dsmc restore vm Cologne -vmrest=instantrestore
  -vmtempdatastore=Verify_datastore
```

Perform a regular (full VM) restore of the virtual machine named San_Jose.

```
dsmc restore vm San_Jose
```

Alternatively, you can also use the following command: `dsmc restore vm San_Jose -vmrest=noni`
Perform an instant restore of the VM named Oslo, with the -pick option to choose a specific backup version.

```
dsmc restore vm Oslo -vmrest=instantrestore -pick
```

Perform a cleanup of the VM and all its components. These components include iSCSI mounts, devices, and temporary data that are associated with the VM name, on the ESX host.

```
dsmc restore vm Oslo -VMREStoretype=VMCLeanup -vmname=Oslo_Verify
```

Perform a query to find all active instant restore sessions and display an abbreviated status for each.

```
dsmc query vm * -VMREStoretype=INSTANTRestore
```

Perform a query to find all active instant restore mode and instant access mode virtual machines.

```
dsmc query vm * -VMREStoretype=ALLtype
```

Perform a query to find all active instant restore mode virtual machines, and obtain detailed status for each virtual machine.

```
dsmc query vm * -VMREStoretype=INSTANTRestore -Detail
```

Perform a query to find all active instant access sessions.

```
dsmc query vm * -VMREStoretype=INSTANTAccess
```

Perform a mount cleanup of all mount operations that are active longer than 24 hours.

```
dsmc restore vm "*" -vmrestoretype=mountcleanupall -vmmountage=24
```

Windows | Linux

Vmskipctlcompression

Use the vmskipctlcompression option for VM backups to specify whether control files (*.ctl) are compressed during VM backup. The option does not affect the compression of data files (*.dat)

You can compress virtual machine control files and data files only when the files are stored in a storage pool that is enabled for client-side deduplication. Use the following options configuration to compress data files and not compress control files:

```
compression yes
vmskipctlcompression yes
```

You must direct the data files to a storage pool that is enabled for client-side deduplication. You can direct the control files to a storage pool that is not enabled for client-side deduplication

You must be licensed to use IBM Spectrum Protect™ for Virtual Environments to use this option.

Supported Clients

Windows This option can be used with supported Windows and Linux clients.

Options file

Place this option in the client options file (dsm.opt), or on the command line.

Syntax

```
                          .-Yes-.
>>-VMSKIPCTLCOMPRESSION--+-----+-------------------------------><
                          '-No--'
```

Parameters

Yes
: Do not compress control files (*.ctl) during VM backup. The option does not affect compression of data files (*.dat).

No
: Control files (*.ctl) can be compressed during VM backup. Whether control files are compressed depends on the value of the compression option.

Linux | Windows

Vmskipmaxvirtualdisks

The vmskipmaxvirtualdisks option specifies how the backup operation processes VMware virtual machine disks (VMDKs) that exceed the maximum disk size.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Use the vmskipmaxvirtualdisks option with the vmmaxvirtualdisks option to specify how the client processes large VMDKs during a backup operation:

- Set the vmskipmaxvirtualdisks option to back up the VMDKs that do not exceed the maximum size (and exclude any VMDKs that exceed the size), or fail the operation.
- Set the vmmaxvirtualdisks option to specify the maximum size of the VMDKs to include.

In V7.1.3 and earlier, the vmskipmaxvirtualdisks option was named vmskipmaxvmdks. In V7.1.4 and later, vmskipmaxvirtualdisks is the preferred option name. However, the client still processes backup operations with the vmskipmaxvmdks name.

Supported clients

Linux This option is valid for 64-bit Linux clients that are configured as data movers that back up VMware virtual machines.

Windows This option is valid for 64-bit Windows clients that are configured as data movers that back up VMware virtual machines.

Options file

Linux Set the vmskipmaxvirtualdisks option in the client system options file (dsm.sys). You can also specify this option as a command-line parameter on the backup vm command.

Windows Set the vmskipmaxvirtualdisks option in the client options file (dsm.opt). You can also specify this option as a command-line parameter on the backup vm command.

Syntax

```
                          .-No--.
>>-VMSKIPMAXVIRTUALDISKS--+-----+-------------------------------><
                          '-Yes-'
```

Parameters

No
: Specifies that backup operations fail if a VMware virtual machine has one or more VMDKs that are larger than the maximum size. This setting is the default value.

Yes
: Specifies that backup operations include VMware VMDKs that are the maximum size (or smaller) and exclude any VMDKs that are larger than the maximum size.

Examples

Options file:

```
vmskipmaxvirtualdisks yes
```

Command line:

Fail a backup operation if a VMDK is larger than 2 TB:

```
backup vm VM1 -vmskipmaxvirtualdisks=no
```

Fail a backup operation if a VMDK is larger than 5 TB:

```
backup vm VM1 -vmskipmaxvirtualdisks=no -vmmaxvirtualdisks=5
```

Back up VMDKs that are 8 TB or smaller and exclude VMDKs that are larger than 8 TB:

```
backup vm VM1 -vmskipvirtualdisks=yes -vmmaxvirtualdisks=8
```

Linux | Windows

Vmskipmaxvmdks

The vmskipmaxvmdks option specifies how the backup operation processes VMware virtual machine disks (VMDKs) that exceed the maximum disk size.

In V7.1.4 and later, vmskipmaxvmdks is renamed vmskipmaxvirtualdisks. Although vmskipmaxvirtualdisks is the preferred name, the client still processes backup operations with the vmskipmaxvmdks name.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Windows

Vmskipphysdisks

Use the vmskipphysdisks option to restore configuration information for physical disks (pass-through disks) that are associated with a Hyper-V virtual machine (VM), if the logical unit numbers (LUNs) that are associated with the volumes on the physical disks are available.

Because physical disks are not included in a VM snapshot, only the configuration information can be restored, and not the data on the volumes.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for Microsoft Hyper-V.

This option is valid only for Microsoft Hyper-V backups and does not apply to VMware backups.

This option is valid only for restoring Hyper-V VMs on Windows Server 2016. This option does not apply to Hyper-V hosts on Windows Server 2012 or Windows Server 2012 R2.

Supported Clients

This option is valid for clients on Windows Server 2016 or later operating systems.

Options File

Place this option in the client options file (dsm.opt), or specify it as a command-line parameter on the restore vm command.

Syntax

```
                    .-NO--.
>>-VMSKIPPHYSDisks--+-----+-----------------------------------><
                    '-YES-'
```

Parameters

NO
: If the original physical disks are available, specify this value to restore the physical disk configuration information that was backed up with the vmprocessvmwithphysdisks yes option. The original physical disks are reconnected to the restored VM. If the original physical disks cannot be located, the restore operation fails. This value is the default.

YES
: Specify this value if you must restore a VM that you backed up with the vmprocessvmwithphysdisks yes option, and the original physical disks cannot be located. This setting causes the client to skip attempts to locate the physical disks, and does not restore the physical disk configuration information.

Examples

Options file:

```
VMSKIPPHYSDISKS YES
```

Command line:

```
dsmc restore vm vm123 -vmskipphysd=yes
```

Related reference:
Vmprocessvmwithphysdisks

Windows

Vmstoragetype

Use the vmstoragetype option with the restore VM command to specify the storage device type from which the snapshot is mounted with IBM Spectrum Protect™ recovery agent.

Windows

You can specify the vmstoragetype option with the restore VM -VMRESToretype=INSTANTRestore or restore VM -VMRESToretype=INSTANTAccess commands.

When vmstoragetype is specified, it is not necessary to set the storage type option in the IBM Spectrum Protect recovery agent GUI. The vmstoragetype overwrites the storage type setting in the recovery agent GUI.

Supported Clients

Windows This option is valid on Windows only.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

Options File

Windows Place this option in the client options file (dsm.opt) on the Windows mount proxy system, or on the command line.

Windows

Syntax

```
                  .-DISK-.
>>-VMSTORAGEType--+-VTL--+-----------------------------------><
                  '-TAPE-'
```

Parameters

Windows DISK

Windows The snapshots to be mounted by the recovery agent are on Disk or File storage pools. This value is the default.

Windows VTL

The snapshots to be mounted by the recovery agent are on VTL storage pools.

Windows TAPE

Windows The snapshots to be mounted by the recovery agent are on Tape storage pools.

Examples

Options file:

```
VMSTORAGETYPE TAPE
```

Command line:

Windows Restore a virtual machine that is named Orion by using the following command:

```
dsmc restore vm Orion -Host=esxi.example.com -datacenter=mydatacenter
  -VMTEMPDAtastore=temp_datastore -VMRESToretype=INSTANTRestore
  -datastore=mydatastore -VMSTORAGEType=VTL
```

This command specifies the name of the virtual machine to restore, the host and data center to restore it to, and the restore type (`-VMRESToretype=INSTANTRestore`). The `-VMSTORAGEType=VTL` option identifies the snapshot (`Orion`) that is to be mounted by the recovery agent is on VTL storage pools. The VMTEMPDAtastore option is a mandatory parameter for instant restore operations.

Linux Windows

Vmtagdatamover

Use the vmtagdatamover option to enable tagging support in the backup-archive client (data mover). When this option is enabled, the client manages backups of virtual machines in VMware inventory objects according to the data protection tags that are set by the IBM Spectrum Protect™ vSphere Client plug-in of the vSphere Web Client, or set with tools such as VMware vSphere PowerCLI Version 5.5 R2 or later.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

For more information about data protection tags, see "Data protection tagging overview" .

The data mover processes data protection tags when the vmtagdatamover option is set to yes. Ensure that the following requirements are met.

Requirements:

- For the data mover:
  - VMware vCenter Server must be at Version 6.0 Update 1 or later.
  - Extra permissions are required for the account that is used for backup or restore operations. These new vCenter permissions are required to perform category and tagging operations. Ensure that the following user permissions are set on the root vCenter Server:

    ```
    Inventory Service > vSphere Tagging > Assign or Unassign vSphere Tag
    Inventory Service > vSphere Tagging > Create vSphere Tag
    Inventory Service > vSphere Tagging > Create vSphere Tag Category
    Inventory Service > vSphere Tagging > Delete vSphere Tag
    Inventory Service > vSphere Tagging > Delete vSphere Tag Category
    Inventory Service > vSphere Tagging > Modify UsedBy Field For Tag
    Inventory Service > vSphere Tagging > Modify UsedBy Field For Category
    ```

    For more information about setting vCenter permissions for backup and restore operations, see technote 7047438.
- In order for the Data Protection for VMware vSphere GUI to function correctly with tagging support, ensure that the following requirements are met during the installation of the GUI:
  - At least one data mover and the Data Protection for VMware vSphere GUI must be installed on the same server. This data mover node must be configured so that the vCenter server credentials are saved. You can save the credentials

by running the configuration wizard to save the data mover node password, or by using the dsmc set password command in the data mover command line.

If you use other data movers, running on virtual machines or physical machines as additional data movers, you can install them on other servers. For tagging support, all these data movers must also be configured with the vmtagdatamover=yes option. These additional data movers do not require the Data Protection for VMware vSphere GUI to be installed on the same server in order for them to work correctly as tag-based data movers.

- Linux For Linux data movers, ensure that you specify the data mover installation directory and the Java™ shared library libjvm.so in the `LD_LIBRARY_PATH` environment variable. The path to libjvm.so is used for tagging support when you enable the vmtagdatamover option on the data mover. For instructions, see "Setting up the data mover nodes in a vSphere environment".
- Linux On Linux operating systems, the Data Protection for VMware vSphere GUI must be installed by using the default user name (`tdpvmware`).
- Linux On Linux data mover nodes, the default password file (/etc/adsm/TSM.sth) must be used.

Supported clients

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows 64-bit clients.

Options file

Linux You can specify this option in the client system-options file (dsm.sys) or on the command line for the backup vm command. You can also include this option on the IBM Spectrum Protect server in a client option set. You cannot set this option in the Preferences Editor.

Windows You can specify this option in the client options file (dsm.opt) or on the command line for the backup vm command. You can also include this option on the IBM Spectrum Protect server in a client option set. You cannot set this option in the Preferences Editor.

Syntax

```
                    .-No--.
>>-VMTAGDATamover--+-----+-------------------------------------><
                    '-Yes-'
```

Parameters

No
The client ignores any data protection settings or tags that are attributed to the VMware asset. This value is the default.

Yes
The client manages backups based on the data protection settings in the IBM Spectrum Protect vSphere Client plug-in or based on the tag values that are attributed to the VMware asset.

When tagging support is enabled, some client options might be affected by the data protection settings. For information about which options are affected, see "Supported data protection tags".

The following examples show how client options can be affected by data protection tags:

- When you use data protection settings or tags to control which VMware virtual machines are backed up, the tag values might overlap the domain.vmfull client option setting. While the domain.vmfull option defines what virtual machines the client protects, the `Excluded` and `Included` tags override what is defined by the domain.vmfull option.
  For example, the following options file statement specifies what is backed up during full virtual machine backup operations:

  ```
  DOMAIN.VMFULL VMHOSTCLUSTER=cluster01,cluster02;VM=Dept20*
  ```

  If you use data protection settings or tags to exclude virtual machine `Dept204`, the `Dept204` virtual machine is not backed up.

- The retention policy setting in the IBM Spectrum Protect vSphere Client plug-in or the tag setting for the `Management Class (IBM Spectrum Protect)` category overrides the include.vm and vmmc client options, but does not override the vmctlmc option.

Tip: If you want to set up a data mover as the default data mover, use the Vmtagdefaultdatamover option.

Examples

Options file:

```
vmtagdat yes
```

Command line:

```
-vmtagdat=yes
```

Linux | Windows

Vmtagdefaultdatamover

Use the vmtagdefaultdatamover option to protect virtual machines, defined in a schedule, that do not have an assigned or inherited `Data Mover` category and tag.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

When you specify a data mover node with the vmtagdefaultdatamover option and the vmtagdatamover yes option, the data mover backs up any new virtual machines that are added to any container in the datacenter, if the container is already in a protection set. A protection set consists of the virtual machines in a container that is assigned the `Schedule (IBM Spectrum Protect)` category and tag. The default data mover also backs up any virtual machines in the protection set that are not assigned the `Data Mover` tag.

When more than one data mover is associated with a schedule, define one data mover as the default data mover with the vmtagdefaultdatamover option. If only one data mover is associated with a schedule, assign that data mover as the default.

Tip: For each schedule, specify only one data mover in its associated data mover list as the default. Otherwise, any new virtual machines and virtual machines that are not assigned the `Data Mover` tag will be backed up more than once.

Data protection tags can be assigned to the vSphere inventory to manage the protection of virtual machines. For the list of supported categories and tags, see "Supported data protection tags".

Supported clients

Linux This option can be used with supported x86_64 Linux data movers.

Windows This option can be used with supported Windows 64-bit data movers.

Options file

Linux You can specify this option in the client system-options file (dsm.sys) or on the command line for the backup vm command. You can also include this option on the IBM Spectrum Protect server in a client option set. You cannot set this option in the Preferences Editor.

Windows You can specify this option in the client options file (dsm.opt) or on the command line for the backup vm command. You can also include this option on the IBM Spectrum Protect server in a client option set. You cannot set this option in the Preferences Editor.

Syntax

```
                          .-No------.
>>-VMTAGDEFAULTdatamover--+---------+-------------------------><
                          +-Yes-----+
                          '-dm_name-'
```

Parameters

No
: The local data mover does not function as a default data mover. Virtual machines that are not assigned the `Data Mover` tag are not protected by this data mover. This value is the default.

Yes
: Specifies that the local data mover (the data mover where you are specifying this option) functions as the default data mover.

  You must also enable the data mover for tagging support by specifying the vmtagdatamover yes option.

dm_name
: The name of the data mover that you want to use as the default data mover. This option is necessary only if you want to set this option in the options file for the default data mover. This option is ignored for any data mover that is not the default data mover.

  It is possible to pass this option down to all data movers on the server schedule command or to include it all data mover option files. Only the default data mover uses this option. Therefore, define only one default data mover.

  You must also specify the vmtagdatamover yes option in the options file on the data mover that you want to designate as the default data mover.

Example

Your Windows Data Protection for VMware configuration uses two data movers, `VC1_DC1_DM1` and `VC1_DC1_DM2`. To designate data mover `VC1_DC1_DM1` as the default data mover, complete the following steps:

1. In the options file for data mover `VC1_DC1_DM1` (dsm.VC1_DC1_DM1.opt), add the following statements:

   ```
   vmtagdatamover yes
   vmtagdefaultdatamover yes
   ```

   or

   ```
   vmtagdatamover yes
   vmtagdefaultdatamover VC1_DC1_DM1
   ```

2. In the options file for data mover `VC1_DC1_DM2` (dsm.VC1_DC1_DM2.opt), add the following statements:

   ```
   vmtagdatamover yes
   vmtagdefaultdatamover VC1_DC1_DM1
   ```

The vmtagdefaultdatamover option can also be passed to a schedule definition or command to assign the default data mover. If the default data mover is defined in the schedule definition, all data movers that are associated with the schedule will be able to identify the default data mover for the protection set.

For example: `dsmc backup vm -vmtagdefaultdatamover=VC1_DC1_DM1`

Set Vmtags

Windows

Vmtempdatastore

Use the vmtempdatastore option with the restore VM command to define a temporary datastore on the ESX host for an instant restore operation.

The datastore created with the vmtempdatastore option is used to temporarily store the configuration of the VM created during restore processing. This option is required during instant restore operations (-vmrestoretype=instantrestore).

This option is only valid for VMware virtual machines. The virtual machines must be hosted on VMware ESXi 5.1 servers, or later versions. To use this option, you must have a license agreement to use IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Supported Clients

Windows This option can be used with supported Windows clients.

Options file

Place this option in the client options file (dsm.opt), or on the command line.

Syntax

```
>>-VMTEMPDAtastore-- --datastore_name-------------------------><
```

Parameters

datastore_name
: Specify the name of an existing datastore on the ESX host. The temporary datastore must be different from the original datastore, or the datastore specified by the datastore option. The datastore that you specify must be a VMFS datastore.

Examples

Options file:

```
VMTEMPDAtastore Verify_Datastore
```

Command line:

```
dsmc restore vm Oslo -VMRESToretype=INSTANTAccess
-vmname=Oslo_instant_restored -VMTEMPDAtastore=Temporary_Datastore
```

Linux | Windows

Vmverifyifaction

Use this option to specify the action to perform if the data mover detects integrity problems with the latest CTL and bitmap files for a virtual machine.

This option affects backup processing for a VM guest only when all of the following conditions are true:

- The previous backup operation for the VM guest was an incremental-forever-incremental backup (`mode=ifincremental`)
- The current backup operation for the VM guest is an incremental-forever-incremental backup
- The data mover detected an integrity problem with the CTL and bitmap data from the previous incremental-forever-incremental backup operation
- The vmverifyiflatest option is set to `yes`

If all of these conditions are not true for a virtual machine, the backup occurs as it normally would; the action that is specified by this option is not initiated.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Supported clients

Linux This option is valid for Linux clients that act as a data mover for VMware guest backups.

Windows This option is valid for Windows clients that act as a data mover for VMware guest backups.

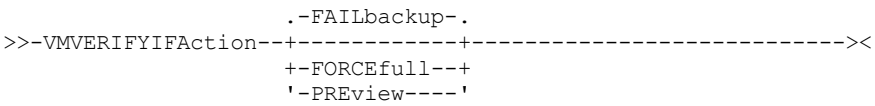
Options file

Windows Set this option in the client options file (dsm.opt).

Linux Set this option in the client options file (dsm.opt) or the client system options file (dsm.sys).

This option can also be included in a client options set, as a parameter on a backup vm command, or on the options parameter in a schedule definition.

Syntax



Parameters

FAILbackup
: This action fails the backup operation. The following messages are written to the data mover error log file (dsmerror.log):

```
ANS9921E Virtual machine disk, vm_name (disk_label),
verification check failed (xxx/yyy).
```

The xxx/yyy in the message indicate the size of the bitmap (xxx) and CTL files (yyy).

```
ANS9919E Failed to find the expected control files for vm_name
```

Perform a full VM backup (set `-mode=IFFull` for the affected virtual machines at a time of your choosing. An alternative is to use the `-vmverifyifaction=forcefull` on the next scheduled incremental-forever-incremental operation to force a full backup of those VMs, if you determine that your scheduled backup window can contain the full VM backups for these VMs. This value is the default action value.

FORCEfull
: This action changes the backup mode from `-mode=ifincremental` to `-mode=iffull`; the current backup becomes a full VM backup. The full VM backup is initiated for you. The following messages are written to the data mover error log file (dsmerror.log):

```
ANS9921E Virtual machine disk, vm_name (disk_label),
verification check failed (xxx/yyy)
```

The xxx/yyy in the message indicate the size of the bitmap (xxx) and CTL files (yyy).

```
ANS9919E Failed to find the expected control files for vm_name

ANS9922I VMVERIFYIFlatest is enabled for vm_name (action: FORCEFULL).

ANS9920W Forcing a full vm backup for vm_name
```

Use this option if your current backup window can contain a full VM backup of the affected virtual machines.

PREview
: This action does not perform any backups. Instead, the CTL and bitmap data for each VM guest that is processed by the backup vm command is restored to a temporary location, where it is checked for integrity. If the integrity check fails, the following messages are written to the data mover error log file (dsmerror.log):

```
ANS9921E Virtual machine disk, vm_name (disk_label),
verification check failed (xxx/yyy)
```

The xxx/yyy in the message indicate the size of the bitmap (xxx) and CTL files (yyy).

`ANS9919E Failed to find the expected control files for vm_name`

`ANS9922I VMVERIFYIFlatest is enabled for vm_name (action: PREVIEW)`

Use this option to validate the integrity of the incremental-forever-incremental backups (`-mode=ifincremental`) that you previously created for one or more a virtual machines.

If the messages indicate that some VMs failed the integrity checks, start a full VM backup (`-mode=iffull`) at a time of your choosing. Alternatively, set `-vmverifyifaction=forcefull` on the next scheduled incremental-forever-incremental operation to force a full backup of those VMs. The backup window must be large enough to accommodate one or more full VM backups.

Linux | Windows

Vmverifyiflatest

This option applies only to VMware virtual machine (VM) backup operations that use the incremental-forever-incremental backup mode (that is, a backup vm command with -mode=IFIncremental specified). If this vmverifyiflatest option is enabled, the data mover runs an integrity check on the CTL and bitmap files that were created on the server during the last backup, if the last backup was an incremental-forever-incremental backup.

If the files pass the integrity tests, the virtual machine is restorable. The current backup proceeds and adds another snapshot to the chain of snapshots for the virtual machine.

If the files fail the integrity tests, the virtual machine is not restorable. The data mover then performs another action, which you specified on the vmverifyifaction option. You can set vmverifyifaction to create a full VM backup immediately, or you can fail the backup completely, and run a full VM backup at another time. A third parameter can be set to just verify the CTL and bitmap files for a virtual machine, without creating a new backup snapshot.

Verification can be performed only if the previous backup operation for the VM used `mode=IFIncr`, and if the current backup operation also uses `mode=IFIncr`. This option has no effect on the other virtual machine backup modes.

Important:
If this option is set to `no`, VM backup processing continues without any verification tests. The processing resources that are involved in performing the integrity checks is negligible. To ensure the continued integrity of your incremental-forever-incremental backup chain, set or use the default value (vmverifyiflatest yes). Do not set this option to `no`, unless you are directed to do so, by IBM® support.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments: Data Protection for VMware.

Supported clients

Linux This option is valid for Linux clients that act as a data mover for VMware guest backups.

Windows This option is valid for Windows clients that act as a data mover for VMware guest backups.

Options file

Windows Set this option in the client options file (dsm.opt).

Linux Set this option in the client options file (dsm.opt) or the client system options file (dsm.sys).

This option can also be included in a client options set, as a parameter on a backup vm command, or on the options parameter in a schedule definition.

Syntax

```
                    .-YES-.
>>-VMVERIFYIFlatest--+-----+-----------------------------------><
                    '-NO--'
```

Parameters

YES
: This setting specifies that validation of the CTL and the bitmap data is performed for each VM that is processed by the current incremental-forever-incremental (mode=IFIncr) backup operation, if the previous backup operation for that VM was also an incremental-forever-incremental backup. This value is the default value.

NO
: This setting specifies that validation of CTL and bitmap data does not occur during incremental-forever-incremental backup processing. Do not set this value unless directed to do so by IBM support.

Examples

Options file:

```
vmverifyiflatest yes
```

Command line:

```
dsmc backup vm vm1 -mode=ifincremental -vmverifyiflatest=yes
```

Linux | Windows

Vmvstortransport

The vmvstortransport option specifies the preferred transports order (hierarchy) to use when backing up or restoring VMware virtual machines. If you do not include a given transport using this option, that transport is excluded and is not used to transfer data.

The transport order that you specify determines how the VMware API for Data Protection (VADP) accesses virtual disk data, but it does not influence the data path that is used between the backup-archive client and the IBM Spectrum Protect™ server. Valid transports include any order or combination of the following options:

nbd
: Network based data transfer. Access virtual disk data using the LAN. This transport path is generally available in all configurations.

nbdssl
: Same as nbd, but the data is encrypted before being sent over the LAN. Encryption can decrease performance.

san
: Storage Area Network transfer: Access virtual disk data using the SAN.

hotadd
: If you use the backup-archive client in a virtual machine, the hotadd transport allows the transport of backed up data to dynamically added storage.

Separate each transport option from the others with a colon, for example, san:nbd:nbdssl:hotadd.

If you do not specify a transport hierarchy, the default transport selection order is san:hotadd:nbdssl:nbd.

The first transport that is available is used to transfer the data. If you want to prevent data transport over a particular path, do not include it in the transport list. For example, if it is important to not disrupt LAN traffic, omit the nbd transports from the hierarchy.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

Linux Set this option in dsm.sys.

Windows Set this option in the client options file (dsm.opt).

Supported clients

Windows This option is valid for Windows clients that are configured to back up or restore virtual machine files using VADP.

Linux This option is valid for Linux clients that are configured to back up or restore virtual machine files using VADP.

Syntax

```
                    .-,----------.
```

```
                        V             |
>>-VMVSTORTransport-----+- ------+-+---------------------------><
                          +-NBD----+
                          +-NBDSSL-+
                          +-SAN----+
                          '-HOTADD-'
```

Examples

If the SAN is available, do not transport backups or restores over the LAN

```
VMVSTORTRANSPORT san
```

The backup-archive client is running in a virtual machine, but do not use the hotadd transport

```
VMVSTORTRANSPORT nbdssl:nbd
```

Use the LAN transport, even if nbdssl is available, to obtain better performance

```
VMVSTORTRANSPORT nbd
```

The SAN transport is preferred, but use nbd when the SAN is not available, and do not use nbdssl or hotadd

```
VMVSTORTRANSPORT san:nbd
```

Windows

Vssaltstagingdir

The vssaltstagingdir option specifies the fully qualified path that contains the system exclude cache and temporary data for VSS snapshot operation.

The backup-archive client determines the path for temporary VSS files from the following prioritized choices:

1. The vssaltstagingdir option is defined in the dsm.opt file.
2. The c:\adsm.sys directory exists and is not empty.
3. If the vssaltstagingdir is not defined and the c:\adsm.sys directory does not exist, the client gets the path from a registry key. The path for temporary VSS files is the DefaultVssStagingDir value, and is generated from the Path value under the HKLM\SOFTWARE\IBM\ADSM\CurrentVersion\BackupClient key. After the DefaultVssStagingDir value is created, the value is not changed if the client is reinstalled to a new location.

Supported Clients

This option is valid for all Windows clients.

Options File

Place this option in the client options file (dsm.opt).

Syntax

```
>>-VSSALTSTAGINGDIR--filepath----------------------------------><
```

Parameters

filepath

Specify the fully qualified path for temporary files that are related to VSS snapshot operations. If any part of the path does not exist, the backup-archive client attempts to create it. The default value is the client installation directory.

In Uniform Naming Convention (UNC) format, the path must contain a drive letter. In the following UNC format example, the path contains the drive letter D$: \\computer7\D$\temp\snapshot.

Examples

Options file:

```
vssaltstagingdir "c:\Users\All Users\Tivoli\adsm.sys"
```

Command line:

```
-vssaltstagingdir ="c:\Users\All Users\Tivoli\adsm.sys"
```

The option is valid only on the initial command line. It is not valid in interactive mode.

Windows

Vssusesystemprovider

The vssusesystemprovider option specifies whether to use the Windows system provider, or to let Windows decide the most suitable provider to use.

Use the vssusesystemprovider option for Microsoft Windows Volume Shadow Copy Service (VSS) operations, such as system state backup or IBM Spectrum Protect™ for Copy Services backups.

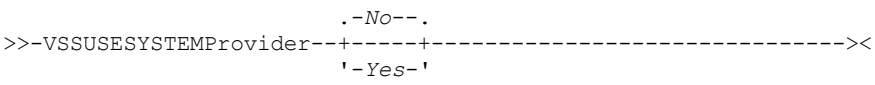
Supported Clients

This option is valid for all Windows clients. The server can also define this option. The IBM Spectrum Protect API does not support this option.

Options File

Place this option in the client options file (dsm.opt).

Syntax



Parameters

Yes
: Specifies that the Microsoft Windows VSS system provider is used.

No
: Specifies that the default system provider is used. This provider might or might not be the same as the system provider, depending on what other providers are installed on the system. Use no if you want to use the default system provider and the default system provider is not the Microsoft Windows VSS provider. No is the default.

Examples

Options file:

```
vssusesystemprovider yes
```

Command line:

Does not apply.

Linux | Windows

Vmtimeout

VMTIMEOut specifies the maximum time, in seconds, to wait before abandoning a backup vm operation, when the INCLUDE.VMTSMVSS option is used to provide application protection. To use this option, the IBM Spectrum Protect™ for Virtual Environments license must be installed.

Each backup vm operation that is performed on a virtual machine that is protected by a INCLUDE.VMTSMVSS option is subject to a timer. The timer value determines how many seconds the client should wait for the application to quiesce activity and truncate its logs so the backup can be performed. The default time out value is sufficient for most environments. However, if your application

data cannot be backed up because the application needs additional time to prepare for the snapshot, you can increase the time out value. This timer applies only to backup vm operations when the INCLUDE.VMTSMVSS option is set for a virtual machine.

Supported clients

Linux This option can be used with supported x86_64 Linux clients.

Windows This option can be used with supported Windows clients.

Options file

Place this option in the client options file. It cannot be set on the command line or in the Preferences editor.

Syntax

```
                .-180----------.
>>-VMTIMEout--+-+----------+-+---------------------------------><
                '-time_out-'
```

Parameters

time_out
Specifies the time to allow, in seconds, for backup operations to complete when a virtual machine is protected by the application protection option, INCLUDE.VMTSMVSS. The value specified must be an integer between 180 and 500. The default is 180 seconds.

Examples

Options file
VMTIMEout 500
Command line
Not applicable; this option cannot be set on the command line.

Related reference:
INCLUDE.VMTSMVSS

Webports

The webports option enables the use of the web client outside a firewall.

The webports option enables the use of the web client outside a firewall by specifying the TCP/IP port number used by the IBM Spectrum Protect™ client acceptor service and web client agent service for communications with the web client.

AIX Linux Solaris Mac OS X Values for both the client acceptor and the web client agent service are required.

Windows Values for both the client acceptor service and the web client agent service are required.

AIX Linux Solaris Mac OS X If you do not specify this option, the default value, zero (0), is used for both ports. This causes TCP/IP to randomly assign a free port number for the client acceptor and the web client agent service.

Windows If you do not specify this option, the default value, zero (0), is used for both ports. This causes TCP/IP to randomly assign a free port number for the client acceptor service and the web client agent service.

Supported Clients

This option is valid for all clients. The IBM Spectrum Protect API does not support this option.

Options File

AIX Linux Solaris Mac OS X Place this option in the dsm.sys file within a server stanza. To set this option in the Client Preferences editor, click Edit > Client Preferences > Web Client , and specify the ports in the Web Agent Port and Web Client

Acceptor Port fields.

Windows Place this option in the client options file (dsm.opt). To set this option in the Client Preferences editor, click Edit > Client Preferences > Web Client , and specify the ports in the Web Agent Port and Web Client Acceptor Port fields.

Syntax

```
>>-WEBPorts-- --cadport-- --agentport-------------------------><
```

Parameters

AIX Linux Mac OS X Solaris cadport

AIX Linux Mac OS X Solaris Specifies the required client acceptor port number. The range of values is 1000 through 32767. If a value is not specified, the default, zero (0), causes TCP/IP to randomly assign a free port number.

Windows cadport

Windows Specifies the required client acceptor service port number. The range of values is 1000 through 32767. If a value is not specified, the default, zero (0), causes TCP/IP to randomly assign a free port number.

agentport

Specifies the required web client agent service port number. The range of values is 1000 through 32767. If a value is not specified, the default, zero (0), causes TCP/IP to randomly assign a free port number.

Examples

Options file:

```
webports 2123 2124
```

Command line:

Windows

```
webports 2123, 2124
```

AIX Linux Solaris Mac OS X Does not apply.

Wildcardsareliteral

The wildcardsareliteral option specifies whether question marks (?) and asterisks (*) are interpreted literally, when they are included in a file list specification on a filelist option.

Ordinarily, the client does not accept wildcard characters (? and *) in a file list specification that is included on a filelist option. Some file systems allow single and double quotation marks in file and directory names. To prevent errors that would otherwise occur, when file specifications are included on a filelist option and they contain wildcard characters, set `wildcardsareliteral yes`. When wildcardsareliteral is set to yes, question marks (?) and asterisks (*) that are included in a file list specification on the filelist option are interpreted literally, and not as wildcard characters.

This option applies to any command that accepts a filelist option as command parameter.

Supported Clients

This option is valid for all supported platforms. The option is applied to any command that takes a file list specification as a parameter.

Options File

Place this option in the client user options file (dsm.opt).

Syntax

```
                        .-no------.
>>-WILDCARDSareliteral--+-+-----+-+--------------------------><
                          '-yes-'
```

Parameters

no
: Specifies that question marks and asterisks are interpreted as wildcards when used in a file list specification that is included on a filelist option. No is the default. If a file list specification on a filelist option includes a question mark or asterisk, an error occurs and the file specification cannot be processed.

yes
: Specifies that asterisks and question marks in a file list specification that is included on a filelist option are interpreted literally, and not as wildcard characters. Specify this value if you are backing up files from a file system that allows wildcard characters in file or directory names.

Examples

Options file:

