthreshold • AIX Linux Solaris Windows lanfreecommmethod • AIX Linux Solaris Windows lanfreeshmport • AIX Linux Solaris Windows lanfreetcpport • maxcmdretries • Windows namedpipename • AIX Linux Solaris Mac OS X nfstimeout • nodename • optfile • password • postschedulecmd/postnschedulecmd (can be included in the schedule definition) • Windows postsnapshotcmd	• preschedulecmd/prenschedulecmd (can be included in the schedule definition) • Windows presnapshotcmd • queryschedperiod • resourceutilization • retryperiod • Windows runasservice • schedlogmax • schedlogname • schedlogretention • schedmode • AIX Linux Solaris Mac OS X servername • sessioninitiation • setwindowtitle • tcpbuffsize • tcpcadaddress • tcpclientaddress • tcpclientport • Windows tcpport • Windows tcpserveraddress • tcpwindowsize • txnbytelimit • Windows usedirectory • virtualnodename	

Client options that can be set by the IBM Spectrum Protect server

Some client options can be set by the IBM Spectrum Protect™ server.

Table 1 lists the options that can be set by the server.

Table 1. Options that can be set by the IBM Spectrum Protect server

Options that can be set by the IBM Spectrum Protect server	

Options that can be set by the IBM Spectrum Protect server	
• AIX Linux Afmskipuncachedfiles • AIX Linux Solaris Archsymlinkasfile • Windows Casesensitiveaware • Changingretries • Collocatebyfilespec • Compressalways • Compression • Deduplication • Dirmc • Disablenqr • Diskcachelocation • Domain • AIX Linux Solaris Windows Domain.image • AIX Linux Solaris Mac OS X Windows Domain.nas • AIX Linux Solaris Mac OS X Windows Encryptiontype • Encryptkey • AIX Linux Solaris Mac OS X Windows Exclude options • Inclexcl • AIX Linux Solaris Mac OS X Windows Include options • maxcandprocs • maxmigrators • Memoryefficientbackup • AIX Linux Solaris Mac OS X Nfstimeout • Postschedulecmd/Postnschedulecmd • AIX Linux Solaris Mac OS X Windows Postsnapshotcmd • Preschedulecmd/Prenschedulecmd • AIX Linux Solaris Mac OS X Windows Preservelastaccessdate • AIX Linux Solaris Mac OS X Windows Presnapshotcmd	• Queryschedperiod • Quiet • Windows Resetarchiveattribute • Resourceutilization • Retryperiod • Schedmode • Scrolllines • Scrollprompt • AIX Linux Snapshotcachesize • AIX Windows Snapshotproviderfs • AIX Linux Windows Snapshotproviderimage • AIX Linux Windows Stagingdirectory • Subdir • Tapeprompt • Txnbytelimit • Verbose • Linux Windows Vmchost • Linux Windows Vmcuser • Linux Windows Vmprocessvmwithindependent • Linux Windows Vmprocessvmwithprdm

Related tasks:
Controlling client operations through client option sets

Client options reference

The following sections contain detailed information about each of the IBM Spectrum Protect™ processing options.

Information for each option includes the following information:

- A description
- A syntax diagram
- Detailed descriptions of the parameters
- Examples of using the option in the client options file (if applicable)
- Examples of using the option on the command line (if applicable)

Options with a command-line example of **Does not apply** cannot be used with command line or scheduled commands.

Mac OS X Note:

1. Do not enclose an option value with single or quotation marks, unless the value is a file specification that contains spaces or wildcard characters. For example, the following option is not valid:

```
passwordaccess  "generate"
```

2. AIX Linux Mac OS X Solaris All options in the dsm.sys file, except for the defaultserver option, must be placed within a server stanza. A server stanza is a collection of options statements in dsm.sys that begins with a SERVERName option and ends either at the next SERVERName option or the end of the file.

- Absolute
  Use the absolute option with the incremental command to force a backup of all files and directories that match the file specification or domain, even if the objects were not changed since the last incremental backup.
- Windows Adlocation
  You can use the adlocation option with the query adobjects or restore adobjects commands to indicate whether the Active Directory objects are to be queried or restored from the local Active Directory Deleted Objects container or from a system state backup on the IBM Spectrum Protect server.
- AIX Linux Afmskipuncachedfiles
  The afmskipuncachedfiles option specifies whether uncached and dirty files in General Parallel File System (GPFS™) Active File Management file sets are processed for backup, archive, and migration operations.
- Archmc
  Use the archmc option with the archive command to specify the available management class for your policy domain to which you want to bind your archived files and directories.
- AIX Linux Solaris Archsymlinkasfile
  The archsymlinkasfile option specifies whether the backup-archive client follows a symbolic link and archives the file or directory to which it points, or archives the symbolic link only. Use this option with the archive command.
- AIX Linux Solaris Mac OS X Asnodename
  Use the asnodename option to allow agent nodes to back up or restore data on behalf of another node (the target node). This enables concurrent operations from multiple nodes to store data to the same target node and file space in parallel.
- Windows Asnodename
  Use the asnodename option to allow an agent node to back up, archive, restore, retrieve, and query data on behalf of a target node.
- Windows Asrmode
  Use the asrmode option with the restore and restore systemstate commands to specify whether to perform a restore operation in system ASR recovery mode.
- Auditlogging
  Use the auditlogging option to generate an audit log that contains an entry for each file that is processed during an incremental, selective, archive, restore, or retrieve operation.
- Auditlogname
  The auditlogname option specifies the path and file name where you want to store audit log information. This option applies when audit logging is enabled.
- AIX Linux Mac OS X Solaris Windows Autodeploy
  Use the autodeploy option to enable or disable an automatic deployment of the client if a restart is required.
- Autofsrename
  The autofsrename option renames an existing file space that is not Unicode-enabled on the IBM Spectrum Protect server so that a Unicode-enabled file space with the original name can be created for the current operation.
- AIX Linux Solaris Automount
  The automount option adds an automounted file system into the domain by mounting it. Use this option with the domain option.
- Linux Windows Backmc
  The backmc option specifies the management class to apply to the backup fastback command for retention purposes.
- Backupsetname
  The backupsetname option specifies the name of a backup set from the IBM Spectrum Protect server.
- Basesnapshotname
  The basesnapshotname option specifies the snapshot to use as the base snapshot, when you perform a snapshot differential (snapdiff) backup of a NetApp filer volume. If you specify this option, you must also use the snapdiff option or an error occurs. If basesnapshotname is not specified, the useexistingbase option selects the most recent snapshot on the filer volume as the base snapshot.
- Cadlistenonport
  The cadlistenonport option specifies whether to open a listening port for the client acceptor.
- Windows Casesensitiveaware
  The casesensitiveaware option specifies whether the Windows backup-archive client attempts to filter out file and directory objects that have name conflicts that are caused by different capitalization of the object names.
- Changingretries
  The changingretries option specifies how many additional times you want the client to attempt to back up or archive a file that is in use. Use this option with the archive, incremental, and selective commands.

- AIX Solaris Windows Class
  The class option specifies whether to display a list of NAS or client objects when using the delete filespace, query backup, and query filespace commands.
- Windows Clientview
  The clientview option is available to users who have upgraded from the IBM® Tivoli® Storage Manager Express® backup client to the enterprise backup-archive client.
- Windows Clusterdisksonly
  The clusterdisksonly option specifies whether the backup-archive client allows the backup of only clustered disks in specific environments.
- Windows Clusternode
  The clusternode option specifies how the backup-archive client manages cluster drives.
- Collocatebyfilespec
  Use the collocatebyfilespec option to specify whether the backup-archive client uses only one server session to send objects generated from one file specification.
- Commmethod
  The commmethod option specifies the communication method you use to provide connectivity for client-server communication.
- Commrestartduration
  The commrestartduration option specifies the maximum number of minutes you want the client to try to reconnect to the IBM Spectrum Protect server after a communication error occurs.
- Commrestartinterval
  The commrestartinterval option specifies the number of seconds you want the client to wait between attempts to reconnect to the IBM Spectrum Protect server after a communication error occurs.
- Compressalways
  The compressalways option specifies whether to continue compressing an object if it grows during compression.
- Compression
  The compression option compresses files before you send them to the server.
- Console
  Use the console option with the query systeminfo command to output information to the console.
- Createnewbase
  The createnewbase option creates a base snapshot and uses it as a source to run a full incremental backup.
- Datacenter
  Specifies the target location of the data center that will contain the restored machine data.
- Datastore
  Specifies the datastore target to be used during VMware restore operation.
- Dateformat
  The dateformat option specifies the format you want to use to display or enter dates.
- AIX Linux Solaris Mac OS X Windows Dedupcachepath
  Use the dedupcachepath option to specify the location where the client-side data deduplication cache database is created.
- AIX Linux Solaris Mac OS X Windows Dedupcachesize
  Use the dedupcachesize option to determine the maximum size of the data deduplication cache file. When the cache file reaches its maximum size, the contents of the cache are deleted and new entries are added.
- AIX Linux Solaris Mac OS X Windows Deduplication
  Use the deduplication option to specify whether to enable redundant client-side data elimination when data is transferred to the IBM Spectrum Protect server during backup and archive processing.
- AIX Linux Solaris Mac OS X Defaultserver
  Use the defaultserver option to specify the name of the IBM Spectrum Protect server to contact for backup-archive services if more than one server is defined in the dsm.sys file.
- Deletefiles
  Use the deletefiles option with the archive command to delete files from your workstation after you archive them.
- Description
  The description option assigns or specifies a description for files when performing archive, delete archive, retrieve, query archive, or query backupset.
- Detail
  Use the detail option to display management class, file space, backup, archive information, and additional information, depending on the command with which it is used.
- Diffsnapshot
  The diffsnapshot option controls whether the backup-archive client creates the differential snapshot when it runs a snapshot difference incremental backup.
- Diffsnapshotname
  The diffsnapshotname option allows you to specify which differential snapshot, on the target filer volume, to use during a snapshot differential backup. This option is only specified if you also specify diffsnapshot=latest.

- Dirmc
  The dirmc option specifies the management class you want to use for directories.
- Dirsonly
  The dirsonly option processes directories *only*. The client does not process files.
- Disablenqr
  The disablenqr option specifies whether the backup-archive client can use the no-query restore method for restoring files and directories from the server.
- Diskbuffsize
  The diskbuffsize option specifies the maximum disk I/O buffer size (in kilobytes) that the client can use when reading files. The diskbuffsize option replaces the largecommbuffers option.
- Diskcachelocation
  The diskcachelocation option specifies the location where the disk cache database is created if the option memoryefficientbackup=diskcachemethod is set during an incremental backup.
- Domain
  The domain option specifies what you want to include for incremental backup.
- AIX Linux Solaris Windows Domain.image
  The domain.image option specifies what you want to include in your client domain for an image backup.
- AIX Solaris Windows Domain.nas
  The domain.nas option specifies the volumes to include in your NAS image backups.
- Linux Windows Domain.vmfull
  The domain.vmfull option specifies the virtual machines (VMs) to include in your full virtual machine image backup operations.
- Linux Dontload
  x86_64 Linux clients can use the dontload option to suppress specific plug-in libraries from being loaded when the backup-archive client is started.
- AIX Linux Solaris Dynamicimage
  Use the dynamicimage option with the backup image command or the include.image option to specify that you want to perform a dynamic image backup.
- AIX Efsdecrypt
  The efsdecrypt option allows you to control whether or not files encrypted by an AIX® Encrypted File System (EFS) are read in encrypted or decrypted format.
- Windows Enable8dot3namesupport
  The enable8dot3namesupport option specifies whether the client backs up and restores short 8.3 names for files that have long names on NTFS file systems.
- Enablearchiveretentionprotection
  The enablearchiveretentionprotection option allows the client to connect to the IBM Spectrum Protect for Data Retention server. This ensures that archive objects will not be deleted from the server until policy-based retention requirements for that object have been satisfied.
- AIX Linux Solaris Mac OS X Windows Enablededupcache
  Use the enablededupcache option to specify whether you want to use a cache during client-side data deduplication. Using a local cache can reduce network traffic between the IBM Spectrum Protect server and the client.
- Enableinstrumentation
  By default, instrumentation data is automatically collected by the backup-archive client and IBM Spectrum Protect API to identify performance bottlenecks during backup and restore processing. To disable or later enable instrumentation, use the enableinstrumentation option.
- AIX Linux Solaris Windows Enablelanfree
  The enablelanfree option specifies whether to enable an available LAN-free path to a storage area network (SAN) attached storage device.
- AIX Linux Solaris Mac OS X Windows Encryptiontype
  Use the encryptiontype option to specify the algorithm for data encryption.
- Encryptkey
  The backup-archive client supports the option to encrypt files that are being backed up or archived to the IBM Spectrum Protect server. This option is enabled with the include.encrypt option.
- Errorlogmax
  The errorlogmax option specifies the maximum size of the error log, in megabytes. The default name for the error log is dsmerror.log.
- Errorlogname
  This option specifies the fully qualified path and file name of the file that contains the error messages.
- Errorlogretention
  The errorlogretention option specifies how many days to maintain error log entries before pruning, and whether to save the pruned entries in other files.

- Exclude options
  Use the exclude options to exclude objects from backup, image, or archive services.
- Linux Windows Fbbranch
  Use the fbbranch option with the backup fastback or archive fastback commands.
- Linux Windows Fbclientname
  Use the fbclientname option with the backup fastback or archive fastback commands.
- Linux Windows Fbpolicyname
  Use the fbpolicyname option with the backup fastback or archive fastback commands.
- Linux Windows Fbreposlocation
  Use the fbreposlocation option with the backup fastback or archive fastback commands.
- Linux Windows Fbserver
  Use the fbserver option with the backup fastback or archive fastback commands.
- Linux Windows Fbvolumename
  Use the fbvolumename option with the backup fastback or archive fastback commands.
- Filelist
  Use the filelist option to process a list of files.
- Filename
  Use the filename option with the query systeminfo command to specify a file name in which to store information.
- Filesonly
  The filesonly option restricts backup, restore, retrieve, or query processing to files *only*.
- AIX Linux Solaris Followsymbolic
  During a backup operation, the followsymbolic option specifies whether you want to use a symbolic link as a virtual mount point. During a restore or retrieve operation, the followsymbolic option specifies how the backup-archive client restores a directory whose name matches a symbolic link on the restore target file system.
- Forcefailover
  The forcefailover option enables the client to immediately fail over to the secondary server.
- Fromdate
  Use the fromdate option with the fromtime option to specify a date and time from which you want to search for backups or archives during a restore, retrieve, or query operation.
- Fromnode
  The fromnode option permits one node to perform commands for another node. A user on another node must use the set access command to permit you to query, restore, or retrieve files for the other node.
- AIX Linux Solaris Mac OS X Fromowner
  The fromowner option specifies an alternate owner from which to restore backup versions or archived files or images. The owner must give access to another to use the files or images.
- Fromtime
  Use the fromtime option with the fromdate option to specify a beginning time from which you want to search for backups or archives during a restore, retrieve, or query operation.
- Groupname
  Use the groupname option with the backup group command to specify the name for a group. You can only perform operations on new groups or the current active version of the group.
- AIX Linux Solaris Mac OS X Groups (deprecated)
  This option is deprecated.
- Host
  The host option specifies the target ESX server location where the new virtual machine is created during a VMware restore operation.
- Httpport
  The httpport option specifies a TCP/IP port address for the web client.
- Hsmreparsetag
  The hsmreparsetag option specifies a unique reparse tag that is created by an HSM product installed on your system.
- AIX Linux Solaris Mac OS X Windows Ieobjtype
  Use the ieobjtype option to specify an object type for a client-side data deduplication operation within include-exclude statements.
- Ifnewer
  The ifnewer option replaces an existing file with the latest backup version only if the backup version is newer than the existing file.
- AIX Windows Imagegapsize
  Use the imagegapsize option with the backup image command, in the options file, or with the include.image option to specify the minimum size of empty regions on a volume that you want to skip during image backup.
- AIX Linux Solaris Windows Imagetofile
  Use the imagetofile option with the restore image command to specify that you want to restore the source image to a file.

- Inactive
  Use the inactive option to display both active and inactive objects.
- Inclexcl
  The inclexcl option specifies the path and file name of an include-exclude options file.
- Include options
  The include options specify objects that you want to include for backup and archive services.
- Incrbydate
  Use the incrbydate option with the incremental command to back up new and changed files with a modification date later than the last incremental backup stored at the server, unless you exclude the file from backup.
- AIX Linux Solaris Windows Incremental
  Use the incremental option with the restore image command to ensure that any changes that were made to the base image are also applied to the restored image.
- Windows Incrthreshold
  The incrthreshold option specifies the threshold value for the number of directories in any journaled file space that might have active objects on the server, but no equivalent object on the workstation.
- Instrlogmax
  The instrlogmax option specifies the maximum size of the instrumentation log (dsminstr.log), in MB. Performance data for the client is collected in the dsminstr.log file during backup or restore processing when the enableinstrumentation option is set to *yes*.
- Instrlogname
  The instrlogname option specifies the path and file name where you want to store performance information that the backup-archive client collects.
- Windows Journalpipe
  The journalpipe option specifies the pipe name of a journal daemon session manager to which the backup clients attach.
- AIX Linux Solaris Windows Lanfreecommmethod
  The lanfreecommmethod option specifies the communications protocol between the IBM Spectrum Protect client and Storage Agent. This enables processing between the client and the SAN-attached storage device.
- AIX Solaris Windows Lanfreeshmport
  Use the lanfreeshmport option when `lanfreecommmethod=SHAREdmem` is specified for communication between the backup-archive client and the storage agent. This enables processing between the client and the SAN-attached storage device.
- AIX Linux Solaris Windows Lanfreetcpport
  The lanfreetcpport option specifies the TCP/IP port number where the IBM Spectrum Protect Storage Agent is listening.
- AIX Linux Mac OS X Solaris Windows Lanfreessl
  Use the lanfreessl option to enable Secure Sockets Layer (SSL), to provide secure client and Storage Agent communications. This option is deprecated if you are connecting to an IBM Spectrum Protect server V8.1.2 and later.
- AIX Linux Solaris Windows Lanfreetcpserveraddress
  The lanfreetcpserveraddress option specifies the TCP/IP address for the IBM Spectrum Protect Storage Agent.
- Windows Language
  The language option specifies the national language in which to present client messages.
- Latest
  Use the latest option to restore the most recent backup version of a file, even if the backup is inactive.
- AIX Linux Solaris Mac OS X Windows Localbackupset
  The localbackupset option specifies whether the backup-archive client GUI bypasses initial logon with the IBM Spectrum Protect server to restore a local backup set on a standalone workstation.
- AIX Linux Solaris Makesparsefile
  Use the makesparsefile option with the restore or retrieve commands to specify how sparse files are recreated.
- Managedservices
  The managedservices option specifies whether the IBM Spectrum Protect client acceptor service manages the scheduler, the web client, or both.
- Maxcmdretries
  The maxcmdretries option specifies the maximum number of times the client scheduler (on your workstation) attempts to process a scheduled command that fails.
- Mbobjrefreshthresh
  The mbobjrefreshthresh (megablock object refresh threshold) option is a number defining a threshold. When the number of IBM Spectrum Protect objects that are needed to describe any 128 MB megablock exceeds this value, the entire megablock is refreshed and the objects that were used to represent this area, in previous backups, are expired.
- Mbpctrefreshthresh
  The mbpctrefreshthresh (megablock percentage refresh threshold) option is a number defining a threshold. When the percentage of IBM Spectrum Protect objects that are needed to describe any 128 MB megablock exceeds this value, the entire megablock is refreshed and the objects that were used to represent this area, in previous backups, are expired.

- Memoryefficientbackup
  The memoryefficientbackup option specifies the memory-conserving algorithm to use for processing full file space backups.
- Mode
  Use the mode option to specify the backup mode to use when performing specific backup operations.
- AIX Solaris Windows Monitor
  The monitor option specifies whether to monitor an image backup or restore of file systems belonging to a Network Attached Storage (NAS) file server.
- Windows Myprimaryserver
  The myprimaryserver option specifies the primary server name that the client uses to log on to the secondary server in failover mode.
- Myreplicationserver
  The myreplicationserver option specifies which secondary server stanza that the client uses during a failover.
- Windows Namedpipename
  The namedpipename option specifies the name of a named pipe to use for communications between a client and a server on the same Windows server domain.
- AIX Solaris Windows Nasnodename
  The nasnodename option specifies the node name for the NAS file server when processing NAS file systems. The client prompts you for an administrator ID.
- AIX Linux Solaris Mac OS X Nfstimeout
  The nfstimeout option specifies the number of seconds the client waits for a status system call on an NFS file system before it times out.
- Nodename
  Use the nodename option in your client options file to identify your workstation to the server. You can use different node names to identify multiple operating systems on your workstation.
- Windows Nojournal
  Use the nojournal option with the incremental command to specify that you want to perform a traditional full incremental backup, instead of the default journal-based backup.
- AIX Nojournal
  Use the nojournal option with the incremental command to specify that you want to perform a traditional full incremental backup, instead of the default journal-based backup.
- Noprompt
  The noprompt option suppresses the confirmation prompt that is presented by the delete group, delete archive, expire, restore image, and set event commands.
- Nrtablepath
  The nrtablepath option specifies the location of the node replication table on the client. The backup-archive client uses this table to store information about each backup or archive operation to the IBM Spectrum Protect server.
- Numberformat
  The numberformat option specifies the format you want to use to display numbers.
- Optfile
  The optfile option specifies the client options file to use when you start a backup-archive client session.
- Password
  The password option specifies a password for IBM Spectrum Protect.
- Passwordaccess
  The passwordaccess option specifies whether you want to generate your password automatically or set as a user prompt.
- AIX Linux Solaris Mac OS X Passworddir
  The passworddir option specifies the directory location in which to store an encrypted password file.
- Pick
  The pick option creates a list of backup versions or archive copies that match the file specification you enter.
- Pitdate
  Use the pitdate option with the pittime option to establish a point in time to display or restore the latest version of your backups.
- Pittime
  Use the pittime option with the pitdate option to establish a point in time to display or restore the latest version of your backups.
- AIX Linux Solaris Mac OS X Windows Postschedulecmd/Postnschedulecmd
  The postschedulecmd/postnschedulecmd option specifies a command that the client program processes after it runs a schedule.
- AIX Linux Windows Postsnapshotcmd
  The postsnapshotcmd option allows you to run operating system shell commands or scripts after the backup-archive client starts a snapshot during a snapshot-based backup operation.

- AIX Linux Solaris Mac OS X Windows Preschedulecmd/Prenschedulecmd
  The preschedulecmd option specifies a command that the client program processes before it runs a schedule.
- AIX Linux Solaris Windows Preservelastaccessdate
  Use the preservelastaccessdate option to specify whether a backup or archive operation changes the last access time.
- Preservepath
  The preservepath option specifies how much of the source path to reproduce as part of the target directory path when you restore or retrieve files to a new location.
- AIX Linux Windows Presnapshotcmd
  The presnapshotcmd option allows you to run operating system commands before the backup-archive client starts a snapshot.
- Queryschedperiod
  The queryschedperiod option specifies the number of hours you want the client scheduler to wait between attempts to contact the server for scheduled work.
- Querysummary
  The querysummary option provides statistics about files, directories and objects that are returned by the query backup or query archive commands.
- Quiet
  The quiet option limits the number of messages that are displayed on your screen during processing..
- Quotesareliteral
  The quotesareliteral option specifies whether single quotation marks (') or double quotation marks (") are interpreted literally, when they are included in a file list specification on a filelist option.
- AIX Linux Solaris Mac OS X Removeoperandlimit
  The removeoperandlimit option specifies that the client removes the 20-operand limit.
- Replace
  The replace option specifies whether to overwrite existing files on your workstation, or to prompt you for your selection when you restore or retrieve files.
- Replserverguid
  The replserverguid option specifies the globally unique identifier (GUID) that is used when the client connects to the secondary server during failover. The GUID is used to validate the secondary server to ensure that it is the expected server.
- Replservername
  The replservername option specifies the name of the secondary server that the client connects to during a failover.
- Replsslport
  The replsslport option specifies the TCP/IP port on the secondary server that is SSL-enabled. The replsslport option is used when the client connects to the secondary server during a failover. This option is deprecated if you are connecting to an IBM Spectrum Protect server V8.1.2 and later.
- Repltcpport
  The repltcpport option specifies the TCP/IP port on the secondary server to be used when the client connects to the secondary server during a failover.
- Repltcpserveraddress
  The repltcpserveraddress option specifies the TCP/IP address of the secondary server to be used when the client connects to the secondary server during a failover.
- Windows Resetarchiveattribute
  Use the resetarchiveattribute option to specify whether the backup-archive client resets the Windows archive attribute on files that are successfully backed up to the IBM Spectrum Protect server.
- Resourceutilization
  Use the resourceutilization option in your option file to regulate the level of resources the IBM Spectrum Protect server and client can use during processing.
- Retryperiod
  The retryperiod option specifies the number of minutes the client scheduler waits between attempts to process a scheduled command that fails, or between unsuccessful attempts to report results to the server. Use this option only when the scheduler is running.
- Revokeremoteaccess
  The revokeremoteaccess option restricts an administrator with client access privilege from accessing a client workstation that is running the web client.
- Windows Runasservice
  The runasservice option forces the client command process to continue running, even if the account that started the client logs off.
- Schedcmddisabled
  The schedcmddisabled option specifies whether to disable the scheduling of commands by the server action=command option on the define schedule server command.
- Schedcmdexception
  The schedcmexception option is used in conjunction with the schedcmddisabled option to disable the scheduling of

commands by the server action=command option on the DEFINE SCHEDULE server command, except for specific command strings.

- Schedgroup
  The schedgroup option assigns a schedule to a group.
- Schedlogmax
  The schedlogmax option specifies the maximum size of the schedule log (dsmsched.log) and web client log (dsmwebcl.log), in megabytes.
- Schedlogname
  The schedlogname option specifies the path and file name where you want to store schedule log information.
- Schedlogretention
  The schedlogretention option specifies the number of days to keep entries in the schedule log (dsmsched.log) and the web client log (dsmwebcl.log), and whether to save the pruned entries in another file.
- Schedmode
  The schedmode option specifies whether you want to use the polling mode (your client node periodically queries the server for scheduled work), or the prompted mode (the server contacts your client node when it is time to start a scheduled operation).
- Schedrestretrdisabled
  The schedrestretrdisabled option specifies whether to disable the execution of restore or retrieve schedule operations.
- Scrolllines
  The scrolllines option specifies the number of lines of information that are displayed on your screen at one time.
- Scrollprompt
  The scrollprompt option specifies whether you want the bakup-archive client to stop and wait after displaying the number of lines of information you specified with the scrolllines option, or scroll through and stop at the end of the information list.
- AIX Linux Solaris Mac OS X Servername
  In your dsm.sys file, the servername option specifies the name you want to use to identify a server and to begin a stanza containing options for that server. You can name and specify options for more than one server.
- Sessioninitiation
  Use the sessioninitiation option to control whether the server or client initiates sessions through a firewall. The default is that the client initiates sessions. You can use this option with the schedule command.
- Setwindowtitle
  Use the setwindowtitle option to modify the title of the administrative client command window during processing.
- AIX Linux Solaris Windows Shmport
  The shmport option specifies the TCP/IP port address of a server when using shared memory. All shared memory communications start with a TCP/IP connection.
- AIX Linux Solaris Windows Showmembers
  Use the showmembers option to display all members of a group.
- AIX Linux Solaris Mac OS X Skipacl
  The skipacl option allows you to include or exclude access control list (ACL) data during a backup or archive operation; by default, ACL data is included.
- AIX Linux Solaris Mac OS X Skipaclupdatecheck
  The skipaclupdatecheck option disables checksum and size comparisons of ACL data.
- Windows Skipmissingsyswfiles
  Use the Skipmissingsyswfiles option to specify whether the backup-archive client skips certain missing VSS writer files and continues the system state backup.
- Windows Skipntpermissions
  The skipntpermissions option bypasses processing of Windows file system security information.
- Windows Skipntsecuritycrc
  The skipntsecuritycrc option controls the computation of the security cyclic redundancy check (CRC) for a comparison of Windows NTFS or ReFS security information during an incremental or selective backup, archive, restore, or retrieve operation.
- Windows Skipsystemexclude
  Use the skipsystemexclude option to specify how to process exclude statements for certain operating system files that the IBM Spectrum Protect for Virtual Environments client skips by default.
- Linux Windows Snapdiff
  Using the snapdiff option with the incremental command streamlines the incremental backup process. The command runs an incremental backup of the files that were reported as changed by NetApp instead of scanning all of the volume for changed files.
- Linux Windows Snapdiffchangelogdir
  The snapdiffchangelogdir option defines the location where the client stores persistent change logs that are used for snapshot differential backup operations.
- Linux Windows Snapdiffhttps
  Specify the snapdiffhttps option to use a secure HTTPS connection for communicating with a NetApp filer during a

snapshot differential backup.

- AIX Linux Snapshotcachesize
  Use the snapshotcachesize option to specify an appropriate size to create the snapshot.
- AIX Windows Snapshotproviderfs
  Use the snapshotproviderfs option to enable snapshot-based file backup and archive operations, and to specify a snapshot provider.
- AIX Linux Windows Snapshotproviderimage
  Use the snapshotproviderimage option to enable snapshot-based image backup, and to specify a snapshot provider.
- AIX Linux Solaris Windows Snapshotroot
  Use the snapshotroot option with the incremental, selective, or archive commands with an independent software vendor application that provides a snapshot of a logical volume, to associate the data on the local snapshot with the real file space data that is stored on the IBM Spectrum Protect server.
- Srvoptsetencryptiondisabled
  The srvoptsetencryptiondisabled option allows the client to ignore encryption options in a client options set from the IBM Spectrum Protect server.
- Srvprepostscheddisabled
  The srvprepostscheddisabled option specifies whether to prevent the pre-schedule and post-schedule commands specified by the IBM Spectrum Protect administrator from executing on the client system, when performing scheduled operations.
- Linux Windows Srvprepostsnapdisabled
  The srvprepostsnapdisabled option specifies whether to prevent the pre-snapshot and post-snapshot commands specified by the IBM Spectrum Protect administrator from executing on the client system, when performing scheduled image snapshot backup operations.
- AIX Linux Solaris Windows Ssl
  Use the ssl option to enable Secure Sockets Layer (SSL) to provide secure client and server communications. When the backup-archive client communicates with an IBM Spectrum Protect server V8.1.1 and earlier V8 levels, and V7.1.7 and earlier levels, it determines whether SSL is enabled. When the backup-archive client communicates with an IBM Spectrum Protect server V8.1.2 and later, SSL is always used and this option controls whether object data is encrypted or not. For performance reasons, it might be desirable to not encrypt the object data.
- AIX Linux Mac OS X Solaris Windows Sslacceptcertfromserv
  Use the sslacceptcertfromserv option to control whether the backup-archive client or the API application accept and trust the IBM Spectrum Protect server's Secure Sockets Layer (SSL) public certificate the first time they connect. This option applies only the first time that the backup-archive client or the API application connects to the IBM Spectrum Protect server. When the SSL public certificate is accepted, future changes to the certificate are not automatically accepted, and must be manually imported to the backup-archive client. You can use this option to connect only to an IBM Spectrum Protect server V8.1.2 and later.
- AIX Linux Mac OS X Solaris Windows Ssldisablelegacytls
  Use the ssldisablelegacytls option to disallow the use of SSL protocols that are lower than TLS 1.2.
- Sslfipsmode
  The sslfipsmode option specifies whether the client uses SSL Federal Information Processing Standards (FIPS) mode for Secure Sockets Layer (SSL) communications with the server. The default is no.
- AIX Linux Mac OS X Solaris Windows Sslrequired
  The sslrequired option specifies the conditions when SSL is or is not required when the client logs on to the IBM Spectrum Protect server or storage agents. To actually enable SSL so client-to-server and client-to-storage-agent communications are secure, you must set the client ssl option to yes. When communicating with the IBM Spectrum Protect server V8.1.2 and later, this option no longer applies since SSL is always used.
- AIX Windows Stagingdirectory
  The stagingdirectory option defines the location where the client stores any data that it generates to perform its operations. The data is deleted when processing is complete.
- Subdir
  The subdir option specifies whether you want to include subdirectories of named directories for processing.
- Windows Systemstatebackupmethod
  Use the systemstatebackupmethod option to specify which backup method to use to back up the system writer portion of the system state data. The method you select is used when you backup the system state data.
- Tapeprompt
  The tapeprompt option specifies whether you want the backup-archive client to wait for a tape mount if it is required for a backup, archive, restore, or retrieve process, or to be prompted for a choice.
- AIX Linux Solaris Mac OS X Windows Tcpadminport
  Use the tcpadminport option to specify a separate TCP/IP port number on which the server waits for requests for administrative client sessions, allowing secure administrative sessions within a private network.
- Tcpbuffsize
  The tcpbuffsize option specifies the size of the internal TCP/IP communication buffer used to transfer data between the

client node and server. Although it uses more memory, a larger buffer can improve communication performance.

- Tcpcadaddress
  The tcpcadaddress option specifies a TCP/IP address for dsmcad. Normally, this option is not needed. Use this option only if your client node has more than one TCP/IP address, or if TCP/IP is not the default communication method.
- Tcpclientaddress
  The tcpclientaddress option specifies a TCP/IP address if your client node has more than one address, and you want the server to contact an address other than the one that was used to make the first server contact.
- Tcpclientport
  The tcpclientport option specifies a TCP/IP port number for the server to contact the client when the server begins the server prompted scheduled operation.
- Tcpnodelay
  The tcpnodelay option specifies whether the client disables the delay of sending successive small packets on the network, per transaction.
- Tcpport
  The tcpport option specifies a TCP/IP port address for the IBM Spectrum Protect server. You can obtain this address from your administrator.
- Tcpserveraddress
  The tcpserveraddress option specifies the TCP/IP address for the IBM Spectrum Protect server. You can obtain this server address from your administrator.
- Tcpwindowsize
  Use the tcpwindowsize option to specify, in kilobytes, the size you want to use for the TCP/IP sliding window for your client node.
- Timeformat
  The timeformat option specifies the format in which you want to display and enter system time.
- AIX Solaris Windows Toc
  Use the toc option with the backup nas command or the include.fs.nas option to specify whether the backup-archive client saves table of contents (TOC) information for each file system backup.
- Todate
  Use the todate option with the totime option to specify an ending date and time to which you want to search for backups or archives during a restore, retrieve, or query operation
- Totime
  Use the totime option with the todate option to specify an ending date and time to which you want to search for backups or archives during a restore, retrieve, or query operation. The backup-archive client ignores this option if you do not specify the todate option.
- Txnbytelimit
  The txnbytelimit option specifies the number of kilobytes the client program buffers before it sends a transaction to the server.
- Type
  Use the type option with the query node command to specify the type of node to query. Use this option with the set event command to activate, hold, or release.
- Updatectime
  Use the updatectime option to check the change time (ctime) attribute during an incremental backup operation.
- Windows Usedirectory
  The usedirectory option queries the Active Directory for the communication method and server with which to connect.
- Useexistingbase
  The useexistingbase option is used when you back up snapshots that are on NetApp filer volumes. The useexistingbase option indicates that the latest snapshot that exists on the volume being backed up, is to be used as the base snapshot, during a snapshot differential backup operation.
- Usereplicationfailover
  The usereplicationfailover option specifies whether automated client failover occurs on a client node.
- AIX Linux Solaris Mac OS X Users (deprecated)
  This option is deprecated.
- V2archive
  Use the v2archive option with the archive command to archive only files to the server.
- Verbose
  The verbose option specifies that you want to display detailed processing information on your screen. This is the default.
- AIX Linux Solaris Windows Verifyimage
  Use the verifyimage option with the restore image command to specify that you want to enable detection of bad sectors on the destination target volume.
- Virtualfsname
  Use the virtualfsname option with the backup group command to specify the name of the virtual file space for the group on which you want to perform the operation. The virtualfsname cannot be the same as an existing file space name.

- AIX | Linux | Solaris | Mac OS X Virtualmountpoint
  The virtualmountpoint option defines a virtual mount point for a file system if you want to consider files for backup that begin with a specific directory within that file system.
- Virtualnodename
  The virtualnodename option specifies the node name of your workstation when you want to restore or retrieve files to a different workstation.
- Windows Vmautostartvm
  Use the vmautostartvm option with the restore VM vmrestoretype=instantaccess command to specify whether the VM created during instant access processing is automatically powered on.
- Linux | Windows Vmbackdir
  The vmbackdir option specifies the temporary disk location where the client saves control files that are created during full VM backup and restore operations of virtual machines.
- Linux | Windows Vmbackuplocation
  Use the vmbackuplocation option with the backup vm or restore vm commands to specify the backup location for virtual machine backup and restore operations.
- Linux | Windows Vmbackupmailboxhistory
  The vmbackupmailboxhistory option specifies whether mailbox history is automatically uploaded with the virtual machine (VM) backup if IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server is detected on a VM.
- Linux | Windows Vmbackuptype
  Use the vmbackuptype option with the backup VM or restore VM command to specify to specify the type of virtual machine backup or restore to complete. You can also use this option on query VM commands to filter the query results to include only virtual machines that were backed up by a specific backup type. For examples, see the query VM command description.
- Linux | Windows Vmchost
  Use the vmchost option with the backup VM, restore VM, or query VM commands to specify the host name of the VMware VirtualCenter or ESX server that you want to backup, restore, or query.
- Linux | Windows Vmcpw
  Use the vmcpw option with the backup VM, restore VM, or query VM commands to specify the password for the VMware VirtualCenter or the ESX user ID that is specified with the vmcuser option.
- Vmctlmc
  This option specifies the management class to use when backing up virtual machine control files.
- Linux | Windows Vmcuser
  Use the vmcuser option with the backup VM, restore VM, or query VM commands to specify the user name of the VMware VirtualCenter or ESX server that you want to backup, restore, or query.
- Linux | Windows Vmdatastorethreshold
  Use the vmdatastorethreshold option to set the threshold percentage of space usage for each VMware datastore of a virtual machine.
- Linux | Windows Vmdefaultdvportgroup
  Use this option to specify the port group for the NICs to use during restore vm operations for a virtual machine that was connected to a distributed virtual port group when it was backed up, but the target host for the restore operation does not contain a similar distributed virtual port group.
- Linux | Windows Vmdefaultdvswitch
  Use this option to specify the distributed virtual switch (dvSwitch) that contains the port group that you set on the vmdefaultdvportgroup option. The option has no effect unless you also specify the vmdefaultdvportgroup option.
- Linux | Windows Vmdefaultnetwork
  Use this option to specify the network for NICs to use during a restore vm operation, for a virtual machine that had been connected to a distributed virtual port group when it was backed up, but the target host for the restore operation does not have any distributed switch port groups configured.
- Windows Vmdiskprovision
  Use the vmdiskprovision option to specify a provisioning policy for the virtual disk file that is used to restore VMware virtual machine data. This option is valid only for restore vm operations where `vmrestoretype=instantrestore` is specified.
- Vmenabletemplatebackups
  The vmenabletemplatebackups option specifies whether the client backs up VMware template virtual machines when it protects virtual machines in a vCenter server. VMware templates virtual machines cannot be backed up when they are in an ESXi host because ESXi does not support templates.
- Windows Vmexpireprotect
  Use this option to protect virtual machine snapshots so that they cannot be expired while an instant restore or instant access operation of VMware VMs or while a file-level restore of a VMware VM is in progress. Use this option to protect virtual machine snapshots so that they cannot be expired while an instant restore or instant access operation of Hyper-V VMs or while a file-level restore of a Hyper-V VM is in progress.
- Vmiscsiadapter
  This option specifies which iSCSI adapter, on the ESX host, to use for instant restore and instant access operations for

VMware virtual machines.

- Windows Vmiscsiserveraddress
  Use the vmiscsiserveraddress option with the restore VM command to specify the host name or the IP address of the iSCSI server that provides the iSCSI targets for instant restore and instant access operations.
- Vmlimitperdatastore
  The vmlimitperdatastore option specifies the number of virtual machines (VMs) and virtual disks in a datastore that can be processed in parallel during an optimized backup operation.
- Vmlimitperhost
  The vmlimitperhost option specifies the number of virtual machines (VMs) and virtual disks in a host that can be processed in parallel during an optimized backup operation.
- Windows Vmlist
  The vmlist option is deprecated for Hyper-V backup operations. To specify one or more Hyper-V virtual machines (VMs) to include in Data Protection for Microsoft Hyper-V backup operations, use the domain.vmfull option or specify the VMs when you run the backup vm command.
- Vmmaxbackupsessions
  The vmmaxbackupsessions option specifies the maximum number IBM Spectrum Protect server sessions that move virtual machine (VM) data to the server that can be included in an optimized backup operation.
- Vmmaxparallel
  The vmmaxparallel option is used to configure optimized backups of several virtual machines by using a single instance of the backup-archive client. This option specifies the maximum number of virtual machines that can be backed up to the IBM Spectrum Protect server at any one time.
- Windows Vmmaxpersnapshot
  Use the vmmaxpersnapshot option to specify the maximum number of virtual machines (VMs) to include in a Hyper-V snapshot. The VMs in the snapshot are backed up to the IBM Spectrum Protect server.
- Vmmaxrestoresessions
  The vmmaxrestoresessions option specifies the maximum number of IBM Spectrum Protect server sessions that can be included in an optimized restore operation for a virtual machine (VM).
- Vmmaxrestoreparalleldisks
  The vmmaxrestoreparalleldisks option enables an IBM Spectrum Protect client to restore multiple virtual disks at the same time.
- Windows Vmmaxsnapshotretry
  Use the vmmaxsnapshotretry option to specify the maximum number of times to retry a snapshot operation of a virtual machine (VM) if the initial snapshot fails with a recoverable condition.
- Vmmaxvirtualdisks
  The vmmaxvirtualdisks option specifies the maximum size of the VMware virtual machine disks (VMDKs) to include in a backup operation.
- Linux Windows Vmmc
  Use the vmmc option to store virtual machine backups by using a management class other than the default management class. For VMware VM backups, the vmmc option is valid only if the vmbackuptype=fullvm option is set.
- Vmmountage
  Use the vmmountage option with the restore VM "*" -vmrestoretype=mountcleanupall command to specify the number of hours that a VM file level restore mount must be active to be cleaned up.
- Linux Windows Vmnoprdmdisks
  This option enables the client to restore configuration information for the pRDM volumes that are associated with a VMware virtual machine, even if the LUNs that were associated with the volumes cannot be found. Because pRDM volumes are not included in virtual machine snapshot, only the configuration information can be restored, and not the data that was on the volumes.
- Linux Windows Vmnovrdmdisks
  This option enables the client to restore configuration information and data for vRDM volumes that are associated with a VMware virtual machine, even if the LUNs that were associated with the volumes cannot be found.
- Linux Windows Vmpreferdagpassive
  The vmpreferdagpassive option specifies whether to back up an active copy or passive copy of a database that is part of a Microsoft Exchange Server Database Availability Group (DAG).
- Linux Windows Vmprocessvmwithindependent
  Use this option to control whether full VMware virtual machine backups are processed if the machine is provisioned with one or more independent disk volumes.
- Vmprocessvmwithphysdisks
  Use the vmprocessvmwithphysdisks option to control whether Hyper-V RCT virtual machine (VM) backups are processed if the VM has one or more physical disks (pass-through disks) provisioned.
- Linux Windows Vmprocessvmwithprdm
  Use this option to control whether full VMware virtual machine backups are processed if the virtual machine has one or more raw device mapping (RDM) volumes provisioned in physical-compatibility mode (pRDM).

- Windows Vmrestoretype
  Use the vmrestoretype option with the query VM or restore VM commands to specify the type of restore operation to perform or query.
- Windows Linux Vmskipctlcompression
  Use the vmskipctlcompression option for VM backups to specify whether control files (*.ctl) are compressed during VM backup. The option does not affect the compression of data files (*.dat)
- Vmskipmaxvirtualdisks
  The vmskipmaxvirtualdisks option specifies how the backup operation processes VMware virtual machine disks (VMDKs) that exceed the maximum disk size.
- Vmskipmaxvmdks
  The vmskipmaxvmdks option specifies how the backup operation processes VMware virtual machine disks (VMDKs) that exceed the maximum disk size.
- Vmskipphysdisks
  Use the vmskipphysdisks option to restore configuration information for physical disks (pass-through disks) that are associated with a Hyper-V virtual machine (VM), if the logical unit numbers (LUNs) that are associated with the volumes on the physical disks are available.
- Windows Vmstoragetype
  Use the vmstoragetype option with the restore VM command to specify the storage device type from which the snapshot is mounted with IBM Spectrum Protect recovery agent.
- Linux Windows Vmtagdatamover
  Use the vmtagdatamover option to enable tagging support in the backup-archive client (data mover). When this option is enabled, the client manages backups of virtual machines in VMware inventory objects according to the data protection tags that are set by the IBM Spectrum Protect vSphere Client plug-in of the vSphere Web Client, or set with tools such as VMware vSphere PowerCLI Version 5.5 R2 or later.
- Linux Windows Vmtagdefaultdatamover
  Use the vmtagdefaultdatamover option to protect virtual machines, defined in a schedule, that do not have an assigned or inherited `Data Mover` category and tag.
- Windows Vmtempdatastore
  Use the vmtempdatastore option with the restore VM command to define a temporary datastore on the ESX host for an instant restore operation.
- Vmverifyifaction
  Use this option to specify the action to perform if the data mover detects integrity problems with the latest CTL and bitmap files for a virtual machine.
- Vmverifyiflatest
  This option applies only to VMware virtual machine (VM) backup operations that use the incremental-forever-incremental backup mode (that is, a backup vm command with -mode=IFIncremental specified). If this vmverifyiflatest option is enabled, the data mover runs an integrity check on the CTL and bitmap files that were created on the server during the last backup, if the last backup was an incremental-forever-incremental backup.
- Linux Windows Vmvstortransport
  The vmvstortransport option specifies the preferred transports order (hierarchy) to use when backing up or restoring VMware virtual machines. If you do not include a given transport using this option, that transport is excluded and is not used to transfer data.
- Windows Vssaltstagingdir
  The vssaltstagingdir option specifies the fully qualified path that contains the system exclude cache and temporary data for VSS snapshot operation.
- Windows Vssusesystemprovider
  The vssusesystemprovider option specifies whether to use the Windows system provider, or to let Windows decide the most suitable provider to use.
- Linux Windows Vmtimeout
  VMTIMEOut specifies the maximum time, in seconds, to wait before abandoning a backup vm operation, when the INCLUDE.VMTSMVSS option is used to provide application protection. To use this option, the IBM Spectrum Protect for Virtual Environments license must be installed.
- Webports
  The webports option enables the use of the web client outside a firewall.
- Wildcardsareliteral
  The wildcardsareliteral option specifies whether question marks (?) and asterisks (*) are interpreted literally, when they are included in a file list specification on a filelist option.

Absolute

Use the absolute option with the incremental command to force a backup of all files and directories that match the file specification or domain, even if the objects were not changed since the last incremental backup.

This option overrides the management class copy group mode parameter for backup copy groups; it does not affect the frequency parameter or any other backup copy group parameters. This option does not override exclude statements, so objects that are excluded from backup are not eligible for backup even when the absolute option is specified.

Important: Before you use the absolute option, consider the following effects that this option can have on backup and IBM Spectrum Protect™ server operations:

- Backups consume more server storage and database resources.
- Backups consume more network bandwidth.
- Server operations, such as inventory expiration, storage pool backup, storage pool migration, reclamation, and node replication, require more time to complete. Data deduplication might help mitigate some of these effects, but it does not avoid the processing that is required to reconstitute the deduplicated data back to its original form when the storage pool is migrated or backed up to non-deduplicated storage.

This option is valid only as a command-line parameter for the incremental command when you are performing the following operations:

- Full or partial progressive incremental backups of file systems or disk drives.
- Snapshot differential backups when createnewbase=yes is also specified.

To force a full backup of a file system that uses journal-based backup, specify both the nojournal and absolute options on the incremental command.

Windows During a domain incremental backup, where systemstate is specified as part of the domain, the absolute option does not force a full backup of system state objects. To force a domain incremental backup operation to create a full backup of system state objects, you must add systemstatebackupmethod full to the client options file.

To use the absolute option on scheduled incremental backups, the IBM Spectrum Protect server administrator must create a separate backup schedule that includes the absolute option on the schedule's options parameter.

Supported Clients

This option is valid for all clients as a command-line parameter for the incremental command. This option cannot be added to a client option set on the IBM Spectrum Protect server.

Syntax

```
>>-ABSolute-------------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Command line:

AIX | Linux | Mac OS X | Solaris

```
dsmc incr -absolute "/Users/sparky/source/*.c"
```

Windows

```
dsmc incr -absolute c:\foo\*.c
```

Windows

Adlocation

You can use the adlocation option with the query adobjects or restore adobjects commands to indicate whether the Active Directory objects are to be queried or restored from the local Active Directory Deleted Objects container or from a system state

backup on the IBM Spectrum Protect™ server.

Supported Clients

This option is valid for supported Windows Server clients. The IBM Spectrum Protect API does not support this option.

Syntax

```
                .-local--.
>>-ADLOCation--+--------+---------------------------------------><
                '-server-'
```

Parameters

server
: Specifies that the Active Directory objects are to be queried or restored from a system state backup on the IBM Spectrum Protect server. Valid for all supported Windows server clients.

local
: Specifies that the Active Directory objects are to be queried or restored from the local Active Directory Deleted Objects container. This is the default.

Example

Command line:

```
query adobjects "cn=Jim Smith" -adlocation=server
```

AIX | Linux

Afmskipuncachedfiles

The afmskipuncachedfiles option specifies whether uncached and dirty files in General Parallel File System (GPFS™) Active File Management file sets are processed for backup, archive, and migration operations.

GPFS Active File Management and *uncached* and *dirty* file states are explained in GPFS product information.

Running HSM on GPFS file systems that use Active File Management file sets is explained in Guidance for integrating IBM Spectrum Scale AFM with IBM Spectrum Protect .

If you back up, archive, or migrate files from a file system that contains Active File Management file sets, set `afmskipuncachedfiles=yes`.

Restriction: If Active File Management is running in Local Update (LU) mode, the afmskipuncachedfiles option in the cache file set must be set to No.

Supported Clients

This option is valid for backup-archive clients that run on AIX® and Linux systems.

Options File

Place this option in the dsm.sys file before any server stanzas.

Syntax

```
                          .-NO--.
>>-AFMSKIPUNCACHEDFILES--+-----+--------------------------------><
                          '-YES-'
```

Parameters

NO
: The Active File Management file state is ignored during backup, archive, and migration operations. Migration operations on uncached or dirty files fail and yield error message ANS9525E. Backup and archive operations on uncached files require Active File Management fetch operations. The fetch operations can cause significant network traffic between the Active File Management home and cache. This parameter is the default.

YES
: Uncached or dirty files in Active File Management file sets are skipped during backup, archive, and migration processing.

Archmc

Use the archmc option with the archive command to specify the available management class for your policy domain to which you want to bind your archived files and directories.

When you archive a file, you can override the assigned management class using the archmc option on the archive command or by using the web client. Overriding the management class using the web client is equivalent to using the archmc option on the archive command.

If you do not use the archmc option, the server binds archived directories to the default management class. If the default management class has no archive copy group, the server binds archived directories to the management class with the shortest retention period.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

AIX | Linux | Solaris | Mac OS X This option is valid for all UNIX and Linux clients. The IBM Spectrum Protect™ API does not support this option.

Windows This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option.

Syntax

```
>>-ARCHMc = -managementclass----------------------------------><
```

Parameters

managementclass
: Specifies an available management class in the active policy set of your policy domain. This management class overrides the default management class and any include statements for the files and directories you are archiving.

Examples

Command line:

Mac OS X

```
dsmc archive -archmc=ret2yrs /Users/van/Documents/budget.jan
```

AIX | Linux | Solaris | Mac OS X

```
dsmc archive -archmc=ret2yrs /home/plan/proj1/budget.jan
```

Windows

```
dsmc archive -archmc=ret2yrs c:\plan\proj1\budget.jan\*
```

AIX | Linux | Solaris

Archsymlinkasfile

The archsymlinkasfile option specifies whether the backup-archive client follows a symbolic link and archives the file or directory to which it points, or archives the symbolic link only. Use this option with the archive command.

Supported Clients

This option is valid for all UNIX clients except Mac OS X. The server can also define this option.

Options File

Place this option in the client user options file (dsm.opt).

Syntax

```
                        .-Yes-.
>>-ARCHSYMLinkasfile--+-----+-----------------------------------><
                      '-No--'
```

Parameters

Yes
: Specifies that the client follows a symbolic link and archives the associated file or directory. This is the default.

No
: Specifies that the client archives the symbolic link and not the associated file or directory.

Examples

Options file:
: archsymlinkasfile no

Command line:
: -archsyml=no

AIX | Linux | Solaris | Mac OS X

Asnodename

Use the asnodename option to allow agent nodes to back up or restore data on behalf of another node (the target node). This enables concurrent operations from multiple nodes to store data to the same target node and file space in parallel.

Your client node must be granted access to the target node by the IBM Spectrum Protect™ server administrative client grant proxynode command, and you must be a root user to use the asnodename option.

When the IBM Spectrum Protect administrator grants a node proxy authority, and you use the asnodename option to become that node, you can query and restore all files as if you had root authority.

An agent node is a client node that has been granted authority to perform client operations on behalf of a target node.

A target node is a client node that grants authority to one or more agent nodes to perform client operations on its behalf.

A proxy operation uses the settings for the target node (such as maxnummp and deduplication) and schedules that are defined on the server. The IBM Spectrum Protect server node settings and schedules for the agent node are ignored.

For example, you can use the following command to back up shared data for file space stored under the node name MyCluster:

```
/cluster1/mydata

dsmc incremental /Users -asnodenodename=MyCluster
```

You can also use the asnodename option to restore data under another node name on the server. You can only restore the data that you own.

The asnodename option differs from the nodename option as follows:

- When using the nodename option, you must enter the password for the node name you specify.
- When using the asnodename option, you must enter the password for your client agent node to access the data stored for the client target node.

Restrictions: You cannot use the asnodename option with -fromnode and you cannot perform NAS backup using asnodename. Also, asnodename can be used for clustered systems, although no specific cluster software is supported.

Supported Clients

This option is valid for all UNIX and Linux clients.

Options File

Place this option in the dsm.sys file *within* a server stanza. You can set this option on the **General** tab of the Preferences editor.

Syntax

```
>>-ASNODEname- --targetnode-------------------------------------><
```

Parameters

targetnode
: Specifies the node name on the IBM Spectrum Protect server under which you want to back up or restore data.

Examples

Options file:
: asnodename mycluster

Command line:
: -asnodename=mycluster

This option is not valid in interactive mode, but it can be defined in the options portion of a schedule definition.

- AIX | Linux | Solaris | Mac OS X Session settings and schedules for a proxy operation
  A proxy operation occurs when an agent node uses the `asnodename target_node_name` option to complete operations on behalf of the specified target node.

Windows

Asnodename

Use the asnodename option to allow an agent node to back up, archive, restore, retrieve, and query data on behalf of a target node.

An *agent node* is a client node that the IBM Spectrum Protect™ administrator grants the authority to perform client operations on behalf of a *target node*. The target node is the client node that the agent node performs the actions for. The administrator uses the grant proxynode command on the IBM Spectrum Protect server to grant this authority.

Agent nodes can be used to distribute the workload of backing up a computer's volumes, across multiple client systems. Each system that is involved in the backup uses its own agent node name, but the backup data is stored in a common file space that is owned by the target node.

For example, assume that you plan to back up four volumes that belong to a node that is named SCORPIO, but the backup operation takes too long to run. You can distribute part of the workload to three other machines: TAURUS, ARIES, and LEO. SCORPIO and the three other machines each back up one of SCORPIO's volumes. Each node that is involved in the backup connects to the server by using its own agent node name, and each node specifies a unique value for the asnodename option. Do not use a computer name or cluster name for the asnodename value. The following table illustrates an example configuration.

Table 1. Setting the value of the asnodename option to distribute backups.

Host name	NODENAME option value	ASNODENAME option value	Volume backed up	Server file space name
SCORPIO	SCORPIO	TARGET_SCORPIO	\\scorpio\r$	\\target_scorpio\r$
TAURUS	TAURUS	TARGET_SCORPIO	\\scorpio\s$	\\target_scoprio\s$
ARIES	ARIES	TARGET_SCORPIO	\\scorpio\t$	\\target_scoprio\t$
LEO	LEO	TARGET_SCORPIO	\\scorpio\u$	\\target_scorpio\u$

To create the relationships between the target node and the proxy nodes, the IBM Spectrum Protect server administrator needs to take the following actions:

1. Register nodes SCORPIO, TAURUS, ARIES, LEO, and TARGET_SCORPIO.
2. Grant nodes SCORPIO, TAURUS, ARIES, and LEO proxy authority to node TARGET_SCORPIO

When you back up or archive data without the asnodename option, the backed up data is stored in a file space on the server that matches the UNC name of the drive on which the original data exists.

When you use the asnodename option to back up data on behalf of a target node, the data is stored in a file space that is owned by the target node. However, instead of using the host name in the file space name, the target node name is used in the file space name. For example, if node TAURUS backs up data on SCORPIO's S drive and sets the asnodename option value to `–asnodename=target_scorpio`, the backup data is stored in a file space named \\target_scorpio\s$. The file space is owned by the TARGET_SCORPIO node.

When you restore or retrieve data, the default behavior is to restore or retrieve the data to a location that matches the file space name.

Continuing with the preceding example, if node SCORPIO uses `–asnodename=target_scorpio` to restore data from \\target_scorpio\s$, the client attempts to restore the data to the S drive on a computer named TARGET_SCORPIO. This operation does not produce the expected result because, in this sample configuration, there is no computer that is named TARGET_SCORPIO.

In the following example, the restore command is entered on the SCORPIO node. The command restores all files and subdirectories from the Users\andy\education directory in the \\target_scorpio\s$ file space to the S drive on the computer that is named SCORPIO:

```
dsmc restore \\target_scorpio\s$\users\andy\education\* s:\
  -subdir=yes -asnodename=target_scorpio
```

The following considerations apply when you use a proxy node to back up or restore data on other nodes:

- A proxy operation uses the settings for the target node (such as maxnummp and deduplication) and schedules that are defined on the IBM Spectrum Protect server. The IBM Spectrum Protect server node settings and schedules for the agent node are ignored.
- You cannot use asnodename with the backup nas command.
- You cannot use asnodename with the fromnode option.
- If you use asnodename to backup and restore volumes that are in a cluster configuration, do not use clusternode yes.
- You cannot use asnodename to back up or restore system state.
- If an agent node restores data from a backup set, the system state object in the backup set is not restored.
- You can use asnodename with the backup image command, but you must specify the volume by UNC name. You cannot use the drive letter.
- If you use the same asnodename value to back up files from different machines, you need to keep track which files or volumes are backed up from each system so that you can restore them to the correct location.
- All agent nodes in a multiple node environment should be of the same platform type.
- Do not use target nodes as traditional nodes, especially if you encrypt your files before backing them up to the server.

Supported Clients

This option is valid for all Windows clients.

Options File

Place this option in the dsm.opt file. You can set this option on the General tab of the Preferences editor.

Syntax

```
>>-ASNODEname- --targetnode-----------------------------------><
```

Parameters

targetnode

Specifies the node name on the IBM Spectrum Protect server under which you want to back up or restore data.

Examples

Options file:

```
asnodename target_scorpio
```

Command line:

This command backs up the entire F: drive to a server file space named \\target_scorpio\f$.

```
dsmc incremental f: -asnodename=target_scorpio
```

This option is not valid in interactive mode, but it can be defined in the options portion of a schedule definition.

- Windows Session settings and schedules for a proxy operation
  A proxy operation occurs when an agent node uses the `asnodename target_node_name` option to complete operations on behalf of the specified target node.

Windows

Asrmode

Use the asrmode option with the restore and restore systemstate commands to specify whether to perform a restore operation in system ASR recovery mode.

This option is used in the context of restore commands generated in the asr.sif file by the backup asr command only.

Supported Clients

This option is valid for supported Windows clients that are running in a Windows Preinstallation Environment; both BIOS and UEFI boot architectures are supported.

Syntax

Parameters

No
: Specifies that the client does not perform the restore operation in system ASR recovery mode.

Yes
: Specifies that the client performs the restore operation in ASR recovery mode. This is the default for Windows clients during ASR recovery. These clients are running in Windows Preinstallation Environment (WinPE) during ASR recovery.

Examples

Command line:

```
restore systemstate -asrmode=yes
restore systemstate -asrmode=yes -inactive -pick
```

This option is valid for an interactive session, but cannot be changed by entering the option while running an interactive session.

Auditlogging

Use the auditlogging option to generate an audit log that contains an entry for each file that is processed during an incremental, selective, archive, restore, or retrieve operation.

The audit log can be configured to capture either a basic level of information or a more inclusive (full) level of information.

The basic level of the audit logging feature captures the information that is in the schedule log and it records information that a file has been backed up, archived, updated, restored, retrieved, expired, deleted, skipped or failed during an incremental backup, selective backup, archive, restore or retrieve operation. In addition, the basic level of audit logging captures the input command for commands run through the backup-archive command line or scheduler clients.

The full level of audit logging records an action for each file that is processed by the backup-archive client. In addition to all of the events recorded by the basic level of audit logging, the full level of audit logging records information for a file that has been excluded or not sent during a progressive incremental backup operation because the file had not changed.

The following is an example of the messages that are issued when the audit log is configured to capture the basic level of information:

AIX Linux Solaris Mac OS X

```
04/21/07 15:25:05 ANS1650I Command:
  sel /home/spike/test/*
04/21/07 15:25:05 ANS1651I Backed Up:

  \\spike\c$\test\file.txt
04/21/07 15:25:05 ANS1659I Skipped:
  \\spike\c$\test\file.txt
```

AIX Linux Solaris Mac OS X The following messages can be issued when the audit log is configured to capture the full level of information (in addition to all messages issued for the basic level of audit logging):

AIX Linux Solaris Mac OS X

```
04/21/07 15:25:05 ANS1660I Excluded:
  /home/spike/test/file.txt
04/21/07 15:25:05 ANS1661I Unchanged:
  /home/spike/test/file.txt
```

Windows The following is an example of the messages that are issued when the audit log is configured to capture the full level of information (in addition to all messages issued for the basic level of audit logging):

Windows

```
04/21/07 15:25:05 ANS1660I Excluded:
  \\spike\c$\test\file.txt
04/21/07 15:25:05 ANS1661I Unchanged:
  \\spike\c$\test\file.txt
```

The audit log is not a substitute or a replacement for the standard error log (`dsmerror.log`) or for the schedule log (`dsmsched.log`). If an error occurs that prevents a file from being processed, a message indicating that an error has occurred is written to the audit log, but the message will not indicate the nature of the error. For problem diagnostics the standard error log must still be used.

The audit log entries only contain a time stamp and object name. There is no information to distinguish between files and directories or any information about the size of an object.

Mac OS X The Mac OS X backup-archive client creates the audit log as a Unicode (UTF-16) file.

Windows When using the Windows backup-archive client, all object names are written in the UNC format. The Windows backup-archive client creates the audit log as a Unicode file.

By default, the name of the audit log is `dsmaudit.log` and it is contained in the same directory as the error log, `dsmerror.log`. The name and location of the audit log can be configured using the auditlogname option. There are no parameters to control the size of the audit log or to prune the audit log. The auditlogname option cannot be set as an option in an IBM Spectrum Protect™ server client options set.

Mac OS X The auditlogging command is supported with backup commands that interact with file-level objects such as backup groups.

AIX Linux Solaris The auditlogging command is not supported with backup commands which interact with image-level objects such as backup image or restore image. The auditlogging command is supported with backup commands that interact with file-level objects such as backup groups.

Windows The auditlogging command is not supported with backup commands which interact with image-level objects such as backup image or restore image. The auditlogging command is supported with backup commands that interact with file-level objects such as backup groups, and backup systemstate.

If you have enabled audit logging for an operation and there is a failure trying to write to the audit log (for example, the disk on which the audit log resides is out of space), the audit logging is disabled for the rest of the operation and the return code for the operation is set to 12, regardless of the outcome of the operation.

Supported Clients

This option is valid for all clients.

Options File

Windows Place this option in the dsm.opt file.

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza.

Syntax

```
                  .-off---.
>>-AUDITLOGGing--+-------+-----------------------------------><
                 +-basic-+
                 '-full--'
```

Parameters

off
: Specifies that the audit logging facility is not engaged. This is the default.

basic
: Specifies that the audit log captures a basic level of information.

full
: Specifies that the audit log captures a more extensive level of information.

Examples

Run an incremental backup with audit logging enabled.

Command line:

```
dsmc i -auditlogging=basic
```

Back up a list of files using the maximum level of auditing, which enables a separate application, such as a Perl script, to verify the results.

Windows

```
dsmc i -filelist=file.lst -auditlogging=full
  -auditlogname="c:\program files\tivoli\tsm\baclient\
  temp_audit001.log"
```

Auditlogname

The auditlogname option specifies the path and file name where you want to store audit log information. This option applies when audit logging is enabled.

Supported Clients

This option is valid for all clients.

Options File

Windows Place this option in the dsm.opt file.

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza.

Syntax

```
>>-AUDITLOGName--filespec---------------------------------------><
```

Parameters

filespec
Specifies the path and file name where you want the backup-archive client to store audit log information.

If you specify a file name only, the file is stored in your current directory. The default is the installation directory with a file name of dsmaudit.log. The dsmaudit.log file cannot be a symbolic link.

Windows In Uniform Naming Convention (UNC) format, the path must contain a drive letter. In the following example, the path contains the drive letter D$: \\computer7\D$\logs\tsmaudit.log.

Examples

Run an incremental backup with audit logging enabled.

AIX Linux Solaris Mac OS X Sample output

Autodeploy

Use the autodeploy option to enable or disable an automatic deployment of the client if a restart is required.

Supported Clients

AIX | Linux | Mac OS X | Solaris This option is valid for AIX®, Linux, Mac, and Solaris clients.

Windows This option is valid for Windows clients

Options File

You can set this option by including it in your client options file. You can also set in using the Java GUI by clicking Edit > Client Preferences and selecting the appropriate option on the General tab.

Windows

Syntax

```
                .-Yes------.
>>-AUTODEPLOY--+----------+-----------------------------------><
               +-No-------+
               '-NOReboot-'
```

Windows

Parameters

Yes
: Specifies that the client is automatically deployed from the server. Yes is the default.
Important:

- When you set autodeploy to yes, if a restart of the client workstation is required to complete the deployment, you cannot disable the restart. The client workstation will be restarted. If it is important that the workstation is not automatically restarted, set autodeploy to noreboot. The deployment will be canceled if a restart is required. The current client is not affected.
- If a restart is required, the deployment manager initiates a restart for the client computer and exits. However, it is possible that you cancel or interrupt the restart. Since the deployment manager is already terminated, a message is not sent to the server to indicate the failure of the restart. The deployment result is still successful. You must restart the computer so that the new client deployment completes.

No
: Specifies that the client is not automatically deployed from the server.

NOReboot
: Specifies that the deployment manager never automatically restarts the client computer, even if a restart is required. If a restart is required, allowing automatic deployment to many machines with the NOReboot parameter can result in only a partial update of, potentially, many clients.

  To alleviate this problem, the deployment manager tries to detect if a restart is required. If a restart is required, the deployment manager cancels the deployment before the new client installation. This guarantees that the client computer

still has a working backup-archive client, and the new client deployment can be rescheduled.

There are rare cases where the deployment manager cannot detect the restart; for example, if client processes are started from a script. In these cases, the new client installation will continue, but a manual restart of the client computer is required.

AIX | Linux | Mac OS X | Solaris

Syntax

```
                .-Yes-.
>>-AUTODEPLOY--+-----+----------------------------------------><
                '-No--'
```

AIX | Linux | Mac OS X | Solaris

Parameters

Yes
: Specifies that the client is automatically deployed from the server. Yes is the default.

No
: Specifies that the client is not automatically deployed from the server.

Examples

AIX | Linux | Mac OS X | Solaris | Windows

Options file:
: autodeploy no

Command line:
: Does not apply.

Windows

Options file:
: autodeploy noreboot

Command line:
: Does not apply.

AIX | Linux | Mac OS X | Solaris | Windows

Important: Use schedmode prompted with the autodeploy option, to enable the scheduler to process the client deployment schedule immediately.

Automatic backup-archive client deployment

Autofsrename

The autofsrename option renames an existing file space that is not Unicode-enabled on the IBM Spectrum Protect™ server so that a Unicode-enabled file space with the original name can be created for the current operation.

Mac OS X When you specify autofsrename yes in your client options file, and the server value of autofsrename is set to client, the IBM Spectrum Protect server generates a unique name by appending `_OLD` to the file space name you specify in the current operation. For example, the server renames the file space `Jaguar` to `Jaguar_OLD`. If the new file space name is too long, the suffix replaces the last characters of the file space name. For example, the `mylongfilesystemname` file space name is renamed to:

```
mylongfilesystem_OLD
```

Mac OS X If the new file space name already exists on the server, the server renames the new file space `Jaguar_OLDx`, where `x` is a unique number.

Mac OS X The server creates new Unicode-enabled file spaces that contain only the data specified in the current operation. For example, assume that `Jaguar` is the name of your startup disk and you archive all of the `.log` files in the `/Users/user5/Documents` directory. Before the archive takes place, the server renames the file space to `Jaguar_OLD`. The archive places the data specified in the current operation into the Unicode-enabled file space named `Jaguar`. The new Unicode-enabled file space now contains only the `/Users/user5/logs` directory and the `*.log` files specified in the operation. The server stores all subsequent full and partial incremental, selective backup, and archive data in the new Unicode-enabled file spaces.

Mac OS X For example, assume that `Jaguar` is the name of your startup disk and you archive all of the `.log` files in the `/Users/user5/Documents` directory. Before the archive takes place, the server renames the file space to `Jaguar_OLD`. The archive places the data specified in the current operation into the Unicode-enabled file space named `Jaguar`. The new Unicode-enabled file space now contains only the `/Users/user5/logs` directory and the `*.log` files specified in the operation. All subsequent full and partial incremental, selective backup, and archive data are stored in the new Unicode-enabled file spaces.

Windows When you specify `autofsrename yes` in your client options file, and the server value of autofsrename is set to `client`, the IBM Spectrum Protect server generates a unique name by appending `_OLD` to the file space name you specify in the current operation. For example, the server renames the file space `\\your-node-name\h$` to `\\your-node-name\h$_OLD`. If the new file space name is too long, the suffix replaces the last characters of the file space name, as follows:

```
\\your-node-name_OLD
```

Windows If the new file space name already exists on the server, the server renames the new file space `\\your-node-name_OLDx`, where `x` is a unique number.

Windows The server creates new Unicode-enabled file spaces that contain only the data specified in the current operation. For example, to archive files from your `H:` disk named `\\your-node\h$`, issue the following archive command:

```
arc h:\logs\*.log
```

Windows Before the archive takes place, the server renames the file space to `\\your-node\h$_OLD`. The archive places the data specified in the current operation into the Unicode-enabled file space named `\\your-node\h$`. The new Unicode-enabled file space now contains only the `\logs` directory and the `*.log` files specified in the operation. All subsequent full and partial incremental, selective backup, and archive data are stored in the new Unicode-enabled file spaces.

Renamed file spaces remain on the server as stabilized file spaces. *These file spaces contain all the original data, which you can restore as long as they remain on the server.*

Note: When an existing file space is renamed during Unicode conversion, any access rules defined for the file space remain applicable to the original file space. New access rules must be defined to apply to the new Unicode file space.

After installation, perform a full incremental backup and rename all existing file spaces that are not Unicode-enabled and back up the files and directories within them under the new Unicode-enabled file spaces. This operation requires increased processing time and storage on the server.

File spaces that are not Unicode-enabled can be viewed in the character set of the locale from which the files were backed up. A workstation running in a different locale might be unable to view or restore from these file spaces. Unicode-enabled file spaces that are backed up in one locale are visible in all other locales, provided that the workstation has the proper fonts installed.

Windows To restore or retrieve from a file space that is not Unicode-enabled, specify the source on the server and the destination on the client. See

Mac OS X The server can define the autofsrename option and override the autofsrename setting on the client.

Supported Clients

Mac OS X This option is valid for Mac OS X only. The server can define the autofsrename option and override the autofsrename setting on the client. The IBM Spectrum Protect API does not support this option.

Windows This option is valid for all Windows clients. The server can define the autofsrename option and override the autofsrename setting on the client. The IBM Spectrum Protect API does not support this option.

Options File

Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the General tab, Rename non-Unicode filespaces during backup/archive drop-down list box of the Preferences editor.

Windows Place this option in the client options file (dsm.opt) file. You can set this option on the General tab, Rename non-Unicode filespaces during backup/archive drop-down list box of the Preferences editor.

Syntax

```
                  .-Prompt-.
>>-AUTOFsrename--+--------+-------------------------------------><
                 +-Yes-----+
                 '-No------'
```

Parameters

Yes
: Specifies that the IBM Spectrum Protectserver automatically renames all file spaces that are not Unicode-enabled in the current backup or archive operation.

No
: Specifies that the server does not rename file spaces that are not Unicode-enabled in the current backup or archive operation.

Prompt
: Specifies that you are prompted whether to rename the file spaces that are not Unicode-enabled in the current operation. This is the default.

Considerations:

- This option applies only when the server sets the autofsrename option to `client`.
- When the client scheduler is running, the default behavior is to not prompt you. The next interactive session prompts you to rename the file space.
- The client prompts you *only* one time per file space. If you specify `no` at the prompt, the client cannot rename the file spaces later. However, the IBM Spectrum Protect administrator can rename the file spaces on the server.
- Mac OS X Windows When backing up files to a file space that is not Unicode-enabled, the Unicode-enabled client skips the files and directories with names containing characters from a code page that is different from the current locale.
- Mac OS X Windows If files and directories with names containing characters from a code page other than the current locale were previously backed up with a client that was not Unicode-enabled, they might be expired. The Unicode-enabled client expires these files if you do not migrate the file space to a Unicode-enabled file space. You can back up and archive these files to a Unicode-enabled file space.

Examples

Options file:

```
autofsrename yes
```

AIX Linux Solaris

Automount

The automount option adds an automounted file system into the domain by mounting it. Use this option with the domain option.

Use this option to specify all automounted file systems that the backup-archive client tries to mount at the following points in time:

- When the client starts
- When the backup is started
- When the the client has reached an automounted file system during backup

Mount the file system before the client does a backup of that file system. If the file system is always mounted before the backup is done, it is unnecessary to explicitly specify an automounted file system in the automount option. However, add this file system in the automount option to ensure that the file system has been mounted at all the points in time mentioned previously. The automounted file systems are remounted if they have gone offline in the meantime during a backup.

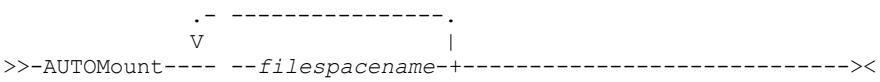
Supported Clients

This option is valid for all UNIX platforms except Mac OS X. The IBM Spectrum Protect™ API does not support this option.

Options File

Place this option in the client user options file (dsm.opt).

Syntax



Parameters

filespacename
: Specifies one or more fully qualified automounted file systems that are mounted and added into the domain.

Examples

Options file:
: automount /home/Fred /home/Sam

Command line:
: Does not apply.

Linux | Windows

Backmc

The backmc option specifies the management class to apply to the backup fastback command for retention purposes.

Use the backmc option with the backup fastback command.

If you back up an object more than once and specify a different management class for each backup, all backup versions of the object are rebound to the last management class specified.

Supported Clients

Linux This option is valid for Linux x86_64 clients.

Windows This option is valid for all Windows clients.

Options File

None. You can specify this option only on the command line or on the scheduler.

Syntax

Parameters

management_class_name
: Specifies the management class name.

Examples

Command line:
```
dsmc backup fastback -fbpolicyname=policy1 -fbserver=server1 -backmc=ret2yrs
```

Backupsetname

The backupsetname option specifies the name of a backup set from the IBM Spectrum Protect™ server.

You can use backupsetname option with the following commands:

- query backup
- query filespace
- Windows query image
- AIX Linux Solaris query image
- Windows query systemstate
- Windows restore image
- AIX Linux Solaris restore image

Note: The following commands take backupsetname as a positional parameter. The backupsetname positional parameter behaves differently from the backupsetname option. See the command explanations for a discussion of how the backupsetname positional parameter affects each of these commands:

- query backupset
- restore
- restore backupset

Supported Clients

AIX Linux Solaris This option is valid for all UNIX and Linux clients. The IBM Spectrum Protect API does not support this option.

Windows This option is valid for all clients. The IBM Spectrum Protect API does not support this option.

Options File

None. You can specify this option only on the command line.

Syntax

```
>>-BACKUPSETName--backupsetname---------------------------------><
```

Parameters

backupsetname
Specifies the name of a backup set from the IBM Spectrum Protect server. You cannot use wildcards.

Examples

Command line:

Mac OS X

```
dsmc query backup /Volumes/bkSets/file.1
  -backupsetname=YEAR_END_ACCOUNTING.12345678
```

AIX Linux Solaris Mac OS X

```
dsmc query backup /usr/projects -subdir=yes
  -backupsetname=YEAR_END_ACCOUNTING.12345678
```

AIX Linux Solaris

```
dsmc restore image /home/proj
  -backupsetname=ACCOUNTING_2007.12345678
```

AIX Linux Solaris Windows

```
dsmc query image -backupsetname=WEEKLY_BSET.21435678
```

Windows

```
dsmc query backup c:\* -subdir=yes
  -backupsetname=weekly_accounting_data.32145678
```

Windows

```
dsmc restore image e:
  -backupsetname=weekly_backup_data.12345678
```

Linux | Windows

Basesnapshotname

The basesnapshotname option specifies the snapshot to use as the base snapshot, when you perform a snapshot differential (snapdiff) backup of a NetApp filer volume. If you specify this option, you must also use the snapdiff option or an error occurs. If basesnapshotname is not specified, the useexistingbase option selects the most recent snapshot on the filer volume as the base snapshot.

If the specified snapshot cannot be found, an error is reported and the backup operation fails.

Supported Clients

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows clients.

Options File

This option can be specified in the client options file or on the command line.

Syntax

```
>>-BASESNAPSHOTName-- --snapshot_name-------------------------><
```

Parameters

snapshot_name
Specifies the name of an existing snapshot to use as the base snapshot. The name specified can be a snapshot name, such as vol1_snap, or it can be the name of a scheduled NetApp backup that has a name like nightly.*x*, where *x* is the sequence number (where nightly.0 is the oldest snapshot).
You can also use a pattern with wildcard characters to select a snapshot. The wildcard characters can be either of the following:

*
An asterisk (*) matches any character.

?
A question mark (?) matches a single character.

The wildcards are useful if your snapshots follow a pattern, such as including the date or data and time as part of the snapshot name. For example, a snapshot created on November 12 2012 at 11:10:00 AM could be saved as `UserDataVol_121103111000_snapshot`. The most recent snapshot that matches the pattern is selected as the existing base. For example, if there are two saved snapshots (`UserDataVol_121103111000_snapshot` and `UserDataVol_121103231000_snapshot`, the `UserDataVol_121103231100_snapshot` is selected because it is 12 hours newer than the other snapshot.