```
WILDCARDSARELITERAL YES
```

Windows Command line:

Windows Assuming that the file system allows wildcard characters in paths, the following are examples of files in a file list specification that can be successfully processed if WILDCARDSARELITERAL is set to YES.

Windows Assume that the command issued is `dsmc sel -filelist=c:\important_files.txt`, where important_files.txt contains the list of files to process.

Windows important_files.txt contains the following list of files:

```
c:\home\myfiles\file?9000
c:\home\myfiles\?file
c:\home\myfiles\**README**version2
c:\home\myfiles\ABC?file*
```

Windows If both WILDCARDSARELITERAL and QUOTESARELITERAL are both set to YES, the following backups can be successfully processed:

```
c:\home\myfiles\"file?
c:\home\myfiles\?file'
c:\home\myfiles\**"README Tomorrow"**
c:\home\myfiles\file*
```

AIX Linux Mac OS X Solaris Command line:

AIX Linux Mac OS X Solaris Assuming that the file system allows wildcard characters in paths, the following are examples of files in a file list specification that can be successfully processed if WILDCARDSARELITERAL is set to YES.

AIX Linux Mac OS X Solaris Assume that the command issued is `dsmc sel -filelist=/home/user1/important_files`, where important_files.txt contains the list of files to process.

AIX Linux Mac OS X Solaris important_files.txt contains the following list of files:

```
/home/user1/myfiles/file?9000
/home/user1/myfiles/?file
/home/user1/myfiles/**README**version2
/home/user1/myfiles/ABC?file*
```

AIX Linux Mac OS X Solaris If both WILDCARDSARELITERAL and QUOTESARELITERAL are both set to YES, the following backups can be successfully processed:

```
/home/user1/myfiles/"file?
/home/user1/myfiles/?file'
/home/user1/myfiles/**"README Tomorrow"**
/home/user1/myfiles/file*
```

Using commands

The backup-archive client provides a command-line interface (CLI) that you can use as an alternative to the graphical user interface (GUI). This topic describes how to start or end a client command session and how to enter commands.

- Start and end a client command session
- Enter client command names, options, and parameters
- Wildcard characters

The following table provides an alphabetical list of the commands and a brief description.

Table 1. Commands

Command	Description
archive	Archives files from a workstation to IBM Spectrum Protect™ storage.
Windows archive fastback	Windows Archives volumes specified by the fbpolicyname, fbclientname and fbvolumename options for long term retention.
Linux Windows backup fastback	Linux Windows Backs up volumes specified by the fbpolicyname, fbclientname and fbvolumename options for long term retention.
backup group	Creates and backs up a group containing a list of files from one or more file space origins to a virtual file space on the IBM Spectrum Protect server.
AIX Linux Solaris Windows backup image	AIX Linux Solaris Windows Creates an image backup of one or more file systems or logical volumes that you specify.
AIX Linux Solaris Windows backup nas	AIX Linux Solaris Windows Creates an image backup of one or more file systems belonging to a Network Attached Storage (NAS) file server.
Windows backup systemstate	Windows Backs up all startable system state and system services components as one object to provide a consistent point-in-time snapshot of the system state. This command is valid for any supported Windows client.
Linux Windows backup vm	Linux Windows Backs up virtual machines specified in the vmlist option.
AIX Solaris Windows cancel process	AIX Solaris Windows Displays a list of current NAS (if NDMP support is enabled) image backup and restore processes for which the administrative user has authority.
cancel restore	Displays a list of restartable restore sessions from which you can select one to cancel.
delete access	Deletes authorization rules for files that are stored on the server. AIX Linux Solaris Windows On those clients that support image backup, this command deletes authorization rules for images that are stored on the server.
delete archive	Deletes archived files from IBM Spectrum Protect server storage.
delete backup	Deletes active and inactive backup files from IBM Spectrum Protect server storage.
delete filespace	Deletes file spaces in IBM Spectrum Protect server storage.
delete group	Deletes a group backup on the IBM Spectrum Protect server.
expire	Inactivates backup objects that you specify in the file specification or with the filelist option.
help	Displays a Table of Contents of help topics for the command-line client.
incremental	Mac OS X AIX Linux Solaris Mac OS X Windows Backs up all new or changed files or directories in the default client domain or from file systems, directories, or files you specify, unless you exclude them from backup services.
loop	Starts an interactive command session.
macro	Executes commands within a macro file that you specify.
AIX Linux Solaris Windows monitor process	AIX Linux Solaris Windows Displays a list of current NAS image backup and restore processes from which you can select one to cancel.
preview archive	Simulates an archive command without sending data to the server.
preview backup	Simulates a backup command without sending data to the server.
query access	Displays a list of current authorization rules.
Windows query adobjects	Windows Displays a list of current authorization rules.
query archive	Displays a list of archived files.
query backup	Displays a list of backup versions.

Command	Description
query backupset	Queries a backup set from a local file or the IBM Spectrum Protect server. On those clients that support tape devices, this command can query a backup set from a tape device.
query filespace	Displays a list of file spaces in IBM Spectrum Protect storage. You can also specify a single file space name to query.
query group	Displays information about group backups and their members.
AIX Linux Solaris Windows query image	AIX Linux Solaris Windows Displays information about image backups.
query inclexcl	Displays a list of include-exclude statements in the order in which they are processed during backup and archive operations.
query mgmtclass	Displays information about available management classes.
query node	Displays all the nodes for which an administrative user ID has authority to perform operations.
query options	Displays all or part of your options and their current settings.
query restore	Displays a list of your restartable restore sessions in the server database.
query schedule	Displays information about scheduled events for your node.
query session	Displays information about your session, including the current node name, when the session was established, server information, and server connection information.
query systeminfo	Gathers IBM Spectrum Protect system information and outputs this information to a file or the console.
Windows query systemstate	Windows Displays information about the backup of the system state on the IBM Spectrum Protect server. This command is valid for all supported Windows clients.
Windows Linux query vm	Windows Linux Verifies the successful backups of the virtual machines from the vStorage backup server.
restart restore	Displays a list of restartable restore sessions from which you can one to restart.
restore	Restores copies of backup versions of your files from the IBM Spectrum Protect server.
Windows restore adobjects	Windows Restores individual Active Directory objects from the local Active Directory Deleted Objects container.
restore backupset	Restores a backup set from the IBM Spectrum Protect server or a local file. On those clients that support tape devices, this command can restore a backup set from a tape device.
restore group	Restores specific members or all members of a group backup.
AIX Linux Solaris Windows restore image	AIX Linux Solaris Windows Restores a file system or raw volume image backup.
AIX Linux Solaris Windows restore nas	AIX Linux Solaris Windows Restores the image of a file system belonging to a Network Attached Storage (NAS) file server.
Windows restore systemstate	Windows Restores a backup of the system state. This command is deprecated for online system restore operations. For more information, see Restore Systemstate.
Linux Windows restore vm	Linux Windows Restores a full VM backup, and returns the full VM backup files to the vmbackdir directory on the vStorage backup server.
retrieve	Retrieves copies of archived files from the IBM Spectrum Protect server.
schedule	Starts the client scheduler on the workstation.
selective	Backs up selected files.

Command	Description
set access	Authorizes another user to access your backup versions or archived copies. AIX Linux Solaris Windows On those clients that support image backup, this command can set authorization rules for images that are stored on the server.
set event	Allows you to specify the circumstances for when archived data is deleted.
Linux Windows set netappsvm	Linux Windows Associates the login credentials for a cluster management server with a NetApp storage virtual machine and the data SVM name (data Vserver). This command must be entered before you can create a snapshot difference incremental backup of a clustered NetApp volume.
set password	Changes the IBM Spectrum Protect password for your workstation.

For proper operation, the was node must be restored to the same location and under the same name.

Important: To avoid problems, restore your data at the Network Deployment Manager node or Application Server node level only.

- Start and end a client command session
  You can start or end a client command session in either batch mode or interactive mode.
- Enter client command names, options, and parameters
  A client command can include one or more of these components: *Command name*, *options*, and *parameters*. The topics that follow describe each of these components.
- Wildcard characters
  Use wildcard characters when you want to specify multiple files with similar names in *one* command. Without wildcard characters, you must repeat the command for each file.
- Client commands reference
  The following sections contain detailed information about each of the backup-archive client commands.
- Archive
  The archive command archives a single file, selected files, or all files in a directory and its subdirectories on a server.
- Linux Windows Archive FastBack
  Use the archive fastback command to archive Tivoli® Storage Manager FastBack volumes specified by the fbpolicyname, fbclientname and fbvolumename options for long-term retention.
- Linux Windows Backup FastBack
  Use the backup fastback command to back up Tivoli Storage Manager FastBack volumes specified by the fbpolicyname, fbclientname and fbvolumename options for long-term retention.
- Backup Group
  Use the backup group command to create and back up a group containing a list of files from one or more file space origins to a virtual file space on the IBM Spectrum Protect server.
- AIX Linux Solaris Windows Backup Image
  The backup image command creates an image backup of one or more volumes on your system.
- AIX Solaris Windows Backup NAS
  The backup nas command creates an image backup of one or more file systems that belong to a Network Attached Storage (NAS) file server, otherwise known as NDMP Backup. You are prompted for the IBM Spectrum Protect administrator ID.
- Windows Backup Systemstate
  Use the backup systemstate command to back up all bootable system state and system services components as a single object, to provide a consistent point-in-time snapshot of the system state.
- Linux Windows Backup VM
  Use the backup vm command to start a full backup of a virtual machine.
- AIX Solaris Windows Cancel Process
  The cancel process command displays a list of current NAS (if NDMP support is enabled) image backup and restore processes for which the administrative user has authority. You are prompted for the IBM Spectrum Protect administrator ID.
- Cancel Restore
  The cancel restore command displays a list of your restartable restore sessions in the server database.
- Delete Access
  The delete access command deletes authorization rules for files that are stored on the server.
- Delete Archive
  The delete archive command deletes archived files from IBM Spectrum Protect server storage. Your administrator must give you the authority to delete archived files.

- Delete Backup
  The delete backup command deletes files, images, and virtual machines that were backed up to IBM Spectrum Protect server storage. Your administrator must give you authority to delete objects.
- Delete Filespace
  The delete filespace command deletes file spaces in IBM Spectrum Protect server storage. A file space is a logical space on the server that contains files you backed up or archived.
- Delete Group
  Use the delete group command to delete a group backup on the IBM Spectrum Protect server.
- Expire
  The expire command deactivates the backup objects that you specify in the file specification or with the filelist option. You can specify an individual file to expire, or a file that contains a list of files to expire. If `OBJTYPE=VM`, this command deactivates the current backup for a virtual machine.
- Help
  Use the help command to display information about commands, options, and messages.
- Incremental
  The incremental command backs up all new or changed data in the locations that you specify, unless you exclude them from backup services.
- Loop
  The loop command starts an interactive command line session that is maintained until you enter `quit`.
- Macro
  The macro command runs a series of commands that you specify in a macro file.
- AIX Solaris Windows Monitor Process
  The monitor process command displays a list of current NAS (if NDMP support is enabled) image backup and restore processes for which the administrative user has authority. You are prompted for the IBM Spectrum Protect administrator ID.
- Preview Archive
  The preview archive command simulates an archive command without sending data to the server.
- Preview Backup
  The preview backup command simulates a backup command without sending data to the server.
- Query Access
  The query access command shows who was given access to backup versions or archive copies of specific files.
- Windows Query Adobjects
  Use the query adobjects command to display information about the deleted objects that are located on the local Active Directory domain.
- Query Archive
  The query archive command displays a list of your archived files and the following information about each file: file size, archive date, file specification, expiration date, and archive description.
- Query Backup
  The query backup command displays a list of backup versions of your files that are stored on the IBM Spectrum Protect server, or that are inside a backup set from the server when the backupsetname option is specified.
- Query Backupset
  The query backupset command queries a backup set from a local file, tape device (if applicable), or the IBM Spectrum Protect server.
- Query Filespace
  The query filespace command displays a list of file spaces for a node. The file spaces are stored on the IBM Spectrum Protect server, or inside a backup set from the server when the backupsetname option is specified. You can also specify a single file space name to query.
- Query Group
  Use the query group command to display information about a group backup and its members.
- Query Image
  The query image command displays information about file system images that are stored on the IBM Spectrum Protect server, or that are inside a backup set from the IBM Spectrum Protect server, when the backupsetname option is specified.
- Query Inclexcl
  The query inclexcl command displays a list of include-exclude statements in the order in which they are processed during backup and archive operations. The list displays the type of option, the scope of the option (archive, all, and so on), and the name of the source file.
- Query Mgmtclass
  The query mgmtclass command displays information about the management classes available in your active policy set.
- Query Node
  The query node command displays all the nodes for which an administrative user ID has authority to perform operations. You are prompted for the IBM Spectrum Protect administrator ID.

- Query Options
  Use the query options command to display all or part of your options and their current settings that are relevant to the command-line client.
- Query Restore
  The query restore command displays a list of your restartable restore sessions in the server database. The list contains these fields: owner, replace, subdir, preservepath, source, and destination.
- Query Schedule
  The query schedule command displays the events that are scheduled for your node. Your administrator can set up schedules to perform automatic backups and archives for you. To plan your work, use this command to determine when the next scheduled events occur.
- Query Session
  The query session command displays information about your session, including the current node name, when the session was established, server information, and server connection information.
- Query Systeminfo
  Use the query systeminfo command to gather information and output this information to a file or the console.
- Windows Query Systemstate
  Use the query systemstate command to display information about a backup of the system state on the IBM Spectrum Protect server, or system state inside a backup set from the IBM Spectrum Protect server, when the backupsetname option is specified.
- Linux Windows Query VM
  Use the query VM command to list and verify the successful backups of virtual machines (VMs).
- Restart Restore
  The restart restore command displays a list of your restartable restore sessions in the server database.
- Restore
  The restore command obtains copies of backup versions of your files from the IBM Spectrum Protect server, or inside a backup set.
- Windows Restore Adobjects
  Use the restore adobjects command to restore individual Active Directory objects from the local Deleted Objects container.
- Restore Backupset
  The restore backupset command restores a backup set from the IBM Spectrum Protect server, a local file, or a local tape device. You can restore the entire backup set, or, in some cases, specific files within the backup set.
- Restore Group
  Use the restore group command to restore specific members or all members of a group backup.
- AIX Linux Solaris Windows Restore Image
  The restore image command restores a file system or raw volume image that was backed up using the backup image command.
- AIX Solaris Windows Restore NAS
  The restore nas command restores the image of a file system that belongs to a Network Attached Storage (NAS) file server. When you are using an interactive command-line session with a non-administrative ID, you are prompted for an administrator ID.
- Windows Restore Systemstate
  The restore systemstate command is deprecated for online system state restore operations.
- Linux Windows Restore VM
  Use the restore vm command to restore a virtual machine that was previously backed up.
- Retrieve
  The retrieve command obtains copies of archived files from the IBM Spectrum Protect server. You can retrieve specific files or entire directories.
- Schedule
  The schedule command starts the client scheduler on your workstation. The client scheduler must be running before scheduled work can start.
- Selective
  The selective command backs up files that you specify. If you damage or mislay these files, you can replace them with backup versions from the server.
- Set Access
  The set access command gives users at other nodes access to your backup versions or archived copies.
- Set Event
  Using the set event command, you can specify the circumstances for when archived data is deleted.
- Set Netappsvm
  The set netappsvm command associates the logon credentials for a cluster management server, which are specified on the set password command, with a NetApp storage virtual machine, and the data storage virtual machine (SVM) name (data Vserver). You must enter this command before you can create a snapshot difference incremental backup of a clustered NetApp volume.

- Set Password
  The set password command changes the IBM Spectrum Protect password for your workstation, or sets the credentials that are used to access another server.
- Linux | Windows Set Vmtags
  The set vmtags command creates data protection tags and categories that can be added to VMware inventory objects. You can manage IBM Spectrum Protect backups of virtual machines in these VMware objects by specifying the tags with tools such as VMware vSphere PowerCLI Version 5.5 R2 or later.

Reading syntax diagrams

Start and end a client command session

You can start or end a client command session in either batch mode or interactive mode.

Use batch mode when you want to enter a *single* client command. The backup-archive client processes the command and returns to the command prompt.

Use interactive mode when you want to enter a *series* of commands. Since the client establishes connection to the server only once for interactive mode, a series of commands can be processed more quickly. The client processes the commands and returns to the `Protect>` prompt.

- Process commands in batch mode
  Some options are valid *only* on the initial command line and not in interactive mode. These options generally affect the operation of the entire session.
- Process commands in interactive mode
  Use the *interactive* mode (or *loop* mode) to enter a series of commands.

Process commands in batch mode

Some options are valid *only* on the initial command line and not in interactive mode. These options generally affect the operation of the entire session.

For example, the command **dsmc query session -errorlogname=myerror.log** is accepted and it does name the error log. However, it is accepted simply because it appears in the initial command, even though the option is not valid for the query command.

There are also some options that are always valid on the initial command line as well as on individual commands in interactive mode. Therefore, certain options are accepted on the initial command line even though they have no effect on the command being entered. For example, **dsmc query session -subdir=yes** is a valid command, but in this case the *-subdir* option has no effect on the command that was entered.

When you enter a *single* command in batch mode, precede it with the executable program name, **dsmc**. For example, to process the incremental command in batch mode, you would enter:

```
dsmc incremental
```

The backup-archive client prompts you each time you enter a command if the passwordaccess option is set to prompt and authentication on the server is set to *On*. Type your password and press Enter.

You can also enter your password using the password option with a command, but your password appears on the screen. For example, if your password is ***secret***, enter:

```
dsmc incremental -password=secret
```

If you set the *passwordaccess* option to generate in your `dsm.opt` file, you do not need to specify the password with the command. The client only prompts you for your password if you are registering your workstation with a server or manually changing your password.

Process commands in interactive mode

Use the *interactive* mode (or *loop* mode) to enter a series of commands.

Enter dsmc on the command line and press Enter. When the `Protect>` command prompt appears, type the command name and press Enter. Do not precede each command with the executable program name, dsmc. Alternatively, you can enter dsmc loop on the command line to start a client command session in interactive mode. Loop is the default command for dsmc.

If a password is required, the backup-archive client prompts you before you enter the first command.

Windows Type your password and press Enter.

AIX Linux Solaris Mac OS X Type your user ID and password and press Enter.

You can also enter your password using the password option with the loop command, but your password appears on the screen. For example, if your password is ***secret***, enter:

```
dsmc loop -password=secret
```

To end an interactive session, enter `quit` at the prompt.

AIX Linux Solaris Mac OS X Note for UNIX and Linux clients:
In loop mode, following a restore operation directly from tape, the mount point is not released in case additional restore requests are made to that volume. If you request a backup operation in the same session and that mount point is the only one available, the backup operation will stop with the following message:

```
Waiting for mount of offline media
```

In this case, the mount point is not released until one of the following conditions is met:

- The device class MOUNTRETENTION limit is satisfied.
- The client idletimeout period is satisfied.
- The dsmc loop session is closed after the restore operation completes, allowing you to start a subsequent loop mode session to perform the backup operation.

Enter client command names, options, and parameters

A client command can include one or more of these components: *Command name*, *options*, and *parameters*. The topics that follow describe each of these components.

- Command name
  The first part of a command is the command name. The command name consists of a single word, such as **help** or **schedule**, or an action word and an object for that action, such as **query archive**.
- Options
  When you enter options with a command, always precede the option with a dash (–). Do not put a space between the dash and the option name.
- Parameters
  Commands can have required parameters, optional parameters, or no parameters at all.
- File specification syntax
  There are some syntax rules that you need to know about when entering file specification parameters such as filespec, sourcefilespec, and destinationfilespec.

Command name

The first part of a command is the command name. The command name consists of a single word, such as **help** or **schedule**, or an action word and an object for that action, such as **query archive**.

Enter the full command name, or its minimum abbreviation.

For example, you can enter any of the following versions of the query schedule command:

```
query schedule
q sc
q sched
query sc
```

Options

When you enter options with a command, always precede the option with a dash (–). Do not put a space between the dash and the option name.

Enter more than one option in any order in a command before or after the file specification. Separate multiple options with a blank space.

There are two groups of options that you can use with commands: Client options (set in your options file), or client command options (used on the command line).

- **Client options**: The group of options that are set in your client options file. You can override an option in the client options file when you enter the option with a command on the command line.
- **Client command options**: Use a client command option *only* when you enter the option with a command on the command line. You cannot set these options in an options file.

- Options in interactive mode
  In interactive mode, options that you enter on the initial command line override the value that you specified in your options file.

Parameters

Commands can have required parameters, optional parameters, or no parameters at all.

Required parameters provide information to perform a task. The most commonly required parameter is a file specification.

For example, if you want to archive a file named budget.fin from the project directory, you would enter the following:

AIX | Linux | Solaris | Mac OS X | Mac OS X

```
dsmc archive /project/budget.fin
```

Windows

```
dsmc archive c:\project\budget.fin
```

Some commands have optional parameters. If you do not enter a value for an optional parameter, the backup-archvie client uses the default value. For example, the restore command includes a required parameter, sourcefilespec, that specifies the path and file name in storage that you want to restore. The optional parameter, destinationfilespec, specifies the path where you want to place the restored files. If you do not specify the destinationfilespec, by default, the client restores the files to the original source path. If you want to restore the files to a *different* directory, enter a value for destinationfilespec.

AIX | Linux | Solaris | Mac OS X | Mac OS X

Example: Restore the file /project/budget.fin to the new path /newproj/newbudg.fin

```
dsmc restore /project/budget.fin /newproj/
```

Windows

Example: Restore the file c:\project\budget.fin to the new path c:\newproj\newbudg.fin

```
dsmc restore c:\project\budget.fin c:\newproj\newbudg.fin
```

Enter parameters in the order indicated in the command syntax diagram.

File specification syntax

There are some syntax rules that you need to know about when entering file specification parameters such as filespec, sourcefilespec, and destinationfilespec.

The following are the syntax rules:

- Do not use wildcards as part of the file space name or anywhere in the destinationfilespec. The one exception to this rule is the set access command where wildcards are permitted in the two lowest levels of the file spec.

  AIX | Linux | Solaris | Mac OS X

  Example: Allow access to all files in all directories in and subordinate to the /home directory:

```
set access backup /home/* * *
set access backup /home/*/* * *
```

AIX Linux Solaris Mac OS X With UNIX clients, do not use wildcards in a directory path name, for example:

```
/home/j*asler/file1.c
```

Windows

Example: Allow access to all files in all directories in and subordinate to the d:\test directory:

```
set access backup d:\test\* * *
set access backup d:\test\*\* * *
```

- There is a maximum number of file specifications per command:
  - The Query commands can accept only one file specification.
  - The restore and retrieve commands can accept a source file specification and a destination file specification.
  - AIX Linux Solaris Mac OS X There is a limit of 20 operands on some commands. This limit is to prevent excessive sessions that are caused when wildcards are expanded by the UNIX shell command processor.
    You can prevent shell expansion from causing you to go over the 20-operand limit by placing quotation marks around your source filespec expansion characters for restore commands.
    Note: Using quotation marks has the side affect of causing a no-query restore.

    You can use the removeoperandlimit option to specify that the backup-archive client removes the 20-operand limit. If you specify the removeoperandlimit option with the incremental, selective, or archive commands, the 20-operand limit is not enforced and is restricted only by available resources or other operating system limits.

- The length of a file specification is limited.
  - AIX Solaris Mac OS X On AIX, Solaris, and Mac: The maximum number of characters for a file name is 255. The maximum combined length of the file name and path name is 1024 characters. The Unicode representation of a character can occupy several bytes, so the maximum number of characters that a file name might contain can vary.
  - Linux On Linux: The maximum length for a file name is 255 bytes. The maximum combined length of both the file name and path name is 4096 bytes. This length matches the PATH_MAX that is supported by the operating system. The Unicode representation of a character can occupy several bytes, so the maximum number of characters that comprises a path and file name can vary. The actual limitation is the number of bytes in the path and file components, which might correspond to an equal number of characters.

    Linux On Linux: For archive or retrieve operations, the maximum length that you can specify for a path and file name (combined) remains at 1024 bytes.

  - Windows The maximum number of bytes for a file name and file path when combined is 6255. However, the file name itself cannot exceed 255 bytes. Furthermore, directory names (including the directory delimiter) within a path are limited to 255 bytes. The Unicode representation of a character can occupy several bytes, so the maximum number of characters that a file name might contain can vary.

    When using the open file support feature with VSS, the backup-archive client adds the snapshot volume name to the path of the objects being processed. The resulting path (snapshot volume name plus object path) must adhere to the limits shown. The snapshot volume name can be up to 1024 bytes.

- AIX Linux Solaris Mac OS X When you enter the sourcefilespec, if the directory name ends with /, then /* is implied.

  Windows When you enter the sourcefilespec, if the directory name ends with \, then * is implied.

  AIX Linux Solaris Mac OS X When you enter a destinationfilespec, if the name ends with /, then it is considered a directory, otherwise it is considered a file.

  Windows When you enter a destinationfilespec, if the name ends with \, then it is considered a directory, otherwise it is considered a file.

  AIX Linux Solaris Mac OS X The following example illustrates these two rules. Even though mydir and yourdir are directories, the command will fail because /* is implied after mydir, and yourdir is considered a file.

  ```
  restore /home/mydir/ /away/yourdir
  ```

  Windows The following example illustrates these two rules. Even though mydir and yourdir are directories, the command will fail because * is implied after mydir, and yourdir is considered a file.

```
restore c:\home\mydir\ c:\away\yourdir
```

- AIX Linux Solaris Mac OS X Windows

  If a file specification does not begin with a directory delimiter, the file specification is assumed to be a subdirectory of the current working directory. The client appends the file specification to the working directory to build the complete path.

  AIX Linux Solaris Mac OS X For example, if the current working directory is /home/me and the command is `dsmc res "/fs/dir1/*" mydir/`, the complete restore path is this: /home/me/mydir

  Windows For example, if the current working directory is c:\home\me and the command is `dsmc res c:\fs\dir1\ mydir\`, the complete restore path is this: c:\home\me\mydir

- AIX Linux Solaris Mac OS X The only command that accepts a simple file space name is the incremental command. The following example is valid:
  AIX Linux Solaris Mac OS X

  ```
  dsmc i /Users
  ```

  The following example is not valid, because the command is the selective command:
  AIX Linux Solaris Mac OS X

  ```
  dsmc sel /Users
  ```

- Windows When a file specification contains spaces, it must be enclosed in quotation marks. For example:

  ```
  dsmc sel "x:\dir one\file1"
  ```

  When a file specification ends with a backslash and is enclosed in quotation marks, an extra backslash (\) must be added to the end of the file specification. If an extra backslash is not added, the filespec will not be processed correctly, and the operation might cause unexpected results.

  The following example is incorrect:

  ```
  dsmc sel "x:\dir one\"
  ```

  The following example is correct:

  ```
  dsmc sel "x:\dir one\\"
  ```

  Here is an example of restoring the contents of one directory to another, when both directory names contain spaces:

  ```
  dsmc rest "x:\dir one\\" "x:\dir two\\"
  ```

- Windows Microsoft Dfs volumes are accessed using the standard UNC names. The following are examples of valid syntax to access MS Dfs volumes:

  ```
  \\Server_Name\Dfs_Root_Name\path
  \\Fault_Tolerant_Name\Dfs_Root_Name\path
  ```

Wildcard characters

Use wildcard characters when you want to specify multiple files with similar names in *one* command. Without wildcard characters, you must repeat the command for each file.

In a command, you can use wildcard characters in the file name or file extension *only*. You cannot use them to specify destination files, file systems, or server names. You cannot specify a directory whose name contains an asterisk (*) or a question mark (?).

Valid wildcard characters that you can use include:

*
: Asterisk. Matches zero or more characters.

?
: Question mark. Matches any single character at the present position.

The following table shows examples of each wildcard.

Table 1. Wildcard characters

Pattern	Matches	Does not match

Pattern	Matches	Does not match
Asterisk (*)		
ab*	ab, abb, abxxx	a, b, aa, bb
ab*rs	abrs, abtrs, abrsrs	ars, aabrs, abrss
ab*ef*rs	abefrs, abefghrs	abefr, abers
abcd.*	abcd.c, abcd.txt	abcd, abcdc, abcdtxt
Question Mark (?)		
ab?	abc	ab, abab, abzzz
ab?rs	abfrs	abrs, abllrs
ab?ef?rs	abdefjrs	abefrs, abdefrs, abefjrs
ab??rs	abcdrs, abzzrs	abrs, abjrs, abkkkrs

Important: Use an asterisk (*) instead of a question mark (?) as a wildcard character when trying to match a pattern on a multibyte code page, to avoid unexpected results.

AIX Linux Solaris Mac OS X Note: In batch mode, enclose values containing wildcards in quotation marks. Otherwise, UNIX shells expand unquoted wildcards, and it is easy to exceed the 20 operand limit. It is more efficient to let the client process wildcard file specifications because many fewer server interactions are needed to complete the task. For example:

```
dsmc selective "/home/me/*.c"
```

Client commands reference

The following sections contain detailed information about each of the backup-archive client commands.

Information for each command includes the following information:

- A description of the command.
- A syntax diagram of the command.
- Detailed descriptions of the command parameters. If the parameter is a constant (a value that does not change), the minimum abbreviation appears in uppercase letters.
- Examples of using the command.

Archive

The archive command archives a single file, selected files, or all files in a directory and its subdirectories on a server.

Archive files that you want to preserve in their current condition. To release storage space on your workstation, delete files as you archive them using the deletefiles option. Retrieve the archived files to your workstation whenever you need them again.

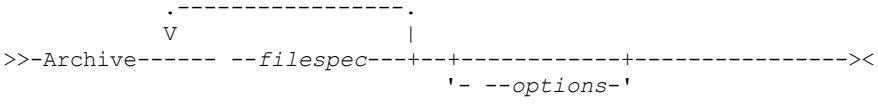
Use the snapshotroot option with the archive command along with an independent software vendor application that provides a snapshot of a logical volume to associate the data on the local snapshot with the real file space data that is stored on the IBM Spectrum Protect™ server. The snapshotroot option does not provide any facilities to take a volume snapshot, only to manage data that is created by a volume snapshot.

AIX AIX® only: You can enable snapshot-based file archive by using the option snapshotproviderfs=*JFS2*.

Supported Clients

This command is valid for all clients.

Syntax



Parameters

filespec

Specifies the path and name of the file you want to archive. Use wildcard characters to include a group of files or to include all files in a directory.
To include multiple file specifications, separate each*filespec* parameter with a space character. If multiple file specifications are included, and two or more of the specifications have common parent directories, then it is possible for the common directory objects to be archived more than once. The conditions under which this behavior occurs are runtime-dependent, but the behavior itself has no adverse effects.

AIX Linux Mac OS X Solaris For example, if the filespec is /home/amr/ice.doc /home/amr/fire.doc, then /home and /home/amr might be archived twice. The file objects ice.doc, and fire.doc, are archived only once.

Windows For example, if the filespec is C:\proposals\drafts\ice.doc C:\proposals\drafts\fire.doc, then C:\proposals and C:\proposals\drafts might be archived twice. The file objects ice.doc and fire.doc are archived only once.

If you want to avoid including the shared parent directory more than once, use separate, non-overlapping archive commands to archive each file specification.
AIX Linux Mac OS X Solaris If you archive a file system, include a trailing slash (/home/).
AIX Linux Mac OS X Solaris There is a limit of 20 operands. This limit prevents excessive sessions that are caused when wildcards are expanded by the UNIX shell command processor. You can prevent shell expansion from causing you to go over the 20-operand limit by placing quotation marks around file specifications that contain wildcards ("home/docs/*").
AIX Linux Mac OS X Solaris You can use the removeoperandlimit option to specify that the 20-operand limit is removed. If you specify the removeoperandlimit option, the 20-operand limit is not enforced and is restricted only by available resources or other operating system limits. For example, remove the 20 operand limit to archive 21 file specifications:

```
selective -removeoperandlimit filespec1 filespec2 ... filespec21
```

Windows If you archive a file system, include a trailing slash (C:\).
Windows You can specify as many file specifications as available resources or other operating system limits allow.
You can use the filelist option, instead of file specifications, to identify which files to include in this operation. However, these two methods are mutually exclusive. You cannot include file specification parameters and use the filelist option. If the filelist option is specified, any file specifications that are included are ignored.

Table 1. Archive command: Related options

Option	Where to use
archmc	Command line only.
AIX Linux Solaris Mac OS X archsymlinkasfile	AIX Linux Solaris Mac OS X Client user-options file (dsm.opt) or command line.
Mac OS X Windows autofsrename	Mac OS X Windows Client options file (dsm.opt) only.
Windows changingretries	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X changingretries	AIX Linux Solaris Mac OS X Client system options file or command line.
Windows compressalways	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X compressalways	AIX Linux Solaris Mac OS X Client user-options file (dsm.opt) or command line.
Windows compression	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X compression	AIX Linux Solaris Mac OS X dsm.sys file within a server stanza or command line.
deletefiles	Command line only.
description	Command line only.

Windows skipntsecuritycrc	Windows Client options file (dsm.opt) or command line.
AIX Linux snapshotcachesize	AIX Linux Client options file (dsm.opt) or include.fs option.
snapshotroot	Command line only.
subdir	Client options file (dsm.opt) or command line.
tapeprompt	Client options file (dsm.opt) or command line.
v2archive	Command line only.

Examples

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Archive a single file that is named `budget` in the `/home/proj1` directory.

Command: archive `/home/proj1/budget`

Windows Task

Windows Archive a single file that is named `budget.jan` in the `c:\plan\proj1` directory.

Command: `archive c:\plan\proj1\budget.jan`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Archive all files in the `/home/proj1` directory with a file extension of `.txt`.

Command: `archive "/home/proj1/*.txt"`

Windows Task

Windows Archive all files in the `c:\plan\proj1` directory with a file extension of `.txt`.

Command: `archive c:\plan\proj1\*.txt`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Archive all files in the directory tree that is headed by the `/home` directory.

Command: `archive -subdir=yes "/home/*"`

Windows Task

Windows Archive all files in the `c:\` drive.

Command: `archive -subdir=yes c:\*.*`

Windows Task

Windows Archive all files in the Microsoft Dfs volume, MyDfsVolume. You must specify ***subdir***=*yes* to archive *all* files in the volume.

Command: `archive \\myserver\mydfsroot\mydfsvolume\*.* -subdir=yes`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Assuming that you initiated a snapshot of the `/usr` file system and mounted the snapshot as `/snapshot/day1`, archive the `/usr/dir1/sub1` directory tree from the local snapshot and manage it on the IBM Spectrum Protect server under the file space name `/usr`.

Command: `dsmc archive /usr/dir1/sub1/ -subdir=yes -snapshotroot=/snapshot/day1`

Windows Task

Windows Assuming that you initiated a snapshot of the `C:\` drive and mounted the snapshot as `\\florence\c$\snapshots\snapshot.0`, archive the `c:\dir1\sub1` directory tree from the local snapshot and manage it on the IBM Spectrum Protect server under the file space name `C:`.

Command: `dsmc archive c:\dir1\sub1\* -subdir=yes -snapshotroot=\\florence\c$\snapshots\snapshot.0`

- Windows Open file support
  If open file support has been configured, the backup-archive client performs a snapshot backup or archive of files that are locked (or "in use") by other applications.

Linux Windows

Archive FastBack

Use the archive fastback command to archive Tivoli® Storage Manager FastBack volumes specified by the fbpolicyname, fbclientname and fbvolumename options for long-term retention.

Before using this command, configure the client to back up and archive Tivoli Storage Manager FastBack data. Also, before you issue this command, at least one snapshot should exist in the FastBack repository for the FastBack policy being archived or backed up.

Windows If a policy specification contains both Windows and Linux FastBack clients, only the Windows volumes will be backed up or archived to the IBM Spectrum Protect™ server by the Windows backup-archvie client.

Linux If a policy specification contains both Windows and Linux FastBack clients, only the Linux volumes will be backed up or archived to the IBM Spectrum Protect server by the Linux backup-archive client.

You can use Tivoli Storage Manager FastBack options to archive the latest snapshots of the following volumes:

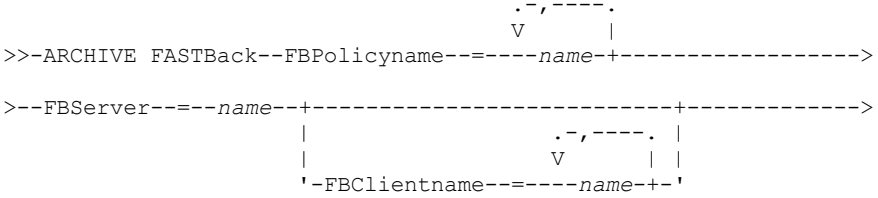
- All clients and volumes associated with a specific FastBack policy or a list of FastBack policies.
- All volumes associated with a specific FastBack client or a list of FastBack clients for a given FastBack policy.
- A specific volume or volumes associated with a specific FastBack client for a given FastBack policy.

Supported Clients

Linux This option is valid for Linux x86_64 clients.

Windows This option is valid for all Windows clients that are configured as FastBack dedicated proxies. This command is also valid for Windows clients that are installed on the FastBack server workstation, or the FastBack Disaster Recovery Hub.

Syntax



```
>--+--------------------------+--------------------------------->
   |                  .-,----. |
   |                  V      | |
   '-FBVolumename--=----name-+-'

>--+--------------------------+--+------------------+---------->
   '-FBReposlocation--=--name-'  '-FBBranch--=--name-'

>--+-----------------+-------------------------------------------><
   '-ARCHMc--=--name-'
```

Important:

1. At least one FBpolicyName is always required.
2. You can specify up to 10 values for FBPolicyName, if no values are specified for both FBClientName and FBVolumeName.
3. When you specify a FBClientName value, there must be only one value for FBPolicyName.
4. You can specify up to 10 values for FBClientName if only one PolicyName is specified, and no values for FBVolumeName are specified.
5. When you specify the FBVolumeName option, you can have only one FBPolicy, and only one FBCLientName specified.
6. You can specify multiple FBVolumeNames if condition 5 is satisfied.
7. You must always specify the FBReposLocation option for Linux.

Parameters

Table 1. Archive FastBack command: Related options

Option	Where to use
fbpolicyname	Command line and scheduler.
fbserver	Command line and scheduler.
fbclientname	Command line and scheduler.
fbvolumename	Command line and scheduler.
fbreposlocation	Command line and scheduler.
fbbranch	Command line and scheduler.
archmc	Command line and scheduler.

Examples

Linux Command line:

Linux The backup-archive client is installed on a Linux proxy client machine. Use this command to archive all FastBack volumes for all Linux FastBack clients that are defined for FastBack policy1:

```
dsmc archive fastback -fbpolicyname=Policy1
  -fbserver=myfbserver -fbreposlocation=myfbserver@WORKGROUP
```

The FastBack server name, -myFbDrHub is the short host name of the FastBack Disaster Recovery Hub server where the repository is located.

The -fbreposlocation parameter specifies the location of the repository. The repository location is required. If you do not provide the repository location, the command fails.

FBServer should point to the short host name of the FastBack DR hub in this case.

Linux Command line:

Linux The repository, rep_server1, is located on the FastBack DR hub, myFbDrHub.

```
dsmc archive fastback -fbpolicyname="Policy 1"
  -fbserver=myFbDrHub -fbreposlocation=\\myFbDrHub\rep_server1
```

The repository location is required. If you do not provide the repository location, the command fails.

The FastBack server name, -myFbDrHub, is the short host name of the FastBack Disaster Recovery Hub where the repository is located.

FBServer should point to the short host name of the FastBack DR hub in this case.

Linux Command line:

Linux Archive all volumes protected by FastBack policy named policy1 from the FastBack server named basil:

```
dsmc archive fastback -Fbpolicyname=policy1
  -FBServer=basil -ARCHMC="my_tsm_mgmt_class"
  -fbreposlocation=basil@WORKGROUP
```

Windows Command line:

Windows The backup-archive client is installed on the FastBack server. Use this command to archive all FastBack volumes for all Windows FastBack clients that are defined for FastBack policy1:

```
dsmc archive fastback -fbpolicyname=Policy1
  -fbserver=myfbserver
```

The repository location is not required. If you provide the repository location, it is ignored.

The FastBack server name, -myfbserver, is the short host name of the FastBack server where the client is running.

Windows Command line:

Windows The backup-archive client is installed on the FastBack Disaster Recovery Hub. Use this command to archive all FastBack volumes for all FastBack clients that are found in the policy named Policy 1:

```
dsmc archive fastback -fbpolicyname="Policy 1"
  -fbserver=myFbServer -fbbranch=branch1
```

The repository location is not required. If you provide the repository location, it is ignored.

The parameter myFbServer specifies the short host name of the FastBack Server whose FastBack branch is specified using the FBBranch option

Windows Command line:

Windows The backup-archive client is installed on a dedicated proxy machine with Tivoli Storage Manager FastBack administrative command line and FastBack mount. The client is connecting to the FastBack server repository. Use this command to archive all FastBack volumes for all FastBack clients that are found in the policy named Policy 1:

```
dsmc archive fastback -fbpolicyname="Policy 1" -fbserver=myFbServer
  -fbreposlocation=\\myFbServer.company.com\REP
```

The repository location is required.

The short host name of the machine where the FastBack server is installed is myFbServer.

Windows Command line:

Windows The backup-archive client is installed on a dedicated proxy machine with Tivoli Storage Manager FastBack administrative command line and FastBack mount. The client is connecting to a remote branch repository on the FastBack Disaster Recovery Hub. Use this command to archive all FastBack volumes for all FastBack clients that are found in the policy named Policy 1:

```
dsmc archive fastback -fbpolicyname="Policy 1" -fbserver=myFbServer
  -fbreposlocation=\\myfbdrhub.company.com\REP
  -fbbranch=aFbServerBranch
```

The repository location is required.

The myFbServer value specified with the -fbserver option is the short host name of the FastBack Server whose FastBack branch is specified using the FBBranch option.

The fbbranch option specifies the branch ID of the FastBack server on the disaster recovery hub.

Windows Command line:

Windows Archive all volumes protected by FastBack policy named policy1 from the FastBack server named basil, and apply management class "my_tsm_mgmt_class" to the archived volumes.

```
dsmc archive fastback -Fbpolicyname=policy1
  -FBServer=basil -ARCHMC=”my_tsm_mgmt_class”
```

Backup FastBack

Use the backup fastback command to back up Tivoli® Storage Manager FastBack volumes specified by the fbpolicyname, fbclientname and fbvolumename options for long-term retention.

Before using this command, configure the client to back up and archive Tivoli Storage Manager FastBack data. Also, before you issue this command, at least one snapshot should exist in the Tivoli Storage Manager FastBack repository for the Tivoli Storage Manager FastBack policy being archived or backed up.

Windows If a policy specification contains both Windows and Linux FastBack clients, only the Windows volumes will be backed up or archived to the IBM Spectrum Protect™ server by the Windows backup-archive client.

Linux If a policy specification contains both Windows and Linux FastBack clients, only the Linux volumes will be backed up or archived to the IBM Spectrum Protect server by the Linux backup-archive client.

Tivoli Storage Manager FastBack options are supported for the incremental backup of the latest snapshots, depending on the option specified:

- All clients and volumes associated with the FastBack policy or a list of FastBack policies.
- All volumes associated with a specific FastBack client or a list of FastBack clients for a given FastBack policy.
- A specific volume or volumes associated with a specific FastBack client for a given FastBack policy.

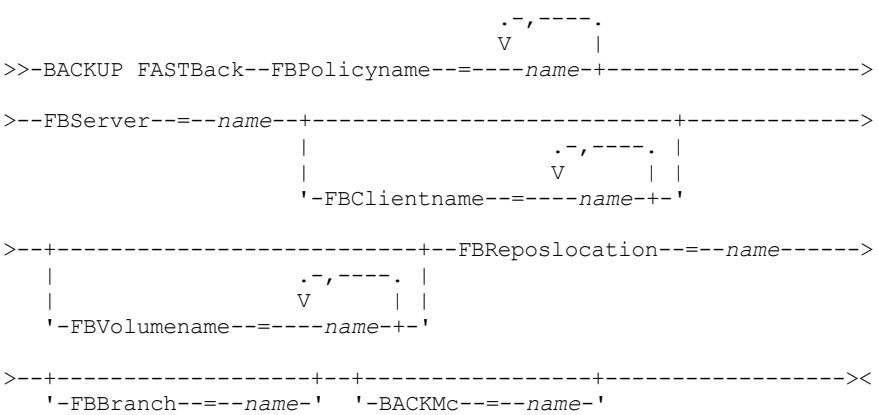
Supported Clients

Linux This command is valid for Linux x86_64 clients that are configured as Tivoli Storage Manager FastBack dedicated proxies.

Windows This command is valid for all Windows clients that are configured as Tivoli Storage Manager FastBack dedicated proxies. This command is also valid for Windows clients that are installed on the Tivoli Storage Manager FastBack server workstation, or the Tivoli Storage Manager FastBack Disaster Recovery Hub.

Linux

Syntax



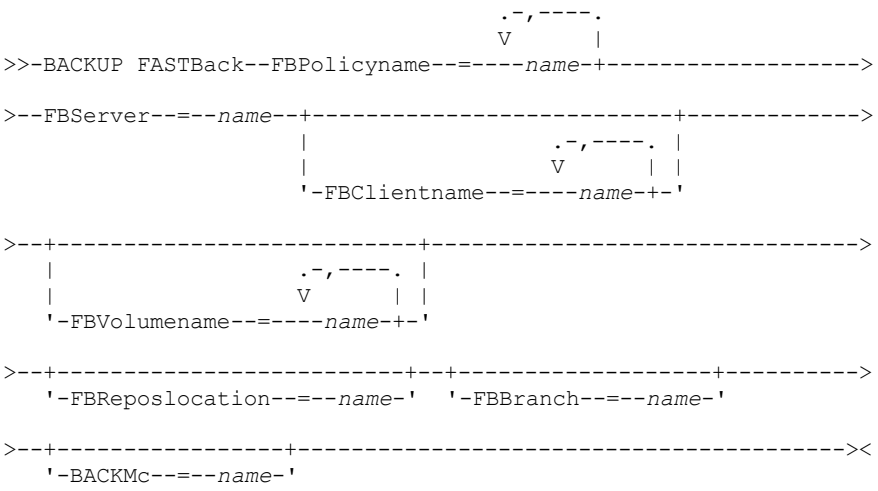
Important:

1. At least one FBpolicyName is always required.
2. You can specify up to 10 values for FBPolicyName, if no values are specified for both FBClientName and FBVolumeName.
3. When you specify a FBClientName value, there must be only one value for FBPolicyName.
4. You can specify up to 10 values for FBClientName if only one PolicyName is specified, and no values for FBVolumeName are specified.

5. When you specify the FBVolumeName option, you can have only one FBPolicy, and only one FBCLientName specified.
6. You can specify multiple FBVolumeNames if condition 5 is satisfied.
7. You must specify the FBReposLocation option.

Windows

Syntax



Important:

1. At least one FBpolicyName is always required.
2. You can specify up to 10 values for FBPolicyName, if no values are specified for both FBClientName and FBVolumeName.
3. When you specify a FBClientName value, there must be only one value for FBPolicyName.
4. You can specify up to 10 values for FBClientName if only one PolicyName is specified, and no values for FBVolumeName are specified.
5. When you specify the FBVolumeName option, you can have only one FBPolicy, and only one FBCLientName specified.
6. You can specify multiple FBVolumeNames if condition 5 is satisfied.

Examples

Linux Command line:

Linux The backup-archive client is installed on a Linux proxy client machine. Use this command to back up all FastBack volumes for all Linux FastBack clients that are defined for FastBack policy1:

```
dsmc backup fastback -fbpolicyname=Policy1
  -fbserver=myfbserver
  -fbreposlocation=myfbserver@WORKGROUP
```

The repository location is required. If you do not provide the repository location, the command will fail.

The FastBack server name, -myfbserver, is the short host name of the FastBack server where the repository is located.

Linux Command line:

Linux The repository, rep_server1, is located on the FastBack Disaster Recovery Hub, myFbDrHub

```
dsmc backup fastback -fbpolicyname="Policy 1"
  -fbserver=myFbDrHub -fbreposlocation=\\myFbDrHub\rep_server1
```

The FastBack server name, -myFbDrHub, is the short host name of the FastBack Disaster Recovery Hub server where the repository is located.

The -fbreposlocation option specifies the location of the repository. The repository location is required. If you do not provide the repository location, the command fails.

The FBServer option should point to the short host name of the FastBack DR hub in this case.

Linux Command line:

Linux Back up all volumes protected by FastBack policy named policy1 from the FastBack server named basil:

```
dsmc backup fastback -Fbpolicyname=policy1
  -FBServer=basil -BACKMC="my_tsm_mgmt_class"
  -fbreposlocation=basil@WORKGROUP
```

Windows Command line:

Windows The backup-archive client is installed on the FastBack server. Use this command to back up all Tivoli Storage Manager FastBack volumes for all Windows FastBack clients that are defined for Tivoli Storage Manager FastBack policy1:

```
dsmc backup fastback -fbpolicyname=Policy1
  -fbserver=myfbserver
```

The repository location is not required. If you provide the repository location, it is ignored.

The FastBack server name, -myfbserver, is the short host name of the FastBack server where the client is running.

Windows Command line:

Windows The backup-archive client is installed on the FastBack disaster recovery hub. Use this command to back up all FastBack volumes for all FastBack clients that are found in the policy named Policy 1:

```
dsmc backup fastback -fbpolicyname="Policy 1"
  -fbserver=myFbServer -fbbranch=branch1
```

The repository location is not required. If you provide the repository location, it is ignored.

The FastBack server name, myFbServer, is the short host name of the FastBack server whose FastBack branch is specified using the FBBranch option

Windows Command line:

Windows The backup-archive client is installed on a dedicated proxy machine with FastBack administrative command line and FastBack mount. The client is connecting to the FastBack server repository. Use this command to back up all FastBack volumes for all FastBack clients that are found in the policy named Policy 1:

```
dsmc backup fastback -fbpolicyname="Policy 1" -fbserver=myFbServer
  -fbreposlocation=\\myFbServer.company.com\REP
```

The repository location is required.

The short host name of the machine where the FastBack server is installed is myFbServer.

Windows Command line:

Windows The backup-archive client is installed on a dedicated proxy machine with FastBack administrative command line and FastBack mount. The client is connecting to a remote branch repository on the FastBack Disaster Recovery Hub. Use this command to back up all FastBack volumes for all FastBack clients that are found in the policy named Policy 1:

```
dsmc backup fastback -fbpolicyname="Policy 1" -fbserver=myFbServer
  -fbreposlocation=\\myfbdrhub.company.com\REP
  -fbbranch=aFbServerBranch
```

The repository location is required.

The myFbServer value specified with the -fbserver option is the short host name of the FastBack Server whose FastBack branch is specified using the FBBranch option.

The fbbranch option specifies the branch ID of the FastBack server on the disaster recovery hub.

Windows Command line:

Windows Back up all volumes protected by FastBack policy named policy1 from the FastBack server named basil, and apply the management class "my_tsm_mgmt_class" to the backed up volumes:

```
dsmc backup fastback -Fbpolicyname=policy1
  -FBServer=basil -BACKMC="my_tsm_mgmt_class"
```

Backup Group

Use the backup group command to create and back up a group containing a list of files from one or more file space origins to a virtual file space on the IBM Spectrum Protect™ server.

AIX AIX® only: You can enable snapshot-based group backup by using the option `snapshotproviderfs=JFS2`.

A group backup allows you to create a consistent point-in-time backup of a group of files that is managed as a single logical entity. Objects in the group are subject to the following processing rules:

- Management class rebinding for grouped objects:
  - During full backups, all objects in a backup group are assigned to the same management class.
  - During differential backups, if a new management class is specified on an include statement for an existing backup group, the following behavior occurs:
    - Any new and changed objects in the backup group are bound to the new management class.
    - Any member objects of the group that are not changed appear as though they have not been bound to the new management class. These unchanged objects are not included in the Total number of objects rebound statistics that are displayed when the Backup Group command completes.
    - The unchanged objects are reassigned to a newly created backup group, and the new backup group is bound to the new management class. However, the original management class name is still displayed for the unchanged group objects.

      Even though the original management class name is still displayed for the unchanged objects, they are effectively bound to the new management class of the backup group.
- Existing exclude statements for any files in the group are ignored.
- All objects in the group are exported together.
- All objects in the group are expired together as specified in the management class. No objects in a group are expired until all other objects in the group are expired, even when another group they belong to gets expired.
- If you are performing full and differential group backups to a sequential device, during a restore the data is in no more than two locations. To optimize restore time, perform periodic full backups to back up the data to one location on the sequential media.
- During a full group backup, all objects in the filelist are sent to the server. During a differential group backup, only data that has changed since the last full backup is sent to the server. Objects in the filelist that have not changed since the last full backups are assigned as members of the differential group backup. This data is not resent to the server, reducing backup time.

The backup group command requires the following options:

filelist
: Specifies a list of files to add to a new group.

groupname
: Specifies the fully qualified name of the group containing a list of files.

virtualfsname
: Specifies the name of the virtual file space for the group on which you want to perform the operation. The virtualfsname option cannot be the same as an existing file space name.

mode

Specifies whether you want to back up all of the files in the filelist or only files that have changed since the last full backup.

Note:

1. If any file in the group backup fails, the entire group backup fails.
2. Use the query group command to query members of a group backup on the IBM Spectrum Protect server.
3. Use the restore group command to restore specific members or all members of a group backup on the server.
4. Unless you are running Mac OS X, use the delete group command to delete a specific group backup from the server.
5. Use the query filespace command to display virtual file space names for your node that are stored on the server.
6. A group backup can be added to a backup set.

AIX Linux Solaris Windows

Supported Clients

AIX Linux Solaris This command is valid for all UNIX and Linux clients except Mac OS X.

Windows This command is valid for all Windows clients.

Syntax

```
>>-Backup GRoup-- --options-------------------------------------><
```

Parameters

Table 1. Backup Group command: Related options

Option	Where to use
filelist	Command line only.
groupname	Command line only.
mode	Command line only.
AIX snapshotproviderfs	AIX System-options file (dsm.sys) within a server stanza or with the include.fs option.
Windows snapshotproviderfs	Windows Client options file (dsm.opt) or with the include.fs option.
Windows snapshotproviderimage	Windows Client options file (dsm.opt) or with include.image option.
virtualfsname	Command line only.

Examples

Mac OS X AIX Linux Solaris Task

Mac OS X AIX Linux Solaris Perform a full backup of all the files in the /home/dir1/filelist1 file to the virtual file space name accounting containing the group leader /home/group1 file.

Command:

```
backup group -filelist=/home/dir1/filelist1 -groupname=group1
-virtualfsname=/virtfs -mode=full
```

Windows Task

Windows Perform a full backup of all the files in the c:\dir1\filelist1 file to the virtual file space name \virtfs containing the group leader `group1` file.

Command:

```
backup group -filelist=c:\dir1\filelist1 -groupname=group1
-virtualfsname=\virtfs -mode=full
```

AIX Linux Solaris Windows

Backup Image

The backup image command creates an image backup of one or more volumes on your system.

You can use the backup image command to back up NTFS or ReFS, or unformatted RAW volumes. If a volume is NTFS-formatted, only those blocks that are used by the file system are backed up. On ReFS volumes, all blocks are backed up.

AIX If you set the imagegapsize option to 0, all blocks, including unused blocks at the end of the volume, are backed up.

AIX If you specify an AIX® JFS2 file system for image backup, only those blocks that are used by the file system are backed up. If you set the imagegapsize option to zero, all blocks, including blocks at the end of the volume, are backed up.

AIX Linux Solaris Note:

1. AIX AIX only: By default, snapshot-based image backup is enabled for JFS2 volumes. To turn off snapshot-based image backups, set `-snapshotproviderimage=NONE` on this command.
2. Linux For the Linux clients, image backup is only supported on partitions with id 0x83 or logical volumes that are created with the Linux Logical Volume Manager. Backing up other partitions, such as extended partitions that contain mounted file systems or database data, can produce inconsistent backup data if the data changes during the image backup operation.
3. Linux For the Linux client, image backup of DASD devices with raw-track access mode on Linux on z Systems™ is not supported.
4. AIX Linux Backup image is not supported on any GPFS™ file system.
5. The IBM Spectrum Protect™ API must be installed to use the backup image command.
6. AIX When you change the attribute of a JFS2 file system to an HSM-managed file system, an image backup is not done for that file system.

Important: The last incremental backup time refers to the server time and the file modification time refers to the client time. If the client and server time are not synchronized, or the client and server are in different time zones, this affects incremental-by-date backup and image backup where `mode=incremental`.

The client backs up the files that have modification dates and times (on the client) that are later than the date and time of the last incremental backup of the file system on which the file is stored (on the server).

If the server time is ahead of the client time, incremental-by-date backups, or image backup with `mode=incremental`, skip the files, which had been created or modified after the last incremental or image backup with a modification date earlier than the last incremental backup time stamp.

If the client time is ahead of the server time, all files that had been created or modified before the last incremental or image backup and have a modification time stamp later than the last incremental backup time stamp, are backed up again. Typically, these files would not get backed up because they had already been backed up.

The backup date can be checked by the query filespace command.

Windows Note:

1. The account that is running the backup-archive client must have administrator authority to successfully perform any type of image backup.
2. The API must be installed to use the backup image command.

AIX Linux Solaris The backup-archive client must support the raw device type on the specific platform to perform an image backup of a raw device. You can perform an image backup only on local devices. Clustered devices or file systems as well as devices or file systems that are shared between two or more systems are not supported. If you want to perform an image backup for a file system that is mounted on a raw device, the raw device must be supported.

Use the include.image option to include a file system or logical volume for image backup, or to specify volume-specific options for image backup.

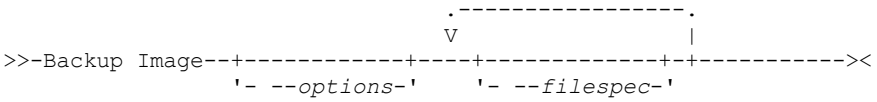
The backup image command uses the compression option.

Supported Clients

AIX Linux Solaris This option is valid for AIX, Linux, and Oracle Solaris clients.

Windows This command is valid for all Windows platforms.

Syntax



Parameters

filespec

Specifies the name of one or more logical volumes. If you want to back up more than one file system, separate their names with spaces. Do not use pattern matching characters. If you do not specify a volume name, the logical volumes that are specified with the domain.image option are processed. If you do not use the domain.image option to specify file systems to process, an error message is displayed and no image backup occurs.

AIX Linux Solaris Specify the file space over which the logical volume is mounted or the logical volume name. If there is a file system that is configured in the system for a given volume, you cannot back up the volume with the device name.

AIX Linux Solaris For example, if the /dev/lv01 file space is mounted on the /home volume, you can issue `backup image /home`, but `backup image /dev/lv01` fails with an error:

```
ANS1063E Invalid path specified
```

Solaris Note: For Sun systems, specify either a file system name or a raw device name (block device type).

Windows Image backup is only supported on a volume that has a mount or a drive letter assigned to it. A volume without a drive letter or mount point cannot be backed up.

Table 1. Backup Image command: Related options

Option	Where to use
Windows asnodename	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris asnodename	AIX Linux Solaris Client system options file (dsm.sys) or command line.
AIX Linux Solaris compressalways	AIX Linux Solaris Client system options file (dsm.sys) or command line.
Windows compressalways	Windows Client options file (dsm.opt) or command line.
compression	Client options file or command line.
AIX Linux Solaris dynamicimage	AIX Linux Solaris Use with the backup image command or the include.image option in the options file.
AIX Linux Windows imagegapsize	AIX Linux Windows Use with the backup image command, the include.image option, or in the options file.
mode	Command line only.
postsnapshotcmd	Use with the backup image command, the include.image option, or in the options file.
presnapshotcmd	Use with the backup image command, the include.image option, or in the options file.
AIX Linux snapshotcachesize	AIX Linux Use with the backup image command, the include.image option, or in the options file.
AIX Linux Windows snapshotproviderimage	AIX Linux Windows Client options file or with include.image option.

Examples

AIX Linux Solaris Task

AIX Linux Solaris Back up the /home/test file space over which the logical volume is mounted and perform an image incremental backup that backs up only new and changed files after the last full image backup.

```
dsmc backup image /home/test -mode=incremental
```

Windows Task

Windows Back up a volume that has no drive letter but is mounted as a mount point.

```
dsmc backup image m:\mnt\myntfs
```

Windows Task

Windows Back up the h drive by using an image incremental backup. An image incremental backup backs up files that are new or changed since the last full image backup.

```
dsmc backup image h: -mode=incremental
```

AIX Linux Task

AIX Linux Perform a static image backup of the logical volume that is mounted at the /home directory.

```
dsmc backup image /home -snapshotproviderimage=none
```

Windows Task

Windows Perform an offline image backup of the f drive.

```
dsmc backup image f: -snapshotproviderimage=none
```

AIX Linux Solaris Task

AIX Linux Solaris Perform a dynamic image backup of the logical volume that is mounted at the /home directory.

Command: `dsmc backup image /home -dynamicimage=yes`

AIX Linux Task

AIX Linux Perform a snapshot image backup of the /home directory.

```
AIX AIX client: dsmc backup image /home
    -snapshotproviderimage=JFS2
Linux LINUX client: dsmc backup image /home
    -snapshotproviderimage=LINUX_LVM
```

Windows Task

Windows Perform an online image backup of the f drive.

```
dsmc backup image f: -snapshotproviderimage=VSS
```

AIX Linux Solaris Task

AIX Linux Solaris Back up the /dev/lv01 raw logical volume.

```
dsmc backup image /dev/lv01
```

Windows Task

Windows Back up the f drive, which is mapped to a volume that has not been formatted with a file system.

```
dsmc backup image f:
```

- AIX Linux Solaris Static, dynamic, and snapshot image backup
  The traditional image backup prevents write access to the volume by other system applications during the operation.
- Windows Offline and online image backup
  The traditional offline image backup prevents write access to the volume by other system applications during the operation.
- AIX Linux Solaris Windows Utilizing image backup to perform file system incremental backup
  There are two methods of utilizing image backups to perform efficient incremental backups of your file system. These backup methods allow you to perform point-in-time restore of your file systems and improve backup and restore performance.

AIX Linux Solaris

Static, dynamic, and snapshot image backup

The traditional image backup prevents write access to the volume by other system applications during the operation.

Use the dynamicimage option to back up the volume as is without remounting it read-only. Corruption of the backup can occur if applications write to the volume while the backup is in progress. In this case, run fsck after a restore.

AIX The dynamicimage option is not supported for JFS2 volumes.

Linux For Linux x86_64 clients only: By default, the backup-archive client runs a snapshot image backup of file systems residing on a logical volume created by the Linux Logical Volume Manager during which the volume is available to other system applications. Snapshot image backup requires a Version 5.1 IBM Spectrum Protect™ server.

AIX For AIX® clients only: By default, backup-archive client runs a snapshot image backup of JFS2 volumes during which the volume is available to other system applications. AIX allows the creation of a snapshot of a JFS2 volume while it is still online. The snapshot is created inside the same volume group as the source volume. You must ensure that the volume group provides enough free disk space to create the snapshot. The snapshot contains the old data blocks while the modified data is stored in the source volume. Use the snapshotcachesize option with the backup image command, in the dsm.sys file, or with the include.image option to specify an appropriate snapshot size so that all old data blocks can be stored while the image backup occurs.

Linux The Linux Logical Volume Manager allows the creation of a snapshot of a logical volume while the logical volume itself is still online. The snapshot is created inside the same volume group as the source logical volume. You must ensure that the volume group provides enough free disk space to create the snapshot. The snapshot contains the old data blocks while the modified data is stored in the source logical volume. Use the snapshotcachesize option with the backup image command, in the dsm.sys file, or with the include.image option to specify an appropriate snapshot size so that all old data blocks can be stored while the image backup occurs. A snapshot size of 100 percent will ensure a valid snapshot.

Windows

Offline and online image backup

The traditional offline image backup prevents write access to the volume by other system applications during the operation.

If open file support has been configured, the backup-archive client performs a snapshot backup or archive of files that are locked (or "in use") by other applications.

Use VSS as the snapshot provider for open file support.

The following considerations apply to offline and online image backups:

- If you create an image of the system drive, you cannot restore it to the original location. Restore of any image requires that the client have an exclusive lock of the volume you are restoring to, so the system drive cannot be restored since the client is unable to lock the system drive. You can restore an image backup of the system drive to an alternate location.
- Because of different system component configurations, the system image not be consistent across components (such as Active Directory). Some of these components can be configured to use different volumes where parts are installed on the system drive and others to non-system volumes.
- Install the IBM Spectrum Protect™ client program on the system drive. The client cannot restore an image to the same volume where the client program is installed.
- Image backup is only supported on volumes that have a mount point or a drive letter assigned. the client will not back up a volume without a mount point or drive letter.
- If bad disk sectors are detected on the source drive during a LAN-free or LAN-based image backup, data corruption occur. In this case, bad sectors are skipped when sending image data to the IBM Spectrum Protect server. If bad disk sectors are detected during the image backup, a warning message is issued after the image backup completes.

AIX Linux Solaris Windows

Utilizing image backup to perform file system incremental backup

There are two methods of utilizing image backups to perform efficient incremental backups of your file system. These backup methods allow you to perform point-in-time restore of your file systems and improve backup and restore performance.

You can perform the backup only on formatted volumes; not on raw logical volumes. You can either use *image backup with file system incremental* or you can use *image backup with image incremental mode* to perform image backups of volumes with mounted file systems.

The following are some examples of using *image backup with file system incremental*.

AIX Linux Solaris

- To perform a full incremental backup of the file system: `dsmc incremental /myfilesystem`
- To perform an image backup of the same file system: `dsmc backup image /myfilesystem`
- To periodically perform incremental backups: `dsmc incremental /myfilesystem`

Windows

- To perform a full incremental backup of the file system: `dsmc incremental h:`
- To perform an image backup of the same file system: `dsmc backup image h:`
- To periodically perform incremental backups: `dsmc incremental h:`

You must follow the next steps in the order shown to ensure that the server records additions and deletions accurately.

AIX Linux Solaris Use this command to restore the file system to its exact state as of the last incremental backup: `dsmc restore image /myfilesystem -incremental -deletefiles`.

Windows Use this command to restore the file system to its exact state as of the last incremental backup: `dsmc restore image h: -incremental -deletefiles`.

During the restore, the client does the following:

- Restores the most recent image on the server.
- Deletes all of the files restored in the previous step which are inactive on the server. These are files which existed at the time of the image backup, but were subsequently deleted and recorded by a later incremental backup.
- Restores new and changed files from the incremental backups.

If you do not follow the steps exactly, two things can occur:

1. After the original image is restored, all files backed up with the incremental command are restored individually.
2. If you perform a backup image before performing an incremental, files deleted from the original image are *not* deleted from the final restored file system.

The following are some examples of using *image backup with image incremental mode*.

AIX Linux Solaris

- To perform an image backup of the same file system: `dsmc backup image /myfilesystem`
- To perform an incremental image backup of the file system: `dsmc backup image /myfilesystem -mode=incremental`

  This sends only those files that were added or changed since the last image backup to the server.

- To periodically perform full image backups: `dsmc backup image /myfilesystem`
- To restore the image: `dsmc restore image /myfilesystem -incremental`

  On restore, the backup-archive client ignores the deletefiles option when the image+image incremental technique of backing up has been used. The restore will include files that were deleted after the last full image backup plus the latest versions of files added or changed after the last image backup.

Windows

- To perform an image backup of the same file system: `dsmc backup image h:`
- To perform an incremental image backup of the file system: `dsmc backup image h: -mode=incremental`

  This sends only those files that were added or changed since the last image backup to the server.

- To periodically perform full image backups: `dsmc backup image h:`
- To restore the image: `dsmc restore image h: -incremental`

  On restore, the backup-archive client ignores the deletefiles option when the image+image incremental technique of backing up has been used. The restore will include files that were deleted after the last full image backup plus the latest versions of files added or changed after the last image backup.

Note: You should perform full image backups periodically in the following cases. This will improve restore time because fewer changes are applied from incrementals.

- When a file system changes substantially (more than 40%).
- Once each month.
- As appropriate for your environment.

The following restrictions apply when using the image backup with image incremental mode:

- The file system can have no previous full incremental backups produced by the incremental command.
- Incremental-by-date image backup does not inactivate files on the server; therefore, when files are restored, none can be deleted.

- If this is the first image backup for the file system, a full image backup is performed.
- Using mode=*incremental* backs up only files with a changed date, not files with changed permissions.
- If file systems are running at or near capacity, an out-of-space condition could result during the restore.

AIX Solaris Windows

Backup NAS

The backup nas command creates an image backup of one or more file systems that belong to a Network Attached Storage (NAS) file server, otherwise known as NDMP Backup. You are prompted for the IBM Spectrum Protect™ administrator ID.

The NAS file server performs the outboard data movement. A server process starts in order to perform the backup.

Use the nasnodename option to specify the node name for the NAS file server. The NAS node name identifies the NAS file server to the IBM Spectrum Protect server; the NAS node name must be registered at the server. Place the nasnodename option in your client options file (dsm.opt). The value in the client options file is the default, but can be overridden on the command line.

Use the toc option with the backup nas command or the include.fs.nas option to specify whether the IBM Spectrum Protect server saves Table of Contents (TOC) information for each file system backup. If you save TOC information, you can use the QUERY TOC server command to determine the contents of a file system backup with the RESTORE NODE server command to restore individual files or directory trees.

You can also use the IBM Spectrum Protect web client to examine the entire file system tree and select files and directories to restore. Creation of a TOC requires that you define the tocdestination attribute in the backup copy group for the management class to which this backup image is bound. TOC creation requires more processing, network resources, storage pool space, and possibly a mount point during the backup operation. If you do not save TOC information, you can still restore individual files or directory trees using the RESTORE NODE server command, if you know the fully qualified name of each file or directory and the image in which that object was backed up.

The toc option is only supported for images that are backed up by Version 5.2 or later client and server.

Specifying mode =*differential* on the BACKUP NODE server command or the backup nas command where no full image exists, shows that a full backup was started. Using the QUERY PROCESS server command shows that a full backup is in process.

Use the mode option to specify whether to perform a full or differential NAS image backup. A full image backup backs up the entire file system. The default is a differential NAS image backup on files that change after the last full image backup. If an eligible full image backup does not exist, a full image backup is performed. If a full image exists, whether it is restorable, or expired and being maintained because of dependent differential images, specifying mode =*differential* sends a differential image backup. If a full image is sent during a differential backup, it is reflected as a full image using the QUERY NASBACKUP server command. The QUERY NASBACKUP server command also displays NAS images that are restorable and displays full image or differential image as the object type.

Use the monitor option to specify whether you want to monitor a NAS file system image backup and display processing information on your screen.

Use the monitor process command to display a list of all processes for which an administrative user ID has authority. The administrative user ID should have at least client owner authority over both the NAS node and the client workstation node they are using either from command line or from the web.

Use the cancel process command to stop NAS backup processing.

Regardless of client platform, NAS file system specifications use the forward slash (/) separator, as in this example: `/vol/vol0`.

Windows NAS file system designations on the command line require brace delimiters {} around the file system names, such as: `{/vol/vol0}`.

Supported Clients

AIX Solaris This command is valid for AIX®, and Solaris clients only.

Windows This command is valid for all Windows clients.

Syntax