```
-basesnapshotname="UserDataVol_*_snapshot"
```

Question marks work well for scheduled backups that follow a consistent name pattern. This syntax selects the latest "nightly" backup as the snapshot to use as the existing base.

```
-basenameshotname="nightly.?"
```

Examples

Options file:

```
basesnapshotname nightly.?
```

```
basesnapshotname volum_base_snap
```

Command line:

```
dsmc incr \\DRFiler\UserDataVol_Mirror_Share -snapdiff
  -useexistingbase -basesnapshotname="nightly.?"
```

Useexistingbase

Cadlistenonport

The cadlistenonport option specifies whether to open a listening port for the client acceptor.

When a listening port is open, it can accept any inbound connections. However, the port is not used when the client acceptor manages only the scheduler and the scheduler runs in polling mode. You can use this option to prevent the acceptor from opening the unused port.

The default setting for this option is yes. Use cadlistenonport no only when managedservices schedule and schedmode polling are used.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Options File

AIX Linux Mac OS X Solaris Place this option in the client system-options file (dsm.sys) within a server stanza.

Windows Place this option in the client options file (dsm.opt).

Syntax

```
                    .-Yes-.
>>-CADLISTENONPort--+-----+-----------------------------------><
                    '-No--'
```

Parameters

Yes
: Specifies that the client acceptor opens a listening port. This parameter is the default.

No
: Specifies that the client acceptor does not open a listening port. Use this setting when you use the client acceptor only to manage the scheduler in polling mode.

  This setting effectively disables other client features that depend on the client acceptor, such as web client backup and restore operations, IBM Spectrum Protect for Virtual Environments: Data Protection for VMware vSphere GUI operations, and IBM Spectrum Protect Snapshot backup and restore operations.

Example

Options file:
: cadlistenonport no

Command line:
: Does not apply.

Schedmode
Windows

Casesensitiveaware

The casesensitiveaware option specifies whether the Windows backup-archive client attempts to filter out file and directory objects that have name conflicts that are caused by different capitalization of the object names.

NTFS and ReFS volumes are case-sensitive and allow case-sensitive file names to be stored. Although the Windows operating system is not case-sensitive, applications such as Windows Services for UNIX (SFU) uses POSIX conventions and allow case-sensitive file names. SFU is typically included with Windows operating systems such as Windows Powered OS and Windows Storage Server. These operating systems are typically deployed on hardware (for example, NAS hardware) which is acting as a dedicated file server in a heterogeneous environment.

If there are UNIX clients that store files on NTFS or ReFS volumes in these Windows file server environments, use the casesensitiveaware option. If this option is not used in these environments, unpredictable results occur during backup and archive operations if case-sensitive file name conflicts are encountered. For homogeneous Windows file server environments, the casesensitiveaware option is not necessary.

For example, if there is a set of objects that are called 'MyWork.xls', 'MYWORK.xls', and 'mywork.xls', because the Windows operating system is not case-sensitive, applications cannot distinguish between two objects named 'mywork.xls' and 'MyWork.xls'

For this reason, the Windows backup-archive client cannot guarantee the restore integrity of such objects. When a name casing conflict arises, the backup-archive client can guarantee only the restore integrity of the first file in an alphabetical sort. On an ASCII-based operating system such as Windows, this means that capital letters come first, alphabetically, before their lowercase counterparts, so 'MySwork.xls' would alphabetically precede 'mywork.xls'.

In this example, if the casesensitiveaware option is used, only 'MyWork.xls' is processed. An error message is issued for `'mywork.xls'` and it is skipped. If 'mywork.xls' is a directory, then the directory subtree 'mywork.xls' would be skipped. In all cases, messages are written to both the local error log and to the IBM Spectrum Protect™ server console to indicate the exact file names of the objects that are skipped.

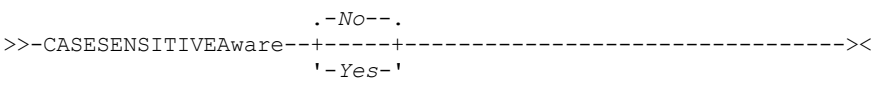
Supported Clients

This option is valid for all Windows clients. The server can also define this option.

Options File

Place this option in the client options file (dsm.opt).

Syntax



Parameters

yes
: Specifies that the client will attempt to identify object names which differ in casing only and filter out objects which have casing conflicts and cannot be guaranteed to be restored properly.

no
: Specifies that the client will not attempt to identify object names which differ in casing only. This is the default.

Changingretries

The changingretries option specifies how many additional times you want the client to attempt to back up or archive a file that is in use. Use this option with the archive, incremental, and selective commands.

This option is applied only when copy serialization, an attribute in a management class copy group, is shared static or shared dynamic.

With shared static serialization, if a file is open during an operation, the operation repeats the number of times that you specify. If the file is open during each attempt, the operation does not complete.

AIX Linux Solaris Mac OS X With shared dynamic serialization, if a file is open during an operation, the operation repeats the number of times that you specify. The backup or archive occurs during the last attempt whether the file is open or not.

Windows With shared dynamic serialization, if a file is open during an operation, the operation repeats the number of times that you specify. The backup or archive occurs during the last attempt whether the file is open or not. Open file support can be used to back up files that are locked or in use.

AIX Linux Solaris Mac OS X Windows

Supported Clients

AIX Linux Solaris Mac OS X This option is valid for all UNIX and Linux clients. The server can also define this option. The IBM Spectrum Protect™ API does not support this option.

Windows This option is valid for all Windows clients. The server can also define this option. The IBM Spectrum Protect API does not support this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Backup tab, Number of retries if file is in use field of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Backup tab, Number of retries if file is in use field of the Preferences editor.

Syntax

```
>>-CHAngingretries- numberretries------------------------------><
```

Parameters

numberretries
: Specifies the number of times a backup or archive operation is attempted if the file is in use. The range of values is zero through 4; the default is 4.

Examples

Options file:

```
changingretries 3
```

Command line:

```
-cha=3
```

AIX Linux Solaris Windows

Class

The class option specifies whether to display a list of NAS or client objects when using the delete filespace, query backup, and query filespace commands.

For example, to display a list of the file spaces belonging to a NAS node, enter the following command:

```
query filespace -class=nas
```

Supported Clients

AIX Solaris This option is valid only for AIX®, Linux, and Oracle Solaris clients. The IBM Spectrum Protect™ API does not support this option.

Windows This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option.

Options File

None. You can specify this option only on the command line.

Syntax

```
              .-client-.
>>-CLASS = -+---------+-----------------------------------------><
            '-nas-----'
```

Parameters

client
: Specifies that you want to display a list of file spaces for a client node. This is the default.

nas
: Specifies that you want to display a list of file spaces for a NAS node.

Examples

None. You can specify this option only on the command line.

Command line:

```
q backup -nasnodename=nodename -class=nas
```

Windows

Clientview

The clientview option is available to users who have upgraded from the IBM® Tivoli® Storage Manager Express® backup client to the enterprise backup-archive client.

You must be connected to the Tivoli Storage Manager Version 5.4 or higher server to use this option. The clientview option allows you to choose either the express view or the standard view of the client graphical user interface (GUI).

Supported Clients

This option is valid for all Windows clients.

Options File

Place this option in the dsm.opt file. To switch to the Express view:

1. In the backup-archive client GUI, select Edit > Preference from the menu bar.
2. From the General tab of the Preferences editor, in the Client View field, click Express.
3. Click OK to save your change.

To switch to the Standard view:

1. In the backup-archive client GUI, click Modify Settings.
2. From the General tab of the Preferences Editor, in the Client View field, click Standard.
3. Click OK to save your change.

Syntax

```
                  .-standard-.
>>-CLIENTVIEW = -+-----------+---------------------------------><
                 '-express--'
```

Parameters

standard
: Specifies that the standard, or enterprise, view of the backup-archive client GUI should be used. The standard view contains the advanced features of the backup-archive client GUI. This is the default.

express
: Specifies that the express view of the backup-archive client GUI should be used. The express view contains the same features as the Express backup client GUI.

Windows

Clusterdisksonly

The clusterdisksonly option specifies whether the backup-archive client allows the backup of only clustered disks in specific environments.

The backup-archive client allows for the backup of only clustered disks when the client is running in the following environments:

- In a Microsoft Cluster Server (MSCS)
- When failover clustering is employed on a supported Windows Server client
- In a VERITAS Cluster Server (VCS) environment, when you set clusternode yes

The backup-archive client previously allowed only backups and restores of data on clustered drives that were mounted as a drive letter.

It is common to find clustered drives that are mounted as volume mount points. Windows Server operating systems allow users to surpass the 26-drive-letter limitation by allowing volume mount points to be defined on a clustered server. The client can protect data on cluster disks that are mounted as drive letters on Windows Server OS computers. The client can also protect data on cluster disks that are mounted as volume mount points. The backup-archive client can automatically determine whether a volume that is using a volume mount point is a cluster volume.

When you set clusterdisksonly yes, the backup-archive client continues to segregate local drives from cluster drives when it evaluates the ALL-LOCAL domain option. When clusterdisksonly no is specified, you must explicitly define the backup domains. When clusterdisksonly no is specified, the backup-archive client also bypasses enumeration of cluster resources to determine which resources represent cluster drives.

Supported Clients

This option is valid for all supported Windows Server clients.

Options File

Place this option in the client options file (dsm.opt).

Syntax

```
                      .-Yes-.
>>-CLUSTERDISKSOnly--+-----+-----------------------------------><
                     '-No--'
```

Parameters

Yes
: Specifies that the client allows only the processing of cluster drives. Yes is the default.

No
: Specifies that the client allows the processing of any disk when clusternode yes is set.

Examples

Scenario 1: Back up a node that manages the local (non-clustered) drives and the system state information

This is the node that is dedicated to the restoration of the physical system if a hardware failure occurs. There are no clustered drives that are mounted as volume mount points.

Options file:

```
CLUSTERNODE NO (default)
CLUSTERDISKSONLY YES (default)
DOMAIN ALL-LOCAL (default)
EXCLUDE c:\...\file.txt
```

Scenario 1b: Back up a node that manages the local (non-clustered) drives and the system state information and bypass enumeration of cluster resources

This is a scenario similar to scenario 1, which can be deployed if the backup-archive client takes an inappropriate amount of time during startup processing. During initialization of the backup-archive client, all of the cluster resources are enumerated to determine which resources represent cluster disk devices. This processing can be skipped by setting clusterdisksonly no.

Options file:

```
CLUSTERNODE NO (default)
CLUSTERDISKSONLY NO
DOMAIN C: D: (local drives must be explicitly enumerated)
EXCLUDE c:\...\file.txt
```

Scenario 2: Back up a node that manages the clustered drives within a cluster resource group and bypass enumeration of cluster resources

This is a scenario that can be deployed if the backup-archive client takes an inappropriate amount of time during startup processing. During initialization of the backup-archive client, all of the cluster resources are enumerated to determine which resources represent cluster disk devices. This processing can be skipped by setting clusterdisksonly no.

Options file:

```
CLUSTERNODE YES
CLUSTERDISKSONLY NO
DOMAIN f: g:
EXCLUDE f:\...\file.txt
```

Scenario 3: Back up a node that manages the clustered drives within a cluster resource group, by using volume mount points as cluster resources

In this scenario, it is assumed that the node is responsible for backing up a cluster resource group that has two drives, f: and f:\mnt. There are clustered drives that are mounted as volume mount points (Windows Server operating systems). Ensure that you define the incremental processing domain as only the volumes within a cluster resource group. If you have multiple cluster resource groups, assign a unique client node to manage each cluster resource group.

Options file

```
CLUSTERNODE YES
CLUSTERDISKSONLY YES
DOMAIN f: f:\mnt
EXCLUDE f:\mnt\...\file.txt
```

Table 1 lists the clusternode and clusterdisksonly combinations.

Table 1. Clusternode and clusterdisksonly combinations

Clusternode	Clusterdisksonly	When to use
no	yes	This is the default behavior if nothing is specified; since the clusterdisksonly option is set to clusterdisksonly yes, the cluster disk map is built. This combination is used for backing up local drives.
yes	yes	This is the default way to run in a cluster node to back up cluster disks, including disks that are exposed as mount points; the cluster disk map is built.
yes	no	For clients that run on Windows Server operating systems, you must specify clusterdisksonly no only if you want to bypass cluster volume enumeration for performance reasons.

Windows

Clusternode

The clusternode option specifies how the backup-archive client manages cluster drives.

Windows The backup-archive client manages clustered drives in the following environments:

- A Microsoft Cluster Server (MSCS)
- Failover Clustering on Windows Server systems
- VERITAS Cluster Server (VCS)

When the clusternode yes is set, only shared cluster drives are available for backup and archive processing. When you set clusternode yes, the node name defaults to the cluster name.

Windows To back up local drives or Windows Server system state, you must set clusternode no.

Note: You must set the clusternode yes for all IBM Spectrum Protect™-managed cluster operations. Inconsistent use of the clusternode option for a given IBM Spectrum Protect cluster node name can cause the cluster node name encrypted password to be invalidated, and prompt the user to reenter the password during the next IBM Spectrum Protect program invocation.

Use the optfile option to properly call the correct (cluster) dsm.opt for all IBM Spectrum Protect programs to ensure proper functionality for cluster related operations. See the optfile option description for more information.

Windows

Supported Clients

This option is valid for Windows Server operating system clients.

Options File

Place this option in the client options file (dsm.opt).

Syntax

```
                .-No--.
>>-CLUSTERnode--+-----+---------------------------------------><
                '-Yes-'
```

Parameters

Windows Yes

Windows Specifies that you want the client to manage cluster drives in the following environments:

- A MSCS
- Failover Clustering on Windows Server systems
- VCS

No

Specifies that you want to back up local disks. This is the default.

Examples

Options file:

cluster no

Command line:

-cluster=yes

This option is valid only on the initial command line. It is not valid in interactive mode.

Collocatebyfilespec

Use the collocatebyfilespec option to specify whether the backup-archive client uses only one server session to send objects generated from one file specification.

Setting the collocatebyfilespec option to yes attempts to eliminate interspersing of files from different file specifications, by limiting the client to one server session per file specification. Therefore, if you store the data to tape, files for each file specification are stored together on one tape (unless another tape is required for more capacity).

Considerations:

- Use the collocatebyfilespec option only if the storage pool is going directly to tape. If you use this option going to a disk storage pool, you could affect some load balancing, and therefore, performance.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

AIX | Linux | Solaris | Mac OS X This option is valid for all UNIX and Linux clients. The server can also define this option.

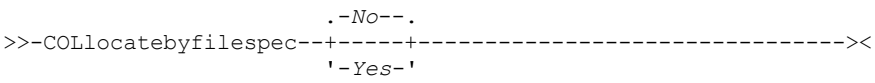
Windows This option is valid for all Windows clients. The server can also define this option.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the client user-options file (dsm.opt).

Windows Place this option in the client options file (dsm.opt).

Syntax



Parameters

Yes
: Specifies that you want the client to use only one server session to send objects generated from one file specification. Therefore, if you store the data to tape, files for each file specification are stored together on one tape, unless another tape is required for more capacity. Restore performance can increase as a result.

No
: Specifies that the client can (depending on the execution dynamics and on the setting of the resourceutilization option of 3 or higher) use more than one server session to send the files from one file specification. This is the default.

  Backup performance might increase as a result. If the files are backed up to tape, files are stored on multiple tapes. Generally, the files specified in the file specification are still contiguous.

Examples

Options file:
: collocatebyfilespec yes

Command line:
: -collocatebyfilespec=yes

This option is valid only on the initial command line. It is not valid in interactive mode.

Commmethod

The commmethod option specifies the communication method you use to provide connectivity for client-server communication.

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Communication tab of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Communication tab of the Preferences editor.

AIX Linux Solaris Mac OS X

Syntax

```
              .-TCPip-----.
>>-COMMMethod-+-----------+-----------------------------------><
              +-SHAREdmem-+
              '-V6TCPIP---'
```

Windows

Syntax

```
              .-TCPip------.
>>-COMMMethod-+------------+-----------------------------------><
              +-SHAREdmem--+
              +-V6TCPIP----+
              '-NAMedpipes-'
```

Parameters

TCPip
The Transmission Control Protocol/Internet Protocol (TCP/IP) communication method. This is the default.

V6Tcpip
Indicates that either TCP/IP V4 or V6 should be used, depending on the system configuration and the results of a domain name service lookup. A valid DNS environment must be available.

Windows NAMedpipes
Windows The interprocess communication method that permits message data streams to pass between a client and a server. Use this communication method with an IBM Spectrum Protect™ server that is running on the same workstation as the client.

AIX Linux Solaris SHAREdmem
AIX Linux Solaris Use the shared memory communication method when the client and server are running on the same system. This provides better performance than the TCP/IP protocol.

AIX Linux Solaris This option is valid for AIX®, Linux, and Oracle Solaris clients.

When specifying this communication method on AIX, the client can be logged in as root or non-root, as long as the server is running as root. If the server is not running as root, the user ID running the client must match the user ID running the server.

Important: When using commmethod sharedmem on Linux, you might receive error message: `ANR8294W Shared Memory Session unable to initialize` on the server or storage agent console. By default, Linux is not set up with sufficient system resources to create the message queues. You must increase the kernel parameter, `MSGMNI`, to 128 (the default is 16). You can modify this parameter by performing the following command:

```
echo 128 > /proc/sys/kernel/msgmni
```

To enable this parameter to remain persistent after rebooting the system, you can instead add the following line to the file `/etc/sysctl.conf`, then reboot the system:

```
kernel.msgmni=128
```

To view the current ipc settings, run this command:

```
ipcs -l
```

Now look at the `max queues system wide` value. The default is 16.

Windows SHAREdmem

Windows Use the shared memory communication method when the client and server are running on the same system. This provides better performance than the TCP/IP protocol.

Note: Use of this communication method requires that both client and server run under the same Windows account.

Examples

Options file:

Use only TCP/IP V4.

```
commmethod tcpip
```

Use both TCP/IP V4 and V6, depending on how the system is configured, and the results of a domain name service lookup.

```
commmethod V6Tcpip
```

Note: The dsmc schedule command cannot be used when both SCHEDMODe prompt and commmethod V6Tcpip are specified.

Command line:

-commm=tcpip

-commm=V6Tcpip

This option is valid only on the initial command line. It is not valid in interactive mode.

Commrestartduration

The commrestartduration option specifies the maximum number of minutes you want the client to try to reconnect to the IBM Spectrum Protect™ server after a communication error occurs.

Note: A scheduled event continues if the client reconnects with the server before the commrestartduration value elapses, even if the startup window of the event has elapsed.

You can use the commrestartduration option and the commrestartinterval in busy or unstable network environments to decrease connection failures.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Communication tab, Common Options section of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Communication tab, Common Options section of the Preferences editor.

Syntax

```
>>-COMMRESTARTDuration- minutes--------------------------------><
```

Parameters

minutes

The maximum number of minutes you want the client to attempt to reconnect with a server after a communication failure occurs. The range of values is zero through 9999; the default is 60.

Examples

Options file:

commrestartduration 90

Command line:

Does not apply.

Commrestartinterval

The commrestartinterval option specifies the number of seconds you want the client to wait between attempts to reconnect to the IBM Spectrum Protect™ server after a communication error occurs.

Note: Use this option only when commrestartduration is a value greater than zero.

You can use the commrestartduration option and the commrestartinterval in busy or unstable network environments to decrease connection failures.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This option is valid for all clients.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Communication tab, Common Options section of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Communication tab, Common Options section of the Preferences editor.

Syntax

```
>>-COMMRESTARTInterval- seconds--------------------------------><
```

Parameters

seconds

The number of seconds you want the client to wait between attempts to reconnect with a server after a communication failure occurs. The range of values is zero through 65535; the default is 15.

Examples

Options file:

commrestartinterval 30

Command line:

Does not apply.

Compressalways

The compressalways option specifies whether to continue compressing an object if it grows during compression.

Use this option with the compression option, and with the archive, incremental, and selective commands.

The compressalways option is ignored when client-side deduplication is enabled.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This option is valid for all clients. The server can also define this option.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the client user-options file (dsm.opt). You can set this option on the Backup tab, Continue Compressing if Object Grows check box of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Backup tab, Continue Compressing if Object Grows check box of the Preferences editor.

Syntax

```
                    .-Yes-.
>>-COMPRESSAlways--+-----+-------------------------------------><
                    '-No--'
```

Parameters

Yes
: File compression continues even if the file grows as a result of compression. This is the default.

No
: Backup-archive client objects are resent uncompressed if they grow during compression. API behavior depends on the application. Application backups might fail.

Examples

Options file:
: compressalways yes

Command line:
: -compressa=no

This option is valid only on the initial command line. It is not valid in interactive mode.

Compression

The compression option compresses files before you send them to the server.

Compressing your files reduces data storage for backup versions and archive copies of your files. It can, however, affect IBM Spectrum Protect™ throughput. A fast processor on a slow network connection benefits from compression, but a slow processor on a fast network connection does not.

Use the compression option with the archive, incremental, and selective commands.

AIX | Linux | Solaris The backup image command uses the compression option value specified in the dsm.sys file. This option is valid on the initial command line and in interactive mode. The server can also define this option which overrides the client value.

Windows The backup image command uses the compression option value specified in the dsm.opt file. This option is valid on the initial command line and in interactive mode. The server can also define this option which overrides the client value.

The backup-archive client backs up a sparse file as a regular file if client compression is off. Set compression yes to enable file compression when backing up sparse files to minimize network transaction time and maximize server storage space.

If you set compressalways yes, compression continues even if the file size increases. To stop compression if the file size grows, and resend the file uncompressed, set compressalways no.

If you set compression yes, you can control compression processing in the following ways:

- Windows Use the exclude.compression option in your client options file (dsm.opt) to exclude specific files or groups of files from compression processing.
- AIX | Linux | Solaris | Mac OS X Use the exclude.compression option in your client system-options file (dsm.sys) to exclude specific files or groups of files from compression processing.
- Windows Use the include.compression option in your client options file (dsm.opt) to include files within a broad group of excluded files for compression processing.

- AIX | Linux | Solaris | Mac OS X Use the include.compression option in your client system-options file (dsm.sys) to include files within a broad group of excluded files for compression processing.

This option controls compression only if your administrator specifies that your client node can compress files before sending them to the server.

The type of compression that the client uses is determined by the combination of compression and client-side data deduplication that is used during backup or archive processing. The following types of compression are used:

LZ4
: A faster and more efficient compression method that the client uses when client-deduplicated data is sent to an LZ4-compatible container storage pool on the IBM Spectrum Protect server. The server must be at version 7.1.5 or later, and must use container storage pools. Client-side LZ4 compression is used only when client-side data deduplication is enabled.

LZW
: A traditional type of compression that the client uses in any of the following situations:

  - Client-deduplicated data is sent to traditional (non-container) storage pools on the server.
  - The client data does not undergo client-side data deduplication. (Does not apply to Data Protection for VMware and Data Protection for Microsoft Hyper-V, in which only client-deduplicated data can be compressed.)
  - The client data undergoes only traditional server-side data deduplication. (Does not apply to Data Protection for VMware and Data Protection for Microsoft Hyper-V, in which only client-deduplicated data can be compressed.)

None
: The object is not compressed by the client. The object is not compressed because the compression option is set to *no*, or the option is not specified during backup or archive processing. Although the object is not compressed by the client, it might be compressed by the server.

You do not need to set the compression type. It is determined by the backup-archive client at the time of backup or archive processing.

Supported Clients

This option is valid for all clients. The server can also define this option.

Options File

AIX | Linux | Mac OS X | Solaris Place this option in the dsm.sys file within a server stanza. You can set this option on the Backup tab, Compress objects check box of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the `Backup` tab, Compress objects check box of the Preferences editor.

Syntax

```
                .-No--.
>>-COMPRESSIon--+-----+---------------------------------------><
                '-Yes-'
```

Parameters

No
: Files are not compressed before they are sent to the server. This is the default.

Yes
: Files are compressed before they are sent to the server.

Examples

Options file:
: compression yes

Command line:
: -compressi=no

This option is valid only on the initial command line. It is not valid in interactive mode.

Console

Use the console option with the query systeminfo command to output information to the console.

- DSMOPTFILE - The contents of the dsm.opt file.
- AIX Linux Solaris Mac OS X DSMSYSFILE - The contents of the dsm.sys file.
- ENV - Environment variables.
- ERRORLOG - The IBM Spectrum Protect™ error log file.
- FILE - Attributes for the file name that you specify.
- Windows FILESNOTTOBACKUP - Enumeration of Windows Registry key:

  ```
  HKEY_LOCAL_MACHINE\
     SYSTEM\
        CurrentControlSet\
           BackupRestore\
              FilesNotToBackup
  ```

  This key specifies those files that backup products should not back up. The query inclexcl command indicates that these files are excluded per the operating system.
- INCLEXCL - Compiles a list of include-exclude in the order in which they are processed during backup and archive operations.
- Windows KEYSNOTTORESTORE - Enumeration of Windows Registry key:

  ```
  HKEY_LOCAL_MACHINE\
     SYSTEM\
        ControlSet001\
           BackupRestore\
              KeysNotToRestore
  ```

  This key specifies those Windows Registry keys that backup products should not restore.
- Windows MSINFO - Windows system information (output from MSINFO32.EXE).
- OPTIONS - Compiled options.
- Windows OSINFO - Name and version of the client operating system
- AIX Linux Solaris Mac OS X OSINFO - Name and version of the client operating system (includes ULIMIT information for UNIX and Linux).
- POLICY - Policy set dump.
- Windows REGISTRY - Windows IBM Spectrum Protect-related Windows Registry entries.
- SCHEDLOG - The contents of the IBM Spectrum Protect schedule log (usually dsmsched.log).
- Windows SFP - The list of files protected by Windows System File Protection, and for each file, indicates whether that file exists. These files are backed up as part of the SYSFILES system object.
- Windows SFP=*filename* - Indicates whether the specified file (*filename*) is protected by Windows System File Protection. For example:

  ```
  SFP=C:\WINNT\SYSTEM32\MSVCRT.DLL
  ```

- Windows SYSTEMSTATE - Windows system state information.
- AIX CLUSTER - AIX® cluster information.
- Windows CLUSTER - Windows cluster information.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

Syntax

```
>>-CONsole-----------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Command line:

```
query systeminfo dsmoptfile errorlog -console
```

Linux | Windows

Createnewbase

The createnewbase option creates a base snapshot and uses it as a source to run a full incremental backup.

Some files might not be backed up when the snapshot difference incremental backup command is run. If the files are skipped, you can run a snapshot difference incremental backup with the createnewbase option to back up these files. See Snapdiff for a list of reasons why a file might not be backed up when the snapshot difference command is run.

One reason that a file can be skipped during backup processing is because the file name is not supported by NetApp Data ONTAP. NetApp Data ONTAP Versions 8.0 and versions lower than 7.3.3 only support file names that are within the 7 bit ASCII character set. NetApp Data ONTAP Version 7.3.3 and versions greater than 8.0.0 support Unicode file names. If you upgraded NetApp Data ONTAP from a version that does not support Unicode file names to a version that does support Unicode files names, run a full incremental backup with the createnewbase=migrate option.

Supported Clients

This option is valid for the following clients:

- Windows All Windows clients
- Linux Linux x86_64 clients

Enter the createnewbase option on the command line. Specify this option with the snapdiff option.

Syntax

```
                  .-No------.
>>-Createnewbase--+---------+---------------------------------><
                  +-Yes-----+
                  +-IGNore--+
                  '-MIGRate-'
```

Parameters

No
: Specifies that a snapshot difference incremental is run. If the backup-archive client detects that the NetApp Data ONTAP file server has been migrated from a version that does not support Unicode file names to a file server that does, a warning message is recorded to the error log and the IBM Spectrum Protect™ server activity log. The warning message indicates that you must run a full incremental backup and logs a return code of 8 even if the operation completed successfully. This parameter is the default value.

Yes
: Specifies that a full incremental is run by creating a new base snapshot and is using it to run a scan-based incremental backup. Use this option to back up any file changes that might not have been detected by the snapshot difference API. If the operation finished successfully, the command ends with a return code of 0.
Do not set createnewbase=yes for any schedule that runs a daily snapshot difference backup. Instead, create a separate, monthly schedule that has the createnewbase=yes option.

IGNore
: Specifies that a snapshot difference incremental backup is run when the backup-archive client detects that the NetApp Data ONTAP file server was upgraded to support Unicode file names.

The ignore option is different from the no parameter because the ignore option suppresses the warning message. Instead, an informational message is recorded in the error log and the IBM Spectrum Protect activity log that informs you to run a full incremental backup.
If the command finishes successfully, it returns a code of 0.
Use the ignore option if you have upgraded the NetApp Data ONTAP file server to support Unicode but you have not yet run a full incremental backup. This option is used only when the backup-archive client has detected that the file server was migrated and a full incremental has not yet been run. The option is ignored for all other times.

MIGRate

Specifies that if the NetApp Data ONTAP file server was upgraded to a version that supports Unicode file names, a base snapshot is taken and a scan-based incremental backup is run. The migrate option is different from the yes option because the migrate option creates a base snapshot only when the client detects that the NetApp Data ONTAP file server version was updated. The yes option creates a base snapshot every time the command is run.
After the incremental backup finishes, no additional migration-related messages are recorded to the error log or the IBM Spectrum Protect server activity log. When the operation finishes, the command ends with a return code of 0.
Use the migrate option if you have upgraded the NetApp Data ONTAP file server to support Unicode but you have not yet run a full incremental backup. The migrate option is ignored if the NetApp Data ONTAP file server has not been upgraded.

Examples

Command line:

```
dsmc incremental -snapdiff -createnewbase=yes /net/home1
```

Linux | Windows

Datacenter

Specifies the target location of the data center that will contain the restored machine data.

Use this option on restore vm commands.

If folders are used within virtual center to organize datacenters, then the folder name needs to be included in the datacenter specification, separated by a slash.

If you are restoring through a ESX server rather than a virtual center, the -datacenter=ha-datacenter option should be used.

The default target location is the datacenter which the virtual machine was stored at the time of backup.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Examples

Restore a virtual machine to USEast datacenter which is organizaed under a folder named Production in the virtual center.

```
dsmc restore vm my_vm -datacenter=Production/USEast
```

Restore a virtual machine backup taken from a virtual center, but using a ESX server at the time of restore.

```
restore vm my_vm -datacenter=ha-datacenter
```

Restore the virtual machine into the USWest datacenter.

```
restore vm my_vm -datacenter=USWEst
```

Linux | Windows

Datastore

Specifies the datastore target to be used during VMware restore operation.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Example

Restore the virtual machine to a datastore named `ds8k_prod1`:

```
restore vm my_vm -datastore=ds8k_prod1
```

Dateformat

The dateformat option specifies the format you want to use to display or enter dates.

Windows Use this option if you want to change the default date format for the language of the message repository you are using.

AIX Linux Solaris Mac OS X Windows By default, the backup-archive and administrative clients obtain format information from the locale definition in effect at the time you start the client. Consult the documentation on your local system for details about setting up your locale definition.

Note:

1. The dateformat option does not affect the web client. The web client uses the date format for the locale that the browser is running in. If the browser is not running in a locale that is supported, the web client uses the date format for US English.
2. When you change the date format and use the schedlogretention option to prune the schedule log, the client removes all entries in the schedule log with a different date format when pruning the log. When you change the date format and use the errorlogretention option to prune the error log, the client removes all entries in the error log with a different date when pruning the log. When changing the date format, copy the schedule log and error log if you want to preserve log entries that contain a different date format.

You can use the dateformat option with the following commands.

- delete archive
- delete backup
- expire
- query archive
- Windows query asr
- query backup
- query filespace
- AIX Linux Solaris query image
- Windows query image
- Windows query systemstate
- restore
- AIX Linux Solaris restore image
- Windows restore image
- AIX Linux Solaris Mac OS X restore nas
- Windows restore nas
- retrieve
- Windows restore registry
- set event

When you include the dateformat option with a command, it must precede the fromdate, pitdate, and todate options.

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client user-options file (dsm.opt). You can set this option on the Regional Settings tab, Date Format drop-down list of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Regional Settings tab, Date Format drop-down list of the Preferences editor.

Syntax

```
>>-DATEformat-- --format_number--------------------------------><
```

Parameters

format_number

Displays the date using one of the following formats. Select the number that corresponds to the date format you want to use:

AIX Linux Solaris 0

AIX Linux Solaris Use the locale-specified date format (does not apply to Mac OS X).

AIX Solaris For AIX® and Solaris: This is the default if the locale-specified date format consists of digits and separator characters.

1

MM/DD/YYYY

AIX Solaris For AIX and Solaris: This is the default if the locale-specified date format consists of anything but digits and separator characters.

AIX Linux Solaris Windows This is the default for the following available translations:

AIX Linux Solaris Windows

- US English
- Chinese (Traditional)
- Korean

2

DD-MM-YYYY

AIX Linux Solaris Windows This is the default for the following available translations:

AIX Linux Solaris Windows

- Brazilian Portuguese
- Italian

3

YYYY-MM-DD

AIX Linux Solaris Windows This is the default for the following available translations:

AIX Linux Solaris Windows

- Japanese
- Chinese (Simplified)
- Polish

4

DD.MM.YYYY

AIX Linux Solaris Windows This is the default for the following available translations:

AIX Linux Solaris Windows

- German
- French
- Spanish
- Czech
- Russian

5

YYYY.MM.DD

AIX Linux Solaris Windows This is the default for the following available translations:

AIX Linux Solaris Windows

- Hungarian

6
YYYY/MM/DD
7
DD/MM/YYYY

Examples

Options file:
dateformat 3
Command line:
-date=3

This option is valid on the initial command line and in interactive mode. If you use this option in interactive mode, it affects only the command with which it is specified. When that command completes, the value reverts to the value at the beginning of the interactive session. This is the value from the dsm.opt file unless overridden by the initial command line or by an option forced by the server.

Additional considerations for specifying time and date formats

The date or time format you specify with this option must be used when using options that take date and time as input. Examples are: totime, fromtime, todate, fromdate, and pittime.

For example, if you specify the timeformat option as `TIMEFORMAT 4`, the value that you provide on the fromtime or totime option must be specified as a time such as `12:24:00pm`. Specifying `13:24:00` would not be valid because `TIMEFORMAT 4` requires an hour integer that is 12 or less. If you want to specify up to 24 hour values on an option, and if you want to use commas as separators, you must specify `TIMEFORMAT 2`.

AIX | Linux | Mac OS X | Solaris

Configuring date and time formats in the system locale configuration file

You can specify date and time formats by configuring them in your system's locale file. If you specify time and date formats in the locale file, they must be defined using a subset of number-producing format specifiers that are supported by the C language `strftime()` function. You can use the following specifiers to set date and time formats in configuration settings for your locale.

Date specifiers

- `%Y` - the year, in four digits. For example, 2011.
- `%y` - the year, last two digits only. For example, 11 not 2011.
- `%m` - the month, as a decimal number (1-12).
- `%d` - the day of the month (1-31).

In the date specifiers, you can specify only one year specifier. Do not specify both `%Y` and `%y`. The E modifier (a capital E) can precede the date specifiers to produce the locale's alternative form for the year, month, or day. If no alternative form exists, the E modifier is ignored. Separate the specifiers with a single 7-bit ASCII character. Commonly used separators include colons (:), commas (,), periods (.), hyphens (-), or forward slash (/) characters. Do not use multibyte characters as separators.

Time specifiers

- `%H` - the hour, in 24-hour form (00-23).
- `%I` - the hour, in 12-hour form (00-12).
- `%M` - minutes after the hour (00-59).
- `%S` - seconds after the minute (00-59)
- `%p` - adds the AM (before noon) or PM (after noon) indicator.

In the time specifiers, you can specify only one hour specifier. Do not specify both `%I` and `%H`.

The O modifier (a capital O) can precede the time specifiers to produce the locale's alternative form for the hour, minutes, or seconds. The O modifier cannot precede the `%p` specifier. Separate the specifiers with a single 7-bit ASCII character. Commonly used separators include colons (:), commas (,), or periods (.). Do not use multibyte characters as separators. Do not specify a separator between the `%p` specifier and the separator that precedes or follows it.

Time format examples, configured in the locale settings

AIX Linux Mac OS X Solaris To set a particular time format, edit the configuration file for your locale and modify the `t_fmt` line to support your needs. Whatever time format you select applies both to output and to input. After the locale configuration file has been edited, the localedef command must be run to create the final locale file.

Table 1. Sample time format settings in the locale configuration (t_fmt line)

Example	Result
"%H:%M:%S"	Displays time in the form *hh:mm:ss* with *hh* ranging from 0 through 23.
"%H,%M,%S"	Displays time in the form *hh,mm,ss* with *hh* ranging from 0 through 23.
"%I,%M,13p"	Displays time in the form *hh,mm,ssA/P* with *hh* ranging from 1 through 12 and *A/P* is the local abbreviation for ante-meridian (AM in English) or post-meridian (PM in English).

Date format examples, configured in the locale settings

AIX Linux Mac OS X Solaris To set a particular date format, edit the configuration file and modify the `d_fmt` line as needed to support your needs. Whatever date format you select applies both to output and to input.

Table 2. Sample date format settings in the locale configuration (d_fmt line)

Example	Result
"%m/%d/%y"	Displays the date in the form MM/DD/YY.
"%d.%m.%Y"	Displays the date in the form DD.MM.YYYY.

Dedupcachepath

Use the dedupcachepath option to specify the location where the client-side data deduplication cache database is created.

This option is ignored if the enablededupcache=no option is set during backup or archive processing.

Supported Clients

This option is valid for all clients. This option is also valid for the IBM Spectrum Protect™ API.

Options File

AIX Linux Solaris Mac OS X Place this option in the system-options file (dsm.sys). You can set this option on the Deduplication Cache Location field of the Preferences editor. The option can be set in the client option set on the IBM Spectrum Protect server.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Deduplication > Deduplication Cache Location text box of the Preferences editor. The option can be set in the client option set on the IBM Spectrum Protect server.

Syntax

```
>>-DEDUPCACHEPath--path----------------------------------------><
```

Parameters

path

Specifies the location where the client-side data deduplication cache database is created if the enablededupcache option is set to yes. The default location is to create the data deduplication cache file in the backup-archive client or API installation directory.

Windows In Uniform Naming Convention (UNC) format, the path must contain a drive letter. In the following UNC format example, the path contains the drive letter D$: \\computer7\D$\stgmgr\dedupecache.

Examples

Options file:

AIX Linux Mac OS X Solaris dedupcachepath /volumes/temp

Windows dedupcachepath c:\logs\dedup\

Command line:

Does not apply.

Related reference:
Enablededupcache

Dedupcachesize

Use the dedupcachesize option to determine the maximum size of the data deduplication cache file. When the cache file reaches its maximum size, the contents of the cache are deleted and new entries are added.

Supported Clients

This option is valid for all clients. This option is also valid for the IBM Spectrum Protect™ API.

Options File

AIX Linux Solaris Mac OS X Place this option in the system-options file (dsm.sys). You can set this option on the Deduplication > Deduplication Cache > Maximum Size field of the Preferences editor. The option can be set in the client option set on the IBM Spectrum Protect server.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Deduplication > Deduplication Cache > Maximum Size field of the Preferences editor. The option can be set in the client option set on IBM Spectrum Protect server.

Syntax

```
>>-DEDUPCACHESize--dedupcachesize-----------------------------><
```

Parameters

dedupcachesize

Specifies the maximum size, in megabytes, of the data deduplication cache file. The range of values is 1 - 2048; the default is 256.

Examples

Options file:

dedupcachesize 1024

Command line:

Does not apply.

Related reference:
Deduplication

Deduplication

Use the deduplication option to specify whether to enable redundant client-side data elimination when data is transferred to the IBM Spectrum Protect™ server during backup and archive processing.

Data deduplication is disabled if the enablelanfree option is set. Backup-archive client encrypted files are excluded from client-side data deduplication. Files from encrypted file systems are also excluded.

To support client-side data deduplication, the following criteria must be met:

- Client-side data deduplication for the node is enabled on the server.

- The storage pool destination for the data must be a storage pool that is enabled for data deduplication. The storage pool must have a device type of "file".
- A file can be excluded from client-side data deduplication processing (by default all files are included).
- The server can limit the maximum transaction size for data deduplication by setting the CLIENTDEDUPTXNLIMIT option on the server. For more information about the option, refer to the IBM Spectrum Protect server documentation.
- The file size must be larger than 2 KB.

Supported Clients

This option is valid for all clients; it can also be used by the IBM Spectrum Protect API.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the system-options file (dsm.sys) within a server stanza. You can set this option by selecting the Deduplication > Enable Deduplication check box of the Preferences editor. The option can be set in the client option set on the IBM Spectrum Protect server.

Windows Place this option in the client options file (dsm.opt). You can set this option by selecting the Deduplication > Enable Deduplication check box of the Preferences editor. The option can be set in the client option set on IBM Spectrum Protect server.

Syntax

```
                    .-No--.
>>-DEDUPLication--+-----+-------------------------------------><
                    '-Yes-'
```

Parameters

No
: Specifies that you do not want to enable client-side data deduplication for backup and archive processing. No is the default.

Yes
: Specifies that you want to enable client-side data deduplication for backup and archive processing.

Examples

Options file:
: deduplication yes

Command line:
: -deduplication=yes

This option is valid only on the initial command line. It is not valid in interactive mode.

Related reference:
Include options
Exclude options

AIX | Linux | Solaris | Mac OS X

Defaultserver

Use the defaultserver option to specify the name of the IBM Spectrum Protect™ server to contact for backup-archive services if more than one server is defined in the dsm.sys file.

By default, the backup-archive contacts the server defined by the first stanza in the dsm.sys file. This option is only used if the servername option is not specified in the client user-options file (dsm.opt).

If you have the HSM client installed on your workstation, and you do not specify a migration server with the migrateserver option, use this option to specify the server to which you want to migrate files. For more information, see the IBM Spectrum Protect for Space Management product documentation on IBM Knowledge Center at http://www.ibm.com/support/knowledgecenter/SSERBH/welcome.

Supported Clients

This option is valid for all UNIX clients.

Options File

Place this option *at the beginning* of the dsm.sys file *before* any server stanzas.

Syntax

```
>>-DEFAULTServer-- --servername-------------------------------><
```

Parameters

servername
: Specifies the name of the default server to which you back up or archive files. The server to which files are migrated from your local file systems can also be specified with this option.

Examples

Options file:
: defaults server_a

Command line:
: Does not apply.

Deletefiles

Use the deletefiles option with the archive command to delete files from your workstation after you archive them.

AIX | Linux | Solaris | Windows You can also use this option with the restore image command and the incremental option to delete files from the restored image if they were deleted after the image was created. Deletion of files is performed correctly if the backup copy group of the IBM Spectrum Protect™ server has enough versions for existing and deleted files.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect API does not support this option.

Syntax

```
>>-DELetefiles-------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Command line:

Mac OS X

```
dsmc archive "/Users/dgordon/Documents/*.c" -deletefiles
```

AIX | Linux | Solaris

```
dsmc archive "/home/foo/*.c" -deletefiles
dsmc restore image /local/data -incremental -deletefiles
```

Windows

```
dsmc archive c:\foo\*.c -deletefiles
dsmc rest image c: -incre -deletefiles
```

Description

The description option assigns or specifies a description for files when performing archive, delete archive, retrieve, query archive, or query backupset.

For example, if you want to archive a file named budget.jan and assign to it the description "2002 Budget for Proj 1", you would enter: AIX | Linux | Solaris | Mac OS X

```
dsmc archive -des="2003 Budget for Proj 1" /home/plan/
proj1/budget.jan
```

Windows

```
dsmc archive -des="2003 Budget for Proj 1" c:\plan\proj1\
budget.jan
```

Note:

1. The maximum length of a description is 254 characters.
2. Enclose the value in quotation marks (" ") if the option value that you enter contains a blank space.

Use the description option with the following commands:

- archive
- delete archive
- query archive
- query backupset
- retrieve

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-DEScription = - --description------------------------------><
```

Parameters

description

Assigns a description to the file you are archiving. If you do not specify a description with the archive command, the default is Archive Date:x, where x is the current system date. Note that the date is always 10 characters long. If your date format uses a two digit year, there are two blank spaces at the end of the date. For example, a default description using a four-digit year might be "Archive Date: 2002/05/03", and the same default with a two-digit year might be `"Archive Date: 02/05/03 "` (note the two spaces at the end). When retrieving files using the two-digit year description, you can enter the -description option string in either of the following ways:

```
-description="ArchiveDate: 02/05/03  "
 or
-description="ArchiveDate: 02/05/03*"
```

If you use the archive command to archive more than one file, the description you enter applies to each file. For example, to archive a group of files and assign the same description, *Project X*, to each file, you would enter:

Mac OS X

```
dsmc archive -description="Project X" "/Users/van/Documents/*.x"
```

AIX | Linux | Solaris | Mac OS X

```
dsmc archive -description="Project X" "/home/allproj/.*"
```

Windows

```
dsmc archive -description="Project X" c:\allproj\*.x
```

You can then use the description to retrieve all of the files.

Examples

Command line:

Mac OS X

```
dsmc archive "/Users/van/Documents/*.prj" -des="2003 Budget for Proj 1"
```

AIX Linux Solaris Mac OS X

```
dsmc archive "/home/foo/*.prj" -des="2003 Budget for Proj 1"
dsmc query backupset -loc=server -descr="My Laptop"
```

Windows

```
dsmc archive -des="2003 Budget for Proj 1" c:\foo\ *.prj
```

Detail

Use the detail option to display management class, file space, backup, archive information, and additional information, depending on the command with which it is used.

Use the detail option with the query mgmtclass command to display detailed information about each management class in your active policy set. If you do not use the detail option, only the management class name and a brief description are displayed on the screen. If you specify the detail option, information about attributes in each copy group contained in each management class is displayed on the screen. A management class can contain a backup copy group, an archive copy group, both, or neither.

AIX Linux Solaris Mac OS X Windows A Unicode-enabled file space might not display correctly if the server cannot display the Unicode name. In this case, use the file space identifier (fsID) of the file space to identify these file spaces on the server. Use the detail option with the delete filespace and query filespace commands to determine the fsID of a file space. The fsID also appears in the file information dialog in the backup-archive client and web client GUIs.

Use the detail option with the query backup and query archive commands to display these attributes of the file that you specify:

- Last modification date
- Last access date
- Compression
- Encryption type
- Client-side data deduplication
- Whether the HSM client migrated or premigrated the file

Windows Use the detail option with the query adobjects command to display detailed information about Active Directory objects, including all of their attributes.

Windows Use the detail option with the query adobjects command to display detailed information about Active Directory objects, including all of their attributes.

Linux Windows Use the detail with the query vm command to display the following statistics:

- The average number of IBM Spectrum Protect™ objects that are needed to describe a single megablock, across all megablocks in a backup.
- The average number of IBM Spectrum Protect objects that are needed to describe a single megablock, for all megablocks in a filespace.
- The ratio of the amount of data, reported by Change Block Tracking, versus the amount of data that was actually backed up, in a specific backup.
- The ratio of the amount of data, reported by Change Block Tracking, versus the amount of data that was actually backed up, for all backups in this filespace.
- The number of backups that were created since the last full backup was created from the production disks.

The values returned on query vm can help you fine tune the heuristics (see the Mbobjrefreshthresh and Mbpctrefreshthresh options) to fine tune the values trigger for megablock refreshes.

Use the detail option with the following commands:

- delete filespace
- incremental

- Windows query adobjects
- query archive
- query backup
- query filespace
- query inclexcl
- query mgmtclass
- Windows query systemstate
- Linux Windows query vm

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients. This option is not set in the client options file; use it by adding it to the command line when you enter any of the commands that support it. The IBM Spectrum Protect API does not support this option.

Syntax

```
>>-DETail-----------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Command line:

```
dsmc query mgmtclass -detail

dsmc query filespace -detail

dsmc query backup file1 -detail
```

Windows

```
dsmc query systemstate -detail
```

Linux Windows

```
dsmc query vm -detail
```

Linux Windows

Diffsnapshot

The diffsnapshot option controls whether the backup-archive client creates the differential snapshot when it runs a snapshot difference incremental backup.

If the differential snapshot is not created by the client, the latest snapshot found on the volume is used as the differential snapshot and as the source for the backup operation.

The default value is to create the differential snapshot. This option is ignored the first time that the snapdiff option is used. The first time the snapdiff option is used on a volume, a snapshot must be created and used as the source for a full incremental backup. Snapshots that are created by the backup-archive client are deleted by the client after the next snapshot difference incremental backup is complete.

Linux Snapshots can be created with the Network Appliance FilerView tool. Use the latest parameter if you want the client to use the most recent snapshot that was created with this or any other method. Snapshots that are created by methods outside of IBM Spectrum Protect™ are never deleted by the client.

Windows Snapshots can be created with the Network Appliance FilerView tool. Use the latest parameter if you want the client to use the most recent snapshot that was created. Whatever method is used to create named snapshots, snapshot names that differ

only by case will not work properly with the snapdiff option. Snapshots that are created by the client will not have the casing problem. Snapshots that are created by methods outside of IBM Spectrum Protect are never deleted by the client.

Supported Clients

Windows This option is valid for all Windows clients.

Linux This option is valid for Linux x86_64 clients.

Syntax

```
                .-create-.
>>-DIFFSNAPSHOT--+--------+-----------------------------------><
                '-latest-'
```

Parameters

create
: Specifies that you want to create a new, persistent, snapshot to use as the source snapshot. This value is the default.

latest
: Specifies that you want to use the latest snapshot that is found on the file server as the source snapshot.

Examples

Linux Command line:

Linux Perform a snapshot difference incremental backup of an NFS mounted file system `/vol/vol1` hosted on the file server `homestore.example.com`, where `/net/home1` is the mount point of `/vol/vol1`.

Linux
```
incremental -snapdiff -diffsnapshot=latest /net/home1
```

The -diffsnapshot option value of latest means that the operation uses the latest snapshot (the active snapshot).

Windows Command line:

Windows Perform a snapdiff incremental backup from a snapshot that was taken of a network share `//homestore.example.com/vol/vol1` mounted on drive `H:`, where `homestore.example.com` is a file server.

Windows
```
incremental -snapdiff H:
```

Windows Perform a snapdiff incremental backup from a snapshot that was taken of a network share `//homestore.example.com/vol/vol1` mounted on drive `H:`, where `homestore.example.com` is a file server. The -diffsnapshot option value of `LATEST` means the operation uses the latest snapshot (the active snapshot) for volume `H:`.

Windows
```
incremental -snapdiff H: -diffsnapshot=latest
```

Linux | Windows

Diffsnapshotname

The diffsnapshotname option allows you to specify which differential snapshot, on the target filer volume, to use during a snapshot differential backup. This option is only specified if you also specify diffsnapshot=latest.

If this option is not specified, diffsnapshot=latest selects the most recent existing snapshot on the filer volume and uses it as the differential snapshot.

Supported Clients

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows clients.

Options File

This option can be specified in the client options file or on the command line.

Syntax

```
>>-DIFFSNAPSHOTName-- --snapshot_name--------------------------><
```

Parameters

snapshot_name
Specifies the name of an existing snapshot to use as the differential snapshot.
You can also use a pattern with wildcard characters to select a snapshot. Wildcards can be either of the following characters:

*
An asterisk (*) matches any character.

?
A question mark (?) matches a single character.

The most recent snapshot that matches the wildcard pattern is selected as the differential snapshot.

Examples

Options file:

```
diffsnapshotname volume_base_snap

diffsnapshotname nightly.?
```

Command line:

```
dsmc incr \\DRFiler\UserDataVol_Mirror_Share -snapdiff
  -useexistingbase -basenameshotname="nightly.?"
  -diffsnapshot=latest -diffsnapshotname="nightly.?"
```

Related reference:
Useexistingbase
Basesnapshotname

Dirmc

The dirmc option specifies the management class you want to use for directories.

If you do not specify this option to associate a management class with directories, the client program uses the management class in the active policy set of your policy domain with the longest retention period. Select a management class for individual directories that retains directories at least as long as it retains the files associated with them.

If you specify a management class with this option, all directories specified in a backup operation are bound to that management class.

The dirmc option specifies the management class of directories that you back up and it does not affect archived directories. Use the archmc option with the archive command to specify the available management class for your policy domain to which you want to bind your archived directories and files. If you do not use the archmc option, the server binds archived directories to the default management class. If the default management class has no archive copy group, the server binds archived directories to the management class with the shortest retention period.

Important: Only extended attributes and ACLs are stored in storage pools. The directory information, other than extended attributes and ACLs, remains in the database. On Windows systems, directories occupy storage pool space.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This option is valid for all clients. The server can also define this option.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the dsm.sys file within a server stanza. You can set this option on the Backup tab, Directory Management Class section in the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Backup tab, Directory Management Class section in the Preferences editor.

Syntax

```
>>-DIRMc-- --mgmtclassname-------------------------------------><
```

Parameters

mgmtclassname
: Specifies the name of the management class that you want to associate with directories. The client uses the management class name that you specify for all of the directories that you back up. If you do not specify this option, the client associates the management class with the longest retention period with directories.

Examples

Options file:
: dirm managdir

Command line
: Does not apply.

Dirsonly

The dirsonly option processes directories *only*. The client does not process files.

Use the dirsonly option with the following commands:

- archive
- incremental
- query archive
- query backup
- restore
- restore backupset
- retrieve
- selective

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-DIrsonly---------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Mac OS X Command line:
: Mac OS X `dsmc query backup -dirsonly "/Users/*"`

AIX Linux Solaris Mac OS X Command line:
: AIX Linux Solaris Mac OS X `dsmc query backup -dirsonly "*"`

Windows Command line:
: Windows `dsmc query backup -dirsonly c:*`

Disablenqr

The disablenqr option specifies whether the backup-archive client can use the no-query restore method for restoring files and directories from the server.

If you set the disablenqr option to no (the default), the client can use the no-query restore process.

If you set the disablenqr option to yes, the client can use only the standard restore process (also known as "classic restore").

Note: There is no option or value to specify that the client can use only the no-query restore method.

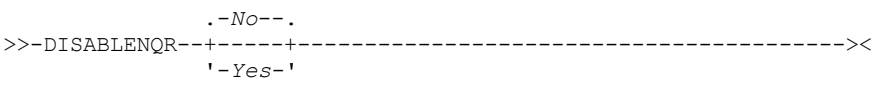
Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option. The server can also define this option.

Options File

Place this option in the dsm.opt file.

Syntax



Parameters

No
: Specifies that the client can use the no-query restore method. This is the default.

Yes
: Specifies that the client uses only the standard restore method. The no-query restore method is not allowed.

Examples

Options file:
: disablenqr yes

Command line
: -disablenqr=yes

Diskbuffsize

The diskbuffsize option specifies the maximum disk I/O buffer size (in kilobytes) that the client can use when reading files. The diskbuffsize option replaces the largecommbuffers option.

Windows Optimal backup, archive migration client performance can usually be achieved if the value for this option is equal to or smaller than the amount of file read ahead provided by the client file system. A larger buffer requires more memory and it might not improve performance.

AIX Linux Solaris Mac OS X Optimal backup, archive, or HSM migration client performance can usually be achieved if the value for this option is equal to or smaller than the amount of file read ahead provided by the client file system. A larger buffer requires more memory and it might not improve performance.

Important: Use the default setting, unless otherwise directed by IBM® support personnel.

AIX Linux Mac OS X Solaris Windows

Supported Clients

This option is valid for all clients.

Options File

Windows Place this option in the client options file (dsm.opt).

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza.

Syntax

```
>>-DISKBuffsize-- --size----------------------------------------><
```

Parameters

Windows size

Windows Specifies the maximum disk I/O buffer size (in kilobytes) that the client uses when reading files. The range of values is 16 through 1023; the default is 32.

AIX Linux Mac OS X Solaris size

AIX Linux Mac OS X Solaris Specifies the maximum disk I/O buffer size (in kilobytes) that the client uses when reading files. The range of values is 16 through 1023; the default is 32. For AIX®: If enablelanfree no is set, the default setting for diskbuffsize is 256.

Examples

Options file:

diskbuffsize 64

Command line:

Does not apply.

Diskcachelocation

The diskcachelocation option specifies the location where the disk cache database is created if the option memoryefficientbackup=diskcachemethod is set during an incremental backup.

You can specify the diskcachelocation option in your option file, or with the include.fs option. If the diskcachelocation option appears in the option file, its value is used for all file systems not represented by an include.fs option containing the diskcachelocation option.

The disk cache is a temporary file which is deleted after the incremental command is run. Use this option to select one of the following:

1. A location that has more free disk space if, when you are using memoryefficientbackup=diskcachemethod, you get the message that the disk cache file cannot be created because you do not have enough disk space.
2. A location on a different physical volume to reduce contention for the disk access mechanism, and therefore improve performance.

Important: For performance reasons, do not use a remote drive for diskcachelocation.

Mac OS X AIX Linux Solaris The actual amount of disk space required for the disk cache file created by disk cache incremental backups depends on the number of files and directories included in the backup and on the average length of the files and directories to be backed up. For UNIX and Linux, estimate 1 byte per character in the path name. For Mac OS X, estimate 4 bytes per character in the path name. For example, if there are 1 000 000 files and directories to be backed up and the average path length is 200 characters, then the database occupies approximately 200 MB for UNIX and Linux, and 800 MB for Mac OS X clients. Another way to estimate for planning purposes is to multiply the number of files and directories by the length of the longest path to establish a maximum database size.

Windows The actual amount of disk space required for the disk cache file created by disk cache incremental backups depends on the number of files and directories included in the backup and on the average length of the files and directories to be backed up. Estimate 2 bytes per character in the path name. For example, if there are 1 000 000 files and directories to be backed up and the average path length is 200 characters, then the database occupies approximately 400 MB. Another way to estimate for planning purposes is to multiply the number of files and directories by the length of the longest path to establish a maximum database size.

AIX Linux Solaris Mac OS X A second disk cache file is created for the list of migrated files when backing up an HSM managed file system. The combined disk cache files, created by disk cache incremental backups and HSM managed file system backups, can require above 400 MB of disk space for each million files being backed up. The disk cache file can become very large. Large file support must be enabled on the file system that is being used for the disk cache file.

Supported Clients

This option is valid for all clients. The server can also define this option.

Options File

Windows Place this option in the client options file (dsm.opt).

AIX Linux Solaris Mac OS X Place this option in the dsm.sys file within a server stanza.

Syntax

```
>>-DISKCACHELocation-- --path---------------------------------><
```

Parameters

path
Specifies the location where the disk cache database is created if memoryefficientbackup=diskcachemethod. The default location is to create the disk cache file in the root of the file space being processed.

Windows In Uniform Naming Convention (UNC) format, the path must contain a drive letter. In the following UNC format example, the path contains the drive letter D$: \\computer7\D$\temp\diskcache.

Examples

AIX Linux Solaris Mac OS X Options file:
AIX Linux Solaris Mac OS X

```
diskcachelocation /home
diskcachelocation /Volumes/hfs2
```

Windows Options file:
Windows

```
diskcachelocation c:\temp
diskcachelocation c:\tivoli\data
```

Command line:
Does not apply.

Domain

The domain option specifies what you want to include for incremental backup.

Domain objects are backed up only if you start the incremental command without a file specification.

AIX Linux Mac OS X Solaris The backup-archive client uses the domain value in the following situations to determine which file systems to process during an incremental backup:

- When you run an incremental backup by using the incremental command, and you do not specify which file systems to process.
- When your IBM Spectrum Protect™ administrator defines a schedule to run an incremental backup for you, but does not specify which file systems to process.
- When you select the Backup Domain action from the backup-archive client GUI

Windows The backup-archive client uses the domain value in the following situations to determine which drives to process during an incremental backup:

- When you run an incremental backup by using the incremental command, and you do not specify which drives to process.
- When your IBM Spectrum Protect administrator defines a schedule to run an incremental backup for you, but does not specify which drives to process.
- When you select the Backup Domain action from the backup-archive client GUI

You can define the domain option in the following locations:

- In an options file.
- On the command line, when entered with a client command.
- In a client option set, which is defined on the server with the define clientopt command.
- As an option on a scheduled command, which is defined on the server with the define schedule command.

If any of these sources contain a domain definition, the client backs up that domain. If more than one source specifies a domain, the client backs up all specified domains. The same domain object can be defined more than once, but the effect is the same as defining it only once. If you do not specify a domain, the client backs up the default domain, as described in the all-local parameter.

You can exclude objects from the domain by specifying the exclusion operator (-) before the object. If any domain definition excludes an object, that object is excluded from the domain, even if another definition includes the object. You cannot use the domain exclusion operator (-) in front of any domain keyword that begins with all-.

If a domain statement excludes one or more objects and no domain statement includes any objects, the result is an empty domain (nothing is backed up). You must specify the objects to include in the domain if any domain statements exclude objects.

AIX Linux Mac OS X Solaris Example 1: This example uses one domain statement to back up all local file systems except for /fs1:

```
domain all-local -/fs1
```

Example 2: This example uses multiple domain statements to back up all local file systems except for /fs1:

```
domain all-local domain -/fs1
```

Example 3: This example excludes /fs1 during a backup operation. If no other domain statement is used, the result is an empty domain. Nothing is backed up.

```
domain -/fs1
```

Windows Example 1: This example uses one domain statement to back up all local file systems except for the system state:

```
domain all-local -systemstate
```

Example 2: This example uses multiple domain statements to back up all local file systems except for the system state:

```
domain all-local domain -systemstate
```

Example 3: This example excludes the system state from a backup operation. If no other domain statement is used, the result is an empty domain. Nothing is backed up.

```
domain -systemstate
```

If you start the incremental command with a file specification, the client ignores any domain definitions and backs up only the file specification.

AIX Linux Mac OS X Solaris You can include a virtual mount point in your client domain.

AIX Linux Important: If you are running GPFS™ for AIX® or GPFS for Linux x86_64 in a multinode cluster, and all nodes share a mounted GPFS file system, the client processes this file system as a local file system. The client backs up the file system on each node during an incremental backup. To avoid this situation, you can do one of the following tasks:

- Explicitly configure the domain statement in the client user options file (dsm.opt) to list the file systems you want that node to back up.
- AIX Linux Set the exclude.fs option in the client system-options file to exclude the GPFS file system from backup services.

AIX Linux Mac OS X Solaris

Automounted file systems

When you perform a backup with the domain option set to all-local, files that are handled by automounter and loopback file systems are not backed up.

If you back up a file system with the domain option set to all-local, any subdirectories that are mount points for an automounted file system (AutoFS) are excluded from a backup operation. Any files that exist on the server for the automounted subdirectory are expired.

When you perform a backup with the domain option set to all-lofs, all explicit loopback file systems (LOFS) are backed up and all automounted file systems are excluded. For loop devices and local file systems that are handled by automounter, set the domain option to all-auto-lofs.

Use the automount option with the domain parameters, all-auto-nfs, and all-auto-lofs to specify one or more automounted file systems to be mounted and added into the domain. If you specify the automount option, automounted file systems are remounted if they go offline during the execution of the incremental command.

Virtual mount points cannot be used with automounted file systems.

AIX Linux Mac OS X Solaris

Linux Important: On some Linux distributions, automounted file system mount points or maps of file system type (AutoFS) might not be listed in the current mount table. As a result, the automounted files systems, which are unmounted during backup or archive processing, might be incorrectly processed and stored as part of a wrong domain (for example, as part of domain all-local, all-nfs, or all-lofs, depending on the actual file system type). Therefore, in such Linux distribution environments, you must specify the appropriate automount option setting to correctly process your domain option setting at all points in time.

Mac OS X For Mac OS X, automounted file systems are not supported. If an automounted file system is part of a domain statement, the backup fails and no files in the automounted file system are processed. Back up and restore the automounted file system from the host system. Do not back up or restore the automounted file system over a network connection.

Supported Clients

This option is valid for all clients. The server can also define this option. The IBM Spectrum Protect API does not support this option.

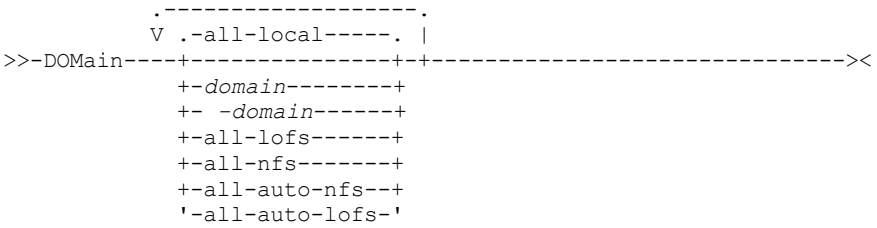
Options File

Windows Place this option in the options file, dsm.opt. You can set this option on the Backup tab, Domain for Backup section of the Preferences editor.

Mac OS X AIX Linux Solaris Mac OS X Place this option in the options file, dsm.opt or dsm.sys. In the dsm.sys file, you must place this option within a server stanza. You can set this option on the Backup tab, Domain for Backup section of the Preferences editor.

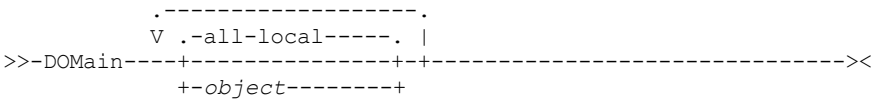
AIX Linux Mac OS X Solaris

Syntax



Windows

Syntax



```
+- -object------+
+-systemstate---+
'- -systemstate-'
```

Parameters

all-local

Windows

Back up all local volumes on the system, and the Windows system state. This is the default setting. Local volumes are defined as volumes that are formatted with a supported file system (ReFS, NTFS, FAT32, or FAT) on a direct-attached storage device, including SAN and iSCSI attached storage. Directories that are mapped to drive letters by using the Windows subst command are included in a backup if the mapped directory is on a local disk.

Windows The following types of volumes are not included when all-local is specified:

- Network attached volumes, including CIFS shares that are mapped to drive letters.
- Removable volumes, including CD/DVD drives, USB thumb drives, and floppy diskette drives. Some USB-attached hard disks are included in the all-local domain if Windows does not classify them as a removable storage device.

AIX Linux Mac OS X Solaris Backs up all local file systems except LOFS file systems and LOFS through automounter. This parameter is the default. The /tmp directory is not included.

AIX Linux Mac OS X Solaris *domain*

AIX Linux Mac OS X Solaris Defines the file systems to include in your default client domain.

When you use *domain* with the incremental command, it processes these file systems in addition to those file systems you specify in your default client domain.

AIX Linux Mac OS X Solaris *-domain*

AIX Linux Mac OS X Solaris Defines the file systems to exclude in your default client domain.

AIX Linux Solaris all-lofs

AIX Linux Solaris Backs up all loopback file systems, except those file systems that are handled by automounter. This parameter is not supported on Mac OS X.

AIX Linux Solaris all-nfs

AIX Linux Solaris Backs up all network file systems, except those file systems that are handled by automounter. This parameter is not supported on Mac OS X.

AIX Linux Solaris all-auto-nfs

AIX Linux Solaris Backs up all network file systems (but not local file systems) which are handled by automounter. This parameter is not supported on Mac OS X.

AIX Linux Solaris all-auto-lofs

AIX Linux Solaris Backs up all loop devices and local file systems that are handled through automounter. This parameter is not supported on Mac OS X.

object

Specifies the domain objects to include in the domain.

An object name must be enclosed in quotation marks if the name includes any spaces.

-object

Specifies the domain objects to exclude from the domain.

An object name must be enclosed in quotation marks if the name includes any spaces.

Windows systemstate

Windows Back up the Windows system state. The systemstate domain is included in the all- local domain.

Windows -systemstate

Windows Exclude system state from backup processing.

Examples

Options file:

An options file can contain more than one domain statement. However, each of the domain statements is an example of a single statement in an options file.

Mac OS X

```
domain all-local
domain all-local -/Volumes/volume2
domain all-local '-/Volumes/Macintosh HD'
```

AIX Linux Solaris

```
domain /tst /datasave /joe
"domain all-local"
domain ALL-LOCAL -/home
domain ALL-NFS -/mount/nfs1
```

Windows

```
domain c: d: e:
domain c: systemstate
domain ALL-LOCAL -systemstate
domain ALL-LOCAL -c:
domain ALL-LOCAL -\\florence\e$
```

A single domain statement can list one or more objects for the domain. You can use more than one domain statement. The following two examples from two options files yield the same domain result:

Example 1

```
...
domain fs1
domain all-local
domain -fs3
...
```

Example 2

```
...
domain all-local fs1 -fs3
...
```

Command line:

Mac OS X

```
-domain="/ /Volumes/volume2"
-domain="all-local -/Volumes/volume2"
```

AIX Linux Mac OS X Solaris

```
-domain="/fs1 /fs2"
-domain=/tmp
-domain="ALL-LOCAL -/home"
```

Windows

```
-domain="c: d:"
-domain="ALL-LOCAL -c: -systemstate"
```

Domain definition interaction

AIX Linux Mac OS X Solaris Domain can be defined in several sources, and the result is a summation of all domain definitions. As an example of the interaction of domain definitions, consider how domain definitions from several sources yield different backup results. In the table, *FS* followed by a number (for example, FS1) is a file system. This table shows only commands that are entered on the command line. For scheduled commands, the command-line column is not relevant, and options from the scheduled command must be considered.

Windows Domain can be defined in several sources, and the result is a summation of all domain definitions. As an example of the interaction of domain definitions, consider how domain definitions from several sources yield different backup results. In the table, *FS* followed by a number (for example, FS1) is a drive. This table shows only commands that are entered on the command line. For scheduled commands, the command-line column is not relevant, and options from the scheduled command must be considered.

Table 1. Interaction of domain definitions from several sources

Options file	Command line	Client option set	Objects backed up using the incremental command
`domain FS1`	`incremental -domain=FS2`	`domain FS3`	FS1 FS2 FS3

Options file	Command line	Client option set	Objects backed up using the incremental command
domain FS1	incremental	domain FS3	FS1 FS3
	incremental -domain=FS2		FS2
	incremental -domain=FS2	domain FS3	FS2 FS3
	incremental	domain FS3	FS3
	incremental		all-local
domain all-local	incremental	domain FS3	all-local + FS3
domain all-local domain -FS1	incremental		all-local, but not FS1
domain -FS1	incremental		none
domain FS1 FS3	incremental	domain -FS3	FS1
domain all-local	incremental	domain -FS3	all-local, but not FS3
	incremental FS1 - domain=all-local		FS1
	incremental FS1	domain all-local	FS1
domain -FS1	incremental FS1		FS1

AIX Linux Solaris Windows

Domain.image

The domain.image option specifies what you want to include in your client domain for an image backup.

Windows Raw logical volumes must be named explicitly.

If you do not specify a file system with the backup image command, the file systems you specify with the domain.image option are backed up.

When you specify a file system with the backup image command, the domain.image option is ignored.

If you do not use the domain.image option to specify file systems in your client options file, and you do not specify a file system with the backup image command, a message is issued and no backup occurs.

Supported Clients

AIX Linux Solaris This option is valid for AIX®, Linux x86_64, Linux on POWER®, and Solaris. The server can also define this option. The IBM Spectrum Protect™ API does not support this option.

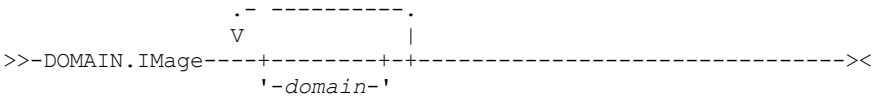
This option is valid for all supported Windows clients. The server can also define this option. The IBM Spectrum Protect API does not support this option.

Options File

AIX Linux Solaris Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option in the Backup > Domain for Backup box in the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option in the Backup > Domain for Backup box in the Preferences editor.

Syntax



Parameters

domain
: Defines the file systems or raw logical volumes to include in your default client image domain.

Examples

AIX Linux Solaris Options file:

AIX Linux Solaris domain.image /fs1 /fs2

Windows Options file:

Windows domain.image d: e: f: domain.image f:\mnt\raw\rawmnt1 f:\mnt\fs\fsmnt1

Command line:

Does not apply.

AIX Solaris Windows

Domain.nas

The domain.nas option specifies the volumes to include in your NAS image backups.

You can specify all-nas to include all the mounted file systems on the NAS file server, except those you exclude with the exclude.fs.nas option.

The backup-archive client uses your domain for NAS image backups when you run a backup nas command and you do not specify which volumes to process.

AIX Solaris When you use this option in your client system options file (dsm.sys), the domain.nas option defines your default domain for NAS image backups. When you perform a NAS file system image backup using the backup nas command, the client adds the volumes that you specify on the command line to the volumes defined in your dsm.sys file. For example, if you enter `domain.nas nas1/vol/vol0 nas1/vol/vol1` in your dsm.sys file and you enter `dsmc backup nas -nasnodename=nas1 /vol/vol2` on the command line, the client backs up the `vol/vol0`, `vol/vol1`, and `vol/vol2` volumes on node `nas1`.

AIX Solaris If you set the domain.nas option to all-nas in the dsm.opt file, the client backs up all mounted volumes on the NAS file server. When performing a backup, if you use a file specification and set the domain.nas option to all-nas in the dsm.sys file, all-nas takes precedence.

Windows When you use this option in your client system options file (dsm.opt), the domain.nas option defines your default domain for NAS image backups.

Windows When you perform a NAS file system image backup using the backup nas command, the client adds volumes that you specify on the command line to the volumes defined in your dsm.opt file. For example, if you enter `domain.nas nas1/vol/vol0 nas1/vol/vol1` in your dsm.opt file and you enter `dsmc backup nas -nasnodename=nas1 /vol/vol2` on the command line, the client backs up the `vol/vol0`, `vol/vol1`, and `vol/vol2` volumes on node `nas1`.

Windows If you set the domain.nas option to all-nas in the dsm.opt file, the client backs up all mounted volumes on the NAS file server. When performing a backup, if you use a file specification and set the domain.nas option to all-nas in the dsm.opt file, all-nas takes precedence.

Supported Clients

AIX Solaris This option is only valid for AIX® and Solaris clients. The server can also define this option.

Windows This option is valid for all Windows clients. The server can also define this option.

Options File

AIX Solaris Place this option in the client system-options file (dsm.sys) within a server stanza.

Windows Place this option in the client options file (dsm.opt).

Syntax

```
                .- -----------.
                V .-all-nas-. |
>>-DOMAIN.Nas----+---------+-+--------------------------------><
                  '-domain--'
```

Parameters

domain
: Defines the volumes you want to process. You cannot exclude volumes by specifying the dash (-) operator.

all-nas
: Processes all mounted volumes on the NAS file server, except those you exclude with the exclude.fs.nas option. This is the default. If there is no domain.nas statement in the dsm.opt file and no volumes specified on the command line, the client backs up all mounted volumes on the NAS server.

Examples

Options file:

```
domain.nas nas1/vol/vol0 nas1/vol/vol1
domain.nas all-nas
```

Command line:
: Does not apply.

Linux | Windows

Domain.vmfull

The domain.vmfull option specifies the virtual machines (VMs) to include in your full virtual machine image backup operations.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments.

This option applies to both VMware and Microsoft Hyper-V virtual machine disks.

Linux | Windows

Domain.vmfull for VMware virtual machines

For VMware virtual machine backups, the domain.vmfull option works with the vmchost option. The vmchost option identifies the vCenter server or ESX server that contains the virtual machines that you want to protect. The domain.vmfull parameters are used to narrow the focus of an operation to a subset of the virtual machines that are running on the system that is identified by vmchost.

You can specify which virtual machines are to be processed by using any of the following techniques:

- Use the VM= option and specify the name of a virtual machine.
- Provide a comma-separated list of virtual machine names.
- Use wildcard syntax to process virtual machines that match the name pattern.
- Use one of the following domain-level parameters:
  - all-vm
  - all-windows
  - schedule-tag
  - vmhost
  - vmfolder
  - vmhostcluster
  - vmdatastore
  - vmresourcepool
  - vmhostfolder
  - vmdatacenter

When you use domain-level parameters, virtual machines that are created in the domain are automatically included when the next backup occurs. For example, if you use the vmfolder parameter to back up all virtual machines included in a folder, any new virtual

machines that get added to that folder are included in the next backup. The same is true of pattern-matched names that are included in a wildcard match.

The virtual machines that are specified on the domain.vmfull option are processed only when the backup vm command is entered without specifying a virtual machine or a list of virtual machines on the command line.

Supported Clients

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows clients.

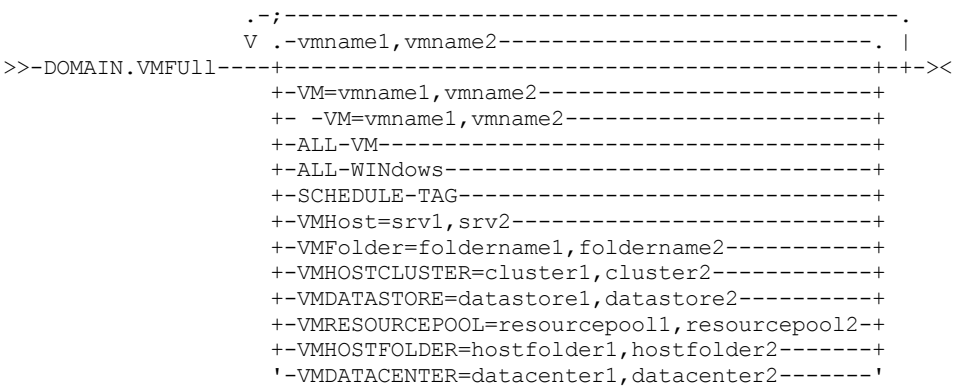
The server can also define this option.

Options file

Set this option in the client options, by using the command line, or by using the VM Backup tab of the Preferences editor. Restriction: The following parameters cannot be set in the Preferences Editor. Include this setting in the options file, or on the command line when you run a backup vm command:

- *vmname*:vmdk=*vmdk_label*
- schedule-tag
- vmresourcepool
- vmhostfolder
- vmdatacenter

Syntax for VMware virtual machines



Syntax rules: Multiple keywords must be separated by a semicolon. Do not include any spaces after the semicolons. Multiple virtual machine or domain names must be separated by commas, with no space characters. For examples, see vm=vmname. The rule about multiple virtual machine or domain names does not apply if you are using the "Schedule-Tag" keyword.

Parameters

vmname

Specifies the virtual machine name that you want to process. The name is the virtual machine display name. You can specify a list of virtual machine host names by separating the names with commas (`vm1,vm2,vm5`).

vm=*vmname*

The vm= keyword specifies that the next set of values is a list of virtual machine names. The vm= keyword is the default and is not required.

In this example, vm= is not specified and commas are used to separate the machine names.