```
                                .-----------------.
                                V                 |
>>-Backup NAS--+------------+------ --filespec---+-------------><
               '- --options-'
```

Parameters

filespec

Specifies the name of one or more file systems on the NAS file server. If you do not specify this parameter, the backup-archive client processes all of the file systems that are defined by the domain.nas option.

If you do not specify the *filespec* or the domain.nas option, the default all-nas value is used for domain.nas and all file systems on the NAS file server are backed up.

Table 1. Backup NAS command: Related options

Option	Where to use
mode	Command line only.
monitor	Command line only.
AIX Solaris nasnodename	AIX Solaris Client options file (dsm.sys) or command line.
Windows nasnodename	Windows Client options file (dsm.opt) or command line.
AIX Solaris toc	AIX Solaris Command line or with the include.fs.nas option in your client options file (dsm.sys).
Windows toc	Windows Command line or with the include.fs.nas option in your client options file (dsm.opt).

Examples

AIX Solaris Task

AIX Solaris Perform the NAS image backup of the entire file system.

Command: `backup nas -mode=full -nasnodename=nas1 /vol/vol0 /vol/vol2`

Windows Task

Windows Perform the NAS image backup of the entire file system.

Command: `backup nas -mode=full -nasnodename=nas1 {/vol/vol0} {/vol/vol2}`

Task

Perform the NAS image backup of the entire file server.

Command: `backup nas -nasnodename=nas1`

AIX Solaris Task

AIX Solaris Perform the NAS image backup of the entire file system and save Table of Contents (TOC) information for the file system backup.

Command: `backup nas -mode=full -nasnodename=netappsj /vol/vol0 -toc=yes`

Windows Task

Windows Perform the NAS image backup of the entire file system and save Table of Contents (TOC) information for the file system backup.

Command: `backup nas -mode=full -nasnodename=netappsj {/vol/vol0} -toc=yes`

Windows

Backup Systemstate

Use the backup systemstate command to back up all bootable system state and system services components as a single object, to provide a consistent point-in-time snapshot of the system state.

Bootable system state components can include the following:

- Active Directory (domain controller only)
- System volume (domain controller only)
- Certificate Server Database
- COM+ database
- Windows Registry
- System and boot files
- ASR writer

System services components can include the following:

- Background Intelligent Transfer Service (BITS)
- Event logs
- Removable Storage Management Database (RSM)
- Cluster Database (cluster node only)
- Remote Storage Service
- Terminal Server Licensing
- Windows Management Instrumentation (WMI)
- Internet Information Services (IIS) metabase
- DHCP database
- Wins database

The list of bootable system state and system services components is dynamic and can change depending on service pack and operating system features installed. The backup-archive client allows for the dynamic discovery and backup of these components.

System state is represented by several VSS writers of type "bootable system state" and "system service". Of these, the System Writer is the largest part of the system state in terms of number of files and size of data. By default, the System Writer backup is incremental. You can use the systemstatebackupmethod option to perform full backups of the System Writer. For more information, about this option, see Systemstatebackupmethod. The client always backs up all other writers in full.

This command also backs up ASR data for Windows clients; BIOS and UEFI boot architectures are supported.

Note:

1. The system and boot files component of system state is backed up only if a member (file) of that component has changed since the last backup. If a member changes, the entire group of files that comprise that component are backed up.
2. The backup-archive client on Windows does not allow the backup of any individual component.
3. By default, system state backups are bound to the default management class. To bind them to a different management class, use the include.systemstate option; specify all as the pattern, and specify the name of the new management class.

   For example: `include.systemstate ALL BASVT2`.

4. Use the query systemstate command to display information about a backup of the system state on the IBM Spectrum Protect™ server.
5. You can no longer restore the system state on a system that is still online. Instead, use the ASR-based recovery method to restore the system state in offline Windows PE mode. For more information, see the following IBM Spectrum Protect wiki articles:
   - Best Practices for Recovering Windows Server 2012 and Windows 8
   - Best Practices for Recovering Windows Server 2012 R2 and Windows 8.1

   If you try to restore the system state with the dsmc restore systemstate command, from the backup-archive client GUI, or from the web client, the following message is displayed:

   ```
   ANS5189E Online SystemState restore has been deprecated. Please use offline
       WinPE method for performing system state restore.
   ```

Supported Clients

This command is valid for all supported Windows clients.

Syntax

```
>>-Backup SYSTEMSTate-----------------------------------------><
```

Parameters

There are no parameters for this command.

Examples

Task
: Back up the system state.

  Command: `backup systemstate`

Linux | Windows

Backup VM

Use the backup vm command to start a full backup of a virtual machine.

Windows

The backup vm command can be used to back up both Microsoft Hyper-V virtual machines and VMware virtual machines. The information for each hypervisor is presented in its own heading. If you are backing up a virtual machine that is part of a Hyper-V setup, you do not need to read the *Backing up VMware virtual machines* text. If you are backing up a VMware virtual machine, you do not need to read the *Backing up Microsoft Hyper-V virtual machines* text.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments.

Linux | Windows

Backing up VMware virtual machines

Use the backup vm command to back up VMware virtual machines.

One or more virtual machines are backed up by the IBM Spectrum Protect data mover node. *Data mover node* is the name that is given to a configuration where the backup-archive client runs on a vStorage backup server and is configured to protect the virtual machines in a Virtual Center or ESX/ESXi server. You must configure the VMware virtual machine before you use this command. For information about configuring the VMware virtual machine, see Preparing the environment for full backups of VMware virtual machines.

A full VM backup stores a backup copy of all virtual disk images and configuration information for a virtual machine. Full VM backups enable a complete restore of a virtual machine, but they take more time and more server space than an incremental backup.

If you set vmenabletemplatebackups option to yes, a backup vm operation includes the template VMs, but only if the vStorage backup server is connected to a vCenter Server, and not to an ESX or ESXi host.

If a snapshot fails during backup processing, the client attempts to back up the VMware virtual machine one more time. To control the number of total snapshot attempts, set the INCLUDE.VMSNAPSHOTATTEMPTS option in the client options file.

Data protection tags are used to configure the backup policy of virtual machines in VMware objects. The tags and categories are created when you use one of the following methods:

- Enable tagging support on the data mover node with the vmtagdatamover option and run the backup vm command.
- Use the IBM Spectrum Protect vSphere Client plug-in to manage IBM Spectrum Protect backups.
- Run the set vmtags command on any data mover node.

When the vmtagdatamover option is set to *yes*, all tags that are assigned to a virtual machine are backed up during backup vm operations. The tags are restored when the restore vm command is run. Tags that are assigned to other inventory objects are not backed up and cannot be restored.

For more information about data protection tags, see Data protection tagging overview.

A Full VM backup uses VMware Changed Block Tracking (CBT) to create content-aware (used-block only) backups. The client enables changed block tracking (CBT) on an ESX or ESXi server when a backup begins. VMware CBT requires an ESX 4.1 (or later)

host, with virtual hardware 7 (or later). You cannot perform incremental or full VM content-aware backups on virtual machines that do not support CBT.

When CBT is enabled, it tracks disk changes when I/O operations are processed by the ESX or ESXi server storage stack on the following disks:

- A virtual disk that is stored on VMFS; the disk can be an iSCSI disk, a local disk, or a disk that is on a SAN.
- A virtual disk that is stored on NFS.
- An RDM that is in virtual compatibility mode.

When I/O operations are not processed by the ESX or ESXi storage stack, changed block tracking cannot be used to track disk changes. The following disks cannot use CBT:

- An RDM that is in physical compatibility mode.
- A disk that is accessed directly from inside a VM. For example, vSphere cannot track changes that are made to an iSCSI LUN that is accessed by an iSCSI initiator in the virtual machine.

Complete information about changed block tracking requirements is described in the *VMware Virtual Disk API Programming Guide* in the VMware product documentation. In the guide, search for "Low Level Backup Procedures" and read the "Changed Block Tracking on Virtual Disks" section.
For VMware servers that do not support CBT, both the used and the unused areas of the disk are backed up and an informational message is logged in the dsmerror.log file. Use the -preview option on the backup vm command to view the current CBT status. CBT status has three values:

Off
: Indicates the CBT configuration parameter (ctkEnabled) is not enabled in the virtual machine's configuration parameters. Off is the default state.

Not Supported
: Indicates that the virtual machine does not support CBT. Changed-block only backups are not possible.

On
: Indicates the virtual machine supports CBT and that CBT is enabled in the virtual machine's configuration parameters (ctkEnabled=true).
The client turns on CBT (it sets ctkEnable=true) with each backup attempt. After the client turns on CBT, it remains on, even if the virtual machine is deleted from the IBM Spectrum Protect server. With CBT enabled, after the first full VM backup is performed, only the changed blocks on the disk are backed up or restored.
If you are no longer performing IBM Spectrum Protect backups of a virtual machine, you can turn off CBT. To turn off CBT, right-click the virtual machine that you want to turn off CBT for in the vSphere client. Click Edit Settings > Options > General > Configuration Parameters. Then, set the ctkEnabled configuration parameter to `false`.

Tip: You can use the compression option with backups only if the backup is being saved to a storage pool that was enabled for client-side deduplication.

Windows For more information about compression, see Compression and encryption processing.

Windows Linux You specify the -vmbackuptype and -mode options to indicate how the backups are to be performed. For full VM backups, use `-vmbackuptype=fullvm`, and specify any of the following mode options:

IFFull
: Incremental-forever-full mode. In this mode, a snapshot of all used blocks on a virtual machine’s disks are backed up to the server. You must be licensed to use IBM Spectrum Protect for Virtual Environments: Data Protection for VMware, or IBM Spectrum Protect for Virtual Environments: Data Protection for Microsoft Hyper-V to use this option.

IFIncremental
: Incremental-forever-incremental. In this mode, a snapshot is created of the blocks that changed since the last backup. You must be licensed to use IBM Spectrum Protect for Virtual Environments: Data Protection for VMware, or IBM Spectrum Protect for Virtual Environments: Data Protection for Microsoft Hyper-V to use this option.

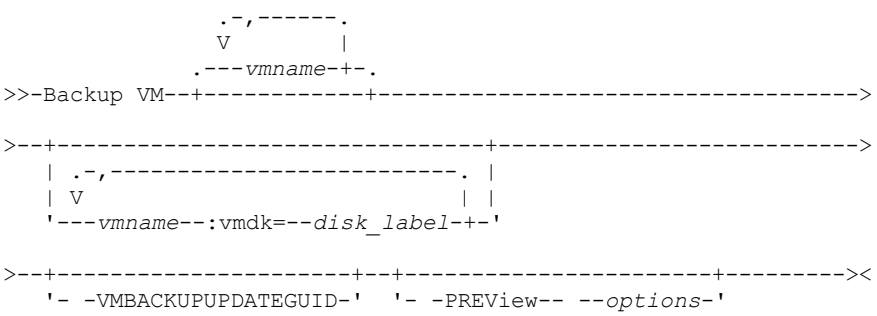
For information about the incremental-forever backup strategy, see IBM Spectrum Protect for Virtual Environments, Data Protection for VMware: Backup and restore types .

Supported Clients

Windows This command is valid on supported Windows clients that are installed on a vStorage backup server that protects VMware virtual machines.

Linux This command is valid only on supported Linux clients that are installed on a vStorage backup server that protects VMware virtual machines.

Syntax



Parameters

vmname

Specify the name of one or more virtual machines that you want to back up. The name is the virtual machine display name. Separate multiple virtual machine names with commas. If you set the vmenabletemplatebackups option to yes, *vmname* can specify the name of a template VM to back up.

VMware vCenter allows for two or more virtual machines to have the same display name. However, the backup-archive client requires that all virtual machine names in a vCenter server configuration be unique. To prevent errors during processing, ensure that all virtual machines have a unique display name.

Wildcard characters can be used in virtual machine names that are specified as this parameter. However, wildcard processing differs, depending on which backup mode is used.

- For backups that use `mode=iffull` or `mode=ifincremental`, wildcards can be used to match VM name patterns. For example:
  - `backup vm VM_TEST*` includes all virtual machines that have names that begin with VM_TEST
  - `backup vm VM??` includes any virtual machine that has a name that begins with the letters "VM", followed by 2 characters

If you do not specify *vmname*, you can identify the virtual machine with the domain.vmfull option.

:vmdk=*disk_label*

This keyword is an extension to the *vmname*. It specifies the label (name) of the virtual machine disk to include in the backup operation. You can exclude a disk by preceding the keyword with the exclusion operator (-). For more ways to include or exclude disks from processing, see Domain.vmfull, Exclude.vmdisk, Include.vmdisk.

-VMBACKUPUPDATEGUID

To use this option, you must have a license agreement to use IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

This option updates the globally unique identifier (GUID) for the virtual machine that you are backing up. This parameter is intended for use only in the following scenario:

You want to restore a previously backed up virtual machine named ORION. But, before you shut down and replace the copy of ORION that is running in your production environment, you want to verify the configuration of the restored virtual machine before you use it to replace the existing ORION.

1. You restore the ORION virtual machine and give it a new name: `dsmc restore vm Orion -vmname=Orion2`
2. You update and verify the ORION2 virtual machine and determine that it is ready to replace the existing virtual machine that is named ORION.
3. You power down and delete ORION.
4. You rename ORION2 so that it is now named ORION.
5. The next time that you backup ORION, by using either an incremental-forever full, or incremental-forever-incremental backup, you add the -VMBACKUPUPDATEGUID parameter to the backup vm command. This option updates the GUID, on the IBM Spectrum Protect server, so the new GUID is associated with the stored backups for the ORION virtual machine. The chain of incremental backups is preserved; there is no need to delete existing backups and replace them with new backups.

-PREView

This option displays information about a virtual machine, including the labels of the hard disks in the virtual machine, and the management class information for a virtual machine.

You can use the disk labels with the `:vmdk=` or `:-vmdk=` keywords to include or exclude disks from a backup operation. The following text is sample output from the -preview parameter:

```
backup vm vm1 -preview
Full BACKUP VM of virtual machines 'VM1'

vmName:vm1
VMDK[1]Label: Hard disk 1
VMDK[1]Name: [ds5k_svt_1] tsmcetlnx14/tsmcetlnx14.vmdk
VMDK[1]Status: Included
VMDK[2]Label: Hard disk 2
VMDK[2]Name: [ds5k_svt_1] tsmcetlnx14/tsmcetlnx14_1.vmdk
VMDK[2]Status: Excluded - user,Independent,pRDM
```

This example output from `-preview` shows that VMDK 2 was excluded by the previous backup. Disks that were included in a backup have a status of `Included`. Disks that were excluded from the backup have a status of `Excluded`, followed by a reason code. The reason codes can be any of the following:

user
: Indicates that the disk was skipped because it was excluded on a domain.vmfull statement, on the command line, or in the client options file.

Independent
: Indicates that the disk is an independent disk. Independent disks cannot be part of a snapshot, so they are excluded from backup vm operations. Ensure that the vmprocessvmwithindependent option is set to yes or the entire virtual machine is bypassed by a backup operation if it contains one or more independent disks.

pRDM
: Indicates that the disk is a physical Raw Device Mapped (pRDM) disk. pRDM disks cannot be part of a snapshot, so they are excluded from backup vm operations. Ensure that the vmprocessvmwithprdm option is set to yes or the entire virtual machine is bypassed by a backup operation if it contains one or more raw device mapping (RDM) volumes that are provisioned in physical-compatibility mode (pRDM).

The output from the -preview parameter also shows the management class name that is associated with the virtual machine, along with information about where the management class was set. This information can help you verify whether the domain and tag values are set correctly for the management class. For example:

```
backup vm -preview
Full BACKUP VM of virtual machines specified in DOMAIN.VMFULL option.

  1. vmName: tag_vm_2
       DomainKeyword:  all-vm
       toolsRunningStatus: guestToolsNotRunning
       toolsVersionStatus: guestToolsNotInstalled
       consolidationNeeded: No
       Change Block Tracking: On
       managementClassName: STANDARD
       managementClassLocation: Node Default

       VMDK[1]Label:   'Hard disk 1' (Hard Disk 1)
       VMDK[1]Name:    '[Raid1-lannds2] tag_vm_2/tag_vm_2.vmdk'
       VMDK[1]Status:  Included
...

12. vmName: vm-jean
       DomainKeyword:  all-vm
       toolsRunningStatus: guestToolsNotRunning
       toolsVersionStatus: guestToolsNotInstalled
       consolidationNeeded: No
       Change Block Tracking: On
       managementClassName: MGMTCLASS1 (invalid)
       managementClassLocation: VM Tag Management Class (IBM Spectrum Protect)

       VMDK[1]Label:   'Hard disk 1' (Hard Disk 1)
       VMDK[1]Name:    '[Raid1-lannds2] vm-jean/vm-jean.vmdk'
       VMDK[1]Status:  Included
```

where:

managementClassName
: Displays the name of the management class that the virtual machine is bound to.

  If the "(invalid)" label is shown next to the management class name, either the name was incorrectly specified, the management class was removed on the IBM Spectrum Protect server, or no backup copy group was found in the management class on the server. When the management class name is invalid, the virtual machine backup operation fails.

managementClassLocation
: Displays where the management class was set. The following locations are possible:

  Node Default
  : The management class is set on the default domain of the VMware datacenter node.

  VMMC option
  : The management class is set with the vmmc option.

  VMCTLMC option
  : The management class is set with the vmctlmc option.

  INCLUDE.VM option
  : The management class is set with the include.vm option.

  VM Tag Management Class (IBM Spectrum Protect)
  : The management class is set as a tag value of the `Management Class (IBM Spectrum Protect)` tag category. Tag values can be set with data protection settings in the IBM Spectrum Protect vSphere Client plug-in in the vSphere Web Client, or by using tools such as VMware vSphere PowerCLI version 5.5 R2 or later.

Important: In order to display the management class information that is set by tags, you must set the vmtagdatamover yes option in the client options file, or you must include the -vmtagdatamover=yes parameter when you run the dsmc backup vm command. If you did not set the vmtagdatamover option or if it is set to no, the client ignores any management class tag values, and displays the management class definition that is set in the default domain of the datacenter node, the vmmc option, or the include.vm option.

Return codes for virtual machine backup operations

Backup operations for virtual machines can complete with the return codes that are shown in the following table.

Return code	Description
0	A command to back up one or more virtual machines completed successfully.
8	A command to back up multiple virtual machines succeeded for only some of the virtual machines that were targeted by the command. Examine the log file to determine the processing status for each of the targeted virtual machines.
12	Indicates that either of the following error conditions occurred: • The backup command could not back up any of the virtual machines that were targets of the backup operation. • The backup command failed and it stopped before all virtual machines that were specified were inspected. Examine the log file to determine the reason for the failure.

vStorage API for data protection example commands

Perform an IFIncremental backup of two VMs named vm3 and vm4.

```
dsmc backup vm vm3,vm4 -vmbackuptype=fullvm -mode=ifincremental
```

Perform an IFFull backup of a VM named vm1.

```
dsmc backup vm vm1 -vmbackuptype=fullvm -mode=iffull
```

Perform an IFFull VM backup of a VM named vm1, but include only Hard Disk 1 in the backup operation.

```
dsmc backup vm "vm1:vmdk=Hard Disk 1" -vmbackuptype=fullvm -mode=iffull
```

Perform an incremental-forever backup of a virtual machine that is named vm1, but exclude Hard Disk 1 and Hard Disk 4 from the backup operation.

```
dcmc backup vm "vm1:-vmdk=Hard Disk 1:-vmdk=Hard Disk 4"
  -vmbackuptype=fullvm -mode=iffull
```

Perform an incremental-forever-full backup of two virtual machines that are named vm1 and vm2. On vm1, back up only Hard Disk 2 and Hard Disk 3. On vm2, back up all virtual disks.

```
dsmc backup vm "vm1:vmdk=Hard Disk 2:vmdk=Hard Disk 3",
  vm2 -vmbackuptype=fullvm -mode=iffull
```

Perform parallel incremental-forever-full backups of the VMware virtual machines that are selected for backup by using the selection criteria (domain parameters) on the domain.vmfull statement. Set the maximum number of parallel backups to 5 virtual machines and 10 sessions and limit the backups to 5 VMs per host and 5 VMs per datastore.

```
dsmc backup vm -vmbackuptype=fullvm -mode=iffull -vmmaxparallel=5
  -vmmaxbackupsessions=10 -vmlimitperhost=5 -vmlimitperdatastore=5
```

Windows

Backing up Microsoft Hyper-V virtual machines

Use the backup vm command to back up Hyper-V virtual machines. You can back up Hyper-V guests that exist on a local disk, a SAN-attached disk, a Cluster Shared Volume (CSV), or guests that exist on a remote file server share. Remote file server shares must be on a Windows Server 2012 or later system.

You specify the backup mode to use when you want to back up a virtual machine by adding the -mode parameter on the command line, or you can set the mode option in the client options file. Any of the following modes can be specified:

IFFull
: Incremental-forever-full mode. In this mode, a snapshot of all used blocks on a virtual machine's disks are backed up to the server. The backup includes configuration information, and all of the disks. You must have a license for IBM Spectrum Protect for Virtual Environments: Data Protection for Microsoft Hyper-V to use this mode. This mode can be used only on Windows clients on Hyper-V hosts that are running in Windows Server 2012 or later environments.

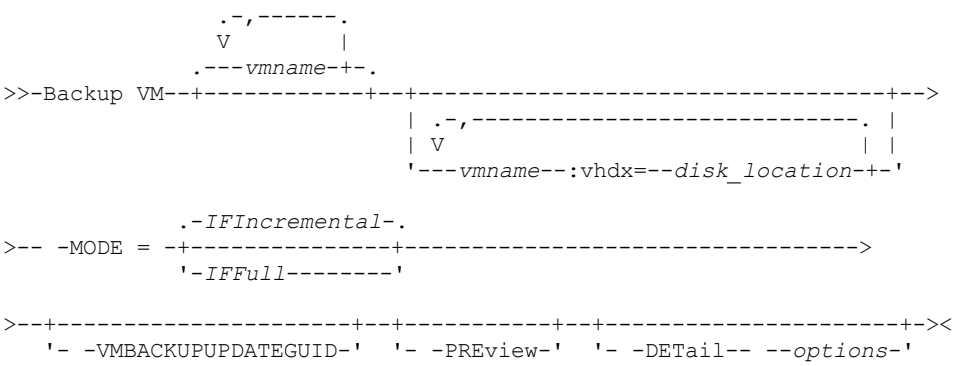
IFIncremental
: Incremental-forever-incremental. In this mode, a snapshot is created of the blocks that were changed since the last backup. The backup includes configuration information, and all of the disks. You must have a license for IBM Spectrum Protect for Virtual Environments: Data Protection for Microsoft Hyper-V to use this mode. This mode can be used only on Windows clients on Hyper-V hosts that are running in a Windows Server 2012 or later environments.

For information about the incremental-forever backup strategy, see Incremental-forever backup strategy.

Supported Clients

This command is valid on supported Windows clients that are installed on a Microsoft Hyper-V host server.

Syntax



Parameters

vmname
Specify the name of the virtual machine that you want to back up; the name is case sensitive. If you specify multiple virtual machine names, separate the names with commas.
Wildcard characters can be used in virtual machine names that are specified as this parameter. However, wildcard processing differs, depending on which backup mode is used.

- For backups that use `mode=iffull` or `mode=ifincremental`, wildcards can be used to match VM name patterns. For example:
  - `backup vm VM_TEST*` includes all virtual machines that have names that begin with VM_TEST
  - `backup vm VM??` includes any virtual machine that has a name that begins with the letters "VM", followed by 2 characters

  If you do not specify a virtual machine name, and if you specify `-mode=ifincremental` or `-mode=iffull`, the domain.vmfull option is used to determine which virtual machines to include in the backup operation.

vmname:vhdx=*disk_location*
This parameter specifies the virtual machine hard disk (VHDX) to include in Hyper-V RCT VM backup operations on Windows Server 2016.

The *vmname* variable specifies the name of the VM to back up. Wildcard characters can be used to select VM names that match a pattern. An asterisk (*) matches any sequence of characters. A question mark (?) matches any single character.

The :vhdx=*disk_location* keyword specifies the location of the VM disk to include in the backup operation. The disk location is specified in the format "*controller_type controller_number disk_location_number_inside_controller*". The controller type must be "SCSI" or "IDE". For example:

```
dsmc backup vm "vm1:VHDX=IDE 1 0"
```

You can obtain the disk location information in the Hyper-V Manager. In the Virtual Machines view, right-click a VM and click Settings. In the Hardware section of the Settings window, locate the IDE Controller or SCI Controller, and click Hard Drive to view the hard disk settings. The controller number and disk location are displayed in the Controller and Location fields. You can also obtain the disk location information by running the Windows PowerShell cmdlet Get-VMHardDiskDrive.

You can exclude a VM disk from backup operations by specifying the exclude operator (-) before the vhdx= keyword. For example, use -vhdx= to exclude a VM disk from the backup operation of a VM:

```
dsmc backup vm "vm1:-VHDX=IDE 1 0:-VHDX=SCSI 0 1"
```

If you specify multiple VM disks to include or exclude, the vhdx= or -vhdx= keyword and associated values must be separated by colons, with no intervening space characters. For example:

```
dsmc backup vm "*:-VHDX=IDE 1 0:-VHDX=SCSI 0 1"
```

If you specify multiple VM names and VM disks, the VM name and associated values must be separated by semicolons, with no intervening space characters. For example:

```
dsmc backup vm "vm1:-VHDX=IDE 1 0:-VHDX=SCSI 0 1;vm2:-VHDX=IDE 1 0:-VHDX=SCSI 0 1"
```

-VMBACKUPUPDATEGUID

You must be licensed to use IBM Spectrum Protect for Virtual Environments: Data Protection for Microsoft Hyper-V to use this option.

This option updates the globally unique identifier (GUID) for the virtual machine that you are backing up. This parameter is intended for use only in the following scenario:

You want to restore a previously backed up virtual machine named ORION. But, before you shut down and replace the copy of ORION that is running in your production environment, you want to verify the configuration of the restored virtual machine before you use it to replace the existing ORION.

1. You restore the ORION virtual machine and give it a new name: `dsmc restore vm Orion -vmname=Orion2`
2. You update and verify the ORION2 virtual machine and determine that it is ready to replace the existing virtual machine that is named ORION.
3. You power down and delete ORION.
4. You rename ORION2 so that it is now named ORION.
5. The next time that you backup ORION, by using either an incremental-forever full, or incremental-forever-incremental backup, you add the -VMBACKUPUPDATEGUID parameter to the backup vm command. This option updates the GUID, on the IBM Spectrum Protect server, so the new GUID is associated with the stored backups for the ORION virtual machine. The chain of incremental backups is preserved; there is no need to delete existing backups and replace them with new backups.

-PREView

This parameter displays additional information about a virtual machine, including the labels of the virtual hard disks that are in the virtual machine.
When you issue the -preview option, the backup operation does not start. You must issue the backup command without the -preview option to start the backup operation.
You can use both the -preview option and the -detail option on the command to display information about subdisks that are included when the backup is run. A subdisk is the AVHDX file that is created when a snapshot is taken of a VHDX file.

Return codes for virtual machine backup operations

Backup operations for virtual machines can complete with the return codes that are shown in the following table.

Return code	Description
0	A command to back up one or more virtual machines completed successfully.
8	A command to back up multiple virtual machines succeeded for only some of the virtual machines that were targeted by the command. Examine the log file to determine the processing status for each of the targeted virtual machines.
12	Indicates that either of the following error conditions occurred: • The backup command could not back up any of the virtual machines that were targets of the backup operation. • The backup command failed and it stopped before all virtual machines that were specified were inspected. Examine the log file to determine the reason for the failure.

Microsoft Hyper-V backup examples

Start an incremental-forever incremental backup of a Hyper-V virtual machine that is named "VM1".

```
dsmc backup vm VM1 -mode=ifincremental
```

Start an incremental-forever-incremental backup of all Hyper-V virtual machines that are specified on the domain.vmfull option.

```
dsmc backup vm -mode=ifincremental
```

For Windows Server 2016 or later operating systems: The following command excludes an IDE disk (with controller number 1 and disk location 0) and a SCSI disk (with controller number 0 and disk location 1) from an incremental-forever incremental Hyper-V RCT backup of a virtual machine, "vm2":

```
dsmc backup vm "vm2:-VHDX=IDE 1 0:-VHDX=SCSI 0 1" -mode=ifincremental
```

For Windows Server 2016 or later operating systems: The following command shows the preview of a Hyper-V RCT backup of a virtual machine, "VM05":

```
dsmc backup vm VM05 -mode=ifincremental -preview
```

In the command output, the -preview parameter displays the VHDX labels in the virtual machine. When the -detail parameter is specified with the -preview parameter, no additional information is shown for Hyper-V RCT backups.

```
Backup VM command started.  Total number of virtual machines to process: 1

  1. VM Name: VM05

        Domain Keyword:       VM05
        Mode:                 Incremental Forever - Incremental
        Target Node Name:     NODE14
        Data Mover Node Name: NODE14
        Cluster Resource:     No

        Disk[1]
        Name: \\node14\d$\Hyper_V_Virtual_Machine\VM05\Virtual Hard Disks\VM05.vhdx
        Capacity:             15.00 GB
        Size:                 10.91 GB
        Status:               included
        Disk Type:            VHDX
        Number of Subdisk:    0
        Controller Location:  IDE 0 0

        Disk[2]
        Name: \\node14\d$\Hyper_V_Virtual_Machine\VM05\Virtual Hard Disks\VM05_Disk2.vhdx
        Capacity:             2.00 GB
        Size:                 132.00 MB
        Status:               included
        Disk Type:            VHDX
        Number of Subdisk:    0
        Controller Location:  SCSI 0 1

Total number of virtual machines processed: 1
```

For Windows Server 2012 or 2012 R2: The following command starts an incremental forever-incremental backup of a Hyper-V virtual machine, "VM3":

```
dsmc backup vm VM3 -mode=ifincremental -preview
```

In the command output, the -preview parameter displays the VHDX labels in the virtual machine:

```
VM Name: VM3

        Domain Keyword:       all-vm
        Mode:                 Incremental Forever - Incremental
        Target Node Name:     NODE1
        Data Mover Node Name: NODE1
        Cluster Resource:     Yes

        Disk[1]
        Name: c:\ClusterStorage\Volume1\Hyper-V\VM3\VM3.VHDX
        Capacity:             40.00 GB
        Size:                 9.09 GB
        Full Backup:          included
        Incremental Backup:   excluded
        Disk Type:            VHDX
        Number of Subdisk:    1

        Disk[2]
        Name: c:\ClusterStorage\Volume3\Hyper-V\VM3\VM3-DISK2.VHDX
        Capacity:             127.00 GB
        Size:                 4.00 MB
        Full Backup:          included
```

```
        Incremental Backup:   excluded
        Disk Type:            VHDX
        Number of Subdisk:    1
```

When the -detail parameter is specified with the -preview parameter, the VHDX labels and their subdisks are shown. The following example output is abbreviated to show only information about one virtual machine and one disk:

```
VM Name: VM3

        Domain Keyword:       all-vm
        Mode:                 Incremental Forever - Incremental
        Target Node Name:     NODE1
        Data Mover Node Name: NODE1
        Cluster Resource:     Yes

        Disk[1]
        Name: c:\ClusterStorage\Volume1\Hyper-V\VM3\VM3.VHDX
        Capacity:             40.00 GB
        Size:                 9.09 GB
        Full Backup:          included
        Incremental Backup:   excluded
        Disk Type:            VHDX
        Number of Subdisk:    1

        Subdisk[1]
        Name: c:\ClusterStorage\Volume1\Hyper-V\VM3\VM3_9B26166-9C3E.avhdx
        Capacity:             40.00 GB
        Size:                 1.25 GB
        Full Backup:          included
        Incremental Backup:   included
        Disk Type:            AVHDX
```

Hyper-V options file examples

The following example specifies individual virtual machines in the client options file, and shows the domain.vmvull option.

```
domain.vmfull vm1,vm2,vm5
```

In the following examples, the domain.vmfull option is used to process specific virtual machine.

For Windows Server 2016 or later operating systems: In the following example, the domain.vmfull option is specified as follows:

```
domain.vmfull VM04,VM05
```

The following command shows a preview of a Hyper-V RCT backup of all virtual machine specified in the domain.vmfull option. The command displays preview information about each virtual machine:

```
dsmc backup vm -mode=iffull -preview
```

The following output is shown:

```
Backup VM command started.  Total number of virtual machines to process: 2

  1. VM Name: VM04

        Domain Keyword:       VM04
        Mode:                 Incremental Forever - Full
        Target Node Name:     NODE14
        Data Mover Node Name: NODE14
        Cluster Resource:     No

        Disk[1]
        Name: \\node14\d$\Hyper_V_Virtual_Machine\VM04\Virtual Hard Disks\VM04.vhdx
        Capacity:             36.00 GB
        Size:                 9.16 GB
        Status:               included
        Disk Type:            VHDX
        Number of Subdisk:    0
        Controller Location:  IDE 0 0

  2. VM Name: VM05

        Domain Keyword:       VM05
```

```
        Mode:                 Incremental Forever - Full
        Target Node Name:     NODE14
        Data Mover Node Name: NODE14
        Cluster Resource:     No

        Disk[1]
        Name: \\node14\d$\Hyper_V_Virtual_Machine\VM05\Virtual Hard Disks\VM05.vhdx
        Capacity:             15.00 GB
        Size:                 10.91 GB
        Status:               included
        Disk Type:            VHDX
        Number of Subdisk:    0
        Controller Location:  IDE 0 0

        Disk[2]
        Name: \\node14\d$\Hyper_V_Virtual_Machine\VM05\Virtual Hard Disks\VM05_Disk2.vhdx
        Capacity:             2.00 GB
        Size:                 132.00 MB
        Status:               included
        Disk Type:            VHDX
        Number of Subdisk:    0
        Controller Location:  SCSI 0 1

Total number of virtual machines processed: 2
```

For Windows Server 2012 or 2012 R2: In the following example, the domain.vmfull option specifies these virtual machines:

```
domain.vmfull BigVM,myGentoox64,HPV2VM3-OLD,Local10
```

The following command shows a preview of an incremental forever-incremental backup operation of all Hyper-V virtual machines: specified in the domain.vmfull option. The command displays preview information about each virtual machine:

```
dsmc backup vm -mode=iffull -preview
```

The following output is shown:

```
1. VM Name: BigVM

        Domain Keyword:       all-vm
        Mode:                 Incremental Forever - Full
        Target Node Name:     MSF
        Data Mover Node Name: MSF
        Cluster Resource:     No

        Disk[1]
        Name: \\lingonberry\c$\Users\michael\Documents\Storage\BigVM.vhdx
        Capacity:             5.85 TB
        Size:                 5.00 MB
        Full Backup:          included
        Incremental Backup:   excluded
        Disk Type:            VHDX
        Number of Subdisk:    0

2. VM Name: Gentoox64

        Domain Keyword:       all-vm
        Mode:                 Incremental Forever - Full
        Target Node Name:     MSF
        Data Mover Node Name: MSF
        Cluster Resource:     No

3. VM Name: HPV2VM3-OLD

        Domain Keyword:       all-vm
        Mode:                 Incremental Forever - Full
        Target Node Name:     MSF
        Data Mover Node Name: MSF
        Cluster Resource:     No

4. VM Name: Local10

        Domain Keyword:       all-vm
        Mode:                 Incremental Forever - Full
        Target Node Name:     MSF
```

```
          Data Mover Node Name: MSF
          Cluster Resource:     No

AIX | Linux | Solaris | Windows

Cancel Process

The cancel process command displays a list of current NAS (if NDMP support is enabled) image backup and restore processes for which the administrative user has authority. You are prompted for the IBM Spectrum Protect™ administrator ID.

From the list, the administrative user can select one process to cancel. Client owner privilege is sufficient authority to cancel the selected NAS image backup or restore processes.

AIX | Solaris | Windows

Supported Clients

AIX | Solaris This command is valid for AIX®, Linux, and Solaris clients only.

Windows This command is valid for all Windows clients.

Syntax

```
>>-Cancel Process-----------------------------------------><
```

Parameters

There are no parameters for this command.

Examples

Task

Cancel current NAS image backup or restore processes.

Command: `cancel process`

Cancel Restore

The cancel restore command displays a list of your restartable restore sessions in the server database.

You can cancel only one restartable restore session at a time. Run the cancel restore command again to cancel more restores. To restart restartable restore sessions, use the restart restore command.

Use the cancel restore command under the following circumstances:

- You cannot back up files that are affected by the restartable restore.
- Windows You want to cancel restartable restore sessions.
- Restartable restore sessions lock the file space so that files cannot be moved off of the sequential volumes of the server.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Cancel Restore-----------------------------------------------><
```

Parameters

There are no parameters for this command.

Examples

Task
: Cancel a restore operation.

```
cancel restore
```

Delete Access

The delete access command deletes authorization rules for files that are stored on the server.

When you delete an authorization rule, you revoke user access to any files or images that are specified by that rule.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Delete-- --ACcess-------------------------------------------><
```

Parameters

There are no parameters for this command.

Examples

Task
: Display a list of current authorization rules and select the rules that you want to delete.

```
delete access
```

See the following screen example:

AIX Linux Solaris Mac OS X

```
Index   Type       Node    Owner   Path
_____   _______    ____________________________
1       Backup     NODE1   USER1   home/dev/proja/list/
2       Archive    NODE3   LUIE    home/fin/budg/depta/
3       Backup     NODE4   USER2   home/plan/exp/deptc/
4       Archive    NODE5   USER2S  home/mfg/invn/parta/
Enter Index of rule(s) to delete, or quit to cancel:
```

AIX Linux Solaris Mac OS X To delete the authorization rules that allow `luie` and `user2s` to access your files or images, type `2 4` or `2,4` and press `Enter`.

Windows

```
Index  Type      Node     Owner    Path
_____  ______    ____________________________
1      Backup    node1    daisy    c:\dev\proja\list.c
2      Archive   node3    marm     c:\fin\budg\depta.jan
3      Backup    node4    susie    c:\plan\exp\deptc.feb
4      Archive   node5    susies   c:\mfg\invn\parta.wip
Enter Index of rule(s) to delete, or quit to cancel:
```

Windows To delete the authorization rules that allow `marm` and `susies` to access your files, type `2 4` or `2,4`, then press `Enter`.

Delete Archive

The delete archive command deletes archived files from IBM Spectrum Protect™ server storage. Your administrator must give you the authority to delete archived files.

Important: When you delete archived files, you cannot retrieve them. Verify that the files are obsolete before you delete them.
AIX Linux Solaris Mac OS X Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Delete ARchive--+------------+------------------------------>
                   '- --options-'

>--+- --filespec----------------------+-----------------------><
   '- --{--filespacename--}--filespec-'
```

Parameters

filespec
: Specifies the path and file name that you want to delete from storage. Use wildcard characters to specify a group of files or all files in a directory. You can also use the filelist option to process a list of files. The backup-archive client opens the file that you specify with this option and processes the list of files within according to the specific command.
Note: If you indicate *filespacename*, do not include a drive letter in the file specification.

{filespacename}
: Specifies the file space (enclosed in braces) on the server that contains the file you want to delete. This is the name on the workstation drive from which the file was archived.

  Use the filespacename if the name was changed, or if you are deleting files that are archived from another node with drive labels that are different from yours.

  Windows You can specify a UNC name; drive label names are only used for removable media.

  Windows You must specify a mixed or lowercase NTFS or ReFS file space name that is enclosed in quotation marks and braces. For example, `{"NTFSDrive"}`. Single quotation marks are valid in loop mode. For example, `{"NTFSDrive"}` and

`{'NTFSDrive'}` are both valid. In batch mode, only single quotation marks are valid. The single quotation mark requirement is a restriction of the operating system.

Table 1. Delete Archive command: Related options

Option	Where to use
dateformat	Client options file (dsm.opt) or command line.
description	Command line only.
filelist	Command line only.
noprompt	Command line only.
numberformat	Client options file (dsm.opt) or command line.
pick	Command line only.
subdir	Client options file (dsm.opt) or command line.
tapeprompt	Client options file (dsm.opt) or command line.
timeformat	Client options file (dsm.opt) or command line.

Examples

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Delete a file that is named `budget`.

```
dsmc delete archive /user/home/proj1/budget
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Delete all files that are archived from the `/user/home/proj1` directory with a file extension of `.txt`.

```
dsmc del arch "/user/home/proj1/*.txt"
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Delete files that are archived from the `/user/project` directory by using the pick option to display a list of archive copies that match the file specification. From the list, you can select the versions to process.

```
dsmc delete archive "/user/project/*" -pick
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Delete selected files from the group of files that are archived with the description "Monthly Budgets 2010" located in `/user/projects` and its subdirectories.

```
dsmc delete ar "/user/projects/*" -description="Monthly Budgets 2010" -pick -subdir=yes
```

Windows Task

Windows Delete files from file space `abc` in the `proj` directory.

```
dsmc delete archive {"abc"}\proj\*
```

Windows Task

Windows Delete a file that is named `budget`.

```
dsmc delete archive c:\plan\proj1\budget.jan
```

Windows Task

Windows Delete all files that are archived from the `c:\plan\proj1` directory with a file extension of `.txt`.

```
delete archive c:\plan\proj1\*.txt
```

Windows Task

Windows Delete files that are archived from the `c:\project` directory by using the pick option to display a list of archive copies that match the file specification. From the list, you can select the versions to process.

```
dsmc delete archive c:\project\* -pick
```

Windows Task

Windows Delete selected files from the group of files that are archived with the description "Monthly Budgets 2013" located in `c:\projects` and its subdirectories.

```
dsmc delete ar c:\projects\* -description="Monthly Budgets 2013" -pick -subdir=yes
```

Delete Backup

The delete backup command deletes files, images, and virtual machines that were backed up to IBM Spectrum Protect™ server storage. Your administrator must give you authority to delete objects.

When you delete files, the IBM Spectrum Protect server takes all of the backed up files that meet the filespec and deltype options that are specified and deactivates them. The server also assigns a deactivation date of *infinite-minus* so that the files are no longer available for restore and are purged, immediately on the subsequent run of file expiration. The file is not physically removed until the expiration process runs.

Important: After you delete backup files, you cannot restore them; verify that the backup files are no longer needed before you delete them. You are prompted to choose whether you want to continue with the delete. If you specify yes, the specified backup files are scheduled for deletion and removed from server storage.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This command is valid for all clients.

AIX Linux Solaris Mac OS X Windows

Syntax

```
>>-Delete BAckup-- --+-----------------------------------+------>
                     '-+-filespec----------------------+-'
                       '-{--filespacename--}--filespec-'

>--+-------------------------------------------------+------------>
   | .-objtype=FILE----------------------------. |
   '-+-----------------------------------------+-'
     +-objtype=IMAGE---------------------------+
     '-objtype=VM-+--------------------+- vmname-'
                  |         .-BOTH---. |
                  '--FROM -+-SERVER-+-'
                           '-LOCAL--'

   .-deltype=ACTIVE-------.
>--+----------------------+-+---------+-----------------------><
   +-+------------------+-+ '-options-'
   | '-deltype=INACTIVE-' |
   '-+--------------+------'
     '-deltype=ALL-'
```

Parameters

filespace/filespec
filespec

Specifies the path and file name that you want to delete from storage. To specify a file in another file space, precede the file name with the file space name. Use wildcard characters to specify a group of files or all files in a directory. Separate file specifications with a space. You can also use the filelist option to process a list of files. The backup-archive client opens the file that is specified with this option and processes the list of files within according to the specific command.
Note: If you indicate *filespacename*, do not include a drive letter in the file specification.

When you use `-deltype=inactive` or `-deltype=active`, use wildcard characters to specify a group of files or all files in a directory.

When you use `-deltype=all`, specify a fully wildcarded directory.

objtype

Specifies the type of object that you want to delete. You can specify either of the following values:

FILE
: Specifies that you want to delete directories and files. This value is the default object type.

IMAGE
: Specifies that you want to delete an image backup. Specifies that you want to delete an image backup. Objtype=image is not supported on Mac OS X.

VM *vmname*
: Specifies that you want to delete one or more versions of a virtual machine backup; the virtual machine is identified by the *vmname* variable parameter. The virtual machine name cannot contain wildcard characters.

  This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments.

  When `objtype=VM` is specified, the filelist option cannot be used. Specifying `objtype=VM` changes the behavior of the `-deltype` option. When `objtype=vm` is specified, you can use either `-deltype=active` or `-deltype=inactive`. You cannot use `-deltype=all`. Specifying `-deltype=inactive` displays a list of both inactive and active backups. You can use this list to specify which virtual machine backups that you want to delete. To delete only active virtual machine backups, use `-deltype=active`.

  When you specify `-objtype=VM`, this command deletes only virtual machine backups that were created with any of the following modes: FULL, IFINCR, and IFFULL. Backups that were created with the full or incremental mode were created with the version 7.1 or earlier client.

  For backups that were created with the version 7.1 or earlier clients: Individual incremental backups (backups that were created by using `MODE=INCR`) that were created after a full backup was run cannot be deleted with this command. However, if you delete a full virtual machine image backup (created by using `MODE=FULL`), and if the server has any incremental backups (`MODE=INCR`) that were created for this VM after the full backup, then deleting the full VM backup also deletes the files that were created by a `MODE=INCR` backup.

  If you delete an active backup for a virtual machine, the most recent inactive copy becomes the active backup. If you specify the -pick or -inactive option, only the backup that you specify is deleted. If you select a backup that is created by `MODE=IFINCR`, only the selected incremental backup is deleted; other incremental backups for the virtual machine are not deleted.

  -FROM
  : Specify the backup location or locations where virtual machine backups are deleted. You can specify one of the following values:

    SERVER
    : Backups of virtual machines are deleted from the IBM Spectrum Protect server.

    LOCAL
    : Persisted snapshots of virtual machines are deleted from the hardware storage.

    BOTH
    : Backups of virtual machines that are on the IBM Spectrum Protect server and snapshots that are on the hardware storage are deleted. This value is the default.
      Specifying this value displays a list of backup locations. From the list, you can select the location from which to delete virtual machine backups.

deltype

Specifies the deletion type. Specify one of the following values:

ACTIVE
: Delete only active file objects. Directory objects are not deleted. This value is the default deletion type.
  Note: If there are any inactive objects, then after the active object is deleted, the most current inactive object is changed from inactive to active.

  To delete all versions of a file, first issue the delete backup command with `-deltype=inactive`, then enter the command again with `-deltype=active`.

INACTIVE
: Delete only inactive file objects. Directory objects are not deleted.

ALL
: Delete all active and inactive objects below a particular directory, including all subdirectories and their files. Note: The parent directory of the deleted files and subdirectories is not deleted. If you specify `deltype=ALL`, you cannot use the pick option because `deltype=ALL` and the pick option are mutually exclusive.

Table 1. Delete Backup command: Related options

Option	Where to use
description	Command line only.
filelist	Command line only.
fromdate	Command line, and in the GUI find function.
fromtime	Command line, and in the GUI find function.
noprompt	Command line only.
pick	Command line only.
pitdate	Command line, and in the GUI find function.
pittime	Command line, and in the GUI find function.
subdir	Client options file (dsm.opt) or command line.
tapeprompt	Client options file (dsm.opt) or command line.
timeformat	Client options file (dsm.opt) or command line.
todate	Command line, and in the GUI find function.
totime	Command line, and in the GUI find function.

Examples

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Delete all active and inactive file objects that are named budget in directory /data/plan/proj1.
Commands:

```
delete backup /data/plan/proj1/budget.jan
  -deltype=inactive
delete backup /data/plan/proj1/budget.jan
  -deltype=active
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Delete all inactive files that have a .txt extension that were backed up from the /data/plan/proj1 directory and its subdirectories.

Command: `delete backup "/data/plan/proj1/*.txt" -deltype=inactive -subdir=yes`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Delete selected active files that are backed up from the /home/marymb/project directory. Use the -pick option to display a list of backup copies that match the file specification. From the list, you can select which versions to delete.

Command: `delete backup "/home/marymb/project/*" -pick`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Delete all active and inactive versions of files and subdirectories in the /home/storman/myproject directory. Then, delete all active and inactive versions of the /user/myproject directory.
Command:

```
delete backup "/home/storman/myproject*"
-deltype=all
```

Windows Task

Windows Delete all active file objects from file space abc in the proj directory.

Command: `delete backup {abc}\proj\*`

Windows Task

Windows Delete all inactive files with a name that ends with .txt that were backed up from the c:\plan\proj1 directory, and its subdirectories.

Command: `delete backup c:\plan\proj1\*.txt -deltype=inactive -subdir=yes`

Windows Task

Windows Delete selected active files that are backed up from the c:\project directory. Use the -pick option to display a list of backup copies that match the file specification. From the list, you can select which versions to delete.

Command: `delete backup c:\project\* -pick`

Windows Task

Windows Delete all active and inactive versions of files and subdirectories in c:\user\myproject.

Command: `delete backup c:\user\myproject\* -deltype=all`

Note: The backup versions of directory object c:\user\myproject are not deleted.

Windows Task

Windows Delete the active backup of a virtual machine that is named vm1.

Command: `delete backup -objtype=vm vm1`

Note: If one or more inactive versions of this backup exist, the most recent becomes the active version.

Windows Task

Windows Delete one or more backup versions of a virtual machine that is named vm_test.

Command: `delete backup -objtype=vm -inactive vm_test`

Note: All versions of backups for this VM node are displayed in a list; you select the versions to delete.

Delete Filespace

The delete filespace command deletes file spaces in IBM Spectrum Protect™ server storage. A file space is a logical space on the server that contains files you backed up or archived.

AIX Linux Solaris Mac OS X Mac OS X You must be an authorized user to use this command.

Mac OS X AIX Linux Solaris Mac OS X IBM Spectrum Protect assigns a separate file space on the server for each workstation file system from which you back up or archive files. The file space name is the same as the file system name.

Windows IBM Spectrum Protect assigns a separate file space on the server for each workstation file system from which you back up or archive files. The file space name is the same as the UNC name.

When you enter the delete filespace command, a list of your file spaces is displayed. From this list, select the file space that you want to delete.

Your IBM Spectrum Protect administrator must give you authority to delete a file space. You need BACKDEL authority if the file space you want to delete contains backup versions, or ARCHDEL authority if the file space contains archive copies. If the file space contains both backup versions and archive copies, you need both types of authority.

Important: When you delete a file space, you delete all backup versions and archive copies within that file space. When you delete a file space, ***you cannot restore the files***. Verify that the files are obsolete before you delete them.

AIX Linux Solaris Mac OS X Windows You can use the delete filespace command to interactively delete NAS file spaces from server storage. Use the nasnodename option to identify the NAS file server. Use the class option to specify the class of the file space to delete.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Delete Filespace--+------------+---------------------------><
                     '- --options-'
```

Parameters

Table 1. Delete Filespace command: Related options

Examples

Task

Delete a file space.

Command: `delete filespace`

AIX Linux Solaris Mac OS X Windows Task

AIX Linux Solaris Mac OS X Windows Delete NAS file spaces from the **dagordon** NAS file server stored on the server.

Command: `delete filespace -nasnodename=dagordon -class=nas`

Delete Group

Use the delete group command to delete a group backup on the IBM Spectrum Protect™ server.

After you delete a group, the group leader (virtualfsname) remains on the IBM Spectrum Protect server. It contains no members (file or directories) but is reported in a subsequent query filespace command. No files are listed if the showmembers option is added. Deleting a group does not remove the file space that it resides in because there might be other groups in it. Use delete filespace if you want to remove the file space and all the data it contains.

Note:

1. Use the inactive option to display both active and inactive group backup versions. By default, the client displays active versions.
2. Use the pick option to select a specific group to delete from the IBM Spectrum Protect server.
3. Use the noprompt option if you want to suppress the confirmation prompt that normally appears before you delete a group backup version. By default, the client prompts you for confirmation before you delete the group backup. Using this option can speed up the delete procedure. However, it also increases the danger of accidentally deleting a group backup version that you want to save. Use this option with caution.
4. Use the query filespace command to display virtual file space names for your node that are stored on the server.

AIX Linux Solaris Windows

Supported Clients

AIX Linux Solaris This command is valid for all UNIX and Linux clients, except for Mac OS X.

Windows This command is valid for all Windows clients.

Syntax

```
>>-Delete GRoup-- --filespec--+------------+------------------><
                              '- --options-'
```

Parameters

filespec
Specifies the virtual file space name and the group name that you want to delete from the server storage.

Table 1. Delete Group command: Related options

Option	Where to use
inactive	Command line only.
noprompt	Command line only.
pick	Command line only.
pitdate	Command line only.
pittime	Command line only.

Examples

AIX Linux Solaris Task

AIX Linux Solaris Delete the current active version of the `/virtfs/group1` group.

Command:

```
delete group /virtfs/group1
```

Windows Task

Windows Delete the current active version of the `virtfs\group1` group.

Command:

```
delete group {virtfs}\group1
```

AIX Linux Solaris Task

AIX Linux Solaris Delete a backup version of the `/virtfs/group1` group from a list of active and inactive versions.

Command:

```
delete group /virtfs/group1 -inactive -pick
```

Windows Task

Windows Delete a backup version of the `virtfs\group1` group from a list of active and inactive versions.

Command:

```
delete group {virtfs}\group1 -inactive -pick
```

Expire

The expire command deactivates the backup objects that you specify in the file specification or with the filelist option. You can specify an individual file to expire, or a file that contains a list of files to expire. If `OBJTYPE=VM`, this command deactivates the current backup for a virtual machine.

When you are working in interactive mode, a prompt notifies you before files are expired.

The expire command does not remove workstation files. If you expire a file or directory that still exists on your workstation, the file or directory is backed up again during the next incremental backup, unless you exclude the object from backup processing.

If you expire a directory that contains active files, those files are not displayed in a subsequent query from the GUI. However, these files are displayed on the command line, if you specify the correct query with a wildcard character for the directory.

AIX Linux Solaris Mac OS X Note: Because the expire command changes the server picture of the client file system without changing the client file system, the expire command is not allowed on files that are on a file system that is monitored by the IBM Spectrum Protect™ journal daemon.
Windows Note: Because the expire command changes the server picture of the client file system without changing the client file system, the expire command is not allowed on files that are on a file system that is monitored by the IBM Spectrum Protect journal service.
AIX Linux Mac OS X Solaris Windows

Supported Clients

This command is valid for all clients.

Syntax

```
              .-OBJTYPE=FILE-- --filespec-.
>>-EXPire-- --+---------------------------+--+----------------------+-->
                                            '-OBJTYPE=VM-- --vmname-'

>--+---------+-------------------------------------------------><
   '-options-'
```

Parameters

OBJTYPE=FILE filespec
: Specifies a path and a file name that you want to expire. You can enter only one file specification on this command. However, you can use wildcards to select a group of files or all the files in a directory. If you specify the filelist option, the `filespec` designation is ignored.

OBJTYPE=VM vmname
: `vmname` specifies the name of a virtual machine. The active backup for the specified virtual machine is expired. The virtual machine name cannot contain wildcard characters.

  When `objtype=VM` is specified, the expire command expires only full virtual machine backups (`MODE=FULL` or `MODE=IFFULL`) for the virtual machine that is specified on the `vmname` parameter. Backups that were created with the full or incremental mode were created with the version 7.1 or earlier client.

  This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments.

Table 1. Expire command: Related options

Option	Where to use
Windows dateformat	Windows Client options file (dsm.opt) or command line.

Windows numberformat	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X numberformat	AIX Linux Solaris Mac OS X Client user-options file (dsm.opt) or command line.
pick	Command line only.
Windows timeformat	Windows Client options file (dsm.opt) or command line.

Option	Where to use
AIX Linux Solaris Mac OS X timeformat	AIX Linux Solaris Mac OS X Client user-options file (dsm.opt) or command line.

Examples

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Deactivate the letter1.txt file in the `home` directory.

Command: `expire "/home/letter1.txt"`

Windows Task

Windows Deactivate the `letter1.txt` file in the home directory.

Command: `expire c:\home\letter1.txt`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Deactivate all files in the /admin/mydir directory.

Command: `expire /admin/mydir/*`

Windows Task

Windows Deactivate all files in the admin\mydir directory.

Command: `expire c:\admin\mydir\*`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Deactivate all files that are named in the /home/avi/filelist.txt file.

Command: `expire -filelist=/home/avi/filelist.txt`

Windows Task

Windows Deactivate all files that are named in the `c:\avi\filelist.txt` file.

Command: `expire -filelist=c:\avi\filelist.txt`

Windows Task

Windows Deactivate the current backup of the virtual machine that is named vm_test.

Command: `expire -objtype=VM vm_test`

Help

Use the help command to display information about commands, options, and messages.

Tip: If you use the help command on the initial command line, no server contact is made and no password is needed.
AIX Linux Solaris Mac OS X Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Help--+---------------------------------+--------------------><
         +-command-name [subcommand-name]-+
         +-option-name--------------------+
         +-TOC-section-number-------------+
         '-[ANS]message-number------------'
```

Entering the help command with no arguments causes help to display the complete table of contents. Either with the initial command or when HELP displays a prompt, you can enter the following parameters.

Parameters

command-name [subcommand-name]
: Specifies a command name and, optionally, a subcommand name or their abbreviation, for example: backup image, or b i. In that case, the combination must be unique. Non-unique abbreviations result in the display of the first section of the entire help file that matches the abbreviation. This parameter is optional.

option-name
: Specifies the name of an option, for example: domain or do. This parameter is optional.

TOC-section-number
: Specifies a table of contents section number, for example: 1.5.3. This parameter is optional.

[ANS]message-number
: Specifies a message number with or without its prefix, for example: ans1036 or 1036. This parameter is optional. The severity code is never necessary. Entering ans1036E results in a not-found response.

Important: If you enter arguments that do not fit these descriptions, you may get unexpected results (or no results) to be displayed. If you enter more than two arguments, your help request is rejected. Where a command name and an option name are the same, for example: incremental (command) and incremental (option), you can get help on the option by entering its table-of-contents section number.

The requested help text is displayed in one or more sections, depending on the number of display lines that are available in your command window. When enough lines are displayed to fill the display space, or when the end of the requested help text is displayed, you see a prompt along with instructions for what can be entered at that prompt. To continue displaying text for your current selection, press enter or type the `'d'` key to scroll down. To scroll up in the current selection, press the `'u'` key and press Enter. Other choices might be presented, so read the prompt instructions.

Proper display of the help text requires a usable display width of 72 characters. A display width fewer than 72 characters causes sentences that are 72 characters wide to wrap to the next line. This can cause the displayed help text to begin somewhere within the section rather than at the beginning. The undisplayed lines can be viewed by using the scrolling function of the terminal to move up.

Examples

Task
: Display the table of contents of the help topics.

  Command: `dsmc help`

Task
: Display the information in help topic 2.1.2

  Command: `dsmc help 2.1.2`

Task
: Display help information on the archive command.

  Command: `dsmc help archive`

Task
: Display help information on message ANS1036.

  Command: `dsmc help 1036`

  Command: `dsmc help ANS1036`

Incremental

The incremental command backs up all new or changed data in the locations that you specify, unless you exclude them from backup services.

AIX | Linux | Solaris | Mac OS X | Windows You can back up all new or changed files or directories in the default client domain or from file systems, directories, or files.

To incrementally back up selected files or directories, enter a file specification in the command. If you do not enter a file specification, the default is to back up files or directories in the default domain.

AIX AIX® only: You can enable snapshot-based incremental backup by using the option `snapshotproviderfs=JFS2`.

The following attributes in the management class that is assigned to the file or directory affect whether the data is backed up:

AIX Linux Solaris Mac OS X Windows Frequency

AIX Linux Solaris Mac OS X Windows The number of days that must elapse between successive backups of the object. The frequency attribute applies only to a full incremental backup.

AIX Linux This management class attribute is ignored during a journal-based backup.

Windows This management class attribute is ignored during a journal-based backup.

Mode

Specifies whether changes since the last backup operation affect the processing. If `mode=modified`, only objects that changed since the last backup operation are processed. If `mode=absolute`, every object is processed, regardless of whether the object changed since the last backup operation.

If the copy group mode is set to modified, it can be overridden by using the client absolute option. For more information about the absolute option, see Absolute.

Serialization

Permits or denies backup of files or directories according to the following values:

- static: To be backed up, data must not be modified during backup or archive.
- shared static: If data in the file or directory changes during each of the allowed attempts to back up or archive it, it is not backed up or archived. The value of the changingretries option determines how many attempts are made. The default is 4.
- dynamic: The object is backed up or archived on the first attempt whether or not data changes during the process.
- shared dynamic: The object is backed up or archived on the last attempt, even if data changes during the process.

Using the include option in an include-exclude list, you can override the default management class for a file or group of files.

You can perform either a full incremental backup or an incremental-by-date backup. The default is a full incremental backup.

AIX Windows Linux If you are journaling a file system and the journal is valid, the full incremental backup performs a journal-based backup. More than one journal-based backup session can be started, but only one journal-based backup session can proceed. All other journal-based backup sessions that need access to the same file space must wait until the current journal-based backup session completes before the next session can proceed. You can perform a full incremental backup without the journal by using the nojournal option.

You can also use the selective command to perform a backup that backs up only the files, directories, or empty directories that you specify regardless of whether they were changed.

AIX Linux Solaris Mac OS X A full incremental backs up all files and directories that are new or were changed since the last incremental backup. During a full incremental backup, the client queries the server. IBM Spectrum Protect™ uses this information when it performs the following actions:

Windows A full incremental backs up all files and directories that are new or were changed since the last incremental backup. During a full incremental backup, the client queries the server or the journal database. IBM Spectrum Protect uses this information when it performs the following actions:

- Backing up new files or directories.
- Backing up files or directories whose contents were changed since the previous backup.
- Marking inactive backup versions on the server for files or directories that are deleted from the workstation.
- Rebinding backup versions to management classes if the management class assignments change.

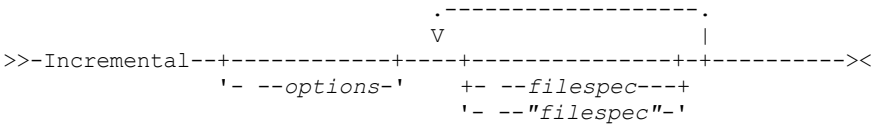
AIX Linux Solaris Mac OS X Windows

Supported Clients

This command is valid for all clients.

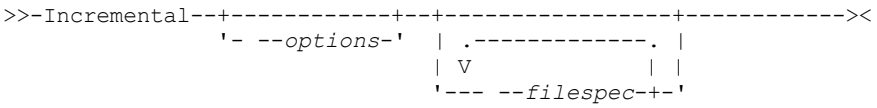
Mac OS X AIX Linux Solaris Mac OS X

Syntax



Windows

Syntax



Parameters

AIX Linux Solaris Mac OS X filespec

AIX Linux Solaris Mac OS X Specifies the path and file name that you want to back up. Use wildcard characters to select a group of files or all the files in a directory. If you do not specify a file specification, the domain option determine what to back up.

If you specify a file system, all new and changed files are backed up. In addition, the last incremental date for the file space is updated on the server. If you specify a file or directory, the last incremental date is not updated. This means that the file or directory might be backed up again if a later backup is performed by using the incrbydate option. If you specify a file system, specify the file system without a trailing slash.

Windows filespec

Windows Specifies the path and file name that you want to back up. Use wildcards to select a group of files or all the files in a directory. You can specify as many file specifications as available resources or other operating system limits permit. Separate file specifications with a space. You can also use the filelist option to process a list of files. The backup-archive client opens the file that you specify with this option and processes the list of files within according to the specific command. If you do not specify a file specification, the domain option determines what to backup.

If you specify a file system, all new and changed files are backed up. In addition, the last incremental date for the file space is updated on the server. If you specify a file or directory, the last incremental date is not updated. This means that the file or directory might be backed up again if a later backup is performed by using the incrbydate option. If you specify a file system, specify the file system without a trailing slash.

AIX Linux Solaris Mac OS X Run an incremental backup for the /home, /usr, and /proj file systems.

```
Incremental /home /usr /proj
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Run an incremental backup for the /proj/test directory.

```
Incremental /proj/test/
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Run an incremental-by-date backup for the /home file system.

```
Incremental -incrbydate /home
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Run an incremental backup of the abc file in the /fs/dir1 directory.

```
Incremental -subdir=yes /fs/dir1/abc
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Run an incremental backup of the directory object /fs/dir1, but not any of the files in the /fs/dir1 directory.

```
Incremental /fs/dir1
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Run an incremental backup of the directory object /fs/dir1, all of the files in the fs/dir1 directory, and all files and subdirectories under /fs/dir1.

```
Incremental -subdir=yes /fs/dir1/
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Assuming that you initiated a snapshot of the /usr file system and mounted the snapshot as /snapshot/day1, run an incremental backup of all files and directories under the local snapshot and manage them on the IBM Spectrum Protect server under the file space name /usr.

```
dsmc inc /usr -snapshotroot=/snapshot/day1
```

Windows Task

Windows Assuming that you initiated a snapshot of the C drive and mounted the snapshot as \\florence\c$\snapshots\snapshot.0, run an incremental backup of all files and directories under the local snapshot and manage them on the IBM Spectrum Protect server under the C:\ drive file space name.

```
dsmc inc c: -snapshotroot=\\florence\c$\snapshots\snapshot.0
```

Linux Task

Linux Run an incremental backup for the /home file system by using the snapdiff option and specify the option to create the difference snapshot. In the following example, /home is the NFS mount point for a NAS/N-Series file server volume.

```
incremental /home -snapdiff -diffsnapshot=create
```

AIX Task

AIX Run an incremental backup of the /proj file system by using the snapdiff option. Specify the option to use the latest snapshot on the file server as the difference snapshot. In the following example, /proj is the NFS mount point for a NAS/N-Series file server volume.

```
incremental /proj -snapdiff -diffsnapshot=latest
```

Windows Task

Windows Run a snapdiff incremental backup from a snapshot taken of a network share //homestore.example.com/vol1 mounted on drive H, where homestore.example.com is a file server.