```
domain.vmfull my_vm1,my_vm2
```

If you specify multiple keywords, such as vm= and vmfolder=, the values that the keywords refer to must be separated by semicolons, with no intervening space characters:

```
domain.vmfull vm=my_vm1;vm=my_vm2
domain.vmfull vm=my_vm1;vmfolder=folder1;vmfolder=folder2
```

Wildcard characters can be used to select virtual machine names that match a pattern. An asterisk (*) matches any sequence of characters. A question mark (?) matches any single character, for example:

- Exclude all files that have "test" in the host name: `-vm=*test*`
- Include all virtual machines with names such as: "test20", "test25", "test29", "test2A": `vm=test2?`

You can exclude a virtual machine from a backup operation by specifying the exclude operator (-) before the vm= keyword. For example, -vm is used to exclude a particular machine, or machines, from a domain level backup, such as, ALL-Windows, ALL-VM, and VMFolder. If "vm1" is the name of a virtual machine in a folder that is named "accountingDept", you can back up all of the virtual machines in the folder, but prevent the virtual machine "vm1" from being backed up. Set the following option:

```
domain.vmfull VMFolder=accountingDept;-vm=vm1
```

You cannot use the exclude operator (-) to exclude a domain, such as ALL-VM, ALL-Windows, or VMFolder. The exclude operator works only at the virtual machine name level.

vmname:vmdk=*vmdk_label*

The `:vmdk=` keyword applies only to VMware virtual machines and its use requires a license for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

This option is typically used to exclude disks (see the :-vmdk syntax) from being backed up. You can also include virtual machine disks by using the INCLUDE.VMDISK option or exclude virtual machine disks by using the EXCLUDE.VMDISK option.

The virtual disks within a virtual machine have disk labels that uniquely identify each virtual disk. You use the :vmdk= keyword to specify the labels of the virtual disks that you want to be included in a Backup VM operation. If you do not specify :vmdk= and a disk label, all virtual disks in the virtual machine are backed up.

Assume that there is a virtual machine named "my_vm_example". This virtual machine has four disks (labeled `Hard Disk 1, Hard Disk 2, Hard Disk 3, Hard Disk 4`). To include only Hard Disk 2 and Hard Disk 3 in a backup, add the :vmdk= keyword and disk label for those disks. Quotation marks are necessary around the parameters because the disk labels contain space characters. For example:

```
domain.vmfull "my_vm_example:vmdk=Hard Disk 2:vmdk=Hard Disk 3"
```

This next example backs up Hard Disk 1 and Hard Disk 2 on VM1, and Hard Disk 3 and Hard Disk 4 on VM2. A comma is used to separate the virtual machine information.

```
domain.vmfull "vm1:vmdk=Hard Disk 1:vmdk=Hard Disk 2",
  "vm2:vmdk=Hard Disk 3:vmdk=Hard Disk 4"
```

Similar to the -vm= keyword, you can also use the exclusion operator (-) with :vmdk= to exclude disks from a backup operation.

To back up a virtual machine (vm1) and exclude disks 3 and 4, use the following syntax:

```
domain.vmfull "vm1:-vmdk=Hard Disk 3:-vmdk=Hard Disk 4"
```

To back up two virtual machines, vm1 and vm2, and exclude the first two disks on each machine, use the following syntax:

```
domain.vmfull "vm1 :-vmdk=Hard Disk 1:-vmdk=Hard Disk 2",
  "vm2:-vmdk=Hard Disk 1:-vmdk=Hard Disk 2"
```

You can include one or more disks on a domain.vmfull statement. You can exclude one or more disks on a domain.vmfull statement. You can mix include and exclude disks on the same statement. For example, the following statement is valid:

```
domain.vmfull
  "vm1:vmdk=Hard Disk 1:-vmdk=Hard Disk 2:vmdk=Hard Disk 3:vmdk:Hard Disk 4"
```

If an include statement is present, all other disks in the virtual machine are excluded from a backup operation, unless the other disks are also specified in an include statement. For example, the following statement excludes all hard disks on vm1, except for Hard Disk 1:

```
domain.vmfull "vm1:vmdk=Hard Disk 1"
```

Both of the following exclude Hard Disk 4 from a backup of vm1:

```
domain.vmfull "vm1:vmdk=Hard Disk 1:vmdk=Hard Disk 2:vmdk=Hard Disk 3"
domain.vmfull "vm1:-vmdk=Hard Disk 4"
```

all-vm
: For VMware virtual machines. This option processes all virtual machines that are defined to the Virtual Center or to the ESX server that is specified on the vmchost option.

all-windows
: For VMware virtual machines. This option processes all virtual machines that are defined to the Virtual Center or to the ESX server that is specified on the vmchost option. The virtual machines must also have a guest operating system type of Windows.

schedule-tag
: For scheduled backups of VMware virtual machines. This option processes all virtual machines that are defined to the Virtual Center server that is specified on the vmchost option.

  The IBM Spectrum Protect server administrator can add this option to a schedule definition to indicate that the schedule is compatible with the `Schedule (IBM Spectrum Protect)` category and tag. Virtual machines in VMware objects that are assigned with the `Schedule` tag are backed up according to the schedule.

  Requirement: To be compatible for tagging, the -domain.vmfull option must contain no additional domain-level parameters other than the Schedule-Tag parameter in the schedule definition. Otherwise, the `Schedule (IBM Spectrum Protect)` tag is ignored. The option is case insensitive and must contain no spaces. Quotation marks that enclose the Schedule-Tag parameter are optional. Virtual machines in VMware containers that are tagged with incompatible schedules are not backed up.

  For more information about the `Schedule` tag, see "Supported data protection tags.".

vmhost=*hostname*
: For VMware virtual machines. This option processes all virtual machines that are defined to the Virtual Center or to the ESX server that is specified on the vmchost option. The host name that you specify must match the fully qualified host name or IP address, as it is specified in the vCenter server Hosts and Clusters view.

  All virtual machines that are added to this host are automatically included in backup and restore processing. To be included, the virtual machines must also be running on the ESX server that is specified by the host name; they cannot be powered off.

  This parameter can include multiple ESX servers that are separated by commas. When the Virtual Center contains multiple ESX servers, this option does not determine the ESX server from which a snapshot is taken. The ESX server from which a snapshot is taken is determined by the VMware VirtualCenter web service.

  When you connect directly to an ESXi or ESX host, the vmchost option applies only if the vmhost is the server that you connect to. If it is not, a warning level message is sent to the console and is recorded in the dsmerror.log file; it is also recorded as a server event message.

  If the vmenabletemplatebackups option is set to yes, and VM templates are part of the domain, they are included in the backup.
  Restriction: VMware templates for virtual machines cannot be backed up when they are in an ESX or ESXi host because ESX and ESXi hosts do not support templates.

vmfolder=*foldername*
: For VMware virtual machines. This option processes all virtual machines that are defined to the Virtual Center or to the ESX server that is specified on the vmchost option. The virtual machines must also exist in the VMware folder that is specified by the folder name. Folder name can include multiple VMware folders that are separated by commas.

vmhostcluster=*hostclustername*
: For VMware virtual machines. This option processes all virtual machines that are defined to the Virtual Center or to the ESX server that is specified on the vmchost option. The virtual machines must also be running on the ESX host cluster that is specified by the host cluster name. To include more than one host cluster name, separate the cluster names with commas: `VMHOSTCLUSTER=cluster1,cluster2`.

  If the vmenabletemplatebackups option is set to yes, and VM templates are part of the domain, they are included in the backup. A VMware host cluster is not available if you connect directly to an ESXi or ESX host. If you connect directly to an ESXi/ESX host and a domain is processed that includes a host cluster, a warning level message is sent to the console and is recorded in the dsmerror.log file; it is also recorded as a server event message.

vmdatastore=*datastorename*
: For VMware virtual machines. This option processes all virtual machines that are defined to the Virtual Center or to the ESX server that is specified on the vmchost option. The configured datastore location for a virtual machine must match the datastore name that is specified by *datastorename*. The datastore name can include multiple datastores that are separated by commas: `VMDATASTORE=datastore1,datastore2`

Virtual machines can have their disk (vmdk files) on more than one datastore; but there is only one default datastore location. This default datastore location is defined in the virtual machine configuration and is always where the virtual machine configuration file (.vmx file) is located. When a machine is selected for backup by using a domain keyword, the virtual machine configuration file, and all of the virtual machine's disks are included in the backup, including the disks that are on a different datastore than the one specified as the domain.

vmresourcepool=*resourcepoolname*
: For VMware virtual machines. This option processes all virtual machines that are defined to the Virtual Center server that is specified on the vmchost option. The virtual machines must also exist in the VMware resource pool that is specified by the resource pool name. The resource pool name can include multiple resource pools that are separated by commas, for example: `VMRESOURCEPOOL=resourcepool1,resourcepool2`

vmhostfolder=*hostfoldername*
: For VMware virtual machines. This option processes all virtual machines that are defined to the Virtual Center server that is specified on the vmchost option. The virtual machines must also exist in the VMware host folder that is specified by the host folder name. The host folder name can include multiple VMware host folders that are separated by commas, for example: `VMHOSTFOLDER=hostfolder1,hostfolder2`

vmdatacenter=*datacentername*
: For VMware virtual machines. This option processes all virtual machines that are defined to the Virtual Center server that is specified on the vmchost option. The virtual machines must also exist in the VMware datacenter that is specified by the datacenter name. The datacenter name can include multiple datacenters that are separated by commas, for example: `VMDATACENTER=datacenter1,datacenter2`

Tip: If you specify more than one container type, for example, `vmfolder=folder1` and `vmhostcluster=cluster2`, all virtual machines that are contained in `folder1` and `cluster2` are protected. The virtual machines do not have to be in both `folder1` and `cluster2`.

You can specify the virtual machines as shown in this example:
```
domain.vmfull=vmfolder=folder1;vmhostcluster=cluster2
```

Examples for VMware virtual machines

Options file:

Include all virtual machines in full VM backup operations.

```
domain.vmfull all-vm
```

Include all virtual machines in full VM backup operations, except for the ones that have a name suffix of _test.

```
domain.vmfull all-vm;-vm=*_test
```

Include all virtual machines that have Windows as the operating system, in full VM backup operations.

```
domain.vmfull all-windows
```

Include all virtual machines in cluster servers 1, 2, and 3 in full VM backup operations.

```
domain.vmfull vmhostcluster=cluster1,cluster2,cluster3
```

Include all virtual machine data in `datastore1` in full VM backup operations.

```
domain.vmfull vmdatastore=datastore1
```

Include all virtual machines in full VM backup operations, but exclude virtual machines testvm1 and testmvm2.

```
domain.vmfull all-vm;-VM=testvm1,testvm2
```

Include the virtual machines that are defined in the VM folders that are named lab1 and lab2 in full VM backup operations.

```
domain.vmfull vmfolder=lab1,lab2
```

Include all virtual machines on the ESX hosts named "brovar", "doomzoo", and "kepler" in full VM backup operations.

```
domain.vmfull vmhost=brovar.example.com,
  doomzoo.example.com,kepler.example.com
```

Include the virtual machines in VMware resource pools `resourcepool_A` and `resourcepool_B` in full VM backup operations.

```
domain.vmfull vmresourcepool=resourcepool_A,resroucepool_B
```

Include the virtual machines that are defined in the VMware host folders named `hostfolder1` and `hostfolder2` in full VM backup operations.

```
domain.vmfull vmhostfolder=hostfolder1,hostfolder2
```

Include all virtual machines in VMware datacenter `dc1` in full VM backup operations.

```
domain.vmfull vmdatacenter=dc1
```

Windows

Domain.vmfull for Microsoft Hyper-V virtual machines

For Hyper-V VM backups, use the domain.vmfull option to specify which Hyper-V VMs are processed when you run a backup vm command, without specifying any Hyper-V VM names.

You can specify which VMs to process by using any of the following techniques:

- Use the VM= option and specify the name of a virtual machine.
- Provide a comma-separated list of virtual machine names.
- Use wildcard syntax to process virtual machines that match the name pattern.
- Use the *vmname*:vhdx= option to specify the VM hard disk (VHDX) to include or exclude during the Hyper-V RCT backup operation of a VM.
- Use the all-vm domain-level parameter. You can also include one or more virtual machines by using the `VM=` keyword, or exclude VMs by using the `-VM=` syntax.

The virtual machines that are specified on the domain.vmfull option are processed only when the backup vm command is entered without specifying a virtual machine or a list of virtual machines on the command line.

Attention: For Microsoft Hyper-V operations, the only valid domain-level parameter for the domain.vmfull option is all-vm. You can also include one or more virtual machines by using the `VM=` keyword, or exclude virtual machines by using the `-VM=` syntax.

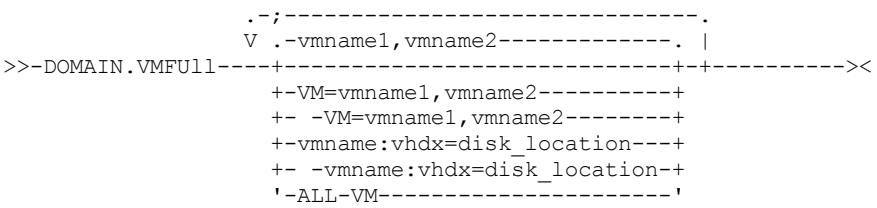
Supported Clients

This option can be used with supported Windows clients. This option can also be defined on the server.

Options file

Set this option in the client options, by using the command line, or by using the VM Backup tab of the Preferences editor. Restriction: The *vmname*:vhdx=*vhdx_location* parameter cannot be set in the Preferences Editor. Include this setting in the options file, or on the command line when you run a backup vm command:

Syntax for Microsoft Hyper-V virtual machines



Syntax rules: Multiple keywords must be separated by a semicolon. There cannot be any spaces after the semicolons. Multiple machine or domain names must be separated by commas, with no space characters. For examples, see `vm=vmname`.

Parameters

vmname
Defines the virtual machine name that you want to process. You can supply a list of virtual machine host names by separating the names with commas (`vm1,VM2,Vm5`). The names are case-sensitive and must match the capitalization that is shown on the Hyper-V host in the Hyper-V Manager > Virtual Machines view.

vm=*vmname*

The vm= keyword specifies that the next set of values is a list of virtual machine names. The vm= keyword is the default and is not required.
In this example, vm= is not specified and commas are used to separate the machine names.

```
domain.vmfull my_vm1,my_vm2
```

If you specify multiple keywords, such as vm= and -vm=, the values that the keywords refer to must be separated by semicolons, with no intervening space characters:

```
domain.vmfull vm=my_vm1;vm=my_vm2
domain.vmfull -vm=my_vm3;-vm=my_vm4
```

Wildcard characters can be used to select virtual machine names that match a pattern. An asterisk (*) matches any sequence of characters. A question mark (?) matches any single character, for example:

- Exclude all files that have "test" in the host name: `-vm=*test*`
- Include all virtual machines with names such as: "test20", "test25", "test29", "test2A":

  ```
  vm=test2?
  ```

You can exclude a virtual machine from a backup operation by specifying the exclude operator (-) before the vm= keyword. For example, -vm is used to exclude a particular machine, or machines, from a domain level backup, such as, ALL-VM. If "vm1" is the name of a virtual machine, you can back up all of the virtual machines in the domain, but prevent the virtual machine "vm1" from being backed up. Set the following option:

```
domain.vmfull all-vm;-vm=vm1
```

You cannot use the exclude operator (-) to exclude a domain, such as ALL-VM. The exclude operator works only at the virtual machine name level.

vmname:vhdx=*vhdx_location*

This option specifies the location of the virtual machine hard disk (VHDX) to include in Hyper-V RCT virtual machine backup operations on the Windows Server 2016 operating system.
The *vmname* variable specifies the name of the virtual machine to back up. Wildcard characters can be used to select virtual machine names that match a pattern. An asterisk (*) matches any sequence of characters. A question mark (?) matches any single character.
The :vhdx=*disk_location* keyword specifies the location of the virtual machine disk to include in the backup operation. The disk location specified by the *disk_location* variable must begin with "SCSI" or "IDE" followed by the controller number and device location number. For example:

```
domain.vmfull "vm1:VHDX=IDE 1 0"
domain.vmfull "vm*:VHDX=SCSI 0 1"
domain.vmfull "vm?:VHDX=SCSI 0 1"
```

You can exclude a virtual machine disk from backup operations by specifying the exclude operator (-) before the vhdx= keyword. For example, use -vhdx= to exclude a VM disk from the backup operation of a virtual machine. For example:

```
domain.vmfull "vm1:-VHDX=IDE 1 0"
```

If you specify multiple virtual machine disks to include or exclude, the vhdx= or -vhdx= keyword and associated values must be separated by colons, with no intervening space characters. For example:

```
domain.vmfull "vm1:vhdx=IDE 1 0:vhdx=SCSI 0 1"
```

If you specify multiple virtual machine names and virtual machine disks, the VM name and associated values must be separated by semicolons, with no intervening space characters. For example:

```
domain.vmfull "vm1:VHDX=IDE 1 0:VHDX=SCSI 0 1;vm2:VHDX=IDE 1 0:VHDX=SCSI 0 1"
domain.vmfull "vm1:-VHDX=IDE 1 0:-VHDX=SCSI 0 1;vm2:-VHDX=IDE 1 0:-VHDX=SCSI 0 1"
```

all-vm

This option specifies that a backup vm operation processes all Hyper-V virtual machines that are known to the Hyper-V host.

Examples for Microsoft Hyper-V virtual machines

Options file:

Include all virtual machines in full VM backup operations.

```
domain.vmfull all-vm
```

Include all virtual machines in full VM backup operations, except for the ones that have a name suffix of _test.

```
domain.vmfull all-vm;-vm=*_test
```

Include all virtual machines in full VM backup operations, but exclude virtual machines testvm1 and testmvm2.

```
domain.vmfull all-vm;-VM=testvm1,testvm2
```

Include IDE disks (with controller 1 and disk location 0) and SCSI disks (with controller 0 and disk location 1) in Hyper-V RCT backup operations of virtual machines `vm1` and `vm2`.

```
domain.vmfull "vm1:VHDX=IDE 1 0:VHDX=SCSI 0 1;vm2:VHDX=IDE 1 0:VHDX=SCSI 0 1"
```

Restriction: You cannot use the all-vm option together with the *vmname:*-vhdx= option in the options file or on the command line.

Linux

Dontload

x86_64 Linux clients can use the dontload option to suppress specific plug-in libraries from being loaded when the backup-archive client is started.

The TIVsm_BAhdw.x86_64 package provided in Linux x86_64 distributions contains software that is required to support snapshot incremental backups for NetAPP and N-Series file servers. When this package is installed on a Linux x86_64 system that is used to perform data mover operations for a virtual machine, the files in this package cause all VMware backup operations to fail. When these failures occur, the following message is displayed:

```
ANS8811E

VMware operations cannot be run when the hardware plug-in product TIVsm-BAhdw is installed and
loaded. Either uninstall the hardware product TIVsm-BAhdw, or set the option DONTLOAD PIHDW in the
options file to prevent the hardware plug-in from being loaded.
```

Use this option to prevent the plug-in library from being loaded into RAM when the client is started. Alternatively, you can uninstall the TIVsm_BAhdw package if it is not needed for snapshot operations.

Supported Clients

This option is only valid for Linux x86_64 clients.

Options File

Place this option in the client system-options file (dsm.sys) within a server stanza.

Syntax

```
>>-DONTLoad----PIHDW-------------------------------------------><
```

Parameters

PIHDW
: Specifies that the hardware plug-in (TIVsm-BAhdw) is not loaded into RAM when the client is started. Use this option on backup-archive clients that have the hardware plug-in installed, to prevent the plug-in from causing failures when performing backup-archive operations on VMware virtual machines. There is no default for the dontload option.
To determine whether the plug-in is installed, enter the following command and examine the output.

```
rpm -q -a | grep TIV
```

If the output contains a package starting with "TIVsm-BAhdw" (followed by a version string), the hardware plug-in package is installed.

Examples

Options file:

```
DONTLoad PIHDW
```

Command line:
Does not apply. Do not use this option on the command line.

Backup VM
Restore VM

AIX | Linux | Solaris

Dynamicimage

Use the dynamicimage option with the backup image command or the include.image option to specify that you want to perform a dynamic image backup.

Supported Clients

This option is valid for AIX®, Solaris, and all Linux clients. The IBM Spectrum Protect™ API does not support this option.

Options File

Place the include.image statement containing the dynamicimage value in the server stanza in your system-options file, dsm.sys. You can also set this option using the Preferences editor.

Syntax

```
>>-DYNAMICImage-- --value---------------------------------------><
```

Parameters

value
Specifies one of the following values:

yes
Use this option only if the volume cannot be unmounted and remounted as read-only. The client backs up the volume as is without remounting it as read-only. Corruption of the backup can occur if applications write to the volume while the backup is in progress. In this case, run fsck after a restore and manually mount the file system in order to regain access to the volume. This option is valid for AIX, Solaris, and all Linux clients.
Note: This option is not allowed for AIX JFS2 file systems.

no
Use this option if you do not want to perform a dynamic image backup. This is the default. The default behavior depends on the platform and file system type. For platforms and file systems that support snapshot, namely AIX JFS2 file systems and LINUX LVM file systems, the default is snapshot-based image backup. For all other UNIX platforms and file systems, the default is static image backup.

Examples

Options file:

```
include.image /kalafs1 dynamicimage=yes
```

Command line on backup image:

```
dynamicimage=yes
```

AIX

Efsdecrypt

The efsdecrypt option allows you to control whether or not files encrypted by an AIX® Encrypted File System (EFS) are read in encrypted or decrypted format.

The efsdecrypt option default is no, which is to back up the encrypted or raw data. If you specify yes, the files are backed up as clear text, which means that they are backed up as normal files, as if the files existed in unencrypted form on the file system.

Important: Whenever you run a backup that includes any files encrypted on an EFS, you must ensure that you use the correct specification of the efsdecrypt option. If the efsdecrypt option value changes between two incremental backups, all encrypted files on EFS file systems are backed up again, even if they have not changed since the last backup. For example, if you are running an incremental backup of encrypted files that were previously backed up as "raw," then ensure that efsdecrypt is specified as no. If you change efsdecrypt to yes, all the files are backed up again in clear text even if they are unchanged, so ensure that you use this option carefully.

Note: This is a global option that is applied to the complete backup. Two separate invocations of the client are required to back up some encrypted files as raw data and others as clear text.

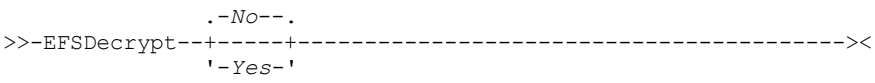
Supported Clients

This option is valid for AIX clients.

Options File

Place this option in the dsm.sys file or the client user-options file (dsm.opt). In the dsm.sys file, you must place this option within a server stanza.

Syntax



Parameters

No
: Encrypted files are read in encrypted or raw data format, and IBM Spectrum Protect™ encryption and compression is forced off. This is the default.

Yes
: Encrypted files are read in decrypted or clear text format.

Examples

Options file:

```
EFSDecrypt yes
```

Command line:

```
-EFSDecrypt=no
```

Windows

Enable8dot3namesupport

The enable8dot3namesupport option specifies whether the client backs up and restores short 8.3 names for files that have long names on NTFS file systems.

Supported Clients

This option is valid for all Windows clients.

A file with a long file name might not have a short 8.3 name if short name generation is disabled on the Windows system. This option is effective only for NTFS file systems.

Options File

Place this option in the client options file (dsm.opt). You can set this option on the General tab of the Preferences editor.

Syntax

```
                              .-No--.
>>-ENABLE8DOT3NAMESupport--+-----+-----------------------------><
                           '-Yes-'
```

Parameters

No
: Short 8.3 names for files with long file names are not backed up or restored. This is the default.

Yes
: Short 8.3 names for files with long file names are backed up and restored.

  Each short name uses up to 14 additional bytes in the server database. Although this is a small number, if there are many files with short 8.3 names on many Windows systems, this can increase the size of the IBM Spectrum Protect™ server database.

Important: Consult with your IBM Spectrum Protect server administrator before you use this option.

The first backup that runs with this option causes all files that have short 8.3 names to be updated on the IBM Spectrum Protect server, even if the files have not otherwise changed. This is because the client is adding the short 8.3 names to the active backup versions.

If this option is enabled for restore, the client attempts to set the short 8.3 name for restored files, even if short name generation is disabled on the Windows system. The client must run under a Windows account that possesses the SE_RESTORE_NAME privilege in order for this option to be effective. See your system administrator if you have questions about account privileges.

During restore, the short 8.3 name of a file is not restored if another object in the same directory already has the same short 8.3 name. In this case, the file is restored and an informational message is logged indicating that the short name could not be set. If the file must be restored with its original short name, you must resolve the conflict with the existing file, and then try the restore again.

Important: This parameter can cause unexpected results in some cases. For example, if the short name of a file changes between the last time the file was backed up and the time it is restored, and there is a link or registry entry that refers to the newer short name, then restoring the file with the older short name invalidates the references to the newer short name.

Examples

Options file:

```
enable8dot3namesupport yes
```

Command line:

```
-enable8dot3namesupport=yes
```

Enablearchiveretentionprotection

The enablearchiveretentionprotection option allows the client to connect to the IBM Spectrum Protect™ for Data Retention server. This ensures that archive objects will not be deleted from the server until policy-based retention requirements for that object have been satisfied.

This option is ignored if the client connects to a server that is not retention protection enabled. If the option is no (the default) and an attempt is made to connect to a data retention server, the connection is refused.

The data retention server is specially configured for this task, so normal backup or restore processing is rejected by the server. When the client is connected to a data retention server, the following commands will not be available. If you attempt to use these commands, a message is displayed indicating that they are not valid with this server.

- incremental
- backup (all subcommands)
- selective
- restore (all subcommands except restore backupset -location=file or -location=tape)

Note: restore backupset -location=file or -location=tape do not connect to any server (except the virtual one) and thus will not be blocked under any circumstances.

- restart restore
- delete backup
- delete group
- expire
- All queries *except:*
  - query access
  - query archive
  - query filespace
  - query inclexcl
  - query managementclass
  - query node
  - query options
  - query schedule
  - query session
  - query systeminfo
  - query tracestatus

Supported Clients

This option is valid for all clients.

Options File

Windows This option is valid only in client options file (dsm.opt) and is not valid in a client option set from the server. It is not valid on any command line.

AIX Linux Solaris Mac OS X This option is valid only in the dsm.sys file *within* a server stanza and is not valid in a client option set from the server. It is not valid on any command line.

Syntax

```
                                        .-No--.
>>-ENABLEARCHIVERETENTIONProtection--+-----+------------------><
                                        '-Yes-'
```

Parameters

No
: The data retention server connection is refused. This is the default.

Yes
: The client connects to a data retention server.

Enablededupcache

Use the enablededupcache option to specify whether you want to use a cache during client-side data deduplication. Using a local cache can reduce network traffic between the IBM Spectrum Protect™ server and the client.

When you perform a backup or archive operation with the data deduplication cache enabled, the specification of data extents that are backed up or archived are saved to the cache database. The next time you run a backup or archive, the client queries the data deduplication cache and identifies the extents of data that have been previously saved to the server. Data extents that are identical to data extents on the server are not resent to the server.

If the server and the cache are not synchronized, the cache is removed and a new one is created.

Only one process can access the distributed data deduplication cache at a time. Concurrent backup instances on a workstation, that use the same server and storage pool, must either use unique node names or unique cache specifications. In this way, all the instances can use a local cache and optimize the client-side data deduplication.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect API also supports this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the system-options file (dsm.sys) within a server stanza. You can set this option on the Deduplication > Enable Deduplication Cache check box of the Preferences editor. The option can be set in the client option set on the IBM Spectrum Protect server.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Deduplication > Enable Deduplication Cache check box of the Preferences editor. The option can be set in the client option set on the IBM Spectrum Protect server.

Syntax

```
                      .-Yes*-.
>>-ENABLEDEDUPCache--+------+---------------------------------><
                      '-No---'
```

Parameters

Yes
: Specifies that you want to enable data deduplication cache. If data deduplication is not enabled, this setting is not valid. Yes is the default for the backup-archive client. No is the default for the IBM Spectrum Protect API.

No
: Specifies that you do not want to enable data deduplication cache.

Examples

Options file:

```
enablededupcache no
```

Command line:

```
-enablededupcache=no
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Enableinstrumentation

By default, instrumentation data is automatically collected by the backup-archive client and IBM Spectrum Protect™ API to identify performance bottlenecks during backup and restore processing. To disable or later enable instrumentation, use the enableinstrumentation option.

With this option enabled, you do not have to wait for a customer service representative to direct you to collect performance data when a problem occurs. Instead, the data can be collected whenever you run a backup or restore operation. This feature can be helpful because you do not have to re-create the problem just to collect performance data. The information is already collected by the client.

This option replaces the -TESTFLAG=instrument:detail, -TESTFLAG=instrument:API, and -TESTFLAG=instrument:detail/API options that are used in previous versions of the client and API.

For each process, the following types of performance instrumentation data are collected:

- The activity names for each thread (such as `File I/O`, `Data Verb`, `Compression`, and `Transaction`), the average elapsed time per activity, and the frequency of the activity.
- The total activity time of each thread.
- The command that was issued and the options that were used.

- The summary of the backup, restore, or query command.

By default, the performance data is stored in the instrumentation log file (dsminstr.log) in the directory that is specified by the DSM_LOG environment variable (or the DSMI_LOG environment variable for API-dependent products such as IBM Spectrum Protect for Databases: Data Protection for Microsoft SQL Server and IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server). If you did not set the DSM_LOG environment variable, the instrumentation log file is stored in the current directory (the directory where you issued the dsmc command).

You can optionally change the name and location of the instrumentation log file by using the instrlogname option. You can also control the size of the log file by specifying the instrlogmax option.

Performance data is not collected for the backup-archive client GUI or web client GUI.

Performance data is collected for the following products when the enableinstrumentation option is specified in the client options file:

- Scheduled file-level backup operations with the backup-archive client
- IBM Spectrum Protect for Virtual Environments: Data Protection for VMware backups
- IBM Spectrum Protect for Virtual Environments: Data Protection for Microsoft Hyper-V backups
- IBM Spectrum Protect for Databases: Data Protection for Microsoft SQL Server backups
- IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server backups

Performance data is also collected during archive and retrieve processing.

Supported Clients

This option is valid for all clients and the IBM Spectrum Protect API.

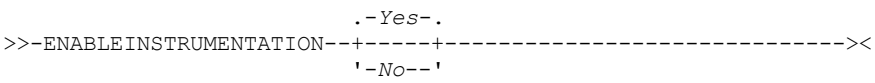
Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. The option can be set in the client option set on the IBM Spectrum Protect server.

Windows Place this option in the client options file (dsm.opt). The option can be set in the client option set on IBM Spectrum Protect server.

Tip: This option is enabled by default, so typically, you do not need to place this option in the client options file unless you need to disable the option.

Syntax



Parameters

Yes
: Specifies that you want to collect performance data during backup and restore operations. The default value is Yes, which means that performance data is collected even if you do not specify this option.

  By default, the performance data is stored in the instrumentation log file (dsminstr.log) in the directory that is specified by the DSM_LOG environment variable. If you did not set the DSM_LOG environment variable, the instrumentation log file is stored in the current directory (the directory where you issued the dsmc command). If the file does not exist, the client creates the file and adds performance data to the file.

No
: Specifies that you do not want to collect performance data during backup and restore operations. If the instrumentation log exists, no more data is added to the file.

Examples

Options file:

```
enableinstrumentation yes
```

Command line:

AIX | Linux | Mac OS X | Solaris

```
dsmc sel /home/mydir/* -subdir=yes -enableinstrumentation=yes
```

Windows

```
dsmc sel c:\mydir\* -subdir=yes -enableinstrumentation=yes
```

This option is valid only on the initial command line. It is not valid in interactive mode.

AIX | Linux | Solaris | Windows

Enablelanfree

The enablelanfree option specifies whether to enable an available LAN-free path to a storage area network (SAN) attached storage device.

A LAN-free path allows backup, restore, archive, and retrieve processing between the backup-archive client and the SAN-attached storage device.

To support LAN-free data movement you must install and configure the IBM Spectrum Protect™ for SAN storage agent on the client workstation.

Note:

1. If you place the enablelanfree option in the client option file (dsm.opt), but zero (0) bytes were transferred through the SAN during an operation, ensure that you bind the data to a LAN-free enabled management class.
2. To restore backup sets in a SAN environment, see for more information.
3. When a LAN-free path is enabled, the SAN Storage Agent settings override the client tcpserveraddress, tcpport, and ssl options. This override action occurs to ensure that both the client and the Storage Agent use the same server communication options.

Supported Clients

AIX | Linux | Solaris This option is valid only for AIX®, Linux x86_64, Linux on POWER®, and Oracle Solaris clients.

Windows This option is valid for all Windows clients.

Options File

AIX | Linux | Solaris Place this option in the dsm.sys file within a server stanza. You can also set this option by selecting the Enable Lanfree check box on the General tab in the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can also set this option by selecting the Enable Lanfree check box on the General tab in the Preferences editor.

Syntax

```
                  .-No--.
>>-ENABLELanfree--+-----+-------------------------------------><
                  '-Yes-'
```

Parameters

Yes
Specifies that you want to enable an available LAN-free path to a SAN-attached storage device.

No
Specifies that you do not want to enable a LAN-free path to a SAN-attached storage device. This is the default.

Examples

Options file:
```
enablelanfree yes
```
Command line:
```
-enablelanfree=yes
```

This option is valid only on the initial command line. It is not valid in interactive mode.

AIX | Linux | Solaris | Mac OS X | Windows

Encryptiontype

Use the encryptiontype option to specify the algorithm for data encryption.

The encryptiontype affects only backup and archive operations. The data that you include is stored in encrypted form, and encryption does not affect the amount of data that is sent or received. During restore and retrieve operations the encrypted data is decrypted with the proper encryption algorithm, regardless of the setting for this option.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This option is valid for all clients.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can also set this option on the Authorization tab of the Preferences editor. The server can override this.

Windows Place this option in the client options file (dsm.opt). You can also set this option on the Authorization tab of the Preferences editor. The server can override this.

Syntax

```
                    .-AES128-.
>>-ENCRYPTIONType--+--------+---------------------------------><
                    '-AES256-'
```

Parameters

AES128
AES 128-bit data encryption. AES 128-bit is the default.
AES256
AES 256-bit data encryption. AES 256-bit data encryption provides the highest level of data encryption available in backup and archive operations.

Examples

Options file:
```
encryptiontype aes128
```
Command line:
Does not apply.

Encryptkey

The backup-archive client supports the option to encrypt files that are being backed up or archived to the IBM Spectrum Protect™ server. This option is enabled with the include.encrypt option.

All files matching the pattern on the include.encrypt specification are encrypted before the data is sent to the server. There are three options for managing the key used to encrypt the files (prompt, save, and generate). All three options can be used with either the backup-archive client or the IBM Spectrum Protect API.

Windows The encryption key password is case-sensitive and can be up to 63 characters in length and include the following characters:

AIX Linux Mac OS X Solaris The encryption key password is case-sensitive and can be up to 64 characters in length and include the following characters:

A-Z
: Any letter, A through Z, uppercase or lowercase. You cannot specify national language characters.

0-9
: Any number, 0 through 9

+
: Plus

.
: Period

_
: Underscore

-
: Hyphen

&
: Ampersand

Note:

1. The API has an alternate way of specifying encryptkey=generate; the previous enableclientencryptkey=yes option can also be specified to request generate encryption processing.
2. The enableclientencryptkey=yes API option is still supported, so it is possible when using the API to specify two conflicting options. For example, enableclientencryptkey=yes and encryptkey=prompt or encryptkey=save.
3. When conflicting values are specified, the API returns an error message.

AIX Linux Solaris Mac OS X Attention: When using the prompt option, your encryption key is not saved in the IBM Spectrum Protect password file on UNIX. If you forget the key, your data cannot be recovered.
Windows Attention: When using the prompt option, your encryption key is not saved in the Windows Registry. If you forget the key, your data cannot be recovered.

Supported Clients

This option is valid for all clients. The server can also define this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Authorization tab, Encryption Key Password section of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Authorization tab, Encryption Key Password section of the Preferences editor.

Syntax

```
                .-save-----.
>>-ENCRYPTKey--+----------+-------------------------------------><
               +-prompt---+
               '-generate-'
```

Parameters

save
: The encryption key password is saved in the backup-archive client password file. A prompt is issued for an initial encryption key password, and after the initial prompt, the saved encryption key password in the password file is used for the backups

and archives of files matching the include.encrypt specification. The key is retrieved from the password file on restore and retrieve operations.

Windows The password can be up to 63 bytes in length.

AIX Linux Mac OS X Solaris The password can be up to 64 bytes in length.

When the save option is specified for an API application, the initial key password must be provided by the application using the API in the dsmInitEx function call. The API itself does not issue a prompt to the user but relies on the application to prompt the user as necessary.

This parameter is the default.

Note: The following restrictions apply:

- This option can only be used when passwordaccess generate is also specified.
- The root user or an authorized user must specify the initial encryption key password.

prompt
The management of the encryption key password is provided by the user. The user is prompted for the encryption key password when the client begins a backup or archive. A prompt for the same password is issued when restoring or retrieving the encrypted file.

Windows This password can be up to 63 bytes in length.

AIX Linux Mac OS X Solaris This password can be up to 64 bytes in length.

When the prompt option is specified for an API application, the key password must be provided by the application using the API in the dsmInitEx function call. The API itself does not issue a prompt to the user but relies on the application to prompt the user as necessary.

generate
An encryption key password is dynamically generated when the client begins a backup or archive. This generated key password is used for the backups of files matching the include.encrypt specification. The generated key password, in an encrypted form, is kept on the IBM Spectrum Protect server. The key password is returned to the client to enable the file to be decrypted on restore and retrieve operations.

Examples

Options file:

```
encryptkey prompt
```

Command line:
Does not apply.

Errorlogmax

The errorlogmax option specifies the maximum size of the error log, in megabytes. The default name for the error log is dsmerror.log.

Log wrapping is controlled by the errorlogmax option. If errorlogmax is set to zero (0), the size of the log is unlimited; logged entries never "wrap" and begin overwriting earlier logged entries. If errorlogmax is not set to zero, the newest log entries overwrite the oldest log entries after the log file reaches its maximum size.

Log pruning is controlled by the errorlogretention option. Pruned logs do not wrap. Instead, log entries that are older than the number of days specified by the errorlogretention option are removed from the log file.

If you change from log wrapping (errorlogmax option) to log pruning (errorlogretention option), all existing log entries are retained and the log is pruned using the new errorlogretention criteria. Pruned log entries are saved in a file called dsmerlog.pru.

If you change from using log pruning (errorlogretention option) to using log wrapping (errlogmax option), all records in the existing log are copied to the dsmerlog.pru log file, the existing log is emptied, and logging begins using the new log wrapping criteria.

If you simply change the value of the errorlogmax option, the existing log is extended or shortened to accommodate the new size. If the value is reduced, the oldest entries are deleted to reduce the file to the new size.

If neither errologmax nor errorlogretention is specified, the error log can grow without any limit on its size. You must manually manage the log contents to prevent the log from depleting disk resources. When the log has been created with neither option specified, if you later issue a command and specify the errorlogretention option, the log is pruned using the retention value specified. When the log has been created with neither option specified, if you later issue a command and specify the errorlogmax option, the existing log is treated as if it was a pruned log. That is, the content of the dsmerror.log file is copied to a file called dsmerlog.pru and new log entries are created in dsmerror.log and the log is wrapped when it reaches its maximum size.

Note: If you specify a non-zero value for errorlogmax (which enables log wrapping), you cannot use the errorlogretention option to create pruned logs. Logs can be pruned or wrapped, but not both.
Logs created with the errorlogmax option contain a log header record that contains information similar to this example record:

```
LOGHEADERREC 661  104857600 IBM Spectrum Protect 8.1.0 Fri Dec 9 06:46:53 2011
```

Note that the dates and time stamps in the LOGHEADERREC text are not translated or formatted using the settings specified on the dateformat or timeformat options.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza.

Windows Place this option in the client options file (dsm.opt).

AIX Linux Solaris Mac OS X Windows You can also set this option on the Client preferences tab in the GUI, by selecting Enable error log file wrapping and by specifying a non-zero maximum size for the log file. To prevent log file wrapping, set the maximum size to zero. When the maximum wrapping is set to zero, clearing or setting the Enable error log file wrapping option has no effect; log wrapping does not occur if the maximum size is set to zero.

Syntax

```
>>-ERRORLOGMAX-- --size----------------------------------------><
```

Parameters

size
: Specifies the maximum size, in megabytes, for the log file. The range of values is 0 to 2047; the default is 0, which disables log file wrapping and allows the log file to grow indefinitely.

Examples

Options file:

```
errorlogmax 2000
```

Command line:

```
-errorlogmax=2000
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Errorlogname

This option specifies the fully qualified path and file name of the file that contains the error messages.

AIX Linux Solaris Mac OS X The value for this option overrides the `DSM_LOG` environment variable. The `dsmwebcl.log` and `dsmsched.log` files are created in the same directory as the error log file you specify with the errorlogname option.

Mac OS X For Mac OS X, the default location is one of the following:

```
~/Library/Logs/tivoli/tsm/
/Library/Logs/tivoli/tsm/
```

Mac OS X The dsmerror.log cannot be a symbolic link.

Windows The value for this option overrides the `DSM_LOG` environment variable. The `dsmwebcl.log` and `dsmsched.log` files are created in the same directory as the error log file you specify with the errorlogname option.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the General tab, Select Error Log button of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the General tab, Select Error Log button of the Preferences editor.

Syntax

```
>>-ERRORLOGName-- --filespec-----------------------------------><
```

Parameters

filespec
The fully qualified path and file name in which to store error log information. If any part of the path you specify does not exist, the client attempts to create it.

AIX Linux Solaris Mac OS X The dsmerror.log file cannot be a symbolic link.

Examples

AIX Linux Solaris Mac OS X Options file:

AIX Linux Solaris Mac OS X
```
errorlogname /tmp/tsmerror.log
```

Windows Options file:

Windows
```
errorlogname c:\temp\dsmerror.log
```

AIX Linux Solaris Mac OS X Command line:

AIX Linux Solaris Mac OS X
```
-errorlogname=/tmp/tsmerror.log
```

Windows Command line:

Windows
```
-errorlogname=c:\temp\dsmerror.log
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Windows The location of the log file specified using the Client Service Configuration Utility or the client configuration wizard overrides the location specified in the client options file (dsm.opt).

Errorlogretention

The errorlogretention option specifies how many days to maintain error log entries before pruning, and whether to save the pruned entries in other files.

The error log is pruned when the first error is written to the log after a client session is started. If the only session you run is the client scheduler, and you run it twenty-four hours a day, the error log might not be pruned according to your expectations. Stop the session and start it again to allow the scheduler to prune the error log.

If you change from log pruning (errorlogretention option) to log wrapping (errorlogmax option), all records in the existing log are copied to the dsmerlog.pru log file, the existing log is emptied, and logging begins using the new log wrapping criteria.

If you change from log wrapping (errorlogmax option) to log pruning (errorlogretention option), all existing log entries are retained and the log is pruned using the new errorlogretention criteria. Pruned log entries are saved in a file called dsmerlog.pru.

If neither errologmax nor errorlogretention is specified, the error log can grow without any limit on its size. You must manually manage the log contents to prevent the log from depleting disk resources. When the log has been created with neither option specified, if you later issue a command and specify the errorlogretention option, the log is pruned using the retention value specified. When the log has been created with neither option specified, if you later issue a command and specify the errorlogmax option, the existing log is treated as if it was a pruned log. That is, the content of the dsmerror.log file is copied to a file called dsmerlog.pru and new log entries are created in dsmerror.log and the log is wrapped when it reaches its maximum size.

Note: If you specify errorlogretention option to create pruned logs, you cannot specify the errorlogmax option. Logs can be pruned or wrapped, but not both.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

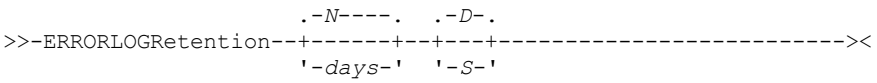
Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza.

Windows Place this option in the client options file (dsm.opt).

AIX Linux Mac OS X Solaris Windows You can also set this option on the Client preferences tab in the GUI, by selecting Prune old entries and by specifying a value for Prune entries older than. Selecting the Save pruned entries option saves the pruned log entries in the dsmerlog.pru log file.

Syntax



Parameters

N or days
: Specifies how long to wait before pruning the error log.

  N
  : Do not prune the error log. This permits the error log to grow indefinitely. This is the default.

  days
  : The number of days to keep log file entries before pruning the log. The range of values is zero through 9999.

D or S
: Specifies whether to save the pruned entries. Enter a space or comma to separate this parameter from the previous one.

  D
  : Discard the error log entries when you prune the log. This is the default.

  S
  : Save the error log entries when you prune the log.

    The pruned entries are copied from the error log to the dsmerlog.pru file located in the same directory as the dsmerror.log file.

Examples

Options file:

Prune log entries from the dsmerror.log file that are older than 365 days and save the pruned entries in dsmerlog.pru.

```
errorlogretention 365 S
```

Command line:

```
-errorlogr=365,S
```

Options file:

Prune log entries from the dsmerror.log file that are older than 365 days and do not save the pruned entries.

```
errorlogretention 365 D
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Exclude options

Use the exclude options to exclude objects from backup, image, or archive services.

Windows For example, you might want to exclude this type of information:

- All temporary files
- Any local caches of network files
- All files that contain compiled object code that you can easily reproduce using other methods
- Your operating system files

AIX Linux Solaris Mac OS X For example, you might want to exclude this type of information:

- All temporary files
- Any local caches of network files
- All files that contain compiled object code that you can easily reproduce using other methods
- Your operating system files

You can exclude specific files from encryption processing during a backup.

Windows You can exclude remotely accessed files by specifying Universal Naming Convention (UNC) names in your exclude statement.

Note:

1. Windows When you exclude a file that was previously included, existing backup versions become inactive during the next incremental backup.
2. AIX Linux Solaris Mac OS X With the exception of exclude.fs, when you exclude a file that was previously included, existing backup versions become inactive during the next incremental backup.
3. Windows The exclude statements are not case sensitive.
4. The server can define exclude options with the inclexcl option.
5. Windows As with other include-exclude statements, you can use the inclexcl option to specify a file that can be in Unicode format, containing exclude statements with file names in Unicode.

AIX Linux Solaris Windows Exclude any system files or images that could corrupt the operating system when recovered. Also exclude the directory containing the IBM Spectrum Protect™ client files.

AIX Linux Solaris Mac OS X To exclude an entire directory called `/any/test`, enter the following:

Windows To exclude an entire directory called `any\test`, enter the following:

AIX Linux Solaris Mac OS X

```
exclude.dir /any/test
```

Windows

```
exclude.dir c:\any\test
```

Windows To exclude subdirectories that begin with `test` under the `any` directory, enter the following:

AIX Linux Solaris Mac OS X To exclude subdirectories that begin with `test` under the `/any` directory, enter the following:

AIX Linux Solaris Mac OS X

```
exclude.dir /any/test*
```

Windows

```
exclude.dir c:\any\test*
```

Windows Note: Defining an exclude statement without using a drive letter, such as `exclude.dir code`, excludes the `code` directory on any drive from processing.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set these options on the Include-Exclude tab, Define Include-Exclude Options section of the Preferences editor.

Windows Place these options in the client options file (dsm.opt). You can set these options on the Include-Exclude tab, Define Include-Exclude Options section of the Preferences editor.

Syntax

```
>>-options-- --pattern-----------------------------------------><
```

Windows exclude, exclude.backup, exclude.file, exclude.file.backup

Windows Use these options to exclude a file or group of files from backup services.

AIX Linux Solaris Mac OS X exclude, exclude.backup, exclude.file, exclude.file.backup

AIX Linux Solaris Mac OS X Use these options to exclude a file or group of files from backup services and space management services (if the HSM client is installed). The exclude.backup option only excludes files from normal backup, but not from HSM.

exclude.archive

Excludes a file or a group of files that match the pattern from archive services *only*.

AIX Linux Solaris Mac OS X exclude.attribute.symlink

AIX Linux Solaris Mac OS X Excludes a file or a group of files that are symbolic links or aliases (aliases apply to Mac OS X) from backup processing only.

Mac OS X Note: For Mac OS X aliases are excluded.

exclude.compression

Excludes files from compression processing if the compression option is set to yes. This option applies to backups and archives.

AIX Linux Solaris Mac OS X Windows exclude.dedup

AIX Linux Solaris Mac OS X Windows Excludes files from client-side data deduplication. To control a client-side data deduplication operation, specify ieobjtype as the value of the exclude.dedup option.

Valid ieobjtype parameters are:

- File
- AIX Linux Solaris Mac OS X Image
- Windows SYSTEMState
- Windows Asr

The default is File.

AIX Linux Solaris Mac OS X exclude.dir

AIX Linux Solaris Mac OS X Excludes a directory, its files, and all its subdirectories and their files from backup processing. For example, the statement `exclude.dir /test/dan/data1` excludes the `/test/dan/data1` directory, its files, and all its subdirectories and their files.

If you exclude a directory that was previously included, the server expires existing backup versions of the files and directories beneath it during the next incremental backup. Use this option to exclude a portion of your data that has no underlying files to back up.

Note: Avoid performing a selective backup, or a partial incremental backup, of an individual file within an excluded directory. The next time that you perform an incremental backup, any files backed up in this manner is expired.

Windows exclude.dir

Windows Excludes a directory, its files, and all its subdirectories and their files from backup processing. For example, the statement `exclude.dir c:\test\dan\data1` excludes the `c:\test\dan\data1` directory, its files, and all its subdirectories and their files.

If you exclude a directory that was previously included, the server expires existing backup versions of the files and directories beneath it during the next incremental backup. Use this option to exclude a portion of your data that has no underlying files to back up.

Note: Avoid performing a selective backup, or a partial incremental backup, of an individual file within an excluded directory. The next time that you perform an incremental backup, any files backed up in this manner is expired.
Note: Defining an exclude statement without using a drive letter, such as `exclude.dir code`, excludes the `code` directory on any drive from processing.

exclude.encrypt

Excludes the specified files from encryption processing. This option does not affect whether files are excluded from backup or archive processing, only whether they are excluded from encryption processing.

AIX Linux Solaris Mac OS X exclude.fs

AIX Linux Solaris Mac OS X Excludes file systems that match the specified pattern from backup, incremental image backup, and archive operations. If files from the excluded file systems were ever backed up, then management class rebinding and deleted file expiration does not occur. However, existing backup versions remain on the server subject to associated management class settings. The files that were previously archived from the excluded file system remain on the server as archive copies.

AIX Linux Solaris Mac OS X The exclude.fs option does NOT prevent the backup or archive of any virtual mount points that are subdirectories of the excluded file system.

AIX Linux Solaris Use exclude.image to exclude file systems from full image backup operations.

AIX Solaris exclude.fs.nas

AIX Solaris Excludes file systems on the NAS file server from an image backup when used with the backup nas command. The NAS node name must be prefixed to the file system name, for example: `netappsj1/vol/vol1`. To apply the exclude to all NAS nodes, replace the NAS node name with a wildcard, for example: `*/vol/vol1`. The backup nas command ignores all other exclude statements including exclude.fs and exclude.dir statements. This option is valid for AIX® and Solaris clients *only*.

Windows exclude.fs.nas

Windows Excludes file systems on the NAS file server from an image backup when used with the backup nas command. The NAS node name must be prefixed to the file system name, for example: `netappsj1/vol/vol1`. To apply the exclude to all NAS nodes, replace the NAS node name with a wildcard, for example: `*/vol/vol1`. The backup nas command ignores all other exclude statements including exclude.dir statements. This option is valid for all Windows clients.

AIX Linux Solaris exclude.image

AIX Linux Solaris Excludes mounted file systems and raw logical volumes that match the specified pattern from full image backup operations. This option is valid for AIX, all Linux clients, and Solaris only. Use exclude.fs to exclude file systems from incremental image backup operations.
Restriction: This option does not apply to Mac OS X.

Windows

Table 1. System services components and corresponding keywords

Component	Keyword
Background Intelligent Transfer Service	BITS
Event log	EVENTLOG
Removable Storage Management	RSM
Cluster Database	CLUSTERDB
Remote Storage Service	RSS
Terminal Server Licensing	TLS
Windows Management Instrumentation	WMI
Internet Information Services (IIS) metabase	IIS
DHCP database	DHCP
Wins database	WINSDB

Parameters

AIX Linux Solaris Mac OS X pattern

AIX Linux Solaris Mac OS X Specifies the file or group of files that you want to exclude.

Note: For NAS file systems: You must prefix the NAS node name to the file specification to specify the file server to which the exclude statement applies. If you do not specify a NAS node name, the file system identified refers to the NAS node name specified in the client system-options file (dsm.sys) or on the command line.

If the pattern begins with a single or double quote or contains any embedded blanks or equal signs, you must surround the value in either single (') or double (") quotation marks. The opening and closing quotation marks must be the same type of quotation marks.

AIX Linux Solaris For the exclude.image option, the pattern is the name of a mounted file system or raw logical volume.

Windows pattern

Windows Specifies the file or group of files that you want to exclude.

Note: For NAS file systems: You must prefix the NAS node name to the file specification to specify the file server to which the exclude statement applies. If you do not specify a NAS node name, the file system identified refers to the NAS node name specified in the client options file (dsm.opt) or on the command line.

If the pattern begins with a single or double quote or contains any embedded blanks or equal signs, you must surround the value in either single (') or double (") quotation marks. The opening and closing quotation marks must be the same type of quotation marks.

- For the exclude.image option, the pattern is the name of a file system or raw logical volume.

Examples

Options file:

AIX Linux Solaris Mac OS X

```
exclude /unix/
exclude /.../core
exclude /home/jones/proj1/*
exclude.archive /.../core
exclude.backup /home/jones/proj1/devplan/
exclude.dir /home/jones/tmp
exclude.backup /users/home1/file1
exclude.image /usr/*/*
exclude.encrypt /users/home2/file1
exclude.compression /home/gordon/proj1/*
exclude.fs.nas netappsj/vol/vol0
exclude.attribute.symlink /.../*
exclude.dedup /Users/Administrator/Documents/Important/.../*
```

Windows

```
exclude ?:\...\swapper.dat
exclude "*:\ea data. sf"
exclude ?:\io.sys
exclude ?:\...\spart.par
exclude c:\*\budget.fin
exclude c:\devel\*
exclude.dir c:\home\jodda
exclude.archive c:\home\*.obj
exclude.encrypt c:\system32\mydocs\*
exclude.compression c:\test\file.txt

exclude.fs.nas  netappsj/vol/vol0
exclude.dedup c:\Users\Administrator\Documents\Important\...\*
exclude.dedup e:\*\* ieobjtype=image
exclude.dedup ALL ieobjtype=systemstate
exclude.dedup ALL ieobjtype=ASR
```

Command line:

Does not apply.

- AIX Linux Solaris Mac OS X Controlling symbolic link and alias processing
  The backup-archive client treats symbolic links and aliases (aliases apply to Mac OS X only) as actual files and backs them up. However, the file referenced by the symbolic link is not backed up. In some cases symbolic links can be easily recreated and need not be backed up.
- Controlling compression processing
  This topic lists some items to consider if you want to exclude specific files or groups of files from compression processing during a backup or archive operation.
- AIX Linux Solaris Mac OS X Windows Processing NAS file systems
  Use the exclude.fs.nas option to exclude file systems from NAS image backup processing.
- Linux Windows Virtual machine exclude options
  Virtual machine include and exclude options influence the behavior of backup and restore operations for virtual machines. These options are processed before any command-line options are processed, so that options on the command line can override options specified on any of the virtual machine include options or virtual machine exclude options. See the individual option descriptions for information about the options.

AIX Linux Mac OS X Solaris

Controlling symbolic link and alias processing

The backup-archive client treats symbolic links and aliases (aliases apply to Mac OS X only) as actual files and backs them up. However, the file referenced by the symbolic link is not backed up. In some cases symbolic links can be easily recreated and need not be backed up.

In addition, backing up these symbolic links can increase backup processing time and occupy a substantial amount of space on the IBM Spectrum Protect™ server. You can use the exclude.attribute.symlink option to exclude a file or a group of files that are symbolic links from backup processing. If necessary, you can use the include.attribute.symlink option to include symbolic links within broad group of excluded files for backup processing.

For example, to exclude all symbolic links from backup processing, except those that exist under the `/home/spike` directory, enter these statements in your dsm.sys file:

```
exclude.attribute.symlink  /.../*
include.attribute.symlink /home/spike/.../*
```

Related reference:
Include options

Controlling compression processing

This topic lists some items to consider if you want to exclude specific files or groups of files from compression processing during a backup or archive operation.

- Remember that the backup-archive client compares the files it processes against the patterns specified in the include-exclude statements, reading from the bottom to the top of the options file.
- AIX Linux Solaris Mac OS X The client processes exclude.fs, exclude.dir, and other include-exclude statements first. The client then considers any exclude.compression statements. For example, consider the following include-exclude list:

  ```
  exclude /home/jones/proj1/*.*
  exclude.compression /home/jones/proj1/file.txt
  include /home/jones/proj1/file.txt
  ```

  The client examines the statements (reading from bottom to top) and determines that the `/home/jones/proj1/file.txt` file is a candidate for backup, but is not a candidate for compression processing.

- Windows The client processes exclude.dir and other include-exclude statements first. The client then considers any exclude.compression statements. For example, consider the following include-exclude list:

  ```
  exclude c:\test\*.*
  exclude.compression c:\test\file.txt
  include c:\test\file.txt
  ```

  The client examines the statements (reading from bottom to top) and determines that the `c:\test\file.txt` file is a candidate for backup, but is not a candidate for compression processing.

- Include-exclude compression processing is valid only for backup and archive processing. The exclude.compression option does not affect whether files are excluded from backup or archive processing, only whether they are excluded from compression processing.

Related reference:
Compression
AIX Linux Solaris Mac OS X Windows

Processing NAS file systems

Use the exclude.fs.nas option to exclude file systems from NAS image backup processing.

Linux Windows Note: The exclude.fs.nas option does not apply to a snapshot difference incremental backup.

A NAS file system specification uses the following conventions:

- NAS nodes represent a unique node type. The NAS node name uniquely identifies a NAS file server and its data to the backup-archive client. You can prefix the NAS node name to the file specification to specify the file server to which the exclude statement applies. If you do not specify a NAS node name, the file system identified applies to all NAS file servers.
- Regardless of the client platform, NAS file system specifications use the forward slash (/) separator, as in this example: `/vol/vol0`.

For example, to exclude `/vol/vol1` from backup services on all NAS nodes, specify the following exclude statement:

```
exclude.fs.nas */vol/vol1
```

Linux Windows

Virtual machine exclude options

Virtual machine include and exclude options influence the behavior of backup and restore operations for virtual machines. These options are processed before any command-line options are processed, so that options on the command line can override options specified on any of the virtual machine include options or virtual machine exclude options. See the individual option descriptions for information about the options.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments.

- Linux Windows Exclude.vmdisk
  The EXCLUDE.VMDISK option excludes a virtual machine disk from backup operations.

Related reference:
Exclude.vmdisk
Linux Windows

Fbbranch

Use the fbbranch option with the backup fastback or archive fastback commands.

The fbbranch option specifies the branch ID of the remote FastBack server to back up or archive. The fbbranch option is only required when the backup-archive client is installed on the FastBack Disaster Recovery Hub or when a dedicated proxy is connecting to a replicated FastBack Disaster Recovery Hub repository. Do not specify the fbbranch option when the backup-archive client is installed on the FastBack server.

Supported Clients

Linux This option is valid for Linux x86_64 clients.

Windows This option is valid for all Windows clients.

Options File

Linux None. You can specify this option only on the command line. The server can also define or override this option.

Windows None. You can specify this option only on the command line. The server can also define or override this option.

Syntax

```
>>-FBBranch=--branch_ID----------------------------------------><
```

Parameters

branch_ID
: Specifies the FastBack server branch ID. The value is part of the disaster recovery configuration of the FastBack server.

Examples

Command line:

```
-FBBranch=oracle
```

On a backup-archive client that is installed on the FastBack Disaster Recovery Hub:

```
dsmc backup fastback -fbpolicyname=policy1 -fbserver=myFbServer
  -fbbranch=oracle
```

Command line:

On a backup-archive client that is connecting to a repository on a remote FastBack Disaster Recovery Hub:

```
dsmc backup fastback -fbpolicyname=policy1 -fbserver=server1
  -Fbreposlocation=\\myDrHub.company.com\REP
  -fbbranch=oracle
```

If the fbbranch option is specified on a backup-archive client workstation that is installed on the FastBack server, the fbbranch option is ignored.

Linux | Windows

Fbclientname

Use the fbclientname option with the backup fastback or archive fastback commands.

The fbclientname option is the name of one or more comma-separated FastBack clients to back up or archive from the backup proxy. The values for the fbclientname option are invalid if more than one policy is specified in the fbpolicyname option.

You cannot include spaces in the fbclientname option values.

If you do not specify any values for the fbvolumename option, all the volumes from all the FastBack clients in the policy that is specified are backed up. If you specify multiple FastBack clients in the fbclientname option, you cannot specify values for the fbvolumename option.

Supported Clients

Linux This option is valid for Linux x86_64 clients.

Windows This option is valid for all Windows clients.

Options File

Linux None. You can specify this option only on the command line.

Windows None. You can specify this option only on the command line. The server can also define or override this option.

Syntax

```
                .-,-----------.
                V             |
>>-FBClientname----client_name-+-------------------------------><
```

Parameters

client_name
: Specifies the name of one or more FastBack clients. You can specify up to 10 FastBack client names.

Important:

When specifying the archive fastback or backup fastback command:

1. At least one FBpolicyName is always required.
2. You can specify up to 10 values for FBPolicyName, if no values are specified for both FBClientName and FBVolumeName.
3. When you specify a FBClientName value, there must be only one value for FBPolicyName.
4. You can specify up to 10 values for FBClientName if only one PolicyName is specified, and no values for FBVolumeName are specified.
5. When you specify the FBVolumeName option, you can have only one FBPolicy, and only one FBCLientName specified.
6. You can specify multiple FBVolumeNames if condition 5 is satisfied.
7. You must always specify the FBReposLocation option for Linux.

Examples

Linux Command line:

Linux

```
dsmc backup fastback -fbpolicyname=Policy1
  -fbclientname=fbclient1,fbclient2
  -fbserver=myFbServer
  -fbreposlocation=/mnt/FBLocation
```

Backs up all volumes for FastBack clients fbclient1 and fbclient2 that are found in policy Policy1.

Windows Command line:

Windows

```
dsmc backup fastback -fbpolicyname=Policy1
  -fbclientname=fbclient1,fbclient2
  -fbserver=myFbServer
  -fbreposlocation=\\myFbServer.company.com\REP
```

Backs up all volumes for FastBack clients fbclient1 and fbclient2 that are found in policy Policy1.

Windows Command line:

Windows

```
dsmc backup fastback -fbpolicyname=Policy1
  -fbclientname=fbclient1
  -fbvolume=c:,f: -fbserver=myFbServer
  -fbreposlocation=\\myFbServer.company.com\REP
```

Backs up volumes C:\ and F:\ for FastBack client fbclient1 found in policy Policy1.

Windows Command line:

Windows

```
dsmc backup fastback -fbpolicyname=Policy1
  -fbclientname=fbWindowsClient,fbLinuxClient
  -fbserver=myFbServer
  -fbreposlocation=\\myFbServer.company.com\REP
```

Backs up all volumes for FastBack client `fbWindowsClient` found in policy Policy1.

The volumes for Linux FastBack client `fbLinuxClient` will not be backed up from the Windows backup-archive client. To back up or archive volumes from a Linux FastBack client, use the Linux backup-archive client.

Linux | Windows

Fbpolicyname

Use the fbpolicyname option with the backup fastback or archive fastback commands.

The fbpolicyname option is the name of one or more comma-separated FastBack policies that you want to back up or archive from the backup proxy. You must specify at least one policy name. Specify multiple policy names using a comma-delimited list of policies. There is no default value.

If one or more FB policy names contain spaces, you must specify them within quotation marks. Here is an example: "FB Policy NAME1, FBPolicy Name 2".

If you do not specify any values for the fbclientname and fbvolumename options, all the volumes from all the FastBack clients in the policies that are specified are backed up. If you specify multiple policies in the fbpolicyname option, you cannot specify values for the fbclientname and fbvolumename options.

Windows If a policy specification contains both Windows and Linux FastBack clients, only the Windows volumes will be backed up or archived to the IBM Spectrum Protect™ server by the Windows backup-archive client.

Linux If a policy specification contains both Windows and Linux FastBack clients, only the Linux volumes will be backed up or archived to the IBM Spectrum Protect server by the Linux backup-archive client.

At least one snapshot should exist in the FastBack repository for the FastBack policies being archived or backed up prior to issuing the dsmc command

Supported Clients

Linux This option is valid for Linux x86_64 clients.

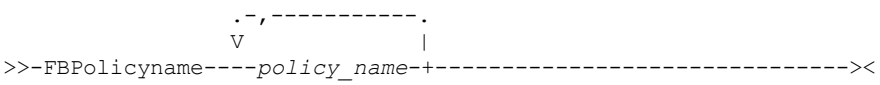
Windows This option is valid for all Windows clients.

Options File

Linux None. You can specify this option only on the command line.

Windows None. You can specify this option only on the command line. The server can also define or override this option.

Syntax



Parameters

policy_name
Specifies the name of the FastBack policies. You can specify up to 10 FastBack policy names.

Important:

When specifying the archive fastback or backup fastback command:

1. At least one FBpolicyName is always required.
2. You can specify up to 10 values for FBPolicyName, if no values are specified for both FBClientName and FBVolumeName.
3. When you specify a FBClientName value, there must be only one value for FBPolicyName.
4. You can specify up to 10 values for FBClientName if only one PolicyName is specified, and no values for FBVolumeName are specified.
5. When you specify the FBVolumeName option, you can have only one FBPolicy, and only one FBCLientName specified. You must specify exactly one FBClientName. It cannot be omitted.
6. You can specify multiple FBVolumeNames if condition 5 is satisfied.
7. You must always specify the FBReposLocation option for Linux.

Examples

Command line:

```
dsmc backup fastback -fbpolicyname=Policy1,Policy2,Policy3
  -fbserver=myFbServer
```

```
-fbreposlocation=\\myFbServer.company.com\REP
```

Backs up all volumes for all FastBack clients found in policies Policy1, Policy2 and Policy3.

To specify policies with spaces, enclose them in double quotation marks, for example:

```
-fbpolicyname="Policy 1,Policy2,Policy3"
```

Linux | Windows

Fbreposlocation

Use the fbreposlocation option with the backup fastback or archive fastback commands.

The fbreposlocation option specifies the location of the Tivoli® Storage Manager FastBack repository for the backup-archive client proxy to connect to issue Tivoli Storage Manager FastBack shell commands necessary to mount appropriate snapshots.

Linux This option is required on Linux systems. There is no default location.

Linux It you specify the fbreposlocation option for a snapshot on the FastBack server, use the server_name@WORKGROUP format.

Linux There are two ways to specify the FastBack repository location on the FastBack Disaster Recovery Hub:

- Specify the complete repository location via the option `-fbreposlocation=\\DR_Hub\rep_server`. When using this format, DR_Hub is the FastBack Disaster Recovery Hub machine name and rep_server is the name of the replicated FastBack server repository on the DR Hub.
- Specify the repository location using a combination of the -fbreposlocation= and -fbbranch options. When using this format, specify the DR Hub repository the location via the option `-fbreposlocation=DR_Hub@WORKGROUP`, and specify the name of the replicated FastBack server repository on the DR Hub using the -fbranch option.

Windows On Windows systems, you do not need to specify the fbreposlocation option when the backup-archive client is installed on a DR Hub server or the FastBack server workstation. When the backup-archive client is installed on a dedicated client proxy, the repository location fbreposlocation option is required.

Windows If you specify the fbreposlocation option for the FastBack Disaster Recovery Hub, specify only the base directory of the DR Hub repository with this option. Then use the fbbranch option to indicate the Branch ID of the server to back up. If you specify the fbreposlocation option for the FastBack server, use the format `\\<fbserver>\REP`. In this case, do not use the fbbranch option.

Linux If you use the format `-fbr=\\<fbserver>\REP`, specify two backslashes before `<fbserver>` and one backslash before REP when using the backup-archive client in interactive mode. If you are using this format as a Linux command `dsmc backup fastback -fbr=\\\\<fbserver>\\REP`, you must specify four backslashes before `<fbserver>` and two backslashes before REP. This is because the Linux shell interprets a backslash as an escape character; the first backslash is treated as an escape character for the following backslash.

Supported Clients

Linux This option is valid for Linux x86_64 clients.

Windows This option is valid for all Windows clients.

Options File

None. You can specify this option only on the command line. The server can also define or override this option.

Syntax

```
>>-FBReposlocation--repository_location------------------------><
```

Parameters

repository_location

Specifies the Tivoli Storage Manager FastBack repository location.

Examples

Linux Command line:

Linux

```
dsmc backup fastback -fbpolicyname=Policy1
  -fbclientname=fbclient1,fbclient2  -fbserver=myFbDrHub
  -fbreposlocation=\\myFbDrHub\rep_myFbServer
```

Note: Because Linux is supported only as a dedicated proxy configuration, a repository location is always required on Linux.

Linux Command line:

Linux

```
dsmc backup fastback -fbpolicyname=Policy1
  -fbclientname=fbclient1,fbclient2  -fbserver=myFbDrHub
  -fbreposlocation=myFbDrHub  -fbbranch=rep_myFbServer
```

Note: Because Linux is supported only as a dedicated proxy configuration, a repository location is always required on Linux.

Windows Command line:

Windows

The fbreposlocation option is only required on a dedicated proxy machine. If the fbreposlocation option is specified on a machine where the FastBack server or FastBack Disaster Recovery Hub is installed, it is ignored.

Use this command when the IBM Spectrum Protect™ dedicated proxy client is connecting to a remote Tivoli Storage Manager FastBack server repository:

```
dsmc backup fastback -fbpolicyname="Policy 1" -fbserver=myFbServer
  -fbreposlocation=\\myFbServer.company.com\REP
```

A repository location is required.

myFbServer is the short host name of the machine where the FastBack server is installed.

Windows Command line:

Windows

Use this command when the IBM Spectrum Protect dedicated proxy client is connecting to a remote repository on the FastBack Disaster Recovery Hub:

```
dsmc backup fastback -fbpolicyname="Policy 1" -fbserver=myFbServer
  -fbreposlocation=\\myfbdrhub.company.com\REP
  -fbbranch=aFbServerBranch
```

A repository location is required.

The myFbServer parameter specifies the short host name of the FastBack Server whose FastBack branch is specified using the FBBranch option.

The fbbranch option specifies the branch ID of the FastBack server on the disaster recovery hub.

Linux | Windows

Fbserver

Use the fbserver option with the backup fastback or archive fastback commands.

The fbserver option specifies the short host name of the Tivoli® Storage Manager FastBack server workstation that owns the repository specified by the fbreposlocation option. For a DR Hub, the fbserver option specifies the short name of the FastBack server workstation whose branch repository the backup-archive client is connecting to.

The fbserver option is a key to retrieving the necessary user credentials required to connect to the FastBack server repository or the DR Hub server repository for mount processing.

Supported Clients

Linux This option is valid for Linux x86_64 clients.

Windows This option is valid for all Windows clients.

Options File

Linux None. You can specify this option only on the command line.

Windows None. You can specify this option only on the command line. The server can also define or override this option.

Syntax

```
>>- -FBServer-- --server_name----------------------------------><
```

Parameters

server_name
Specifies the short hostname of the machine on which the FastBack server is installed.

Examples

Linux Command line:

Linux The backup-archive client is installed on a Linux proxy client machine. Use this command to archive all FastBack volumes for all Linux FastBack clients that are defined for FastBack policy1:

```
dsmc archive fastback -fbpolicyname=Policy1
  -fbserver=myfbserver
  -fbreposlocation=myfbserver@WORKGROUP
```

The repository location is required. If you do not provide the repository location, the command will fail.

The FastBack server name, -myfbserver, is the short host name of the FastBack server where the repository is located.

Linux Command line:

Linux The repository, rep_server1, is located on the FastBack Disaster Recovery Hub, myFbDrHub.

```
dsmc archive fastback -fbpolicyname="Policy 1"
  -fbserver=myFbDrHub
  -fbreposlocation=\\myFbDrHub\rep_server1
```

The FastBack server name, -myFbDrHub is the short host name of the FastBack Disaster Recovery Hub server where the repository is located

The -fbreposlocation specifies the location of the repository. The repository location is required. If you do not provide the repository location, the command fails.

-fbserver should point to the short host name of the FastBack DR hub in this case.

Linux Command line:

Linux Archive all volumes protected by FastBack policy named policy1 from the FastBack server named basil:

```
dsmc archive fastback -Fbpolicyname=policy1
  -FBServer=basil -ARCHMC="my_tsm_mgmt_class"
  -fbreposlocation=basil@WORKGROUP
```

Windows Command line:

Windows The IBM Spectrum Protect™ backup-archive client is running on the FastBack server machine whose short name is myFbServer:

```
dsmc archive fastback -fbpolicyname=Policy1 -fbserver=myFbServer
```

Windows Command line:

Windows The IBM Spectrum Protect backup-archive client is running on the FastBack Disaster Recovery Hub machine and is connecting to the FastBack Server branch repository branch1. The short host name of the FastBack server is myFbServer:

```
dsmc archive fastback -fbpolicyname=Policy1 -fbserver=myFbServer
  -fbbranch=branch1
```

Windows Command line:

Windows The backup-archive client is running on a dedicated proxy machine and is connecting to a remote FastBack server repository. The FastBack server is installed on a machine whose short name is myFbServerMachine:

```
dsmc archive fastback -fbpolicyname=Policy1 -fbserver=myFbServerMachine
  -fbreposlocation=\\myFbServerMachine.company.com\Rep
```

Windows Command line:

Windows The backup-archive client is running on a dedicated proxy machine and is connecting to a remote FastBack repository on the FastBack DR Hub. The FastBack Server with branch ID branch1 is installed on a machine whose short name is myFbServer.

```
dsmc backup fastback -fbpolicyname=Policy1 -fbserver=myFbServer
  -fbreposlocation=\\myDrHubMachine.company.com\Rep
  -fbbranch=branch1
```

Linux | Windows

Fbvolumename

Use the fbvolumename option with the backup fastback or archive fastback commands.

The fbvolumename option is the name of one or more comma-separated Tivoli® Storage Manager FastBack volumes to back up or archive from the backup proxy. Values for the fbvolumename option are not valid if more than one FastBack client is specified in the fbclientname option.

If you specify multiple FastBack clients in the fbclientname option, you cannot specify values for the fbvolumename option.

Supported Clients

Linux This option is valid for Linux x86_64 clients.

Windows This option is valid for all Windows clients.

Options File

Linux None. You can specify this option only on the command line.

Windows None. You can specify this option only on the command line. The server can also define or override this option.

Syntax

```
                .-,-----------.
                V             |
>>-FBVolumename----volume_name-+-----------------------------><
```

Parameters

volume_name
: Specifies the name of the Tivoli Storage Manager FastBack volumes. You can specify up to 10 FastBack volume names.

Important:

When specifying the archive fastback or backup fastback command:

1. At least one FBpolicyName is always required.
2. You can specify up to 10 values for FBPolicyName, if no values are specified for both FBClientName and FBVolumeName.
3. When you specify a FBClientName value, there must be only one value for FBPolicyName.
4. You can specify up to 10 values for FBClientName if only one PolicyName is specified, and no values for FBVolumeName are specified.
5. When you specify the FBVolumeName option, you can have only one FBPolicy, and only one FBCLientName specified. You must specify exactly one FBClientName. It cannot be omitted.
6. You can specify multiple FBVolumeNames if condition 5 is satisfied.

7. Linux You must specify the FBReposLocation option.

Examples

Linux Command line:

Linux

```
dsmc backup fastback -fbpolicyname=Policy1 -fbclientname=client1
  -fbvolumename=data1,data2 -fbserver=myFbDrHub
  -fbreposlocation=\\myFbDrHub\rep_server1
```

Backs up volumes data1 and data2 from FastBack client client1 found in policy Policy1.

Windows Command line:

Windows

```
dsmc backup fastback -fbpolicyname=Policy1 -fbclientname=client1
  -fbvolumename=c:,f: -fbserver=myFbServer
  -fbreposlocation=\\myFbServer.company.com\REP
```

Backs up volumes C:\ and F:\ from FastBack client Client1, found in policy Policy1.

Windows Command line:

Windows

```
dsmc archive fastback -fbpolicyname=Policy1 -fbclientname=client1
  -fbvolumename=c:,f: -fbserver=myFbServer
  -fbreposlocation=\\myFbServer.company.com\REP
```

Archives volumes C: and F: from FastBack client Client1, found in policy Policy1.

Filelist

Use the filelist option to process a list of files.

You can use the filelist option with the following commands:

- archive
- Windows backup group
- AIX Linux Solaris Mac OS X backup group
- delete archive
- delete backup
- expire
- incremental
- query archive
- query backup
- restore
- retrieve
- selective

The backup-archive client opens the file you specify with this option and processes the list of files within according to the specific command. Except for the restore and retrieve commands, when you use the filelist option, the client ignores all other file specifications on the command line.

The files (entries) listed in the filelist must adhere to the following rules:

- Each entry must be a fully-qualified or a relative path to a file or directory. Note that if you include a directory in a filelist entry, the directory is backed up, but the contents of the directory are not.
- Each path must be specified on a single line. A line can contain only one path.
- Paths must not contain control characters, such as 0x18 (CTRL-X), 0x19 (CTRL-Y) and 0x0A (newline).
- By default, paths must not contain wildcard characters. Do not include asterisk (*) or question marks (?) in a path. This restriction can be overridden if you enable the option named wildcardsareliteral. For more information about that option, see Wildcardsareliteral.
- Mac OS X Windows The filelist can be an MBCS file or a Unicode file with all Unicode entries. For Mac OS X, the filelist can be encoded in the current operating system language or UTF-16.
- If it is set, the client option called quotessareliteral allows quotation marks in a file specification to be interpreted literally, as quotation marks and not as delimiters. For more information about that option, see Quotesareliteral. If quotesareliteral

and wildcardsareliteral are not set, quotation mark and wildcard processing works as described in the following list:

- If a path or file name contains a space, enclose the entire path in quotation marks (") or single quotation marks (').
  For example "C:\My Documents\spreadsheet.xls" or 'C:\My documents\spreadsheet.xls'.
- If a path contains one or more single quotation marks ('), enclose the entire entry in quotation marks ("). If a path contains one or more quotation marks, enclose the entire path in single quotation marks. File list processing does not support paths that include a mix of quotation marks and single quotation marks.

  The following examples illustrate the correct and incorrect use of quotation marks and single quotation marks in paths.

  This path example contains a single quotation mark, so the path must be enclosed in quotation marks:

  ```
  "/home/gatzby/mydir/gatzby's_report.out"
  ```

  This path example contains quotation marks, so it must be enclosed in single quotation marks:

  ```
  '/home/gatzby/mydir/"top10".out'
  ```

  This path example contains a space character, so it must be enclosed in either quotation marks or single quotation marks:

  ```
  "/home/gatzby/mydir/top 10.out"
  ```

  or

  ```
  '/home/gatzby/mydir/top 10.out'
  ```

  This path example is not supported for filelist processing because it contains unmatched delimiters (" and ’):

  ```
  /home/gatzby/mydir/andy's_"top 10" report.out
  ```

  These paths are not supported for filelist processing because they contain wildcard characters:

  ```
  /home/gatzby*
  /home/*/20??.txt
  ```

- Any IBM Spectrum Protect™ filelist entry that does not comply with these rules is ignored.

AIX Linux Mac OS X Solaris Windows The following are examples of valid paths in a filelist:

AIX Linux Solaris Mac OS X

```
/home/dir/file1
/usr/tivoli/file2
/usr/avi/dir1
/fs1/dir2/file3
"/fs2/Ha Ha Ha/file.txt"
"/fs3/file.txt"
```

Windows

```
c:\myfiles\directory\file1
c:\tivoli\mydir\yourfile.doc
..\notes\avi\dir1
..\fs1\dir2\file3
"d:\fs2\Ha Ha Ha\file.txt"
"d:\fs3\file.txt"
```

To override standard processing of quotation marks and wildcard characters, see Quotesareliteral and Wildcardsareliteral.

You can use the filelist option during an open file support operation. In this case, the client processes the entries in the filelist from the virtual volume instead of the real volume.

If an entry in the filelist indicates a directory, only that directory is processed and not the files within the directory.

If the file name (the `filelistspec`) you specify with the filelist option does not exist, the command fails. The client skips any entries in the filelist that are not valid files or directories. The client logs errors and processing continues to the next entry.

AIX Linux Solaris Mac OS X Use file specifications with the restore and retrieve commands to denote the destination for the restored filelist entries. For example, in the following restore command, the file specification `/user/record/` represents the restore destination for all entries in the filelist.

```
restore -filelist=/home/dir/file3 /usr/record/
```

AIX Linux Solaris Mac OS X However, in the following selective command, the file specification `/usr/record/` is ignored.

```
selective -filelist=/home/dir/file3 /usr/record/
```

Windows Use file specifications with the restore and retrieve commands to denote the destination for the restored filelist entries. For example, in the following restore command, `d:\dir\` represents the restore destination for all entries in the filelist.

```
restore -filelist=c:\filelist.txt d:\dir\
```

Windows However, in the following selective command, the file specification `d:\dir\` is ignored.

```
selective -filelist=c:\filelist.txt d:\dir\
```

If you specify a directory in a filelist for the delete archive or delete backup command, the directory is not deleted. filelists that you use with the delete archive or delete backup command should not include directories.

The entries in the list are processed in the order they appear in the filelist. For optimal processing performance, pre-sort the filelist by file space name and path.

Note: The client might back up a directory twice if the following conditions exist:

- The filelist contains an entry for the directory
- The filelist contains one or more entries for files within that directory
- No backup of the directory exists

AIX Linux Solaris Mac OS X For example, your filelist includes the entries `/home/dir/file1` and `/home/dir`. If the `/dir` directory does not exist on the server, the `/home/dir` directory is sent to the server a second time.

Windows For example, your filelist includes the entries `c:\dir0\myfile` and `c:\dir0`. If the `\dir0` directory does not exist on the server, the `c:\dir0` directory is sent to the server a second time.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect API does not support this option.

Syntax

```
>>-FILEList = - --filelistspec--------------------------------><
```

Parameters

filelistspec
: Specifies the location and name of the file that contains the list of files to process with the command.
Note: When you specify the filelist option on the command line, the subdir option is ignored.

Examples

AIX Linux Solaris Mac OS X Command line:

```
AIX Linux Solaris Mac OS X sel -filelist=/home/avi/filelist.txt
```

Windows Command line:

```
Windows sel -filelist=c:\avi\filelist.txt
```

Filename

Use the filename option with the query systeminfo command to specify a file name in which to store information.

You can store information gathered from one or more of the following items:

- DSMOPTFILE - The contents of the dsm.opt file.

- AIX Linux Solaris Mac OS X DSMSYSFILE - The contents of the dsm.sys file.
- AIX Linux Solaris Mac OS X Windows ENV - Environment variables.
- ERRORLOG - The IBM Spectrum Protect™ error log file.
- FILE - Attributes for the file name that you specify.
- Windows FILESNOTTOBACKUP - Enumeration of Windows Registry key:

  ```
  HKEY_LOCAL_MACHINE\
     SYSTEM\
        CurrentControlSet\
           BackupRestore\
              FilesNotToBackup
  ```

  This key specifies those files that back up products should not back up. The query inclexcl command indicates that these files are excluded per the operating system.
- INCLEXCL - Compiles a list of include-exclude in the order in which they are processed during backup and archive operations.
- Windows KEYSNOTTORESTORE - Enumeration of Windows Registry key:

  ```
  HKEY_LOCAL_MACHINE\
     SYSTEM\
        ControlSet001\
           BackupRestore\
              KeysNotToRestore
  ```

  This key specifies those Windows Registry keys that back up products should not restore.
- Windows MSINFO - Windows system information (output from MSINFO32.EXE).
- OPTIONS - Compiled options.
- Windows OSINFO - Name and version of the client operating system.
- AIX Linux Solaris Mac OS X OSINFO - Name and version of the client operating system (includes ULIMIT information for UNIX and Linux).
- POLICY - Policy set dump.
- Windows REGISTRY - IBM Spectrum Protect-related Windows Registry entries.
- SCHEDLOG - The contents of the schedule log (usually dsmsched.log.
- Windows SFP - The list of files protected by Windows System File Protection, and for each file, indicates whether that file exists. These files are backed up as part of the SYSFILES system object.
- Windows SFP=*filename* - Indicates whether the specified file (*filename*) is protected by Windows System File Protection. For example:

  ```
  SFP=C:\WINNT\SYSTEM32\MSVCRT.DLL
  ```

- Windows SYSTEMSTATE - Windows system state information.
- AIX CLUSTER - AIX® cluster information.
- Windows CLUSTER - Windows cluster information.

Note: The query systeminfo command is intended primarily as an aid for IBM® support to assist in diagnosing problems, although users who are familiar with the concepts addressed by this information might also find it useful. If you use the console option, no special formatting of the output is performed to accommodate screen height or width. Therefore, the console output might be difficult to read due to length and line-wrapping. In this case, use the filename option with the query systeminfo command to allow the output to be written to a file that can subsequently be submitted to IBM support.
AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

Syntax

```
>>-FILEName = - --outputfilename------------------------------><
```

Parameters

outputfilename
: Specifies a file name in which to store the information. If you do not specify a file name, by default the information is stored in the dsminfo.txt file.

Examples

Command line:

```
query systeminfo dsmoptfile errorlog -filename=tsminfo.txt
```

Filesonly

The filesonly option restricts backup, restore, retrieve, or query processing to files *only*.

You cannot restore or retrieve directories from the IBM Spectrum Protect™ server when using the filesonly option with the restore or retrieve commands. However, directories with default attributes are created, if required, as placeholders for files that you restore or retrieve.

You can also use the filesonly option with the following commands:

- archive
- incremental
- query archive
- query backup
- restore
- restore backupset
- restore group
- retrieve
- selective

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect API does not support this option.

Syntax

Parameters

There are no parameters for this option.

Examples

AIX | Linux | Solaris | Mac OS X | Windows Command line:

AIX | Linux | Solaris | Mac OS X | Windows

```
dsmc incremental -filesonly
```

AIX | Linux | Solaris

Followsymbolic

During a backup operation, the followsymbolic option specifies whether you want to use a symbolic link as a virtual mount point. During a restore or retrieve operation, the followsymbolic option specifies how the backup-archive client restores a directory whose name matches a symbolic link on the restore target file system.

For backup operations, the followsymbolic option can influence the virtualmountpoint option setting. If you use the virtualmountpoint option to specify a symbolic link as a virtual mount point, you must also set the followsymbolic option.

During restore and retrieve operations, followsymbolic can influence how the client handles a symbolic link on the file system. Set followsymbolic only when the client attempts to restore a directory whose name matches a symbolic link on the restore target file system.

If you specify `followsymbolic=no` (the default), the client does not restore the contents of the directory, but returns this error message:

```
ANS4029E Error processing 'filespace name path-name file-name':
unable to build a directory path; a file exists with the same name
as a directory.
```

If you specify `followsymbolic=yes`, the client restores the contents of the directory to the target of the symbolic link.

For example, assume the client backed up a file with this path: /fs1/dir1/subdir1/file1. Assume also that a symbolic link /fs1/dir1, that exists on the restore target file system, links to the directory /fs88/dir88/subdir88. Restore the file with the command:

```
restore /fs1/dir1/subdir1/file1
```

If you specify `followsymbolic=no`, the client does not restore the file, but returns the preceding error message. If you specify `followsymbolic=yes`, the client restores file1 to the /fs88/dir88/subdir88/subdir1/file1 directory.

If you restore a symbolic link (not a directory) whose name matches a symbolic link on the restore target file system, the client restores the symbolic link.

If a symbolic link is used as a virtual mount point, the path to the link target must be specified by using an absolute file path.

Use this option with the restore and retrieve commands, or in the client user-options file (dsm.opt).

Supported Clients

This option is valid for all UNIX clients except Mac OS X.

Options File

Place this option in the client options file (dsm.opt).

Syntax

```
                    .-No--.
>>-FOLlowsymbolic--+-----+-------------------------------------><
                    '-Yes-'
```

Parameters

No
: Do not back up a virtual mount point that is a symbolic link. Do not restore a directory if the restore target file system contains a symbolic link with matching name. This is the default.

Yes
: Restore the contents of a directory to the target of a symbolic link.

Examples

Options file:
```
followsymbolic Yes
```
Command line:
```
-fol=Yes
```

Forcefailover

The forcefailover option enables the client to immediately fail over to the secondary server.

You can use the forcefailover option to immediately connect to the secondary server, even if the primary server is still online. For example, you can use this option to verify that the backup-archive client is failing over to the expected secondary server.

Do not edit this option during normal operations.

Supported Clients

This option is valid for all clients.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the client-system options file (dsm.sys).

Windows Place this option in the client options file (dsm.opt).

Syntax

```
                    .-No--.
>>-FORCEFAILOVER--+-----+-------------------------------------><
                    '-Yes-'
```

Parameters

Yes
: Specifies that the client immediately connects to the secondary server.

No
: Specifies that the client fails over to the secondary server during the next logon if the primary server is unavailable. This value is the default.

Examples

Options file:
```
FORCEFAILOVER yes
```
Command line:
```
-FORCEFAILOVER=yes
```

Automated client failover configuration and use
Related tasks:
Configuring the client for automated failover

Fromdate

Use the fromdate option with the fromtime option to specify a date and time from which you want to search for backups or archives during a restore, retrieve, or query operation.

Files that were backed up or archived before this date and time are not included, although older directories might be included, if necessary, to restore or retrieve the files.

Use the fromdate option with the following commands:

- delete backup
- query archive
- query backup
- restore
- restore group
- retrieve

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-FROMDate = - --date-----------------------------------------><
```

Parameters

date
Specifies the date from which you want to search for backup copies or archived files. Enter the date in the format you selected with the dateformat option.

When you include dateformat with a command, it must precede the fromdate, pitdate, and todate options.

Examples

Mac OS X Command line:
Mac OS X `dsmc query backup -fromdate=12/11/2003 "/Users/van/Documents/*"`
AIX Linux Solaris Mac OS X Command line:
AIX Linux Solaris Mac OS X `dsmc query backup -fromdate=12/11/2003 /home/dilbert/*`
Windows Command line:
Windows `dsmc query backup -fromdate=12/11/2003 c:\Windows\Program Files\*.exe`

Fromnode

The fromnode option permits one node to perform commands for another node. A user on another node must use the set access command to permit you to query, restore, or retrieve files for the other node.

Use the fromnode option with the following commands:

- query archive
- query backup
- query filespace
- Windows query group
- AIX Linux Solaris query image
- query mgmtclass
- restore
- restore group
- AIX Linux Solaris Windows restore image
- retrieve

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

Syntax

```
>>-FROMNode = - --node----------------------------------------><
```

Parameters

node
Specifies the node name on a workstation or a file server whose backup copies or archived files you want to access.

Examples

Mac OS X Command line:
Mac OS X `dsmc query archive -fromnode=bob -subdir=yes "/Users/van/Documents/*"`
AIX Linux Solaris Mac OS X Command line:
AIX Linux Solaris Mac OS X `dsmc query archive -fromnode=bob -subdir=yes "/home/jones/*"`
Windows Command line:
Windows `dsmc query archive -fromnode=bob -subdir=yes d:\`

Windows Note: The backup-archive client can use file space information when restoring files. The file space information can contain the name of the computer from which the files were backed up. If you restore from another backup-archive client node and do not specify a destination for the restored files, the client uses the file space information to restore the files. In such a case,

the client attempts to restore the files to the file system on the original computer. If the restoring computer has access to the file system of the original computer, you can restore files to the original file system. If the restoring computer can not access the file system of the original computer, the client can return a network error message. If you want to restore the original directory structure but on a different computer, specify only the target file system when you restore. This is true when restoring files from another node and when retrieving files from another node.

AIX | Linux | Solaris | Mac OS X

Fromowner

The fromowner option specifies an alternate owner from which to restore backup versions or archived files or images. The owner must give access to another to use the files or images.

For example, to restore files from the `/home/devel/proja` directory belonging to *usermike* on system ***puma***, and place the restored files in a directory you own named `/home/id/proja`, enter the following command:

```
dsmc restore -fromowner=usermike -fromnode=puma /home/devel/proja/
/home/id/proja/
```

Mac OS X Note: Archiving image restores does not apply to Mac OS X operating systems.

Non-root users can specify fromowner=*root* to access files owned by the root user if the root user has granted them access.

Note: If you specify the fromowner option without the fromnode option, the active user must be on the same node as the fromowner user.

Use the fromowner option with the following commands:

- query archive
- query backup
- query group
- query image
- restore
- restore image
- restore group
- retrieve

Supported Clients

This option is valid for all UNIX and Linux clients.

Syntax

```
>>-FROMOwner = - --owner---------------------------------------><
```

Parameters

owner
: Name of an alternate owner.

Examples

Command line:

```
dsmc query archive "/home/id/proja/*" -fromowner=mark
```

Fromtime

Use the fromtime option with the fromdate option to specify a beginning time from which you want to search for backups or archives during a restore, retrieve, or query operation.

The backup-archive client ignores this option if you do not specify the fromdate option.

Use the fromtime option with the following commands:

- delete backup
- query archive
- query backup
- restore
- restore group
- retrieve

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-FROMTime = - --time----------------------------------------><
```

Parameters

time

Specifies a beginning time on a specific date from which you want to search for backed up or archived files. If you do not specify a time, the time defaults to 00:00:00. Specify the time in the format you selected with the timeformat option.

When you include the timeformat option in a command, it must precede the fromtime, pittime, and totime options.

Examples

AIX Linux Solaris Mac OS X Command line:

AIX Linux Solaris Mac OS X
```
dsmc q b -timeformat=4 -fromt=11:59AM -fromd=06/30/2003 -
tot=11:59PM -tod=06/30/2003 /home/*
```

Windows Command line:

Windows
```
dsmc q b -timeformat=4 -fromt=11:59AM -fromd=06/30/2003 -tot=11:59PM -tod=06/30/2003
c:\*
```

Groupname

Use the groupname option with the backup group command to specify the name for a group. You can only perform operations on new groups or the current active version of the group.

AIX Linux Solaris Windows

Supported Clients

AIX Linux Solaris This option is valid for all UNIX and Linux clients except Mac OS X.

Windows This option is valid for all Windows clients.

Syntax

```
>>-GROUPName = - --name----------------------------------------><
```

Parameters

name

Specifies the name of the group which contains the files backed up using the filelist option. Directory delimiters are not allowed in the group name since the group name is not a file specification, but a name field.

Examples

Command line:

AIX | Linux | Solaris

```
backup group -filelist=/home/dir1/filelist1 -groupname=group1
-virtualfsname=/virtfs -mode=full
```

Windows

```
backup group -filelist=c:\dir1\filelist1 -groupname=group1
-virtualfsname=\virtfs -mode=full
```

AIX | Linux | Solaris | Mac OS X

Groups (deprecated)

This option is deprecated.

Linux | Windows

Host

The host option specifies the target ESX server location where the new virtual machine is created during a VMware restore operation.

Use this option on restore vm commands to specify the ESX host server to restore the data to.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Example

Restore the virtual machine to the ESX server named vmesxbld1.

```
restore vm -host=vmesxbld1.us.acme.com
```

Httpport

The httpport option specifies a TCP/IP port address for the web client.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Web Client tab, in the HTTP Port field of the Preferences editor.

Windows Place this option in the client system options file (dsm.opt). You can set this option on the Web Client tab, in the HTTP Port field of the Preferences editor.

Syntax

```
>>-HTTPport-- --port_address---------------------------------><
```

Parameters

port_address

Specifies the TCP/IP port address that is used to communicate with the web client. The range of values is 1000 through 32767; the default is 1581.

Examples

Options file:

```
httpport 1502
```

Windows Command line:

Windows

```
-httpport=1502
```

AIX Linux Solaris Mac OS X Command line:

AIX Linux Solaris Mac OS X Does not apply.

Hsmreparsetag

The hsmreparsetag option specifies a unique reparse tag that is created by an HSM product installed on your system.

Many HSM products use reparse points to retrieve or recall migrated files. After a file is migrated, a small stub file, with the same name as the original file, is left on the file system. The stub file is a reparse point that triggers a recall of the original file when a user or application accesses the stub file. The reparse point includes a unique identifier called a *reparse tag* to identify which HSM product migrated the file.

If the IBM Spectrum Protect™ backup-archive client does not recognize the reparse tag in a stub file, the Backup-Archive Client causes the HSM product to recall the original file. You can prevent files from being recalled if you specify the reparse tag with the hsmreparsetag option.

The backup-archive client recognizes the reparse tag of HSM products from the following companies:

- International Business Machines Corp.
- Wisdata System Co. Ltd.
- BridgeHead Software Ltd.
- CommVault Systems, Inc.
- Data Storage Group, Inc.
- Enigma Data Solutions, Ltd.
- Enterprise Data Solutions, Inc.
- Global 360
- GRAU DATA AG
- Hermes Software GmbH
- Hewlett Packard Company
- International Communication Products Engineering GmbH
- KOM Networks
- Memory-Tech Corporation
- Moonwalk Universal
- Pointsoft Australia Pty. Ltd.
- Symantec Corporation

If the HSM product you use is not in the preceding list, use the hsmreparsetag option to specify the reparse tag. Ask your HSM product vendor for the reparse tag used by the product.

Supported clients

This option is valid for all Windows clients.

Option file

Place this option in the client options file (dsm.opt).

Syntax

```
>>---HSMREPARSETAG----reparse_tag_value-----------------------><
```

Parameters

reparse_tag_value
: A decimal (base 10) or hexadecimal (base 16) value that specifies the reparse tag.

Examples

Options file:
: Specify an HSM reparse tag in decimal format:

```
hsmreparsetag 22
```

: Specify an HSM reparse tag in hexadecimal format:

```
hsmreparsetag 0x16
```

Command line:
: Does not apply.

Ieobjtype

Use the ieobjtype option to specify an object type for a client-side data deduplication operation within include-exclude statements.

The ieobjtype option is an additional parameter to the include.dedup or exclude.dedup options.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API also supports this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the system-options file (dsm.sys). You can set this option on the Include/Exclude tab of the Preferences editor. The option can be set in the client option set on the IBM Spectrum Protect server.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Include/Exclude tab of the Preferences editor. The option can be set in the client option set on IBM Spectrum Protect server.

Syntax

```
              .-File--------.
>>-IEObjtype--+-Image-------+---------------------------------><
              +-SYSTEMState-+
              '-Asr---------'
```

Parameters

File
: Specifies that you want to include files for, or exclude files from, client-side data deduplication processing. File is the default.

Image
: Specifies that you want to include images for, or exclude images from, client-side data deduplication processing.

Windows System State
: Windows Specifies that you want to include system state for, or exclude system state from, client-side data deduplication processing.

Windows Asr
: Windows Specifies that you want to include automatic system recovery objects for, or exclude ASR objects from, client-side data deduplication processing.

Examples

Options file:

Windows
```
exclude.dedup e:\*\* ieobjtype=image
```
AIX Linux Mac OS X Solaris
```
exclude.dedup /home/*/* ieobjtype=image
```

Command line:

Does not apply.

Related reference:
Exclude options
Include options

Ifnewer

The ifnewer option replaces an existing file with the latest backup version only if the backup version is newer than the existing file.

Only active backups are considered unless you also use the inactive or latest options.

Note: Directory entries are replaced with the latest backup version, whether the backup version is older or newer than the existing version.

Use the ifnewer option with the following commands:

- restore
- restore backupset
- restore group
- retrieve

Note: This option is ignored if the replace option is set to No.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-IFNewer-----------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

AIX Linux Mac OS X Solaris Command line:

AIX Linux Mac OS X Solaris Mac OS X
```
dsmc restore "/Users/grover/Documents/*" -sub=y -rep=y
-ifnewer
```
AIX Linux Mac OS X Solaris AIX Linux Mac OS X Solaris
```
dsmc restore "/home/grover/*" -
sub=y -rep=y -ifnewer
```

Windows Command line:

Windows
```
dsmc restore -ifnewer d:\logs\*.log
```

AIX Linux Windows

Imagegapsize

Use the imagegapsize option with the backup image command, in the options file, or with the include.image option to specify the minimum size of empty regions on a volume that you want to skip during image backup.

Use this option for LAN-based and LAN-free image backup.

For example, if you specify a gap size of 10, this means that an empty region on the disk that is larger than 10 KB in size is not backed up. Gaps that are exactly 10 KB are backed up. Empty regions that are exactly 10 KB and that are smaller than 10 KB is backed up, even though they do not contain data. However, an empty region that is smaller than 10 KB is backed up, even though it does not contain data. A smaller image gap size means less data needs to be transferred, but with potentially decreased throughput. A larger image gap size results in more data being transferred, but with potentially better throughput.

Windows Place the include.image statement containing the imagegapsize value in your `dsm.opt` file.

Supported Clients

AIX Linux This option is valid for AIX®, Linux, and JFS2 clients only. The IBM Spectrum Protect™ API does not support this option.

Windows This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option.

Options File

AIX Place this option in the server stanza of the client systems options file (dsm.sys), or in the include.image statement in the dsm.sys file.

Windows Place this option in the client options file (dsm.opt).

Syntax

```
>>-IMAGEGapsize-- --size----------------------------------------><
```

Parameters

AIX size

AIX Specifies the minimum size of empty regions in an AIX JFS2 file system that should be skipped during an image backup. You can specify `k` (kilobytes) `m` (megabytes) or `g` (gigabytes) qualifiers with the value. Without a qualifier, the value is interpreted in kilobytes. Valid values are 0 through 4294967295 KB. If you specify a value of 0, all blocks, including unused blocks at the end of the volume, is backed up. If you specify any value other than 0, unused blocks at the end of the volume are not backed up. For LAN-based and LAN-free image backup the default value is 32 KB. This option is applicable to both static and snapshot-based image backup.
Note: This option is valid for AIX JFS2 file systems. If you specify an imagegapsize that is greater than 0 for a file system other than AIX JFS2, you get a warning message.

Windows size

Windows Specifies the minimum size of empty regions in a formatted logical volume that should be skipped during an image backup. You can specify `k` (kilobytes) `m` (megabytes) or `g` (gigabytes) qualifiers with the value. Without a qualifier, the value is interpreted in KB. Valid values are 0 through 4294967295 KB. If you specify a value of 0, all blocks, including unused blocks at the end of the volume, is backed up. If you specify any value other than 0, unused blocks at the end of the volume are not backed up. For LAN-based and LAN-free image backup the default value is 32 KB.
Note: Because of operating system limitations, use this option for NTFS file systems only. If you specify an imagegapsize that is greater than 0 for a file system other than NTFS, you get a warning message.

Examples

AIX Options file:

AIX Add the following to the server stanza in the dsm.sys file: `imagegapsize 1m`

Include-exclude list example: `include.image /kalafs1 imagegapsize=-128k`

Windows Options file:

Windows `imagegapsize 1m`

Include-exclude list example: `include.image h: MYMC imagegapsize=1m`

Command line:

```
-imagegapsize=64k
```

AIX Linux Solaris Windows

Imagetofile

Use the imagetofile option with the restore image command to specify that you want to restore the source image to a file.

You might need to restore the image to a file if bad sectors are present on the target volume, or if you want to manipulate the image data. Later, you can use a data copy utility of your choice to transfer the image from the file to a disk volume.

Linux Linux supports mounting an image file as a logical volume, so you can get access to file data within the image. The following are some examples:

AIX Linux Solaris

- The file system `/usr` has been backed up by the backup-archive client. The following command restores the file system image to the file `/home/usr.img`:

  ```
  # dsmc restore image /usr /home/usr.img -imagetofile
  ```

- To mount the image file at the `/mnt/usr` directory, the following mount command can be executed:

  ```
  # mount /home/usr.img /mnt/usr -o loop=/dev/loop0
  ```

AIX Linux Solaris Now the image contents are available from `/mnt/usr` as if a regular file system was mounted at that directory.

Supported Clients

AIX Linux Solaris This option is valid only for AIX®, Oracle Solaris, and all Linux clients. The IBM Spectrum Protect™ API does not support this option.

Windows This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option.

Syntax

```
>>-IMAGETOfile-------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

AIX Linux Solaris Command line:

AIX Linux Solaris `dsmc restore image /usr /home/usr.img -imagetofile`

Windows Command line:

Windows `dsmc restore image d: e:\diskD.img -imagetofile`

Inactive

Use the inactive option to display both active and inactive objects.

You can use the inactive option with the following commands:

- delete group
- Windows query asr
- query backup
- AIX Linux Solaris Mac OS X query group
- AIX Linux Solaris Windows query image
- AIX Linux Solaris Mac OS X Windows query nas
- Windows query systemstate
- Windows query vm (vmbackuptype=fullvm and vmbackuptype=hypervfull)
- restore
- AIX Linux Solaris Mac OS X Windows restore group

- AIX Linux Solaris Windows restore image
- AIX Linux Solaris Mac OS X Windows restore nas
- Windows restore vm (vmbackuptype=fullvm and vmbackuptype=hypervfull)

AIX Linux Solaris Mac OS X Windows Important: When using the inactive option during a restore operation, also use the pick or some other filtering option because, unlike the latest option, all versions are restored in an indeterminate order. This option is implicit when pitdate is used.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-INActive---------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Mac OS X Command line:

Mac OS X
```
dsmc restore "/Users/zoe/Documents/*" -inactive -pick
```

AIX Linux Solaris Mac OS X Command line:

AIX Linux Solaris Mac OS X
```
dsmc restore "/home/zoe/*" -inactive -pick
```

Windows Command line:

Windows
```
dsmc restore -inactive c:\id\projecta\ -pick
```

Inclexcl

The inclexcl option specifies the path and file name of an include-exclude options file.

Multiple inclexcl statements are permitted. However, you must specify this option for each include-exclude file.

Windows Ensure that you store your include-exclude options file in a directory to which all users have read access.

AIX Linux Solaris Mac OS X Ensure that you store your include-exclude options file in a directory to which all users have read access, such as `/etc`.

When processing occurs, the include-exclude statements within the include-exclude file are placed in the list position occupied by the inclexcl option, in the same order, and processed accordingly.

AIX Linux Solaris Mac OS X If you have the HSM client installed on your workstation, you can use an include-exclude options file to exclude files from backup and space management, from backup only or from space management only.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients. The server can also define this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the dsm.sys file *within* a server stanza. You can set this option on the Include-Exclude tab of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Include-Exclude tab of the Preferences editor.

Syntax

```
>>-INCLExcl-- --filespec---------------------------------------><
```

Parameters

filespec
: Specifies the path and file name of *one* include-exclude options file.

Examples

Options file:

Mac OS X

```
INCLExcl /Users/user1/Documents/backup.excl
```

AIX Linux Solaris Mac OS X

```
inclexcl /usr/dsm/backup.excl
inclexcl /etc/inclexcl.def
```

Windows

```
inclexcl c:\dsm\backup.excl
```

Command line:
: Does not apply.

- Considerations for Unicode-enabled clients
  An include-exclude file can be in Unicode or non-Unicode format.

Include options

The include options specify objects that you want to include for backup and archive services.

The include options specify any of the following:

- Mac OS X Objects within a broad group of excluded objects that you want to include for backup and archive services.
- AIX Linux Solaris Objects within a broad group of excluded objects that you want to include for backup, archive, image, and space management services.
- Windows Objects within a broad group of excluded objects that you want to include for backup, archive, and image services.
- Files that are included for backup or archive processing that you want to include for encryption processing.
- Files that are included for backup or archive processing that you also want to include for compression processing.
- Objects to which you want to assign a specific management class.
- A management class to assign to all objects to which you do not explicitly assign a management class.
- File spaces to which you want to assign memory-efficient backup processing
- File spaces where you want to use the diskcachelocation option to cause specific file systems to use different, specific locations for their disk cache.

If you do not assign a specific management class to objects, the default management class in the active policy set of your policy domain is used. Use the query mgmtclass command to display information about the management classes available in your active policy set.

Windows You can include remotely accessed files by specifying Universal Naming Convention (UNC) names in your include statement.

Remember: The backup-archive client compares the files it processes against the patterns specified in the include-exclude statements, reading from the bottom to the top of the options file.
Note:

1. Windows The exclude.dir statement overrides all include statements that match the pattern.
2. AIX Linux Solaris Mac OS X The exclude.fs and exclude.dir statements override all include statements that match the pattern.
3. Windows The include statements are not case-sensitive.
4. The server can also define these options with the inclexcl option.

Supported Clients

This option is valid for all clients. The server can also define include.fs.nas.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set these options on the Include-Exclude tab in the Preferences editor.

Windows Place these options in the client options file (dsm.opt). You can set these options on the Include-Exclude tab in the Preferences editor.

Syntax

```
>>-options-- --pattern-- --+-----------------------+----------><
                           '- --optional_parameter-'
```

include, include.backup, include.file

Use these options to include files or assign management classes for backup processing.
The include option affects archive and backup processing. If you want to assign different management classes for archive and backup processing, always specify include.archive and include.backup with their own management classes. In this example, the `archmc` management class is assigned when an archive operation is performed. The management class is assigned when an archive operation is performed because include.backup is used only for backup processing, and not for archive processing. AIX Linux Solaris Mac OS X

```
include.archive /home/test/* archmc
include.backup /home/test/*
```

Windows

```
include.archive c:\test\*\ archmc
include.backup c:\test\*
```

include.archive

Includes files or assigns management classes for archive processing.

Mac OS X AIX Linux Solaris Mac OS X include.attribute.symlink

Mac OS X AIX Linux Solaris Mac OS X

Includes a file or a group of files that are symbolic links or aliases, within a broad group of excluded files for backup processing only.

Mac OS X Note: For Mac OS X, aliases are included.

include.compression

Includes files for compression processing if you set the compression option to yes. This option applies to backups and archives.

AIX Linux Solaris Mac OS X Windows include.dedup

AIX Linux Solaris Mac OS X Windows Includes files for client-side data deduplication. To control a client-side data deduplication operation, specify ieobjtype as the value of the include.dedup option. By default, all data deduplication-eligible objects are included for client-side data deduplication.
Valid ieobjtype parameters are:

- File
- Image
- Windows SYSTEMState
- Windows Asr

The default is File.

include.encrypt

Includes the specified files for encryption processing. By default, the client does not perform encryption processing.
Notes:

1. The include.encrypt option is the only way to enable encryption on the backup-archive client. If no include.encrypt statements are used, encryption does not occur.

2. Encryption is not compatible with client-side deduplication. Files that are included for encryption are not deduplicated by client-side deduplication.
3. Encryption is not compatible with VMware virtual machine backups that use the incremental forever backup modes (MODE=IFIncremental and MODE=IFFull). If the client is configured for encryption, you cannot use incremental forever backup.
4. Encryption is not compatible with the IBM Spectrum Protect™ for Virtual Environments Data Protection for VMware Recovery Agent. If the client is configured for encryption, you can use the client to restore backups that were created with the full or incremental backup modes (MODE=Full and MODE=Incremental). However, you cannot use the Recover Agent to restore the encrypted backups. Backups that were created with the full or incremental mode were created with the version 7.1 or earlier client.

AIX Linux Solaris include.fs

AIX Linux Solaris

AIX For AIX® JFS2 file systems: Use the snapshotcachesize option in the dsm.sys file or with the include.fs option, to specify an appropriate snapshot size so that all old data blocks can be stored while the snapshot-based file backup or archive occurs.

To control how the client processes your file space for incremental backup, you can specify these additional options in your dsm.sys file, as values of the include.fs option: diskcachelocation and memoryefficientbackup.

Each of the include.fs, memoryefficientbackup and diskcachelocation options must be on the same line in the options file.

```
include.fs /home
     memoryefficientbackup=diskcachemethod
     diskcachelocation=/usr
include.fs /usr
     memoryefficientbackup=diskcachemethod
     diskcachelocation=/home
include.fs /Volumes/hfs3
     memoryefficientbackup=diskcachemethod
     diskcachelocation=/Volumes/hfs2
 AIX JFS2 filesystems only: include.fs
     /kalafs1 snapshotproviderfs=JFS2
```

If these options appear both in the options file and an include.fs option, the include.fs values are used for the specified file space in place of any values in an option file or on the command line.

Windows include.fs

Windows If open file support has been configured, the client performs a snapshot backup or archive of files that are locked (or in use) by other applications. The snapshot allows the backup to be taken from a point-in-time copy that matches the file system at the time the snapshot is taken. Subsequent changes to the file system are not included in the backup. You can set the snapshotproviderfs parameter of the include.fs option to none to specify which drives do not use open file support.
To control how the client processes your file space for incremental backup, you can specify these additional options in your dsm.opt file as values of the include.fs option: diskcachelocation and memoryefficientbackup.

```
include.fs d: memoryefficientbackup=diskcachem
  diskcachelocation=e:\temp
include.fs e: memoryefficientbackup=diskcachem
  diskcachelocation=c:\temp
```

If these options appear both in the options file and an include.fs option, the include.fs values are used for the specified file space in place of any values in an option file or on the command line.

AIX Solaris include.fs.nas

AIX Solaris Use the include.fs.nas option to bind a management class to Network Attached Storage (NAS) file systems. You can also specify whether the client saves Table of Contents (TOC) information during a NAS file system image backup, using the toc option with the include.fs.nas option in your dsm.sys file. This option is only valid for AIX and Solaris clients.

Windows include.fs.nas

Windows Use the include.fs.nas option to bind a management class to Network Attached Storage (NAS) file systems. You can also specify whether the client saves Table of Contents (TOC) information during a NAS file system image backup, using the toc option with the include.fs.nas option in your client options file (dsm.opt).

AIX Linux Solaris include.image

AIX Linux Solaris Includes a file space or logical volume, or assigns a management class when used with the backup image command. The backup image command ignores all other include options.

Linux For Linux x86_64 clients: Use the snapshotcachesize option in these situations:

- With the backup image command
- In the dsm.sys file
- With the include.image option

Using the snapshotcachesize option in these situations lets you specify an appropriate snapshot size, so that all old data blocks can be stored while the image backup occurs.

A snapshot size of 100 percent ensures a valid snapshot.

AIX For AIX JFS2 file systems: Use the snapshotcachesize option in these situations:

- With the backup image command
- In the dsm.sys file
- With the include.image option

Using the snapshotcachesize option in these situations lets you specify an appropriate snapshot size, so that all old data blocks can be stored while the image backup occurs.

AIX Linux Solaris This option is valid for AIX, Linux, and Oracle Solaris clients.

Windows include.image

Windows Includes a file space or logical volume, or assigns a management class when used with the backup image command. The backup image command ignores all other include options.

By default, the client performs an offline image backup. To enable and control an online image operation, you can specify these options in your dsm.opt file as values of the include.image option: snapshotproviderimage, presnapshotcmd, postsnapshotcmd.

Windows include.systemstate

Windows This option binds system state backups to the specified management class. If you specify this option, specify all as the pattern. If you do not specify this option system state backups are bound to the default management class.

Parameters

pattern

Specifies the objects to include for backup or archive processing or to assign a specific management class.

AIX Linux Solaris Note: For NAS file systems: You must prefix the NAS node name to the file specification to specify the file server to which the include statement applies. If you do not specify a NAS node name, the file system identified refers to the NAS node name specified in the client system-options file (dsm.sys) or on the command line.

Windows Note: For NAS file systems: You must prefix the NAS node name to the file specification to specify the file server to which the include statement applies. If you do not specify a NAS node name, the file system identified refers to the NAS node name specified in the client options file (dsm.opt) or on the command line.

If the pattern begins with a single or double quotation mark, or contains any embedded blanks or equal signs, you must surround the value in either single (') or double (") quotation marks. The opening and closing quotation marks must be the same type of quotation marks.

AIX Linux Solaris For the include.image option, the pattern is the name of a mounted file system or raw logical volume.

Windows For the include.image option, the pattern is the name of a file system or raw logical volume.

Windows

Note: When you specify include.systemstate, the only valid pattern is all.

optional_parameter

management_class_name

Specifies the name of the management class to assign to the objects. If a management class is not specified, the default management class is used. To associate a management class with a backup group on an include statement, use the following syntax:

AIX Linux Mac OS X Solaris

```
include virtual_filespace_name\group_name management_class_name
```

Windows

```
include virtual_filespace_name/group_name management_class_name
```

where:

virtual_filespace_name
Specifies the name of the IBM Spectrum Protect server virtual filespace that you associated with the group, on the Backup Group command.

group_name
Is the name of the group that you created when you ran the Backup Group command.

management_class_name
Is the name of the management class to associate with the files in the group.
For example, a group named MyGroup is stored in a virtual file space called MyVirtualFileSpace. To associate a management class, named TEST, with the group, use the following syntax: AIX Linux Mac OS X Solaris

```
include MyVirtualFileSpace/MyGroup TEST
```

Windows

```
include MyVirtualFileSpace\MyGroup TEST
```

Controlling symbolic link and alias processing

IBM Spectrum Protect™ treats symbolic links and aliases (aliases apply to Mac OS X only) as actual files and backs them up. However, the file referenced by the symbolic link is not backed up.

In some cases symbolic links and aliases can be easily recreated and need not be backed up. In addition, backing up these symbolic links or aliases can increase backup processing time and occupy a substantial amount of space on the IBM Spectrum Protect server.

You can use the exclude.attribute.symlink option to exclude a file or a group of files that are symbolic links or aliases from backup processing. If necessary, you can use the include.attribute.symlink option to include symbolic links or aliases within broad group of excluded files for backup processing. For example, to exclude all symbolic links or aliases from backup processing, except those that exist under the `/home/spike` directory, enter these statements in your dsm.sys file:

```
exclude.attribute.symlink  /.../*
include.attribute.symlink /home/spike/.../*
```

Exclude options
Windows

Compression and encryption processing

Consider the following information if you want to include specific files or groups of files for compression and encryption during a backup or archive operation.

- You must set the compression option to *yes* to enable compression processing. If you do not specify the compression option or you set the compression option to *no*, the backup-archive client does not perform compression processing.
- The client processes exclude.dir and other include-exclude statements first. The client then considers any include.compression and include.encrypt statements. For example, consider the following include-exclude list:

  ```
  exclude c:\test\file.txt
  include.compression c:\test\file.txt
  include.encrypt c:\test\file.txt
  ```

  The client examines the `exclude c:\test\file.txt` statement first and determines that `c:\test\file.txt` is excluded from backup processing and is, therefore, not a candidate for compression or encryption processing.

- Include-exclude compression and encryption processing is valid for backup and archive processing *only*.

- As with other include-exclude statements, you can use the inclexcl option to specify a file that is in Unicode format, which contains include.compression and include.encrypt specifying Unicode files. See Inclexcl for more information.

Related reference:
Compression
AIX | Linux | Solaris

Compression and encryption backup processing

This topic lists some items to consider if you want to include specific files or groups of files for compression and encryption processing during a backup or archive operation.

- You must set the compression option to *yes* to enable compression processing. If you do not specify the compression option or you set the compression option to *no*, the backup-archive client does not perform compression processing.
- The client processes exclude.fs, exclude.dir, and other include-exclude statements first. The client then considers any include.compression and include.encrypt statements. For example, consider the following include-exclude list:

  ```
  exclude /home/jones/proj1/file.txt
  include.compression /home/jones/proj1/file.txt
  include.encrypt /home/jones/proj1/file.txt
  ```

  The client examines the `exclude /home/jones/proj1/file.txt` statement first and determines that `/home/jones/proj1/file.txt` is excluded from backup processing and is, therefore, not a candidate for compression and encryption processing.

- Include-exclude compression and encryption processing is valid for backup and archive processing *only*.

Compression
AIX | Linux | Solaris | Mac OS X | Windows

Processing NAS file systems

Use the include.fs.nas option to bind a management class to NAS file systems and to control whether Table of Contents information is saved for the file system backup.

Linux | Windows Note: The include.fs.nas option does not apply to incremental snapshot difference incremental backup.

A NAS file system specification uses the following conventions:

- NAS nodes represent a new node type. The NAS node name uniquely identifies a NAS file server and its data to the backup-archive client. You can prefix the NAS node name to the file specification to specify the file server to which the include statement applies. If you do not specify a NAS node name, the file system you specify applies to all NAS file servers.
- Regardless of the client operating system, NAS file system specifications use the forward slash (/) separator, as in this example: `/vol/vol0`.
- Windows NAS file system designations that are specified on the command line require brace delimiters ({ and }) around the file system names, such as: `{/vol/vol0}`. Do not use brace delimiters if you specify this option in the option file.

Use the following syntax:

```
>>-pattern-- mgmtclassname- toc=value--------------------------><
```

Where:

pattern
: Specifies the objects to include for backup services, to assign a specific management class, or to control TOC creation. You can use wildcards in the pattern.

mgmtclassname
: Specifies the name of the management class to assign to the objects. If a management class is not specified, the default management class is used.

toc=value
: For more information, see Toc.

Example 1: To assign a management class to the /vol/vol1 file system of a NAS node that is called `netappsj`, specify the following include statement:

```
include.fs.nas netappsj/vol/vol1 nasMgmtClass toc=yes
```

Example 2: To assign the same management class to all paths that are subordinate to the /vol/ file system on a NAS node called `netappsj` (for example, /vol/vol1, /vol/vol2, and /vol/vol3), specify the following include statement:

```
include.fs.nas netappsj/vol/* nasMgmtClass toc=yes
```

Linux | Windows

Virtual machine include options

Virtual machine include and exclude options influence the behavior of backup and restore operations for virtual machines. These options are processed before any command-line options are processed, so that options on the command line can override options specified on any of the virtual machine include options or virtual machine exclude options. See the individual option descriptions for information about the options.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments.

- Linux | Windows Include.vm
  For virtual machine operations, this option overrides the management class that is specified on the vmmc option.
- Linux | Windows Include.vmdisk
  The INCLUDE.VMDISK option includes a virtual machine (VM) disk in backup operations. If you do not specify one or more disk labels, all disks in the VM are backed up.
- Linux | Windows INCLUDE.VMSNAPSHOTATTEMPTS
  Use the INCLUDE.VMSNAPSHOTATTEMPTS option to determine the total number of snapshot attempts to try for a virtual machine (VM) backup operation that fails due to snapshot failure.
- Linux | Windows INCLUDE.VMTSMVSS
  The INCLUDE.VMTSMVSS option notifies virtual machine applications that a backup is about to occur. This option allows the application to truncate transaction logs and commit transactions so that the application can resume from a consistent state when the backup completes. An optional parameter can be specified to suppress truncation of the transaction logs. To use this option, you must have a license agreement to use IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

Related reference:
Include.vmdisk
INCLUDE.VMTSMVSS
INCLUDE.VMSNAPSHOTATTEMPTS
Linux | Windows

Include.vm

For virtual machine operations, this option overrides the management class that is specified on the vmmc option.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments.

The management class specified on the vmmc option applies to all VMware backups.

The management class specified on the vmmc option applies to all Hyper-V backups.

You can use the include.vm option to override that management class, for one or more virtual machines. The include.vm option does not override or affect the management class that is specified by the vmctlmc option. The vmctlmc option binds backed-up virtual machine control files to a specific management class.

Supported Clients

Linux This option can be used with supported Linux clients that are configured to back up VMware virtual machines.

Windows This option can be used with supported Windows clients that are configured to back up VMware virtual machines.

Windows This option can be used with supported Windows clients that are configured to back up Hyper-V virtual machines.

Options File

Set this option in the client options file.

Syntax

```
>>-INCLUDE.VM-- --vmname-- --+---------------+-----------------><
                            '-mgmtclassname-'
```

Parameters

vmname
: Required parameter. Specifies the name of a virtual machine that you want to bind to the specified management class. The name is the virtual machine display name. Only one virtual machine can be specified on each include.vm statement. However, you can specify as many include.vm statements as needed to bind each virtual machine to a specific management class.

  You can include wildcards in the virtual machine name. An asterisk (*) matches any character string. A question mark (?) matches a single character. If the virtual machine name contains a space character, enclose the name in double quotation marks (").

  Tip: If the virtual machine name contains special characters, type the question mark wildcard in place of the special characters when you specify the virtual machine name.

mgmtclassname
: Optional parameter. Specifies the management class to use when the specified virtual machine is backed up. If this parameter is not specified, the management class defaults to the global virtual machine management class that is specified by the vmmc option.

Examples

Assume that the following management classes exist and are active on the IBM Spectrum Protect server:

- MCFORTESTVMS
- MCFORPRODVMS
- MCUNIQUEVM

Example 1
: The following include.vm statement in the client options file binds all virtual machines that have names that begin with VMTEST to the management class called MCFORTESTVMS:

  ```
  include.vm vmtest* MCFORTESTVMS
  ```

Example 2
: The following include.vm statement in the client options file binds a virtual machine that is named WHOPPER VM1 [PRODUCTION] to the management class called MCFORPRODVMS:

  ```
  include.vm "WHOPPER VM1 ?PRODUCTION?" MCFORPRODVMS
  ```

  The virtual machine name must be enclosed in quotation marks because it contains space characters. Also, the question mark wildcard is used to match the special characters in the virtual machine name.

Example 3
: The following include.vm statement in the client options file binds a virtual machine that is named VM1 to a management class that is named MCUNIQUEVM:

  ```
  include.vm VM1 MCUNIQUEVM
  ```

Linux | Windows

Include.vmdisk

The INCLUDE.VMDISK option includes a virtual machine (VM) disk in backup operations. If you do not specify one or more disk labels, all disks in the VM are backed up.

This option is available only if you are using the IBM Spectrum Protect™ for Virtual Environments licensed product. For more information about this option, see the IBM Spectrum Protect for Virtual Environments product documentation on IBM® Knowledge Center at http://www.ibm.com/support/knowledgecenter/SSERB6/welcome.

The INCLUDE.VMDISK option specifies the label of a VM disk to be included in a backup vm operation. If you include a disk on the backup vm command, the command-line parameters override any INCLUDE.VMDISK statements in the options file.

This option applies to both VMware and Microsoft Hyper-V virtual machine disks.

Linux | Windows

INCLUDE.VMDISK for VMware virtual machines

Use the INCLUDE.VMDISK option to include a VMware virtual machine in backup operations.

Supported clients

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows clients.

Options file

Set this option in the client options file. Command line parameters override statements in the options file.

Syntax for VMware virtual machines

```
>>-INCLUDE.VMDISK--vmname-- -vmdk_label----------------------><
```

Parameters

vmname
Specifies the name of the virtual machine that contains a disk that you want to include in a Backup VM operation. The name is the virtual machine display name. You can specify only one virtual machine name on each INCLUDE.VMDISK statement. Specify additional INCLUDE.VMDISK statements for each virtual machine disk to include.
The virtual machine name can contain an asterisk (*), to match any character string, and question mark (?) to match any one character. Surround the VM name with quotation marks (" ") if the VM name contains space characters.
Tip: If the virtual machine name contains special characters, such as bracket characters ([or]), the virtual machine name might not be correctly matched. If a virtual machine name uses special characters in the name, you might need to use the question mark character (?) to match the special characters in the VM name

For example, to include `Hard Disk 1` in the backup of a virtual machine named `"Windows VM3 [2012R2]"`, use this syntax in the options file: `INCLUDE.VMDISK "Windows VM3 ?2012R2?" "Hard Disk 1"`

vmdk_label
Specifies the disk label of the disk that you want to include. Wildcard characters are not allowed. Use the Backup VM command with the -preview option to determine the disk labels of disks in a given virtual machine. See "Backup VM" for the syntax.

Examples

Options file
Assume that a virtual machine named vm1 contains four disks, labeled Hard Disk 1, Hard Disk 2, Hard Disk 3, and Hard Disk 4. To include only disk 2 in a Backup VM operations, specify the following in the options file:

```
INCLUDE.VMDISK "vm1" "Hard Disk 2"
```

Include disks 2 and 3 in Backup VM operations:

```
INCLUDE.VMDISK "vm1" "Hard Disk 2"
INCLUDE.VMDISK "vm1" "Hard Disk 3"
```

Command line

Include a single disk when backing up vm1:

```
dsmc backup vm "vm1:vmdk=Hard Disk 1"
```

Include disk 2 and disk 3 on vm1:

```
dsmc backup vm "vm1:vmdk=Hard Disk 2:vmdk=Hard Disk 3"
```

Windows

INCLUDE.VMDISK for Microsoft Hyper-V virtual machines

Use the INCLUDE.VMDISK option to include a VM disk from Hyper-V RCT backup operations on Windows Server 2016 or later operating systems.

Supported clients

This option can be used with Windows Server 2016 or later clients.

Options file

Set this option in the client options file. Command-line parameters override statements in the options file.

Syntax for Microsoft Hyper-V virtual machines

```
>>-INCLUDE.VMDISK--vmname-- -disk_location--------------------><
```

Parameters

vmname

Specifies the name of the VM that contains a disk that you want to include from a backup vm operation. The name is the virtual machine display name. You can specify only one VM name on each INCLUDE.VMDISK statement. Specify additional INCLUDE.VMDISK statements for each VM disk to include.
The VM name can contain an asterisk (*) to match any character string, and a question mark (?) to match any one character.
If the VM name contains space characters, surround the VM name with quotation marks (" ").
Tip: If the VM name contains special characters, such as bracket characters ([) or (]), the VM name might not be correctly matched. If a VM name includes special characters, use a question mark (?) to represent the special characters.
For example, to include a SCSI VM disk in the backup of a virtual machine named `"Windows VM3 [2012R2]"`, use this syntax in the options file:

```
INCLUDE.VMDISK "Windows VM3 ?2012R2?" "SCSI 0 1"
```

disk_location

Specify the location of the VM disk to include in a Hyper-V RCT backup operation. The disk location label must begin with "SCSI" or "IDE" followed by the controller number and device location number. Wildcard characters are not allowed.
Tip: Use the backup vm command with the -preview option to determine the location of disks in a given virtual machine. See the "Backup VM" topic for the syntax.

Examples

Options file

Virtual machine `vm1` contains an IDE VM disk (VHDX) at controller number 1 and device location 0. To include this VHDX in backup vm operations, specify the following statement in the options file:

```
INCLUDE.VMDISK vm1 "IDE 1 0"
```

Virtual machine `vm2` contains a SCSI VM disk at controller number 0 and device location 1. Include this VHDX in backup operations by specifying the following statement in the options file:

```
INCLUDE.VMDISK vm2 "SCSI 0 1"
```

Command line

Include a single IDE disk (at controller number 1 and device location 0) when virtual machine `vm1` is backed up:

```
dsmc backup vm "vm1:vhdx=IDE 1 0"
```

Include a SCSI disk (at controller number 0 and device location 1) in the backup operation of virtual machine `vm2`:

```
dsmc backup vm "vm2:vhdx=SCSI 0 1"
```

Linux | Windows

INCLUDE.VMSNAPSHOTATTEMPTS

Use the INCLUDE.VMSNAPSHOTATTEMPTS option to determine the total number of snapshot attempts to try for a virtual machine (VM) backup operation that fails due to snapshot failure.

Supported Clients

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments.

Linux This option can be used with supported Linux clients that are configured to back up VMware virtual machines.

Windows This option can be used with supported Windows clients that are configured to back up VMware virtual machines.

Windows This option can be used with supported Windows clients that are configured to back up VMs on Hyper-V hosts that run on Windows Server 2016 operating systems.

Options File

This option is valid in the client options file (dsm.opt). It can also be included on the server in a client options set. It is not valid on the command line.

Syntax

```
>>-INCLUDE.VMSNAPSHOTATTEMPTS--vmname--num_with_quiescing------->

>--num_without_quiescing---------------------------------------><
```

Parameters

vmname
A required positional parameter that specifies the name of the virtual machine to attempt the total number of snapshots for, if a backup attempt fails due to snapshot failure. The name is the virtual machine display name.
Only one virtual machine can be specified on each INCLUDE.VMSNAPSHOTATTEMPTS statement. However, to configure the total snapshot attempts for other virtual machines, you can use the following methods:

- For each virtual machine that you want this option to apply to, specify as many INCLUDE.VMSNAPSHOTATTEMPTS statements as needed to reattempt snapshots that failed.
- Use wildcard characters for the *vmname* parameter value to specify virtual machine names that match the wildcard pattern. An asterisk (*) matches any character string. A question mark (?) matches a single character. If the virtual machine name contains a space character, enclose the name in double quotation marks (").

Tip: If the virtual machine name contains special characters, type the question mark wildcard (?) in place of the special characters when you specify the virtual machine name.

num_with_quiescing

A positional parameter that specifies the following action:

For VMware backup operations:

- For Windows virtual machines with IBM Spectrum Protect application protection enabled, *num_with_quiescing* specifies the number of times to attempt the snapshot with IBM Spectrum Protect VSS quiescing and Microsoft Windows system provider VSS quiescing. VSS quiescing applies only to Windows virtual machines.

  Depending on the number that you specify, the first snapshot attempt is always made with IBM Spectrum Protect VSS quiescing. Subsequent snapshot attempts are made with Windows system provider VSS quiescing.

- For Windows virtual machines without IBM Spectrum Protect application protection enabled and for Linux virtual machines, *num_with_quiescing* specifies the number of times to attempt the snapshot with VMware Tools file system quiescing.

The maximum value that you can specify is ten (10). The default value is two (2). The minimum value that you can specify is zero (0).

For Hyper-V RCT backup operations:

The *num_with_quiescing* parameter specifies the number of times to attempt snapshots with quiescing to create application-consistent backups.

You can specify a value in the range 0 - 10. The default value is 2.

num_without_quiescing

For VMware backup operations:

A positional parameter that specifies the number of times to attempt the snapshot with VMware Tools file system quiescing and application (VSS) quiescing disabled after the specified number of attempts with VSS quiescing (*num_with_quiescing*) completes. For example, you can specify this parameter for a virtual machine that is already protected by an IBM® Data Protection agent that is installed in a guest virtual machine.

The maximum value that you can specify is ten (10). The minimum value that you can specify is zero (0), which is the default value.

Important: When this parameter is applied to a virtual machine backup, the backup is considered crash-consistent. As a result, operating system, file system, and application consistency are not guaranteed. An `include.vmsnapshotattempts 0 0` entry is not valid. Backup operations require at least one snapshot.

For Hyper-V RCT backup operations:

The *num_without_quiescing* option specifies the number of times to attempt snapshots without quiescing after the specified number of attempts in the *num_with_quiescing* option are completed.

You can specify a value in the range 0 - 10. The default value is 0.

Important: When this parameter is applied to a VM backup, the backup is considered crash-consistent. As a result, operating system, file system, and application consistency are not guaranteed. An `include.vmsnapshotattempts 0 0` entry is not valid. Backup operations require at least one snapshot.

Examples

VMware examples:

Example 1

The following INCLUDE.VMSNAPSHOTATTEMPTS statement in the client options file tries two total snapshot attempts (with VSS quiescing) for virtual machine VM_a:

```
INCLUDE.VMSNAPSHOTATTEMPTS VM_a 2 0
```

Example 2

The following INCLUDE.VMSNAPSHOTATTEMPTS statement in the client options file tries three total snapshot attempts for Windows virtual machines that match the vmServer_Dept* string:

- The first attempt is made with IBM Spectrum Protect VSS quiescing.
- The second attempt is made with Windows system provider VSS quiescing.
- The third snapshot attempt is taken without VSS quiescing.

```
INCLUDE.VMSNAPSHOTATTEMPTS vmServer_Dept* 2 1
```

Example 3

The following INCLUDE.VMSNAPSHOTATTEMPTS statement in the client options file tries one total snapshot attempt (with VSS quiescing) for virtual machines that match the vmDB_Dept* string:

```
INCLUDE.VMSNAPSHOTATTEMPTS vmDB_Dept* 1 0
```

Example 4

The following INCLUDE.VMSNAPSHOTATTEMPTS statement in the client options file tries two total snapshot attempts (with VSS quiescing) for all virtual machines:

- The first attempt is made with IBM Spectrum Protect VSS quiescing.
- The second attempt is made with Windows system provider VSS quiescing.

```
INCLUDE.VMSNAPSHOTATTEMPTS * 2 0
```

Example 5

In this example, the virtual machine DB15 has an IBM Data Protection agent that is installed in a guest virtual machine and does not need an application-consistent snapshot. The following INCLUDE.VMSNAPSHOTATTEMPTS statement in the client options file tries one total snapshot attempt (without VSS quiescing) for virtual machine DB15:

```
INCLUDE.VMSNAPSHOTATTEMPTS DB15 0 1
```

Hyper-V examples:

Example 1

Specify the following statement in the client options file to make two total snapshot attempts at crash-consistent backups for all Hyper-V VMs that begin with `LinuxVM`:

```
INCLUDE.VMSNAPSHOTATTEMPTS LinuxVM* 0 2
```

Example 2

Specify the following statement in the client options file to try three snapshot attempts for virtual machine VM1: two application-consistent snapshot attempts, and if they fail, to try one crash-consistent snapshot attempt:

```
INCLUDE.VMSNAPSHOTATTEMPTS VM1 2 1
```

Windows If you are restoring application protection backups, see Shadow copy considerations for restoring an application protection backup from the data mover.

Related reference:
INCLUDE.VMTSMVSS

Linux | Windows

INCLUDE.VMTSMVSS

The INCLUDE.VMTSMVSS option notifies virtual machine applications that a backup is about to occur. This option allows the application to truncate transaction logs and commit transactions so that the application can resume from a consistent state when the backup completes. An optional parameter can be specified to suppress truncation of the transaction logs. To use this option, you must have a license agreement to use IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

When a virtual machine is included by this option, IBM Spectrum Protect provides application protection. That is, the client freezes and thaws the VSS writers and, optionally, truncates the application logs. If a virtual machine is not protected by this option, application protection is provided by VMware, and VMware freezes and thaws the VSS writers, but application logs are not truncated.

Important: Before you begin application protection backups, ensure that the application database, such as the Microsoft SQL Server database or Microsoft Exchange Server database, is on a non-boot drive (any drive other than the boot drive), in case a diskshadow revert operation is needed during restore.

Supported clients

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows clients.

Options file

Set this option in the client options file. This option cannot be set by the preferences editor or on the command line.

Syntax

```
>>-INCLUDE.VMTSMVSS----vmname---- --OPTions=KEEPSqllog--------><
```

Parameters

vmname

Specifies the name of the virtual machine that contains the applications to quiesce. The name is the virtual machine display name. Specify one virtual machine per INCLUDE.VMTSMVSS statement. For example, to include a virtual machine named Windows VM3 [2012R2], use this syntax in the options file: `INCLUDE.VMTSMVSS "Windows VM3 [2012R2]"`.

To protect all virtual machines with this option, use an asterisk as a wildcard (INCLUDE.VMTSMVSS *). You can also use question marks to match any single character. For example, INCLUDE.VMTSMVSS vm?? protects all virtual machines that have names that begin with vm and are followed by any two characters (vm10, vm11, vm17, and so on).

Tip: If the virtual machine name contains special characters, such as bracket characters ([or]), the virtual machine name might not be correctly matched. If a virtual machine name uses special characters in the name, you can use the question mark character (?) to match the special characters in the virtual machine name.

There is no default value for this parameter. To enable application protection, you must include virtual machines to be protected on one or more INCLUDE.VMTSMVSS statements. Make sure that you do not exclude a disk on a virtual machine (by using the EXCLUDE.VMDISK option) if the disk contains application data that you want protected.

OPTions=KEEPSqllog

If the `OPTions KEEPSqllog` parameter is specified on an INCLUDE.VMTSMVSS statement, the parameter prevents SQL server logs from being truncated when a backup-archive client that is installed on a data mover node backs up a virtual machine that is running a SQL server. Specifying this parameter allows the SQL server administrator to manually manage (backup, and possibly truncate) the SQL server logs, so that they can be preserved and be used to restore SQL transactions to a specific checkpoint, after the virtual machine is restored.
When this option is specified, the SQL log is not truncated and the following message is displayed and logged on the server:

```
ANS4179I IBM Spectrum Protect application protection
did not truncate the Microsoft SQL Server logs on VM 'VM'.
```

You can remove the `OPTIONS=KEEPSQLLOG` option to enable truncation of the SQL logs when a backup completes.
Note: The client does not back up the SQL log files. The SQL administrator must back up the log files so that they can be applied after the database is restored.

Examples

Options file

Configure application protection for a virtual machine that is named vm_example:

```
INCLUDE.VMTSMVSS vm_example
```

Configure application protection for vm11, vm12, and vm15:

```
INCLUDE.VMTSMVSS vm11
INCLUDE.VMTSMVSS vm12
INCLUDE.VMTSMVSS vm15 options=keepsqllog
```

Command line

Not applicable; this option cannot be specified on the command line.

Exclude.vmdisk
Include.vmdisk
INCLUDE.VMSNAPSHOTATTEMPTS

Incrbydate

Use the incrbydate option with the incremental command to back up new and changed files with a modification date later than the last incremental backup stored at the server, unless you exclude the file from backup.

Important: Files that are modified or created after their respective directory was processed by the backup-archive client, but before the incremental-by-date backup completes, are not backed up and will not be backed up in future incremental-by-date backups, unless the files are modified again. For this reason, a run a regular incremental backup periodically, without specifying the incrbydate option.

An incremental-by-date updates the date and time of the last incremental at the server. If you perform an incremental-by-date on only part of a file system, the date of the last full incremental is not updated and the next incremental-by-date backs up these files again.

AIX | Linux | Mac OS X | Solaris Important:

Mac OS X The last incremental backup time refers to the server time and the file modification time refers to the client time. If the client and server time are not synchronized, or the client and server are in different time zones, this affects incremental-by-date backup with `mode=incremental`.

AIX | Linux | Solaris The last incremental backup time refers to the server time and the file modification time refers to the client time. If the client and server time are not synchronized, or the client and server are in different time zones, this affects incremental-by-date backup and image backup with `mode=incremental`.

AIX | Linux | Solaris | Mac OS X | Windows Both full incremental backups and incrementals-by-date backups backup new and changed files. An incremental-by-date takes less time to process than a full incremental and requires less memory. However, unlike a full incremental backup, an incremental-by-date backup does not maintain current server storage of all your workstation files for the following reasons:

- AIX | Linux | Solaris | Mac OS X | Windows It does not expire backup versions of files that are deleted from the workstation.
- It does not rebind backup versions to a new management class if the management class has changed.
- AIX | Linux | Solaris | Mac OS X It does not back up files with attributes that have changed, such as Access control list (ACL) data, unless the modification dates and times have also changed.
- Windows It does not back up files with attributes that have changed, such as NTFS security information, unless the modification dates and times have also changed.
- It ignores the copy group frequency attribute of management classes.

AIX | Linux | Mac OS X | Solaris | Windows Tip: If you have limited time during the week to perform backups, but extra time on weekends, you can maintain current server storage of your workstation files by performing an incremental backup with the incrbydate option on weekdays and a full incremental backup on weekends.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-INCRbydate-------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Command line:

```
dsmc incremental -incrbydate
```

AIX | Linux | Solaris | Windows

Incremental

Use the incremental option with the restore image command to ensure that any changes that were made to the base image are also applied to the restored image.

If you also use the deletefiles option, changes include the deletion of files and directories that were in the original image but later deleted from the workstation.

AIX Linux Solaris Note: Using the incremental option with the restore image command to perform a dynamic image backup is not supported.

AIX Linux Solaris Windows

Supported Clients

AIX Linux Solaris This option is valid only for AIX®, Linux x86_64, Linux on POWER®, and Solaris. The IBM Spectrum Protect™ API does not support this option.

Windows This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option.

Syntax

```
>>-INCREmental-------------------------------------------------><
```

Examples

AIX Linux Solaris Command line:

AIX Linux Solaris
```
res i "/home/devel/projecta/*" -incremental
```

Windows Command line:

Windows
```
res i d: -incremental
```

Windows

Incrthreshold

The incrthreshold option specifies the threshold value for the number of directories in any journaled file space that might have active objects on the server, but no equivalent object on the workstation.

When a Windows client deletes a file or directory with a long name, it sometimes reports this using a compressed name. After the object is deleted, the compressed name might be reused and the deletion notice can no longer identify a unique object. During a journaled incremental backup of a file space, this can result in the *no active version* response from the server resulting in an unsuccessful expire for an object.

The incrthreshold option allows you to specify what to do when this condition arises:

- If you set the incrthreshold option to 0 (the default), no action is taken. The primary consequence is that, during a restore of such a directory, these objects might be inadvertently restored. When the next non-journaled incremental backup is run on this directory, the IBM Spectrum Protect™ server expires all objects in the directory that exist on the server but not on the workstation.
- If you specify a value greater than zero, the client saves the directory name of an object in the journal during journaled backups. During a full file space journaled incremental backup, if the number of directories in the file space is greater than or equal to this value, a full incremental backup of each directory occurs. This takes place automatically after completion of the journaled backup and does not require entry of another command.
- If you set the incrthreshold option to 1, the client performs a full incremental backup of these directories whenever a *no active version* response is received during a full file space journaled incremental backup.

Supported Clients

This option is for all Windows clients.

Options File

Place this option in the client options file (dsm.opt). You can set this option on the Backup > Threshold for non-journal incremental backup field of the Preferences editor.

Syntax

```
>>-INCRTHreshold--numberdirectories---------------------------><
```

Parameters

numberdirectories
Specifies the threshold value for the number of directories in any journaled file space that might contain active files that should be expired. When this threshold is reached during a full file space journaled incremental, the client initiates an incremental backup on each such directory at the completion of the journaled backup. The range of values is 0 through 2,000,000,000; the default is 0.

Examples

Options file:

```
incrthreshold 1
```

Command line:

```
-increthreshold=1
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Instrlogmax

The instrlogmax option specifies the maximum size of the instrumentation log (dsminstr.log), in MB. Performance data for the client is collected in the dsminstr.log file during backup or restore processing when the enableinstrumentation option is set to *yes*.

If you change the value of the instrlogmax option, the existing log is extended or shortened to accommodate the new size. If the value is reduced, the oldest entries are deleted to reduce the file to the new size.

Supported Clients

This option is valid for all clients and the IBM Spectrum Protect™ API.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. The option can be set in the client option set on the IBM Spectrum Protect server.

Windows Place this option in the client options file (dsm.opt). The option can be set in the client option set on the IBM Spectrum Protect server.

Syntax

```
>>-INSTRLOGMAX-- --size----------------------------------------><
```

Parameters

size
Specifies the maximum size, in MB, for the instrumentation log file. The range of values is 0 - 2047. The default value is 25.

When the size of the dsminstr.log file exceeds the maximum size, the log file is renamed to dsminstr.log.bak. Subsequent instrumentation data continues to be saved to the dsminstr.log file.

If you specify 0, the log file grows indefinitely.

Examples

Options file:

```
instrlogmax 100
```

Command line:

AIX Linux Mac OS X Solaris

```
dsmc sel /home/mydir/* -subdir=yes -enableinstrumentation=yes -instrlogmax=100
```

Windows

```
dsmc sel c:\mydir\* -subdir=yes -enableinstrumentation=yes -instrlogmax=100
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Related reference:
Enableinstrumentation
Instrlogname

Instrlogname

The instrlogname option specifies the path and file name where you want to store performance information that the backup-archive client collects.

When you use the enableinstrumentation yes option to collect performance data during backup and restore operations, the client automatically stores the information in a log file.

By default, the performance data is stored in the instrumentation log file (dsminstr.log) in the directory that is specified by the DSM_LOG environment variable (or the DSMI_LOG environment variable for the API-dependent products IBM Spectrum Protect™ for Databases: Data Protection for Microsoft SQL Server and IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server). If you did not set the DSM_LOG environment variable, the instrumentation log file is stored in the current directory (the directory where you issued the dsmc command).

Use this option only when you want to change the file name and location of the instrumentation log.

If you want to control the size of the log file, use the instrlogmax option.

Supported Clients

This option is valid for all clients and the IBM Spectrum Protect API.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. The option can be set in the client option set on the IBM Spectrum Protect server.

Windows Place this option in the client options file (dsm.opt). The option can be set in the client option set on the IBM Spectrum Protect server.

AIX Linux Solaris Mac OS X
Important: Set the `DSM_LOG` environment variable to name a directory where the log is to be placed. The directory that is specified must have permissions that allow write-access from the account under which the client is run. The root directory is not a valid value for `DSM_LOG`.

Windows
Important: Set the `DSM_LOG` environment variable to name a directory where the log is to be placed. The directory that is specified must have permissions that allow write-access from the account under which the client is run.

Syntax

```
>>-INSTRLOGNAME-- --filespec-----------------------------------><
```

Parameters

filespec
: Specifies the path and file name where you want to store performance information during backup or restore processing. If any part of the path that you specify does not exist, the client attempts to create it.

Windows If you specify a file name only, the file is stored in the directory that is specified by the DSM_LOG environment variable. If you did not set the DSM_LOG environment variable, the instrumentation log file is stored in the current directory (the directory where you issued the dsmc command).

AIX Linux Solaris If you specify a file name only, the file is stored in the directory that is specified by the DSM_LOG environment variable. If you did not set the DSM_LOG environment variable, the instrumentation log file is stored in the current directory (the directory where you issued the dsmc command). The instrumentation log file cannot be a symbolic link.

Mac OS X For Mac OS X, if you specify a file name only, the file is stored in your default folder. The default directories are:

```
~/Library/Logs/tivoli/tsm
/Library/Logs/tivoli/tsm
```

This instrumentation log file name replaces the previous instrumentation log file name dsminstr.report.pXXX that was created by the TESTFLAG=instrument:detail or instrument:API option.

Examples

Options file:

AIX Linux Solaris For AIX®, Linux, and Oracle Solaris clients:

```
instrlogname /home/user1/mydir/mydsminstr.log
```

Mac OS X For Mac OS X clients:

```
instrlogname /Users/user1/Library/Logs/mydsminstr.log
```

Windows For Windows clients:

```
instrlogname c:\mydir\mydsminstr.log
```

Command line:

AIX Linux Solaris For AIX, Linux, and Oracle Solaris clients:

```
dsmc sel /home/user1/mydir/* -subdir=yes -instrlogname=/usr/log/mydsminstr.log
```

Mac OS X For Mac OS X clients:

```
dsmc sel /Users/user1/mydir/* -subdir=yes -
instrlogname=/Users/user1/Library/Logs/mydsminstr.log
```

Windows For Windows clients:

```
dsmc sel c:\mydir\* -subdir=yes -instrlogname=c:\temp\mydsminstr.log
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Related reference:
Enableinstrumentation
Instrlogmax
Windows

Journalpipe

The journalpipe option specifies the pipe name of a journal daemon session manager to which the backup clients attach.

Supported Clients

This option is for all Windows clients.

Options File

Place this option in the client options file (dsm.opt).