```
incremental -snapdiff H:
```

Windows Task

Windows Run a snapdiff incremental backup from a snapshot taken of a network share //homestore.example.com/vol1 mounted on drive H, where homestore.example.com is a file server. The -diffsnapshot option value of LATEST means that the operation uses the latest snapshot (the active snapshot) for volume H.

```
incremental -snapdiff H: -diffsnapshot=LATEST
```

- Windows Open file support
  If open file support has been configured, the backup-archive performs a snapshot backup or archive of files that are locked (or "in use") by other applications.
- Windows Journal-based backup
  If the journal engine service is installed and running, then by default the incremental command performs a journal-based backup on file systems that are being monitored by the journal engine service.
- AIX Linux Journal-based backup
  A backup for a particular file system is journal-based when the IBM Spectrum Protect journal daemon is installed and configured to journal the file system, and a valid journal has been established.
- Backing up NTFS or ReFS volume mount points
  If you perform an incremental backup of a file system on which a volume mount point exists, IBM Spectrum Protect backs up the directory (junction) where the volume is mounted, but it does not traverse or back up the data on the mounted volume.
- Windows Back up Microsoft Dfs root
  If you perform an incremental backup of Microsoft Dfs root with dfsbackupmntpnt=*yes* specified, the backup-archive client

backs up only the junction points, *not* the subtree under the junctions.

- Incremental-by-Date
  An incremental-by-date backup backs up new and changed files with a modification date later than the date of the last incremental backup stored at the server, unless the files are excluded from backup by an **exclude** statement.
- Associate a local snapshot with a server file space
  Use the snapshotroot option with the incremental command in conjunction with a vendor-supplied application that provides a snapshot of a logical volume, to associate the data on the local snapshot with the real file space data that is stored on the IBM Spectrum Protect server.

Windows

Open file support

If open file support has been configured, the backup-archive performs a snapshot backup or archive of files that are locked (or "in use") by other applications.

Use VSS as the snapshot provider; set snapshotproviderimage or snapshotproviderfs to VSS.

Note:

1. You can use the include.fs option to set snapshot options on a per file system basis.
2. Open file support is only available for local fixed volumes (mounted to either drive letters or volume mount points) formatted with NTFS file systems. This support includes SAN-attached volumes that meet these requirements.
3. If the client is unable to create a snapshot, failover to non-OFS backup occurs; the same backup support that would be done if the OFS feature was not configured.
4. To enable open file support in a cluster environment all systems in the cluster should have the OFS feature configured.

Windows

Journal-based backup

If the journal engine service is installed and running, then by default the incremental command performs a journal-based backup on file systems that are being monitored by the journal engine service.

The backup-archive client does not use the journaling facility inherent in Windows NTFS or ReFS file systems or any other journaled file system.

The journal engine service records changes to an object or its attributes in a journal database. During a journal-based backup, the client obtains a list of files that are eligible for backup from the journal database. Performing backups regularly maintains the size of the journal.

Journal-based backup can increase backup performance. With journal-based backup, the client does not scan the local file system or obtain information from the server to determine which files to process. Journal-based backup also reduces network traffic between the client and server.

The client filters the list by using the current include-exclude list. IBM Spectrum Protect™ processes, expires, and updates the resulting files according to policy constraints, such as serialization. The management-class copy frequency attribute is ignored during journal-based backup.

The journal engine service excludes specific system files (pagefile, registry, and so on) from having changes recorded in the journal. Because changes to these files are not journaled, the client does not back up these files. See the journal service configuration file tsmjbbd.ini, which is in the backup-archive client installation directory, for specific system files that are excluded.

To support journal-based backup, you must install the journaling engine service. Install this service by using the dsmcutil command or the GUI Setup wizard.

If the file specification on the incremental command is a file space, the client processes any journal entries for that file space. The client processes directories and file specifications that contain wildcards in the same way. The client uses the domain list if you do not specify a file specification.

Note: Journal-based backup might not fall back to the traditional incremental backup if the policy domain of your node is changed on the server, depending on when the policy set within the domain was last updated and the date of the last incremental. In this case, you must force a full traditional incremental backup to rebind the files to the new domain. Use the nojournal option with the

incremental command to specify that you want to perform a traditional full incremental backup, instead of the default journal-based backup.

When a user deletes a file with a long name, the Windows operating system might supply a short (compressed) name to the journal engine service. After the object is deleted, the compressed name can be reused and the deletion notice might no longer identify a unique object. During a journaled incremental backup, the attempt to expire the file fails because the compressed name is not known to the server. When this failure occurs, a record is placed in the journal, which indicates that the current directory is not exactly represented at the server. Use the incrthreshold option to specify what action is taken when this occurs.

The journal database is considered invalid and the client reverts to the traditional full incremental backup when any of the following events occur:

- A journaled file space name changes.
- The client node name changes.
- The client contacts a different server to do the backup.
- A policy changes occurs (new policy set activation).
- The journal is corrupted (out of space conditions, disk error).
- The journal service is not running.
- The journal service is stopped or started for any reason, even if it is restarted because the system is rebooted.

Journal-based backup differs from the traditional full incremental backup in the following ways:

- IBM Spectrum Protect does not enforce non-default copy frequencies (other than 0).
- Attribute changes to an object require a backup of the entire object.

You can use the nojournal option with the incremental command to perform a traditional full incremental backup instead of the default journal-based backup.

Multiple journal-based backup sessions are possible.

AIX Linux

Journal-based backup

A backup for a particular file system is journal-based when the IBM Spectrum Protect™ journal daemon is installed and configured to journal the file system, and a valid journal has been established.

AIX Journal-based backup is supported on the AIX® Backup-Archive Client, on JFS and JFS2 file systems.

Linux Journal-based backup is supported on the Linux Backup-Archive client on Ext2, Ext3, Ext4; XFS, ReiserFS, JFS, VxFS, and NSS. GPFS™ is not supported for journal-based backups on Linux.

If the journal daemon is installed and running, then by default the incremental command performs a journal-based backup on file systems which are being monitored by the journal engine daemon. The following conditions must be met in order to successfully perform a journal-based backup:

- The journal daemon must be set up to monitor the file system that contains the files and directories being backed up.
- A full incremental backup must have been run successfully at least once on the file system being backed up.
- The file space image of the file system at the server cannot have been modified by an administrative command since the last full incremental backup.
- The storage management policy for the files being backed up cannot have been updated since the last full incremental backup.

The journal daemon records changes to an object or its attributes in a journal database. During a journal-based backup, the client obtains a list of files that are eligible for backup from the journal database. Journal-based backup can increase backup performance because the client does not scan the local file system or contact the server to determine which files to process. Journal-based backup also reduces network traffic between the client and server

The backup-archive client filters the list based on the current include-exclude list and processes, expires, and updates the resulting files according to policy constraints, such as serialization. However, the client ignores the server frequency attribute during a journal-based backup. The reason for this is because a journal-based backup eliminates the backup version query to the server; therefore, the client does not know how many days have transpired since the last backup of the file.

The journal daemon does not record changes in UNIX special files.

The journal daemon excludes specific system files from having changes recorded in the journal. Because changes to these files are not journaled, the client does not back up these files. See the journal daemon configuration file `tsmjbbd.ini` located in the backup-archive client installation directory for specific system files that are excluded.

Note:

1. When using antivirus software, there are limitations to journal-based backup. Some antivirus software can incorrectly generate change notifications to the IBM Spectrum Protect journal service, causing files that have not changed to be incorrectly backed up during journal based backup. To avoid these problems, use Norton Anti-Virus Corporate Edition 8.0 and higher.
2. A journal-based backup might not fall back to the traditional incremental backup if the policy domain of your node is changed on the server. This depends on when the policy set within the domain was last updated and the date of the last incremental backup. In this case, you must force a full traditional incremental backup to rebind the files to the new domain. Use the nojournal option with the incremental command to specify that you want to perform a traditional full incremental backup, instead of the default journal-based backup.

   AIX Add an exclude snapshot statement to the `tsmjbbd.ini` file for AIX 6.1 (or later) to prevent JFS2 internal snapshot directories from being monitored by the journal-based backup daemon. If you do not exclude the snapshot directories, the files in them are backed up. Backing up the snapshot directories is redundant and wastes server space.

Under the following conditions, the journal database is considered invalid and the client reverts to the traditional full incremental backup:

- A journaled file space name has changed.
- The client node name has changed.
- The client contacts a different server to do the backup.
- Policy changes have occurred (new policy set activation).
- The journal is corrupt (out of space conditions, disk error).
- The journal is not running.

Journal-based backup differs from the traditional full incremental backup in the following ways:

- IBM Spectrum Protect does not enforce non-default copy frequencies (other than 0).
- Changes to UNIX special files are not detected.

You can use the nojournal option with the incremental command to perform a traditional full incremental backup instead of the default journal-based backup.

Windows

Backing up NTFS or ReFS volume mount points

If you perform an incremental backup of a file system on which a volume mount point exists, IBM Spectrum Protect™ backs up the directory (junction) where the volume is mounted, but it does not traverse or back up the data on the mounted volume.

For example, if C:\mount is a mount point, then an incremental backup of the C:\ drive backs up only the junction (C:\mount), and not the data under C:\mount.

- Backing up data on NTFS or ReFS mounted volumes
  Backing up a volume from the mount point is especially useful for volumes that have no drive letter assignment. If the volume mounted on the mount point can also be referenced by drive letter, then the volume does not have to be backed up over the mount point.

Related concepts:
Restoring NTFS or ReFS volume mount points
Restoring data on NTFS mounted volumes
Backing up data on NTFS or ReFS mounted volumes
Windows

Back up Microsoft Dfs root

If you perform an incremental backup of Microsoft Dfs root with dfsbackupmntpnt=*yes* specified, the backup-archive client backs up only the junction points, *not* the subtree under the junctions.

If you want to traverse the Dfs tree and back up the files and subdirectories of any junction it encounters, specify the dfsbackupmntpnt=*no* option. If you want to backup both the Dfs tree structure and the date contained in the Dfs tree you must run two backups: one with dfsbackupmntpnt=*yes* and one with dfsbackupmntpnt=*no*.

This option has no effect if you are backing up individual junctions. The ***exclude.dir*** option behavior for Dfs junctions is same as for mounted virtual volumes.

Note: If a Dfs root is added or modified, the client will not back it up. You must specify the Dfs root in the domain option in the client options file (dsm.opt) regardless of whether DOMAIN ALL-LOCAL is specified.

Incremental-by-Date

An incremental-by-date backup backs up new and changed files with a modification date later than the date of the last incremental backup stored at the server, unless the files are excluded from backup by an **exclude** statement.

Windows If an incremental-by-date is performed on only part of a file system, the date of the last full incremental is not updated, and the next incremental-by-date will back up these files again. Use the query filespace command to determine the date and time of the last incremental backup of the entire file system.

AIX Linux Solaris Mac OS X If an incremental-by-date is performed on only part of a file system, the date of the last full incremental is not updated, and the next incremental-by-date will back up these files again. Changes to the access control lists (ACL) or Extended Attributes do not cause the files to be backed up during an incremental-by-date. Use the query filespace command to determine the date and time of the last incremental backup of the entire file system.

To perform an incremental-by-date backup, use the incrbydate option with the incremental command.

AIX Linux Solaris Mac OS X Windows Unlike a full incremental, an incremental-by-date does not maintain current server storage of *all* your workstation files for the following reasons:

- AIX Linux Solaris Mac OS X Windows It does not expire backup versions of files that are deleted from the workstation.
- It does not rebind backup versions to a new management class if the management class has changed.
- It does not back up files with attributes that have changed, unless the modification dates and times have also changed.
- It ignores the copy group frequency attribute of management classes.

AIX Linux Solaris Mac OS X Windows For these reasons, if you have limited time during the week to perform backups, but extra time on the weekends, you can perform an incremental-by-date backup on weekdays and a full incremental backup on weekends to maintain current server storage of your workstation files.

If the incremental command is retried because of a communication failure or session loss, the transfer statistics will display the number of bytes that the client attempted to transfer during all command attempts. Therefore, the statistics for bytes transferred might not match the file statistics, such as those for file size.

Associate a local snapshot with a server file space

Use the snapshotroot option with the incremental command in conjunction with a vendor-supplied application that provides a snapshot of a logical volume, to associate the data on the local snapshot with the real file space data that is stored on the IBM Spectrum Protect™ server.

The snapshotroot option does not provide any facilities to take a volume snapshot, only to manage data created by a volume snapshot.

Loop

The loop command starts an interactive command line session that is maintained until you enter `quit`.

If you are required to enter a password, you are prompted for it before the loop mode prompt appears.
Note: It is not possible to enter loop mode without a valid server contact. One of the consequences is that certain commands, such as `restore backupset -location=file`, are only accepted on the initial command line when a valid server is not available.

In an interactive command line session, it is unnecessary to precede each command name with **dsmc** and your password, if one is required.

Windows In interactive mode, options that you enter on the initial command line override the value that you specified in your client options file (dsm.opt). This value remains in effect for the entire interactive session unless overridden by a different value on a given interactive command. For example, if you set the subdir option to *yes* in your client options file (dsm.opt), and you specify subdir=*no* on the initial command line, the subdir=*no* setting remains in effect for the entire interactive session unless overridden by the subdir=*yes* value on a given interactive command. However, the subdir=*yes* value only affects the command it is entered on. When that command completes, the value reverts back to subdir=*no*, the value at the beginning of the interactive session.

AIX Linux Solaris Mac OS X In interactive mode, options that you enter on the initial command line override the value that you specified in your client user-options file (dsm.opt) or dsm.sys file. This value remains in effect for the entire interactive session unless overridden by a different value on a given interactive command. For example, if you set the subdir option to *yes* in your client user-options file (dsm.opt), and you specify subdir=*no* on the initial command line, the subdir=*no* setting remains in effect for the entire interactive session unless overridden by the subdir=*yes* value on a given interactive command. However, the subdir=*yes* value only affects the command it is entered on. When that command completes, the value reverts back to subdir=*no*, the value at the beginning of the interactive session.

You can enter all valid commands in interactive mode *except* the schedule and loop commands.

There are some options that you cannot use in the interactive session created by the loop command and are identified in the option description by this statement: *This option is valid only on the initial command line. It is not valid in interactive mode.*

AIX Linux Solaris Mac OS X Note:

1. In loop mode, following a restore operation directly from tape, the mount point is not released in case additional restore requests are made to that volume. If you request a backup operation in the same session and that mount point is the only one available, the backup operation stops with the following message:

   ```
   Waiting for mount of offline media
   ```

   In this case, the mount point is not released until one of the following conditions is met:
   - The device class MOUNTRETENTION limit is satisfied.
   - The client idletimeout period is satisfied.
   - The dsmc loop session is closed after the restore operation completes, allowing you to start a subsequent loop mode session to perform the backup operation.
2. In interactive mode, you cannot enter a file specification that contains national language characters. If a command contains national characters, process the command in batch mode by preceding the command with the executable program name, **dsmc**.

Supported Clients

This command is valid for all clients.

Syntax

```
>>-LOOP-------------------------------------------------------><
```

Parameters

There are no parameters for this command.

Examples

Task

Start an interactive command line session.

Command: `dsmc`

At the `Protect>` prompt, enter a command.

Windows To end an interactive session, enter `quit`

AIX Linux Solaris Mac OS X There are two methods for ending an interactive session:

AIX Linux Solaris Mac OS X

- Enter `quit`
- If you set editor=*yes*, you can do the following:
  1. Press the Escape key (Esc).
  2. Type Q and press the Enter key.

AIX Linux Solaris Mac OS X Note: The default setting is editor=*yes*.

Note: To interrupt a dsmc command before the client has finished processing, enter QQ on the IBM Spectrum Protect™ console. In many cases, but not all, this interrupts the command.

Macro

The macro command runs a series of commands that you specify in a macro file.

By including the macro command within a macro file, you can nest as many as 10 levels of commands.

Comment lines are not supported within the macro file that you specify for the macro command.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-MAcro-- --macroname-----------------------------------------><
```

Parameters

macroname
: Specifies the fully qualified name of the file that contains the commands.

Examples

The following is an example of how to use the macro command.

Task
: Selectively back up files in the following directories:

- Windows `c:\devel\project\proja`
- Windows `c:\devel\project\projb`
- Windows `c:\devel\project\projc`
- AIX Linux Solaris Mac OS X `/devel/project/proja`
- AIX Linux Solaris Mac OS X `/devel/project/projb`
- AIX Linux Solaris Mac OS X `/devel/project/projc`

AIX Linux Solaris Mac OS X Windows **Command:** `macro backabc.mac`

Where `backabc.mac` contains the following statements: AIX Linux Solaris Mac OS X

```
Selective /devel/project/proja/
Selective /devel/project/projb/
Selective /devel/project/projc/
```

Windows

```
selective c:\devel\project\proja\*.*
selective c:\devel\project\projb\*.*
selective c:\devel\project\projc\*.*
```

AIX Linux Solaris Windows

Monitor Process

The monitor process command displays a list of current NAS (if NDMP support is enabled) image backup and restore processes for which the administrative user has authority. You are prompted for the IBM Spectrum Protect™ administrator ID.

The administrative user can then select one process to monitor. Client owner privilege is sufficient authority to monitor the selected NAS image backup or restore processes.

Supported Clients

AIX | Linux | Solaris This command is valid for AIX®, Linux, and Solaris clients only.

Windows This command is valid for all Windows clients.

Syntax

```
>>-MONitor Process-------------------------------------------><
```

Parameters

There are no parameters for this command.

Examples

Task
: Monitor current NAS image backup or restore processes.

  Command: `monitor process`

Preview Archive

The preview archive command simulates an archive command without sending data to the server.

The preview archive command generates a tab-delineated text file that can be imported into a spreadsheet program. The preview contains information such as whether the file is excluded or included. If the file is excluded, the pattern, or reason, that the file is excluded is listed, along with the source for the pattern.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This command is valid for all clients.

Syntax

```
                              .- -filter=ALL--.
>>-PREview--Archive--filespec--+- -filter=INCL-+---------------->
                              '- -filter=EXCL-'

>--+----------------------+--+-----------+---------------------->
   '- -FILEName= filename-'  '- -CONsole-'

   .- -TRAverse=Yes-.
>--+----------------+-----------------------------------------><
   '- -TRAverse=No--'
```

Parameters

filespec
: Specifies the path and file name that you want to archive. Use wildcard characters to select a group of files or all the files in a directory.

-filter

Specifies the output to display. You can display included objects, excluded objects, or both.

ALL
: Display output for included and excluded objects. This is the default.

INCLuded
: Display output for included objects only.

EXCLuded
: Display output for excluded objects only.

-FILEName=
: Specifies the filename in which to write the tab-delineated output. The default is dsmprev.txt.

-CONsole
: Output is written to the console, and the file.

-TRAverse
: Preview the current directory and subdirectories.

Yes
: Preview the current directories and subdirectories. This is the default.

No
: Preview only the current directory, not subdirectories.

Important: Specifying **-traverse** does not preview directories excluded using the exclude.dir option.

Preview Backup

The preview backup command simulates a backup command without sending data to the server.

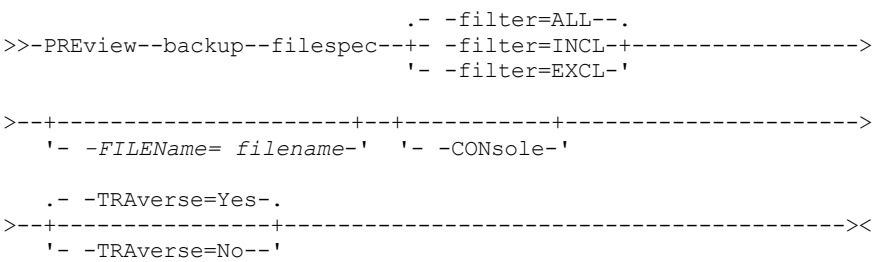
The preview backup command generates a tab-delineated text file that can be imported into a spreadsheet program. The preview contains information such as whether the file is excluded or included. If the file is excluded, the pattern, or reason, that the file is excluded is listed, along with the source for the pattern.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This command is valid for all clients.

Syntax



Parameters

filespec
: Specifies the path and file name that you want to back up. Use wildcard characters to select a group of files or all the files in a directory.

-filter
: Specifies the output to display. You can display included objects, excluded objects, or both.

ALL
: Display output for included and excluded objects. This is the default.

INCLuded
: Display output for included objects only.

EXCLuded

Display output for excluded objects only.

-FILEName=
Specifies the filename in which to write the tab-delineated output. The default is dsmprev.txt.

-CONsole
Output is written to the console, and the file.

-TRAverse
Preview the current directory and subdirectories.

Yes
Preview the current directories and subdirectories. This is the default.

No
Preview only the current directory, not subdirectories.

Important: Specifying **-traverse** does not preview directories excluded using the exclude.dir option.

Query Access

The query access command shows who was given access to backup versions or archive copies of specific files.

The backup-archive client displays a list of authorization rules that you defined with the set access command or with the Utilities > Node Access List menu in the backup-archive client graphical user interface (GUI).

The following information is included.

- Authority that you gave a user to restore backup versions or retrieve archive copies.
- The node name of the user to whom you gave authorization.
- AIX | Linux | Solaris | Mac OS X The ID of the user at that node to whom you gave authorization.
- The files to which the user has access.

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Query ACcess-------------------------------------------------><
```

Parameters

There are no parameters for this command.

Examples

Task
Display a list of users who have access to your files.

Command: `query access`

Windows

Query Adobjects

Use the query adobjects command to display information about the deleted objects that are located on the local Active Directory domain.

On Windows Server operating system clients, Active Directory object information can also be displayed from full system-state backups on the server.

Supported Clients

This command is valid for Windows Server OS clients only.

Syntax

```
>>-Query ADOBJects--+-------------------+--+---------+---------><
                    '- --sourcepathspec-'  '-options-'
```

Parameters

sourcepathspec

Specifies the Active Directory object or container to query. You can specify an asterisk (*) as a wildcard character. You can specify either the full distinguished name of an object or a container, or just the name attribute (cn or ou), where the wildcard might be used. You can also specify object GUID enclosed in braces ({}). The following special characters require an escape character, the backslash, (\), if any of them are contained in the name:

- \
- #
- +
- =
- <
- >

For example, `"cn=test#"` is entered as `"cn=test\#"`.

The client cannot display any object names that contain an asterisk (*) as part of the name.

Table 1. Query Adobjects command: Related options

Option	Where to use
adlocation	Command line only.
dateformat	Client options file (dsm.opt) or command line.
detail	Command line only.
pitdate (option is ignored when adlocation is not specified)	Command line only.
pittime (option is ignored when adlocation is not specified)	Command line only.
scrolllines	Client options file (dsm.opt) or command line.
scrollprompt	Client options file (dsm.opt) or command line.
timeformat	Client options file (dsm.opt) or command line.

Examples

Task

Query all local deleted objects.

Command: `query adobjects`

Task

Query all local deleted objects for a user with the name starting with `Fred`.

Command: `query adobjects "cn=Fred*" -detail`

Task

Query all objects that are located in the `Users` container of the `bryan.test.example.com` domain from the server.

Command: `query adobjects "cn=Users,DC=bryan,DC=test,DC=ibm,DC=com" -adloc=server`

Task

Query all local deleted objects for organizational unit `testou`.

Command: `query adobjects "ou=testou"`

Task
Query the local deleted object with a GUID of `E079130D-3451-4C69-8349-31747E26C75B`.

Command: `query adobjects {E079130D-3451-4C69-8349-31747E26C75B}`

Query Archive

The query archive command displays a list of your archived files and the following information about each file: file size, archive date, file specification, expiration date, and archive description.

If you use the detail option with the query archive command, the client displays the following additional information:

- Last modification date
- AIX Linux Solaris Mac OS X Last access date
- AIX Linux Solaris Mac OS X Last file attributes (inode) change date
- Windows Creation date
- Compression type
- Encryption type
- AIX Linux Mac OS X Solaris Windows Client-side data deduplication
- Retention initiation
- Whether the file is on hold
- AIX Linux Size of ACL metadata (IBM Spectrum Scale™), for AIX® and Linux clients
- AIX Linux Server storage information (media class, volume ID, and restore order), for AIX and Linux clients

The following example shows sample output when the query archive command is issued with the detail option:.

AIX Linux Mac OS X Solaris

```
Size Archive Date - Time File - Expires on - Description
---- ------------------- ----------------------------
219 B 08/15/2016 09:32:13 /Volumes/Data/info.txt 08/16/2016

```

For more information about the compression type, see Compression.

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Query ARchive--+------------+-------------------------------->
                  '- --options-'

>--+- --filespec----------------------+--+- --filespec---+-----><
   '- --{--filespacename--}--filespec-'  '- --"filespec"-'
```

Parameters

AIX Linux Solaris Mac OS X filespec

AIX Linux Solaris Mac OS X Specifies the path and file name that you want to query. Use wildcard characters to specify a group of files or all the files in a directory. If you use wildcard characters, enclose the file specification in double quotation marks. Specify an asterisk (*) to query all archived files in the current directory.

Windows filespec

Windows Specifies the path and file name that you want to query. Use wildcard characters to specify a group of files or all the files in a directory.

If you include filespacename, do not include a drive letter in the file specification. Drive label names are only used for removable media.

Windows {filespacename}

Windows Specifies the file space (enclosed in braces) on the server that contains the file that you want to query. The file space is the name on the workstation drive from which the file was archived. The following example is valid for specifying a UNC name: {'\\machine\C$'}.
Use the filespacename if the name was changed or if you are querying files that were archived from another node with drive labels that are different from yours.
Note: You must specify a mixed or lowercase NTFS filespacename that is enclosed in quotation marks within braces, for example, {"NTFSDrive"}. Single quotation marks or double quotation marks are valid in loop mode. For example: {"NTFSDrive"} and {'NTFSDrive'} are both valid. In batch mode, only single quotation marks are valid.

Table 1. Query Archive command: Related options

Option	Where to use
Windows dateformat	Windows Client options file (dsm.opt) or command line.

AIX Linux Solaris Mac OS X subdir	AIX Linux Solaris Mac OS X Client user-options file (dsm.opt) or command line.

Option	Where to use
Windows timeformat	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X timeformat	AIX Linux Solaris Mac OS X Client user-options file (dsm.opt) or command line.
todate	Command line only.
totime	Command line only.

Examples

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Display a list of all your archived files in the current working directory.

Command: `q archive "*"`

Windows Task

Windows Display a list of all your archived files in the `c:\proj` directory.

Command: `q ar c:\proj\*`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Display a list of all your archived files in the `/devel` directory and all of its subdirectories.

Command: `query archive "/devel/*" -subdir=yes`

Windows Task

Windows Display a list of archived files from your `c:` drive with the description "January Ledgers".

Command: `query archive c:\ -su=y -descr="January Ledgers"`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Display a list of all your archived files in the current directory. Use the dateformat and timeformat options to reformat the dates and times.

Command: `q ar -date=5 -time=1 "*"`

Windows Task

Windows Display a list of all your archived files in the `c:\proj` directory. Use the dateformat and timeformat options to reformat the dates and times.

Command: `q ar -date=5 -time=4 c:\proj\*`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Display a list of all your archived files in the current directory. Use the detail option to display the last modification date and the last access date of each file.

Command: `q ar -detail "*"`

Windows Task

Windows Display a list of all your archived files in the `c:\dir1` directory. Use the detail option to display the last modification date and the creation date of each file.

Command: `q ar -detail c:\dir1\*`

Windows Task

Windows Display a list of archived files in the `c:\proj` directory that contains a file extension of `.dev`. Use the dateformat and timeformat options.

Command: `q ar -date=5 -time=4 c:\proj\*.dev`

Windows Task

Windows Recently you changed the label of your `c:\` drive to `store` and archive some files. Then, yesterday the label was changed to `dev` and some more files were archived. Display a list of all the files you archived in the `c:\proj` directory when the label was `store`.

Command: `q ar {store}\proj\*`

Windows Task

Windows Recently you archived files from a diskette labeled `docs`. Display a list of all the files you archived.

Command: `q ar {docs}\*`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Display a list of archived files in the `/home/proj` directory whose first four characters of the file name begin with `proj`.

Command: `q ar "/home/proj/proj*"`

Query Backup

The query backup command displays a list of backup versions of your files that are stored on the IBM Spectrum Protect™ server, or that are inside a backup set from the server when the backupsetname option is specified.

The command displays the following file information:

- File specification
- File size
- Backup date
- Whether the file is active or inactive
- The management class that is assigned to the file. Only the first 10 characters of the management class name are displayed.

If you use the detail option with the query backup command, the client displays the following extra information:

- Last modification date
- AIX Linux Solaris Mac OS X Last access date
- AIX Linux Solaris Mac OS X Last file attributes (inode) change date
- Windows Creation date
- Compression type
- Encryption type
- Client-side data deduplication
- AIX Linux Whether the file is migrated or premigrated. A value of `Yes` means that the file is migrated or premigrated. A value of `No` means that the file is not migrated or premigrated.
- AIX Linux File inode number
- AIX Linux Size of ACL metadata (IBM Spectrum Scale™)
- AIX Linux Server storage information (media class, volume ID, and restore order)

The following example shows sample output when the query backup command is issued with the detail option:

AIX Linux Mac OS X Solaris

```
      Size        Backup Date               Mgmt Class           A/I File

Compression Type: LZ4  Encryption Type: None    Client-deduplicated: YES
```

For more information about the compression type, see Compression.

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Query Backup--+------------+---------------------------------->
                 '- --options-'

>--+- --filespec----------------------+--+- --filespec---+-----><
   '- --{--filespacename--}--filespec-'  '- --"filespec"-'
```

Parameters

AIX Linux Solaris Mac OS X filespec

AIX Linux Solaris Mac OS X Specifies the path and file name that you want to query. Use wildcard characters to specify a group of files or all the files in a directory. If you use wildcard characters, enclose the file specification in double quotation marks. Specify an asterisk (*) to display information about backup versions for all of your files in the current directory. Do not use wildcards characters when you query NAS file system images with `-class=nas` option setting.

Windows filespec

Windows Specifies the path and file name that you want to query. Use wildcard characters to specify a group of files or all the files in a directory. Do not use wildcard characters when you query NAS file system images with `-class=nas` option setting.

If you include filespacename, do not include a drive letter in the file specification. Drive label names are only used for removable media.

You can also use the following value for *filespec*:

systemstate
: Displays the list of backup versions of Windows system state.

Windows {filespacename}

Windows Specifies the file space, enclosed in braces, on the server that contains the file you want to query. This is the drive label or UNC name on the workstation drive from which the file was backed up. The following example shows how to specify a UNC name: `{'\\machine\C$'}`.

Use the *filespacename* if the name has changed, or if you want to query files backed up from another node with drive label names that are different from yours.

You must specify a mixed or lowercase NTFS or ReFS file space name that is enclosed in quotation marks and braces. For example, `{"NTFSDrive"}`. Single quotation marks or double quotation marks are valid in loop mode. For example: `{"NTFSDrive"}` and `{'NTFSDrive'}` are both valid. In batch mode, only single quotation marks are valid.

AIX Linux Solaris Mac OS X timeformat	AIX Linux Solaris Mac OS X Client user-options file (dsm.opt) or command line.
todate	Command line only.
totime	Command line only.

Examples

Windows
```
dsmc query backup c:\* -subdir=yes -querysummary
```

Windows
```
dsmc query archive c:\* -subdir=yes -querysummary
```

Windows Task

Windows Query files from the `abc` file space `proj` directory.

```
dsmc query backup {"abc"}\proj\*.*
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Display a list of all active and inactive backup versions of your files in the current directory.

```
dsmc query backup -inactive "*"
```

Windows Task

Windows Display a list of all active and inactive backup versions that were backed up from the `c:\proj` directory.

```
dsmc q backup -ina c:\proj\*
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Display a list of all your backups in the current directory. Use the detail option to display the last modification date and the last access date of each file.

```
dsmc q backup -detail "*"
```

Windows Task

Windows Display a list of all your backups in the `c:\dir1` directory. Use the detail option to display the last modification date and the creation date of each file.

```
dsmc q backup -detail c:\dir1\*
```

Windows Task

Windows Display a list of all active and inactive backup versions that were backed up from the `c:\proj` directory. Use the dateformat and timeformat options to reformat the dates and times.

```
dsmc q b -date=5 -time=4 -ina c:\proj\*
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Display a list of files that were backed up from the `/home/proj` directory with file names that begin with proj.

```
dsmc q b "/home/proj/proj*"
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Display a list of active and inactive backup file versions in the `/home` file system.

```
dsmc q b -ina -su=yes /home/
```

Windows Task

Windows Last week you backed up files from a diskette labeled **docs**. Display a list of those files.

```
dsmc q b {docs}\*
```

AIX Linux Solaris Task

AIX Linux Solaris Query file system images from the nas2 NAS file server.

```
dsmc query backup -nasnodename=nas2 -class=nas
```

Windows Task

Windows Query file system images from the nas2 NAS file server.

```
dsmc query backup -nasnodename=nas2 -class=nas
```

Windows Task

Windows Display a list of all files from your c drive that are contained in the backup set `weekly_accounting_data.32145678`.

```
dsmc query backup c:\* -subdir=yes -backupsetname=weekly_accounting_data.32145678
```

Windows Task

Windows Display information about all the active and inactive backup versions of the system state on the server.