```
JournalPipe \\.\pipe\jnlSessionMgr1
```

Syntax

```
>>-JOURNALPipe--pipename----------------------------------------><
```

Parameters

pipename
: Specify the name of the pipe the client attaches to when performing a journal-based backup. The default pipe name is \\.\pipe\jnlSessionMgr.

Examples

Options file:

```
JOURNALPipe \\.\pipe\jnlSessionMgr
```

Command line:

This option cannot be set on the command line.

AIX Linux Solaris Windows

Lanfreecommmethod

The lanfreecommmethod option specifies the communications protocol between the IBM Spectrum Protect™ client and Storage Agent. This enables processing between the client and the SAN-attached storage device.

AIX Linux Solaris If you are using LAN failover, you must have lanfreecommmethod in the dsm.sys file within a server stanza.

Windows If you are using LAN failover, you must have lanfreecommmethod TCPip in the client options file (dsm.opt).

AIX Linux Solaris For AIX®, Linux and Solaris, use the lanfreeshmport option to specify the shared memory port number where the Storage Agent is listening.

Windows For Windows, use the lanfreeshmport option to uniquely identify the storage agent to which the client is trying to connect.

Supported Clients

AIX Linux Solaris This option is valid for AIX, Linux, and Oracle Solaris clients.

Windows This option is valid for all Windows clients.

Options File

AIX Linux Solaris Place this option in the dsm.sys file within a server stanza.

Windows Place this option in the client options file (dsm.opt).

Syntax

```
>>-LANFREECommmethod-- --commmethod----------------------------><
```

Parameters

commmethod
: Specifies the supported protocol for the backup-archive client:

  AIX Linux Solaris TCPip
  : AIX Linux Solaris The Transmission Control Protocol/Internet Protocol (TCP/IP) communication method.

Use the lanfreetcpport option to specify the TCP/IP port number where the Storage Agent is listening. The TCP/IP communication method is the default for non-root users on all supported platforms.

Windows TCPip

Windows The Transmission Control Protocol/Internet Protocol (TCP/IP) communication method.

Use the lanfreetcpport option to specify the TCP/IP port number where the Storage Agent is listening.

V6Tcpip

Indicates that either TCP/IP v4 or v6 should be used, depending on the system configuration and results of a domain name service lookup. The only time this is not true is when dsmc schedule is used and schedmode is prompt. A valid DNS environment must be available.

Windows NAMedpipes

Windows The interprocess communication method that permits message data streams to pass between a client and a server. This is the default. Do not specify the lanfreetcpport option if you want to use the NAMedpipes communication method for LAN-free communication.

Windows SHAREdmem

Windows Use the shared memory communication method when the client and Storage Agent are running on the same system. Shared memory provides better performance than the TCP/IP protocol. The backup-archive client must have local administrator permissions.

AIX Linux Solaris SHAREdmem

AIX Linux Solaris Use the shared memory communication method when the client and Storage Agent are running on the same system. Shared memory provides better performance than the TCP/IP protocol. This is the default communication method for AIX, Linux, and Solaris root users. When specifying this communication method on `AIX`, the backup-archive client user can be logged in as root or non-root, as long as the Storage Agent is running as root. If the Storage Agent is not running as root, the user ID running the backup-archive client must match the user ID running the Storage Agent.

Examples

Options file:

lanfreecommmethod tcp

Use only TCP/IP v4

lanfreecommmethod V6Tcpip

Use both TCP/IP v4 or v6, depending on how the system is configured and the results of a domain name service lookup.

Command line:

```
-lanfreec=tcp
```

```
-lanfreec=V6Tcpip
```

This option is valid only on the initial command line. It is not valid in interactive mode.

AIX Linux Solaris Windows

Lanfreeshmport

Use the lanfreeshmport option when `lanfreecommmethod=SHAREdmem` is specified for communication between the backup-archive client and the storage agent. This enables processing between the client and the SAN-attached storage device.

Supported Clients

AIX Linux Solaris This option is valid for AIX®, Linux, and Oracle Solaris clients.

Windows This option is valid for all Windows clients.

Options File

AIX Linux Solaris Place this option in the client system-options file (dsm.sys) within a server stanza.

Windows Place this option in the client options file (dsm.opt).

Syntax

```
>>-LANFREEShmport-- --port_address-----------------------------><
```

Parameters

port_address
: Specifies the number that is used to connect to the storage agent. The range of values is 1 through 32767.

  For Windows clients, the default is 1.

  For all clients except Windows clients, the default is 1510.

Examples

Options file:

```
lanfrees 1520
```

Command line:

```
-lanfrees=1520
```

This option is valid only on the initial command line. It is not valid in interactive mode.

AIX | Linux | Solaris | Windows

Lanfreetcpport

The lanfreetcpport option specifies the TCP/IP port number where the IBM Spectrum Protect™ Storage Agent is listening.

Use this option when you specify lanfreecommmethod=TCPip for communication between the backup-archive client and Storage Agent. Do not specify the lanfreetcpport option if you want to use the NAMedpipes communication method for LAN-free communication.

Supported Clients

AIX | Linux | Solaris This option is valid only for AIX®, Linux x86_64, Linux on POWER®, and Oracle Solaris clients.

Windows This option is valid for all Windows clients.

Options File

AIX | Linux | Solaris Place this option in the dsm.sys file within a server stanza.

Windows Place this option in the client options file (dsm.opt).

Syntax

```
>>-LANFREETCPPort-- --port_address-----------------------------><
```

Parameters

port_address
: Specifies the TCP/IP port number where the Storage Agent is listening. The range of values is 1 through 32767; the default is 1500.

  Note: The client lanfreetcpport value must match Storage Agent tcpport value for communications with the Storage Agent (virtual server). The client tcpport value must match the server tcpport value for communications with the actual server.

Examples

Options file:

```
lanfreetcpp 1520
```

Command line:

```
-lanfreetcpp=1520
```

This option is valid only on the initial command line. It is not valid in interactive mode.

AIX | Linux | Solaris | Windows

Lanfreessl

Use the lanfreessl option to enable Secure Sockets Layer (SSL), to provide secure client and Storage Agent communications. This option is deprecated if you are connecting to an IBM Spectrum Protect™ server V8.1.2 and later.

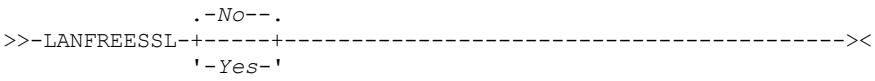
Supported Clients

This option is supported on all clients, except for Mac OS X clients.

Options File

Place this option in the client options file. You cannot set this option in the GUI or on the command line.

Syntax



Parameters

No
: Specifies that the backup-archive client does not use SSL when communicating with the Storage Agent. No is the default.

Yes
: Specifies that the backup-archive client enables SSL when communicating with the Storage Agent. To enable SSL, specify lanfreessl=yes and change the value of the lanfreetcpport option. Changing the value of the lanfreetcpport option is necessary because the IBM Spectrum Protect Storage Agent is typically set up to listen for SSL connections on a separate port.

Examples

Options file:

```
lanfreessl yes
lanfreessl no
```

Command line:
: Not applicable. You cannot set this option on the command line.

AIX | Linux | Solaris | Windows

Lanfreetcpserveraddress

The lanfreetcpserveraddress option specifies the TCP/IP address for the IBM Spectrum Protect™ Storage Agent.

Use this option when you specify lanfreecommmethod=TCPip or V6Tcpip for communication between the backup-archive client and Storage Agent.

Overriding the default for this option is useful when configuring LAN-free in an environment where the client and storage agent are running on different systems. You can obtain this Storage Agent address from your administrator.

Supported Clients

AIX | Linux | Solaris This option is valid only for AIX®, Linux x86_64, Linux on POWER®, and Oracle Solaris clients.

Windows This option is valid for all supported Windows clients.

Options File

Place this option in the client system-options file.

Syntax

```
>>-LANFREETCPServeraddress-- --stagent_address-----------------><
```

Parameters

stagent_address
: Specifies a 1 to 64 character TCP/IP address for a server. Specify a TCP/IP domain name or a numeric IP address. The numeric IP address can be either a TCP/IP v4 or TCP/IP v6 address. The default value is 127.0.0.1 (localhost).

Examples

Options file:

```
LANFREETCPServeraddress stagent.example.com

LANFREETCPServeraddress 192.0.2.1
```

Command line:
: Does not apply.

Windows

Language

The language option specifies the national language in which to present client messages.

You can use US English (ENU) with all clients.

The language that is displayed by the backup-archive client Java™ GUI is defined by the Windows display locale and not the Windows system locale. For example, if the Windows system and input locale is French, but the display locale is Russian, the language that is displayed by the Java GUI is Russian by default, if the language option is not used. If you want to display the Java GUI in US English or another language, you can override the default display language by specifying the language option.

Tip: The language option does not affect the web client. The web client displays in the language associated with the locale of the browser. If the browser is running in a locale that client does not support, the web client is displayed in US English.

Supported Clients

This option is valid for all Windows clients.

Options File

Place this option in the client options file (dsm.opt). You can set this option on the Regional Settings tab, Language drop-down list of the Preferences editor.

Syntax

```
>>-LANGuage-- --language----------------------------------------><
```

Parameters

language
Specifies the language that you want to use. The available languages include:

- ENU (English, United States).
- PTB (Brazilian Portuguese)
- CHS (Chinese, Simplified)
- CHT (Chinese, Traditional)
- FRA (Standard French)
- DEU (Standard German)
- ITA (Standard Italian)
- JPN (Japanese)
- KOR (Korean)
- ESP (Standard Spanish)
- CSY (Czech)
- HUN (Hungarian)
- PLK (Polish)
- RUS (Russian)

Examples

Options file:

```
language enu
```

Command line:

Does not apply.

Latest

Use the latest option to restore the most recent backup version of a file, even if the backup is inactive.

You can use the latest option with the following commands:

- restore
- restore group

If you are performing a point-in-time restore (using the pitdate option), it is not necessary to specify latest since this option is implicit when pitdate is used.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-LATest-----------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Mac OS X Command line:

Mac OS X
```
dsmc restore "/Users/devel/projecta/*" -latest
```

AIX Linux Solaris Mac OS X Command line:

AIX Linux Solaris Mac OS X
```
dsmc restore "/home/devel/projecta/*" -latest
```

Windows Command line:

Windows
```
dsmc restore c:\devel\projecta\ -latest
```

AIX Linux Solaris Mac OS X Windows

Localbackupset

The localbackupset option specifies whether the backup-archive client GUI bypasses initial logon with the IBM Spectrum Protect™ server to restore a local backup set on a standalone workstation.

If you set the localbackupset option to yes, the GUI does not attempt initial logon with the server. In this case, the GUI only enables the restore functionality.

If you set the localbackupset option to no (the default), the GUI attempts initial logon with the server and enables all GUI functions.

Note: The restore backupset command supports restore of local backup sets on a standalone workstation without using the localbackupset option.

Supported Clients

This option is valid for all clients.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza.

Windows Place this option in the dsm.opt file.

Syntax

```
                    .-No--.
>>-LOCALbackupset--+-----+-------------------------------------><
                    '-Yes-'
```

Parameters

No
: Specifies that the GUI attempts initial logon with the server and enables all functions. This is the default.

Yes
: Specifies that the GUI does not attempt initial logon with the server and enables only the restore functionality.

Examples

Options file:

```
localbackupset yes
```

This option is not valid with the dsmc command-line client.

AIX | Linux | Solaris

Makesparsefile

Use the makesparsefile option with the restore or retrieve commands to specify how sparse files are recreated.

Sparse files do not have disk space allocated for every block in the whole address space, leading to holes within the file. The backup-archive client detects sparse files during a backup operation and marks them as sparse on the IBM Spectrum Protect™ server. Holes are detected by their content, which is always zeros.

If you set the makesparsefile option to yes (default), holes within the file are not written to disk so no additional disk space is allocated during a restore.

If you set the makesparsefile option to no, holes are not recreated, leading to disk blocks allocated for the whole address space. This might result in a larger amount of used disk space. Ensure that you have enough disk space to restore all data.

On some UNIX and Linux systems, it might be necessary to back up system specific files as non-sparse files. Use the makesparsefile option for files where the existence of physical disk blocks is required, such as ufsboot on Solaris, which is executed during boot time. The boot file loader of the operating system accesses physical disk blocks directly and does not support sparse files.

Supported Clients

This option is valid for all UNIX and Linux clients except Mac OS X.

Options File

Place this option in the client user options file (dsm.opt).

Syntax

```
                    .-Yes-.
>>-MAKESParsefile--+-----+-------------------------------------><
                    '-No--'
```

Parameters

Yes
: Specifies that holes within the file are not written so that no additional disk space is allocated during a restore. This is the default.

No
: Specifies that holes are not recreated leading to disk blocks allocated for the whole address space.

Examples

Options file:
```
makesparsefile no
```
Command line:
```
-makesparsefile=no
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Managedservices

The managedservices option specifies whether the IBM Spectrum Protect™ client acceptor service manages the scheduler, the web client, or both.

Restriction: You cannot use the dsmcad for scheduling when you set the sessioninitiation option to serveronly.
The client acceptor daemon serves as an external timer for the scheduler. When the scheduler is started, it queries the server for the next scheduled event. The event is either executed immediately or the scheduler exits. The client acceptor daemon restarts the scheduler when it is time to execute the scheduled event.
Note:

1. If you set the schedmode option to prompt, the server prompts the client acceptor daemon when it is time to run the schedule. The scheduler connects to and disconnects from the server when the client acceptor daemon is first started.

   The dsmc schedule command cannot be used when both schedmode prompt and commmethod V6Tcpip are specified.

2. Mac OS X For Mac OS X, if you do not specify the managedservices option, the client acceptor daemon manages both the scheduler program and the web client, by default.
3. Windows Set the passwordaccess option to generate in your client options file (dsm.opt) and generate a password, so IBM Spectrum Protect can manage your password automatically.
4. AIX Linux Solaris Mac OS X Set the passwordaccess option to generate in your dsm.sys file and generate a password, so IBM Spectrum Protect can manage your password automatically.

Using the client acceptor daemon to manage the scheduler service can provide the following benefits:

- Memory retention problems that can occur when using traditional methods of running the scheduler are resolved. Using the client acceptor daemon to manage the scheduler requires very little memory between scheduled operations.
- The client acceptor daemon can manage both the scheduler program and the web client, reducing the number of background processes on your workstation.
- AIX | Linux | Solaris | Mac OS X To use the web client, you must specify this option in the client system-options file.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect API does not support this option.

Options File

Windows Place this option in the client options file (dsm.opt). You can set this option on the Web Client tab of the Preferences editor.

AIX | Linux | Solaris | Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Web Client tab of the Preferences editor.

AIX | Linux | Solaris | Mac OS X | Windows

Syntax

```
>>-MANAGEDServices--mode---------------------------------------><
```

Parameters

mode
Specifies whether the client acceptor daemon manages the scheduler, the web client, or both.

Windows webclient
Windows Specifies that the client acceptor daemon manages the web client.
AIX | Linux | Solaris | Mac OS X webclient
AIX | Linux | Solaris | Mac OS X Specifies that the client acceptor daemon manages the web client. This is the default for UNIX and Linux. Both webclient and schedule are the defaults for Mac OS X.
Mac OS X | Windows schedule
Mac OS X | Windows Specifies that the client acceptor daemon manages the scheduler. Both webclient and schedule are the defaults for Mac OS X.
Mac OS X none
Mac OS X For Mac OS X, specifies that the client acceptor daemon not manage the web client or schedules. Set managedservices to none to enable the dsmc schedule command.

Examples

Windows Options file:
Windows The following are examples of how you might specify the managedservices option in your client options file (dsm.opt).

Task
Specify that the client acceptor daemon manages only the web client.

```
managedservices webclient
```

Task
Specify that the client acceptor daemon manages only the scheduler.

```
managedservices schedule
```

Task
Specify that the client acceptor daemon manages both the web client and the scheduler.

```
managedservices schedule webclient
```

Note: The order in which these values are specified is not important.

Mac OS X | AIX | Linux | Solaris | Mac OS X Options file:

Mac OS X | AIX | Linux | Solaris | Mac OS X The following are examples of how you might specify the managedservices option in your client system-options file (dsm.sys).

Task

Specify that the client acceptor daemon manages only the web client.

```
managedservices webclient
```

Task

Specify that the client acceptor daemon manages only the scheduler.

```
managedservices schedule
```

Task

Specify that the client acceptor daemon manages both the web client and the scheduler.

```
managedservices schedule webclient
```

Note: The order in which these values are specified is not important.

Mac OS X Task

Mac OS X For Mac OS X, to use the dsmc schedule command, specify:

```
managedservices none
```

Command line:

Does not apply.

Maxcmdretries

The maxcmdretries option specifies the maximum number of times the client scheduler (on your workstation) attempts to process a scheduled command that fails.

The command retry starts only if the client scheduler has not yet backed up a file, never connected to the server, or failed before backing up a file. This option is only used when the scheduler is running.

Your IBM Spectrum Protect™ administrator can also set this option. If your administrator specifies a value for this option, that value overrides what you specify in the client options file after your client node successfully contacts the server.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect API does not support this option. The server can also define this option.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Scheduler tab, in the Maximum command retries field of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Scheduler tab, in the Maximum command retries field of the Preferences editor.

Syntax

```
>>-MAXCMDRetries-- --maxcmdretries-----------------------------><
```

Parameters

maxcmdretries

Specifies the number of times the client scheduler can attempt to process a scheduled command that fails. The range of values is zero through 9999; the default is 2.

Examples

Options file:

```
maxcmdr 4
```

Command line:

```
-maxcmdretries=4
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Linux | Windows

Mbobjrefreshthresh

The mbobjrefreshthresh (megablock object refresh threshold) option is a number defining a threshold. When the number of IBM Spectrum Protect™ objects that are needed to describe any 128 MB megablock exceeds this value, the entire megablock is refreshed and the objects that were used to represent this area, in previous backups, are expired.

When you backup a virtual machine, the data is stored on the IBM Spectrum Protect server in 128 MB units, called *megablocks*. If an area on the production disk changes and a new incremental backup is performed, a new megablock is created to represent the changes that were made to the previously backed up data. Because a new megablock can be created with each incremental backup, eventually the megablocks can adversely affect the performance of the IBM Spectrum Protect database, and therefore, adversely affect the performance of most IBM Spectrum Protect operations.

Use this option when estimating IBM Spectrum Protect objects that represent production data for each virtual machine backup. For example, when the number of IBM Spectrum Protect objects exceed this value, the megablock is refreshed. This action means that the entire 128-MB block is copied to the server and is represented as a single IBM Spectrum Protect object. The minimum value is 2 and the maximum value is 8192. The default value is 50.

Supported clients

Linux | Windows This option is valid for data movers that protect VMware virtual machines. To use this option, you must have a license agreement to use IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

Windows This option is valid for data movers that protect Microsoft Hyper-V virtual machines. You must be licensed to use IBM Spectrum Protect for Virtual Environments: Data Protection for VMware, or IBM Spectrum Protect for Virtual Environments: Data Protection for Microsoft Hyper-V to use this option.

Options file

This option is valid in the client options file (dsm.opt). It can also be included on the server in a client options set. It is not valid on the command line.

Syntax

```
                      .-50------.
>>-MBOBJREFRESHTHRESH -+---------+-----------------------------><
                      '-integer-'
```

Parameters

The minimum value you can specify is 2 megablocks, the largest value is 8192 megablocks; the default is 50 megablocks.

Examples

Set this option to trigger a megablock refresh when the number of objects needed to represent an updated megablock exceeds 20 objects:

```
MBOBJREFRESHTHRESH 20
```

Linux | Windows

Mbpctrefreshthresh

The mbpctrefreshthresh (megablock percentage refresh threshold) option is a number defining a threshold. When the percentage of IBM Spectrum Protect™ objects that are needed to describe any 128 MB megablock exceeds this value, the entire megablock is refreshed and the objects that were used to represent this area, in previous backups, are expired.

When you backup a virtual machine, data is stored on the IBM Spectrum Protect server in 128 MB units, called *megablocks*. If an area on the production disk changes and a new incremental backup is performed, a new megablock is created to represent the changes that were made to the previously backed up data. Because a new megablock can be created with each incremental backup, eventually the megablocks can adversely affect the performance of the IBM Spectrum Protect database, and therefore, adversely affect the performance of most IBM Spectrum Protect operations.

Use this option when estimating the amount of additional data that is backed up for each virtual machine. For example, when a 128-MB block of a production disk changes more than the percentage specified, the entire 128-MB block is copied to the server. The block is represented as a single IBM Spectrum Protect object.

Supported clients

Linux | Windows This option is valid for clients that act as data mover nodes that protect VMware virtual machines. To use this option, you must have a license agreement to use IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

Windows This option is valid for clients that act as data mover nodes that protect Microsoft Hyper-V virtual machines. You must be licensed to use IBM Spectrum Protect for Virtual Environments: Data Protection for VMware, or IBM Spectrum Protect for Virtual Environments: Data Protection for Microsoft Hyper-V to use this option.

Options file

This option is valid in the client options file (dsm.opt). It can also be included on the server in a client options set. It is not valid on the command line.

Syntax

```
                        .-50------.
>>-MBPCTREFRESHTHRESH -+---------+----------------------------><
                        '-integer-'
```

Parameters

The minimum value you can specify is 1 percent, the largest value is 99 percent; the default is 50 percent.

Examples

Set this option to trigger a megablock refresh when 50 percent (or more) of the objects in a megablock on a production disk have changed:

```
MBPCTREFRESHTHRESHOLD 50
```

Memoryefficientbackup

The memoryefficientbackup option specifies the memory-conserving algorithm to use for processing full file space backups.

One method backs up one directory at a time, using less memory. The other method uses much less memory, but requires more disk space.

Use the memoryefficientbackup option with the incremental command when your workstation is memory constrained. You can also use this option as a parameter to the include.fs option in order to select the algorithm that the backup-archive client uses on a per-filespace basis.

Windows Use memoryefficientbackup=diskcachemethod for any file space that has too many files for the client to complete the incremental backup with either the default setting, memoryefficientbackup=no, or with memoryefficientbackup=yes. The disk

cache file created by the initial disk cache incremental backup can require up to 5 GB of disk space for each million files or directories being backed up.

AIX Linux Solaris Mac OS X Use memoryefficientbackup=diskcachemethod for any file space that has too many files for the client to complete the incremental backup with either the default setting, memoryefficientbackup=no, or with memoryefficientbackup=yes.

Mac OS X AIX Linux Solaris Mac OS X The actual amount of disk space required for the disk cache file created by disk cache incremental backups depends on the number of files and directories included in the backup and on the average path length of the files and directories to be backed up. For UNIX and Linux estimate 1 byte per character in the path name. For Mac OS X, estimate 4 bytes per character in the path name. For example, if there are 1 000 000 files and directories to be backed up and the average path length is 200 characters, then the database occupies approximately 200 MB for UNIX and Linux, and 800 MB for Mac OS X clients. Another way to estimate for planning purposes is to multiply the number of files and directories by the length of the longest path to establish a maximum database size.

Windows The actual amount of disk space required for the disk cache file created by disk cache incremental backups depends on the number of files and directories included in the backup and on the average path length of the files and directories to be backed up. Estimate 2 bytes per character in the path name. For example, if there are 1 000 000 files and directories to be backed up and the average path length is 200 characters, then the database occupies approximately 400 MB. Another way to estimate for planning purposes is to multiply the number of files and directories by the length of the longest path to establish a maximum database size.

AIX Linux Solaris Mac OS X A second disk cache file is created for the list of migrated files when backing up an HSM managed file system. The combined disk cache files, created by disk cache incremental backups and HSM managed file system backups, can require above 400 MB of disk space for each million files being backed up. The disk cache file can become very large. Large file support must be enabled on the file system that is being used for the disk cache file.

Supported Clients

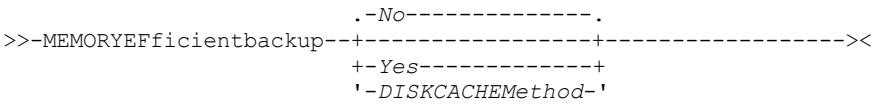
This option is valid for all clients. The server can also define this option.

Options File

AIX Linux Solaris Mac OS X This option is allowed in dsm.opt and within a server stanza in dsm.sys, but the value in dsm.opt is ignored if it also appears in dsm.sys. You can also place this option on the initial command line. In interactive mode, this option can be used with the incremental command. You can also set this option on the Performance Tuning tab in the Preferences editor, and selecting the Use memory-saving algorithm check box.

Windows Place this option in the client user-options file (dsm.opt), or on the initial command line. You can also set this option on the Performance Tuning tab in the Preferences editor, and selecting the Use memory-saving algorithm check box.

Syntax



Parameters

No
: Your client node uses the faster, more memory-intensive method when processing incremental backups. This is the default.

Yes
: Your client node uses the method that requires less memory when processing incremental backups.

Diskcachemethod
: Your client node uses the method that requires much less memory but more disk space when processing incremental backups for full file systems.

Examples

Options file:

```
memoryefficientbackup yes
memoryefficientbackup diskcachem
```

Command line:

```
-memoryef=no
```

AIX | Linux | Solaris | Windows

Mode

Use the mode option to specify the backup mode to use when performing specific backup operations.

The mode option has no effect on a when backing up a raw logical device.

You can use the mode option with the following backup commands:

backup image
: To specify whether to perform a selective or incremental image backup of client file systems.

AIX | Solaris | Windows backup nas
: To specify whether to perform a full or differential image backup of NAS file systems.

backup group
: To specify whether to perform a full or differential group backup containing a list of files from one or more file space origins.

backup vm
: Linux | Windows For VMware virtual machines, this parameter specifies whether to perform an incremental-forever-full or incremental-forever-incremental backup of VMware virtual machines.

: Windows For Microsoft Hyper-V virtual machines, this parameter specifies whether to perform an incremental-forever full or incremental-forever-incremental backup of Hyper-V virtual machines.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments.

Supported Clients

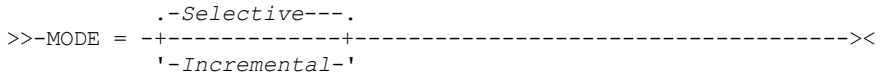
This option is valid on all supported clients, except Mac OS. The IBM Spectrum Protect API does not support this option.

Linux | Windows This option is valid for data movers that protect VMware virtual machines. To use this option, you must have a license agreement to use IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

Windows This option is valid for data movers that protect Microsoft Hyper-V virtual machines. You must be licensed to use IBM Spectrum Protect for Virtual Environments: Data Protection for VMware, or IBM Spectrum Protect for Virtual Environments: Data Protection for Microsoft Hyper-V to use this option.

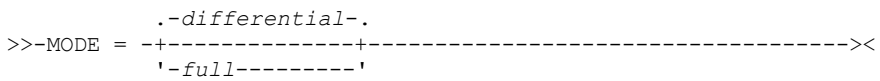
Syntax

For image backups of client file systems

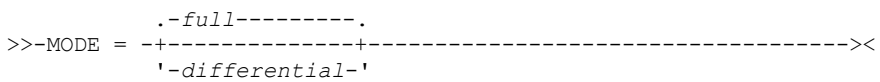


AIX | Solaris | Windows

For image backup of NAS file systems

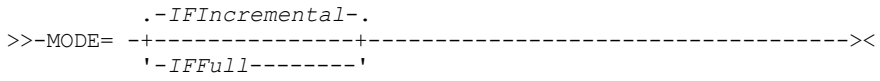


For group backups



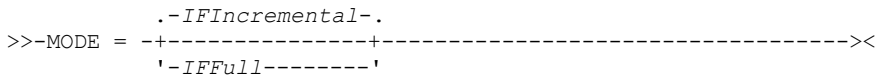
Linux | Windows

For backing up VMware virtual machines



Windows

For backing up Microsoft Hyper-V virtual machines



Parameters

Image backup parameters

selective
: Specifies that you want to perform a full (selective) image backup. This is the default mode for image backups of client file systems.

incremental
: Specifies that you want to back up only the data that has changed since the most recent image backup. If an image backup has not already been created, then the first backup is a full image backup (mode=selective), regardless of what mode option you specify.

AIX | Solaris | Windows

NAS backup parameters

differential
: This is the default for NAS objects. Specifies that you want to perform a NAS backup of files that changed since the last full backup. If there is no copy of a full image stored on the IBM Spectrum Protect server, a full backup occurs. If a full image exists, whether it is restorable, or expired and being maintained because of dependent differential images, specifying MODE=differential sends a differential image backup. If a full image is sent during a differential backup, it is reflected as a full image using the QUERY NASBACKUP server command.

  A full image can be eligible for expiration based on versioning or retention (verexists retextra), but still be maintained on the server to allow for restoring dependent differential images. A full image that is eligible for expiration cannot be selected for restore, so it is not displayed using the QUERY NASBACKUP server command. The differential image backups that depend on an "expired" full image can be restored.

full
: Specifies that you want to perform a full backup of NAS file systems.

Group backup parameters

full
: Specifies that you want to perform a full backup of group objects. This is the default for group backups.

differential
: Specifies that you want to perform a group backup of files that changed since the last full backup. If there is no copy of a full image stored on the IBM Spectrum Protect server, a full backup occurs. If a full image exists, whether it is restorable, or expired and being maintained because of dependent differential images, specifying MODE=differential sends a differential image backup. If a full image is sent during a differential backup, it is reflected as a full image using the QUERY GROUP server command.

  A full image can be eligible for expiration based on versioning or retention (verexists retextra), but still be maintained on the server to allow for restoring dependent differential images. A full image that is eligible for expiration cannot be selected for restore, so it is not displayed using the QUERY GROUP server command. The differential image backups that depend on an "expired" full image can be restored.

Linux | Windows

VMware virtual machine parameters

IFFull
Specifies that you want to perform an incremental-forever-full backup of a virtual machine. An incremental-forever-full backup backs up all used blocks on a VMware virtual machine's disks.

By default, the first backup of a VMware virtual machine is an incremental-forever-full (`mode=iffull`) backup, even if you specify `mode=ifincremental` (or let the mode option default). Subsequent backups default to `mode=ifincremental`.

You cannot use this backup mode to back up a virtual machine if the client is configured to encrypt the backup data.

For a description of the incremental-forever backup strategy for VMware virtual machines, see Backup and restore types.

IFIncremental
Specifies that you want to perform an incremental-forever-incremental backup of a virtual machine. An incremental-forever-incremental backup backs up only the disk blocks that have changed since the last backup.

This mode is the default backup mode for VMware virtual machine backups.

You cannot use this backup mode to back up a virtual machine if the client is configured to encrypt the backup data.

Windows

Microsoft Hyper-V virtual machine parameters

IFIncremental
Specifies that you want to perform an incremental-forever-incremental backup of a Hyper-V virtual machine. An incremental-forever-incremental backup backs up only the disk blocks that have changed since the last backup.

This mode is the default backup mode for Hyper-V backups.

You cannot use this backup mode to back up a virtual machine if the client is configured to encrypt the backup data.

For a description of the incremental-forever backup strategy for Hyper-V virtual machines, see Incremental-forever backup strategy.

IFFull
Specifies that you want to perform an incremental-forever-full backup of a Hyper-V virtual machine. An incremental-forever-full backup backs up all used blocks on a virtual machine's disks.

By default, the first backup of a Hyper-V virtual machine is an incremental-forever-full (`mode=iffull`) backup, even if you specify `mode=ifincremental` (or let the mode option default). Subsequent backups default to `mode=ifincremental`.

You cannot use this backup mode to back up a virtual machine if the client is configured to encrypt the backup data.

Examples

Task

Linux | Windows Perform a backup of a VMware virtual machine named vm1, using the incremental-forever-incremental mode to back up only the data that has changed since the last backup.

```
dsmc backup vm vm1 -mode=ifincremental
 -vmbackuptype=full
```

Windows Task

Windows Perform an incremental-forever-full VM backup of a Hyper-V VM named msvm1

```
dsmc backup vm msvm1 -mode=iffull
```

Windows Task

Windows Perform an incremental-forever-incremental backup of a Hyper-V VM named msvm1

```
dsmc backup vm msvm1 -mode=ifincremental
```

AIX Solaris Task

AIX Solaris Perform the NAS image backup of the entire file system.

```
dsmc backup nas -mode=full -nasnodename=nas1
 /vol/vol0 /vol/vol1
```

Windows Task

Windows Perform the NAS image backup of the entire file system.

```
dsmc backup nas -mode=differential -nasnodename=nas1
 {/vol/vol0} {/vol/vol1}
```

AIX Linux Task

AIX Linux Back up the `/home/test` file space using an image incremental backup that backs up only new and changed files after the last full image backup.

```
dsmc backup image /home/test -mode=incremental -snapshotproviderimage=none
```

Windows Task

Windows Back up the `c:` drive using an image incremental backup that backs up only new and changed files after the last full image backup.

```
dsmc backup image c: -mode=full
```

AIX Linux Solaris Task

AIX Linux Solaris Perform a full backup of all the files in filelist `/home/dir1/filelist1` to the virtual file space name `/virtfs` containing the group leader `/home/group1` file.

```
dscm backup group -filelist=/home/dir1/filelist1
 -groupname=group1 -virtualfsname=/virtfs -mode=full
```

Windows Task

Windows Perform a full backup of all the files in filelist `c:\dir1\filelist1` to the virtual file space name `\virtfs` containing the group leader `c:\group1` file.

```
dsmc backup group -filelist=c:\dir1\filelist1 -groupname=group1
 -virtualfsname=\virtfs -mode=incremental -vmbackuptype=fullvm
```

AIX Linux Solaris Windows

Monitor

The monitor option specifies whether to monitor an image backup or restore of file systems belonging to a Network Attached Storage (NAS) file server.

If you specify monitor=*yes*, the backup-archive client monitors the current NAS image backup or restore operation and displays processing information on your screen. This is the default.

If you specify monitor=*no*, the client does not monitor the current NAS image backup or restore operation and is available to process the next command.

Use this option with the backup nas or restore nas commands.

Supported Clients

AIX Linux Solaris This option is valid for AIX®, Linux, and Solaris clients *only*.

Windows This option is valid for all Windows clients.

Syntax

```
                .-Yes-.
>>-MONitor = -+-----+-----------------------------------------><
              '-No--'
```

Parameters

Yes
: Specifies that you want to monitor the current NAS image backup or restore operation and display processing information on your screen. This is the default.

No
: Specifies that you do not want to monitor the current NAS image backup or restore operation.

Examples

Command line:

AIX | Linux | Solaris

```
backup nas -mode=full -nasnodename=nas1 -monitor=yes
/vol/vol0 /vol/vol1
```

Windows

```
backup nas -mode=full -nasnodename=nas1 -monitor=yes
{/vol/vol0} {/vol/vol1}
```

Windows

Myprimaryserver

The myprimaryserver option specifies the primary server name that the client uses to log on to the secondary server in failover mode.

During the normal (non-failover) logon process, the myprimaryserver option is sent to the client and is saved in the dsm.opt file. Do not edit this option during normal operations.

Important: If you change the value for the myprimaryserver option, authentication information such as the IBM Spectrum Protect™ password and encryption key will no longer work with the new primary server. You will be prompted for the password and encryption key for operations that require authentication. Therefore, do not change this value even if you change the secondary server connection information.

Supported Clients

This option is valid only for Windows clients.

Options File

This option is placed in the client options file (dsm.opt).

Syntax

```
>>-MYPRIMARYServer----primary_servername----------------------><
```

Parameters

primary_servername
: Specifies the name of the primary server to be used for authentication during a failover. The primary server is the IBM Spectrum Protect server that a client uses for normal production.

Examples

Options file:

```
*** These options should not be changed manually
REPLSERVERNAME          TARGET
   REPLTCPSERVERADDRESS 192.0.2.9
   REPLTCPPORT          1501
   REPLSERVERGUID       60.4a.c3.e1.85.ba.11.e2.af.ce.00.0c.29.2f.07.d3

MYREPLICATIONServer TARGET
MYPRIMARYSERVERNAME SERVER1
*** end of automatically updated options
```

Command line:
Does not apply.

Related concepts:
Automated client failover configuration and use
Related tasks:
Configuring the client for automated failover

Myreplicationserver

The myreplicationserver option specifies which secondary server stanza that the client uses during a failover.

The secondary server stanza is identified by the replservername option and contains connection information about the secondary server.

This option is set by the IBM Spectrum Protect™ server administrator for the client node. During the normal (non-failover) logon process, the option is sent to the client and is saved in the client options file.

Do not edit this option during normal operations.

Edit this option only during situations such as the following ones:

- The primary server is offline and the information for the secondary server is not in the options file.
- The secondary server information is out-of-date or incorrect.

Any values that you edit are removed or updated the next time you log in to the primary server.

Supported Clients

This option is valid for all clients.

Options File

AIX | Linux | Solaris | Mac OS X This option is placed within a server stanza in the dsm.sys file.

Windows This option is placed in the client options file (dsm.opt).

Syntax

```
>>-MYREPLICATIONServer----repl_servername----------------------><
```

Parameters

repl_servername
Specifies the name of the stanza for the secondary server to be used during a failover. This value is usually the name of the secondary server, not the host name of the server. Also, the value of the repl_servername parameter is not case-sensitive, but the value must match the value that is specified for the REPLSERVERName option.

Examples

Options file:

```
MYREPLICATIONServer TargetReplicationServer1
```

Command line:

Does not apply.

AIX Linux Mac OS X Solaris Options file:

AIX Linux Mac OS X Solaris The following example demonstrates how to specify options for three different servers in the dsm.sys file, and how to reference the secondary server. Connection information for multiple secondary server is presented in stanzas. Each stanza is identified by the replservername option and the name of the secondary server. The servername stanza must contain the myreplicationserver option, which points to the secondary server that is specified by the replservername stanza. Only one secondary server can be specified per servername stanza.

```
REPLSERVERNAME    TargetReplicationServer1
  REPLTCPSERVERADDRESS TargetReplicationServer1
  REPLTCPPORT          1505
  REPLSSLPORT          1506

Windows

Namedpipename

The namedpipename option specifies the name of a named pipe to use for communications between a client and a server on the same Windows server domain.

Supported Clients

This option is valid for all Windows clients.

Options File

Place this option in the client options file (dsm.opt). You can set this option on the Communication tab of the Preferences editor.

Syntax

```
>>-NAMedpipename-- --name-------------------------------------><
```

Parameters

name
: The name of a named pipe. The default is **\\.\pipe\Server1**.

Examples

Options file:

```
namedpipename \\.\pipe\dsmser1
```

Command line:

```
-namedpipename=\\.\pipe\dsmser1
```

This option is valid only on the initial command line. It is not valid in interactive mode.

AIX | Linux | Solaris | Windows

Nasnodename

The nasnodename option specifies the node name for the NAS file server when processing NAS file systems. The client prompts you for an administrator ID.

The node name identifies the NAS file server to the IBM Spectrum Protect™ server. The server must register the NAS file server.

AIX | Linux | Solaris You can specify this option on the command line or in the client system-options file (dsm.sys).

AIX | Linux | Solaris You can override the default value in the dsm.sys file by entering a different value on the command line. If you do not specify the nasnodename option in the dsm.sys file, you must specify this option on the command line when processing NAS file systems.

Windows You can specify this option on the command line or in the client options file (dsm.opt).

Windows You can override the default value in the dsm.opt file by entering a different value on the command line. If you do not specify the nasnodename option in the dsm.opt file, you must specify this option on the command line when processing NAS file systems.

You can use the nasnodename option with the following commands:

- backup nas
- delete filespace
- query backup
- query filespace
- restore nas

You can use the delete filespace command to interactively delete NAS file spaces from server storage.

AIX | Linux | Solaris Use the nasnodename option to identify the NAS file server. Place the nasnodename option in your client system-options file (dsm.sys). The value in the client system-options file is the default, but this value can be overridden on

the command line. If the nasnodename option is not specified in the client system-options file, you must specify this option on the command line when processing NAS file systems.

Windows Use the nasnodename option to identify the NAS file server. Place the nasnodename option in your client options file (dsm.opt). The value in the client options file is the default, but this value can be overridden on the command line. If the nasnodename option is not specified in the client options file, you must specify this option on the command line when processing NAS file systems.

Use the class option to specify the class of the file space to delete. To display a list of file spaces belonging to a NAS node so that you can choose one to delete, use the -class=nas option.

To delete NAS file spaces using the web client, see the topic for backing up your data.

Supported Clients

AIX Linux Solaris This option is only valid for the AIX®, Linux, and Solaris clients. The IBM Spectrum Protect API does not support this option.

Windows This option is valid for all Windows clients. The IBM Spectrum Protect client API does not support this option.

Options File

AIX Linux Solaris Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the General tab of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the General tab of the Preferences editor.

Syntax

```
>>-NASNodename-- --nodename-----------------------------------><
```

Parameters

nodename
: Specifies the node name for the NAS file server.

Examples

Options file:

```
nasnodename nas2
```

Command line:

```
-nasnodename=nas2
```

AIX Linux Solaris Mac OS X

Nfstimeout

The nfstimeout option specifies the number of seconds the client waits for a status system call on an NFS file system before it times out.

You can use this option to mitigate the default behavior of status calls on file systems. For example, if an NFS file system is stale, a status system call is timed out by NFS (soft mounted) or hang the process (hard mounted).

When the value of this option is changed to a value other than zero, a new thread is created by a caller thread to issue the status system call. The new thread is timed out by the caller thread and the operation can continue.

Solaris Note: On Solaris, the nfstimeout option can fail if the NFS mount is hard. If a hang occurs, deactivate the nfstimeout option and mount the NFS file system soft mounted, as follows:

```
mount -o soft,timeo=5,retry=5 machine:/filesystem /mountpoint
```

The parameters are defined as follows:

soft
: Generates a soft mount of the NFS file system. If an error occurs, the stat() function returns with an error. If the option hard is used, stat() does not return until the file system is available.

timeo=n
: Sets the time out for a soft mount error to *n* tenths of a second.

retry=n
: Set the internal retries and the mount retries to *n*, the default is 10000.

Supported Clients

This option is for all UNIX and Linux clients. The server can also define this option.

Options File

Place this option in the dsm.sys file within a server stanza *or* the client options file (dsm.opt).

Syntax

```
>>-NFSTIMEout-- --number----------------------------------------><
```

Parameters

number
: Specifies the number of seconds the client waits for a status system call on a file system before timing out. The range of values is 0 through 120; the default is 0 seconds.

Examples

Options file:
```
nfstimeout 10
```
Command line:
```
-nfstimeout=10
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Nodename

Use the nodename option in your client options file to identify your workstation to the server. You can use different node names to identify multiple operating systems on your workstation.

When you use the nodename option, you are prompted for the password that is assigned to the node that you specify, if a password is required.

If you want to restore or retrieve files from the server while you are working from a different workstation, use the virtualnodename option. You can also use the asnodename option, if it is set up by the administrator.

Windows If you are working from a different workstation, you can use the nodename option even if the passwordaccess option is set to generate. To prevent this, use the virtualnodename option instead of nodename.

Windows The node name is not necessarily the TCP/IP host name.

When connecting to a server, the client must identity itself to the server. This login identification is determined in the following manner:

- AIX Linux Solaris Mac OS X In the absence of a nodename entry in the dsm.sys file, or a virtualnodename entry in the client user-options file (dsm.opt), or a virtual node name specified on a command line, the default login ID is the name that the hostname command returns.
- AIX Linux Solaris Mac OS X If a nodename entry exists in the dsm.sys file, the nodename entry overrides the name that the hostname command returns.
- AIX Linux Solaris Mac OS X If a virtualnodename entry exists in the client system-options file (dsm.sys), or a virtual node name is specified on a command line, it cannot be the same name as the name returned by the hostname

command. When the server accepts the virtual node name, a password is required (if authentication is on), even if the passwordaccess option is generate. When a connection to the server is established, access is permitted to any file that is backed up using this login ID.

- Windows In the absence of a nodename entry in the dsm.opt file, or a virtualnodename entry in the client options file (dsm.opt), or a virtual node name specified on a command line, the default login ID is the name that the hostname command returns.
- Windows If a nodename entry exists in the dsm.opt file, the nodename entry overrides the name that the hostname command returns.
- Windows If a virtualnodename entry exists in the client options file (dsm.opt), or a virtual node name is specified on a command line, it cannot be the same name as the name returned by the hostname command. When the server accepts the virtual node name, a password is required (if authentication is on), even if the passwordaccess option is generate. When a connection to the server is established, access is permitted to any file that is backed up using this login ID.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the dsm.sys file within a server stanza. You can set this option on the General tab, in the Node Name field of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the General tab, in the Node Name field of the Preferences editor.

Syntax

```
>>-NODename-- --nodename----------------------------------------><
```

Parameters

AIX Linux Solaris Mac OS X nodename

AIX Linux Solaris Mac OS X Specifies a 1 to 64 character node name for which you want to request IBM Spectrum Protect™ services. The default is the value returned with the hostname command.

Not specifying a node name permits the node name to default to the host name of the workstation

Windows nodename

Windows Specifies a 1 to 64 character node name for which you want to request IBM Spectrum Protect services. The default is the value returned with the hostname command.

Not specifying a node name permits the node name to default to the host name of the workstation

Examples

Options file:

```
nodename cougar
```

Windows Command line:

Windows `-nodename=cougar`

Windows This option is valid only on the initial command line. It is not valid in interactive mode.

Windows

Nojournal

Use the nojournal option with the incremental command to specify that you want to perform a traditional full incremental backup, instead of the default journal-based backup.

Journal-based incremental backup differs from the traditional full incremental backup in the following ways:

- Non-default copy frequencies (other than 0) are not enforced on the IBM Spectrum Protect™ server.
- Attribute changes to an object require a backup of the entire object.

For these reasons, you might want to use the nojournal option periodically to perform a traditional full incremental backup.

Supported Clients

This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option.

Syntax

```
>>-NOJournal-------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Command line:

```
dsmc incr c: -nojournal
```

AIX | Linux

Nojournal

Use the nojournal option with the incremental command to specify that you want to perform a traditional full incremental backup, instead of the default journal-based backup.

Journal-based incremental backup differs from the traditional full incremental backup in the following ways:

- Non-default copy frequencies (other than 0) are not enforced on the IBM Spectrum Protect™ server.
- UNIX special file changes are not detected by the Journal daemon and are not, therefore, backed up.

For these reasons, you want to use the nojournal option periodically to perform a traditional full incremental backup.

Supported Clients

This option is valid for the AIX® and Linux backup-archive client.

Syntax

```
>>-NOJournal-------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Command line:

```
dsmc incr /home -nojournal
```

Noprompt

The noprompt option suppresses the confirmation prompt that is presented by the delete group, delete archive, expire, restore image, and set event commands.

- delete archive
- delete backup
- delete group
- expire
- AIX Linux Solaris Windows restore image

Mac OS X Note: The restore image command does not apply to Mac OS X operating systems.
AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-NOPrompt---------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Mac OS X Command line:

Mac OS X
```
dsmc delete archive -noprompt "/Users/van/Documents/*"
```

AIX Linux Solaris Mac OS X Command line:

AIX Linux Solaris Mac OS X
```
dsmc delete archive -noprompt "/home/project/*"
```

Windows Command line:

Windows
```
dsmc delete archive -noprompt c:\home\project\*
```

Nrtablepath

The nrtablepath option specifies the location of the node replication table on the client. The backup-archive client uses this table to store information about each backup or archive operation to the IBM Spectrum Protect™ server.

The server to which you back up your data must be at version 7.1 or newer and must replicate client node data to the secondary server.

When a failover occurs, the information that is on the secondary server might not be the most recent version if replication did not happen before the failover. The client can compare the information in the node replication table against the information that is on the secondary server to determine whether the backup on the server is the most recent backup version.

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys).

Windows Place this option in the client options file (dsm.opt).

This option can also be configured in the client option set on the IBM Spectrum Protect server.

Syntax

```
>>-NRTABLEPath----path----------------------------------------><
```

Parameters

path

Specifies the location where the node replication table database is created. The default location is the backup-archive client installation directory.

AIX Linux Mac OS X Solaris For non-root users, you must specify a path that your user ID has write access to, such as a temporary directory. Most non-root users do not have access to the client installation directory.

AIX Linux Mac OS X Solaris Restriction: The node replication table cannot be created in the root directory (/). If you choose to specify a location for the node replication table, do not specify the root directory.
Windows Restriction: The node replication table cannot be created in the C:\ directory. If you choose to specify a location for the node replication table, do not specify the C:\ directory.

Example

Options file:

AIX Linux Mac OS X Solaris
```
nrtablepath /Volumes/nrtbl
```
Windows
```
nrtablepath C:\nrtbl
```

Command line:

Does not apply.

Related tasks:
Determining the status of replicated client data
Configuring the client for automated failover

Numberformat

The numberformat option specifies the format you want to use to display numbers.

Windows Use this option if you want to change the default number format for the language of the message repository you are using.

AIX Solaris The AIX® and Solaris clients support locales other than English that describe every user interface that varies with location or language.

AIX Linux Solaris Mac OS X Windows By default, the backup-archive and administrative clients obtain format information from the locale definition in effect at the time the client is called. Consult the documentation on your local system for details about setting up your locale definition.

Note: The numberformat option does not affect the web client. The web client uses the number format for the locale that the browser is running in. If the browser is not running in a supported locale, the web client uses the number format for US English.

You can use the numberformat option with the following commands:

- delete archive
- delete backup
- expire
- query archive
- Windows query asr
- query backup
- AIX Linux Solaris Windows query image
- AIX Linux Solaris AIX Mac OS X Windows query nas
- Windows query systemstate
- restore
- AIX Linux Solaris Windows restore image
- AIX Linux Solaris Mac OS X Windows restore nas
- Windows restore registry
- retrieve
- set event

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Windows Place this option in the client user-options file (dsm.opt). You can set this option on the Regional Settings tab, Number Format field of the Preferences editor.

Syntax

```
>>-NUMberformat-- --number-------------------------------------><
```

Parameters

number

Displays numbers using any one of the following formats. Specify the number (0–6) that corresponds to the number format you want to use.

0

Use the locale-specified date format. This is the default (does not apply to Mac OS X).

1

1,000.00

AIX Linux Solaris Mac OS X Windows This is the default for the following available translations:

AIX Linux Solaris Mac OS X Windows

- US English

- Italian
- Spanish

6

1'000,00

AIX Solaris For AIX and Solaris: To define number formats, modify the following lines in the source file of your locale. Whatever format you select applies both to output and to input.

AIX | Solaris

decimal_point
: The character that separates the whole number from its fractional part.

thousands_sep
: The character that separates the hundreds from the thousands from the millions.

grouping
: The number of digits in each group that is separated by the thousands_sep character.

Examples

Options file:

```
num 4
```

Command line:

```
-numberformat=4
```

This option is valid on the initial command line and in interactive mode. If you use this option in interactive mode, it affects only the command with which it is specified. When that command completes, the value reverts to the value at the beginning of the interactive session. This is the value from the dsm.opt file unless overridden by the initial command line or by an option forced by the server.

Optfile

The optfile option specifies the client options file to use when you start a backup-archive client session.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This option is valid for all clients.

Syntax

```
>>-OPTFILE = - --file_name--------------------------------------><
```

Parameters

file_name
: Specifies an alternate client options file, if you use the fully qualified path name. If you specify only the file name, the client assumes the file name specified is located in the current working directory. The default is dsm.opt.

  AIX | Linux | Solaris | Mac OS X **Restriction:** Specify the full path when you use this option with the client acceptor daemon (dsmcad), because the client acceptor daemon changes its working directory to root ("/") after initialization.

Examples

Command line:

AIX | Linux | Solaris | Mac OS X | Windows

```
dsmc query session -optfile=myopts.opt
```

AIX | Linux | Solaris | Mac OS X

Client acceptor daemon:

AIX | Linux | Solaris | Mac OS X

```
dsmcad -optfile=/usr/tivoli/tsm/client/ba/bin/myopts.opt
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Password

The password option specifies a password for IBM Spectrum Protect™.

If you do not specify this option and your administrator has set authentication to On, you are prompted for a password when you start a backup-archive client session.

Note:

1. If the server prompts for a password, the password is not displayed as you enter it. However, if you use the password option on the command line, your password is displayed as you enter it.
2. If the IBM Spectrum Protect server name changes or the backup-archive clients are directed to a different server, all clients must re-authenticate with the server because the stored encrypted password must be regenerated.

The password option is ignored when the passwordaccess option is set to generate.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This option is valid for all clients.

Options File

Windows Place this option in the client options file (dsm.opt).

AIX | Linux | Solaris | Mac OS X Place this option in the client user-options file (dsm.opt).

Syntax

```
>>-PASsword-- --password---------------------------------------><
```

Parameters

password
Specifies the password you use to log on to the IBM Spectrum Protect server.

Passwords can be up to 63 character in length. Password constraints vary, depending on where the passwords are stored and managed, and depending on the version of the server that your client connects to.

If your IBM Spectrum Protect server is at version 6.3.3 or later, and if you use an LDAP directory server to authenticate passwords
Use any of the following characters to create a password:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9 . ! @ # $ % ^ & * _ - + = ` ( )
| { } [ ] : ; < > , ? / ~
```

Passwords are case-sensitive and are subject to more restrictions that can be imposed by LDAP policies.

If your IBM Spectrum Protect server is at version 6.3.3 or later, and if you do not use an LDAP directory server to authenticate passwords
Use any of the following characters to create a password:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9 . ! @ # $ % ^ & * _ - + = ` ( )
| { } [ ] : ; < > , ? / ~
```

Passwords are stored in the IBM Spectrum Protect server database and are not case-sensitive.

If your IBM Spectrum Protect server is earlier than version 6.3.3
Use any of the following characters to create a password:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9
_ - & + .
```

Passwords are stored in the IBM Spectrum Protect server database and are not case-sensitive.

AIX Linux Mac OS X Solaris Windows Remember:

On the command line, enclose all parameters that contain one or more special characters in quotation marks. Without quotation marks, the special characters can be interpreted as shell escape characters, file redirection characters, or other characters that have significance to the operating system.

Windows

On Windows systems:

Enclose the command parameters in quotation marks (").

Command line example:

```
dsmc set password "t67@#$%^&" "pass2><w0rd"
```

AIX Linux Solaris

On AIX®, Linux, and Solaris systems:

Enclose the command parameters in single quotation marks (').

Command line example:

```
dsmc set password -type=vmguest 'Win 2012 SQL' 'tsml2dag\administrator' '7@#$%^&7'
```

Quotation marks are not required when you type a password with special characters in an options file.

Examples

Options file:

```
password secretword
```

Command line:

```
-password=secretword
```

Windows -password="secret>shhh"

AIX Linux Mac OS X Solaris -password='my>pas$word'

This option is valid only on the initial command line. It is not valid in interactive mode.

Passwordaccess

The passwordaccess option specifies whether you want to generate your password automatically or set as a user prompt.

Your administrator can require a password for your client node by enabling the authentication feature. Ask your administrator if a password is required for your client node.

If a password is required, you can choose one of the following methods:

- Set the password for your client node yourself and have the client prompt for it each time you request services.
- Let the client automatically generate a new password for your client node each time it expires, encrypt and store the password in a file, and retrieve the password from that file when you request services. You are not prompted for the password.
- If the server is not configured to require a password to log on to it, you can still be prompted to enter your node password when the backup-archive client establishes a connection with the server. This behavior occurs if this option, passwordaccess, is allowed to default or if you set it to passwordaccess prompt. The password that you supply in response to the prompt is used only to encrypt your login information; it is not used to log onto the server. In this configuration, you can avoid entering a password by setting this option to passwordaccess generate. Setting passwordaccess generate causes the client to create, store, and submit the password for you. When passwordaccess generate is set, the password option is ignored.

Setting the passwordaccess option to generate is required in the following situations:

- AIX Linux When using the HSM client.
- When using the web client.
- AIX Solaris Windows When performing NAS operations.
- When using IBM Spectrum Protect™ for Workstations.

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the dsm.sys file within a server stanza. You can set this option on the Authorization tab, in the Password Access section of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Authorization tab, in the Password Access section of the Preferences editor.

Syntax

```
                    .-prompt---.
>>-PASSWORDAccess--+----------+-------------------------------><
                    '-generate-'
```

Parameters

prompt
: You are prompted for your client node password each time a client connects to the server. This is the default.

  To keep your client node password secure, enter commands without the password and wait for the client to prompt you for the password.

  AIX Linux Solaris Mac OS X Each user must know the IBM Spectrum Protect password for your client node. Any user who knows the password for your client node can gain access to all backups and archives that originate from your client node. For example: If the user enters the node name and password for your client node from a different client node, the user becomes a virtual root user.

  API applications must supply the password when a session is initiated. The application is responsible for obtaining the password.

generate
: Encrypts and stores your password locally and generates a new password when the old password expires. The new password is randomly generated by the client. Password constraints vary, depending on where the passwords are stored and managed, and depending on the version of the server that your client connects to. Generated passwords are 63 characters in length and contain at least two of the following characters:

  - upper case letters
  - lower case letters
  - numeric characters
  - special characters

  Additionally, the first and last character of a generated password is an alphabetic character, and they can be either upper or lower case. Generated passwords do not contain repeated characters.

A password prompt is displayed when registering a workstation with a server using open registration or if your administrator changes your password manually.

AIX Linux Solaris Mac OS X When logging in locally, users do not need to know the password for the client node. However, by using the nodename option at a remote node, users can access files they own and files to which another user grants access.

Examples

Options file:
```
passwordaccess generate
```
Command line:
: Does not apply.

AIX Linux Solaris Mac OS X

Passworddir

The passworddir option specifies the directory location in which to store an encrypted password file.

AIX Linux Solaris Mac OS X The default directory for AIX® is /etc/security/adsm and for other UNIX and Linux platforms it is /etc/adsm. The default directory for Mac is /Library/Preferences/Tivoli Storage Manager. Regardless of where it is stored, the password file that is created by the client is always named TSM.sth. In turn three files comprise a password file. TSM.KDB stores the encrypted passwords. TSM.sth stores the random encryption key that is used to encrypt passwords in the TSM.KDB file. This file is protected by the file system. TSM.IDX is an index file that is used to track the passwords in the TSM.KDB file.

AIX Linux Solaris Mac OS X

Supported Clients

This option is valid for all UNIX clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza.

Syntax

```
>>-PASSWORDDIR-- --directoryname------------------------------><
```

Parameters

directoryname
: Specifies the path in which to store the encrypted password file. The name of the password file is TSM.sth. If any part of the specified path does not exist, IBM Spectrum Protect™ attempts to create it.

Examples

Mac OS X AIX Linux Solaris Mac OS X Options file:

Mac OS X AIX Linux Solaris Mac OS X Mac OS X

```
passworddir "/Users/user1/Library/Preferences/Tivoli Storage Manager/"
```

AIX Linux Solaris Mac OS X

```
passworddir /etc/security/tsm
```

Command line:
: Does not apply.

Pick

The pick option creates a list of backup versions or archive copies that match the file specification you enter.

From the list, you can select the versions to process. Include the inactive option to view both active and inactive objects.

AIX Linux Solaris Windows For images, if you do not specify a source file space and destination file space, the pick list contains all backed up images. In this case, the images selected from the pick list are restored to their original location. If you specify the source file space and the destination file space, you can select only one entry from the pick list.

Use the pick option with the following commands:

- delete archive
- delete backup
- delete group
- expire
- restore

- Windows restore asr
- restore group
- AIX Linux Solaris Windows restore image
- AIX Linux Solaris Mac OS X Windows restore nas
- Windows restore vm
- retrieve

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-PIck-----------------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Mac OS X Command line:

Mac OS X `dsmc restore "/Users/van/Documents/*" -pick -inactive`

AIX Linux Solaris Mac OS X Command line:

AIX Linux Solaris Mac OS X `dsmc restore "/home/project/*" -pick -inactive`

Windows Command line:

Windows `dsmc restore c:\project\* -pick -inactive`

Pitdate

Use the pitdate option with the pittime option to establish a point in time to display or restore the latest version of your backups.

Files that were backed up *on or before* the date and time you specify, and which were not deleted *before* the date and time you specify, are processed. Backup versions that you create after this date and time are ignored.

Use the pitdate option with the following commands:

- delete backup
- Windows query asr
- query backup
- query group
- AIX Linux Solaris Windows query image
- Windows query nas
- Windows query systemstate
- Windows query vm (vmbackuptype=fullvm and vmbackuptype=hypervfull)
- restore
- AIX Linux Solaris Mac OS X Windows restore group
- AIX Linux Solaris Windows restore image
- AIX Linux Solaris Mac OS X Windows restore nas
- Windows restore vm (vmbackuptype=fullvm and vmbackuptype=hypervfull)

When pitdate is used, the inactive and latest options are implicit.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-PITDate = - --date-----------------------------------------><
```

Parameters

date
: Specifies the appropriate date. Enter the date in the format you selected with the dateformat option.

  When you include dateformat with a command, it must precede the fromdate, pitdate, and todate options.

Examples

Mac OS X Command line:

```
dsmc restore "/Volumes/proj4/myproj/*" -sub=y -pitdate=08/01/2003 -pittime=06:00:00
```

AIX Linux Solaris Mac OS X Command line:

```
dsmc restore "/fs1/*" -sub=y -pitdate=08/01/2003 -
pittime=06:00:00
```

Windows Command line:

```
dsmc restore -pitdate=08/01/2003 c:\myfiles\
```

Pittime

Use the pittime option with the pitdate option to establish a point in time to display or restore the latest version of your backups.

Files that were backed up *on or before* the date and time you specify, and which were not deleted *before* the date and time you specify, are processed. Backup versions that you create after this date and time are ignored. This option is ignored if you do not specify pitdate option.

Use the pittime option with the following commands:

- delete backup
- Windows query asr
- query backup
- AIX Linux Solaris Windows query image
- Windows query nas
- Windows query systemstate
- Windows query vm(vmbackuptype=fullvm and vmbackuptype=hypervfull)
- restore
- AIX Linux Solaris Windows restore image
- AIX Linux Solaris Mac OS X Windows restore nas
- Windows restore vm (vmbackuptype=fullvm and vmbackuptype=hypervfull)

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-PITTime = - --time-----------------------------------------><
```

Parameters

time
: Specifies a time on a specified date. If you do not specify a time, the time defaults to 23:59:59. Specify the time in the format you selected with the timeformat option.

  When you include the timeformat option in a command, it must precede the fromtime, pittime, and tottime options.

Examples

Mac OS X Command line:

Mac OS X
```
dsmc query backup -pitt=06:00:00 -pitd=08/01/2003 "/Volumes/proj5/myproj/*"
```

AIX | Linux | Solaris | Mac OS X Command line:

AIX | Linux | Solaris | Mac OS X
```
dsmc q b "/fs1/*" -pitt=06:00:00 -pitd=08/01/2003
```

Windows Command line:

Windows
```
dsmc query backup -pitt=06:00:00 -pitd=08/01/2003 c:\myfiles\
```

Postschedulecmd/Postnschedulecmd

The postschedulecmd/postnschedulecmd option specifies a command that the client program processes after it runs a schedule.

If you want the client program to wait for the command to complete before it continues with other processing, use the postschedulecmd option. If you do not want to wait for the command to complete before the client continues with other processing, specify the postnschedulecmd option.

Return code handling and scheduled action behavior depends on both the option specified, and the type of operation that is scheduled:

- For scheduled operations where the scheduled action is something other than COMMAND:

  If the postschedulecmd command does not complete with return code 0 (zero), the return code for the scheduled event is either 8, or the return code of the scheduled operation, whichever is greater. If you do not want the postschedulecmd command to be governed by this rule, you can create a script or batch file that starts the command and exits with return code 0. Then configure postschedulecmd to start the script or batch file.

- For scheduled operations where the scheduled action is COMMAND:

  The return code from the command specified on the postschedulecmd option does not affect the return code that is reported to the server when the scheduled event completes. If you want the results of postschedulecmd operations to affect the return code of the scheduled event, include the postschedulecmd operations in the scheduled action command script instead of using the postschedulecmd option.

- If the scheduler action cannot be started, and the command specified on the preschedulecmd option completes with a return code of zero (0), the command specified by the postschedulecmd option is run.
- The return code from an operation specified on the postnschedulecmd option is not tracked, and does not influence the return code of the scheduled event.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option. The server can also define this option.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Scheduler tab in the Schedule Command text box in the Preferences editor. The server can also define these options.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Scheduler tab in the Schedule Command text box in the Preferences editor. The server can also define these options.

Syntax

```
>>-+-POSTSChedulecmd--+-- --cmdstring--------------------------><
   '-POSTNSChedulecmd-'
```

Parameters

cmdstring

Specifies the command to process. You can enter a command to be run after a schedule with this option. Use only one postschedulecmd option.

AIX Linux Solaris Mac OS X If the command string contains blanks, enclose the command string in quotation marks. If you placed quotation marks within the command string, then enclose the entire command string in single quotation marks.

Windows Specify the command string just as you would enter it from the operating system command prompt. If the command string contains any blank spaces, enclose the command string in single quotation marks. For example:

```
'net stop someservice'
```

Use a blank, or null, string for *cmdstring* if you want to prevent any commands from running that the IBM Spectrum Protect server administrator uses for postschedulecmd or preschedulecmd. If you specify a blank or null string on either option, it prevents the administrator from using a command on both options.

If your administrator uses a blank or null string on the postschedulecmd option, you cannot run a post-schedule command.

Mac OS X For Mac OS X, if the postschedulecmd schedule command is an AppleScript, you must use the osascript command to run the script. For example, if "Database Script" is an AppleScript, enter this command:

```
postschedulecmd osascript "/Volumes/La Pomme/Scripting/
  Database Script"
```

Examples

Mac OS X Options file:

Mac OS X For Mac OS X: `postschedulecmd "/Volumes/La Pomme/Scripting/postsched.sh"`

AIX Linux Solaris Mac OS X Options file:

AIX Linux Solaris Mac OS X `postschedulecmd "restart database"`

The command string is a valid command for restarting your database.

Windows Options file:

Windows

```
posts startdb.cmd
posts 'rename c:\myapp\logfile.log logfile.new'
posts 'net start "simple service"'
posts 'rename "c:\myapp\log file.log" "log file.new"'
posts '"C:\Program Files\MyTools\runreport.bat"
  log1.in log2.in'
```

Mac OS X Command line:

Mac OS X `-postschedulecmd="/Volumes/La Pomme/Scripting/postsched.sh"`

AIX Linux Solaris Mac OS X Windows Command line:

AIX Linux Solaris Mac OS X Windows `-postschedulecmd="'restart database'"`

This option is valid only on the initial command line. It is not valid in interactive mode.

DEFINE SCHEDULE command
AIX Linux Windows

Postsnapshotcmd

The postsnapshotcmd option allows you to run operating system shell commands or scripts after the backup-archive client starts a snapshot during a snapshot-based backup operation.

Windows This option can be used in conjunction with the presnapshotcmd option to allow you to quiesce an application while a snapshot is created, and then to restart that application after the snapshot is started. This option is only valid if OFS or online image backup has been configured.

AIX AIX® only: This option is only applicable to JFS2 snapshot-based file backup or archive and snapshot-based image backup. For a snapshot-based file backup or archive, use this option with the backup command, the include.fs option, or in the

dsm.sys file.

Linux Linux only: This option is only valid if the LVM is installed and configured on your system, allowing you to perform a snapshot-based image backup operation.

AIX Linux AIX and Linux only: For a snapshot-based image backup, use this option with the backup image command, the include.image option, or in the dsm.sys file.

Windows For an online image backup, use this option with the backup image command, the include.image option, or in the dsm.opt file.

Windows For open file support operations, use the postsnapshotcmd option in an include.fs statement or in your client options file (dsm.opt).

If the postsnapshotcmd fails the operation continues, but appropriate warnings are logged.

Windows Attention: During image backup operations or snapshot differential backup operations, if the command that you include on either the presnapshotcmd or postsnapshotcmd statement starts an asynchronous process, the command might not complete before the backup operation finishes. If the command does not complete before the backup completes, temporary files might be locked, which prevents them from being deleted. A database event occurs and the following message is recorded in the dsmerror.log file:

```
ANS0361I DIAG: ..\..\common\db\cacheobj.cpp( 777): dbDelete():
 remove('C:\adsm.sys\SystemExcludeCache__24400820.TsmCacheDB'):
  errno 13: "Permission denied".
```

The file that is specified in the message (cacheobj.cpp) can be manually deleted after the command that was started by the presnapshotcmd or postsnapshotcmd option completes.

Supported Clients

AIX Linux This option is valid for AIX clients and Linux x86_64 clients only. The IBM Spectrum Protect™ API does not support this option. The server can also define this option.

Windows This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option. The server can also define this option.

Options File

AIX Linux Place this option in the client system-options file (dsm.sys) within a server stanza. You can also set this option on the Image-Snapshot tab of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can also set this option on the Image-Snapshot tab of the Preferences editor.

Syntax

```
>>---POSTSNAPshotcmd---- --"cmdstring"-------------------------><
```

Parameters

AIX Linux "cmdstring"

AIX Linux Specifies a command to process.

Use the srvprepostsnapdisabled option to prevent the IBM Spectrum Protect server administrator from executing operating system commands on the client system.

If the command string contains blanks, enclose the command string in quotation marks:

```
"resume database myDb"
```

If you placed quotation marks within the command string, then enclose the entire command string in single quotation marks:

```
'resume database "myDb"'
```

Windows "cmdstring"

Windows Specifies the quiesce command to process.

Use a blank, or null, string for "cmdstring" if you want to prevent any commands from running that the administrator uses for postsnapshotcmd. If you specify a blank or null string, it prevents the administrator from using a command on this option. If your administrator uses a blank or null string on the postsnapshotcmd option, you cannot run a post-snapshot command.

Use the srvprepostsnapdisabled option to prevent the IBM Spectrum Protect server administrator from executing operating system commands on the client system.

If the command string contains blanks, enclose the command string in quotation marks:

```
"resume database myDb"
```

If you placed quotation marks within the command string, then enclose the entire command string in single quotation marks:

```
'resume database "myDb"'
```

Examples

AIX Linux Options file:

AIX Linux `postsnapshotcmd "any command"`

The command string is a valid command for restarting your application.

Windows Options file:

Windows `postsnapshotcmd "restart application"`

The command string is a valid command for restarting your application.

AIX Linux Command line:

AIX Linux `backup image -postsnapshotcmd="any command"`

Windows Command line:

Windows `backup image -postsnapshotcmd="restart application"`

This option is valid only on the initial command line. It is not valid in interactive mode.

Preschedulecmd/Prenschedulecmd

The preschedulecmd option specifies a command that the client program processes before it runs a schedule.

The client program waits for the command to complete before it starts the schedule. If you do not want it to wait, specify prenschedulecmd.

Note:

1. Successful completion of the preschedulecmd command is considered to be a prerequisite to running the scheduled operation. If the preschedulecmd command does not complete with return code 0, the scheduled operation and any postschedulecmd and postnschedulecmd commands will not run. The client reports that the scheduled event failed, and the return code is 12. If you do not want the preschedulecmd command to be governed by this rule, you can create a script or batch file that invokes the command and exits with return code 0. Then configure preschedulecmd to invoke the script or batch file. The return code for the prenschedulecmd command is not tracked, and does not influence the return code of the scheduled event.
2. The server can also define the preschedulecmd option (and the prenschedulecmd option).

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option. The server can also define this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Scheduler tab, in the Schedule Command dialog box in the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Scheduler tab, in the Schedule Command dialog box in the Preferences editor.

Syntax

```
>>-+-PRESChedulecmd--+-- --cmdstring--------------------------><
   '-PRENSChedulecmd-'
```

Parameters

cmdstring

Specifies the command to process. Use only one preschedulecmd option. You can enter a command to be executed before a schedule using this option.

AIX Linux Solaris Mac OS X If the command string contains blanks, enclose the command string in quotation marks. If you placed quotation marks within the command string, then enclose the entire command string in single quotation marks.

Windows Specify the command string just as you would enter it from the operating system command prompt; if the string you specify would require quotation marks to run it at a Windows prompt, include the quotation marks as needed. If the command string contains any blank spaces, enclose the command string in single quotation marks.

Windows In this example, single quotation marks are needed because the command string contains space characters:

```
'net stop someservice'
```

Windows In this next example, double quotation marks are needed because both the file being renamed, and the new file name, contain space characters. Because the command string does contain space characters, the entire string must be enclosed in single quotation marks.

```
presc 'rename "c:\myapp\log file.log" "log file.old"'
```

Use a blank or null string for cmdstring if you want to prevent any commands from running that the IBM Spectrum Protect server administrator uses for postschedulecmd and preschedulecmd. If you specify a blank or null string on either option, it prevents the administrator from using a command on both options.

If your administrator uses a blank or null string on the preschedulecmd option, you cannot run a pre-schedule command.

Mac OS X For Mac OS X, if the preschedulecmd schedule command is an AppleScript, you must use the osascript command to run the script. For example, if "Database Script" is an apple script, enter this command:

```
preschedulecmd osascript "/Volumes/La Pomme/Scripting/
  Database Script"
```

Examples

Options file:

AIX Linux Solaris Mac OS X

```
preschedulecmd "<the quiesce command of your database product>
database"
```

AIX Linux Solaris Mac OS X The command string is a valid command for quiescing your database.

Windows

```
presc stopdb.cmd
presc 'rename c:\myapp\logfile.log logfile.old'
presc 'net stop "simple service"'
presc 'rename "c:\myapp\log file.log" "log file.old"'
presc '"C:\Program Files\MyTools\runreport.bat"
   log1.in log2.in'
```

AIX Linux Solaris Mac OS X Command line:

AIX Linux Solaris Mac OS X

```
-preschedulecmd="'quiesce database'"
```

Windows Command line:

Windows `-preschedulecmd='"quiesce database"'`

This option is valid only on the initial command line. It is not valid in interactive mode.

Related concepts:
Client return codes

Preservelastaccessdate

Use the preservelastaccessdate option to specify whether a backup or archive operation changes the last access time.

A backup or archive operation can change the last access time of a file. After an operation, the backup-archive client can reset the last access time to the value before the operation. The last access time can be preserved, rather than modified, by the backup-archive client. Resetting the last access time requires extra processing for each file that is backed up or archived.

If you enable open file support, the last access date for files is always preserved regardless of the setting for preservelastaccessdate. When open file support is enabled, do not use the preservelastaccessdate option.

Use this option with the incremental, selective, or archive commands.

Note:

1. This option applies only to files; it does not apply to directories.
2. AIX Linux Mac OS X Solaris Resetting the last access date affects backup and archive performance.
3. Resetting the last access date can affect applications that rely on accurate last-access dates such as a Storage Resource Management (SRM) application.
4. AIX Linux On file systems that are not managed by the IBM Spectrum Protect™ for Space Management client or when non-root users back up or archive, the ctime attribute is reset. The last changed time and date (ctime) attribute is reset to the date and time of the backup or archive operation.
5. AIX Linux The updatectime option takes precedence over the preservelastaccessdate option. If both options are set to yes, the preservelastaccessdate option is ignored
6. AIX Linux On file systems that are not managed by the IBM Spectrum Protect for Space Management client, do not use `preservelastaccessdate yes` and the GPFS™ mmbackup command. The mmbackup command and `preservelastaccessdate yes` selects all files for each backup operation.
7. Windows The last access date cannot be preserved on files that are write-protected either by the read-only attribute or by a restrictive NTFS security permission.
8. You cannot reset the last access date of read-only files. The preservelastaccessdate option ignores read-only files and does not change their date.

Supported Clients

This option is valid for all clients.

The server can also define this option.

Options File

AIX Linux Mac OS X Solaris Place this option in the client user options file (dsm.opt). You can set this option on the Backup tab of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Backup tab of the Preferences editor.

Syntax

```
                            .-No--.
>>-PRESERVELAstaccessdate--+-----+----------------------------><
                            '-Yes-'
```

Parameters

No

A backup or archive operation can change the last access date. This value is the default.

Yes
A backup or archive operation does not change the last access date.

Examples

Options file:

```
preservelastaccessdate yes
```

AIX Linux Mac OS X Solaris Command line:

```
Incremental /proj/test/test_file -preservelastaccessdate=yes
```

Windows Command line:

```
dsmc incr c: e: f: -preservelastaccessdate=yes
```

AIX Linux Guidance for integrating IBM Spectrum Scale AFM with IBM Spectrum Protect

AIX Linux Using IBM Spectrum Protect include and exclude options with IBM Spectrum Scale mmbackup command

Preservepath

The preservepath option specifies how much of the source path to reproduce as part of the target directory path when you restore or retrieve files to a new location.

Use the -subdir=yes option to include the entire subtree of the source directory (directories and files below the lowest-level source directory) as source to be restored. If a required target directory does not exist, it is created. If a target file has the same name as a source file, it is overwritten. Use the -replace=prompt option to have the client prompt you before files are overwritten.

Use the preservepath option with the following commands:

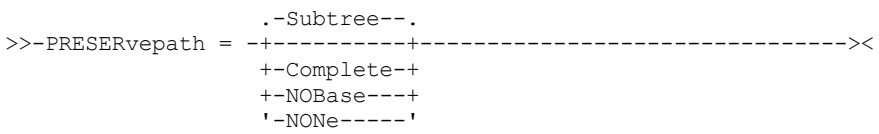
- restore
- restore backupset
- restore group
- retrieve

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option. The server can also define this option.

Syntax



Parameters

Subtree
Creates the lowest-level source directory as a subdirectory of the target directory. Files from the source directory are stored in the new subdirectory. This is the default.

Complete
Restores the entire path, starting from the root, into the specified directory. The entire path includes all the directories except the file space name.

NOBase
Restores the contents of the source directory without the lowest level, or base directory, into the specified destination directory.

NONe

Restores all selected source files to the target directory. No part of the source path at or above the source directory is reproduced at the target.

If you specify SUBDIR=yes, the client restores all files in the source directories to the single target directory.

Examples

AIX Linux Solaris Mac OS X Command line:

AIX Linux Solaris Mac OS X Assume that the server file space contains the following backup copies:

```
/fs/h1/m1/file.a
/fs/h1/m1/file.b
/fs/h1/m1/l1/file.x
/fs/h1/m1/l1/file.y
```

AIX Linux Solaris Mac OS X This command:

AIX Linux Solaris Mac OS X

```
dsmc res /fs/h1/m1/ /u/ann/ -preser=complete
```

Restores these directories and files:

```
/u/ann/h1/m1/file.a
/u/ann/h1/m1/file.b
```

AIX Linux Solaris Mac OS X This command:

AIX Linux Solaris Mac OS X

```
dsmc res /fs/h1/m1/ /u/ann/ -preser=nobase
```

Restores these directories and files:

```
/u/ann/file.a
/u/ann/file.b
```

AIX Linux Solaris Mac OS X This command:

AIX Linux Solaris Mac OS X

```
dsmc res backupset /fs/h1/m1/ /u/ann/ -su=yes
-preser=nobase -loc=file
```

Restores these directories and files:

```
/u/ann/file.a
/u/ann/file.b
/u/ann/file.x
/u/ann/file.y
```

AIX Linux Solaris Mac OS X This command:

AIX Linux Solaris Mac OS X

```
dsmc res /fs/h1/m1/ /u/ann/ -preser=subtree
```

Restores these directories and files:

```
/u/ann/m1/file.a
/u/ann/m1/file.b
```

AIX Linux Solaris Mac OS X This command:

AIX Linux Solaris Mac OS X

```
dsmc res /fs/h1/m1/ /u/ann/ -preser=none
```

Restores these directories and files:

```
/u/ann/file.a
/u/ann/file.b
```

AIX Linux Solaris Mac OS X This command:

AIX Linux Solaris Mac OS X

```
dsmc res /fs/h1/m1/ /u/ann/ -su=yes -preser=complete
```

Restores these directories and files:

```
/u/ann/h1/m1/file.a
/u/ann/h1/m1/file.b
/u/ann/h1/m1/l1/file.x
/u/ann/h1/m1/l1/file.y
```

AIX Linux Solaris Mac OS X This command:

AIX Linux Solaris Mac OS X

```
dsmc res /fs/h1/m1/ /u/ann/ -su=yes -preser=nobase
```

Restores these directories and files:

```
/u/ann/file.a
/u/ann/file.b
/u/ann/l1/file.x
/u/ann/l1/file.y
```

AIX Linux Solaris Mac OS X This command:

AIX Linux Solaris Mac OS X

```
dsmc res /fs/h1/m1/ /u/ann/ -su=yes -preser=subtree
```

Restores these directories and files:

```
/u/ann/m1/file.a
/u/ann/m1/file.b
/u/ann/m1/l1/file.x
/u/ann/m1/l1/file.y
```

AIX Linux Solaris Mac OS X This command:

AIX Linux Solaris Mac OS X

```
dsmc res /fs/h1/m1/ /u/ann/ -su=yes -preser=none
```

Restores these directories and files:

```
/u/ann/file.a
/u/ann/file.b
/u/ann/file.x
/u/ann/file.y
```

Windows Command line:

Windows Assume the server file space contains the following backup copies:

```
c:\h1\m1\file.a
c:\h1\m1\file.b
c:\h1\m1\l1\file.x
c:\h1\m1\l1\file.y
```

Windows This command:

Windows `dsmc res backupset my.backupset.file /fs/h1/m1/ /u/ann/ -su=yes` creates a local backupset file named "my.backupset.file".

Restores these directories and files:

```
c:\ann\h1\m1\file.a
c:\ann\h1\m1\file.b
```

Windows This command:

Windows `dsmc res c:\h1\m1\ c:\ann\ -preser=nobase.`

Restores these directories and files:

```
c:\ann\file.a
c:\ann\file.b
```

Windows This command:

Windows `dsmc res c:\h1\m1\ c:\ann\ -preser=subtree.`

Restores these directories and files:

```
c:\ann\m1\file.a
c:\ann\m1\file.b
```

Windows This command:

Windows `dsmc res c:\h1\m1\ c:\ann\ -preser=none.`

Restores these directories and files:

```
c:\ann\file.a
c:\ann\file.b
```

Windows This command:

Windows

```
dsmc res c:\h1\m1\ c:\ann\ -su=yes -preser=
complete
```

Restores these directories and files:

```
c:\ann\h1\m1\file.a
c:\ann\h1\m1\file.b
c:\ann\h1\m1\l1\file.x
c:\ann\h1\m1\l1\file.y
```

Windows This command:

Windows `dsmc res c:\h1\m1\ c:\ann\ -su=yes -preser=nobase.`

Restores these directories and files:

```
c:\ann\file.a
c:\ann\file.b
c:\ann\l1\file.x
c:\ann\l1\file.y
```

Windows This command:

Windows `dsmc res c:\h1\m1\ c:\ann\ -su=yes -preser=subtree.`

Restores these directories and files:

```
c:\ann\m1\file.a
c:\ann\m1\file.b
c:\ann\m1\l1\file.x
c:\ann\m1\l1\file.y
```

Windows This command:

Windows `dsmc res c:\h1\m1\ c:\ann\ -su=yes -preser=none.`

Restores these directories and files:

```
c:\ann\file.a
c:\ann\file.b
c:\ann\file.x
c:\ann\file.y
```

Windows This command:

Windows

```
dsmc res backupset c:\h1\m1\ c:\ann\ -su=yes
-preser=nobase -loc=file
```

Restores these directories and files:

```
c:\ann\file.a
c:\ann\file.b
c:\ann\file.x
c:\ann\file.y
```

AIX Linux Windows

Presnapshotcmd

The presnapshotcmd option allows you to run operating system commands before the backup-archive client starts a snapshot.

This allows you to quiesce an application before the client starts the snapshot during a snapshot-based backup or archive.

Windows This option can be used in conjunction with the postsnapshotcmd option to allow you to quiesce an application while a snapshot is created, and then to restart that application after the snapshot is started. This option is only valid if OFS or online image backup has been configured.

AIX AIX® only: This option is only applicable to JFS2 snapshot-based file backup or archive and snapshot-based image backup. For a snapshot-based file backup or archive, use this option with the backup command, the include.fs option, or in the dsm.sys file.

Linux Linux only: This option is only valid if the LVM is installed and configured on your system, allowing you to perform a snapshot-based image backup.

AIX Linux AIX and Linux only: For a snapshot-based image backup, use this option with the backup image command, the include.image option, or in the dsm.sys file.

Windows For an online image backup, use this option with the backup image command, the include.image option, or in the dsm.opt file.

Windows For open file support operations, use the presnapshotcmd option in an include.fs statement or in your client options file (dsm.opt).

If the presnapshotcmd fails it is assumed that the application is not in a consistent state and the client stops the operation and display the appropriate error message.

Windows Attention: During image backup operations or snapshot differential backup operations, if the command that you include on either the presnapshotcmd or postsnapshotcmd statement starts an asynchronous process, the command might not complete before the backup operation finishes. If the command does not complete before the backup completes, temporary files might be locked, which prevents them from being deleted. A database event occurs and the following message is recorded in the dsmerror.log file:

```
ANS0361I DIAG: ..\..\common\db\cacheobj.cpp( 777): dbDelete():
 remove('C:\adsm.sys\SystemExcludeCache__24400820.TsmCacheDB'):
  errno 13: "Permission denied".
```

The file that is specified in the message (cacheobj.cpp) can be manually deleted after the command that was started by the presnapshotcmd or postsnapshotcmd option completes.

Supported Clients

AIX Linux This option is valid for AIX JFS2 and Linux x86_64 clients only. The IBM Spectrum Protect™ API does not support this option. The server can also define this option.

Windows This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option. The server can also define this option.

Options File

AIX Linux Place this option in the client system-options file (dsm.sys) within a server stanza. You can set also this option on the **Image-Snapshot** tab of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set also this option on the Image-Snapshot tab of the Preferences editor.

Syntax

```
>>---PRESNAPshotcmd---- --"cmdstring"--------------------------><
```

Parameters

AIX Linux "cmdstring"

AIX Linux Specifies a command to process.

Use the srvprepostsnapdisabled option to prevent the IBM Spectrum Protect server administrator from running operating system commands on the client system.

If the command string contains blanks, enclose the command string in quotation marks:

```
"quiesce database myDb"
```

If you placed quotation marks within the command string, then enclose the entire command string in single quotation marks:

```
'resume database "myDb"'
```

Windows "cmdstring"

Windows Specifies the quiesce command to process.

Use a blank, or null, string for "cmdstring" if you want to prevent any commands from running that the administrator uses for presnapshotcmd. If you specify a blank or null string, it prevents the administrator from using a command on this option. If your administrator uses a blank or null string on the presnapshotcmd option, you cannot run a pre-snapshot command.

Use the srvprepostsnapdisabled option to prevent the IBM Spectrum Protect server administrator from running operating system commands on the client system.

If the command string contains blanks, enclose the command string in quotation marks:

```
"quiesce database myDb"
```

If you placed quotation marks within the command string, then enclose the entire command string in single quotation marks:

```
'resume database "myDb"'
```

Examples

AIX Linux Options file:

AIX Linux

```
presnapshotcmd "any shell command or script"
```

Windows Options file:

Windows

```
presnapshotcmd "<insert your application quiesce command here>
  application"
```

The command string is a valid command for quiescing your application.

AIX Linux Command line:

AIX Linux

```
backup image -presnapshotcmd="any shell command or script"
```

Windows Command line:

Windows

```
backup image -presnapshotcmd="<insert your application quiesce command
  here> application"
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Queryschedperiod

The queryschedperiod option specifies the number of hours you want the client scheduler to wait between attempts to contact the server for scheduled work.

This option applies only when you set the schedmode option to polling. This option is used only when the scheduler is running.

Your administrator can also set this option. If your administrator specifies a value for this option, that value overrides the value set in your client options file after your client node successfully contacts the server.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option. The server can also define this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza.

Windows Place this option in the client options file (dsm.opt).

Syntax

```
>>-QUERYSCHedperiod-- --hours---------------------------------><
```

Parameters

hours
: Specifies the number of hours the client scheduler waits between attempts to contact the server for scheduled work. The range of values is 1 through 9999; the default is 4.

Example

Options file:

```
querysch 6
```

Querysummary

The querysummary option provides statistics about files, directories and objects that are returned by the query backup or query archive commands.

The following statistics are provided by the querysummary option:

- The aggregate number of files and directories that are returned by the query backup or query archive command
- The aggregate amount of data of the objects that are returned by the query backup or query archive command
- The classic restore memory-utilization estimate to restore objects that are returned by the query backup or query archive command
- The total number of unique server volumes where the objects that are returned by the query command reside

Windows Single objects that span multiple volumes only include one volume in the total number of volumes statistics. For example, if `c:\bigfile` spans two volumes, only one of the volumes is counted in the estimated number of volumes.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-QUERYSUMMARY-----------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

AIX Linux Solaris Mac OS X

Command line:

AIX Linux Solaris Mac OS X `dsmc q ba '/usr/fs1/*' -sub=yes -querysummary`

AIX Linux Solaris Mac OS X

```
[root@kaveri:/home/cpark] $ dsmc q ba '/kalafs1/*' -sub=yes -querysummary
IBM Spectrum Protect
```

```

Quiet

The quiet option limits the number of messages that are displayed on your screen during processing..

For example, when you run the incremental, selective, or archive commands, information might appear about each file that is backed up. Use the quiet option if you do not want to display this information

When you use the quiet option, error and processing information appears on your screen, and messages are written to log files. If you do not specify quiet, the default option, verbose is used.

Supported Clients

This option is valid for all clients. The server can also define the quiet option, overriding the client setting. The IBM Spectrum Protect™ API does not support this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the client user-options file (dsm.opt). You can set this option on the Command Line tab, Do not display process information on screen checkbox of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Command Line tab, Do not display process information on screen checkbox of the Preferences editor.

Syntax

```
>>-QUIET-----------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Options file:

```
quiet
```

Command line:

```
-quiet
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Quotesareliteral

The quotesareliteral option specifies whether single quotation marks (') or double quotation marks (") are interpreted literally, when they are included in a file list specification on a filelist option.

Ordinarily, the client requires you to use single or double quotation marks to delimit file specifications that contain space characters. Some file systems allow single and double quotation marks in file and directory names.

To prevent errors that would otherwise occur, when file specifications are included on a filelist option and they contain single quotation marks (') or double quotation marks (") , set `quotesareliteral yes`. When quotesareliteral is set to yes, quotation marks that are included in a file list specification on a filelist option are interpreted literally, as quotation marks, and not as delimiters.

This option applies to any command that accepts a filelist option as command parameter.

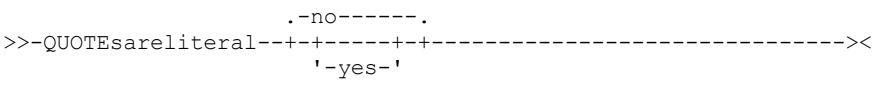
Supported Clients

This option is valid for all supported platforms. The option is applied to any command that takes a file list specification as a parameter.

Options File

Place this option in the client user options file (dsm.opt).

Syntax



Parameters

no
: Specifies that single quotation marks (') and double quotation marks (") are interpreted as delimiters for file list specifications included on a filelist option. No is the default setting.

yes
: Specifies that single quotation marks (') and double quotation marks (") are interpreted literally, and not as delimiters, for file list specifications that are included on a filelist option. Specify this value if you are backing up files from a file system that allows quotation marks in file or directory names.

Examples

Options file:

```
QUOTESARELITERAL YES
```

Windows Command line:

Windows Assuming that the file system allows quotation marks in paths, the following are examples of files in a file list specification that can be successfully processed if QUOTESARELITERAL is set to YES.

Windows Assume the command that is issued is `dsmc sel -filelist=c:\important_files.txt`, where important_files.txt contains the list of files to process.

Windows important_files.txt contains the following list of files:

```
c:\home\myfiles\"file"1000
c:\home\myfiles\'file'
c:\home\myfiles\file'ABC
c:\home\myfiles\ABC"file"
```

AIX Linux Mac OS X Solaris Command line:

AIX Linux Mac OS X Solaris Assuming that the file system allows quotation marks in paths, the following are examples of files in a file list specification that can be successfully processed if QUOTESARELITERAL is set to YES

AIX | Linux | Mac OS X | Solaris Assume the command that is issued is `dsmc sel -filelist=/home/user1/important_files`, where important_files.txt contains the list of files to process.

AIX | Linux | Mac OS X | Solaris

```
/home/user1/myfiles/"file"1000
/home/user1/myfiles/'file'
/home/user1/myfiles/file'ABC
/home/user1/myfiles/ABC"file"
```

AIX | Linux | Solaris | Mac OS X

Removeoperandlimit

The removeoperandlimit option specifies that the client removes the 20-operand limit.

If you specify the removeoperandlimit option with the incremental, selective, or archive commands, the 20-operand limit is not enforced and is restricted only by available resources or other operating system limits.

The removeoperandlimit option can be useful if you generate scripts which can invoke the command-line client with a large number of operands. For example, you can prescan a directory tree looking for files to back up. As each *eligible* file is discovered, it is added to the operand list of a selective command. Later, this selective command is submitted by a controlling script. In this case, specifying the removeoperandlimit option removes the 20-operand limit.
Note:

1. The removeoperandlimit option *must* be placed immediately after the incremental, selective, or archive command before any file specifications.
2. This option does not accept a value. If this option is specified on a command, the 20-operand limit is removed.
3. Because it adversely affects performance to allow the shell to expand wild cards, use the removeoperandlimit option in backup or archive operations in which wild cards are not used.
4. The removeoperandlimit option is valid only on the incremental, selective, or archive commands in batch mode. It is not valid in the client options file (dsm.opt) or dsm.sys file.

Supported Clients

This option is valid for all UNIX and Linux clients.

Syntax

```
>>-REMOVEOPerandlimit-----------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Command line:

```
-removeoperandlimit
```

Replace

The replace option specifies whether to overwrite existing files on your workstation, or to prompt you for your selection when you restore or retrieve files.

Important: The replace option does not affect recovery of directory objects. Directory objects are always recovered, even when specifying replace=no. To prevent overwriting existing directories, use the filesonly option.

You can use this option with the following commands:

- restore
- restore backupset
- restore group

- retrieve

Note: Replace prompting does not occur during a scheduled operation. If you set the replace option to prompt, the backup-archive client skips files without prompting you during a scheduled operation.
AIX Linux Solaris Mac OS X Windows

Supported Clients

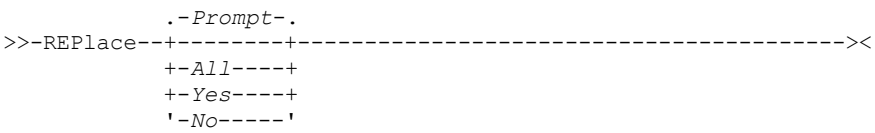
This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the client user-options file (dsm.opt). You can set this option on the Restore tab, Action for files that already exist section of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Restore tab, Action for files that already exist section of the Preferences editor.

Syntax



Parameters

Prompt
: For nonscheduled operations, you specify whether to overwrite existing files. For scheduled operations, existing files are not overwritten and no prompts are displayed. This is the default.

AIX Linux Solaris Mac OS X All
: AIX Linux Solaris Mac OS X All existing files are overwritten, including read-only files. If access to a file is denied, you are prompted to skip or overwrite the file. No action is taken on the file until there is a response to the prompt.

Windows All
: Windows All existing files are overwritten, including read-only files. All locked files are replaced when the system is rebooted. If access to a file is denied, you are prompted to skip or overwrite the file. No action is taken on the file until there is a response to the prompt.

Yes
: Existing files are overwritten, *except* read-only files. For nonscheduled operations, you specify whether to overwrite existing read-only files. For scheduled operations, existing read-only files are not overwritten and no prompts are displayed. If access to a file is denied, the file is skipped.

Windows No
: Windows Existing files are not overwritten. No prompts are displayed.

  Mac OS X **Note:** When restoring or retrieving files with the replace option set to no, existing files are not overwritten, but existing directories are overwritten. To leave existing directories intact during a restore or retrieve operation, select the Options > All selected files and directories > Files only from the backup-archive client GUI.

AIX Linux Solaris Mac OS X No
: AIX Linux Solaris Mac OS X Existing files are not overwritten. No prompts are displayed.

Windows Note: You can choose to replace locked files when the system is rebooted. The client cannot perform an in-place restore of active files. However, it stages restored versions of active files for replacement during the next reboot, except for files containing named streams, sparse files, and directories. You can only restore these files if they are unlocked.

Examples

Options file:
```
replace all
```
Command line:
```
-replace=no
```

This option is valid on the initial command line and in interactive mode. If you use this option in interactive mode, it affects only the command with which it is specified. When that command completes, the value reverts to the value at the beginning of the interactive session. This is the value from the dsm.opt file unless overridden by the initial command line or by an option forced by the server.

Replserverguid

The replserverguid option specifies the globally unique identifier (GUID) that is used when the client connects to the secondary server during failover. The GUID is used to validate the secondary server to ensure that it is the expected server.

The replication GUID is different from the machine GUID of the server. It is generated one time for a server that is doing the replication and never changes.

This option must be specified within a replservername stanza in the client options file. The replservername stanza contains connection information about the secondary server.

This option is set by the IBM Spectrum Protect™ server administrator for the client node. During the normal (non-failover) logon process, the option is sent to the client and is saved in the client options file.

Do not edit this option during normal operations.

Edit this option only during situations such as the following ones:

- The primary server is offline and the information for the secondary server is not in the options file.
- The secondary server information is out-of-date or incorrect.

Any values that you edit are removed or updated the next time you log in to the primary server.

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X This option is placed in the dsm.sys file within the replservername stanza.

Windows This option is placed in the client options file (dsm.opt).

Syntax

```
>>-replserverguid----serverguid--------------------------------><
```

Parameters

serverguid
: Specifies the GUID of the secondary server that is used during a failover.

Examples

Options file:

```
REPLSERVERGUID 91.0f.ef.90.5c.cc.11.e1.ae.34.08.00.00.00.00.02
```

Command line:

Does not apply.

AIX Linux Mac OS X Solaris Options file:

AIX Linux Mac OS X Solaris The following example demonstrates how to specify options for three different servers in the dsm.sys file, and how to reference the secondary server. Connection information for multiple secondary server is presented in stanzas. Each stanza is identified by the replservername option and the name of the secondary server. The servername stanza must contain the myreplicationserver option, which points to the secondary server that is specified by the replservername stanza. Only one secondary server can be specified per servername stanza.

```
REPLSERVERNAME    TargetReplicationServer1
  REPLTCPSERVERADDRESS TargetReplicationServer1
```

```
  REPLTCPPORT          1505

Replservername

The replservername option specifies the name of the secondary server that the client connects to during a failover.

The replservername option begins a stanza in the client options file that contains connection information about the secondary server.

This option is set by the IBM Spectrum Protect™ server administrator for the client node. During the normal (non-failover) logon process, the option is sent to the client and is saved in the client options file.

Do not edit this option during normal operations.

Edit this option only during situations such as the following ones:

- The primary server is offline and the information for the secondary server is not in the options file.
- The secondary server information is out-of-date or incorrect.

Any values that you edit are removed or updated the next time you log in to the primary server.

Supported Clients

This option is valid for all clients.

Options File

AIX | Linux | Solaris | Mac OS X This option is placed in the client-system options dsm.sys.

Windows This option is placed in the client options file (dsm.opt).

Syntax

```
>>-replservername----repl_servername---------------------------><
```

Parameters

repl_servername
Specifies the name of the secondary server to be used during a failover. This value is usually the name of the secondary server, not the host name of the server.

Examples

Options file:

```
REPLSERVERName TargetReplicationServer1
```

Command line:

Does not apply.

AIX | Linux | Mac OS X | Solaris Options file:

AIX | Linux | Mac OS X | Solaris The following example demonstrates how to specify options for three different servers in the dsm.sys file, and how to reference the secondary server. Connection information for multiple secondary server is presented in stanzas. Each stanza is identified by the replservername option and the name of the secondary server. The servername stanza must contain the myreplicationserver option, which points to the secondary server that is specified by the replservername stanza. Only one secondary server can be specified per servername stanza.

```
REPLSERVERNAME    TargetReplicationServer1
  REPLTCPSERVERADDRESS TargetReplicationServer1
  REPLTCPPORT          1505
  REPLSSLPORT          1506

Replsslport

The replsslport option specifies the TCP/IP port on the secondary server that is SSL-enabled. The replsslport option is used when the client connects to the secondary server during a failover. This option is deprecated if you are connecting to an IBM Spectrum Protect™ server V8.1.2 and later.

The replsslport option is sent to the client by the primary server only if the secondary server is configured for SSL.

This option is applicable only when the client is configured to use SSL for secure communications between the IBM Spectrum Protect server and client. If the client is not configured to use SSL, the port that is specified by the repltcpport option is used. You can determine whether the client uses SSL by verifying the SSL client option.

This option must be specified within a replservername stanza in the client options file. The replservername stanza contains connection information about the secondary server.

During the normal (non-failover) logon process, this option is sent to the client and is saved in the client options file.

Do not edit this option during normal operations.

Edit this option only during situations such as the following ones:

- The primary server is offline and the information for the secondary server is not in the options file.
- The secondary server information is out-of-date or incorrect.

Any values that you edit are removed or updated the next time you log in to the primary server.

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X This option is placed in the dsm.sys file within the replservername stanza.

Windows This option is placed in the client options file (dsm.opt).

Syntax

```
>>-replsslport----port_address---------------------------------><
```

Parameters

port_address
: Specifies the TCP/IP port address that is enabled for SSL and that is used to communicate with the secondary server.

Examples

Options file:

```
REPLSSLPORT 1506
```

Command line:

Does not apply.

Repltcpserveraddress

The repltcpserveraddress option specifies the TCP/IP address of the secondary server to be used when the client connects to the secondary server during a failover.

This option must be specified within a replservername stanza in the client options file. The replservername stanza contains connection information about the secondary server.

This option is set by the IBM Spectrum Protect™ server administrator for the client node. During the normal (non-failover) logon process, the option is sent to the client and is saved in the client options file.

Do not edit this option during normal operations.

Edit this option only during situations such as the following ones:

- The primary server is offline and the information for the secondary server is not in the options file.
- The secondary server information is out-of-date or incorrect.

Any values that you edit are removed or updated the next time you log in to the primary server.

Supported Clients

This option is valid for all clients.

Options File

AIX | Linux | Solaris | Mac OS X This option is placed in the dsm.sys file within the replservername stanza.

Windows Place this option in the client options file (dsm.opt).

Syntax

```
>>-REPLTCPServeraddress----server_address----------------------><
```

Parameters

server_address

Specifies a TCP/IP address for a server that is 1 - 64 characters in length. Specify a TCP/IP domain name or a numeric IP address. The numeric IP address can be either a TCP/IP v4 or TCP/IP v6 address. You can use only IPv6 addresses if you specified the `commmethod V6Tcpip` option.

Examples

Options file:

```
REPLTCPServeraddress dsmchost.example.com
```

Command line:

Does not apply.

AIX | Linux | Mac OS X | Solaris Options file:

Windows

Resetarchiveattribute

Use the resetarchiveattribute option to specify whether the backup-archive client resets the Windows archive attribute on files that are successfully backed up to the IBM Spectrum Protect™ server.

The client also resets the archive attribute during incremental backups if it is determined that there is already an active object on the server. The resetarchiveattribute option is useful in conjunction with applications, such as IBM Spectrum Control™, as a simple way to report on the backup status of files.

The Windows archive attribute is used to indicate that a file has changed since the last backup. After the client resets the archive attribute, the Windows operating system turns the attribute back to ON after the file has been modified. The client does not use the Windows archive attribute to determine if a file is a candidate for incremental backup, but only manipulates this attribute for reporting purposes. The client uses a much more sophisticated method to determine candidacy for incremental backup.

There are several applications which manipulate or examine the Windows archive attribute. Be aware of the ramifications of using the resetarchiveattribute option in conjunction with these products.

If you set the resetarchiveattribute option to yes, after a file has been successfully backed up to the IBM Spectrum Protect server, the client resets the Windows archive attribute on the local file system:

- The Windows archive attribute is reset during incremental and selective backups after the file has been successfully committed to the IBM Spectrum Protect server database. This attribute is not reset for archive, or image operations.
- The Windows archive attribute is not reset when processing system objects or system state objects.
- The Windows archive attribute is not reset for directory entries.

In addition, in order for the local file system to reflect the current active object inventory on the IBM Spectrum Protect server, the resetarchiveattribute option instructs the client to reset the Windows archive attribute on the local file system if it is determined

during incremental backup that a valid, active backup copy of the file already exists on the server. This behavior is not displayed in the following cases:

- Incremental backup operations which do not examine the stored client attributes on the server, such as journal-based backup or incremental-by-date processing.
- Files that are not examined during an incremental backup operation because they are excluded from backup processing.

The client does not guarantee the accuracy of the current setting of the Windows archive attribute. For example, if the resetarchiveattribute option is set to yes and a file examined by a reporting product indicates that the Windows archive attribute is OFF for a particular file, this does not necessarily mean that a valid, active backup copy of the file exists on the IBM Spectrum Protect server. Factors that could contribute to this type of situation include:

- An independent software vendor product is manipulating the Windows archive attribute
- A file space was deleted from the server
- A backup tape was lost or destroyed

There should be no significant performance degradation when using the resetarchiveattribute option. The resetarchiveattribute option does not affect restore processing.

Supported Clients

This option is valid for all Windows clients. The server can also define this option.

Options File

This option is valid in the client options file (dsm.opt) or server client options set. You can set this option on the Backup tab of the Preferences editor.

Syntax

```
                            .-No--.
>>-RESETARCHIVEATTRibute = -+-----+----------------------------><
                            '-Yes-'
```

Parameters

Yes
: Specifies that you want to reset the Windows archive attribute for files during a backup operation.

No
: Specifies that you do not want to reset the Windows archive attribute for files during a backup operation. This is the default.

Examples

Options file:

```
resetarchiveattribute yes
```

Resourceutilization

Use the resourceutilization option in your option file to regulate the level of resources the IBM Spectrum Protect™ server and client can use during processing.

Supported Clients

This option is valid for all clients. The server can also define this option. The IBM Spectrum Protect API does not support this option.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the dsm.sys file within a server stanza. You can set this option on the General tab, in the Resource Utilization field of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the General tab, in the Resource Utilization field of the Preferences editor.

Syntax

```
>>-RESOURceutilization-- --number-----------------------------><
```

Parameters

number
: Specifies the level of resources the IBM Spectrum Protect server and client can use during processing. The range of values that you can specify is 1 - 100. The default value is 2.

Examples

Options file:
```
resourceutilization 7
```

Command line:
```
-resourceutilization=7
```

This option is valid only on the initial command line. It is not valid in interactive mode.

- Regulating backup and archive sessions
  When you request a backup or archive, the client can use more than one session to the server.
- Regulating restore sessions
  When you request a restore, the default is to use a maximum of one session.
- Multiple client session considerations
  This topic lists some items to consider when working with multiple client sessions.

Regulating backup and archive sessions

When you request a backup or archive, the client can use more than one session to the server.

The default is to use a maximum of two sessions; one to query the server and one to send file data. The client can use only one server session if you set the resourceutilization option to 1.

A client can use more than the default number of sessions when it connects to the IBM Spectrum Protect™ server. For example, `resourceutilization 10` permits up to eight sessions with the server. Multiple sessions can be used for querying the server and sending file data.

Multiple query sessions are used when you specify multiple file specifications with a backup or archive command. For example, if you enter the following commands and you specify `resourceutilization 5`, the client might start a second session to query files on file space `B`.

```
inc /Volumes/filespaceA /Volumes/filespaceB
```

Whether the second session starts depends on how long it takes to query the server about files that are backed up on file space `A`. The client might also try to read data from the file system and send it to the server on multiple sessions.

Note: During a backup operation, if you enter multiple file specifications, the result might be that files from one file specification are stored on multiple tapes and interspersed with files from different file specifications. This can decrease restore performance. Setting the collocatebyfilespec option to yes eliminates interspersing of files from different file specifications, by limiting the client to one server session per file specification. Therefore, if you store the data to tape, files for each file specification are stored together on one tape (unless another tape is required for more capacity).

Regulating restore sessions

When you request a restore, the default is to use a maximum of one session.

Additional restore sessions are based on:

- resourceutilization value
- how many tapes on which the requested data is stored
- how many tape drives are available
- the maximum number of mount points that are allowed for the node

Note:

1. If all of the files are on disk, only one session is used. There is no multi-session for a pure disk storage pool restore. However, if you are performing a restore in which the files are on 4 tapes and others are on disk, you could use up to 5 sessions during the restore.
2. The IBM Spectrum Protect™ server can set the maximum number of mount points a node can use on the server by using the MAXNUMMP parameter. If the resourceutilization option value exceeds the value of the MAXNUMMP on the server for a node, the backup can fail with an `Unknown System Error` message.
3. You can get a multi-session restore from your single restore command, and from a single volume on the server, if that volume is device class FILE.

For example, if the data you want to restore is on 5 different tape volumes, the maximum number of mount points is 5 for your node, and resourceutilization is set to 3, then 3 sessions are used for the restore. If you increase the resourceutilization setting to 5, then 5 sessions are used for the restore. There is a 1 to 1 relationship between the number of restore sessions that are allowed and the resourceutilization setting. Multiple restore sessions are only allowed for no-query restore operations.

Multiple client session considerations

This topic lists some items to consider when working with multiple client sessions.

The following factors can affect the throughput of multiple sessions:

- The ability of the server to handle multiple client sessions. Is there sufficient memory, multiple storage volumes, and processor cycles to increase backup throughput?
- The ability of the client to drive multiple sessions (sufficient processor cycles, memory, etc.).
- The configuration of the client storage subsystem. File systems that are striped across multiple disks, using either software striping or RAID-5 can better handle an increase in random read requests than a single drive file system. Additionally, a single drive file system might not see performance improvement if it attempts to handle many random concurrent read requests.
- Sufficient bandwidth in the network to support the increased traffic.

Potentially undesirable aspects of running multiple sessions include:

- The client could produce multiple accounting records.
- The server might not start enough concurrent sessions. To avoid this, the server *maxsessions* parameter must be reviewed and possibly changed.
- A query node command might not summarize client activity.
- It is possible that files are restored instead of hard links.
  Restoring files instead of hard links can occur when the following criteria are all true:
  - You restore an entire file system.
  - During the restore operation, the value of the *resourceutilization* option is greater than 1.
  - The file system contained hard links when the file system was backed up.

  The chance of restoring linked files instead of hard links increases as the number of sessions increases. When you restore a file system that contained hard links when the file system was backed up, set `resourceutilization=1` to ensure that hard links are restored.

Retryperiod

The retryperiod option specifies the number of minutes the client scheduler waits between attempts to process a scheduled command that fails, or between unsuccessful attempts to report results to the server. Use this option only when the scheduler is running.

Windows Your administrator can also set this option. If your administrator specifies a value for this option, that value overrides the value in your client options file after your client node successfully contacts the server.

AIX Linux Solaris Mac OS X Your administrator can also set this option. If your administrator specifies a value for this option, that value overrides the value in your client system options file after your client node successfully contacts the server.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Scheduler tab, in the Retry period field of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Scheduler tab, in the Retry period field of the Preferences editor.

Syntax

```
>>-RETRYPeriod-- --minutes-------------------------------------><
```

Parameters

minutes
: Specifies the number of minutes the client scheduler waits between attempts to contact the server, or to process a scheduled command that fails. The range of values is 1 through 9999; the default is 20.

Examples

Options file:

```
retryp 10
```

Command line:

```
-retryperiod=10
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Revokeremoteaccess

The revokeremoteaccess option restricts an administrator with client access privilege from accessing a client workstation that is running the web client.

This option does not restrict administrators with client owner, system, or policy privilege from accessing your workstation through the web client.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Web Client tab of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Web Client tab of the Preferences editor.

Syntax

```
                        .-None---.
>>-REVOKEremoteaccess--+--------+------------------------------><
                        '-Access-'
```

Parameters

None
: Does not revoke access to administrators who have client access authority for the client. This is the default.

Access
: Revokes access to administrators who have client access authority for the client.

Examples

Options file:

```
revokeremoteaccess none
```

Command line:
: Does not apply.

Windows

Runasservice

The runasservice option forces the client command process to continue running, even if the account that started the client logs off.

Use this option with the AT command and the dsmc sched command when you schedule client command batch jobs. The runasservice option is *not* valid in any options file (dsm.opt or tsmasr.opt).

Important: Use the scheduler service when running IBM Spectrum Protect™ services unattended. Set runasservice=yes only to schedule client commands using the Windows AT command. Setting runasservice=yes might interfere with other interactive uses of the backup-arcchive client.

Supported Clients

This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option.

Syntax

```
                .-No--.
>>-RUNASSERVice--+-----+---------------------------------------><
                '-Yes-'
```

Parameters

No
: Does not force the client command process to continue running, even if the account that started the client logs off. This is the default.

Yes
: Forces the client command process to continue running, even if the account that started the client logs off.

  Restrictions:

  1. When runasservice=yes, the setting for the REPLACE is always overridden to the behavior of replace=no.
  2. The option runasservice=yes cannot be used with passwordaccess=prompt.
  3. Backup, archive, restore and retrieve operations performed with runasservice=yes that encounter prompts always fail. To avoid this problem, either save the encryption key password with encryptkey=save, or turn off the runasservice option.

Examples

Command line:

```
-runasservice=yes
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Schedcmddisabled

The schedcmddisabled option specifies whether to disable the scheduling of commands by the server action=command option on the define schedule server command.

This option does not disable the preschedulecmd and postschedulecmd commands. However, you can specify preschedulecmd or postschedulecmd with a blank or a null string to disable the scheduling of these commands.

You can disable the scheduling of commands defined by your IBM Spectrum Protect™ administrator by setting the schedcmddisabled option to yes.

Use the query schedule command to query the schedules defined by your administrator.

Supported Clients

This option is valid for all clients. The server can also define this option. The IBM Spectrum Protect API does not support this option.

Options File

Windows Place this option in the client options file (dsm.opt).

AIX Linux Solaris Mac OS X Place this option in the dsm.sys file within a server stanza.

Syntax

```
                      .-No--.
>>-SCHEDCMDDisabled--+-----+-----------------------------------><
                      '-Yes-'
```

Parameters

Yes
: Specifies that the server disables the scheduling of commands using the action=command option on the DEFINE SCHEDULE server command.

No
: Specifies that the server does not disable the scheduling of commands using the action=command option on the DEFINE SCHEDULE server command. This is the default.

Examples

Options file:

```
schedcmddisabled no
```

Command line:

Does not apply.

Schedcmdexception

The schedcmexception option is used in conjunction with the schedcmddisabled option to disable the scheduling of commands by the server action=command option on the DEFINE SCHEDULE server command, except for specific command strings.

You must specify the exact string that matches the "objects" definition in the schedule for the scheduled server command to be accepted. If the string does not match exactly (for example, there is an extra space or the capitalization is different), the scheduled command action is blocked.

You can provide multiple schedcmexception options in the options file. This option is not honored if schedcmddisabled is not enabled. The placement of this option in the options file is independent of the placement of the schedcmddisabled option.

Supported Clients

This option is valid for all clients. This option is not valid in the IBM Spectrum Protect™ server client options set.

Options File

Windows Place this option in the client options file (dsm.opt).

AIX Linux Solaris Mac OS X Place this option in the dsm.sys file within a server stanza.

Syntax

```
>>-SCHEDCMDException--string----------------------------------><
```

Parameters

string
: For commands scheduled by the action=command option on the DEFINE SCHEDULE server command, this parameter indicates the objects pattern to enable if the schedcmddisabled=yes option is specified. This parameter is case sensitive, and must match the command string on the IBM Spectrum Protect server schedule definition.

Example

Options file:

```
schedcmddisabled yes
Windows schedcmdexception "start dir c: /s"
schedcmdexception "start echo hello, world!"
```

Schedgroup

The schedgroup option assigns a schedule to a group.

An example of the use of this option is to group multiple daily local backup schedules with a single server backup schedule.

Supported Clients

This option is valid for all clients as a command-line option for the server DEFINE SCHEDULE command. This option cannot be added to a client option set that is on the IBM Spectrum Protect™ server.

Syntax

```
>>-SCHEDGROUP-- --schedule_group_name-------------------------><
```

Parameters

schedule_group_name
: Specifies the name of the schedule group. You can specify up to 30 characters for the name.
For a list of valid characters that you can use in the schedule group name, see Naming IBM Spectrum Protect objects

Examples

The following example commands group schedules SCHED_A_1, SCHED_A_2, SCHED_A_3, and SCHED_A_4 in to schedule group GROUP_A.

Command line:

This example shows a local backup at 6 AM:

```
define schedule standard SCHED_A_1 Type=Client ACTion=Backup SUBACTion=VM OPTions='-
vmfulltype=vstor -vmbackuptype=fullvm -vmbackuplocation=local -domain.vmfull="SCHEDULE-TAG" -
```

```
asnodename=DC_SARTRE_WB -SCHEDGROUP=GROUP_A' STARTDate=02/06/2017 STARTTime=06:00:00
SCHEDStyle=Enhanced DAYofweek=ANY
```

This example shows a local backup at 12 PM:

```
define schedule standard SCHED_A_2 Type=Client ACTion=Backup SUBACTion=VM OPTions='-
vmfulltype=vstor -vmbackuptype=fullvm -vmbackuplocation=local -domain.vmfull="SCHEDULE-TAG" -
asnodename=DC_SARTRE_WB -SCHEDGROUP=GROUP_A' STARTDate=02/06/2017 STARTTime=12:00:00
SCHEDStyle=Enhanced DAYofweek=ANY
```

This example shows a local backup at 6 PM:

```
define schedule standard SCHED_A_3 Type=Client ACTion=Backup SUBACTion=VM OPTions='-
vmfulltype=vstor -vmbackuptype=fullvm -vmbackuplocation=local -domain.vmfull="SCHEDULE-TAG" -
asnodename=DC_SARTRE_WB -SCHEDGROUP=GROUP_A' STARTDate=02/06/2017 STARTTime=18:00:00
SCHEDStyle=Enhanced DAYofweek=ANY
```

This example shows a local and server backup at midnight:

```
define schedule standard SCHED_A_4 Type=Client ACTion=Backup SUBACTion=VM OPTions='-
vmfulltype=vstor -vmbackuptype=fullvm -vmbackuplocation=both -domain.vmfull="SCHEDULE-TAG" -
asnodename=DC_SARTRE_WB -SCHEDGROUP=GROUP_A' STARTDate=02/06/2017 STARTTime=00:00:00
SCHEDStyle=Enhanced DAYofweek=ANY
```

Tip: Ensure that each schedule in the group can complete before the next schedule is set to start.
This option is valid only on the initial command line. It is not valid in interactive mode.

Schedlogmax

The schedlogmax option specifies the maximum size of the schedule log (dsmsched.log) and web client log (dsmwebcl.log), in megabytes.

This option causes the log files that get created for scheduler events (dsmsched.log) and web client events (dsmwebcl.log) to wrap around when they reach their maximum size. As scheduler and web client events are logged, log records are added to the end of the log files until the maximum specified size is reached. When the maximum specified size is reached, a log record saying `Continued at beginning of file` is placed as the last record in the file. Subsequent logging is resumed at the beginning of the file. The end of the wrapped log is indicated by a record saying `END OF DATA`.

When you set the schedlogmax option, scheduler and web client log messages are not saved in a prune file. If you want to prune logs and save the pruned log entries to another file, see the schedlogretention option.

If you change from log wrapping (schedlogmax option) to log pruning (schedlogretention option), all existing log entries are retained and the log is pruned using the new schedlogretention criteria.

If you change from log pruning (schedlogretention option) to log wrapping (schedlogmax option), all records in the existing logs are copied to a file containing the pruned entries. For example, log records pruned from the dsmsched.log file are copied to dsmsched.pru. Log records pruned from dsmwebcl.log are copied to dsmweblog.pru. The existing logs (dsmsched.log and dsmwebcl.log) are emptied, and logging begins using the new log wrapping criteria.

If you simply change the value of the schedlogmax option, the existing log is extended or shortened to accommodate the new size. If the value is reduced, the oldest entries are deleted to reduce the file to the new size.

If neither schedlogmax nor schedlogretention is specified, the error log can grow without any limit on its size. You must manually manage the log contents to prevent the log from depleting disk resources. When the log has been created with neither option specified, if you later issue a command and specify the schedlogretention option, the log is pruned using the retention value specified. When the log has been created with neither option specified, if you later issue a command and specify the schedlogmax option, the existing log is treated as if it was a pruned log. That is, the content of the dsmsched.log file is copied to a file called dsmsched.pru, the content of dsmwebcl.log is copied to a file called dsmwebcl.pru, and new log entries are created in dsmsched.log and dsmwebcl.log, and both files wrap when they reach their maximum size.

Note: If you specify a non-zero value for schedlogmax (which enables log wrapping), you cannot use the schedlogretention option to create pruned logs. Logs can be pruned or wrapped, but not both.
Logs created with the schedlogmax option contain a log header record that contains information similar to this example record:

```
LOGHEADERREC 661  104857600 IBM Spectrum Protect 8.1.0.0 Fri Dec 9 06:46:53 2014
```

Note that the dates and time stamps in the LOGHEADERREC text are not translated or formatted using the settings specified on the dateformat or timeformat options.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza.

Windows Place this option in the client options file (dsm.opt).

AIX Linux Mac OS X Solaris Windows You can also set this option on the Client Preferences > Scheduler tab in the GUI, by selecting Enable scheduler log file wrapping and by specifying a non-zero maximum size for the log file. To prevent log file wrapping, set the maximum size to zero. When the maximum wrapping is set to zero, clearing or setting the Enable scheduler log file wrapping option has no effect; log wrapping does not occur if the maximum size is set to zero.

Syntax

```
>>-SCHEDLOGMAX-- --size----------------------------------------><
```

Parameters

size
: Specifies the maximum size, in megabytes, for the log file. The range of values is 0 to 2047; the default is 0, which disables log file wrapping and allows the log file to grow indefinitely.

Examples

Options file:

```
schedlogmax 100
```

Command line:

```
-schedlogmax=100
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Schedlogname

The schedlogname option specifies the path and file name where you want to store schedule log information.

Use this option only when you want to store schedule log information. This option applies only when the scheduler is running.

If this option is not used, the `dsmsched.log` file is created in the same directory as the `dsmerror.log` file.

When you run the schedule command, output from scheduled commands appears on your screen. Output is also sent to the file you specify with this option. If any part of the path you specify does not exist, the client attempts to create it.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Scheduler tab, in the Schedule Log text box, in the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Scheduler tab, in the Schedule Log text box, in the Preferences editor.

AIX Linux Solaris Mac OS X

Note: Set the `DSM_LOG` environment variable to name a directory where the log is to be placed. The directory specified must have permissions which allow write access from the account under which the client is run. The root directory is not a valid value for

DSM_LOG.

Windows

Note: Set the DSM_LOG environment variable to name a directory where the log is to be placed. The directory specified must have permissions which allow write access from the account under which the client is run.

Syntax

```
>>-SCHEDLOGName-- --filespec-----------------------------------><
```

Parameters

filespec

Specifies the path and file name where you want to store schedule log information when processing scheduled work. If any part of the path you specify does not exist, the client attempts to create it.

Windows If you specify a file name only, the file is stored in your current directory. The default is the current working directory with a file name of `dsmsched.log`.

AIX Linux Solaris Mac OS X If you specify a file name only, the file is stored in your current directory. The default is the current working directory with a file name of `dsmsched.log`. The `dsmsched.log` file *cannot* be a symbolic link.

Mac OS X For Mac OS X, if you specify a file name only, the file is stored in your default folder. The default directories are:

```
~/Library/Logs/tivoli/tsm
/Library/Logs/tivoli/tsm
```

Examples

Options file:

Mac OS X

```
SCHEDLOGN /Users/user1/Library/Logs/schedlog.jan
```

AIX Linux Solaris Mac OS X

```
schedlogname /home/mydir/schedlog.jan
```

Windows

```
schedlogname c:\mydir\schedlog.jan
```

Mac OS X Command line:

Mac OS X `-schedlogname=/Users/user1/Library/Logs/schedlog.jan`

AIX Linux Solaris Mac OS X Command line:

AIX Linux Solaris Mac OS X `-schedlogname=/home/mydir/schedlog.jan`

Windows Command line:

Windows `-schedlogn=c:\mydir\schedlog.jan`

This option is valid only on the initial command line. It is not valid in interactive mode.

Schedlogretention

The schedlogretention option specifies the number of days to keep entries in the schedule log (dsmsched.log) and the web client log (dsmwebcl.log), and whether to save the pruned entries in another file.

The schedule log (dsmsched.log) is pruned when the scheduler starts and after a scheduled event completes. Pruned entries are written to a file called dsmsched.pru.

The web client log (dsmwebcl.log) is pruned during the initial start of the client acceptor daemon. Pruned entries are written to a file called dsmwebcl.pru.

If you change from log pruning (schedlogretention option) to log wrapping (schedlogmax option), all records in the existing log are copied to the pruned log (dsmsched.pru and dsmwebcl.pru), and the existing logs (dsmsched.log and dsmwebcl.log) are emptied, and logging begins using the new log wrapping criteria.

If you change from log wrapping (schedlogmax option) to log pruning (schedlogretention option), all existing log entries are retained and the log is pruned using the new schedlogretention criteria. Pruned entries are saved in their corresponding *.pru files.

If neither schedlogmax nor schedlogretention is specified, the logs can grow without any limit on their size. You must manually manage the log contents to prevent the log from depleting disk resources. When the log has been created with neither option specified, if you later issue a command and specify the schedlogretention option, the log is pruned using the retention value specified. When the log has been created with neither option specified, if you later issue a command and specify the schedlogmax option, the existing log is treated as if it was a pruned log. That is, the content of the dsmsched.log file is copied to a file called dsmsched.pru, the content of dsmwebcl.log is copied to dsmwebcl.pru, and new log entries are created in both dsmsched.log and dsmwebcl.log, and both files wrap when they reach their maximum size.

Note: If you specify schedlogretention option to create pruned logs, you cannot specify the schedlogmax option. Logs can be pruned or wrapped, but not both.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza.

Windows Place this option in the client options file (dsm.opt).

AIX Linux Mac OS X Solaris Windows You can also set this option on the Client preferences > Scheduler tab in the GUI, by selecting Prune old entries and by specifying a value for Prune entries older than. Selecting the Save pruned entries option saves the pruned scheduler log entries in the dsmsched.pru log file. Selecting Save pruned entries also saves web client log entries in the dsmwebcl.pru log file.

Syntax

```
                        .-N----.  .-D-.
>>-SCHEDLOGRetention--+------+--+---+-------------------------><
                      '-days-'  '-S-'
```

Parameters

N or days
: Specifies how long to wait before pruning the log.

  N
  : Do not prune the log. This permits the log to grow indefinitely. This is the default.

  days
  : Specifies the number of days to keep log file entries before pruning. The range of values is zero through 9999.

D or S
: Specifies whether to save the pruned entries. Use a space or comma to separate this parameter from the previous one.

  D
  : Discards the log entries when pruning the log. This is the default.

  S
  : Saves the log entries when pruning the log.

    Pruned entries are copied to the file of pruned entries (dsmsched.pru or dsmsched.pru), which is stored in the same directory as the log.

Examples

Options file:
```
schedlogretention 30 S
```
Command line:
```
-schedlogretention=30,S
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Schedmode

The schedmode option specifies whether you want to use the polling mode (your client node periodically queries the server for scheduled work), or the prompted mode (the server contacts your client node when it is time to start a scheduled operation).

All communication methods can use the client polling mode, but only TCP/IP can use the server prompted mode.

This option applies only if you are using the TCP/IP communication method, and the schedule command is running.

Windows Your administrator can specify that the server support both modes or just one mode. If your administrator specifies that both modes are supported, you can select either schedule mode. If your administrator specifies only one mode, you must specify that mode in your dsm.opt file or scheduled work is not processed.

AIX Linux Solaris Mac OS X Your administrator can specify that the server support both modes or just one mode. If your administrator specifies that both modes are supported, you can select either schedule mode. If your administrator specifies only one mode, you must specify that mode in your dsm.sys file or scheduled work is not processed.

Windows If you specify prompted mode, you should consider supplying values for the tcpclientaddress and tcpclientport options in your dsm.opt file or on the schedule command; the client can then be contacted at either an address or a port of your choice (useful for client systems with multiple network interface cards).

AIX Linux Solaris Mac OS X If you specify prompted mode, you should consider supplying values for the tcpclientaddress and tcpclientport options in your dsm.sys file or on the schedule command; the client can then be contacted at either an address or a port of your choice (useful for client systems with multiple network interface cards).

Note:

1. Windows When changing the setting of this option in the client options file (dsm.opt) you must stop and restart the scheduler service for the setting to take effect.
2. AIX Linux Solaris Mac OS X When changing the setting of this option in the dsm.sys file you must stop and restart the scheduler service for the setting to take effect.
3. The server can also define this option.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Scheduler tab, in the Schedule Mode section in the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Scheduler tab, in the Schedule Mode section in the Preferences editor.

Syntax

```
              .-POlling--.
>>-SCHEDMODe--+----------+-------------------------------------><
              '-PRompted-'
```

Parameters

POlling
: The client scheduler queries the server for scheduled work at prescribed time intervals. This is the default. You can set the time intervals using the queryschedperiod option.

AIX Linux Solaris Mac OS X Windows PRompted

AIX | Linux | Solaris | Mac OS X | Windows The client scheduler waits for the server to contact your client node when scheduled work needs to be done.
Note:

1. Windows Use schedmode prompted in conjunction with the autodeploy option, to enable the scheduler to process the client deployment schedule immediately.
2. If you use the dsmc schedule command and both schedmode prompted and commmethod V6Tcpip are specified, the client and IBM Spectrum Protect™ server must be configured for IPv6. Additionally, the client host name must be set up for the IPv6 address.

Examples

Options file:

```
schedmode prompted
```

Command line:

```
-schedmod=po
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Related reference:
Windows Autodeploy
Cadlistenonport
Tcpclientaddress
Tcpclientport

Schedrestretrdisabled

The schedrestretrdisabled option specifies whether to disable the execution of restore or retrieve schedule operations.

Supported Clients

This option is valid for all clients. The server cannot define this option. The IBM Spectrum Protect™ API does not support this option.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the dsm.sys file within a server stanza for the scheduler. You can set this option on the Scheduler tab in the Schedule Command section in the Preferences editor.

Windows Place this option in the client options file (dsm.opt) for the scheduler. You can set this option on the Scheduler tab in the Schedule Command section in the Preferences editor.

Syntax

```
                          .-No--.
>>-SCHEDRESTRETRDisabled--+-----+------------------------------><
                          '-Yes-'
```

Parameters

No
: Specifies that the client does not disable the execution of restore and retrieve schedule operations. This parameter is the default.

Yes
: Specifies that the client disables the execution of restore and retrieve schedule operations.

Examples

Options file:

```
schedrestretrdisabled yes
```

Command line:

Does not apply.

Scrolllines

The scrolllines option specifies the number of lines of information that are displayed on your screen at one time.

Use this option when you set the scrollprompt option to Yes.

You can use the scrolllines option with the following commands only:

- delete filespace
- query archive
- query backup
- query backupset
- query filespace
- query group
- AIX Linux Solaris Windows query image
- AIX Linux Solaris Mac OS X Windows query nas
- AIX Linux Solaris Mac OS X Windows query node
- query options

Supported Clients

This option is valid for all clients. The server can also define this option. The IBM Spectrum Protect™ API does not support this option.

Options File

Place this option in the client user-options file (dsm.opt). You can set this option in Command Line > Number of lines to display in the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option in Command Line > Number of lines to display in the Preferences editor.

Syntax

```
>>-SCROLLLines-- --number---------------------------------------><
```

Parameters

number
: Specifies the number of lines of information that are displayed on your screen at one time. The range of values is 1 through 80; the default is 20.

Examples

Options file:

```
scrolllines 25
```

Command line:

```
-scrolll=25
```

This option is valid on the initial command line and in interactive mode. If you use this option in interactive mode, it affects only the command with which it is specified. When that command completes, the value reverts to the value at the beginning of the interactive session. This is the value from the dsm.opt file unless overridden by the initial command line or by an option forced by the server.

Scrollprompt

The scrollprompt option specifies whether you want the bakup-archive client to stop and wait after displaying the number of lines of information you specified with the scrolllines option, or scroll through and stop at the end of the information list.

You can use the scrollprompt option with the following commands only:

- delete filespace
- query archive
- query backup
- query backupset
- query filespace
- query group
- AIX Linux Solaris Windows query image
- AIX Linux Solaris Mac OS X Windows query nas
- AIX Linux Solaris Mac OS X Windows query node
- query options

Supported Clients

This option is valid for all clients. The server can also define this option. The IBM Spectrum Protect™ API does not support this option.

Options File

Place this option in the client user-options file (dsm.opt). You can set this option on the Command Line tab, Pause after displaying the following number of lines field of the Preferences editor.

Syntax

```
                .-No--.
>>-SCROLLPrompt--+-----+---------------------------------------><
                '-Yes-'
```

Parameters

No
: Scrolls to the end of the list and stops. This is the default.

Yes
: Stops and waits after displaying the number of lines you specified with the scrolllines option. The following prompt is displayed on the screen:

```
Press 'Q' to quit, 'C' to continuous scroll, or 'Enter' to
continue.
```

Examples

Options file:

```
scrollprompt yes
```

Command line:

```
-scrollp=yes
```

This option is valid on the initial command line and in interactive mode. If you use this option in interactive mode, it affects only the command with which it is specified. When that command completes, the value reverts to the value at the beginning of the interactive session. This is the value from the dsm.opt file unless overridden by the initial command line or by an option forced by the server.

AIX Linux Solaris Mac OS X

Servername

In your dsm.sys file, the servername option specifies the name you want to use to identify a server and to begin a stanza containing options for that server. You can name and specify options for more than one server.

The following example demonstrates how to specify options for two different servers:

In your client user-options file (dsm.opt), the servername option specifies which server, of those named in your dsm.sys file, to contact for backup-archive services. When specified in a client user-options file (dsm.opt) or on the command line, the servername option overrides the default server specified in your client system options file.

Note:

1. You cannot use the servername option to override the server that is specified for migration in your client system options file.
2. If the IBM Spectrum Protect™ server name changes or backup-archive clients are directed to a different IBM Spectrum Protect server, all clients must have a new password initialized for the new server name.

Supported Clients

This option is for all UNIX and Linux clients.

Options File

Place this option in the client user options file (dsm.opt) and in the client system options file (dsm.sys). In the dsm.sys file, the servername option is the beginning of a server stanza.

Do not modify this option in dsm.opt when you are running the Backup-Archive client in a command-line session or when your are running the Backup-Archive client GUI.

Syntax

```
>>-SErvername-- --servername-----------------------------------><
```

Parameters

servername
: In your dsm.sys file, specify the name you want to assign to a particular server. In your client user-options file (dsm.opt) or on the command line, specify the name of the server you want to contact for backup-archive services. The value of *servername* in dsm.opt must match a *servername* value in dsm.sys, or the client cannot contact the server.

  A server name is not case sensitive; it can have up to 64 characters.

Examples

Options file:

```
servername server_a
```

Command line:

```
-se=server_b
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Sessioninitiation

Use the sessioninitiation option to control whether the server or client initiates sessions through a firewall. The default is that the client initiates sessions. You can use this option with the schedule command.

AIX Linux Solaris Mac OS X For the client scheduler, you do not need to open any ports on the firewall. If you set the sessioninitiation option to serveronly, the client will not attempt to contact the server. All sessions must be initiated by server prompted scheduling on the port defined on the client with the tcpclientport option. The sessioninitiation option only affects the behavior of the client scheduler running in the prompted mode. If you set the sessioninitiation option to serveronly, with the exception of client acceptor daemon-managed schedulers, the command-line client, the backup-archive client GUI, and web client GUI still attempts to initiate sessions.

Windows For the client scheduler, you do not need to open any ports on the firewall. If you set the sessioninitiation option to serveronly, the client will not attempt to contact the server. All sessions must be initiated by server prompted scheduling on the port defined on the client with the tcpclientport option. The sessioninitiation option only affects the behavior of the client scheduler running in the prompted mode. If you set the sessioninitiation option to serveronly, with the exception of client acceptor

daemon-managed schedulers, the command-line client, the backup-archive client GUI, and web client GUI still attempt to initiate sessions.

Attention: You cannot use the dsmcad for scheduling when you set the sessioninitiation option to serveronly

AIX Linux Solaris Mac OS X Note: If you set the sessioninitiation option to serveronly, the client setup wizard and scheduler service are unable to authenticate to the IBM Spectrum Protect™ server. In this case, you can execute the scheduler from the command line (`dsmc schedule`) and enter the password for your node when prompted.

Windows Note: If you set the sessioninitiation option to serveronly, the client setup wizard and scheduler service are unable to authenticate to the IBM Spectrum Protect server. In this case, you can execute the scheduler from the command line (dsmc schedule) and enter the password for your node when prompted, or use the following dsmcutil command to update the password:

```
dsmcutil updatepw /node:nnn /commServer:server1.example.com /password:ppp
/validate:no
```

A similar problem can occur if an encryption key is required for backup operations. In this case, you can execute the scheduler from the command line (`dsmc schedule`) and enter the encryption key when prompted. After the password and encryption key are updated, you must restart the scheduler.

If you set the sessioninitiation option to client, the client initiates sessions with the server by communicating on the TCP/IP port defined with the server option tcpport. This is the default. Server prompted scheduling can be used to prompt the client to connect to the server.

Note:

1. The IBM Spectrum Protect server can specify SESSIONINITiation=clientorserver or SESSIONINITiation=serveronly on the register node and update node commands. If the server specifies SESSIONINITiation=clientorserver, the client can decide which method to use. If the server specifies SESSIONINITiation=serveronly, all sessions are initiated by the server.
2. If sessioninitiation is set to serveronly, the value for the tcpclientaddress client option must be the same as the value for the HLAddress option of the update node or register node server command. The value for the tcpclientport client option must be the same as the value for the LLAddress option of the update node or register node server command.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect API does not support this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the dsm.sys file within a server stanza. You can set this option on the Scheduler tab, Session Initiation field of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Scheduler tab, Session Initiation field of the Preferences editor.

Syntax

```
                      .-Client-----.
>>-SESSIONINITiation--+------------+---------------------------><
                      '-SERVEROnly-'
```

Parameters

Client

Specifies that the client initiates sessions with the server by communicating on the TCP/IP port defined with the server option TCPPORT. This is the default. Server prompted scheduling can be used to prompt the client to connect to the server.

AIX Linux Solaris Mac OS X SERVEROnly

AIX Linux Solaris Mac OS X Specifies that the server will not accept client requests for sessions. All sessions must be initiated by server prompted scheduling on the port defined on the client with the tcpclientport option. Except for client acceptor daemon-managed schedulers, the command-line client, the backup-archive client GUI, and web client GUI still attempt to initiate sessions.

AIX Linux Solaris Mac OS X If the server AUTHENTICATION option is set to LDAP, do not set the client sessioninitiation option to serveronly; if you do, schedules cannot run.

Windows SERVEROnly

Windows Specifies that the server will not accept client requests for sessions. All sessions must be initiated by server prompted scheduling on the port defined on the client with the tcpclientport option. Except for client acceptor daemon-managed schedulers, the command-line client, the backup-archive client GUI, and web client GUI still attempt to initiate sessions.
Windows If the server AUTHENTICATION option is set to LDAP, do not set the client sessioninitiation option to serveronly; if you do, schedules cannot run.

Examples

Options file:
```
sessioninitiation serveronly
```
Command line:
```
schedule -sessioninitiation=serveronly
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Setwindowtitle

Use the setwindowtitle option to modify the title of the administrative client command window during processing.

For example, when you run the administrative client command (dsmadmc) on the client node and the administrative client connects to the IBM Spectrum Protect™ server, the following text is displayed in the title of the command window:

```
CONNECTED TO SERVER: servername(serverhostname)
```

where *servername* is the name of the IBM Spectrum Protect server, and *serverhostname* is the host name of the IBM Spectrum Protect.

When you use the setwindowtitle option, any user-defined title of the command window is overwritten. After you disconnect the administrative client from the IBM Spectrum Protect server, the window title is reset to the user-defined window title.

AIX Linux Solaris On AIX®, Linux, and Oracle Solaris operating systems, the terminal window title is reset to the title "Terminal" after you disconnect from the server.

Supported Clients

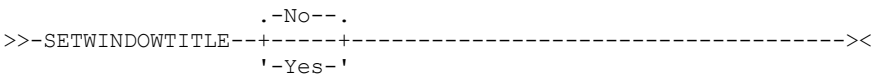
This option is valid for all clients.

Options File

AIX Linux Mac OS X Solaris Place this option in the client user-options file (dsm.opt) or the client system-options file (dsm.sys).

Windows Place this option in the client options file (dsm.opt).

Syntax



Parameters

No
The title of the administrative client command window is not changed during processing. This parameter is the default.

Yes
The IBM Spectrum Protect server name and host server name is displayed in the title of the administrative client command window.

Examples

Options file:

```
SETWINDOWTITLE YES
```

Command line:

```
-setwindowtitle=yes
```

This option is valid only on the initial command line. It is not valid in interactive mode.

AIX Linux Solaris Windows

Shmport

The shmport option specifies the TCP/IP port address of a server when using shared memory. All shared memory communications start with a TCP/IP connection.

AIX Linux Solaris Note: The value specified for the shmport option in the dsm.sys file must match the value specified for shmport in the server options file.
Windows Note: The value specified for the shmport option in the client options file (dsm.opt) must match the value specified for shmport in the server options file.

Supported Clients

AIX Linux Solaris This option is valid for AIX®, Linux, and Oracle Solaris clients.

Windows This option is valid for all Windows clients.

Options File

AIX Linux Solaris Place this option in the client system-options file (dsm.sys) within a server stanza.

Windows Place this option in the client options file (dsm.opt).

Syntax

```
>>-SHMPort-- --port_number--------------------------------------><
```

Parameters

port_number

AIX Linux Solaris Specifies the port number. You can specify a value from 1000 to 32767. The default value is 1510.

Windows Specifies the port number. You can specify a value from 1 to 32767. The default value is 1510.

Examples

Options file:

```
shmport 1580
```

Command line:

Does not apply.

AIX Linux Solaris Windows

Showmembers

Use the showmembers option to display all members of a group.

AIX Linux Solaris You can use the showmembers option with the query group, and restore group commands.

Windows You can use the showmembers option with the query group, query systemstate, and restore group, commands.

The showmembers option is not valid with the inactive option. If you want to display members of a group that are not currently active, use the pitdate and pittime options.

AIX | Linux | Solaris | Windows

Supported Clients

AIX | Linux | Solaris This option is valid for all UNIX and Linux clients except Mac OS X.

Windows This option is valid for all Windows clients.

Syntax

```
>>-SHOWMembers-------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Command line:

AIX | Linux | Solaris

```
restore group /virtfs/* -pick -showmembers
```

Windows

```
restore group {virtfs}\* -pick -showmembers
```

AIX | Linux | Solaris | Mac OS X

Skipacl

The skipacl option allows you to include or exclude access control list (ACL) data during a backup or archive operation; by default, ACL data is included.

When this option is set to yes, the backup-archive client does not include ACL data when it backs up or archives files and directories. The default is no, which enables the ACL data to be included when objects are copied to the server. You should only set the skipacl to yes when ACLs are not defined on the file system, or when you are certain that you do not need the ACL data when the files are retrieved or restored.

Supported Clients

This option is valid for all UNIX and Linux clients. On Linux and AIX systems, setting skipacl to yes also omits the extended attributes.

Options File

Place this option in the client user options (dsm.opt) file.

Syntax

```
            .-No--.
>>-SKIPACL--+-----+---------------------------------------------><
            '-Yes-'
```

Parameters

No
: If you specify No, the ACL data is backed up. This is the default.

Yes

If you specify Yes, the ACL data is not backed up, and consequently, it cannot be restored. skipacl=yes overrides skipaclupdatecheck settings.

Examples

Options file:

```
skipacl yes
```

AIX | Linux | Solaris | Mac OS X

Skipaclupdatecheck

The skipaclupdatecheck option disables checksum and size comparisons of ACL data.

When set to yes (default is no), the backup-archive client will not perform checksum and size comparisons before or after backup and during incremental processing (ACL checksum from previous backup and current ACL) to detect ACL updates. However, current ACL data is backed up if the file is selected for backup due to other reasons. If only ACLs are updated on a file, the next incremental backup will not recognize this ACL update, and the file is not backed up.

Supported Clients

This option is valid for all UNIX and Linux clients.

Options File

Place this option in the client user options (dsm.opt) file.

Syntax

```
                        .-No--.
>>-SKIPACLUPdatecheck--+-----+---------------------------------><
                        '-Yes-'
```

Parameters

No
: If you specify No, the client performs checksum and size comparisons of the ACL data, before and after backup and during incremental processing. This is the default.

Yes
: If you specify Yes, the client does not perform checksum and size comparisons of the ACL data.

Examples

Options file:

```
skipaclup yes
```

Windows

Skipmissingsyswfiles

Use the Skipmissingsyswfiles option to specify whether the backup-archive client skips certain missing VSS writer files and continues the system state backup.

Setting the skipmissingsyswfile option to yes causes certain VSS writer files that are not found during a system state backup to be skipped. This option is effective only for missing files from the following VSS writers:

- System Writer
- Windows Deployment Service Writer
- Event Log writer

Consider the following items before you use the skipmissingsyswfile option:

- Setting the skipmissingsyswfile option to *yes* enables backups that might have failed to complete with previous versions of the backup-archive client.
- There is a small risk of an inconsistent backup because a file is skipped.
- This risk is minimized by these factors:
  - The backup can be done only when the system is running.
  - Critical system files are protected from deletion by Microsoft Windows.

Supported Clients

This option is valid for Windows clients.

Options File

Place this option in the client options file (dsm.opt).

Syntax

```
                          .-Yes-.
>>-SKIPMISSingsyswfiles--+-----+-------------------------------><
                          '-No--'
```

Parameters

Yes
: Specifies that you want the backup-archive client to skip certain files that are not found during system state backup. The files that are not found are logged to both the error log and the server activity log. The final return code is set to 8. This is the default.

No
: Specifies that you want the backup-archive client to stop the backup when files are not found during system state backup. The files that are not found are logged to the error log and to the server activity log. The final return code is 12.

Examples

Options file:

```
SKIPMISSingsyswfiles yes
```

Command line:

```
-SKIPMISSingsyswfiles=yes
```

Backup Systemstate
Windows

Skipntpermissions

The skipntpermissions option bypasses processing of Windows file system security information.

You can use this option for incremental backups, selective backups, restore operations, and for archive and retrieve operations.

Supported Clients

This option is valid for all Windows clients.

Options File

Place this option in the client options file (dsm.opt). It applies to incremental, selective, restore, archive, and retrieve commands. You can also set this option on the General tab of the Preferences editor.

Syntax

```
                        .-No--.
>>-SKIPNTPermissions--+-----+---------------------------------><
                        '-Yes-'
```

Parameters

No
: If you specify No, Windows file system security information is backed up, restored, archived, or retrieved. This is the default setting.

Yes
: If you specify Yes, Windows file system security information is not backed up, restored, archived, or retrieved.

Examples

Options file:

```
skipntp yes
```

Command line:

```
-skipntp=yes
```

Windows

Skipntsecuritycrc

The skipntsecuritycrc option controls the computation of the security cyclic redundancy check (CRC) for a comparison of Windows NTFS or ReFS security information during an incremental or selective backup, archive, restore, or retrieve operation.

If you set the skipntsecuritycrc option to no (the default), performance might be slower because the program must retrieve all the security descriptors.

Use this option with the following commands:

- archive
- incremental
- restore
- retrieve
- selective

Supported Clients

This option is valid for all Windows clients.

Options File

Place this option in the client options file (dsm.opt).

Syntax

```
                        .-No--.
>>-SKIPNTSecuritycrc--+-----+---------------------------------><
                        '-Yes-'
```

Parameters

No
: If you specify No, the security CRC is generated during a backup. This is the default setting.

Yes
: If you specify Yes, the security CRC is not generated during a backup. All the permissions are backed up, but the program cannot determine if the permissions are changed during the next incremental backup. When the skipntpermissions option is set to yes, the skipntsecuritycrc option does not apply.

Examples

Options file:

```
skipnts no
```

Command line:

```
-skipnts=no
```

Windows

Skipsystemexclude

Use the skipsystemexclude option to specify how to process exclude statements for certain operating system files that the IBM Spectrum Protect™ for Virtual Environments client skips by default.

By default, IBM Spectrum Protect for Virtual Environments clients skip certain Windows operating system files that are not normally required for system recovery during virtual machine (VM) backup operations. These files can include Windows system files, temporary internet files, and files in the Recycle Bin.

You can use this option to skip the processing of exclude statements for these operating system files. By not processing these exclude statements, the time it takes to back up VMs might be reduced.

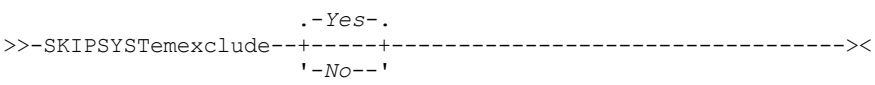
Support clients

This option is valid for IBM Spectrum Protect for Virtual Environments clients on Windows operating systems only.

Options file

This option is valid in the client options file (dsm.opt) or on the command line. The option can be set in the client option set on the IBM Spectrum Protect server. The option is ignored for all other clients.

Syntax



Parameters

Yes
: Specify this parameter to skip the processing of exclude statements for certain Windows operating system files during VM backup operations. This parameter is the default.

No
: Specify this parameter to process exclude statements of Windows operating system files. When you select this parameter and run a file backup of the Hyper-V host, the operating system files are excluded.

Examples

Options file

```
SKIPSYSTemexclude yes
```

Command line

```
dsmc backup vm -SKIPSYST=yes
dsmc incr -skipsyst=no
```

Linux | Windows

Snapdiff

Using the snapdiff option with the incremental command streamlines the incremental backup process. The command runs an incremental backup of the files that were reported as changed by NetApp instead of scanning all of the volume for changed files.

Windows The snapdiff (snapshot difference) option is for backing up NAS/N-Series file server volumes that are NFS or CIFS attached.

Windows Restriction: None of the NetApp predefined shares, including `C$`, works with the IBM Spectrum Protect™ snapshot difference option because the backup-archive client cannot determine their mount points programmatically.

You must configure a user ID and password on the backup-archive client to enable snapshot difference processing.

Use this option with an incremental backup of a NAS file server volume, instead of a simple incremental backup or an incremental backup with the snapshotroot option, whenever the NAS file server is running ONTAP 7.3.0, or later. Do not use the snapdiff and snapshotroot options together.

Linux Restriction: Incremental backups with snapshot difference processing are only available with the Linux x86_64 backup-archive client.

The first time that you run an incremental backup with the snapshot difference option, a snapshot is created (the base snapshot) and a traditional incremental backup is run by using this snapshot as the source. The name of the snapshot that is created is recorded in the IBM Spectrum Protect server database. The initial incremental backup must complete without failure in order for the next backup operation to use snapshot difference processing.

The second time an incremental backup is run with this option, a newer snapshot is either created, or an existing one is used (depending on the value set for the diffsnapshot option) to find the differences between these two snapshots. The second snapshot is called the *diffsnapshot*, or differences snapshot. The client then incrementally backs up the files that are reported as changed, by NetApp, to the IBM Spectrum Protect server. The file system that you select for snapshot difference processing must be mounted to the root of the volume. You cannot use the snapdiff option for any file system that is not mounted to the root of the volume. After you backed up the data with the snapdiff option, the snapshot that was used as the base snapshot is deleted from the snapshot directory.

Windows On Windows systems, the snapshot directory is in ~snapshot.

Linux On Linux systems, the snapshot directory is in .snapshot.

The client does not delete any snapshots that it did not create.

When a snapshot-differential-incremental backup operation completes, the client ensures that only the most recently-registered base snapshot persists on the filer volume. All snapshots that are created by a snapshot-differential-incremental backup on the backup-archive client begin with the characters "TSM_". If you use a snapshot tool other than the backup-archive client to produce snapshots, ensure that you do not use the string "TSM_" at the beginning of the snapshot name. If the snapshot names begin with "TSM_", the files are deleted when the client initiates the next snapshot-differential-incremental backup operation.

To run a snapshot-differential-incremental backup of read-only NetApp filer volumes, the useexistingbase option must be specified to prevent an attempt to create a snapshot on the read-only volume. Also, specify the name of the base snapshot to use (basesnapshotname option) and the name of the differential snapshot to use (diffsnapshotname option).

For NAS and N-Series file servers that are running ONTAP 7.3.0, or later, you can use the createnewbase option to back up any files that were skipped because of one of the following reasons:

- A file is excluded because the include-exclude file has an exclude rule in effect. A file is excluded when you did not change the include-exclude file, but you removed the rule that excluded the file. The NetApp API detects file changes only between two snapshots, not changes to the include-exclude file.
- If you added an include statement to the option file, that include option does not take effect unless NetApp detects that the file changes occurred. The client does not inspect each file on the volume during backup.
- You used the dsmc delete backup command to explicitly delete a file from the IBM Spectrum Protect server inventory. NetApp does not detect that a file was manually deleted from the server. Therefore, the file remains unprotected in IBM Spectrum Protect storage until it is changed on the volume and the change is detected by NetApp, signaling the client to back it up again.
- Policy changes such as changing the policy from mode=modified to mode=absolute are not detected.
- The entire file space is deleted from the IBM Spectrum Protect inventory. This action causes the snapshot difference option to create a snapshot to use as the source, and runs a full incremental backup.
- A file is excluded from backup because the file name contains a character that is not in the 7 bit-ASCII character set. The createnewbase option creates a base snapshot and uses it as a source to run a full incremental backup. NetApp controls what constitutes a changed object.

Tip: You can use the snapdiffhttps option to run snapshot-differential-incremental backups of NetApp filers with a secure HTTPS connection. To successfully run snapshot-differential-incremental backups, previous releases of the backup-archive client

required HTTP administrative access to be enabled on the NetApp filer. With the snapdiffhttps option, you can establish a secure administrative session with the NetApp filer regardless of whether HTTP administrative access is enabled on the filer.
In the list of options that are used by the traditional incremental command, the last column shows the interaction of each option with the snapdiff option. The following information describes the definitions of *valid*, *not valid*, and *no effect*:

Valid
: Processing runs normally when the option is used.

Not valid
: If the option is used with the snapdiff option, an error message is generated.

No effect
: The option can be used, but it is ignored.