```
dsmc query backup -ina systemstate
```

- AIX Linux Solaris Mac OS X Windows Query NAS file system images

  You can use the query backup command to display information about file system images backed up for a NAS file server. The client prompts you for an administrator ID.

Query Backupset

The query backupset command queries a backup set from a local file, tape device (if applicable), or the IBM Spectrum Protect™ server.

This command displays the backup set name, generation date, retention (for a backup set on the IBM Spectrum Protect server), and user-supplied description.

Supported Clients

This command is valid for all clients.

AIX Solaris Tape support is only available on AIX® and Oracle Solaris clients.

Syntax

```
>>-Query BACKUPSET--+---------+--BACKUPSETName=----------------->
                    '-options-'

>--+-backupsetname-+--+----------------------+----------------><
   +-localfilename-+   '-LOCation=--+-server-+-'
   '-tapedevice----'                +-file---+
                                    '-tape---'
```

Parameters

BACKUPSETName=

Specifies the name of a backup set you want to query. You can use wildcards to specify the backup set name. If you use wildcards or do not specify a backup set name, all backup sets that you own are displayed. This parameter is required.

AIX Linux Solaris Mac OS X When a backup set is created, the server assigns root as the owner of the backup set. When querying a backup set on the server, a non-root user does not see the backup set listed, even if they know the backup set name and use it in the query.

The value of backupsetname depends on the location of the backup set, and corresponds to one of these three choices:

backupsetname

Specifies the name of the backup set from the server. If the location parameter is specified, you must set `-location=server`.

localfilename

Specifies the file name of the first backup set volume. You must set `-location=file`.

tapedevice

Specifies the name of the tape device that contains the backup set volume. You must use a Windows native device driver, not the device driver that is provided by IBM. You must set `-location=tape`.

LOCation=

Specifies where the backup-archive client searches for the backup set. If you do not specify the location parameter, the client searches for backup sets on the IBM Spectrum Protect server.

server

Specifies that the client searches for the backup set from the server. This location is the default.

file

Specifies that the client searches for the backup set from a local file.

tape

Specifies that the client searches for the backup set from a local tape device.

Table 1. Query Backupset command: Related options

Option	Where to use
AIX Linux Solaris Mac OS X description	AIX Linux Solaris Mac OS X Command line only.
Windows description	Windows Command line only.
Windows scrolllines	Windows Client options file (dsm.opt) or command line.
AIX Linux Mac OS X Solaris scrolllines	AIX Linux Mac OS X Solaris Client user-options file (dsm.opt) or command line.
Windows scrollprompt	Windows Client options file (dsm.opt) or command line.
AIX Linux Mac OS X Solaris scrollprompt	AIX Linux Mac OS X Solaris Client user-options file (dsm.opt) or command line.

Examples

Task

Query all backup sets from the IBM Spectrum Protect server.

Command: `query backupset -backupsetname=*`

Task
Query a backup set that is called `monthy_financial_data` from the IBM Spectrum Protect server.

Command: `query backupset -backupsetname=monthly_financial_data.12345678`

AIX Linux Mac OS X Solaris Task
AIX Linux Mac OS X Solaris Query the backup set in the file `/home/budget/weekly_budget_data.ost`.

Command: `dsmc query backupset -backupsetname="/home/budget/weekly_budget_data.ost" -loc=file`

Windows Task
Windows Query the backup set in the file `c:\budget\weekly_budget_data.ost`.

Command: `query backupset -backupsetname=c:\budget\weekly_budget_data.ost loc=file`

AIX Linux Solaris Mac OS X Task
AIX Linux Solaris Mac OS X Query the backup set from the /dev/rmt0 tape device.

Command: `dsmc query backupset -backupsetname=/dev/rmt0 -loc=tape`

Windows Task
Windows Query the backup set from the \\.\tape0 tape device.

Command: `dsmc query backupset -backupsetname=\\.\tape0 -loc=tape`

- Query Backupset without the backupsetname parameter
  The query backupset command can be used without the backupsetname parameter.

Query Filespace

The query filespace command displays a list of file spaces for a node. The file spaces are stored on the IBM Spectrum Protect™ server, or inside a backup set from the server when the backupsetname option is specified. You can also specify a single file space name to query.

A *file space* is a logical space on the server that contains files you backed up or archived. A separate file space is assigned on the server for each node at your workstation from which you back up or archive files.

A separate file space is assigned on the server for each file system at your workstation from which you back up or archive files. The file space name is the same as the file system name.

Windows A Unicode file space name might not display correctly if the server is unable to display the Unicode name. In this case, use the file space identifier (fsID) to identify these file spaces on the server. Use the query filespace command with the detail option to determine the fsID of a file space.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Query Filespace--+------------------+--+------------+------->< 
                    '- --filespacename-'  '- --options-'
```

Parameters

filespacename
Specifies an optional character string that can include wildcards. Use this argument to specify a subset of file spaces. The default is to display all file spaces.

Table 1. Query Filespace command: Related options

Option	Where to use
backupsetname	Command line only.
Windows AIX Linux Solaris Mac OS X class	Windows AIX Linux Solaris Mac OS X Command line only.
Windows dateformat	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X dateformat	AIX Linux Solaris Mac OS X Client user-options file (dsm.opt) or command line.
detail	Command line only.
fromnode	Command line only.
AIX Linux Solaris Mac OS X Mac OS X fromowner	AIX Linux Solaris Mac OS X Mac OS X Command line only.
AIX Linux Solaris Mac OS X nasnodename	AIX Linux Solaris Mac OS X Client system options file (dsm.sys) or command line.
Windows nasnodename	Windows Client options file (dsm.opt) or command line.
Windows scrolllines	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X scrolllines	AIX Linux Solaris Mac OS X Client user-options file (dsm.opt) or command line.
Windows scrollprompt	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X scrollprompt	AIX Linux Solaris Mac OS X Client user-options file (dsm.opt) or command line.
Windows timeformat	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X timeformat	AIX Linux Solaris Mac OS X Client user-options file (dsm.opt) or command line.

Examples

AIX Linux Solaris Mac OS X Windows Display your file spaces. Use the dateformat and timeformat options to reformat the dates and times.

```
query filespace -date=5 -time=4
```

AIX Linux Solaris Mac OS X Display the /home file space.

```
query filespace /home
```

AIX Linux Solaris Mac OS X Display file space names that include the pattern `smith`.

```
query filespace "*smith*"
```

AIX Linux Solaris Mac OS X Windows Query a file space from the `nas2` NAS file server.

```
query filespace -nasnodename=nas2 -class=nas
```

Windows Display the \\florence\c$ file space.

```
query filespace \\florence\c$
```

Windows Display all of the file space names on the server with a file space name that ends in `'$'` belonging to system named `florence`.

```
query filespace \\florence\*$
```

Windows Display file spaces in the backup set named `monthly_accounting.23456789`.

```
query filespace -backupsetname=monthly_accounting.23456789
```

Display detailed file space information that shows the replication status during a failover.

Command:

```
query filespace -detail
```

Output:

```
#   Last Incr Date       Type    fsID  Unicode  Replication  File Space Name
---  --------------       ------ ----  -------  -----------  --------------
  1  00/00/0000 00:00:00  HFS       3  Yes      Current      /

       Last Store Date     Server                 Local
       ---------------     ------                 -----
          Backup Data :    04/29/2013 16:49:55    04/29/2013 16:49:55
        Archive Data :     No Date Available      No Date Available
```

- AIX Linux Solaris Mac OS X Windows Query NAS file spaces
  Use the nasnodename option to identify the NAS file server to query. When using an interactive command-line session with a non-administrative ID, the client prompts you for an administrator ID.

Query Group

Use the query group command to display information about a group backup and its members.

Note:

1. Use the showmembers option to display and select individual group members that you want to query. The showmembers option is not valid with the inactive option. If you want to display members of a group that are not currently active, use the pitdate and pittime options to specify the backup date and time of the member you want to query.
2. AIX Linux Solaris Windows Use the query filespace command to display virtual file space names for your node that are stored on the IBM Spectrum Protect™ server.
3. If you perform a full and differential group backup, a query of this group using the -inactive option displays two active backups of the same name, one of type FULL and one of type DIFF.

   Windows These backups inactivate any previous full and differential backups:

   Windows

   ```
   Protect> q group {\fs}\v1 -inactive

   Size Backup Date          Mgmt Class A/I Group
   ---- -----------          ---------- --- ------
    978 B 06/02/2007 11:57:04  DEFAULT   A  FULL \fs\v1
     32 B 06/05/2007 13:52:04  DEFAULT   A  DIFF \fs\v1
   ```

   AIX Linux Solaris

   ```
   Protect> q group {/fs}/v1 -inactive

   Size Backup Date          Mgmt Class A/I Group
   ---- -----------          ---------- --- ------
    978 B 06/02/2007 11:57:04  DEFAULT   A  FULL /fs/v1
     32 B 06/05/2007 13:52:04  DEFAULT   A  DIFF /fs/v1
   ```

   If you query a group backup without the -inactive option, the query displays only the latest group backup, whether it is type FULL or type DIFF:

   Windows

   ```
   Protect> q group {\fs}\v1

   Size Backup Date          Mgmt Class A/I Group
   ---- -----------          ---------- --- ------
     32 B 06/05/2007 13:52:04  DEFAULT   A  DIFF \fs\v1
   ```

   AIX Linux Solaris

   ```
   Protect> q group {/fs}/v1

   Size Backup Date          Mgmt Class A/I Group
   ---- -----------          ---------- --- ------
     32 B 06/05/2007 13:52:04  DEFAULT   A  DIFF /fs/v1
   ```

Supported Clients

AIX Linux Solaris This command is valid for all clients, except for Mac OS X.

Windows This command is valid for all clients.

Syntax

```
>>-Query GRoup-- --filespec--+------------+--------------------><
                             '- --options-'
```

Parameters

Windows filespec

Windows Specifies the virtual file space name (enclosed in braces) and the group name on the server that you want to query.

AIX Linux Solaris filespec

AIX Linux Solaris Specifies the virtual file space name and the group name on the server that you want to query.

Table 1. Query Group command: Related options

Option	Where to use
fromnode	Command line only.
AIX Linux Solaris fromowner	AIX Linux Solaris Command line only.
inactive	Command line only.
pitdate	Command line only.
pittime	Command line only.
AIX Linux Solaris Windows showmembers (does not apply to Mac OS X)	AIX Linux Solaris Windows Command line only.

Examples

AIX Linux Solaris Task

AIX Linux Solaris Display all the groups in the `/virtfs` file space.

Command:

```
query group /virtfs/*
```

Windows Task

Windows Display all the groups in the `virtfs` file space.

Command:

```
query group {virtfs}\*
```

AIX Linux Solaris Task

AIX Linux Solaris Display active and inactive versions of the `/virtfs/group1` file space.

Command:

```
query group /virtfs/group1 -inactive
```

Windows Task

Windows Display active and inactive versions of the `virtfs\group1` file space.

Command:

```
query group {virtfs}\group1 -inactive
```

AIX Linux Solaris Task

AIX Linux Solaris Display the `/virtfs/group1` file space. Use the showmembers option to display a list of group members from which you can select one or more to query.

Command:

```
query group /virtfs/group1 -showmembers
```

Windows Task

Windows Display the `virtfs\group1` file space. Use the showmembers option to display a list of group members from which you can select one or more to query.

Command:

```
query group {virtfs}\group1 -showmembers
```

AIX Linux Solaris Windows

Query Image

The query image command displays information about file system images that are stored on the IBM Spectrum Protect™ server, or that are inside a backup set from the IBM Spectrum Protect server, when the backupsetname option is specified.

The following information about file system images is displayed:

- Image Size - The volume size which was backed up.
- AIX Linux Solaris Stored Size - The actual image size that is stored on the server. The stored image on the IBM Spectrum Protect server is the same size as the volume capacity. For online snapshot-based image backups, the stored image can be larger than the file system based on the size of the cache files. The stored image on the server is the same size as the volume capacity.
- Windows Stored Size - The actual image size that is stored on the server. Because image backup allows you to back up only used blocks in a file system, the stored image size on the IBM Spectrum Protect server could be smaller than the volume size. For online image backups, the stored image can be larger than the file system based on the size of the cache files.
- File system type
- Backup date and time
- Management class that is assigned to image backup
- Whether the image backup is an active or inactive copy
- The image name

Note: The IBM Spectrum Protect API must be installed to use the query image command.

Supported Clients

AIX Linux Solaris This option is valid for AIX®, Linux, and Oracle Solaris clients.

Windows This command is valid for all Windows clients.

Syntax

```
>>-Query IMage--+------------+--+- --logicalvolumename-+-------><
                '- --options-'  '- --filespacename-----'
```

Parameters

logicalvolumename
: The name of a logical volume you want to query. You must specify the exact name of the image. You cannot use wildcards. The default is all active images (unless restricted by one or more options).

filespacename
: Specifies the file system name that you want to query.

  Omitting *logicalvolumename* and *filespacename* causes all images to be displayed.

Table 1. Query Image command: Related options

Option	Where to use
backupsetname	Command line only.
AIX Linux Solaris dateformat	AIX Linux Solaris Client user option file (dsm.opt) or command line.

Option	Where to use

fromnode	Command line only.
AIX Linux Solaris fromowner	AIX Linux Solaris Command line only.
inactive	Command line only.
AIX Linux Solaris numberformat	AIX Linux Solaris Client user option file (dsm.opt) or command line.
Windows numberformat	Windows Client option file (dsm.opt) or command line.
pitdate	Command line only.
pittime	Command line only.
AIX Linux Solaris scrolllines	AIX Linux Solaris Client user options file (dsm.opt) or command line.
Windows scrolllines	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris scrollprompt	AIX Linux Solaris Client user options file (dsm.opt) or command line.
Windows scrollprompt	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris timeformat	AIX Linux Solaris Client user option file (dsm.opt) or command line.
Windows timeformat	Windows Client option file (dsm.opt) or command line.

Examples

Task

Display all backed up images.

Command: `q image`

AIX Linux Solaris Task

AIX Linux Solaris Display all backed up images that are owned by `kutras` at node `avalon`.

Command: `query image -fromnode=avalon -fromowner=kutras`

AIX Linux Solaris Task

AIX Linux Solaris Display active and inactive version of the `/usr` image.

Command: `q i /usr -inactive`

Windows Task

Windows Display active and inactive version of the `h:` image.

Command: `q im h: -inactive`

Task

Display all images that are contained within the backup set `weekly_backup_data.32145678`.

Command: `query image -backupsetname=weekly_backup_data.32145678`

Query Inclexcl

The query inclexcl command displays a list of include-exclude statements in the order in which they are processed during backup and archive operations. The list displays the type of option, the scope of the option (archive, all, and so on), and the name of the source file.

The backup-archive client excludes some files from file system backup and restore operations. You can use the query inclexcl command to display a list of these files. In the output of the command, these files have `Operating System` next to the path.

You can test the validity of patterns you want to use in your include-exclude list before you actually insert them in your options file. See the *test pattern* explanation.

Use the detail option to display the management class that is associated with an include-exclude statement.

Windows Use the display option to display the files that are included or excluded from a file system back up operation.

Supported Clients

This command is valid for all clients.

Syntax

AIX | Linux | Mac OS X | Solaris

```
>>-Query INCLexcl-- --+--------------+--+----------+-----------><
                      '-test pattern-'  '- -DETail-'
```

Windows

```
>>-Query INCLexcl--+--------------+--+----------+--+-----------------------+-><
                  '-test pattern-'  '- -DETail-'  |           .-basic---. |
                                                  '--DISPLAY=--+-vssexcl-+-'
                                                               '-all-----'
```

Parameters

test pattern
: Use for testing the validity of patterns you want to use in your include-exclude list. When you use a test pattern with this command, the following occurs:

  - The internal include-exclude list is not displayed
  - The pattern is processed as if it came from an include-exclude statement, including all the usual error checking
  - The pattern is displayed as it would appear in the include-exclude list

  If the test pattern has no errors, the compiled pattern result is the same as the test pattern.

-DETail
: Displays the management class that is associated with the include-exclude statement.

Windows -DISPLAY=basic | vssexcl | all
: Windows -DISPLAY=basic displays the files and directories that have been included or excluded by one of the following methods:

  - The objects were included or excluded in the client options file.
  - The objects were included or excluded in a server-side client option set.
  - The objects were excluded by the operating system because they are contained in the `HKEY_LOCAL_MACHINES\SYSTEM\CurrentControlSet\BackupRestore\FilesNotToBackup` registry key.
  - The objects were explicitly excluded by the client.

  This is the default if a display value is not specified.
  Windows -DISPLAY=vssexcl displays a list of files that are excluded from a file system backup, because they are included when a system state backup is performed. Files that are backed up by a backup systemstate operation are protected by the VSS writer; you cannot include these files in a file system backup by adding them to an include statement in the dsm.opt file, or client option set.
  Windows -DISPLAY=all displays all files that are included or excluded during a file system backup.

Examples

Task
: Exclude a file from deduplication by excluding it in the client options file:

```
Exclude Dedup *\...\file2
```

Task

Display a basic list of include-exclude statements. Command:

```
query inclexcl
```

Windows Task

Windows Display a list of files that are excluded from file system backups because the VSS writer includes them in system state backups.

```
query inclexcl -display=vssexcl
```

Task

Display a list of include-exclude statements. Display the management class that is associated with each statement.

```
query inclexcl -detail
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Test the validity of this pattern: `/.../?x?/*.log`

```
query inclexcl /.../?x?/*.log
```

Windows Task

Windows Test the validity of this pattern: `..\?x?\*.log`

```
query inclexcl ..\?x?\*.log
```

Query Mgmtclass

The query mgmtclass command displays information about the management classes available in your active policy set.

Your administrator defines management classes that contain attributes which control whether a file is eligible for backup or archive services. Management classes also determine how backups and archives are managed on the server.

Windows Your active policy set contains a default management class; it can contain any number of extra management classes. You can assign specific management classes to files using include options that are located in the client options file (dsm.opt). If you do not assign a management class to a file, the default management class is used.

AIX Linux Solaris Mac OS X Your active policy set contains a default management class; it can contain any number of extra management classes. You can assign specific management classes to files using include options that are located in the client user-options file (dsm.opt). If you do not assign a management class to a file, the default management class is used.

When you archive files, you can override the assigned management class by using the archmc option.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Query Mgmtclass--+------------+----------------------------><
                    '- --options-'
```

Parameters

Table 1. Query Mgmtclass command: Related options

Option	Where to use
detail	Command line only.
fromnode	Command line only.

Examples

AIX Linux Solaris Mac OS X Windows Task

AIX Linux Solaris Mac OS X Windows Display default and available management classes.

Command: `query mgmtclass`

Query Node

The query node command displays all the nodes for which an administrative user ID has authority to perform operations. You are prompted for the IBM Spectrum Protect™ administrator ID.

Ideally, the administrative user ID has at least client owner authority over the client workstation node they are using either from the command line or from the web.

Use the type option to specify the type of node to filter for. The following are the valid values:

- AIX Linux Solaris Mac OS X Windows nas
- client
- server
- any

The default is any.
Note: When the IBM Spectrum Protect for Virtual Environments: Data Protection for VMware license file is installed on a vStorage backup server, the platform string that is stored on the IBM Spectrum Protect server is set to "TDP VMware" for every nodename that is used on that machine. The platform string can be used in the context of PVU calculations. If a nodename is being used to back up the machine with standard Backup-Archive client functions (for example, file-level or image backup), then this platform string would be interpreted as a "client" for the purposes of PVU calculations.

For more information about processor value units, see *Estimating processor value units* in the IBM Spectrum Protect server documentation.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Query Node--+------------+-----------------------------------><
               '- --options-'
```

Parameters

Table 1. Query Node command: Related options

Option	Where to use
type	Command line only.
Windows scrolllines	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X scrolllines	AIX Linux Solaris Mac OS X Client user options file (dsm.opt) or command line.
Windows scrollprompt	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X scrollprompt	AIX Linux Solaris Mac OS X Client user options file (dsm.opt) or command line.

Examples

AIX Linux Solaris Mac OS X Windows Task

AIX Linux Solaris Mac OS X Windows Display all NAS nodes.

Command: `query node -type=nas`

Mac OS X Task

Mac OS X Display all client nodes that are backup-archive clients.

Command: `query node -type=client`

Query Options

Use the query options command to display all or part of your options and their current settings that are relevant to the command-line client.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Query Options--+-------------+---- --pattern-----------------><
                  '- --options-'
```

Parameters

pattern

An optional character string that can include wildcards. Use this argument to specify a subset of options. The default is to display all options.

Table 1. Query Options command: Related options

Option	Where to use
Windows scrolllines	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X scrolllines	AIX Linux Solaris Mac OS X Client user options file (dsm.opt) or command line.
Windows scrollprompt	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X scrollprompt	AIX Linux Solaris Mac OS X Client user options file (dsm.opt) or command line.

Examples

Task

Display all options and their values.

```
query options
```

Task

Display only options that begin with *comm*.

```
query options comm*
```

Task

Display the value of the replace option.

```
query options replace
```

Task

Issue the command to display all options and their values. The failover status information is displayed.

```
query options
```

Output:

```
MYPRIMARYSERVERNAME: SERVER1
MYREPLICATIONSERVER: TARGET
     REPLSERVERNAME: TARGET
            Address: 192.0.2.9
               Port: 1501
            SSLPort: 1502
               GUID: 39.5a.da.d1.ae.92.11.e2.82.d3.00.0c.29.2f.07.d3
               Used: yes
```

Query Restore

The query restore command displays a list of your restartable restore sessions in the server database. The list contains these fields: owner, replace, subdir, preservepath, source, and destination.

A restartable restore session is created when a wildcard restore command fails because of network outage, client failure, server outage, or a similar problem. When such a failure occurs, the file space is locked on the server and its files cannot be moved off the sequential volumes of the server. To unlock the file space, either restart the restore and allow it to complete (query restore command), or cancel the restore (cancel restore command). Use query restore to determine if you have any restartable restore sessions and which file spaces are affected.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Query Restore---------------------------------------------><
```

Parameters

There are no parameters for this command.

Examples

Windows Task

Windows The following example displays the output when you use query restore:

```
--- Restartable Restore Information ---
Restartable Session: 1
    Start date/time: 10/17/2001 15:18:22
             Source: {"\\ers\c$"}\data\proposals\*
        Destination: - not specified by user -

Restartable Session: 2
    Start date/time: 10/17/2001 15:20:01
             Source: {"\\ers\c$"}\data\spreadsheets\*
        Destination: - not specified by user -
```

Mac OS X | AIX | Linux | Solaris | Mac OS X Task

Mac OS X | AIX | Linux | Solaris | Mac OS X Display your restartable restore session in the server database.

Command: `query restore`

AIX | Linux | Mac OS X | Solaris | Windows

Query Schedule

The query schedule command displays the events that are scheduled for your node. Your administrator can set up schedules to perform automatic backups and archives for you. To plan your work, use this command to determine when the next scheduled events occur.

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Query SChedule-----------------------------------------------><
```

Parameters

There are no parameters for this command.

Examples

Task
: Display your scheduled events.

  Command: `query schedule`

Query Session

The query session command displays information about your session, including the current node name, when the session was established, server information, and server connection information.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-Query SEssion-------------------------------------------------><
```

Parameters

There are no parameters for this command.

Examples

AIX | Linux | Solaris | Mac OS X | Windows Task

AIX | Linux | Solaris | Mac OS X | Windows Display your session information.

Command: `query session`

A sample query session display follows:

```
Server Name.............: HALLEY_SERVER1
Server Type.............: Windows
Archive Retain Protect..: "No"
Server Version..........: Ver. 6, Rel. 2, Lev. 0.0
Last Access Date........: 09/03/2009 09:08:13
Delete Backup Files.....: "No"
Delete Archive Files....: "Yes"
Deduplication...........: "Server Only"

Node Name...............: HALLEY
User Name...............:
```

Possible client-side deduplication values:

- None
  - Displayed when connected to a pre V6.1 IBM Spectrum Protect™ server
- Server Only
- Client Or Server

AIX Linux Solaris Task
AIX Linux Solaris

A sample query session display with LAN-free enabled follows:

```
IBM Spectrum Protect Server Connection Information

Server Name.............: TEMPLAR
Server Type.............: AIX
Archive Retain Protect..: "No"
Server Version..........: Ver. 6, Rel. 1, Lev. 4.0
Last Access Date........: 08/12/10   22:10:15
Delete Backup Files.....: "No"
Delete Archive Files....: "Yes"

Node Name...............: LAN2
User Name...............: root

Storage Agent Name......: TEMPLAR_STA
Storage Agent Type......: AIX
Storage Agent Version...: Ver. 6, Rel. 1, Lev. 3.3
```

Query Systeminfo

Use the query systeminfo command to gather information and output this information to a file or the console.

This command is intended primarily as an aid for IBM® support to help diagnosing problems. However, users who are familiar with the concepts addressed by this information might also find it useful.

If you use the console option, no special formatting of the output is performed to accommodate screen height or width. Therefore, the console output can be difficult to read due to length and line-wrapping. If the console output is difficult to read, use the filename option with the query systeminfo command. This combination allows the output to be written to a file that can be submitted to IBM support.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This command is valid for all clients.

Syntax

```
                    .-------------.
                    V             |
>>-Query SYSTEMInfo------ --item---+--+------------+-----------><
                                    '- --options-'
```

Parameters

item
: Specifies one or more items from which you want to gather information and output the information to the file name that you specify with the filename option or to the console. The default is to gather all items.

You can gather information on one or more of the following items:

- DSMOPTFILE - The contents of dsm.opt file.
- AIX Linux Solaris Mac OS X DSMSYSFILE - The contents of the dsm.sys file.
- AIX Linux Solaris Mac OS X Windows ENV - Environment variables.
- ERRORLOG - The client error log file.
- FILE - Attributes for the file name that you specify.

- Windows FILESNOTTOBACKUP - Enumeration of Windows Registry key:

  ```
  HKEY_LOCAL_MACHINE\
     SYSTEM\
        CurrentControlSet\
           BackupRestore\
              FilesNotToBackup
  ```

  This key specifies those files that are not to be backed up. The query inclexcl command indicates that these files are excluded per the operating system.

- INCLEXCL - Compiles a list of include-exclude in the order in which they are processed during backup and archive operations.
- Windows KEYSNOTTORESTORE - Enumeration of Windows Registry key:

  ```
  HKEY_LOCAL_MACHINE\
     SYSTEM\
        ControlSet001\
           BackupRestore\
              KeysNotToRestore
  ```

  This key specifies those Windows Registry keys that are not to be restored.

- Windows MSINFO - Windows system information (output from MSINFO32.EXE).
- OPTIONS - Compiled options.
- Windows OSINFO - Name and version of the client operating system
- AIX Linux Solaris Mac OS X OSINFO - Name and version of the client operating system (includes ULIMIT information for UNIX).
- POLICY - Policy set dump.
- Windows REGISTRY - IBM Spectrum Protect™-related Windows Registry entries.
- AIX Linux Solaris Mac OS X Windows SCHEDLOG - The contents of the schedule log (usually dsmsched.log).
- Windows SFP - The list of files that are protected by Windows System File Protection, and for each file, indicates whether that file exists. These files are backed up as part of the SYSFILES system object.
- Windows SFP=<*filename*> - Indicates whether the specified file (*filename*) is protected by Windows System File Protection. For example:

  ```
  SFP=C:\WINNT\SYSTEM32\MSVCRT.DLL
  ```

- Windows SYSTEMSTATE - Windows system state information.
- AIX CLUSTER - AIX® cluster information.
- Windows CLUSTER - Windows cluster information.
- ENCRYPT - Available encryption methods.

Note:

1. AIX Linux Solaris Mac OS X Use the filename option to specify a file name in which to store the information that is gathered from the items you specify. If you do not specify a file name, by default the information is stored in the /Library/Application Support/tivoli/tsm/client/ba/bin/dsminfo.txt file (for Mac OS X) or the dsminfo.txt file (for other UNIX and Linux).
2. Windows Use the filename option to specify a file name in which to store the information gathered from the items you specify. If you do not specify a file name, by default the information is stored in the dsminfo.txt file.
3. Use the console option if you want to output the information to the console.

Table 1. Query Systeminfo command: Related options

Option	Where to use
console	Command line only.
filename	Command line only.

Examples

Task

Gather and store the contents of the dsm.opt file and the IBM Spectrum Protect error log file in the `tsminfo.txt` file.

Command: `query systeminfo dsmoptfile errorlog -filename=tsminfo.txt`

Windows

Query Systemstate

Use the query systemstate command to display information about a backup of the system state on the IBM Spectrum Protect™ server, or system state inside a backup set from the IBM Spectrum Protect server, when the backupsetname option is specified.

The output indicates whether the object is active ("A") or inactive ("I"). Only active objects are listed unless the inactive option is specified with the command. The backup-archive client on Windows supports standard and detailed format.

Supported Clients

This command is valid for supported Windows clients only.

Syntax

```
>>-Query SYSTEMSTate--+----------+----------------------------><
                      '- options-'
```

Parameters

Table 1. Query Systemstate command: Related options

Option	Where to use
backupsetname	Command line only.
dateformat	Client option file (dsm.opt) or command line.
inactive	Command line only.
numberformat	Client option file (dsm.opt) or command line.
pitdate	Command line only.
pittime	Command line only.
showmembers	Command line only.
timeformat	Client option file (dsm.opt) or command line.
detail	Command line only.

Examples

Task

Display information about the active backup of the system state on the IBM Spectrum Protect server.

Command: `query systemstate`

Task

Display information about the active backup of the system state on the IBM Spectrum Protect server.

Command: `query systemstate -detail`

Task

Display information about the active backup of the system state that is contained within the backup set `daily_backup_data.12345678`.

Command: `query systemstate -backupsetname=daily_backup_data.12345678`

Task

To display information about Active Directory, enter the following command: `query systemstate -detail`.

Locate information that is related to Active Directory in the output.

Linux Windows

Query VM

Use the query VM command to list and verify the successful backups of virtual machines (VMs).

Windows
The query VM command can be used to determine which Microsoft Hyper-V virtual machines and VMware virtual machines have been backed up to the server. The information for each hypervisor is presented in its own section. If you are querying the backups of Hyper-V virtual machines, you can skip over the *Query VM for VMware virtual machines* text. If you are querying backups of VMware virtual machines, you do not need to read the *Query VM for Hyper-V virtual machines* text.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments.

Linux Windows

Query VM for VMware virtual machines

Use the query vm command to determine which VMware virtual machines were backed up.

Supported Clients

Linux This command is valid on Linux clients that are installed on a vStorage backup server.

Windows This command is valid on Windows clients that are installed on a vStorage backup server.

Syntax

```
>>-Query VM-- --vmname--+-------------------+--+---------+-----><
                        |         .-BOTH---. |  '-options-'
                        '--FROM -+-SERVER-+-'
                                 '-LOCAL--'
```

Parameters

vmname
: Specifies the virtual machine host name that you want to query. If you omit the virtual machine name, the command displays all VM backups on the IBM Spectrum Protect server.

-FROM
: Specifies the backup location or locations to query. You can specify one of the following values:

  SERVER
  : The query is limited to backups that are on the IBM Spectrum Protect server.

  LOCAL
  : The query is limited to persisted snapshots that are on the hardware storage.

  BOTH
  : The query lists information for both backups that are on the IBM Spectrum Protect server and snapshots that are on the hardware storage. This value is the default.

Table 1. Query VM command: Related options for VMware virtual machine queries.

Option	Where to use
detail Valid for vmbackuptype=fullvm Windows Valid for -vmrestoretype	Command line.

Option	Where to use
inactive Valid for vmbackuptype=fullvm	Command line.
pitdate Valid for vmbackuptype=fullvm	Command line.
pittime Valid for vmbackuptype=fullvm	Command line.
vmbackuptype	Command line or client options file.
vmchost	Command line or client options file.
vmcpw	Command line or client options file.
vmcuser	Command line or client options file.

Windows The following command returns a list of VMs that are running an instant restore operation.

```
q vm * -vmrestoretype=instantrestore
```

Linux | Windows Query all VMware virtual machines that were backed up using `-vmbacktype=fullvm`:

```
q vm * -vmbackuptype=fullvm
```

Windows

Query VM for Microsoft Hyper-V virtual machines

Use the query vm command to determine which Hyper-V virtual machines were backed up.

Supported Clients

This command is valid on Windows clients that are installed on a Hyper-V host system.

Syntax

```
>>-Query VM-- --vmname--+---------+--------------------------><
                        '-options-'
```

Parameters

vmname

Specifies the virtual machine host name that you want to query. The virtual machine name is case-sensitive. If you specify a VM name on the command, the name cannot contain wildcard characters.

If you omit the virtual machine name, the command displays all VM backups on the IBM Spectrum Protect server.

Windows

Table 2. Query VM command: Related options for Hyper-V virtual machine queries.

Option	Where to use
detail	Command line. Displays the details of each disk (label, name) and its status (protected or excluded), and incremental-forever backup performance statistics.
inactive	Command line.
pitdate	Command line.
pittime	Command line.

Windows

Examples

Task

List all virtual machines that have been backed up by Data Protection for Microsoft Hyper-V on the Hyper-V host.

```
dsmc query vm
```

Windows

Query VM examples (Hyper-V)

The following example shows a query VM command that displays summary information about all Hyper-V virtual machines that have been backed up.

```
dsmc query vm

Query Virtual Machine for Full VM backup

 #      Backup Date       Mgmt Class  Size         Type     A/I Location  Virtual Machine
---  -------------------  ----------  -----------  ------   --- --------  ---------------
  1  03/19/2017 17:54:34  STANDARD       17.00 GB  IFFULL    A  SERVER    DeptA_VM05

The detailed output also includes the snapshot type and disk information such as the following information:

Snapshot type
: The type of snapshot that was taken during the VM backup operation:

  Hyper-V RCT Application Consistent
  : A quiesced snapshot that was created with Hyper-V Resilient change Tracking (RCT) on Windows Server 2016.

  Hyper-V RCT Crash Consistent
  : A non-quiesced snapshot that was created with Hyper-V RCT on Windows Server 2016.

  Hyper-V VSS
  : A snapshot that was created with Volume Shadow Copy Service (VSS) on Windows Server 2012 or Windows Server 2012 R2.

Disk[*n*]Location
: The disk location of VM disk *n*, where *n* is a number. The disk location consists of the disk controller type, "IDE" or "SCSI", followed by the controller number and device location number.

Disk[*n*]Status
: The backup status of VM disk *n*, where *n* is a number.

  Protected
  : Indicates that the data on the VM disk is backed up.

  Skipped: Excluded by user
  : Indicates that the VM disk is excluded during backup operations as specified by the exclude.vmdisk option. For more information, see Exclude.vmdisk.

  Skipped: Physical disk
  : Indicates that the VM disk is a physical disk (pass-through disk) and its data is not backed up. Only the disk configuration information is backed up. For more information, see Vmprocessvmwithphysdisks.

The following example shows the syntax to use to list detailed output for a specific virtual machine named `DeptA_VM_W2k08R2`.

```
dsmc query vm DeptA_VM_W2k08R2 -detail

```

Restart Restore

The restart restore command displays a list of your restartable restore sessions in the server database.

You can restart only one restartable restore session at a time. Run the restart restore command again to restart further restores.

The restarted restore uses the same options that you used in the failed restore. The restarted restore continues from the point at which the restore previously failed.

To cancel restartable restore sessions, use the cancel restore command. Use the restart restore command when:

- Restartable restore sessions lock the file space at the server so that files cannot be moved off the sequential volumes of the server.
- You cannot back up files that are affected by the restartable restore.