Table 1. Incremental command: Related options

Option	Where specified	With snapdiff
AIX Linux asnodename	AIX Linux Client system options file (dsm.sys) or command line.	AIX Linux Valid
Windows asnodename	Windows Client options file (dsm.opt) or command line.	Windows Valid
AIX Linux automount	AIX Linux Client options file (dsm.opt).	AIX Linux No effect
Windows autofsrename	Windows Client options file (dsm.opt) only.	Windows No effect
AIX Linux basesnapshotname	AIX Linux Client options file (dsm.opt) or command line.	AIX Linux Valid
Windows basesnapshotname	Windows Client options file (dsm.opt) or command line.	Windows Valid
AIX Linux changingretries	AIX Linux Client system options file (dsm.sys) or command line.	AIX Linux No effect
Windows changingretries	Windows Client options file (dsm.opt) or command line.	Windows No effect
Windows compressalways	Windows Client options file (dsm.opt) or command line.	Windows Valid
AIX Linux compressalways	AIX Linux Client options file (dsm.opt) or command line.	AIX Linux Valid
Windows compression	Windows Client options file (dsm.opt) or command line.	Windows Valid
AIX Linux compression	AIX Linux Client system options file (dsm.sys) within a server stanza, or command line.	AIX Linux Valid
AIX Linux Windows createnewbase	AIX Linux Windows Command line only.	AIX Linux Windows Valid
diffsnapshot	Command line only.	Valid
AIX Linux diffsnapshotname	AIX Linux Client options file (dsm.opt) or command line.	AIX Linux Valid
Windows diffsnapshotname	Windows Client options file (dsm.opt) or command line.	Windows Valid
dirsonly	Command line only.	Valid
Windows domain	Windows Client options file (dsm.opt) or command line only.	Windows Valid
AIX Linux domain	AIX Linux Client system options file (dsm.sys), client user-options file (dsm.opt), or command line.	AIX Linux Valid

Option	Where specified	With snapdiff
AIX Linux efsdecrypt	AIX Linux Client system options file (dsm.sys), client user-options file (dsm.opt), or command line.	AIX Linux No effect
AIX Linux enablelanfree	AIX Linux Client system options file (dsm.sys) or command line.	AIX Linux Valid
Windows enablelanfree	Windows Client options file (dsm.opt) or command line.	Windows Valid
AIX Linux encryptiontype	AIX Linux system-options file (dsm.sys) within a server stanza.	AIX Linux Valid
Windows encryptiontype	Windows Client options file (dsm.opt).	Windows Valid
Windows encryptkey	Windows Client options file (dsm.opt).	Windows Valid
AIX Linux encryptkey	AIX Linux System-options file (dsm.sys) within a server stanza.	AIX Linux Valid
AIX Linux exclude.fs.nas	AIX Linux Client system options file (dsm.sys).	AIX Linux No effect
Windows exclude.fs.nas	Windows Client options file (dsm.opt).	Windows No effect
filelist	Command line only.	Not valid
filesonly	Command line only.	Valid
AIX Linux followsymboliclink	AIX Linux Client options file (dsm.opt).	AIX Linux No effect
AIX Linux include.fs.nas	AIX Linux Client system options file (dsm.sys) or command line.	AIX Linux No effect
Windows include.fs.nas	Windows Client options file (dsm.opt) or command line.	Windows No effect
AIX Linux inclexcl	AIX Linux Client system options file (dsm.sys).	AIX Linux Valid, but only when a file change is detected by NetApp.
Windows inclexcl	Windows Client options file (dsm.opt).	Windows Valid, but only when a file change is detected by NetApp.
incrbydate	Command line only.	Not valid
Windows memoryefficientbackup	Windows Client options file (dsm.opt), server, or command line.	Windows No effect
AIX Linux memoryefficientbackup	AIX Linux This option is allowed in both dsm.sys and dsm.opt, but the value in dsm.opt is ignored if it is also in dsm.sys. You can also place this option within a server stanza, or on the initial command line.	AIX Linux No effect
monitor	Command line only.	Not valid
AIX Linux nojournal	AIX Linux Command line only.	AIX Linux Not valid
Windows nojournal	Windows Command line only.	Windows Not valid
AIX Linux postsnapshotcmd	AIX Linux Client system options file (dsm.sys) or with the include.fs option.	AIX Linux Valid

Option	Where specified	With snapdiff
Windows postsnapshotcmd	Windows Client options file (dsm.opt) or with the include.fs option.	Windows Valid
AIX Linux preservelastaccessdate	AIX Linux Client user-options file (dsm.opt) or command line.	AIX Linux Valid
Windows preservelastaccessdate	Windows Client options file (dsm.opt) or command line.	Windows Valid
AIX Linux presnapshotcmd	AIX Linux Client system options file (dsm.sys) or with the include.fs option.	AIX Linux Valid
Windows presnapshotcmd	Windows Client options file (dsm.opt) or with the include.fs option.	Windows Valid
AIX Linux removeoperandlimit	AIX Linux Command line only.	AIX Linux Valid
Windows resetarchiveattribute	Windows Client options file (dsm.opt).	Windows Valid
AIX Linux skipaclupdatecheck	AIX Linux Client options file (dsm.opt).	AIX Linux Valid
Windows skipntpermissions	Windows Client options file (dsm.opt) or command line.	Windows Valid
Windows skipntsecuritycrc	Windows Client options file (dsm.opt) or command line.	Windows Valid
AIX Linux Windows snapdiffhttps	AIX Linux Windows Command line only.	AIX Linux Windows Valid
AIX Linux snapshotcachesize	AIX Linux Client system options file (dsm.sys) or with the include.fs option.	AIX Linux No effect
AIX Linux snapshotproviderfs	AIX Linux System-options file (dsm.sys) within a server stanza or with the include.fs option.	AIX Linux Not valid
Windows snapshotproviderfs	Windows Client options file (dsm.opt) or with the include.fs option.	Windows Not valid
AIX Linux snapshotproviderimage	AIX Linux Client system options file (dsm.sys) or with the include.image option.	AIX Linux Not valid
Windows snapshotproviderimage	Windows Client options file (dsm.opt) or with the include.image option.	Windows Not valid
snapshotroot	Command line only.	Not valid
subdir	Client options file (dsm.opt) or command line.	Not valid
AIX Linux tapeprompt	AIX Linux Client options file (dsm.opt) or command line.	AIX Linux Valid
Windows tapeprompt	Windows Client options file (dsm.opt) or command line.	Windows Valid
AIX Linux toc	AIX Linux Command line only.	AIX Linux Not valid
Windows toc	Windows Command line only.	Windows Not valid
AIX Linux useexistingbase	AIX Linux Command line only.	AIX Linux Valid
Windows useexistingbase	Windows Command line only.	Windows Valid

Option	Where specified	With snapdiff
virtualfsname	Command line only.	Not valid
AIX Linux virtualmountpoint	AIX Linux Client system options file (dsm.sys).	AIX Linux Not valid

Supported Clients

Windows This option is valid for all Windows clients.

Linux This option is valid for Linux x86_64 clients.

Syntax

```
>>-SNAPDiff-------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Linux Command line:

Linux Perform a snapshot-differential-incremental backup of an NFS mounted file system `/vol/vol1` hosted on the file server `homestore.example.com`, where `/net/home1` is the mount point of `/vol/vol1`.

Linux
```
incremental -snapdiff -diffsnapshot=latest /net/home1
```

Windows Command line:

Windows Perform a snapshot-differential-incremental backup from a snapshot that is taken of a network share `//homestore.example.com/vol/vol1` mounted on drive `H:`, where `homestore.example.com` is a file server.

Windows
```
incremental -snapdiff H:
```

Windows Perform a snapshot-differential-incremental backup from a snapshot that is taken of a network share `//homestore.example.com/vol/vol1` mounted on drive `H:`, where `homestore.example.com` is a file server. The -diffsnapshot option value of `LATEST` means that the operation uses the latest snapshot (the active snapshot) for volume `H:`.

Windows
```
incremental -snapdiff H: -diffsnapshot=latest
```

Command line:

Run a one-time full incremental backup after detecting that the NetApp server has migrated to a unicode-enabled file server from a server that did not support unicode file names. AIX Linux

```
dsmc incremental -snapdiff -createnewbase=migrate /net/home1
```

Windows

```
dsmc incremental -snapdiff -createnewbase=migrate h:
```

Run a snapshot-differential-incremental backup after detecting that the NetApp server has migrated to a unicode-enabled file server from a server that did not support unicode file names. This command suppresses the warning message.

AIX Linux

```
dsmc incremental -snapdiff -createnewbase=ign /net/home1
```

Windows

```
dsmc incremental -snapdiff -createnewbase=ign h:
```

Perform a full incremental backup because you made some include or exclude changes: AIX Linux

```
dsmc incremental -snapdiff -createnewbase=yes /net/home1
```

Windows

```
dsmc incremental -snapdiff -createnewbase=yes h:
```

Snapdiffchangelogdir

The snapdiffchangelogdir option defines the location where the client stores persistent change logs that are used for snapshot differential backup operations.

Important: If you previously used snapshot differential backups with a backup-archive client that is older than Version 8.1.2, the first snapshot differential backup that you run with the V8.1.2 or later client will be a full progressive incremental backup. To avoid this full progressive incremental backup, move the existing change log files from the old location specified by the stagingdirectory option to the new location specified by the snapdiffchangelogdir option before you run the first snapshot differential backup. For example, run the following copy command: Linux

```
cp -R /tmp/TSM/TsmSnapDiff /opt/tivoli/tsm/client/ba/TsmSnapDiff
```

Windows

```
xcopy C:\Users\Bob\AppData\Local\Temp\TSM\TsmSnapDiff
"C:\Program Files\Tivoli\TSM\baclient\TsmSnapDiff" /s /y
```

The change log files have the following naming patterns: Linux

```
.../TSM/TsmSnapDiff/.TsmSnapdiffChangeLogs/NetAppFiler/
SnapdiffChangeLog__VolumeName__.tsmDB
.../TSM/TsmSnapDiff/.TsmSnapdiffChangeLogs/NetAppFiler/
SnapdiffChangeLog__VolumeName__.tsmDB.Lock
```

Windows

```
...\TSM\TsmSnapDiff\.TsmSnapdiffChangeLogs\NetAppFiler\
SnapdiffChangeLog__VolumeName__.tsmDB
...\TSM\TsmSnapDiff\.TsmSnapdiffChangeLogs\NetAppFiler\
SnapdiffChangeLog__VolumeName__.tsmDB.Lock
```

where:

- *NetAppFiler* is the host name or IP address of the storage virtual machine (SVM) from the cluster management server or the 7-mode file server.
- *VolumeName* is the volume that you want to protect.

Supported Clients

Linux This option is valid for Linux x86_64 clients. This option can also be defined on the server.

Windows This option is valid for all Windows clients. This option can also be defined on the server.

Options File

Linux Place this option in the client options file (dsm.opt). When snapdiffchangelogdir is specified on the command line, it overrides the values that are specified in the options file. You can set this option on the General tab of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). When snapdiffchangelogdir is specified on the command line, it overrides the values that are specified in the options file. You can set this option on the General tab of the Preferences editor.

Syntax

```
>>-SNAPDIFFCHANGELOGDir--path---------------------------------><
```

Parameters

path

Specifies the directory path where the client stores persistent change logs for snapshot differential backup operations. If you do not specify the snapdiffchangelogdir option, the client uses the directory where the client is installed. The default installation directory is: Linux

```
/opt/tivoli/tsm/client/ba
```

Windows

```
C:\Program Files\Tivoli\TSM\baclient
```

The exact name of the change log file is in the following format: Linux

```
snapdiff_change_log_dir/TsmSnapDiff/.TsmSnapdiffChangeLogs/NetAppFiler/
SnapdiffChangeLog__VolumeName__.tsmDB
```

Windows

```
snapdiff_change_log_dir\TsmSnapDiff\.TsmSnapdiffChangeLogs\NetAppFiler\
SnapdiffChangeLog__VolumeName__.tsmDB
```

where:

- *snapdiff_change_log_dir* is the name of the directory for storing the snapshot differential change logs, as specified by the snapdiffchangelogdir option.
- *NetAppFiler* is the host name or IP address of the storage virtual machine (SVM) from the cluster management server or the 7-mode file server.
- *VolumeName* is the volume that you want to protect.

A lock file is also created to prevent the change log file from being updated by different snapshot differential backups that are running at the same time.
Windows In Uniform Naming Convention (UNC) format, the path must contain a drive letter. In the following UNC format example, the path contains the drive letter:

```
\\computer7\C$\tsmdata
```

Examples

Options file:

Linux
```
snapdiffchangelogdir /tmp/tsmdata
```
Windows
```
snapdiffchangelogdir c:\tsmdata
```

Command line:

Linux
```
-snapdiffchangelogd=/tmp/tsmdata
```
Windows
```
-snapdiffchangelogd="c:\tsmdata"
```

Linux | Windows

Snapdiffhttps

Specify the snapdiffhttps option to use a secure HTTPS connection for communicating with a NetApp filer during a snapshot differential backup.

When you specify this option, the backup-archive client can establish a secure administrative session with the NetApp filer regardless of whether HTTP administrative access is enabled on the NetApp filer.

Important: The default communication protocol that the backup-archive client uses to establish the administrative session with the NetApp filer is HTTP. To use a secure HTTPS connection, you must specify the snapdiffhttps option whenever you run a snapshot differential backup.

Restrictions:

The following restrictions apply to snapshot differential backups with HTTPS:

- The HTTPS connection is used only to securely transmit data over the administrative session between the backup-archive client and the NetApp filer. The administrative session data includes information such as filer credentials, snapshot information, and file names and attributes that are generated by the snapshot differencing process. The HTTPS connection is not used to transmit normal file data that is accessed on the filer by the client through file sharing. The HTTPS connection also does not apply to normal file data transmitted by the client to the IBM Spectrum Protect™ server through the normal IBM Spectrum Protect client/server protocol.
- The snapdiffhttps option does not apply to vFilers because the HTTPS protocol is not supported on the NetApp vFiler.
- The snapdiffhttps option is available only by using the command-line interface. It is not available for use with the backup-archive client GUI.

Supported Clients

Windows This option is valid for all Windows clients.

Linux This option is valid for Linux x86_64 clients.

Options File

This option is valid only on the command-line interface. You cannot enter it in a client options file.

Syntax

```
>>-SNAPDIFFHTTPS-----------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Linux Command line:

Linux Issue the following command on a Linux system, with an NFS mounted file system `/vol/vol1` hosted on the file server `homestore.example.com`, where `/net/home1` is the mount point of `/vol/vol1`.

```
dsmc incr /net/home1 -snapdiff -snapdiffhttps
```

Windows Command line:

Windows Issue the following command on a Windows system with a network share `\\netapp1\vol1`, where `netapp1` is a filer.

```
dsmc incr \\netapp1\vol1 -snapdiff -snapdiffhttps
```

Windows Command line:

Windows Issue the following command on a Windows system with a network share `\\netapp1.example.com\petevol` mounted on drive `v:`, where `netapp1.example.com` is a filer.

```
dsmc incr v: -snapdiff -snapdiffhttps

Snapshotcachesize

Use the snapshotcachesize option to specify an appropriate size to create the snapshot.

AIX Linux The size estimation is needed for storing the original data blocks for modified and deleted data for the point in time when the snapshot was taken.

AIX Linux For snapshot-based file backup or archive, use the snapshotcachesize option with the include.fs option, or in the server stanza in the dsm.sys file.

AIX Linux For snapshot-based image backups, use the snapshotcachesize option with the backup image command, the include.image option, or in your dsm.sys file.

Supported Clients

AIX Linux This option is valid for AIX® and Linux clients *only*. The IBM Spectrum Protect™ API does not support this option. The server can also define this option.

Options File

AIX Linux Place this option in the server stanza in the dsm.sys file. You can set this option on the Image-Snapshot tab of the Preferences editor.

Syntax

```
>>-SNAPSHOTCACHESize-- --size-----------------------------------><
```

Parameters

AIX Linux

size

Specifies an appropriate size to create the snapshot for storing the original data blocks for modified and deleted data for the point in time when the snapshot was taken. The value is the percent of the file system size that is changed due to file system activity. The range of values is 1 to 100 percent. For AIX JFS2 and Linux the default value is 100 percent of the file system size. If a sufficient amount of free space is not available to create the snapshot, the command fails with an error message. You can then either increase the size of the volume group or retry the operation. If based on your experience with your AIX JFS2 file system activity, you find that a snapshot size of 100 percent is not necessary, you can fine-tune the value.

AIX Linux

Examples

Options file:

```
snapshotcachesize 95
AIX AIX only: include.fs /kalafs1
  snapshotproviderfs=JFS2 snapshotcachesize=95
AIX AIX only: include.image /kalafs2
  snapshotcachesize=95
Linux Linux only: include.image /linuxfs1
  snapshotcachesize=100
```

Command line:

```
-snapshotcachesize=95
```

AIX | Windows

Snapshotproviderfs

Use the snapshotproviderfs option to enable snapshot-based file backup and archive operations, and to specify a snapshot provider.

AIX You must be a root user to perform a snapshot-based file backup or archive operation. If you are not a root user, the operation fails with an error message.

AIX | Windows

Supported Clients

AIX This option is valid for AIX® clients only. The IBM Spectrum Protect™ API does not support this option. The server can also define this option.

Windows This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option. The server can also define this option.

Options File

AIX Specify this option in the server stanza of the system-options file, dsm.sys, to enable snapshots for all JFS2 file systems on the client. You can override the client-wide option for a specific operation by specifying this option on the command line for the backup and archive commands. You can also override the client-wide option for a specific file system by using the include.fs statement in the dsm.sys file. You can also set this option using the Preferences editor.

Windows Specify this option in the client options file, dsm.opt, to enable snapshots. You can override the client-wide option for a specific operation by specifying this option on the command line for the backup and archive commands. You can also override the client-wide option for a specific file system by using the include.fs statement in the dsm.opt file. You can also set this option using the Preferences editor.

Syntax

```
>>-SNAPSHOTPROVIDERFs-- --value--------------------------------><
```

Parameters

value

Specifies one of the following values:

AIX JFS2

AIX Specifies that you want to perform a snapshot-based file backup or archive while the file system is available to other system applications. Valid for JFS2 file systems on AIX clients *only*.

Windows VSS

Windows Specifies that VSS should be used to provide OFS support.

AIX NONE

AIX Specifies that no snapshots should be used. A file backup or archive operation is performed using the specified file system. This is the default.

Windows NONE

Windows Specifies that no snapshot provider should be used; OFS support is turned off. This is the default.

Examples

AIX Options file:

AIX

```
snapshotproviderfs JFS2
include.fs   /kalafs1   snapshotproviderfs=JFS
```

Windows Options file:

Windows

```
snapshotproviderfs VSS
include.fs d: snapshotproviderfs=vss
```

AIX Command line:

AIX `-SNAPSHOTPROVIDERFs=JFS2`

Windows Command line:

Windows `-SNAPSHOTPROVIDERFs=VSS`

AIX Linux Windows

Snapshotproviderimage

Use the snapshotproviderimage option to enable snapshot-based image backup, and to specify a snapshot provider.

AIX Linux You must be a root user to perform a snapshot-based image backup operation. If you are not a root user, the operation fails with an error message.

AIX Linux Windows

Supported Clients

AIX Linux This option is valid for AIX® and Linux clients only. The IBM Spectrum Protect™ API does not support this option. The server can also define this option.

Windows This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option. The server can also define this option.

Options File

AIX Linux Specify this option in the server stanza of the system-options file, dsm.sys, to enable snapshots for all the file systems on the client. You can override the client-wide option for a specific operation by specifying this option on the command line for the backup image command. You can also override the client-wide option for a specific file system using the include.image statement in the dsm.sys file. You can also set this option using the Preferences editor.

Windows Specify this option in the client options file, dsm.opt, to enable snapshots for all the file systems on the client. You can override the client-wide option for a specific operation by specifying this option on the command line for the backup image command. You can also override the client-wide option for a specific file system using the include.image statement in the dsm.opt file. You can also set this option using the Preferences editor.

Syntax

```
>>-SNAPSHOTPROVIDERImage-- --value-----------------------------><
```

Parameters

value

Specifies one of the following values:

AIX JFS2

AIX Specifies that you want to perform a snapshot-based image backup while the file system is available to other system applications. This is the default for JFS2 file systems. Valid for AIX clients *only*.

Linux LINUX_LVM

Linux Specifies that you want to perform a snapshot-based image backup while the file system is available to other system applications. This is the default for file systems residing on logical volumes created by the Linux Logical Volume Manager. Valid for Linux clients *only*.

Windows VSS

Windows Specifies that the VSS should be used to provide online image support.

AIX Linux NONE

AIX Linux Specifies that you do not want to perform a snapshot-based image backup operation. This performs a static image backup operation using the specified file system. This is the default for file systems other than AIX JFS2 and Linux LVM.

Windows NONE

Windows Specifies that no snapshot provider should be used. This turns off online image support. This is the default

Examples

AIX Linux Options file:

AIX Linux

```
snapshotprovideri JFS2
include.image   /kalafs1   snapshotprovideri=JFS2
```

Windows Options file:

Windows

```
snapshotprovideri VSS
include.image d: snapshotprovideri=vss
```

Command line:

```
-SNAPSHOTPROVIDERImage=NONE
```

AIX Linux Solaris Windows

Snapshotroot

Use the snapshotroot option with the incremental, selective, or archive commands with an independent software vendor application that provides a snapshot of a logical volume, to associate the data on the local snapshot with the real file space data that is stored on the IBM Spectrum Protect™ server.

AIX Linux Solaris The snapshotroot option can be used to back up NFS mounted file systems. Both the backup specification (source) and the snapshotroot value can be an NFS mounted file specification. For example, the snapshotroot option can be used to backup an NFS file system that is hosted on a network-attached storage (NAS) that supports snapshot.

AIX Linux Solaris Windows This option should be used with an incremental backup of a NAS file server volume instead of a simple incremental or incremental with snapshotroot option whenever the NAS file server is running ONTAP V7.3 for performance reasons. The snapdiff and snapshotroot options should not be used together.

Windows The snapshotroot option can be used to back up network share mounted file systems. Both the backup specification (source) and the snapshotroot value can be a network share mounted file specification. For example, the snapshotroot option can be used to back up a network share file system hosted on a network-attached storage (NAS) that supports snapshot.

AIX Linux Solaris In the following example, `filesystem test495` is NFS-mounted from a NAS file server `philo` and `/philo/test945/.snapshot/backupsnap` represents the snapshot that is created at the NAS file server.

Windows In the following example, `c:\snapshots\snapshot.0` is network share that is mounted from a NAS file server and `\\florance\c$` represents the snapshot that is created at the NAS file server.

Windows

```
dsmc incr \\florance\C$ -snapshotroot=c:\shapshots
   \snapshot.0
```

AIX Linux Solaris Windows You can also specify a directory with the snapshotroot option when you backup each file set as a separate file space.

The snapshotroot option does not provide any facilities to take a volume snapshot, only to manage data that is created by a volume snapshot.

AIX Linux Solaris For example, consider an application that takes a snapshot of the `/usr file system` and mounts it as `/snapshot/day1`. If you back up this data by using the following command, a unique file space that is called `/snapshot/day1` is created on the server.

```
dsmc incremental /snapshot/day1
```

AIX Linux Solaris However, you might want to associate the snapshot data with the data already processed for the `/usr` file system. Using the snapshotroot option, you can associate the data with the file space corresponding to the `/usr` file system on the IBM Spectrum Protect server:

```
dsmc incremental /usr -snapshotroot=/snapshot/day1
```

Windows For example, consider an application that takes a snapshot of the `c:` drive and mounts it as the NTFS junction point `\\florence\c$\snapshots\snapshot.0`. If you back up this data by using the following command, a unique file space that is called `\\florence\c$\snapshots\snapshot.0` is created on the server.

```
dsmc incremental \\florence\c$\snapshots\snapshot.0
```

Windows However, you might want to associate the snapshot data with the data already processed for the `c:` drive `(\\florence\c$)`. Using the snapshotroot option, you can associate the data with the file space corresponding to the `c:` drive `(\\florence\c$)` on the IBM Spectrum Protect server:

```
dsmc incr c: -snapshotroot=\\florence\c$\snapshots\snapshot.0
-or-
dsmc incr \\florence\c$ -snapshotroot=\\florence\c$\snapshots\
  snapshot.0
```

On a subsequent day, you can back up a snapshot that was written to an alternative location, but managed under the same file space on the server: AIX Linux Solaris

```
dsmc incremental /usr -snapshotroot=/snapshot/day2
```

Windows

```
dsmc incr c: -snapshotroot=\\florence\c$\snapshots\snapshot.1
```

You can perform incremental backups, selective backups, or archives of a single directory, directory structure, or single file by using the snapshotroot option. In all instances, the snapshotroot option must identify the root of the logical volume that was created by the snapshot. For example: AIX Linux Solaris

```
dsmc incremental /usr/dir1/* -subdir=yes
  -snapshotroot=/snapshot/day1
dsmc selective /usr/dir1/sub1/file.txt
  -snapshotroot=/snapshot/day1
dsmc archive /usr/dir1/sub1/*.txt
  -snapshotroot=/snapshot/day1
```

Windows

```
dsmc incr c:\dir1\* -subdir=yes  -snapshotroot=\\florence\c$\
  snapshots\snapshot.1
dsmc sel c:\dir1\sub1\file.txt -snapshotroot=\\florence\c$\
  snapshots\snapshot.1
dsmc archive c:\mydocs\*.doc -snapshotroot=\\florence\c$\
  snapshots\snapshot.1
```

AIX Linux Solaris If you want to include or exclude specific file specifications, the include and exclude statements should contain the name of the file system that was the source of the snapshot (the `/usr` file system), and not the name of the target of the snapshot `(/snapshot/day1)`. Doing this allows you to preserve a set of include and exclude statements regardless of the name of the logical volume to which the snapshot is written. The following are examples of include and exclude statements.

```
include /usr/dir1/*.txt 1yrmgmtclass
exclude /usr/mydocs/*.txt
```

Windows If you want to include or exclude specific file specifications, the include and exclude statements should contain the name of the file system that was the source of the snapshot (the `c:` drive), and not the name of the target of the snapshot `(\\florence\c$\snapshots\snapshot.1)`. Doing this allows you to preserve a set of include and exclude statements regardless of the name of the logical volume to which the snapshot is written. The following are examples of include and exclude statements.

```
include c:\dir1\.../*.txt lyrmgmtclass
exclude \\florence\c$\mydocs\*.doc
```

The following include-exclude statements are not valid because they contain the name of the snapshot: AIX Linux Solaris

```
include /snapshot/day1/dir1/*.txt 1yrmgmtclass
exclude /snapshot/day1/mydocs/*.txt
```

Windows

```
include \\florence\c$\snapshots\snapshot.1\dir1\...\
  *.txt 1yrmgmtclass
exclude \\florence\c$\mydocs\*.doc
```

You must use the snapshotroot option with a single file specification for an incremental, selective, or archive operation. You cannot specify multiple file specifications or no file specifications. For example, these commands are valid: AIX Linux Solaris

```
dsmc incremental /usr -snapshotroot=/snapshot/day1
dsmc incremental /usr/dir1/* -snapshotroot=/snapshot/day1
```

Windows

```
dsmc incr c: -snapshotroot=\\florence\c$\snapshots\snapshot.0
dsmc incr c:\dir1\* -snapshotroot=\\florence\c$\snapshots\
  snapshot.0
```

The following command is invalid because it contains two file specifications: AIX Linux Solaris

```
dsmc incremental /usr/dir1/* /home/dir2/*
  -snapshotroot=/snapshot/day1
```

Windows

```
dsmc incr c:\dir1\* e:\dir1\* -snapshotroot=\\florence\c$\
  snapshots\snapshot.0
```

The following command is invalid because it contains no file specification: AIX Linux Solaris

```
dsmc incremental -snapshotroot=/snapshot/day1
```

Windows

```
dsmc incr -snapshotroot=\\florence\c$\snapshots\snapshot.0
```

Notes:

1. Ensure that the snapshotroot option references a snapshot of the correct volume. Ensure that snapshotroot location refers to the root of the snapshot. If these rules are not followed, unintended results, such as files that expire incorrectly, can result.
2. If you specify the filelist option and the snapshotroot option, all files that are specified in the filelist option are assumed to be in the same file system. If there are entries in the filelist in a different file system, they are skipped and an error is logged. If the filelist contains files that were created in the file system after the snapshot was taken, these entries are also skipped, and an error is logged.
3. Windows You cannot use the snapshotroot option with any backup command, such as backup image, or backup systemstate, and so on.
4. Linux Windows You cannot use the snapshotroot option with the snapdiff option.
5. Windows Use the snapshotroot option with caution if you are using the IBM Spectrum Protect journal-based backup feature. Since there is no coordination between the IBM Spectrum Protect journal and the vendor-acquired snapshot provider (VSS), unwanted behavior can occur with journal notifications received after the snapshot occurs. For example, files might not be backed up, or they might be backed up redundantly to the IBM Spectrum Protect server.
6. You can use the snapshotroot option with the preschedulecmd and postschedulecmd options, or in an automated script that you run with the client scheduler.

Supported Clients

This option is valid for the following clients:

- AIX Linux Solaris UNIX and Linux clients except Mac OS X.
- Windows All Windows clients.

Syntax

```
>>-SNAPSHOTRoot = - --snapshot_volume_name---------------------><
```

Parameters

snapshot_volume_name
: Specifies the root of the logical volume that is created by the independent software vendor snapshot application.

Examples

AIX Linux Solaris Command line:

```
dsmc incremental /usr -SNAPSHOTRoot=/snapshot/day1
```

Windows Command line:

```
dsmc incr c: -SNAPSHOTRoot=\\florence\c$\snapshots\snapshot.0
```

Srvoptsetencryptiondisabled

The srvoptsetencryptiondisabled option allows the client to ignore encryption options in a client options set from the IBM Spectrum Protect™ server.

If the option is set to yes in the client options file, the client ignores the following options in a client options set from the server:

- encryptkey generate
- exclude.encrypt
- include.encrypt

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect API does not support this option.

Options File

Windows Place this option in the client options file (dsm.opt).

AIX Linux Solaris Mac OS X Place this option in the client options file (dsm.sys) within a server stanza.

Syntax

```
                                .-no--.
>>-SRVOPTSETENCryptiondisabled--+-----+------------------------><
                                '-yes-'
```

Parameters

yes
: The backup-archive client ignores the values of the listed encryption options in a client options set from the IBM Spectrum Protect server.

no
: The backup-archive client processes the setting of the listed encryption options in a client options set from the IBM Spectrum Protect server. This is the default.

Examples

Options file:

```
srvoptsetencryptiondisabled no
```

Command line:
: Does not apply.

Srvprepostscheddisabled

The srvprepostscheddisabled option specifies whether to prevent the pre-schedule and post-schedule commands specified by the IBM Spectrum Protect™ administrator from executing on the client system, when performing scheduled operations.

The srvprepostscheddisabled option can be used in conjunction with the schedcmddisabled and srvprepostscheddisabled options to disable the execution of any unwanted operating system command by the IBM Spectrum Protect administrator on a client node.

Supported Clients

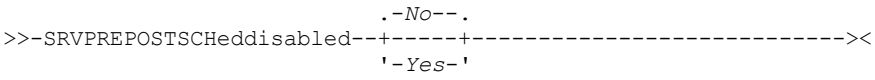
This option is valid for all backup-archive clients that use the IBM Spectrum Protect client scheduler. The server cannot define this option.

Options File

AIX | Linux | Mac OS X | Solaris Place this option in the dsm.sys file within a server stanza for the scheduler. You can set this option on the Scheduler tab of the Preferences editor, in the Schedule Command section.

Windows Place this option in the client options file (dsm.opt) for the scheduler. You can set this option on the Scheduler tab of the Preferences editor, in the Schedule Command section.

Syntax



Parameters

No
: Specifies that the client allows pre-schedule and post-schedule commands defined by the IBM Spectrum Protect administrator to execute on the client system, when performing scheduled operations. If a pre-schedule or a post-schedule command is defined by both the client and the IBM Spectrum Protect administrator, the command defined by the administrator overrides the corresponding command defined in the client option file. This is the default.

Yes
: Specifies that the client prevents pre-schedule and post-schedule commands defined by the IBM Spectrum Protect administrator to execute on the client system, when performing scheduled operations. If a pre-schedule or a post-schedule command is defined by both the client and the IBM Spectrum Protect administrator, the command defined by the administrator will *not* override the corresponding command defined in the client option file. This option can be used in conjunction with the schedcmddisabled and srvprepostscheddisabled options.

Examples

Options file:

```
srvprepostscheddisabled yes
```

Command line:

Does not apply.

Linux | Windows

Srvprepostsnapdisabled

The srvprepostsnapdisabled option specifies whether to prevent the pre-snapshot and post-snapshot commands specified by the IBM Spectrum Protect™ administrator from executing on the client system, when performing scheduled image snapshot backup operations.

The srvprepostsnapdisabled option can be used in conjunction with the schedcmddisabled and srvprepostsnapdisabled options to disable the execution of any unwanted operating system command by the IBM Spectrum Protect administrator on a client node.

Supported Clients

Linux This option is valid for Linux clients that support the image snapshot backup command. The server cannot define this option. The IBM Spectrum Protect API does not support this option.

Windows This option is valid for Windows clients that support the image snapshot backup command. The server cannot define this option. The IBM Spectrum Protect API does not support this option.

Options File

Linux Place this option in the dsm.sys file within a server stanza for the scheduler. You can set this option on the Snapshot tab of the Preferences editor, in the Snapshot Options section.

Windows Place this option in the client options file (dsm.opt) for the scheduler. You can set this option on the Snapshot tab of the Preferences editor, in the Snapshot Options section.

Syntax

```
                              .-No--.
>>-SRVPREPOSTSNApdisabled--+-----+-----------------------------><
                           '-Yes-'
```

Parameters

No
: Specifies that client allows pre-snapshot and post-snapshot commands defined by the IBM Spectrum Protect administrator to execute on the client system, when performing scheduled image snapshot backup operations. If a pre-snapshot or a post-snapshot command is defined by both the client and the IBM Spectrum Protect administrator, the command defined by the administrator overrides the corresponding command defined in the client option file. This is the default.

Yes
: Specifies that the client does not allow pre-snapshot and post-snapshot commands defined by the IBM Spectrum Protect administrator to execute on the client system, when performing scheduled image snapshot backup operations. If a pre-snapshot or a post-snapshot command is defined by both the client and the IBM Spectrum Protect administrator, the command defined by the administrator will *not* override the corresponding command defined in the client option file. This option can be used in conjunction with the schedcmddisabled and srvprepostsnapdisabled options.

Examples

Options file:

```
srvprepostsnapdisabled yes
```

Command line:

Does not apply.

Ssl

Use the ssl option to enable Secure Sockets Layer (SSL) to provide secure client and server communications. When the backup-archive client communicates with an IBM Spectrum Protect™ server V8.1.1 and earlier V8 levels, and V7.1.7 and earlier levels, it determines whether SSL is enabled. When the backup-archive client communicates with an IBM Spectrum Protect server V8.1.2 and later, SSL is always used and this option controls whether object data is encrypted or not. For performance reasons, it might be desirable to not encrypt the object data.

Supported Clients

This option is valid for all supported clients.

Options File

AIX Linux Mac OS X Solaris Place this option in the client system-options file (dsm.sys) within a server stanza. You can also set this option on the Communication tab of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can also set this option on the Communication tab of the Preferences editor.

Syntax

```
        .-No--.
>>-SSL--+-----+-------------------------------------------------><
        '-Yes-'
```

Parameters for communicating with an IBM Spectrum Protect server V8.1.1 and earlier V8 levels, and V7.1.7 and earlier levels.

No
: Specifies that the backup-archive client does not use SSL to encrypt information. No is the default.

Yes
: Specifies that the backup-archive client uses SSL to encrypt information.

  To enable SSL, specify SSL Yes and change the value of the TCPPORT option. Changing the value of the TCPPORT option is generally necessary because the IBM Spectrum Protect server is typically set up to listen for SSL connections on a separate port.

Parameters for communicating with an IBM Spectrum Protect server V8.1.2 and later.

No
: Specifies that the backup-archive client does not use SSL to encrypt object data when communicating with the server. All other information is encrypted. No is the default.

Yes
: Specifies that the backup-archive client uses SSL to encrypt all information, including object data, when communicating with the server.

  To use SSL for all data, specify SSL Yes.

Examples

Options file:
```
ssl yes
```
Command line:
: Does not apply.

Sslacceptcertfromserv

Use the sslacceptcertfromserv option to control whether the backup-archive client or the API application accept and trust the IBM Spectrum Protect™ server's Secure Sockets Layer (SSL) public certificate the first time they connect. This option applies only the first time that the backup-archive client or the API application connects to the IBM Spectrum Protect server. When the SSL public certificate is accepted, future changes to the certificate are not automatically accepted, and must be manually imported to the backup-archive client. You can use this option to connect only to an IBM Spectrum Protect server V8.1.2 and later.

Supported Clients

This option is valid for all supported clients.

Options File

AIX | Linux | Mac OS X | Solaris Place this option in the client system-options file (dsm.sys) within a server stanza.

Windows Place this option in the client options file (dsm.opt).

Syntax

```
                          .-Yes-.
>>-SSLACCEPTCERTFROMSERV--+-----+------------------------------><
```

```
                    '-No--'
```

Parameters

Yes
: Specifies that the backup-archive client does automatically accept the IBM Spectrum Protect server's public certificate. Yes is the default.

No
: Specifies that the backup-archive client does not automatically accept the IBM Spectrum Protect server's public certificate.

  To disable SSLACCEPTCERTFROMSERV, specify sslacceptcertfromserv no.

Examples

Options file:
```
sslacceptcertfromserv no
```
Command line:
: Does not apply.

Ssldisablelegacytls

Use the ssldisablelegacytls option to disallow the use of SSL protocols that are lower than TLS 1.2.

Supported Clients

This option is valid for all supported clients.

Options File

AIX | Linux | Mac OS X | Solaris Place this option in the dsm.sys file. You can also set this option in the GUI by selecting the Require TLS 1.2 or above check box on the Communication tab of the Preferences editor. You cannot set this option on the command line.

Windows Place this option in the client options (dsm.opt) file. You can also set this option in the GUI by selecting the Require TLS 1.2 or above check box on the Communication tab of the Preferences editor. You cannot set this option on the command line.

Syntax

```
                          .-No--.
>>-SSLDISABLELEGACYtls--+-----+--------------------------------><
                          '-Yes-'
```

Parameters

No
: Specifies that the backup-archive client does not require TLS 1.2 for SSL sessions. It allows connection at TLS 1.1 and lower SSL protocols. When the backup-archive client communicates with an IBM Spectrum Protect™ server V8.1.1 and earlier V8 levels, and V7.1.7 and earlier levels, No is the default.

Yes
: Specifies that the backup-archive client requires that all SSL sessions use TLS 1.2 (or higher) protocol. When the backup-archive client communicates with an IBM Spectrum Protect server V8.1.2 and later, Yes is the default.

Examples

Options file:
```
ssldisablelegacytls yes
```
Command line:
: Does not apply.

Sslfipsmode

The sslfipsmode option specifies whether the client uses SSL Federal Information Processing Standards (FIPS) mode for Secure Sockets Layer (SSL) communications with the server. The default is no.

Supported clients

This option is supported on all clients.

Options File

Set this option in the client options file. You cannot specify it as a command-line parameter and you cannot set this option in a client options set.

Syntax

```
                  .-No--.
>>-SSLFIPSMODE = -+-----+--------------------------------------><
                  '-Yes-'
```

Parameters

No
: Specifies that the client does not use SSL FIPS mode for secure communications with the server. SSL in FIPS mode is supported only by version 6.3 and newer versions of the server. Set this client option to no if the client uses SSL to connect to a server that is not at V6.3, or newer.

Yes
: Specifies that the client uses SSL FIPS mode for secure communications with the server. Setting this option to yes restricts SSL session negotiation to use only FIPS-approved cipher suites. SSL FIPS mode is only supported by the V6.3 (or newer) server.

Example

To enable SSL FIPS mode on the client:

```
SSLFIPSMODE yes
```

Sslrequired

The sslrequired option specifies the conditions when SSL is or is not required when the client logs on to the IBM Spectrum Protect™ server or storage agents. To actually enable SSL so client-to-server and client-to-storage-agent communications are secure, you must set the client ssl option to yes. When communicating with the IBM Spectrum Protect server V8.1.2 and later, this option no longer applies since SSL is always used.

Supported Clients

This option is supported on all clients.

Options File

Place this option in the client options file or in the GUI, on the Communications tab. You cannot set this option on the command line.

Syntax

```
                .-Default----.
>>-SSLREQuired-+------------+----------------------------------><
                +-Yes--------+
```

```
                +-No---------+
                '-SERVERonly-'
```

Parameters

Default
: This setting indicates that SSL is required to secure communications between the client and server, and client and storage agents, if `AUTHENTICATION=LDAP` is set on the server. To secure communications by using SSL, you must also set `ssl=yes` on the client.
If `AUTHENTICATION=LOCAL` is set on the server, this setting indicates that SSL is not required. Even though SSL is not required when `AUTHENTICATION=LOCAL` and `sslrequired=default`, you can still use SSL by setting the client ssl option to yes.

Yes
: Indicates that SSL is always required to secure communications between the client and server, and between the client and storage agents. `sslrequired=yes` has no dependency on the server AUTHENTICATION option. If you set `sslrequired=yes` on the client, you must also set `ssl=yes` on the client.

No
: Indicates that you do not require SSL to be used to secure communications between the client and server or between the client and storage agents. Choose this option only if you use a virtual private network or other method to secure your session communications. You can still enable SSL by setting `ssl=yes` on the client; but `sslrequired=no` specifies that SSL is not a prerequisite.

SERVERonly
: Indicates that SSL is required for client-to-server communications and not for server-to-storage agent communications. To use SSL for client to server communications, set `sslrequired=serveronly` and `ssl=yes`. The server setting for the AUTHENTICATION option can be either LOCAL or LDAP.
For client to storage agent communications, use the client lanfreessl option to enable SSL.

The following table describes the situations under which authentication succeeds or fails, depending on the settings of the SSLREQUIRED option on the server, and client, and the setting of the ssl option on the client. The table results assume that valid credentials are supplied.

Table 1. Effects of server and client SSL settings on success or failure of login attempts

SSLREQUIRED option (server setting)	sslrequired option (client setting)	ssl option (client setting)	Authentication success or failure
Yes	Yes	Yes	Authentication succeeds
Yes	Yes	No	Authentication fails; the client rejects the session
Yes	No	Yes	Authentication succeeds
Yes	No	No	Authentication fails; the server rejects the session
No	Yes	Yes	Authentication succeeds
No	Yes	No	Authentication fails; the client rejects the session
No	No	Yes	Authentication succeeds
No	No	No	Authentication succeeds

The following text describes how setting `SSLREQUIRED=DEFAULT` and `SSLREQUIRED=SERVERONLY` on the server affects the ssl option on the client.

If the server sets `SSLREQUIRED=DEFAULT` and `AUTHENTICATION=LDAP`, the client must set `ssl=yes` or authentication fails.

If the server sets `SSLREQUIRED=DEFAULT` and `AUTHENTICATION=LOCAL`, the client can set `ssl=yes` or `ssl=no`.

If the server sets `SSLREQUIRED=SERVERONLY`, you must set `ssl=yes` on the client. The client lanfreessl option can be set to yes, to secure communications with a storage agent, or to no if secure communications with storage agents is not needed.

Examples

Options file:

```
sslrequired yes
sslrequired no
sslrequired default
sslrequired serveronly
```

Command line:

Not applicable; you cannot set this option on the command line.

Linux | Windows

Stagingdirectory

The stagingdirectory option defines the location where the client stores any data that it generates to perform its operations. The data is deleted when processing is complete.

Windows The client uses the stagingdirectory location for Active Directory object query and restore operations. The client also uses the stagingdirectory location for temporary files when the client processes files that were migrated with IBM Spectrum Protect™ HSM for Windows.

Important: Starting with Version 8.1.2, the snapdiffchangelogdir option is used to specify the location to store change logs for snapshot differential backup operations. The stagingdirectory option is no longer used for this purpose. For more information, see Snapdiffchangelogdir.

Supported Clients

Linux This option is valid for Linux clients. The server can also define this option.

Windows This option is valid for all Windows clients. The server can also define this option.

Options File

Linux Place this option in the client options file (dsm.opt). When stagingdirectory is specified on the command line, it overrides the values that are specified in the options file.

Windows Place this option in the client options file (dsm.opt). When stagingdirectory is specified on the command line, it overrides the values that are specified in the options file.

Syntax

```
>>-STAGINGDIRectory--path-------------------------------------><
```

Parameters

path

Linux Specifies the directory path where the client writes staging data. If you do not specify a staging directory, the client stores temporary data in the temporary file system (typically /tmp).

Windows Specifies the directory path where the client writes staging data. If you do not specify a staging directory, the client checks for the existence of the USER environment variables in the following order, and uses the first path found:

1. The path that is specified by the TMP user variable.
2. The path that is specified by the TMP system variable.
3. The path that is specified by the TEMP user variable.
4. The path that is specified by the TEMP system variable.
5. The Windows system directory.

Windows In Uniform Naming Convention (UNC) format, the path must contain a drive letter. In the following UNC format example, the path contains the drive letter D$:

```
\\computer7\D$\temp\tsmstaging
```

Examples

Options file:

Linux `stagingdirectory /usr/tsmdata`
Linux `stagingdirectory /private/tmp`
Windows `stagingdirectory c:\tsmdata`

Command line:

Linux `-stagingdir="/tmp/tsmtempdata"`
Windows `-stagingdir="e:\tsmdata"`

http://www.ibm.com/support/knowledgecenter/SSERBH

Subdir

The subdir option specifies whether you want to include subdirectories of named directories for processing.

You can use the subdir option with the following commands:

- archive
- delete archive
- delete backup
- AIX Linux Solaris Mac OS X Windows incremental
- query archive
- query backup
- restore
- restore backupset
- restore group
- retrieve
- selective

If you set the subdir option to `yes` when backing up a specific path and file, the backup-archive client recursively searches all of the subdirectories under that path, and looks for any instances of the specified file that exist under any of those subdirectories. For example, assume that a file called myfile.txt exists on a client in the following directories:

```
//myfile.txt
/dir1/myfile.txt
/dir1/dir_a/myfile.txt
/dir1/dir_b/myfile.txt
```

Performing a selective backup of that file, as follows, backs up all four instances of myfile.txt:

```
dsmc sel /myfile.txt -subdir=yes
```

Similarly, the following command displays all instances of myfile.txt if you specify subdir=yes in the client options file or in a client options set.

```
dsmc restore /myfile.txt -pick
```

Supported Clients

This option is valid for all clients. The server can also define this option. The IBM Spectrum Protect™ API does not support this option.

Options File

Windows Place this option in the client options file (dsm.opt).

AIX Linux Solaris Mac OS X Place this option in the client user-options file (dsm.opt).

Syntax

```
          .-No--.
>>-SUbdir--+-----+-----------------------------------------><
          '-Yes-'
```

Parameters

No
: Subdirectories are not processed. This is the default.

Yes
: Subdirectories are processed. Because the client program searches all subdirectories of a directory that is being processed, processing can take longer to complete. Specify Yes only when necessary.

  If you use the preservepath option in addition to subdir=`yes`, it can affect which subdirectories are processed.

  AIX Linux Solaris Mac OS X If a subdirectory is a mounted file system, it is not processed even if you specify subdir=`yes`.

Note:

1. When you run the client in interactive mode, and if you use the -subdir=yes option, the setting persists for all commands entered in interactive mode, until you end interactive mode, by typing `Quit`.
2. If subdir=yes is in effect when you restore multiple files, place a directory delimeter character at the end of the destination file specification. If the delimeter is omitted, the client displays a message indicating that the destination file specification is not valid.
3. It is a best practice to include only the default value for subdir (No) in a client options file or a client options set.

Examples

Options file:

```
subdir no
```

Command line:

Mac OS X To restore the structure:

```
/Users/mike/dir1
/Users/mike/dir1/file1
/Users/mike/dir1/dir2
/Users/mike/dir1/dir2/file1
```

enter any of the following commands:

```
dsmc rest "/Users/van/dir1/*" /Users/mike/ -su=yes
dsmc rest "/Users/van/dir1/file*" /Users/mike/ -su=yes
dsmc rest "/Users/van/dir1/file1*" /Users/mike/ -su=yes
```

AIX Linux Solaris Mac OS X To restore the structure:

```
/path2/dir1
/path2/dir1/file1
/path2/dir1/dir2
/path2/dir1/dir2/file1
```

enter any of the following commands:

```
dsmc rest "/path/dir1/*" /path2/ -su=yes
dsmc rest "/path/dir1/file*" /path2/ -su=yes
dsmc rest "/path/dir1/file1*" /path2/ -su=yes
```

Windows To restore the structure:

```
\path2\dir1
\path2\dir1\file1
\path2\dir1\dir2
\path2\dir1\dir2\file1
```

enter any of the following commands:

```
rest \path\dir1\* \path2\ -su=yes
rest \path\dir1\file* \path2\ -su=yes
```

```
rest \path\dir1\file1* \path2\ -su=yes
```

This option is valid on the initial command line and in interactive mode. If you use this option in interactive mode, it affects only the command with which it is specified. When that command completes, the value reverts to the value at the beginning of the interactive session. This is the value from the dsm.opt file unless overridden by the initial command line or by an option forced by the server.

Windows

Systemstatebackupmethod

Use the systemstatebackupmethod option to specify which backup method to use to back up the system writer portion of the system state data. The method you select is used when you backup the system state data.

Supported clients

This option is valid for Windows clients.

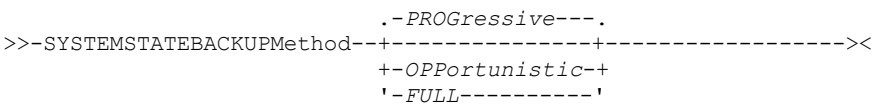
Options file

Place this option in the client options file (dsm.opt). When specified in the dsm.opt file, the option affects system state backups created by BACKUP SYSTEMSTATE commands, and system state data backed up by INCREMENTAL commands. However, the only command that you can specify this option on is the BACKUP SYSTEMSTATE command.

Schedule definitions

You can also specify this option on the options parameter of a schedule definition on schedules that have both action=backup and subaction=systemstate set. Defining an infrequent schedule with this option set to FULL ensures that you periodically perform a full backup of Windows system state data.

Syntax



Parameters

PROGressive

With the PROGressive method, the system writer portion of the system state data is backed up using the progressive incremental backup method. That is, if system writer files have not changed since the last system state backup, they are not included in this backup. Only the changed system writer files are backed up. This is the default system state backup method.

This type of system state backup uses the least network bandwidth and IBM Spectrum Protect™ server storage, but it increases the amount of server database processing required to keep track of the changes.

OPPortunistic

With the OPPortunistic method, if any system writer files have changed since the last system state backup, all system writer files are backed up.

This method, like the PROGressive method, also uses the least network bandwidth and IBM Spectrum Protect server storage if system writer files have not changed since the last system state backup. If any system writer files have changed since the last system state backup then the system writer is backed up in full, which uses more network bandwidth and server storage. With the OPPortunistic method, the amount of server database processing that occurs is less than that caused by the PROGressive method.

FULL

When FULL is specified, all system writer files are backed up, even if they have not changed since the last system state backup.

This type of system state backup uses the most network bandwidth and IBM Spectrum Protect server storage because all system writer files are backed up during each system state backup operation. However, this system state backup method causes little server database processing.

Examples

Options file:

```
SYSTEMSTATEBACKUPMETHOD FULL
SYSTEMSTATEBACKUPMETHOD OPPORTUNISTIC
```

Command line:

```
backup systemstate -SYSTEMSTATEBACKUPMETHOD=FULL
```

Tapeprompt

The tapeprompt option specifies whether you want the backup-archive client to wait for a tape mount if it is required for a backup, archive, restore, or retrieve process, or to be prompted for a choice.

In the backup-archive client GUI, the Media Mount dialog can display the `Information Not Available` value in the Device and Volume Label fields if you perform a standard (also known as classic) restore or retrieve operation. This value means that this information is only available for no-query restore or retrieve operations; not a standard restore or retrieve operation. The Device field displays the name of the device on which to mount the media needed to process an object. The Volume Label field displays the name of the volume needed to process an object.

Tape prompting does not occur during a scheduled operation regardless of the setting for the tapeprompt option.

The tapeprompt option can be used with the following commands:

- archive
- delete archive
- delete backup
- incremental
- restore
- retrieve
- selective

Note: The server can also define this option.

Supported Clients

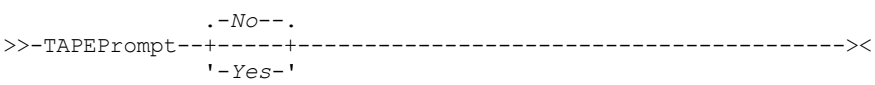
This option is valid for all clients.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the client user-options file (dsm.opt). You can set this option on the General tab, Prompt before mounting tapes check box of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the General tab, Prompt before mounting tapes check box of the Preferences editor.

Syntax



Parameters

No
: You are not prompted for your choice. The server waits for the appropriate tape to mount. This is the default.

Note: For API applications, this permits backup directly to tape.

Yes
: You are prompted when a tape is required to back up, archive, restore, or retrieve data. At the prompt, you can wait for the appropriate tape to be mounted, always wait for a tape to be mounted, skip a particular object, skip all objects on a single tape, skip all objects on all tapes, or cancel the entire operation.

Examples

Options file:
```
tapeprompt yes
```
Command line:
```
-tapep=yes
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Tcpadminport

Use the tcpadminport option to specify a separate TCP/IP port number on which the server waits for requests for administrative client sessions, allowing secure administrative sessions within a private network.

The client tcpadminport setting depends on how the IBM Spectrum Protect™ server tcpadminport and adminonclientport options are configured. The server has a tcpadminport setting that indicates on which port the server listens for administrative sessions, and the adminonclientport setting, which can be either yes or no.

If tcpadminport is not set on the server, then administrative sessions are allowed on the same port as client sessions.

If tcpadminport is set on the server, then administrative sessions are allowed on the port specified by that setting. In this case, if adminonclientport yes is in effect, then administrative sessions can connect on either the regular client port or the port specified by tcpadminport. If adminonclientport no is in effect, then administrative sessions can connect only on the port specified by tcpadminport.

Supported Clients

This option is valid for all clients. The server can also define this option. The IBM Spectrum Protect API does not support this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the dsm.sys file within a server stanza. You can set this option on the Communication tab, in the Admin Port field in the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Communication tab, in the Admin Port field in the Preferences editor.

Syntax

```
>>-TCPADMINPort--+- ------------------+------------------------><
                 '-admin_port_address-'
```

Parameters

admin_port_address
: Specifies the port number of the server. The default value is the value of the tcpport option.

Examples

Options file:
```
tcpadminport 1502
```

Tcpbuffsize

The tcpbuffsize option specifies the size of the internal TCP/IP communication buffer used to transfer data between the client node and server. Although it uses more memory, a larger buffer can improve communication performance.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Communication tab, in the Buffer Size field in the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Communication tab, in the Buffer Size field in the Preferences editor.

Syntax

```
>>-TCPBuffsize-- --size----------------------------------------><
```

Parameters

size
: Specifies the size, in kilobytes, that you want to use for the internal TCP/IP communication buffer. The range of values is 1 through 512; the default is 32.

  Depending on the operating system communication settings, your system might not accept all values in the range of 1 through 512.

Examples

Options file:

```
tcpb 32
```

Command line:

```
-tcpbuffsize=32
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Tcpcadaddress

The tcpcadaddress option specifies a TCP/IP address for dsmcad. Normally, this option is not needed. Use this option only if your client node has more than one TCP/IP address, or if TCP/IP is not the default communication method.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Options File

Windows Place this option in the client options file (dsm.opt).

AIX Linux Solaris Mac OS X Place this option in the dsm.sys file within a server stanza.

Syntax

```
>>-TCPCADAddress-- --cad_address------------------------------><
```

Parameters

AIX Linux Solaris Mac OS X Windows cad_address

AIX Linux Solaris Mac OS X Windows Specifies a TCP/IP Internet domain name or a numeric IP address. If you specify an IPv6 addresses, you must specify the commmethod V6Tcpip option.

Examples

Options file:

```
tcpcada dsmclnt.example.com
```

Command line:

```
-tcpcadaddress=192.0.2.0
```

```
-tcpcadaddress=mycompany.example.com
```

AIX Linux Solaris Mac OS X Windows

```
-tcpcadaddress=2001:0DB8:0:0:0:0:0:0
```

This option is valid only on the initial command line of the dsmcad program. It is not valid with other dsm modules.

Tcpclientaddress

The tcpclientaddress option specifies a TCP/IP address if your client node has more than one address, and you want the server to contact an address other than the one that was used to make the first server contact.

The server uses this address when it begins the server prompted scheduled operation.

Use this option only if you use the prompted parameter with the schedmode option.

If sessioninitiation is set to serveronly, the value for the tcpclientaddress client option should be the same as the value for the HLAddress server setting.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the dsm.sys file *within* a server stanza. You can set this option on the Scheduler tab, Your TCP/IP address field of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Scheduler tab, Your TCP/IP address field of the Preferences editor.

Syntax

```
>>-TCPCLIENTAddress-- --client_address-------------------------><
```

Parameters

client_address

Specifies the TCP/IP address you want the server to use to contact your client node. Specify a TCP/IP Internet domain name or a numeric IP address. The numeric IP address can be either a TCP/IPv4 or TCP/IPv6 address. You can only use IPv6 addresses if you specified the commmethod *V6Tcpip* option.

Examples

AIX Linux Mac OS X Solaris Options file:

AIX Linux Mac OS X Solaris

```
tcpclienta dsmclnt.example.com
or
tcplienta 192.0.2.21
```

Windows Command line:

Windows

```
-tcpclientaddress=192.0.2.0
-tcpclientaddress=example.mycompany.mydomain.com
-tcpclientaddress=2001:0DB8:0:0:0:0:0:0
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Tcpclientport

The tcpclientport option specifies a TCP/IP port number for the server to contact the client when the server begins the server prompted scheduled operation.

Use this option only if you specify the prompted parameter with the schedmode option.

If sessioninitiation is set to serveronly, the value for the tcpclientport client option should be the same as the value for the LLAddress server option.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the dsm.sys file within a server stanza. You can set this option on the Scheduler tab, in the Your TCP/IP port field in the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Scheduler tab, in the Your TCP/IP port field in the Preferences editor.

Syntax

```
>>-TCPCLIENTPort-- --client_port_address----------------------><
```

Parameters

client_port_address
: Specifies the TCP/IP port address you want the server to use to contact your client node. The range of values is 1 through 32767; the default is 1501.

Examples

Options file:

```
tcpclientp 1502
```

Command line:

```
-tcpclientport=1492
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Tcpnodelay

The tcpnodelay option specifies whether the client disables the delay of sending successive small packets on the network, per transaction.

Change the value from the default of yes only under one of the following conditions:

- You are directed to change the option by IBM® technical support.
- You fully understand the effects of the TCP Nagle algorithm on network transmissions. Setting the option to no enables the Nagle algorithm, which delays sending small successive packets.

AIX Linux Solaris Mac OS X Windows

Supported Clients

AIX Linux Solaris Mac OS X This option is valid for all UNIX and Linux clientst.

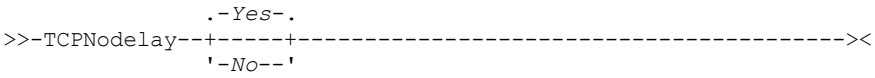
Windows This option is valid for all Windows clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Communication tab in the Preferences editor. Select Send transaction to the server immediately.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Communication tab in the Preferences editor. Select Send transaction to the server immediately.

Syntax



Parameters

No
: Specifies that the server does not allow successive small packets to be sent immediately over the network. Setting this option to no can degrade performance.

Yes
: Specifies that the server or client allows successive small packets to be sent immediately over the network. The default is yes.

Examples

Options file:

```
tcpnodelay yes
```

Command line:

Does not apply.

Tcpport

The tcpport option specifies a TCP/IP port address for the IBM Spectrum Protect™ server. You can obtain this address from your administrator.

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Communication tab, in the Server Port field in the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Communication tab, in the Server Port field in the Preferences editor.

Syntax

```
>>-TCPPort-- --port_address-------------------------------------><
```

Parameters

port_address
: Specifies the TCP/IP port address that is used to communicate with a server. The range of values is 1 through 32767; the default is 1500.

Examples

Options file:

```
tcpp 1501
```

Windows Command line:

Windows `-tcpport=1501`

AIX Linux Solaris Mac OS X Command line:

AIX Linux Solaris Mac OS X Does not apply.

Windows This option is valid only on the initial command line. It is not valid in interactive mode.

Tcpserveraddress

The tcpserveraddress option specifies the TCP/IP address for the IBM Spectrum Protect™ server. You can obtain this server address from your administrator.

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Communication tab, in the Server Address field in the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Communication tab, in the Server Address field in the Preferences editor.

If this option is not specified, the client attempts to contact a server running on the same computer as the backup-archive client.

Syntax

```
>>-TCPServeraddress-- --server_address-------------------------><
```

Parameters

server_address
: Specifies a 1 to 64 character TCP/IP address for a server. Specify a TCP/IP domain name or a numeric IP address. The numeric IP address can be either a TCP/IP v4 or TCP/IP v6 address. You can only use IPv6 addresses if you specified the commmethod V6Tcpip option.

Examples

Options file:

```
tcps dsmchost.example.com
```

AIX Linux Solaris Mac OS X Command line:

AIX Linux Solaris Mac OS X Does not apply.

Windows Command line:

Windows `-tcpserveraddress=129.33.24.99`

```
-tcpserveraddress=2002:92b:111:221:128:33:10:249
```

Windows This option is valid only on the initial command line. It is not valid in interactive mode.

Tcpwindowsize

Use the tcpwindowsize option to specify, in kilobytes, the size you want to use for the TCP/IP sliding window for your client node.

The sending host cannot send more data until it receives an acknowledgment and a TCP receive window update. Each TCP packet contains the advertised TCP receive window on the connection. A larger window allows the sender to continue sending data and can improve communication performance.

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the Communication tab, Window Size field of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Communication tab, Window Size field of the Preferences editor.

Syntax

```
>>-TCPWindowsize-- --window_size-------------------------------><
```

Parameters

AIX Linux Solaris Mac OS X window_size

AIX Linux Solaris Mac OS X Specifies the size, in kilobytes, to use for your client node TCP/IP sliding window. The range of values is 0 through 2048. A value of 0 allows the client to use the operating system default TCP window size. Values from 1 to 2048 indicate that the window size is in the range of 1KB to 2MB. If you specify a value less than 1, the TCP window size defaults to 1. If you specify a value greater than 2048, the TCP window size defaults to 2048.

AIX Linux Solaris Mac OS X For backup-archive clients, the default value for this parameter is 63 KB.

AIX Linux Solaris Mac OS X For IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware, the default value for this parameter is 512 KB.

AIX Linux Solaris Mac OS X

Notes:

- The TCP window acts as a buffer on the network. It is not related to the tcpbuffsize option, or to the send and receive buffers allocated in client or server memory.
- A window size larger than the buffer space on the network adapter might degrade throughput due to resending packets that were lost on the adapter.
- Depending on the operating system communication settings, your system might not accept all values in the range of values.
- The tcpwindowsize option overrides the operating system's default TCP/IP session send and receive window sizes.

Windows window_size

Windows Specifies the size, in kilobytes, to use for your client node TCP/IP sliding window. The range of values is 0 through 2048. A value of 0 allows the client to use the operating system default TCP window size. Values from 1 to 2048 indicate that the window size is in the range of 1KB to 2MB. If you specify a value less than 1, the TCP window size defaults to 1. If you specify a value greater than 2048, the TCP window size defaults to 2048.

Windows For backup-archive clients, the default value for this parameter is 63 KB.

Windows For IBM Spectrum Protect for Virtual Environments: Data Protection for VMware, the default value for this parameter is 512 KB.

Windows

Notes:

- The TCP window acts as a buffer on the network. It is not related to the tcpbuffsize option, or to the send and receive buffers allocated in client or server memory.

- A window size larger than the buffer space on the network adapter might degrade throughput due to resending packets that were lost on the adapter.
- Depending on the operating system communication settings, your system might not accept all values in the range of values.
- The tcpwindowsize option overrides the operating system's default TCP/IP session send and receive window sizes.
- Windows provides a larger TCP receive window size when communicating with hosts that also provide this support, known as RFC1323. In these environments, a value greater than 63 can be useful.

Examples

Options file:

```
tcpwindowsize 63
```

Command line:

```
-tcpw=63
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Timeformat

The timeformat option specifies the format in which you want to display and enter system time.

Windows Use this option if you want to change the default time format for the language of the message repository you are using.

By default, the backup-archive and administrative clients obtain format information from the locale definition in effect at the time the client is called. Consult the documentation on your local system for details about setting up your locale definition.

Note: The timeformat option does not affect the web client. The web client uses the time format for the locale that the browser is running in. If the browser is not running in a locale that the client supports, the web client uses the time format for US English.

You can use the timeformat option with the following commands:

- delete archive
- delete backup
- expire
- query archive
- Windows query asr
- query backup
- query filespace
- AIX Linux Solaris Windows query image
- query nas
- Windows query systemstate
- restore
- AIX Linux Solaris Windows restore image
- AIX Solaris Windows restore nas
- Windows restore registry
- retrieve
- set event

When you include the timeformat option with a command, it must precede the fromtime, pittime, and totime options.

Supported Clients

This option is valid for all clients.

Options File

AIX Linux Solaris Mac OS X Place this option in the client user-options file (dsm.opt). You can set this option on the Regional Settings tab, Time Format field of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Regional Settings tab, Time Format field of the Preferences editor.

Syntax

```
>>-TIMEformat-- --format_number--------------------------------><
```

Parameters

format_number

Displays time in one of the formats listed here. Select the format number that corresponds to the format you want to use. When you include the timeformat option in a command, it must precede the fromtime, pittime, and totime options.

AIX | Linux | Solaris 0

AIX | Linux | Solaris Use the locale-defined time format (does not apply to Mac OS X). This value is the default if the locale-specified format consists of digits, separator characters, and, if applicable, the AM or PM string.

1

23:00:00

AIX | Linux | Mac OS X | Solaris This is the default if the locale-specified format does not consist of digits, separator characters, and, if applicable, the AM or PM string.

2

23,00,00

3

23.00.00

4

12:00:00 A/P

5

A/P 12:00:00

Examples

Options file:

```
timeformat 4
```

Command line:

```
-time=3
```

This option is valid on the initial command line and in interactive mode. If you use this option in interactive mode, it affects only the command with which it is specified. When that command completes, the value reverts to the value at the beginning of the interactive session. This is the value from the dsm.opt file unless overridden by the initial command line or by an option forced by the server.

Additional considerations for specifying time and date formats

The date or time format you specify with this option must be used when using options that take date and time as input. Examples are: totime, fromtime, todate, fromdate, and pittime.

For example, if you specify the timeformat option as `TIMEFORMAT 4`, the value that you provide on the fromtime or totime option must be specified as a time such as `12:24:00pm`. Specifying `13:24:00` would not be valid because `TIMEFORMAT 4` requires an hour integer that is 12 or less. If you want to specify up to 24 hour values on an option, and if you want to use commas as separators, you must specify `TIMEFORMAT 2`.

AIX | Linux | Mac OS X | Solaris

Configuring date and time formats in the system locale configuration file

You can specify date and time formats by configuring them in your system's locale file. If you specify time and date formats in the locale file, they must be defined using a subset of number-producing format specifiers that are supported by the C language `strftime()` function. You can use the following specifiers to set date and time formats in configuration settings for your locale.

Date specifiers

- `%Y` - the year, in four digits. For example, 2011.
- `%y` - the year, last two digits only. For example, 11 not 2011.
- `%m` - the month, as a decimal number (1-12).
- `%d` - the day of the month (1-31).

In the date specifiers, you can specify only one year specifier. Do not specify both `%Y` and `%y`. The E modifier (a capital E) can precede the date specifiers to produce the locale's alternative form for the year, month, or day. If no alternative form exists, the E modifier is ignored. Separate the specifiers with a single 7-bit ASCII character. Commonly used separators include colons (:), commas (,), periods (.), hyphens (-), or forward slash (/) characters. Do not use multibyte characters as separators.

Time specifiers

- `%H` - the hour, in 24-hour form (00-23).
- `%I` - the hour, in 12-hour form (00-12).
- `%M` - minutes after the hour (00-59).
- `%S` - seconds after the minute (00-59)
- `%p` - adds the AM (before noon) or PM (after noon) indicator.

In the time specifiers, you can specify only one hour specifier. Do not specify both `%I` and `%H`.

The O modifier (a capital O) can precede the time specifiers to produce the locale's alternative form for the hour, minutes, or seconds. The O modifier cannot precede the `%p` specifier. Separate the specifiers with a single 7-bit ASCII character. Commonly used separators include colons (:), commas (,), or periods (.). Do not use multibyte characters as separators. Do not specify a separator between the `%p` specifier and the separator that precedes or follows it.

Time format examples, configured in the locale settings

AIX Linux Mac OS X Solaris To set a particular time format, edit the configuration file for your locale and modify the `t_fmt` line to support your needs. Whatever time format you select applies both to output and to input. After the locale configuration file has been edited, the localedef command must be run to create the final locale file.

Table 1. Sample time format settings in the locale configuration (t_fmt line)

Example	Result
"%H:%M:%S"	Displays time in the form *hh:mm:ss* with *hh* ranging from 0 through 23.
"%H,%M,%S"	Displays time in the form *hh,mm,ss* with *hh* ranging from 0 through 23.
"%I,%M,13p"	Displays time in the form *hh,mm,ssA/P* with *hh* ranging from 1 through 12 and *A/P* is the local abbreviation for ante-meridian (AM in English) or post-meridian (PM in English).

Date format examples, configured in the locale settings

AIX Linux Mac OS X Solaris To set a particular date format, edit the configuration file and modify the `d_fmt` line as needed to support your needs. Whatever date format you select applies both to output and to input.

Table 2. Sample date format settings in the locale configuration (d_fmt line)

Example	Result
"%m/%d/%y"	Displays the date in the form MM/DD/YY.
"%d.%m.%Y"	Displays the date in the form DD.MM.YYYY.

AIX Solaris Windows

Toc

Use the toc option with the backup nas command or the include.fs.nas option to specify whether the backup-archive client saves table of contents (TOC) information for each file system backup.

You should consider the following when deciding whether you want to save TOC information:

- If you save TOC information, you can use the QUERY TOC server command to determine the contents of a file system backup in conjunction with the RESTORE NODE server command to restore individual files or directory trees.
- You can also use the web client to examine the entire file system tree and select files and directories to restore.

- Creation of a TOC requires that you define the TOCDESTINATION attribute in the backup copy group for the management class to which this backup image is bound. Note that TOC creation requires additional processing, network resources, storage pool space, and possibly a mount point during the backup operation.
- If you do not save TOC information, you can still restore individual files or directory trees using the RESTORE NODE server command, provided that you know the fully qualified name of each file or directory and the image in which that object was backed up.

Supported Clients

AIX Solaris This option is only valid for AIX® and Solaris clients. The IBM Spectrum Protect™ API does not support this option.

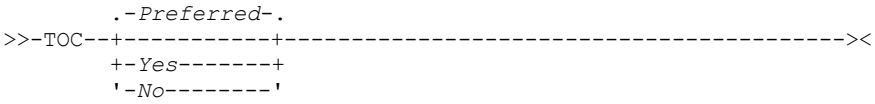
Windows This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option.

Options File

AIX Solaris Place the include.fs.nas statement containing the toc value in the dsm.sys file within a server stanza.

Windows Place the include.fs.nas statement containing the toc value in the client options file (dsm.opt).

Syntax



Parameters

Yes
: Specifies that the client saves TOC information during a NAS file system image backup. However, the backup fails if an error occurs during creation of the TOC.

No
: Specifies that the client does not save TOC information during a NAS file system image backup.

Preferred
: Specifies that the client saves TOC information during a NAS file system image backup. The backup does not fail if an error occurs during creation of the TOC. This is the default.

Note: If the mode option is set to differential and you set the toc option to preferred or yes, but the last full image does not have a TOC, the client performs a full image backup and creates a TOC.

Examples

Options file:

```
include.fs.nas netappsj/vol/vol0 homemgmtclass toc=yes
```

AIX Solaris Command line:

AIX Solaris
```
backup nas -nasnodename=netappsj /vol/vol0 -toc=yes
```

Windows Command line:

Windows
```
backup nas -nasnodename=netappsj {/vol/vol0} -toc=yes
```

Todate

Use the todate option with the totime option to specify an ending date and time to which you want to search for backups or archives during a restore, retrieve, or query operation

Use the todate and totime options with the fromtime and fromdate options to request a list of backed up or archived files within a period of time. For example, you might request a list of files that were backed up between 6:00 AM on July 1, 2002 and 11:59 PM on July 30, 2002.

Use the todate option with the following commands:

- delete backup
- query archive
- query backup
- restore
- restore group
- retrieve

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-TODate = - --date-------------------------------------------><
```

Parameters

date
: Specifies an ending date. Enter the date in the format you selected with the dateformat option.

  When you include dateformat with a command, it must precede the fromdate, pitdate, and todate options.

Examples

Mac OS X Command line:

Mac OS X
```
dsmc restore "/Users/agordon/Documents/*" -todate=12/11/2003
```

AIX Linux Solaris Mac OS X Command line:

AIX Linux Solaris Mac OS X
```
dsmc restore "/home/user1/*" -todate=12/11/2003
```

Windows Command line:

Windows
```
dsmc restore -todate=12/11/2003 c:\myfiles\
```

Totime

Use the totime option with the todate option to specify an ending date and time to which you want to search for backups or archives during a restore, retrieve, or query operation. The backup-archive client ignores this option if you do not specify the todate option.

Use the totime and todate options with the fromtime and fromdate options to request a list of files that were backed up within a period of time. For example, you might request a list of files that were backed up between 6:00 AM on July 1, 2003 and 11:59 PM on July 30, 2003.

Use the totime option with the following commands:

- delete backup
- query archive
- query backup
- restore
- restore group
- retrieve

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-TOTime = - --time-------------------------------------------><
```

Parameters

time

Specifies an ending time. If you do not specify a time, the time defaults to 23:59:59. Specify the time in the format you selected with the timeformat option.

When you include the timeformat option in a command, it must precede the fromtime, pittime, and totime options.

Examples

Mac OS X Command line:

Mac OS X
```
dsmc restore "/Users/van/Documents/myfiles/*" -todate=09/17/2003 -totime=23:00:00
```

AIX | Linux | Solaris | Mac OS X Command line:

AIX | Linux | Solaris | Mac OS X
```
dsmc restore "/home/user1/*" -todate=09/17/2003 -
totime=23:00:00
```

Windows Command line:

Windows
```
dsmc query backup -totime=23:59:00 -todate=06/30/2003 c:\mybackups\
```

Txnbytelimit

The txnbytelimit option specifies the number of kilobytes the client program buffers before it sends a transaction to the server.

A *transaction* is the unit of work exchanged between the client and server. A transaction can contain more than one file or directory, called a *transaction group*.

You can control the amount of data sent between the client and server, before the server commits the data and changes to the server database, using the txnbytelimit option. Controlling the amount of data sent changes the speed of the client to perform the transactions. The amount of data sent applies when files are batched together during backup or when receiving files from the server during a restore procedure.

After the txngroupmax number is reached, the client sends the files to the server, even if the transaction byte limit is not reached.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This option is valid for all clients.

Options File

AIX | Linux | Solaris | Mac OS X Place this option in the client system-options file (dsm.sys) within a server stanza. You can set this option on the General tab, in the Transaction Buffer Size field in the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the General tab, in the Transaction Buffer Size field in the Preferences editor.

Syntax

```
>>-TXNBytelimit-- --number-------------------------------------><
```

Parameters

number

Specifies the number of kilobytes the client program sends to the server before committing the transaction. The range of values is 300 through 34359738368 (32 GB). The default is 25600 KB. The number can be specified as an integer or as an integer with one of the following unit qualifiers:

- K or k (kilobytes)
- M or m (megabytes)
- G or g (gigabytes)

If no unit qualifier is specified, the integer is in kilobytes.

Restriction: The txnbytelimit option does not support decimal numbers, and only one-unit letters are allowed. For example: K, M, or G.

Examples

Options file:

```
txnb 25600
txnb 2097152
txnb 2097152k
txnb 2048m
txnb 2g
txnb 32G
```

Command line:

```
-txnb=25600
-txnb=16G
```

This option is valid only on the initial command line. It is not valid in interactive mode.

AIX Solaris Windows

Type

Use the type option with the query node command to specify the type of node to query. Use this option with the set event command to activate, hold, or release.

Supported Clients

AIX This option is also valid for the set password command with the TSM type on AIX® clients.

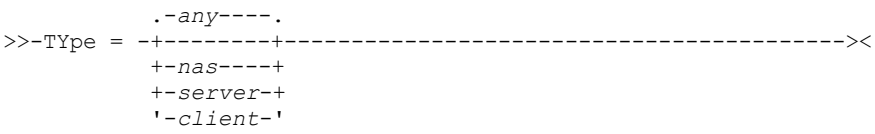
Windows This option is also valid for the set password command with the TSM or FILER type.

AIX Solaris This option is only valid for AIX and Solaris clients. The IBM Spectrum Protect™ API does not support this option.

Windows This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option.

AIX Solaris Windows

Syntax



Parameters

nas
: Specifies all NAS nodes registered at the server.

server
: Specifies client nodes that are other IBM Spectrum Protect servers.

client
: Specifies client nodes that are backup-archive clients.

Examples

Command line:

AIX Solaris Windows

```
query node -type=nas
```

AIX Linux

Updatectime

Use the updatectime option to check the change time (ctime) attribute during an incremental backup operation.

Supported Clients

This option is valid for AIX® and Linux clients on GPFS™ file systems only. The server can also define this option.

Options File

Place this option in the client user options file (dsm.opt).

Syntax

```
                .-no--.
>>-UPDATECTime--+-----+---------------------------------------><
                '-yes-'
```

Parameters

no
: The backup-archive client does not check the change time (ctime attribute) during a backup operation. This value is the default.

yes
: The backup-archive client checks the change time (ctime attribute) during a backup operation. If the ctime attribute changed since the last backup operation, the ctime attribute is updated on the IBM Spectrum Protect™ server. The object is not backed up unless it has either ACLs or extended attributes. The client checks files and directories.

Examples

Options file:

```
updatect yes
```

Command line:

```
dsmc incr /proj/gpfs/test/ -updatectime=yes
```

Windows

Usedirectory

The usedirectory option queries the Active Directory for the communication method and server with which to connect.

This option overrides the commmethod parameters specified in the client options file (dsm.opt). Optimally, the administrator enables only one server and one specific communication protocol for a given client node. The specification of this information in Active Directory is done using the IBM Spectrum Protect™ server on Windows, which has a wizard to assist with this configuration. If a node is registered to more than one server published in Active Directory, the first server returned in the Active Directory query is used. If the client cannot contact the server, the client session fails.

Supported Clients

This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option.

Options File

Place this option in the client options file (dsm.opt). You can set this option on the Communication tab of the Preferences editor.

Syntax

```
                .-No--.
>>-USEDIRectory--+-----+---------------------------------------><
```

```
'-Yes-'
```

Parameters

Yes
: Specifies that the client ignores commmethod parameters set in the client options file and query the Active Directory for the communication method and server with which to connect.

No
: Specifies that the client uses the communication method specified in the option file. If there is no communication method specified in the option file the default communication method and server are used.

Examples

Options file:

```
usedirectory no
```

Command line:

```
-usedir=yes
```

This option is valid only on the initial command line. It is not valid in interactive mode.

AIX | Linux | Windows

Useexistingbase

The useexistingbase option is used when you back up snapshots that are on NetApp filer volumes. The useexistingbase option indicates that the latest snapshot that exists on the volume being backed up, is to be used as the base snapshot, during a snapshot differential backup operation.

If this option is not specified, a new snapshot is created on the volume that is being backed up. Because target filer volumes are read only volumes, useexistingbase must be specified when performing snapshot differential backups of target filer volumes. If useexistingbase is not specified, snapshot differential backups of a target filer volume fail because the new snapshot cannot be created on the read only volume.

When backing up target filer volumes, use both the useexistingbase option and the diffsnapshot=latest option to ensure that the most recent base and most recent differential snapshots are used during the volume backup

Supported Clients

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows clients.

Options File

This option is only valid on the command line.

Syntax

```
>>-USEEXISTINGBase-------------------------------------------><
```

Parameters

This option has no parameters

Examples

Options file:

Does not apply.

Command line:

```
dsmc incr \\DRFiler\UserDataVol_Mirror_Share -snapdiff
  -useexistingbase -basenameshotname="nightly.?"
```

Basesnapshotname

Usereplicationfailover

The usereplicationfailover option specifies whether automated client failover occurs on a client node.

Use this option to enable a client node for failover or to prevent it from failing over to the secondary server. This option overrides the configuration that is provided by the IBM Spectrum Protect™ server administrator settings on the primary server.

Supported Clients

This option is valid for all clients.

Options File

AIX | Linux | Solaris | Mac OS X Place this option within a server stanza in the dsm.sys file.

Windows Place this option in the client options file (dsm.opt).

Syntax

```
                              .-Yes-.
>>-USEREPLICATIONFailover--+-----+------------------------------><
                           '-No--'
```

Parameters

Yes
: Specifies that you want the client to automatically fail over to the secondary server if the primary server is unavailable. The client uses the configuration that is provided by the primary server to connect to the secondary server. This value is the default.

No
: Specifies that the client does not automatically fail over to the secondary server.

Examples

Options file:
```
USEREPLICATIONFailover no
```
Command line:
: Does not apply.

AIX | Linux | Solaris | Mac OS X

Users (deprecated)

This option is deprecated.

V2archive

Use the v2archive option with the archive command to archive only files to the server.

The backup-archive client will not process directories that exist in the path of the source file specification.

This option differs from the filesonly option in that the filesonly option archives the directories that exist in the path of the source file specification.

The v2archive and dirsonly options are mutually exclusive and an error message is displayed if you use both options in the same archive command.

If you use this option, you might want to consider the following:

- You might experience performance problems when retrieving large amounts of data archived with this option.
- You might want to use this option only if you are concerned about expiration performance on a server that already contains extremely large amounts of archived data.
- If there are multiple files with the same name for the v2archive option, the files are archived multiple times, with their directory structure. The v2archive option archives only the files.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect™ API does not support this option.

Syntax

```
>>-V2archive-------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Mac OS X This command:

Mac OS X
```
dsmc archive "/Users/user2/Documents/*" -v2archive -su=y.
```

Archives these files:

```
/Users/user2/Documents/file1
/Users/user2/Documents/file2
/Users/user2/Documents/file3
/Users/user2/Documents/dir2/file4
/Users/user2/Documents/dir2/file5
```

Note: The client does not archive `/Users/user2/Documents` and `/Users/user2/Documents/dir2`.

AIX Linux Solaris Mac OS X This command:

AIX Linux Solaris Mac OS X
```
dsmc archive "/home/relx/dir1/*" -v2archive -su=y.
```

Archives these files:

```
/home/relx/dir1/file1
/home/relx/dir1/file2
/home/relx/dir1/file3
/home/relx/dir1/dir2/file4
/home/relx/dir1/dir2/file5
```

Note: The client does not archive `/home/relx/dir1` and `/home/relx/dir1/dir2`.

Windows This command:

Windows
```
dsmc archive c:\relx\dir1\ -v2archive -su=y
```

Archives these files:

```
c:\relx\dir1\file1
c:\relx\dir1\file2
c:\relx\dir1\file3
c:\relx\dir1\dir2\file4
c:\relx\dir1\dir2\file5
```

Note: The client does not archive `c:\relx\dir1` and `c:\relx\dir1\dir2`.

Verbose

The verbose option specifies that you want to display detailed processing information on your screen. This is the default.

When you run the incremental, selective, or archive commands, information is displayed about each file that is backed up. Use the quiet option if you do not want to display this information.

The following behavior applies when using the verbose and quiet options:

- If the server specifies either the quiet or verbose option in the server client option set, the server settings override the client values, even if force is set to no on the server.
- If you specify quiet in your dsm.opt file, and you specify -verbose on the command line, -verbose prevails.
- If you specify both -quiet and -verbose on the same command, the last option encountered during options processing prevails. If you specify -quiet -verbose, -verbose prevails. If you specify -verbose -quiet, -quiet prevails.

Mac OS X The information is displayed on your screen in the Scheduler Status window. This option only applies when you are running the scheduler and the client is performing scheduled work.

Supported Clients

This option is valid for all clients. The server can also define this option. The IBM Spectrum Protect™ API does not support this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the client user-options file (dsm.opt). You can set this option on the Command Line tab, Do not display process information on screen checkbox of the Preferences editor.

Windows Place this option in the client options file (dsm.opt). You can set this option on the Command Line tab, Do not display process information on screen checkbox of the Preferences editor.

Syntax

```
>>-VErbose-----------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

Options file:

```
verbose
```

Command line:

```
-verbose
```

This option is valid only on the initial command line. It is not valid in interactive mode.

AIX Linux Solaris Windows

Verifyimage

Use the verifyimage option with the restore image command to specify that you want to enable detection of bad sectors on the destination target volume.

If bad sectors are detected on the target volume, the backup-archive client issues a warning message on the console and in the error log.

Supported Clients

AIX Linux Solaris This option is valid only for AIX®, Oracle Solaris, and all Linux clients. The IBM Spectrum Protect™ API does not support this option.

Windows This option is valid for all Windows clients. The IBM Spectrum Protect API does not support this option.

Syntax

```
>>-VERIFYImage-------------------------------------------------><
```

Parameters

There are no parameters for this option.

Examples

AIX Linux Solaris Command line:

AIX Linux Solaris
```
dsmc restore image /usr -verifyimage
```

Windows Command line:

Windows
```
dsmc restore image d: -verifyimage
```

Virtualfsname

Use the virtualfsname option with the backup group command to specify the name of the virtual file space for the group on which you want to perform the operation. The virtualfsname cannot be the same as an existing file space name.

AIX Linux Solaris Windows

Supported Clients

AIX Linux Solaris This option is valid for all UNIX and Linux clients except for Mac OS X.

Windows This option is valid for all Windows clients.

Syntax

```
>>-VIRTUALFsname = - --fsname---------------------------------><
```

Parameters

fsname
Specifies the name of the container for the group on which you want to perform the operation.

Examples

Command line:

Mac OS X

```
backup group -filelist=/Users/van/Documents/filelist1 -groupname=group1
-virtualfsname=/virtfs -mode=full
```

AIX Linux Solaris

```
backup group -filelist=/home/dir1/filelist1 -groupname=group1
-virtualfsname=/virtfs -mode=full
```

Windows

```
backup group -filelist=c:\dir1\filelist1 -groupname=group1
-virtualfsname=\virtfs -mode=full
```

AIX Linux Solaris

Virtualmountpoint

The virtualmountpoint option defines a virtual mount point for a file system if you want to consider files for backup that begin with a specific directory within that file system.

Using the virtualmountpoint option to identify a directory within a file system provides a direct path to the files you want to back up, saving processing time. It is more efficient to define a virtual mount point within a file system than it is to define that file system using the domain option, and then to use the exclude option in your include-exclude options list to exclude the files that you do not want to back up.

Use the virtualmountpoint option to define virtual mount points for multiple file systems, for local and remote file systems, and to define more than one virtual mount point within the same file system. Virtual mount points cannot be used in a file system handled by automounter.

You can use the virtualmountpoint option to back up unsupported file systems, with certain limitations. For information about using virtualmountpoint with unsupported file systems, see File system and ACL support.

Note: If the directory that you want to specify as a virtual mount point is a symbolic link, set the followsymbolic option to Yes. If that option is set to no (the default), you are not permitted to use a symbolic link as a virtual mount point. Also, if you back up a file system, then add a virtual mount point, and then do another incremental on the file system, the files and directories in the virtual mount point directory are expired, because they are logically contained within the virtual mount point directory and not the file system.

After you define a virtual mount point, you can specify the path and directory name with the domain option in either the default client options file or on the incremental command to include it for incremental backup services. When you perform a backup or archive using the virtualmountpoint option, the query filespace command lists the virtual mount point in its response along with other file systems. Generally, directories that you define as virtual mount points are treated as actual file systems and require that the virtualmountpoint option is specified in the dsm.sys file to restore or retrieve the data.

Note: When you specify a virtualmountpoint option, the path that it specifies is added to the default backup domain (domain all-local). The virtualmountpoint path is always considered a local "mount point" regardless of the real file system type it points to.

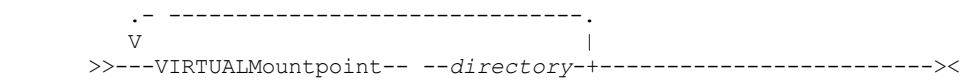
Supported Clients

This option is valid for all UNIX clients except Mac OS X. The IBM Spectrum Protect™ API does not support this option.

Options File

Place this option in the client system-options file (dsm.sys) within a server stanza.

Syntax



Parameters

directory
: Specifies the path and directory name for the directory you want to use as the virtual mount point for a file system. You cannot use wildcard characters in either the path or directory names.

  Define only one virtual mount point with each virtualmountpoint option that you include in your client system-options file. Use the virtualmountpoint option as many times as necessary to define all of the virtual mount points that you want to use.

Examples

Options file:

```
virtualmountpoint /afs/xyzcorp.com/home/ellen
virtualmountpoint /afs/xyzcorp.com/home/ellen/test/data
```

Command line:
: Does not apply.

Virtualnodename

The virtualnodename option specifies the node name of your workstation when you want to restore or retrieve files to a different workstation.

When you use the virtualnodename option in your client options file, or with a command:

- Windows You must specify the name you specified with the nodename option in your client options file (dsm.opt). This name should be different from the name returned by the hostname command on your workstation.
- AIX Linux Solaris Mac OS X You must specify the name you specified with the nodename option in your client system-options file (dsm.sys). This name should be different from the name returned by the hostname command on your workstation.
- The client prompts for the password assigned to the node that you specify, if a password is required (even when the passwordaccess option is set to generate). If you enter the correct password, you have access to all backups and archives that originated from the specified node.

When connecting to a server, the client must identity itself to the server. This login identification is determined in the following ways:

- If the nodename and virtualnodename options are not specified, or a virtual node name is not specified on the command line, the default login ID is the name returned by the hostname command.
- If the nodename option is specified, the name specified with the nodename option overrides the name returned by the hostname command.
- If the virtualnodename option is specified, or a virtual node name is specified on a command line, it cannot be the same name as the name returned by the hostname command.

Windows Note: The client can use file space information when restoring files. The file space information can contain the name of the computer from which the files were backed up. If you restore from another client node and do not specify a destination for the restored files, the client uses the file space information to restore the files. In such a case, the client attempts to restore the files to the file system on the original computer. If the restoring computer has access to the file system of the original computer, you can restore files to the original file system. If the restoring computer can not access the file system of the original computer, the client can return a network error message. If you want to restore the original directory structure but on a different computer, specify only the target file system when you restore. This is true when restoring files from another node and when retrieving files from another node.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This option is valid for all clients.

Options File

Windows Place this option in the client options file (dsm.opt).

AIX Linux Solaris Mac OS X Place this option in the client user-options file (dsm.opt).

Syntax

```
>>-VIRTUALNodename-- --nodename-------------------------------><
```

Parameters

nodename
: Specifies a 1- to 64-character name that identifies the node for which you want to request IBM Spectrum Protect™ services. There is no default.

Examples

Options file:
```
virtualnodename cougar
```
Command line:
```
-virtualn=banshee
```

This option is valid only on the initial command line. It is not valid in interactive mode.

Windows

Vmautostartvm

Use the vmautostartvm option with the restore VM vmrestoretype=instantaccess command to specify whether the VM created during instant access processing is automatically powered on.

This option is only valid for VMware virtual machines. The virtual machines must be hosted on VMware ESXi 5.1 servers, or later versions. To use this option, you must have a license agreement to use IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Supported Clients

Windows This option can be used with supported Windows clients.

Options file

Place this option in the client options file (dsm.opt), or on the command line. This option is only valid when used for an operation where `vmrestoretype=instantaccess`.

Syntax

```
                    .-NO--.
>>-VMAUTOSTARTvm--+-----+--------------------------------------><
                    '-YES-'
```

Parameters

NO
: The VM created for instant access is not started automatically. The VM must be started manually. This is the default setting. The default provides an opportunity to reconfigure the VM before you power it on, to avoid potential conflicts with existing virtual machines.

YES
: The VM created for instant access is started automatically.

Examples

Options file:

```
VMAUTOSTARTvm NO
```

Command line:

```
dsmc restore vm Oslo -VMRESToretype=INSTANTAccess -vmname=Oslo_verify
-VMAUTOSTARTvm=YES
```

Linux | Windows

Vmbackdir

The vmbackdir option specifies the temporary disk location where the client saves control files that are created during full VM backup and restore operations of virtual machines.

Supported Data Movers

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments.

When a client on a data mover node starts a full VM backup of a virtual machine, the client creates metadata in files that are associated with the backed up virtual machine and its data. The files that contain the metadata are referred to as *control files*.

During full VM backup operations, the metadata is saved on a disk in the data mover node until the backup completes and both the virtual machine data and the control files are saved to server storage. During a full VM restore operation, the control files are copied from the server and are temporarily stored on the data mover disk, where they are used to restore the virtual machine and

its data. After a backup or a restore operation completes, the control files are no longer needed and the client deletes them from their temporary disk location.

The directory that is specified by this option must be on a drive that contains sufficient free space to contain the control information from a full VM backup.

Linux | Windows This option is valid for Linux and Windows data movers that are installed on a vStorage backup server.

Windows This option is valid for Windows data movers that are installed on a Hyper-V server.

Options File

Set this option in the client options file, or specify it on the command line as an option for the backup vm or restore vm commands.

Syntax

```
>>-VMBACKDir--directory----------------------------------------><
```

Parameters

directory

Specifies the path where the control files are stored on the backup server.

Windows The default is c:\mnt\tsmvmbackup\fullvm\

Linux The default is /tmp/tsmvmbackup/fullvm/

Examples

Options file:

Windows
```
VMBACKD c:\mnt\tsmvmbackup\
```

Linux
```
VMBACKD /tmp/tmsvmbackup/
```

Command line:

Windows
```
dsmc backup vm -VMBACKUPT=fullvm -VMBACKD=G:\virtual_machine\control_files\
```

Windows
```
dsmc restore vm -VMBACKUPT=fullvm -VMBACKD=G:\san_temp\
```

Linux
```
dsmc backup vm -VMBACKUPT=fullvm -VMBACKD=/home/vmware/control_files
```

Linux
```
dsmc restore vm -VMBACKUPT=fullvm -VMBACKD=/home/mine/bkup_ctrl
```

Linux | Windows

Vmbackuplocation

Use the vmbackuplocation option with the backup vm or restore vm commands to specify the backup location for virtual machine backup and restore operations.

This option is only valid for VMware virtual machines. To use this option, you must have a license agreement to use IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

For restore operations, this option is ignored if the vmrestoretype option is set to mountcleanup or mountcleanupall.

Supported Clients

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows clients.

Options file

This option must be specified on the command line of a backup vm or restore vm command. You cannot set this option in the client options file.

Syntax

```
                          .-SERVER-.
>>- -VMBACKUPLOCation-- --+-LOCAL--+--------------------------><
                          '-BOTH---'
```

Parameters

SERVER
: For backup operations, specifies that virtual machines are backed up to the IBM Spectrum Protect server.
For restore operations, specifies that virtual machines are restored from the IBM Spectrum Protect server.
This value is the default.

LOCAL
: For backup operations, specifies that virtual machines are backed up on the hardware storage. The backup is a full virtual machine image snapshot, even if an incremental backup is specified.
To create a local backup, the virtual machine must be stored in a VMware virtual volume (VVOL) datastore. If any virtual disk of the virtual machine is not in a VVOL datastore, the local backup is not allowed.
For restore operations, specifies that virtual machines are restored from persisted snapshots that are on the hardware storage.
By restoring from a local snapshot, you can only revert an existing virtual machine. You cannot restore a deleted virtual machine, and you cannot restore a virtual machine to a different name or location.
Local restore is not valid if the following parameters are used for the restore vm command:

- VMNAME
- DATACENTER
- HOST
- DATASTORE
- :vmdk

This value is also not valid if the vmrestoretype option is set to one of the following values. If these values are set, an error message is displayed.

- instantaccess
- instantrestore
- mount

Because no network data movement is needed for local snapshots, backup and restore operations can be faster than server backup and restore operations.

BOTH
: For backup operations, specifies that virtual machines are backed up to the IBM Spectrum Protect server and are also backed up locally. The local backup is always a full image snapshot of the VMs, even if incremental backups are configured for the server.
For restore operations, specifies that virtual machines are restored from the latest active version regardless whether it is a local or a server backup. If both active backups have the same timestamp, the local backup is used for the restore.
This value is not valid with the parameters and vmrestoretype option values that are listed above for the LOCAL value.

Examples

Command line:
: Perform a full server and local backup for virtual machine vm1:

```
dsmc backup vm vm1 -vmbackuplocation=BOTH -vmbackuptype=FUllvm
```

Perform a local restore for virtual machine vm1:

```
dsmc restore vm vm1 -vmbackuplocation=LOCAL
```

Vmbackupmailboxhistory

The vmbackupmailboxhistory option specifies whether mailbox history is automatically uploaded with the virtual machine (VM) backup if IBM Spectrum Protect™ for Mail: Data Protection for Microsoft Exchange Server is detected on a VM.

Supported Clients

Linux Windows This option is valid on clients that act as a data mover for VMware guest backups.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

Options File

Linux Place this option in the client system-options file (dsm.sys) within a server stanza.

Windows Place this option in the client options file (dsm.opt).

Syntax

```
                              .-Yes-.
>>-VMBACKUPMAILBoxhistory--+-----+-----------------------------><
                           '-No--'
```

Parameters

Yes
: The mailbox history is automatically uploaded with the VM backup if IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server is detected on a VM.

No
: The mailbox history is not automatically uploaded with the VM backup.

Examples

Options file:
: vmbackupmailboxhistory yes

Linux Windows

Vmbackuptype

Use the vmbackuptype option with the backup VM or restore VM command to specify to specify the type of virtual machine backup or restore to complete. You can also use this option on query VM commands to filter the query results to include only virtual machines that were backed up by a specific backup type. For examples, see the query VM command description.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments.

Linux

You can specify a VMware full VM backup.

Windows

You can specify a VMware full VM backup or a Hyper-V full VM backup.

Supported Clients

Linux This option is valid on Linux data movers that are installed on a vStorage backup server. The server can also define this option.

Windows This option is valid on Windows data movers that are installed on a vStorage backup server. The server can also define this option.

Windows This option is valid on Windows data movers that are installed on a Microsoft Hyper-V system. The server can also define this option.

Options File

Linux Place this option in the client system-options file (dsm.sys) within a server stanza.

Windows Place this option in the client options file (dsm.opt), or on the command line.

Linux

Syntax

```
                  .-FUllvm-.
>>-VMBACKUPType--+--------+-----------------------------------><
```

Linux

Parameters

FUllvm
: Specify this value to run a traditional full VM backup of a VMware virtual machine. This is the default backup type for Linux clients.

Windows

Syntax

```
                  .-FUllvm-----.
>>-VMBACKUPType--+-HYPERVFULL-+-------------------------------><
```

Windows

Parameters

FUllvm
: Specify this value to run a traditional full VM backup of a VMware virtual machine. This is the default backup type for Windows clients that run on Windows server systems, where the Hyper-V server role is not enabled. Contrast with `vmbackuptype=hypervfull`.

HYPERVFULL
: Specifies that you are backing up one or more Hyper-V virtual machines. If you enable the Hyper-V server role, this value is the default backup type. If you specify vmbackuptype=hypervfull, all of the options that are associated with backing up VMware files from a vStorage backup server are ignored (for example: VMCHOST, VMCUSER, VMCPW, VMFULLNODELETE).

Examples

Options file:
: `VMBACKUPT full`

Command line:
: Linux Windows `dsmc backup vm vm1 -VMBACKUPT=full -vmchost=virtctr -vmcuser=virctr_admin -vmcpw=xxxxx`

  Performs a full virtual-machine backup of `vm1.example.com` using the VMware VirtualCenter machine `virtctr.example.com`, to the IBM Spectrum Protect server, using machine name `vm1`.

  Windows `dsmc backup vm -VMBACKUPT=hypervfull -vmlist="VM 1,VM 2"`

  Performs a full virtual-machine backup of Hyper-V virtual machines named "VM 1" and "VM 2", to the IBM Spectrum Protect server.

Linux Windows

Vmchost

Use the vmchost option with the backup VM, restore VM, or query VM commands to specify the host name of the VMware VirtualCenter or ESX server that you want to backup, restore, or query.

Use the VirtualCenter if it is available. If you cannot use a VirtualCenter server and you need to perform backups of multiple systems on multiple ESX servers, do not specify this option, but instead specify the option with the command so that it can be

varied for each ESX server.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Supported Clients

This command is valid for clients that are configured to perform an off-host backup of a VMware virtual machine. The server can also define this option.

Windows This option is not supported for Hyper-V backups.

Options File

Windows Place this option in the client options file (dsm.opt), or on the command line.

Linux Place this option in the client options file (dsm.opt), the client system options file (dsm.sys), or on the command line.

Syntax

```
>>-VMCHost-- --hostname----------------------------------------><
```

Parameters

hostname
: Specifies the host name of the VMware VirtualCenter or ESX server that you want to backup, restore, or query.

Examples

Options file:

```
VMCH vcenter.storage.usca.example.com
```

Command line:

```
-VMCH=esx1.storage.usca.example.com
```

Linux | Windows

Vmcpw

Use the vmcpw option with the backup VM, restore VM, or query VM commands to specify the password for the VMware VirtualCenter or the ESX user ID that is specified with the vmcuser option.

Use the VirtualCenter if it is available. If you cannot use a VirtualCenter server and you need to perform backups of multiple systems on multiple ESX servers, do not specify this option, but instead specify the option with the command so that it can be varied for each ESX server.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Supported Clients

Linux This option is valid only on supported Linux clients that are installed on a vStorage backup server that is used to backup a VMware virtual machine.

Windows This option is valid only on supported Windows clients that are installed on a vStorage backup server that is used to backup a VMware virtual machine. This option is not valid for Hyper-V backups.

Options File

Windows Place this option in the client options file (dsm.opt), or on the command line.

Linux Place this option in the client system options file (dsm.sys), or on the command line.

1. Click Edit > Client Preferences > VM Backup. In the Password field, type the password that you want to have saved.
2. Click OK.

As an alternative to the preferences editor, you can store the password locally by using the set password command. For example:

```
dsmc SET PASSWORD -type=vm
vcenter.us.ibm.com Administrator secret
```

Syntax

```
>>-VMCPw-- --pwname-------------------------------------------><
```

Parameters

pwname
: Specifies the password for the VMware VirtualCenter or ESX server that you want to backup, restore, or query.

Examples

Options file:

```
VMCPw SECRET
```

Command line:

```
-VMCPw=SECRET
```

Related reference:
Set Password
Linux Windows

Vmctlmc

This option specifies the management class to use when backing up virtual machine control files.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments.

By default, virtual machine control files are bound to the default management class. The vmmc option can be used to specify a different management class to which virtual machine data and virtual machine control files are bound. The vmctlmc option overrides the default management class and the vmmc option for the virtual machine control files.

Under certain conditions, it might be desirable or necessary to bind the control files to a different management class than the data files.

The vmctlmc option is required if virtual machine data files are backed up to tape. Virtual machine control files must be backed up to a disk-based storage pool that does not migrate to tape. The storage pool can be composed of random access volumes and sequential file volumes; the storage pool can also be a deduplicated pool. Use the vmctlmc option to specify a management class that stores data in such a storage pool.

Restriction: The management class that is specified by the vmctlmc option determines only the destination storage pool for virtual machine control files. Retention of the control files is determined by the vmmc option, if specified, or by the default management class. The retention for the virtual machine control files always matches the retention of the virtual machine data files.

Supported Clients

Linux Windows This option is valid for clients that act as data mover nodes that protect VMware virtual machines.

Windows This option is valid for clients that act as data mover nodes that protect Microsoft Hyper-V virtual machines.

The option can only be used for virtual machine backups that use an incremental-forever backup mode.

This option is available only if you have a license to use either IBM Spectrum Protect for Virtual Environments: Data Protection for VMware or IBM Spectrum Protect for Virtual Environments: Data Protection for Microsoft Hyper-V.

Options File

Linux Place this option in the system options file dsm.sys.

Windows Place this option in the client options file dsm.opt.

Syntax

```
>>-VMCTLmc--class_name-----------------------------------------><
```

Parameters

class_name
: Specifies a management class that applies to backing up virtual machine control files. If you do not set this option, the management class that is specified on the vmmc option is used. If you do not set this option and the vmmc option is not set, the default management class of the node is used.

Examples

Options file:

```
vmctlmc diskonlymc
```

Command line:

Does not apply.

Linux | Windows

Vmcuser

Use the vmcuser option with the backup VM, restore VM, or query VM commands to specify the user name of the VMware VirtualCenter or ESX server that you want to backup, restore, or query.

Use the VirtualCenter if it is available. If you cannot use a VirtualCenter server and you need to perform backups of multiple systems on multiple ESX servers, do not specify this option, but instead specify the option with the command so that it can be varied for each ESX server.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Supported Clients

This option is valid for clients that are configured as to perform an off-host backup of VMware virtual machines. The server can also define this option.

Windows This option is not valid for Hyper-V backups.

Options File

Windows Place this option in the client options file (dsm.opt), or on the command line.

Linux Place this option in the client options file (dsm.opt), the client system options file (dsm.sys), or on the command line.

Syntax

```
>>-VMCUser-- --username-----------------------------------------><
```

Parameters

username
: Specifies the user name of the VMware VirtualCenter or ESX server that you want to backup, restore, or query.

When working with a virtual center, a user id with access to the Windows system hosting the virtual center is required. This user id must either have administrator privileges, or the minimum privileges that are identified in technote 1659544.

Examples

Options file:

```
VMCUser administrator
```

Command line:

```
backup vm -VMCUser=domainname\administrator
```

Command line:

Example of connecting to an ESX server:

```
backup vm -VMCUser=root
```

Linux | Windows

Vmdatastorethreshold

Use the vmdatastorethreshold option to set the threshold percentage of space usage for each VMware datastore of a virtual machine.

When you specify this option, space usage is checked before a virtual machine snapshot is created. If the threshold is exceeded, the virtual machine is not backed up. By setting this option, you can prevent out-of-space errors when you back up virtual machines.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Supported clients

Linux You can use this option with supported x86_64 Linux clients.

Windows You can use this option with supported Windows 64-bit clients.

Options file

Linux You can specify this option in the client system-options file (dsm.sys) or on the command line by using the backup vm command. You can also include this option on the IBM Spectrum Protect Version 7.1.5 or later server in a client option set. You cannot set this option in the Preferences Editor.

Windows You can specify this option in the client options file (dsm.opt) or on the command line by using the backup vm command. You can also include this option on the IBM Spectrum Protect Version 7.1.5 or later server in a client option set. You cannot set this option in the Preferences Editor.

Syntax

```
>>-VMDATASTORETHreshold----percent-----------------------------><
```

Parameters

percent

Specifies the threshold percentage of each VMware datastore of the virtual machine to be backed up. You can specify an integer from 0 - 100. The default value is 100. If you do not set this option, the client begins a virtual machine backup without first verifying the existing space usage.

Requirements:

- Ensure that the threshold is low enough so that the snapshot does not use up all the available space in the VMware datastores. Otherwise, you will run out of space on the VMware datastores and the snapshot will not be created.
- If you use multiple clients that act as data mover nodes, you must add this option to the options file for each data mover.

- The client checks the data usage of the VMware datastore that contains the virtual machine disk snapshots. By default, the snapshots are created in the same directory as that of the parent virtual disk (.vmdk) file.

  If you change the snapshot location to a new directory on the same datastore or on another datastore with the workingDir option in the VM configuration file, ensure that the path of the working directory is correct. If the path is incorrect, the client might validate the data usage of the wrong datastore.

If you use the EXCLUDE.VMDISK option to exclude one or more disks from a backup, the threshold check is still run on these disks. Even though these disks are not backed up, VMware still takes a snapshot of these disks.

Independent disks are not checked during space verification processing because a snapshot of these disks does not use any VMware datastore space.

Example 1

Virtual machine `vm1` spans `datastore1` and `datastore2`. Set the vmdatastorethreshold option to 90 to ensure that both VMware datastores are at most 90% full before the virtual machine is backed up.

Options file:
```
vmdatastorethreshold 90
```
Command line:
```
dsmc backup vm vm1 -vmdatastorethreshold=90
```

Example 2

The datastore threshold of `datastore2` is set to 85. The datastore threshold is exceeded during the backup of virtual machine `vm5`. The following error message is displayed:

```
ANS14200E The virtual machine 'vm5' could not be backed up because the
data usage of datastore 'datastore2' exceeded the datastore threshold
of 85%.
```

Increase the value of the vmdatastorethreshold option to 95 and restart the backup.

Options file:
```
vmdatastorethreshold 95
```
Command line:
```
dsmc backup vm vm5 -vmdatastorethreshold=95
```

Linux | Windows

Vmdefaultdvportgroup

Use this option to specify the port group for the NICs to use during restore vm operations for a virtual machine that was connected to a distributed virtual port group when it was backed up, but the target host for the restore operation does not contain a similar distributed virtual port group.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

This option does not apply to backup or restore operations for Microsoft Hyper-V virtual machines.

Supported clients

Linux This option is valid for Linux clients that are installed on a vStorage backup server.

Windows This option is valid for Windows clients that are installed on a vStorage backup server.

Options file

Linux Place this option in the client options file (dsm.opt), in the client system options file (dsm.sys), or specify it as a command-line parameter on the restore vm command.

Windows Place this option in the client options file (dsm.opt), or specify it as a command-line parameter on the restore vm command.

Syntax

```
>>-VMDEFAULTDVPORTGROUP--portgroup_name-----------------------><
```

Parameters

portgroup name
Specifies the name of the port group to use. The port group name is case sensitive.

Examples

Option file:

```
VMDEFAULTDVPORTGROUP dvPortGroup
```

Command line:

```
dsmc restore vm vm123 -VMDEFAULTDVPORTGROUP=dvPortGroup
```

Related reference:
Vmdefaultnetwork
Vmdefaultdvswitch
Linux Windows

Vmdefaultdvswitch

Use this option to specify the distributed virtual switch (dvSwitch) that contains the port group that you set on the vmdefaultdvportgroup option. The option has no effect unless you also specify the vmdefaultdvportgroup option.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

This option does not apply to backup or restore operations for Microsoft Hyper-V virtual machines.

Supported clients

Linux This option is valid for Linux clients that are installed on a vStorage backup server.

Windows This option is valid for Windows clients that are installed on a vStorage backup server.

Options file

Linux Place this option in the client options file (dsm.opt), in the client system options file (dsm.sys), or specify it as a command-line parameter on the restore vm command.

Windows Place this option in the client options file (dsm.opt), or specify it as a command-line parameter on the restore vm command.

Syntax

```
>>-VMDEFAULTDVSWITCH--dvSwitch--------------------------------><
```

Parameters

dvSwitch
Specifies the name of the virtual switch to use. The virtual switch name is case sensitive.

Examples

Option file:

```
VMDEFAULTDVSWITCH dvSwitch
```

Command line:

```
dsmc restore vm vm123 -VMDEFAULTDVSWITCH=dvSwitch -VMDEFAULTDVPORTGROUP=dvPortGroup
```

Related reference:
Vmdefaultdvportgroup
Linux | Windows

Vmdefaultnetwork

Use this option to specify the network for NICs to use during a restore vm operation, for a virtual machine that had been connected to a distributed virtual port group when it was backed up, but the target host for the restore operation does not have any distributed switch port groups configured.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

This option does not apply to restore operations for Microsoft Hyper-V virtual machines.

Supported clients

Linux This option is valid for Linux clients that are installed on a vStorage backup server.

Windows This option is valid for Windows clients that are installed on a vStorage backup server.

Options file

Linux Place this option in the client options file (dsm.opt), in the client system options file (dsm.sys), or specify it as a command-line parameter on the restore vm command.

Windows Place this option in the client options file (dsm.opt), or specify it as a command-line parameter on the restore vm command.

Syntax

```
>>-VMDEFAULTNETWORK--vm_network_name--------------------------><
```

Parameters

vm_network_name
Specifies the name of the virtual machine network to use. The network name is case sensitive. If the name contains space characters, enclose it in quotation marks.

Examples

Option file:

```
VMDEFAULTNETWORK "VM Network"
```

Command line:

```
dsmc restore vm vm123 -VMDEFAULTNETWORK="VM Network"
```

Related reference:
Vmdefaultdvportgroup
Vmdefaultdvswitch
Windows

Vmdiskprovision

Use the vmdiskprovision option to specify a provisioning policy for the virtual disk file that is used to restore VMware virtual machine data. This option is valid only for restore vm operations where `vmrestoretype=instantrestore` is specified.

This option is only valid for VMware virtual machines. The virtual machines must be hosted on VMware ESXi 5.1 servers, or later versions. To use this option, you must have a license agreement to use IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Supported Clients

Windows This option can be used with supported Windows clients.

Options file

Place this option in the client options file (dsm.opt), or on the command line.

Syntax

```
                    .-THICK-.
>>-VMDISKPROvision--+-------+---------------------------------><
                    '-THIN--'
```

Parameters

THICK
: Creates a virtual disk in a default thick format; where the space that is required for the virtual disk is allocated when the virtual disk is created. This setting is the default value.

THIN
: Creates a virtual disk in a thin format.
Note: If you are restoring a virtual machine and you specify thin provisioning, the datastore that you restore the VM to must have enough free space to accommodate the total capacity of the VM disk, and not just the amount of disk that is used. For example, if a thin-provisioned VM has 300 GB total capacity for its disk, you cannot restore that VM to a datastore that has less than 300 GB available, even if only a portion of the total capacity is being used.

Examples

Options file:

```
VMDISKPROvision THIN
```

Command line:

```
dsmc restore vm Mainz -VMRESToretype=INSTANTRestore
 -VMTEMPDAtastore=Temporary_Datastore -VMDISKPROvision=THIN
```

Linux | Windows

Vmenabletemplatebackups

The vmenabletemplatebackups option specifies whether the client backs up VMware template virtual machines when it protects virtual machines in a vCenter server. VMware templates virtual machines cannot be backed up when they are in an ESXi host because ESXi does not support templates.

When this option is enabled, you can include VMware template machines in full VM backup operations. You use the existing Backup VM command and the DOMAIN.VMFULL option to specify the virtual machines to include in the backup operation.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Incremental backups are not supported and snapshots are not taken, so you must use MODE=IFFULL. Use MODE=IFFULL to force a new backup of VMware template virtual machines, even if they were not changed since the last backup.

When vmenabletemplatebackups is enabled, any backup process that is initiated by using MODE=IFINCREMENTAL is processed by using MODE=IFFULL. VMware template VMs are included in a backup only if they were changed since the last backup occurred.

With this option enabled, make sure that the vmvstortransport options include NBDSSL or NBD. Using only the SAN or HOTADD transport modes with this option enabled causes backups of the template machines to fail.

Supported clients

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows clients.

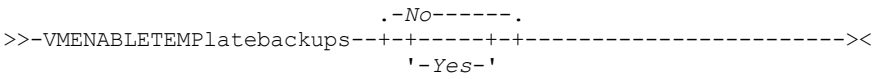
Options file

Linux You can set this option on the command line, in the client system options file (dsm.sys), client options file (dsm.opt), or on the server in a client options set.

Windows You can set this option on the command line, in the client options file (dsm.opt), or on the server in a client options set.

Linux | Windows You can also set it in the preferences editor on the VM Backup tab (select the Backup virtual machine templates option).

Syntax



Parameters

No
Specifies that template virtual machines are not included in full VM backup operations; this is the default setting.

Yes
Specifies that template VMs are included in full VM backup operations.

Examples

Options file
vmenabletemplatebackups yes

Command line
Back up a VMware template VM

```
dsmc backup vm vmname -VMENABLETEMPLATEBACKUPS=YES
```

where *vmname* is the template machine name.

Command line
Restore a VMware template VM to the same location and name

```
dsmc restore vm vmname -VMENABLETEMPLATEBACKUPS=YES
```

where *vmname* is the template machine name.

Command line
Restore a template virtual machine to a new location

```
dsmc restore vm vmname -vmname=win7x64
  -datastore=datastore22 -host=supersht.labx.com
   -datacenter="Lab Center" -VMENABLETEMPLATEBACKUPS=YES
```

where *vmname* is the template machine name. "win7x64" is the new template VM name. The new data center, host, and datastore are also included.

Windows

Vmexpireprotect

Use this option to protect virtual machine snapshots so that they cannot be expired while an instant restore or instant access operation of VMware VMs or while a file-level restore of a VMware VM is in progress. Use this option to protect virtual machine snapshots so that they cannot be expired while an instant restore or instant access operation of Hyper-V VMs or while a file-level restore of a Hyper-V VM is in progress.

During a mount or restore operation, the snapshot on the IBM Spectrum Protect™ server is locked to prevent it from expiring during the operation. Expiration might occur because another snapshot is added to the snapshot sequence. This option specifies whether to prevent or allow snapshot expiration during a mount or a restore operation.

Supported Clients

Windows This option can be used with supported Windows clients that are configured to restore virtual machines.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments.

Options File

For restoring VMware virtual machines, set this option in the client options file (dsm.opt) or on a restore vm command where the vmrestoretype option is set to instantaccess or instantrestore.

For restoring file-level backups for virtual machines, specify this option in the client options file, or on the restore vm command.

Note: File-level backups were created with the version 7.1 or earlier backup-archive clients.

Syntax

```
                    .-No--.
>>-VMEXPIREPROTECT--+-Yes-+-----------------------------------><
```

Parameters

Yes
: Specify Yes to protect the snapshot from expiration. The snapshot on the IBM Spectrum Protect server is locked and the snapshot is protected from expiration during a mount or a restore operation.

No
: Specify No to disable expiration protection. This value is the default. The snapshot on the IBM Spectrum Protect server is not locked and the snapshot is not protected from expiration. If the snapshot that is being mounted or restored is expired, the result of the mount or restore operation is unpredictable. For example, the mount point can become unusable or contain errors. However, expiration does not affect the current active copy of the virtual machine. The active copy cannot expire during an operation.

  When the snapshot is on a target replication server, the snapshot cannot be locked because it is in read-only mode. A lock attempt by the server causes the mount or restore operation to fail.

  To avoid the lock attempt and prevent such a failure, disable expiration protection by specifying No, or by allowing this option to default.

Examples

Client options file:
: VMEXPIREPROTECT YES

Command line:
: Run an instant access operation for a VMware virtual machine:

```
dsmc restore vm vm1 -vmname=new_vm1 -vmrestoretype=instantaccess
  -vmexpireprotect=no
```

To restore files from a virtual machine backup, use the IBM Spectrum Protect recovery agent GUI.

For information about the IBM Spectrum Protect recovery agent, see the IBM Spectrum Protect for Virtual Environments documentation.

Windows

Vmiscsiadapter

This option specifies which iSCSI adapter, on the ESX host, to use for instant restore and instant access operations for VMware virtual machines.

Supported Clients

This option is valid for 64-bit Windows clients that are configured as data movers that backup VMware virtual machines.

Options File

Set this option in the client options file (dsm.opt). You can also specify this option as a command-line parameter on the restore vm command that initiates an instant restore or instant access operation. To use this option, you must have a license agreement to use IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Syntax

```
>>-VMISCSIAdapter=--iSCSI_adapter_name------------------------><
```

iSCSI_adapter_name
: Specifies the name of the iSCSI adapter to connect to on the ESX host. If you do not specify this option, the first iSCSI adapter that is found on the host is used.

Examples

Options file:

```
vmiscsiadapter "vmhba36"
```

Command line:

```
dsmc restore vm "Haifa" -VMRESToretype=INSTANTAccess -vmname="Haifa_verify" -
VMISCSIAdapter="vmhba36"
```

Windows

Vmiscsiserveraddress

Use the vmiscsiserveraddress option with the restore VM command to specify the host name or the IP address of the iSCSI server that provides the iSCSI targets for instant restore and instant access operations.

The vmiscsiserveraddress option is valid for all instant operations (`vmrestoretype=instantaccess` and `vmrestoretype=instantrestore`) for VMware virtual machines.

The virtual machines must be hosted on VMware ESXi 5.1 servers, or later versions. To use this option, you must have a license agreement to use IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Supported Clients

Windows This option can be used with supported Windows clients.

Options file

Place this option in the client options file (dsm.opt), or on the command line.

Syntax

```
>>-VMISCSIServeraddress-- --iSCSI serverhost name or IP address-><
```

Parameters

iSCSI serverhost name or IP address

Specify the host name or IP address of the iSCSI server that supplies the iSCSI target disks. This iSCSI server must connect the data mover machine with all of the ESX hosts that are used for instant restore operations. If vmiscsiserveraddress is not specified, the host name or IP address of the data mover machine is used.

For instant restore operations, the IP address of the network card in the data mover machine that is used for the iSCSI transfer should be in the same subnet as the iSCSI adapter on the ESX host.

For file restore mount operations, the Windows and Linux mount proxy systems must be in the same network range.

Examples

Options file:

```
VMISCSIServeraddress 192.168.42.50
```

Command line:

```
dsmc restore vm Oslo -VMRESToretype=INSTANTAccess -vmname=Oslo_verify
-VMISCSIServeraddress=odin.oslo.no.xyzco.com
```

Linux | Windows

Vmlimitperdatastore

The vmlimitperdatastore option specifies the number of virtual machines (VMs) and virtual disks in a datastore that can be processed in parallel during an optimized backup operation.

An optimized backup operation is one in which parallel backup capability is enabled at the VM, virtual disk, or subdisk level.

The vmlimitperdatastore option works with the vmmaxparallel, vmmaxbackupsessions, and vmlimitperhost options to optimize backup operations and to help control the amount of resources that the backup can create on a host in the vSphere infrastructure. Adjust the values of these options to find the values that provide optimal performance for the backups that are in your environment.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Supported clients

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows clients. This option is not valid for Data Protection for Microsoft Hyper-V backups.

Options file

Linux This option is valid in the client system options file (dsm.sys), in the client options file (dsm.opt) or on the command line for Backup VM. It can also be included on the server in a client options set. It cannot be set in the Preferences Editor.

Windows This option is valid in the client options file (dsm.opt) or on the command line for Backup VM. It can also be included on the server in a client options set. It cannot be set in the Preferences Editor.

Syntax

```
                          .-0-----------.
>>-VMLIMITPERDatastore-- --+-+---------+-+--------------------><
                            '-integer-'
```

Parameters

integer

Specifies the maximum number of VMs in any one datastore that are included during an optimized backup operation. The maximum that you can specify is 50 VMs. The default is 0 (zero).

Specifying 0 means that you are not concerned about how many VMs can be backed up in parallel from a datastore. Instead, you want to limit the maximum number of VMs to include in a backup by using the value that you specify on the vmmaxparallel option. The vmlimitperdatastore option is enforced even when VM data exists in two or more datastores.

Examples

Options file

VMLIMITPERD 5

Command line:

```
dsmc backup vm -VMLIMITPERD=5
```

Backing up multiple virtual machines in parallel

Linux | Windows

Vmlimitperhost

The vmlimitperhost option specifies the number of virtual machines (VMs) and virtual disks in a host that can be processed in parallel during an optimized backup operation.

An optimized backup operation is one in which parallel backup capability is enabled at the VM, virtual disk, or subdisk level.

The vmlimitperhost option works with the vmmaxparallel, vmmaxbackupsessions, and vmlimitperdatastore options to optimize backup operations and to help control the amount of resources that the backup can create on a host in the vSphere infrastructure. Adjust the values of these options to find the values that provide optimal performance for the backups that are in your environment.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Supported clients

Linux This option can be used with supported x86_64 Linux clients.

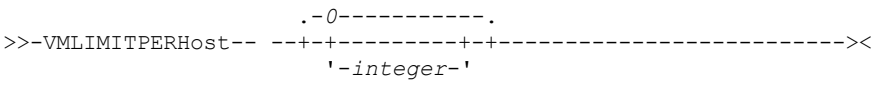
Windows This option can be used with supported Windows clients. This option is not valid for Data Protection for Microsoft Hyper-V backups.

Options file

Linux This option is valid in the client system options file (dsm.sys), in the client options file (dsm.opt) or on the command line for Backup VM. It can also be included on the server in a client options set. It cannot be set in the Preferences Editor.

Windows This option is valid in the client options file (dsm.opt) or on the command line for Backup VM. It can also be included on the server in a client options set. It cannot be set in the Preferences Editor.

Syntax



Parameters

integer

Specifies the maximum number of VMs in any one ESX server that can be included in an optimized backup operation. The maximum that you can specify is 50 VMs. The default is 0 (zero).

Specifying 0 means that you are not concerned about how many VMs can be backed up in parallel from an ESX server. Instead, you want to limit the maximum number of VMs to include in a backup by using the limit that you specify on the vmmaxparallel option.

Examples

Options file

Backing up multiple virtual machines in parallel

Windows

Vmlist

The vmlist option is deprecated for Hyper-V backup operations. To specify one or more Hyper-V virtual machines (VMs) to include in Data Protection for Microsoft Hyper-V backup operations, use the domain.vmfull option or specify the VMs when you run the backup vm command.

If you need to use the vmlist option, see the documentation in previous releases of IBM Spectrum Protect™.

Related reference:
Domain.vmfull
Backup VM

Linux | Windows

Vmmaxbackupsessions

The vmmaxbackupsessions option specifies the maximum number IBM Spectrum Protect™ server sessions that move virtual machine (VM) data to the server that can be included in an optimized backup operation.

An optimized backup operation is one in which parallel backup capability is enabled at the VM, virtual disk, or subdisk level.

The vmmaxbackupsessions option works with the vmmaxparallel, vmlimitperdatastore, and vmlimitperhost options to optimize backup operations and to help control the amount of resources that the backup can create on a host in the vSphere infrastructure. Adjust the values of these options to find the values that provide optimal performance for the backups that are in your environment.

Supported clients

This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows clients. This option is not valid for Data Protection for Microsoft Hyper-V backups.

Options file

Linux This option is valid in the client system options file (dsm.sys), in the client options file (dsm.opt), or on the command line for Backup VM. It can also be included on the server in a client options set. It cannot be set in the Preferences Editor.

Windows This option is valid in the client options file (dsm.opt) or on the command line for Backup VM. It can also be included on the server in a client options set. It cannot be set in the Preferences Editor.

Syntax

```
                              .-vmmaxparallelvalue-.
>>-VMMAXBACKUPSEssions-- --+-+---------+--------+--------------><
                             '-integer-'
```

Parameters

integer

Specifies the maximum number of IBM Spectrum Protect server sessions that can be created during the backup operation.

Review the following information for using the vmmaxbackupsessions option along with the vmmaxparallel option or the maxnummp server parameter:

vmmaxparallel

The vmmaxparallel option specifies the maximum number of virtual machines that can be backed up to the IBM Spectrum Protect server at any one time. The value of the vmmaxbackupsessions option must be equal to or greater than the value of the vmmaxparallel option.

If the value is less than the value of the vmmaxparallel option, the following message is returned and the value is changed to the same value as the vmmaxparallel option:

ANS9995W `The value of the VMMAXBACKUPSESSIONS option is number_value. This value must be greater than or equal to the value of the VMMAXPARALLEL option, which is number_value. The value will be set to the value of the VMMAXPARALLEL option.`

maxnummp

The maxnummp server parameter specifies the maximum number of mount points a node is allowed to use on the server when the copy destination of the storage pool is FILE or TAPE. The maxnummp parameter must be equal to or greater than the vmmaxparallel and vmmaxbackupsessions option settings. When multiple instances of the client are backing up files, or when a single client performs parallel backups, more mount points might be needed.

If the values for vmmaxparallel or vmmaxbackupsessions exceed the value for maxnummp, ANS0266I and other messages are displayed. Depending on the message, the client reduces the value of the vmmaxparallel option to match the number that is specified by maxnummp parameter or prohibits additional sessions from being opened for the specified VM. In either situation, the backup operation continues.

If additional ANS0266I errors are detected, the client reduces the vmmaxparallel value by 1 and attempts to continue the backup. If vmmaxparallel is decremented to 1 and the client receives more ANS0266I errors, the client ends the backup and issues the following error:

ANS5228E `A backup VM operation failed because VMMAXPARALLEL was reduced to 1 and the client still cannot obtain a server mount point.`

Contact your server administrator if you want the value that is currently set for maxnummp increased so your node can support additional parallel backup sessions.

On Windows Server 2012 and 2012 R2, during Hyper-V virtual machine backups, IBM Spectrum Protect creates VSS snapshots of all volumes that contain virtual machine data. Backup data is read from the VSS snapshots, and not from data that is on the live file system. In many cases, when IBM Spectrum Protect attempts to create several snapshots concurrently, the VSS software provider might fail to satisfy a snapshot request for several virtual machines. The failures occur because the VSS software snapshot provider can not handle the load that is created by several backups that are attempted in parallel. To avoid this issue, use a VSS hardware snapshot provider instead of a VSS software provider.

The maximum that you can specify is 100 sessions. The default is the value that is set for the vmmaxparallel option.

Examples

Options file

```
VMMAXBACKUPS 10
```

Command line:

```
dsmc backup vm -VMMAXBACKUPS=10
```

Backing up multiple virtual machines in parallel

Linux | Windows

Vmmaxparallel

The vmmaxparallel option is used to configure optimized backups of several virtual machines by using a single instance of the backup-archive client. This option specifies the maximum number of virtual machines that can be backed up to the IBM Spectrum Protect™ server at any one time.

An optimized backup operation is one in which parallel backup capability is enabled at the VM, virtual disk, or subdisk level.

The vmmaxparallel option works with the vmmaxbackupsessions, vmlimitperhost, and vmlimitperdatastore options to optimize backup operations and to help control the amount of resources that the backup can create on a host in the vSphere infrastructure. Adjust the values of these options to find the values that provide optimal performance for the backups that are in your environment.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments.

For Data Protection for Microsoft Hyper-V, this option is valid only for Hyper-V backup operations on Windows Server 2012 and 2012 R2 operating systems.

Supported clients

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows clients.

Options file

Linux This option is valid in the client system options file (dsm.sys) or on the command line for the Backup VM command. It can also be included on the server in a client options set. It cannot be set in the Preferences Editor.

Windows This option is valid in the client options file (dsm.opt) or on the command line for the Backup VM command. It can also be included on the server in a client options set. It cannot be set in the Preferences Editor.

Syntax

```
                    .-4-----------.
>>-VMMAXParallel--+-+---------+-+------------------------------><
                    '-integer-'
```

Parameters

integer

Specifies the maximum number of virtual machines that can be backed up at any one time during an optimized backup operation. The default is 4. The maximum is 50.

Tip: When you use client-side data deduplication, a data deduplication session is started for each VM. This data deduplication session is not counted as one of the vmmaxparallel sessions.

Review the following information for using the vmmaxparallel option in conjunction with the vmmaxbackupsessions option or the maxnummp server parameter:

vmmaxbackupsessions

The vmmaxbackupsessions specifies the maximum number of sessions that move virtual machine data to the server that can be included in an optimized backup operation. The value of the vmmaxbackupsessions option must be equal to or greater than the value of the vmmaxparallel option.

maxnummp

The maxnummp server parameter specifies the maximum number of mount points a node is allowed to use on the server when the copy destination of the storage pool is FILE or TAPE. The maxnummp parameter must be equal to or greater than the vmmaxparallel and vmmaxbackupsessions option settings. When multiple instances of the client are backing up files, or when a single client performs parallel backups, more mount points might be needed.
If the values for vmmaxparallel or vmmaxbackupsessions exceed the value for maxnummp, ANS0266I and other messages are displayed. Depending on the message, the client reduces the value of the vmmaxparallel option to match the number that is specified by maxnummp parameter or prohibits additional sessions from being opened for the specified VM. In either situation, the backup operation continues.
If additional ANS0266I errors are detected, the client reduces the vmmaxparallel value by 1 and attempts to continue the backup. If vmmaxparallel is decremented to 1 and the client receives more ANS0266I errors, the client ends the backup and issues the following error:
ANS5228E `A backup VM operation failed because VMMAXPARALLEL was reduced to 1 and the client still cannot obtain a server mount point.`
Contact your server administrator if you want the value that is currently set for maxnummp increased so your node can support additional parallel backup sessions.
On Windows Server 2012 and 2012 R2, during Hyper-V virtual machine backups, IBM Spectrum Protect creates VSS snapshots of all volumes that contain virtual machine data. Backup data is read from the VSS snapshots, and not from data that is on the live file system. In many cases, when IBM Spectrum Protect attempts to create several snapshots concurrently, the VSS software provider might fail to satisfy a snapshot request for several virtual machines. The failures occur because the VSS software snapshot provider can not handle the load that is created by several backups that are attempted in parallel. To avoid this issue, use a VSS hardware snapshot provider instead of a VSS software provider.

Examples

Options file

```
VMMAXP 10
```

Windows Command line:

Windows `dsmc backup vm -VMMAXP=10`

Backing up multiple virtual machines in parallel
Windows

Vmmaxpersnapshot

Use the vmmaxpersnapshot option to specify the maximum number of virtual machines (VMs) to include in a Hyper-V snapshot. The VMs in the snapshot are backed up to the IBM Spectrum Protect™ server.

By increasing the number of VMs in a snapshot, you can reduce the number of snapshots that are taken for a backup operation. This capability reduces the scheduling contention that can be experienced during cluster backup operations of VMs on Clustered Shared Volumes (CSVs).

A snapshot with more VMs takes longer to complete and increases the load on the system. A larger number of VMs means that the snapshot persists longer, which can affect performance.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments: Data Protection for Microsoft Hyper-V.

This option is valid only for Hyper-V backup operations on Windows Server 2012 and 2012 R2 operating systems.

Supported clients

This option is valid for all supported Windows clients. This option can also be defined on the server.

Options file

This option is valid in the client options file (dsm.opt) or on the command line for the Backup VM command. It can also be included on the server in a client options set. It cannot be set in the Preferences Editor.

Syntax

```
                    .-20------.
>>-VMMAXPERSnapshot--+-integer-+-------------------------------><
```

Parameters

integer

Specifies the maximum number of VMs that can be included in a Hyper-V snapshot. The default is 20. The maximum is 100. The minimum is 1.

If some VMs reside on local volumes and some VMs reside on Clustered Shared Volumes (CSVs), the number of VMs in a snapshot might be less than the vmmaxpersnapshot setting. A snapshot cannot contain a mixture of VMs on local and CSV volumes.

To avoid creating a snapshot that spans volumes, the number of VMs in a snapshot might be less than the maximum number if the VMs are on different volumes. For example, four VMs are on Volume A and one VM is on Volume B. A snapshot is taken with only four VMs (from Volume A) even though the maximum setting is five. A second snapshot is taken for Volume B.

Examples

Options file

```
vmmaxpersnapshot 10
```

Command line

```
dsmc backup vm -vmmaxpers=10
```

Tuning scheduled VM backups for Windows Server 2012 and 2012 R2 clusters
Linux | Windows

Vmmaxrestoresessions

The vmmaxrestoresessions option specifies the maximum number of IBM Spectrum Protect™ server sessions that can be included in an optimized restore operation for a virtual machine (VM).

A optimized restore operation is one in which parallel restore capability is enabled at the subdisk level of a virtual disk.

Supported clients

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows clients. This option is not valid for Data Protection for Microsoft Hyper-V backups.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

Options file

Linux This option is valid in the client system options file (dsm.sys), in the client options file (dsm.opt), or on the command line for Restore VM. It can also be included on the server in a client options set. It cannot be set in the Preferences Editor.

Windows This option is valid in the client options file (dsm.opt) or on the command line for Restore VM. It can also be included on the server in a client options set. It cannot be set in the Preferences Editor.

Syntax

```
                              .-1-----------.
>>-VMMAXRESTORESessions-- --+-+---------+-+--------------------><
                            '-integer-'
```

Parameters

integer

Specifies the number of IBM Spectrum Protect server sessions that are created during the restore operation. The default is 1.

Examples

Options file

VMMAXRESTORES 10

Windows Command line:

Windows
```
dsmc restore vm -VMMAXRESTORES=10
```

Related reference:

Restore VM

Linux | Windows

Vmmaxrestoreparalleldisks

The vmmaxrestoreparalleldisks option enables an IBM Spectrum Protect™ client to restore multiple virtual disks at the same time.

You can specify the number of disk sessions to be opened, up to a maximum of 50. The number of disk restore sessions available is specified by the vmmaxrestoresessions option. Available sessions are allocated across the number of disk sessions specified by vmmaxrestoreparalleldisks, by rounding down the number of sessions per disk to the nearest whole number.

Supported clients

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows clients. This option is not valid for Data Protection for Microsoft Hyper-V backups.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

Options file

Linux This option is valid in the client system options file (dsm.sys), or on the command line for Restore VM. It can also be included on the server in a client options set. It cannot be set in the Preferences Editor.

Windows This option is valid in the client options file (dsm.opt) or on the command line for Restore VM. It can also be included on the server in a client options set. It cannot be set in the Preferences Editor.

Syntax

```
                                  .-1-----------.
>>-VMMAXRESTOREPARALLELDisks-- --+-+---------+-+---------------><
                                '-integer-'
```

Parameters

integer

Specifies the number of virtual hard disks that can be restored simultaneously. The default is 1. The maximum is 50.

Examples

Task

Set a maximum of 10 simultaneous restore operations for virtual disks in the VM vm1:

```
dsmc restore vm vm1 -vmmaxrestoreparalleldisks=10 -vmmaxrestoresessions=20
```

This will assign 2 simultaneous restore sessions per virtual disk.

Related reference:
Restore VM
Windows

Vmmaxsnapshotretry

Use the vmmaxsnapshotretry option to specify the maximum number of times to retry a snapshot operation of a virtual machine (VM) if the initial snapshot fails with a recoverable condition.

During a VM backup, if a snapshot of a VM fails due to a temporary condition, Data Protection for Microsoft Hyper-V automatically retries the snapshot operation up to the number of times that is specified by the vmmaxsnapshotretry option. If the snapshot still fails after the maximum number of retries is reached, the snapshot operation for the VM is not retried and the backup attempt fails.

For example, a recoverable condition might be caused by two backup requests that started at about the same time, backing up VMs that reside on the same volume. One backup operation reports that the snapshot failed because the backup cannot be started while another backup is running for the same VM. In this case, Data Protection for Microsoft Hyper-V will retry the snapshot operation after the first VM backup is completed.

If the initial error is not recoverable, a snapshot is not attempted. For example, if an error occurs with the Volume Shadow Copy Services (VSS) writer during the initial snapshot process, the backup processing stops and Data Protection for Microsoft Hyper-V does not retry the snapshot operation.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for Microsoft Hyper-V.

This option is valid only for Hyper-V backup operations on Windows Server 2012 and 2012 R2 operating systems.

Supported clients

This option is valid for all supported Windows clients. This option can also be defined on the server.

Options file

This option is valid in the client options file (dsm.opt) or on the command line for the Backup VM command. It can also be included on the server in a client option set. It cannot be set in the Preferences Editor.

Syntax

```
                    .-20------.
>>-VMMAXSNApshotretry--+-integer-+----------------------------><
```

Parameters

integer

Specifies the maximum number of times to retry the snapshot operation of a VM if the initial snapshot attempt fails with a recoverable condition. The default is 20. The maximum is 30. The minimum is 1.

For example, if the vmmaxsnapshotretry option is set to 12, Data Protection for Microsoft Hyper-V retries the snapshot operation up to 12 times after the initial snapshot failed during a VM backup operation. If the snapshot still fails after 12 retries are reached, no more retries are attempted, and the backup attempt fails.

At least 10 minutes must elapse before the next snapshot retry attempt. The time between attempts will be longer when the failed VM is part of a snapshot with VMs that are currently being backed up. The backup operation of the other VMs must be completed and the snapshot is removed by the backup operation before a retry attempt can be made.

Examples

Options file

```
vmmaxsna 12
```

Command line

```
dsmc backup vm -vmmaxsna=12
```

Tuning scheduled VM backups for Windows Server 2012 and 2012 R2 clusters

Linux Windows

Vmmaxvirtualdisks

The vmmaxvirtualdisks option specifies the maximum size of the VMware virtual machine disks (VMDKs) to include in a backup operation.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Use the vmmaxvirtualdisks option with the vmskipmaxvirtualdisks option to specify how the client processes large VMDKs during a backup operation:

- Set the vmmaxvirtualdisks option to specify the maximum size of the VMDKs to include.
- Set the vmskipmaxvirtualdisks option to back up the VMDKs that do not exceed the maximum size (and exclude any VMDKs that exceed the size), or fail the operation.

Supported clients

Linux This option is valid for 64-bit Linux clients that are configured as data movers that back up VMware virtual machines.

Windows This option is valid for 64-bit Windows clients that are configured as data movers that back up VMware virtual machines.

Options file

Linux Set the vmmaxvirtualdisks option in the client system options file (dsm.sys). You can also specify this option as a command-line parameter on the backup vm command.

Windows Set the vmmaxvirtualdisks option in the client options file (dsm.opt). You can also specify this option as a command-line parameter on the backup vm command.

Syntax

```
                      .-2----------.
>>-VMMAXVIRTUALDisks--+-size ------+--------------------------><
                      '-2...8, 999-'
```

Parameters

size

Specifies the maximum size, in terabytes, of the VMDKs to include in a backup operation. The range is an integer 2 - 8; the default is 2. The maximum is 8.
To ensure that the VMware VMDK size that is included in backup operations is always the maximum size, specify 999. Use this value as the most effective method to ensure that the maximum value is always set. This value prevents the need to continuously modify the option files.

When you also specify the vmskipmaxvirtualdisks yes option, VMDKs that are the specified maximum size or smaller are backed up and VMDKs that are larger than the specified maximum size are excluded.
When you also specify the vmskipmaxvirtualdisks no option, backup operations fail if a VMDK is larger than the specified maximum size.

Examples

Options file:

```
vmmaxvirtualdisks 3
```

Command line:

Back up VMDKs that are 5 TB or smaller and exclude VMDKs that are larger than 5 TB:

```
backup vm VM1 -vmmaxvirtualdisks=5 -vmskipmaxvirtualdisks=yes
```

Back up VMDKs that are 3 TB or smaller and fail the backup operation if a VMDK is larger than 3 TB:

```
backup vm VM1 -vmmaxvirtualdisks=3 -vmskipmaxvirtualdisks=no
```

Back up VMDKs that are 8 TB or smaller and exclude VMDKs that are larger than 8 TB:

```
backup vm VM1 -vmmaxvirtualdisks=8 -vmskipmaxvirtualdisks=yes
```

or

```
backup vm VM1 -vmmaxvirtualdisks=999 -vmskipmaxvirtualdisks=yes
```

Linux | Windows

Vmmc

Use the vmmc option to store virtual machine backups by using a management class other than the default management class. For VMware VM backups, the vmmc option is valid only if the vmbackuptype=fullvm option is set.

Supported Clients

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments.

Linux | Windows This option is valid for clients that are configured to back up VMware virtual machines. The server can also define this option.

Windows This option is valid for clients that are configured to back up Hyper-V virtual machines. The server can also define this option.

Options File

Linux Place this option in the client options file dsm.opt, in the client system options file dsm.sys, or on the command line.

Windows Place this option in the client options file (dsm.opt), or on the command line.

Syntax

```
>>-VMMC--management_class_name---------------------------------><
```

Parameters

management_class_name
Specifies a management class that applies to the backed up virtual machine data. If you do not set this option, the default management class of the node is used.

Examples

Task:

Run a backup of the virtual machine that is named `myVirtualMachine` and save the backup according to the management class that is named `myManagmentClass`.

```
dsmc backup vm "myVirtualMachine" -vmmc=myManagmentClass
```

Windows

Vmmountage

Use the vmmountage option with the restore VM "*" -vmrestoretype=mountcleanupall command to specify the number of hours that a VM file level restore mount must be active to be cleaned up.

Supported Clients

Windows This option is only valid for Windows clients.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Options File

Windows None. You can specify this option only on the command line.

Syntax

```
>>-VMMOUNTAge = - --hours---------------------------------------><
```

Parameters

hours

Specifies the number of hours that a VM file level restore mount must be active to be cleaned up. All active mount operations that exceed this period are cleaned up.
The value that is specified must be an integer between 0 and 10000. The default is 0.

Examples

Command line:

Clean up all mount operations that are active longer than 24 hours:

```
dsmc restore vm "*" -VMRESToretype=MOUNTCLEANUPALL -VMMOUNTAge=24
```

Clean up all active mount operations:

```
dsmc restore vm "*" -VMRESToretype=MOUNTCLEANUPALL -VMMOUNTAge=0
```

or

```
dsmc restore vm "*" -VMRESToretype=MOUNTCLEANUPALL
```

Linux Windows

Vmnoprdmdisks

This option enables the client to restore configuration information for the pRDM volumes that are associated with a VMware virtual machine, even if the LUNs that were associated with the volumes cannot be found. Because pRDM volumes are not included in virtual machine snapshot, only the configuration information can be restored, and not the data that was on the volumes.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

This option does not apply to backups of Microsoft Hyper-V virtual machines.

Supported Clients

This option is valid for Windows and Linux clients that are installed on a vStorage backup server.

Options File

Windows Place this option in the client options file (dsm.opt), or specify it as a command-line parameter on the restore vm command.

Linux Place this option in the client options file (dsm.opt), in the client system options file (dsm.sys), or specify it as a command-line parameter on the restore vm command.

Syntax

```
                    .-NO--.
>>-VMNOPRDmdisks--+-----+-------------------------------------><
                  '-YES-'
```

Parameters

YES
: Specify this value if you must restore a virtual machine that you backed up with `-vmprocesswithprdm=yes`, and the original LUNs that were mapped by the raw device mappings file cannot be located. This setting causes the client to skip attempts to locate the missing LUNs used by the pRDM volumes, and restore the configuration information (disk labels) that were associated with them. The pRDM volumes are restored as thin-provisioned VMFS VMDKs. You can then use the vSphere client to create the necessary pRDM mappings.

NO
: Setting `-vmnoprdmdisk=no` causes restore operations for virtual machines that were backed up with `-processvmwithprdm=yes` to fail if the original LUNs that were mapped to by the raw device mappings file cannot be located. This value is the default value.

Examples

Option file:

```
VMNOPRDMDISKS YES
```

Command line:

```
dsmc restore vm vm123 -vmnoprdmdisks=yes
```

Linux | Windows

Vmnovrdmdisks

This option enables the client to restore configuration information and data for vRDM volumes that are associated with a VMware virtual machine, even if the LUNs that were associated with the volumes cannot be found.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

This option does not apply to backups of Microsoft Hyper-V virtual machines.

Supported Clients

This option is valid for Windows and Linux clients that are installed on a vStorage backup server.

Options File

Windows Place this option in the client options file (dsm.opt), or specify it as a command-line parameter on the restore vm command.

Linux Place this option in the client options file (dsm.opt), in the client system options file (dsm.sys), or specify it as a command-line parameter on the restore vm command.

Syntax

```
                    .-NO--.
>>-VMNOVRDmdisks--+-----+-------------------------------------><
                  '-YES-'
```

Parameters

YES
: Specify this value if you must restore a virtual machine that you backed up, and the original LUNs that were mapped by the raw device mappings file cannot be located. This setting causes the client to skip attempts to locate the missing LUNs used by the vRDM volumes, and restore the configuration information (disk labels) and the data that was backed up. The vRDM volumes are restored as thin-provisioned VMFS VMDKs.

NO
: Setting `-vmnovrdmdisk=no` causes restore operations for virtual machines that had vRDM volume to fail, if the original LUNs that were mapped to by the raw device mappings file cannot be located. This value is the default value.

Examples

Option file:

```
VMNOVRDMDISKS YES
```

Command line:

```
dsmc restore vm vm123 -vmnovrdmdisks=yes
```

Vmpreferdagpassive

The vmpreferdagpassive option specifies whether to back up an active copy or passive copy of a database that is part of a Microsoft Exchange Server Database Availability Group (DAG).

This option applies to Microsoft Exchange Server workloads that run inside VMware virtual machine guests that are protected by IBM Spectrum Protect™ for Virtual Environments.

Use the vmpreferdagpassive option with the backup vm command.

Supported Clients

Linux | Windows This option is valid on clients that act as a data mover for VMware guest backups.

Options File

Linux Place this option in the client system-options file (dsm.sys) within a server stanza.

Windows Place this option in the client options file (dsm.opt).

Syntax

```
                        .-No--.
>>-VMPREFERDAGPassive--+-----+--------------------------------><
                       '-Yes-'
```

Parameters

No
: Back up the Microsoft Exchange Server database in a DAG regardless of whether it is an active copy or passive copy. This value is the default.

Yes

Skip the backup for an active database copy in a DAG if a valid passive copy is available on another server. If no valid passive copy is available, the active database copy is backed up.

Examples

Options file:

vmpreferdagpassive yes

Linux | Windows

Vmprocessvmwithindependent

Use this option to control whether full VMware virtual machine backups are processed if the machine is provisioned with one or more independent disk volumes.

Independent disk volumes do not support snapshots. Any independent disk volumes found on a virtual machine are not be processed as part of the backup operation. When the virtual machine is restored, the backup-archive client recovers the virtual machine, and only the volumes that participated in snapshot operations are restored. Configuration information and content of the independent disk volumes is not preserved in the information that is stored on the IBM Spectrum Protect™ server. Users must recreate the independent disk volumes on the restored machine.

If the virtual machine also contains one or more raw device mapping (RDM) volumes configured in physical-compatibility mode (pRDM), use the vmprocessvmwithprdm option to control whether the client backs up any files on the virtual machine if an independent disk is present.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

This option is only valid for VMware backups and does not pertain to Microsoft Hyper-V backups.

Supported Clients

This option is valid for Windows and Linux clients that are configured as a VMware backup server. The server can also define this option.

Options File

Windows Place this option in the client options file (dsm.opt) or on the command-line

Linux Place this option in the client options file (dsm.opt), in the client system options file (dsm.sys), or on the command-line.

Syntax

```
                                .-NO--.
>>-VMPROCESSVMWITHINDEPENDENT--+-----+-------------------------><
                                '-YES-'
```

Parameters

No

The backup of the virtual machine fails if one or more independent disk volumes are detected. No is the default.

Yes

Virtual machines that contain one or more independent disk volumes are backed-up. However, the independent disk volumes are not be processed as part of the virtual machine backup operation.
If the virtual machine also contains one or more raw device mapping (RDM) disks that are provisioned in physical-compatibility mode, the VMPROCESSVMWITHPRDM option must also be specified.

Examples

Option file:

```
VMPROCESSVMWITHINDEPENDENT Yes
```

Command line:

```
dsmc backup vm vmlocal -vmbackuptype=fullvm -vmprocessvmwithindependent=yes
```

Windows

Vmprocessvmwithphysdisks

Use the vmprocessvmwithphysdisks option to control whether Hyper-V RCT virtual machine (VM) backups are processed if the VM has one or more physical disks (pass-through disks) provisioned.

A VM can access the storage on a physical disk that is connected directly to the Hyper-V server. This physical disk is called a *pass-through disk*.

When you set this option to `yes`, the data on any physical disks is excluded from backup operations, but the configuration information for the physical disks is saved with the VM backup. During a restore operation, you can restore the physical disk configuration by setting the vmskipphysdisks no option. If the original physical disks are available, they are reconnected to the restored VM.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for Microsoft Hyper-V.

This option is valid only for Microsoft Hyper-V backups and does not apply to VMware backups.

This option is valid only for RCT backups on Windows Server 2016. This option does not apply to Hyper-V VSS backups on Windows Server 2012 or Windows Server 2012 R2.

Supported Clients

This option is valid for clients on Windows Server 2016 or later operating systems.

Options File

Place this option in the client options file (dsm.opt) or specify it as a command-line parameter on the backup vm command.

Syntax

```
                              .-NO--.
>>-VMPROCESSVMWITHPHYSDisks--+-----+---------------------------><
                              '-YES-'
```

Parameters

No
: The backup operation of the VM fails if one or more physical disks are detected. This value is the default.

Yes
: VMs that contain one or more physical disks are backed up. This option backs up the physical disk configuration without backing up the data on the physical disks.

Examples

Options file:

```
VMPROCESSVMWITHPHYSDISKS Yes
```

Command line:

```
dsmc backup vm vmlocal -vmprocessvmwithphysd=yes
```

Related reference:
Vmskipphysdisks

Linux | Windows

Vmprocessvmwithprdm

Use this option to control whether full VMware virtual machine backups are processed if the virtual machine has one or more raw device mapping (RDM) volumes provisioned in physical-compatibility mode (pRDM).

pRDM volumes do not support snapshots. Any pRDM volumes found on a virtual machine are not processed as part of the backup operation. When the virtual machine is restored, the backup-archive client recovers the virtual machine, and only the volumes that participated in snapshot operations are restored. Configuration information and content of the pRDM volumes is not preserved in the information stored on the IBM Spectrum Protect™ server. Users must re-create the pRDM volumes on the restored machine.

This option does not apply to virtual machines that have one or more RDM volumes that are provisioned in virtual-compatibility mode (vRDM). Because vRDM volumes do support snapshot operations, they are included in a full VMware virtual machine backup.

If the virtual machine also contains one or more independent disks, use the vmprocessvmwithindependent option to control whether the client backs up any files on the virtual machine if an independent disk is present.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

This option is only valid for VMware backups and does not pertain to Microsoft Hyper-V backups.

Supported Clients

This option is valid for Windows and Linux clients that are configured as a VMware backup server. The server can also define this option.

Options File

Windows Place this option in the client options file (dsm.opt) or on the command line

Linux Place this option in the client options file (dsm.opt), in the client system options file (dsm.sys), or on the command line.

Syntax

```
                          .-NO--.
>>-VMPROCESSVMWITHPRDM--+-----+--------------------------------><
                          '-YES-'
```

Parameters

No
: The backup of the virtual machine fails if one or more pRDM volumes are detected. No is the default.

Yes
: Virtual machines that contain one or more raw device mapping (RDM) volumes that are provisioned in physical-compatibility mode (pRDM) are backed up. However, the pRDM volumes are not processed as part of the virtual machine backup operation.
If the virtual machine also contains one or more independent disks, the vmprocessvmwithindependentdisk option must also be specified.

Examples

Option file:

```
VMPROCESSVMWITHPRDM Yes
```

Command line:

```
dsmc backup vm vmlocal -vmbackuptype=fullvm -vmprocessvmwithprdm=yes
```

Windows

Vmrestoretype

Use the vmrestoretype option with the query VM or restore VM commands to specify the type of restore operation to perform or query.

This option is only valid for VMware virtual machines. The virtual machines must be hosted on VMware ESXi 5.1 servers, or later versions. To use this option, you must have a license agreement to use IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

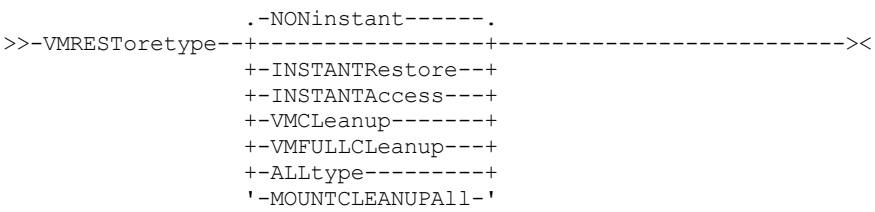
Supported Clients

Windows This option can be used with supported Windows clients.

Options file

This option must be specified on the command line of a restore vm or query vm command. You cannot set this option in the client options file.

Syntax



Parameters

noninstant
: Specifies that classic full VM restore is performed. This is the default restore type.

instantrestore
: Specifies that an instant restore is performed. During an instant restore operation, the VM is started during the restore operation. When this restore type is specified on a query VM command, the command returns a list of VMs running an instant restore operation.
Important: For instant restore operations, ensure that both the temporary datastore that you specify with the vmtempdatastore option and the VMware datastore that is specified by the datastore option on the restore VM command have enough free storage to save the virtual machine that you are restoring, and the snapshot file that contains changes made to the data.

instantaccess
: Specifies that a temporary restore of the backed-up VM is performed. Use this restore type when you want to restore a VM temporarily, to test the integrity of a backup, before you run an instant restore. Any changes that are made to the temporary VM are not saved.
When this restore type is specified on a query vm command, the command returns a list of VMs that are running an instant access operation.

vmcleanup
: Specifies that a cleanup of the selected VM and its components is performed.
For instant access operations, this option removes the temporary VM and all of its components.
For instant restore operations, this option removes only the components that are no longer needed (for example the iSCSI mounts). The virtual machine is not removed. Cleanup operations are not allowed when the VM is still running on the iSCSI disks. To force this behavior see vmfullcleanup.

vmfullcleanup
: The VM and all its components are removed regardless of the current state. Do not start a full clean up operation while vMotion is still migrating a virtual machine.

alltype
: Queries all active instant access and instant restore sessions.

mountcleanupall

Cleans up active VM file level restore mount operations that are older than the period specified with the vmmountage option. You must specify restore vm "*" to use the mountcleanupall option.

Examples

Command line:

Perform an instant access of the VM named Oslo. The original VM still exists. As a result, the -vmname option is used to assign the new name Oslo_verify.

```
dsmc restore vm Oslo -vmrest=instantaccess -vmname=Oslo_verify
```

Perform an instant restore of the VM named Cologne.

```