Options from the failed session supersede new or changed options for the restarted session.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-RESTArt Restore-----------------------------------------><
```

Parameters

There are no parameters for this command.

Examples

Task
: Restart a restore.

Command: `restart restore`

Restore

The restore command obtains copies of backup versions of your files from the IBM Spectrum Protect™ server, or inside a backup set.

To restore files, specify the directories or selected files, or select the files from a list. Restore files to the directory from which you backed them up or to a different directory. The backup-archive client uses the preservepath option with the subtree value as the default for restoring files.

AIX Linux Solaris Mac OS X Note:

1. On UNIX and Linux systems when a symbolic link is created its modification time is set to the current system time and cannot be changed. So, when restoring a symbolic link its modification date and time is set to the date and time of the restore, not to the date and time the link had when it was backed up. As a result, the client backs up the symbolic link during the next incremental backup because its modification time changed since the last backup.

Windows Note:

1. When you restore directory, its modification date and time is set to the date and time of the restore, not to the date and time the directory had when it was backed up. This is because the client restores the directories first, then adds the files to the directories.
2. An error occurs if you attempt to restore a file whose name is the same the short name of an existing file. For example, if you attempt to restore a file that you specifically named ABCDEF~1.DOC into the same directory where a file named abcdefghijk.doc exists, the restore fails because the Windows operating system equates the file named abcdefghijk.doc to a short name of ABCDEF~1.DOC. The restore function treats this as a duplicate file.
   If this error occurs, perform any of the following actions to correct it:
   - Restore the file with the short file name to a different location.
   - Stop the restore and change the name of the existing file.
   - Disable the short file name support on Windows.
   - Do not use file names that would conflict with the short file naming convention; for example, do not use ABCDEF~1.DOC.

If you set the subdir option to yes when you restore a specific path and file, the client recursively restores all subdirectories under that path, and any instances of the specified file that exist under any of those subdirectories.

AIX Linux Solaris Mac OS X When you restore an entire directory or directory tree, and you do not specify the inactive, latest, pick, todate, and fromdate options on the restore command, the client tracks which objects are restored. If the restore process is interrupted for any reason, you can restart the restore at the point of interruption by entering the restart restore command. It is possible to create more than one restartable restore session. Restores are only restartable if the file specification is fully wildcarded. For example, for a restore that is restartable, enter:

```
dsmc rest /home/* -sub=yes
```

AIX Linux Solaris Mac OS X For a restore that is not restartable, enter:

```
dsmc rest "/Users/user1/file?.c" -sub=yes
```

AIX Linux Solaris Mac OS X Use the query restore command to display a list of your restartable restore sessions in the server database. Further backups of the file system cannot be performed unless the restartable restore completes by using the restart restore command or is canceled by using the cancel restore command.

```
dsmc rest "/Users/user1/file?.c" -sub=yes
```

Windows For more information, see the Microsoft Knowledge Base article Q121007, entitled *How to Disable the 8.3 Name Creation on NTFS Partitions*, for more information.

Windows If the restore command is tried again because of a communication failure or session loss, the transfer statistics display the bytes that the client attempted to transfer across all command attempts. Therefore, the statistics for bytes transferred might not match file statistics, such as those for file size.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This command is valid for all clients.

Syntax

```
            .- --FILE-.
>>-REStore--+---------+--+-----------+------------------------>
                         '- --options-'

>--+- --sourcefilespec---------------------+------------------->
   '- --{--filespacename--}--sourcefilespec-'

>--+- --sourcefilespec---+--+-----------------------+---------->
   '- --"sourcefilespec"-'  '- --destinationfilespec-'

>--+-----------------------------------+------------------------>
   '-BACKUPSETName=--+-backupsetname-+-'
                     +-localfilename-+
                     '-tapedevice----'

>--+-----------------------+---------------------------------><
   '-LOCation=--+-server-+-'
                +-file---+
                '-tape---'
```

Parameters

file

This parameter specifies that the source file specification is an explicit file name. This parameter is required when you restore a file name from the current path, when you do not specify a relative or absolute path, and when the file name conflicts with one of the reserved restore command keywords, such as restore backupset.

sourcefilespec

Specifies the path and file name in storage that you want to restore. Use wildcard characters to specify a group of files or all the files in a directory.

Windows Note: If you include filespacename, do not include a drive letter in the file specification.

{filespacename}

Specifies the file space (enclosed in braces) on the server that contains the files you want to restore. This is the name on the workstation drive from which the files were backed up.

Specify the file space name if the drive label name has changed or if you are restoring files that were backed up from another node that had drive labels that are different from yours.

Windows Note: You must specify a mixed or lowercase NTFS or ReFS file space name that is enclosed in quotation marks and braces. For example, {"NTFSDrive"}. Single quotation marks or double quotation marks are valid in loop mode. For example: {"NTFSDrive"} and {'NTFSDrive'} are both valid. In batch mode, only single quotation marks are valid. The single quotation marks requirement is a restriction of the operating system.

destinationfilespec

Specifies the path and file name where you want to place the restored files. If you do not specify a destination, the client restores the files to the original source path.

Windows When you enter the destinationfilespec, consider the following points:

- If the sourcefilespec names a single file, the destinationfilespec can be a file or a directory. If you are restoring a single file, you can optionally end the specification with a file name if you want to give the restored file a new name.
- If the sourcefilespec is wildcarded or `subdir=yes` is specified, the destinationfilespec must be a directory and end with a directory delimiter (\).

Note: If the destination path or any part of it does not exist, the client creates it.

AIX Linux Solaris Mac OS X Note: If you do not specify a destination, the client determines whether the original file system can be reached. If the original file system cannot be reached, the client will not restore the file. In this case, you can specify a different destination and try the command again.

BACKUPSETName=

Specifies the name of a backup set. This parameter is optional. If you specify the backupsetname parameter with the restore command, you cannot use the pick option.

The value of backupsetname depends on the location of the backup set, and corresponds to one of the following options:

backupsetname

Specifies the name of the backup set from the IBM Spectrum Protect server. If the location parameter is specified, you must set `-location=server`. If the backup set resides in IBM Spectrum Protect server storage, the backup set must have a TOC.

localfilename
: Specifies the file name of the first backup set volume. You must set `-location=file`.

tapedevice
: Specifies the name of the tape device that contains the backup set volume. You must use a Windows-provided device driver, not the device driver that is provided by IBM. You must set `-location=tape`.

LOCation=
: Specifies where the client searches for the backup set. If you do not specify the location parameter, the client searches for backup sets on the IBM Spectrum Protect server.

server
: Specifies that the client searches for the backup set from the server. This is the default location.

file
: Specifies that the client searches for the backup set from a local file.

tape
: Specifies that the client searches for the backup set from a local tape device.

Examples

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore a single file named `budget` in the `/Users/user1/Documents` directory.

```
restore /home/devel/projecta/budget
```

Windows Task

Windows Restore a single file named `budget.fin`.

```
restore c:\devel\projecta\budget.fin
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore a single file named `budget`, which exists in the current directory.

```
restore file budget
```

Windows Task

Windows Restore a single file named `budget.fin`, which exists in the current directory.

```
restore file budget.fin
```

Windows Task

Windows Restore files from the `abc` file space `proj` directory.

```
rest {"abc"}\proj\*.*
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore all files with a file extension of `.c` from the `/home/devel/projecta` directory.

```
restore "/home/devel/projecta/*.c"
```

Windows Task

Windows Restore all files with a file extension of `.c` from the `c:\devel\projecta` directory.

```
rest c:\devel\projecta\*.c
```

Windows Task

Windows Restore all files with an extension of `.c` from the `\devel\projecta` directory that is located in the `winnt` file space.

```
rest {winnt}\devel\projecta\*.c
```

Windows Task

Windows Restore all files with a file extension of `.c` from the `c:\devel\projecta` directory to the `c:\newdevel\projectn\projecta` directory. If the `projectn` or `projectn\projecta` directory does not exist, it is created.

```
restore c:\devel\projecta\*.c c:\newdevel\projectn\
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore files in the `/user/project` directory. Use the pick and inactive options to select active and inactive backup versions.

```
restore "/user/project/*" -pick -inactive
```

Windows Task

Windows Restore files in the `c:\project` directory. Use the pick and inactive options to select active and inactive backup versions.

```
restore c:\project\* -pi -ina
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore all files from the `/home/devel/projecta` directory that end with the character `.c` to the `/home/newdevel/projectn/projecta` directory. If the `projectn` or the `projectn/projecta` directory does not exist, it is created.

```
restore "/home/devel/projecta/*.c" /home/newdevel/projectn/
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore all files in the `/home/mydir` directory to their state as of 1:00 PM on August 17, 2002.

```
restore -pitd=8/17/2002 -pitt=13:00:00 /home/mydir/
```

Windows Task

Windows Restore all files in the `c:\mydir` directory to their state as of 1:00 PM on August 17, 2002.

```
restore -pitd=8/17/2002 -pitt=13:00:00 c:\mydir\
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore all objects in the `/home/myid/` directory. Since this restore operation is fully wildcarded, if the restore process is interrupted, a restartable restore session is created.

```
res "/home/myid/*"
```

Windows Task

Windows Restore a file from the renamed file space `\\your-node\h$_OLD` to its original location. Enter both the source and destination as follows:

```
res \\your-node\h$_OLD\docs\myresume.doc h:\docs\
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore all files in the `/home/mydir` directory to their state as of 1:00 PM on August 17, 2002.

```
restore -pitd=8/17/2002 -pitt=13:00:00 /home/mydir/
```

Windows Task

Windows Restore all files in the `c:\mydir` directory to their state as of 1:00 PM on August 17, 2002.

```
restore -pitd=8/17/2002 -pitt=13:00:00 c:\mydir\
```

Windows Task

Windows Restore a single file named `budget.fin` contained within the backup set `daily_backup_data.12345678`.

```
restore c:\projecta\budget.fin -backupsetname=daily_backup_data.12345678 -location=server
```

- Restoring NTFS or ReFS volume mount points
  When restoring a file system that contains a volume mount point, only the mount point (directory) is restored. The data on the volume mounted on that directory is not restored.

- Windows Restore Microsoft Dfs junctions
  To restore Microsoft Dfs junctions, you must restore Microsoft Dfs root.
- Windows Restore active files
  When restoring active and inactive versions of the same file using the replace option, only the most recently restored file is replaced.
- Windows Universal Naming Convention restores
  The client stores files on the IBM Spectrum Protect server using the Windows Universal Naming Convention (UNC), not the drive letter. The UNC name is the network name for the file. The system name is a part of the UNC name. For example, if your system name is STAR and you have a file named c:\doc\h2.doc, the UNC name is \\star\c$\doc\h2.doc.
- Mac OS X Windows Restore from file spaces that are not Unicode-enabled
  If you want to restore from file spaces that are not Unicode-enabled, you must specify the source on the server and a destination on the client, prior to installing the Unicode-enabled client.
- Windows Restore named streams
  The backup-archive client restores named streams on a file basis only.
- Windows Restore sparse files
  When restoring sparse files to a non-NTFS or non-ReFS file system, set the IBM Spectrum Protect server communication time-out value (idletimeout) to the maximum value of 255 to avoid client session timeout.

Windows

Restoring NTFS or ReFS volume mount points

When restoring a file system that contains a volume mount point, only the mount point (directory) is restored. The data on the volume mounted on that directory is not restored.

A mount point can also be restored individually. For example, C:\mount is a mount point and has been backed up as part of the C:\ drive on the system named STORMAN. The following command can be used to restore this mount point:

```
dsmc restore {\\storman\c$}\mount
```

The braces ({ and }) are required if you also backed up the data on the mounted volume from the mount point. Without the braces, the client restores data from the file space with the longest name that matches the file specification. If you backed up the data through the mount point, the backups are stored in a file space named \\storman\c$\mount. The braces are used to specify that the data be restored from the \\storman\c$ file space.
The mount point cannot be restored if any of the following conditions is true:

- The mount point already exists.
- A non-empty directory matching the mount point name exists.
- A file matching the mount point name exists.

- Restoring data on NTFS mounted volumes
  The mount point must exist before the data on the mounted volume can be restored to its original location.

Related concepts:
Restoring data on NTFS mounted volumes
Backing up NTFS or ReFS volume mount points
Backing up data on NTFS or ReFS mounted volumes
Windows

Restore Microsoft Dfs junctions

To restore Microsoft Dfs junctions, you must restore Microsoft Dfs root.

If you select the junction point itself, the backup-archive client restores data under junction, but not the junction itself. If you select a junction point that no longer exists under Dfs root, the client creates a local directory under Dfs root with the same name as the junction before restoring data.

Windows

Restore active files

When restoring active and inactive versions of the same file using the replace option, only the most recently restored file is replaced.

Windows

Universal Naming Convention restores

The client stores files on the IBM Spectrum Protect™ server using the Windows Universal Naming Convention (UNC), not the drive letter. The UNC name is the network name for the file. The system name is a part of the UNC name. For example, if your system name is STAR and you have a file named c:\doc\h2.doc, the UNC name is \\star\c$\doc\h2.doc.

When you restore files on the same system from which they were backed up, you can use the local drive letter or the UNC name to refer to the file. For example, either of the following will restore c:\doc\h2.doc to its original location:

```
dsmc restore c:\doc\h2.doc
dsmc restore \\star\c$\doc\h2.doc
```

When you restore files on a system with a different name, then you must use the UNC name to refer to the file. This is true even if you are restoring to the same physical system, but the system name has changed since the backup occurred.
For example, if you back up c:\doc\h2.doc on system STAR and you want to restore it to system METEOR then you must use the UNC name to refer to the file. You must also specify a destination restore location. This is because the default behavior is to restore the file to its original location, which would be on system STAR. To restore the file to system METEOR, you can run either of the following on METEOR:

```
dsmc restore \\star\c$\doc\h2.doc c:\
dsmc restore \\star\c$\doc\h2.doc \\meteor\c$\
```

Mac OS X | Windows

Restore from file spaces that are not Unicode-enabled

If you want to restore from file spaces that are not Unicode-enabled, you must specify the source on the server and a destination on the client, prior to installing the Unicode-enabled client.

Mac OS X Note: This Unicode section applies only to Mac OS X.

Windows If you want to restore from file spaces that are not Unicode-enabled, you must specify the source on the server and a destination on the client. For example, you backed up your `H` disk named `\\your-node\h$` prior to installing the Unicode-enabled client. After the installation, you issue the following command for a selective backup:

Windows

```
sel h:\logs\*.log
```

Mac OS X For example, assume that `Jaguar` is the name of your startup disk and you back up all of the `.log` files in the `/Users/user5/Documents` directory. Before the backup takes place, the server renames the file space to `Jaguar_OLD`. The backup places the data specified in the current operation into the Unicode-enabled file space named `/`. The new Unicode-enabled file space now contains only the `/Users/user5/Documents` directory and the `*.log` files specified in the operation.

Mac OS X If you want to restore a file from the *renamed* (old) file space to its original location, you must enter both the source and destination as follows:

```
restore Jaguar_OLD/Users/user5/Documents
  /mylog.log /Users/user5/Documents/
```

Windows Before the backup takes place, the server renames the file space to `\\your-node\h$_OLD`. The backup continues placing the data specified in the current operation into the Unicode-enabled file space named `\\your-node\h$`. That file space now contains only the `\logs` directory and the `*.log` files. If you want to restore a file from the (old) *renamed* file space to its original location, you must enter both the source and destination as follows:

```
restore \\your-node\h$_OLD\docs\myresume.doc h:\docs\
```

Windows

Restore named streams

The backup-archive client restores named streams on a file basis only.

Windows directories can contain named streams. Named streams attached to a directory will always be overwritten (regardless of the value of the prompt option) during a restore operation.

Windows

Restore sparse files

When restoring sparse files to a non-NTFS or non-ReFS file system, set the IBM Spectrum Protect™ server communication time-out value (idletimeout) to the maximum value of 255 to avoid client session timeout.

The backup-archive client is restricted to restoring sparse files that are less than 4 gigabytes in size.

The following issues apply if more data is restored than the Microsoft disk quota allows:

- If the user who performs the restore has a disk quota (for example, the user belongs to the Backup Operator Group), the client does not restore any data that exceeds the disk quota of the restore user and displays a "Disk Full" message.
- If the user who performs the restore does not have a disk quota (for example, the user belongs to the Administrator Group), the client does restore all data and transfers ownership of the files that exceed the disk quota of the original owner to the user who is performing the restore (in this case, the Administrator).

Windows

Restore Adobjects

Use the restore adobjects command to restore individual Active Directory objects from the local Deleted Objects container.

Backup-archive clients that run on Windows Server platforms can restore individual Active Directory objects from full system-state backups stored on the IBM Spectrum Protect™ server.

Supported Clients

This command is valid for Windows Server OS clients.

Syntax

```
>>-Restore ADOBJects--+----------------+--+---------+----------><
                      '-sourcepathspec-'  '-options-'
```

Parameters

sourcepathspec
: Specifies the Active Directory object or container to restore. If a container is specified, its contents are also restored. You can either specify the full distinguished name of an object or a container, or just the name attribute ('cn' or 'ou'), where the wildcard might be used. The following special characters require an escape character, the backslash, (\), if any of them are contained in the name:

  - \
  - #
  - +
  - =
  - <
  - >

  For example, "`cn=test#`" is entered as "`cn=test\#`".

  The client cannot display any object names that contain an asterisk (*) as part of the name.

  Do not use wildcards when you specify a distinguished name.

Table 1. Restore Adobjects command: Related options

Option	Where to use

Option	Where to use
adlocation	Command line only.
dateformat (the option is ignored when adlocation is not specified)	Client options file (dsm.opt) or command line.
pitdate (the option is ignored when adlocation is not specified)	Command line only.
pittime (the option is ignored when adlocation is not specified)	Command line only.
replace	Client options file (dsm.opt) or command line.
timeformat (the option is ignored when adlocation is not specified)	Client options file (dsm.opt) or command line.

Examples

Task

Restore a specific deleted Active Directory object.

Command: `restore adobj "CN=Administrator,CN=Users,DC=bryan,DC=test,DC=ibm,DC=com"`

Task

Restore all deleted objects that were originally located in the Users container.

Command: `restore adobj "CN=Users,DC=bryan,DC=test,DC=ibm,DC=com"`

Task

Restore individual Active Directory objects from the IBM Spectrum Protect server. Use the pitdate and pittime options to select from a list of more recent and less recent backup versions.
Command: `restore adobj "cn=guest" -adloc=server -pitdate=03/17/2008 -pittime=11:11:11`

Task

Restore all deleted users with the name starting with `Fred`.

Command: `restore adobjects "cn=Fred*"`

Task

Restore all deleted organizational units with the name `testou`.

Command: `restore adobjects "ou=testou"`

Restore Backupset

The restore backupset command restores a backup set from the IBM Spectrum Protect™ server, a local file, or a local tape device. You can restore the entire backup set, or, in some cases, specific files within the backup set.

AIX | Linux | Mac OS X | Solaris | Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-REStore Backupset--+--------------------------------------+--->
                      '-+------------------+--sourcefilespec-'
                        '-{filespacename}-'

>--+---------------------+--+---------+-- -BACKUPSETName= ------>
   '-destinationfilespec-'  '-options-'

>--+-backupsetname-+--+--------------------------+-------------><
```

```
   +-localfilename-+  '- -LOCation= --+-server-+-'
   '-tapedevice----'                 +-file---+
                                     '-tape---'
```

Parameters

{filespacename}
Specifies the file space (enclosed in braces) on the server that contains the files you want to restore. This is the name on the workstation drive from which the files were backed up, or the virtual file space name for a group.

Specify a file space name when you restore a backup set containing a group.

Specify a file space name when the *sourcefilespec* does not exist on the target computer. This can occur if the drive label name has changed or if you are restoring files that were backed up from another node that had drive labels that are different from yours.

Windows Note: You must specify a mixed or lowercase NTFS or ReFS file space name that is enclosed in quotation marks and braces. For example, {"NTFSDrive"}. Single quotation marks are valid in loop mode. For example: {"NTFSDrive"} and {'NTFSDrive'} are both valid. In batch mode, only single quotation marks are valid. The single quotation marks requirement is a restriction of the operating system.

sourcefilespec
Specifies the source path of a portion of the backup set. The default is to restore the entire backup set.

destinationfilespec
Specifies the destination path for the restored files. If you do not specify a *sourcefilespec*, you cannot specify a *destinationfilespec*. If you do not specify a destination, the backup-archive client restores the files to the original source path. If you are restoring more than one file, you must end the file specification with a directory delimiter (/), otherwise, the client assumes that the last name is a file name and reports an error. If you are restoring a single file, you can optionally end the destination file specification with a file name if you want to give the restored file a new name. When the *sourcefilespec* does not exist on the target workstation, you must specify *destinationfilespec*.

-BACKUPSETName=
Specifies the name of the backup set from which to perform a restore operation. You cannot use wildcard characters to specify the backup set name. The value of *backupsetname* depends on the location of the backup set, and corresponds to one of the following three choices:

backupsetname
Specifies the name of the backup set on the server from which to perform a restore operation. If location option is specified, you must set `-location=server`.

localfilename
Specifies the file name of the first backup set volume. You must set `-location=file`.

tapedevice
Specifies the name of the tape device containing the backup set volume. You must use a Windows-provided device driver, not the device driver that is provided by IBM. You must set `-location=tape`.

-LOCation=
Specifies the location of the backup set. If you do not specify the location parameter, the client searches for backup sets on the IBM Spectrum Protect server. If you specify the location parameter, the value must be one of the following three choices:

server
Specifies that the backup set is on the IBM Spectrum Protect server. Server is the default location.

file
Specifies that the backup set is on an available file system.

tape
Specifies that the backup set is on an available tape device.

Table 1. Restore Backupset command: Related options

Option	Where to use
dirsonly	Command line only.
filesonly	Command line only.
ifnewer	Command line only.

Option	Where to use
preservepath	Command line only.
Windows quiet	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X quiet	AIX Linux Solaris Mac OS X Client user options file (dsm.opt) or command line.
Windows replace	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X replace	AIX Linux Solaris Mac OS X Client user options file (dsm.opt) or command line.
Windows skipntpermissions	Windows Client options file (dsm.opt) or command line.
Windows subdir	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X subdir	AIX Linux Solaris Mac OS X Client user options file (dsm.opt) or command line.

Examples

Task

Restore the entire backup set called monthly_financial_data.87654321 from the server.

```
dsmc restore backupset
  -backupsetname=monthly_financial_data.87654321
   -loc=server
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore the entire backup set contained in the file: /home/budget/weekly_budget_data.ost.

```
dsmc restore backupset
  -backupsetname="/home/budget/weekly_budget_data.ost"
   -loc=file
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore the entire backup set from the /dev/rmt0 device.

```
dsmc restore backupset
  "-backupsetname=/dev/rmt0" -loc=tape
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore a single file named /home/jones/budget.dev from the /dev/rmt0 tape device, to the original source path.

```
dsmc restore backupset
  -backupsetname=/dev/rmt0 "/home/jones/budget.dev"
   -loc=tape
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore all files in the budget directory that contain a file extension of .txt from the tapes on the /dev/rmt0 device, to the original source path.

```
dsmc restore backupset "/home/budget/*.txt"
  -backupsetname=/dev/rmt0 -loc=tape
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore the entire backup set contained in local file named "/home/jones/bset01.file"

```
dsmc restore backupset
  -backupsetname="/home/jones/bset01.file"
   -loc=file
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore groups from the backup set mybackupset.12345678 on the IBM Spectrum Protect server to the /home/devel/projectb directory. The groups' virtual file space is accounting.

```
dsmc restore backupset {/accounting}/*
   /home/devel/projectb/
  -backupsetname=mybackupset.12345678 -loc=server
   -subdir=yes
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore groups from the local backup set mybackupset.ost to the /home/devel/projectb/ directory. The groups' virtual file space is accounting.

```
dsmc restore backupset {/accounting}/*
   /home/devel/projectb/
   -backupsetname=mybackupset.ost
   -loc=server -subdir=yes
```

Windows Task

Windows Restore the entire backup set from the \\.\tape0 device.

```
dsmc restore backupset
  -backupsetname=\\.\tape0 -loc=tape
```

Windows Task

Windows Restore groups from the backup set mybackupset.12345678 on the IBM Spectrum Protect server to the c:\newdevel\projectn directory. The groups' virtual file space is accounting.

```
dsmc restore backupset {accounting}\*
   c:\newdevel\projectn\
   -backupsetname=mybackupset.12345678
   -loc=server -subdir=yes
```

Windows Task

Windows Restore the entire backup set contained in the file: c:\budget\weekly_budget_data.ost.

```
dsmc restore backupset
  -backupsetname=c:\budget\weekly_budget_data.ost
  -loc=file
```

Windows Task

Windows Restore the \budget\ directory and subdirectories from the backup set contained in the file: c:\budget\weekly_budget_data.ost.

```
dsmc restore backupset m:\budget\*
  -backupsetname=c:\budget\weekly_budget_data.ost
  -loc=file -subdir=yes
```

Windows Task

Windows Restore the file \budget\salary.xls from the backup set contained in the file: c:\budget\weekly_budget_data.ost.

```
dsmc restore backupset m:\budget\salary.xls
  -backupsetname=c:\budget\weekly_budget_data.ost
  -loc=file -subdir=yes
```

- Restore backup sets: considerations and restrictions
  This topic lists some considerations and restrictions that you must be aware of when restoring backup sets.
- AIX Linux Solaris Mac OS X Windows Restore backup sets in a SAN environment
  You can restore backup sets in a storage area network (SAN) in the following ways:
- Restore Backupset without the backupsetname parameter
  The restore backupset command can be used without the backupsetname parameter.

Restore backup sets: considerations and restrictions

This topic lists some considerations and restrictions that you must be aware of when restoring backup sets.

Backup set restore considerations

Consider the following when restoring backup sets:

- If the object you want to restore was generated from a client node whose name is different from your current node, specify the original node name with the filespacename parameter on any of the restore commands.

- If you are unable to restore a backup set from portable media, check with your IBM Spectrum Protect™ administrator to ensure that the portable media was created on a device using a compatible format.
- If you use the restore backupset command on the initial command line with the parameter `-location=tape` or `-location=file`, the client does not attempt to contact the IBM Spectrum Protect server.
- When restoring a group from a backup set:
    - The entire group, or all groups, in the virtual file space are restored. You cannot restore a single group by specifying the group name, if there are several groups in the same virtual file space. You cannot restore a part of a group by specifying a file path.
    - Specify a group by using the following values:
        - Specify the virtual file space name with the filespacename parameter.
        - Use the subdir option to include subdirectories.
- Limited support is provided for restoring backup sets from tape devices attached to the client system. A native device driver provided by the device manufacturer must always be used. The device driver provided by IBM to be used with the IBM Spectrum Protect server cannot be used on the client system for restoring local backup sets.
- Mac OS X | AIX | Linux | Solaris If a backup set contains files from several owners, the backup set itself is owned by the root user ID, and non-root user IDs cannot see the backup set. In this case, non-root user IDs can restore their files by obtaining the backup set name from the IBM Spectrum Protect administrator. Non-root users can restore only their own files.
- Mac OS X | AIX | Linux | Solaris | Windows To enable the client GUI to restore a backup set from a local device, without requiring a server connection, use the localbackupset option.

Backup set restore restrictions

Be aware of the following restrictions when restoring backup sets:

- A backup set data that was backed up with the API cannot be restored or used.
- AIX | Linux | Solaris | Windows You cannot restore image data from a backup set using the restore backupset command. You can restore image data from a backup set only with the restore image command.
- AIX | Linux | Solaris | Windows You cannot restore image data from a local backup set (`location=tape` or `location=file`). You can restore image data from a backup set only from the IBM Spectrum Protect server.

AIX | Linux | Solaris | Mac OS X | Windows

Restore backup sets in a SAN environment

You can restore backup sets in a storage area network (SAN) in the following ways:

- If the backup set is on a SAN-attached storage device, specify the device using the *filename* parameter and use the location=*tape* option, where applicable. The backup-archive client restores the backup set directly from the SAN-attached storage device, gaining high-speed restore performance.
  AIX | Linux | Solaris Note: You must ensure that the correct tape is mounted in the SAN-attached tape drive prior to issuing the restore command. The backup-archive client will not initiate a SCSI autochanger to mount the tape automatically.
- If the backup set is not on local media or a SAN-attached storage device, you can specify the backup set using the backupsetname option. Use the location=*server* option to restore the backup set directly from the server using the LAN.

Restore Backupset without the backupsetname parameter

The restore backupset command can be used without the backupsetname parameter.

The preferred syntax for restore backupset command requires the backupsetname parameter. Before the introduction of the backupsetname parameter, the backup-archive client restored backup sets with a different syntax. The previous syntax is supported, but whenever possible, follow the syntax that requires the backupsetname parameter. The previous syntax is documented for those cases when it cannot be replaced by the preferred syntax.

AIX | Linux | Solaris | Mac OS X | Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-REStore Backupset--+-------------------------------------+--->
                      '-+-----------------+--sourcefilespec-'
                        '-{filespacename}-'

>--+---------------------+--+---------+--+-backupsetname-+------>
   '-destinationfilespec-'  '-options-'  +-localfilename-+
                                         '-tapedevice----'

>--+-----------------------+-----------------------------------><
   '-LOCation=--+-server-+-'
                +-file---+
                '-tape---'
```

Parameters

options
: All options that are valid with the preferred syntax of restore backupset are valid with the previous syntax of restore backupset.

{filespacename}
: Specifies the file space (enclosed in braces) on the server that contains the files you want to restore. This is the name on the workstation drive from which the files were backed up, or the virtual file space name for a group.

  Specify a file space name when you restore a backup set containing a group.

  Specify a file space name when the *sourcefilespec* does not exist on the target computer. This can occur if the drive label name has changed or if you are restoring files that were backed up from another node that had drive labels that are different from yours.

  Windows Note: You must specify a mixed or lowercase NTFS or ReFS file space name that is enclosed in quotation marks and braces. For example, {"NTFSDrive"}. Single quotation marks are valid in loop mode. For example: {"NTFSDrive"} and {'NTFSDrive'} are both valid. In batch mode, only single quotation marks are valid. The single quotation marks requirement is a restriction of the operating system.

sourcefilespec
: Specifies the source path of a portion of the backup set. The default is to restore the entire backup set.

destinationfilespec
: Specifies the destination path for the restored files. If you do not specify a *sourcefilespec*, you cannot specify a *destinationfilespec*. If you do not specify a destination, the client restores the files to the original source path. If you are restoring more than one file, you must end the file specification with a directory delimiter (/), otherwise, the client assumes that the last name is a file name and reports an error. If you are restoring a single file, you can optionally end the destination file specification with a file name if you want to give the restored file a new name. When the *sourcefilespec* does not exist on the target workstation, you must specify the *destinationfilespec*.

backupsetname
: Specifies the name of the backup set from the IBM Spectrum Protect™ server. If the location parameter is specified, you must set `-location=server`.

localfilename
: Specifies the file name of the first backup set volume. You must set `-location=file`.

tapedevice
: Specifies the name of the tape device containing the backup set volume. You must use a Windows-provided device driver, not the device driver that is provided by IBM. You must set `-location=tape`.

LOCation=
: Specifies the location of the backup set. If you do not specify the location parameter, the client searches for backup sets on the IBM Spectrum Protect server. If you specify the location parameter, the value must be one of the following three choices:

  server
  : Specifies that the backup set is on the server. Server is the default location.

  file
  : Specifies that the backup set is on an available file system.

  tape

Specifies that the backup set is on an available tape device.

Examples

Task

Restore the entire backup set called `monthly_financial_data.87654321` from the server.

```
dsmc restore backupset monthly_financial_data.87654321 -loc=server
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore the entire backup set contained in the file: `/home/budget/weekly_budget_data.ost`.

```
dsmc restore backupset "/home/budget/weekly_budget_data.ost" -loc=file
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore the entire backup set from the `/dev/rmt0` device.

```
dsmc restore backupset "/dev/rmt0" -loc=tape
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore a single file named `/home/jones/budget.dev` from the `/dev/rmt0` tape device, to the original source path.

```
dsmc restore backupset /dev/rmt0 "/home/jones/budget.dev" -loc=tape
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore all files in the budget directory that contain a file extension of `.txt` from the tape(s) on the `/dev/rmt0` device, to the original source path.

```
dsmc restore backupset /dev/rmt0 "/home/budget/*.txt" -loc=tape
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore the entire backup set contained in local file `"/home/jones/bset01.file"`

```
dsmc restore backupset "/home/jones/bset01.file" -loc=file
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore groups from the backup set `mybackupset.12345678` on the IBM Spectrum Protect server to the `/home/devel/projectb` directory. The groups' virtual file space is `accounting`.

```
dsmc restore backupset mybackupset.12345678 {/accounting}/* /home/devel/projectb/ -loc=server
-subdir=yes
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Restore groups from the local backup set `mybackupset.ost` to the `/home/devel/projectb/` directory. The groups' virtual file space is `accounting`.

```
dsmc restore backupset mybackupset.ost {/accounting}/* /home/devel/projectb/ -loc=server -
subdir=yes
```

Windows Task

Windows Restore the entire backup set from the `\\.\tape0` device.

```
dsmc restore backupset \\.\tape0 -loc=tape
```

Windows Task

Windows Restore groups from the backup set `mybackupset.12345678` on the IBM Spectrum Protect server to the `c:\newdevel\projectn` directory. The groups' virtual file space is `accounting`.

```
dsmc restore backupset mybackupset.12345678 {accounting}\* c:\newdevel\projectn\ -loc=server -
subdir=yes
```

Windows Task

Windows Restore the entire backup set contained in the file: `c:\budget\weekly_budget_data.ost`.

```
dsmc restore backupset c:\budget\weekly_budget_data.ost -loc=file
```

Windows Task

Windows Restore the `\budget\` directory and subdirectories from the backup set contained in the file: `c:\budget\weekly_budget_data.ost`.

```
dsmc restore backupset c:\budget\weekly_budget_data.ost m:\budget\* -loc=file -subdir=yes
```

Windows Task

Windows Restore the file `\budget\salary.xls` from the backup set contained in the file: `c:\budget\weekly_budget_data.ost`.

```
dsmc restore backupset c:\budget\weekly_budget_data.ost m:\budget\salary.xls -loc=file -
subdir=yes
```

Restore Group

Use the restore group command to restore specific members or all members of a group backup.

Note:

1. Use the pick option to display a list of groups from which you can select one group to restore.
2. Use the showmembers option with the pick option to display and restore one or more members of a group. In this case, you first select the group from which you want to restore specific members, then you select one or more group members to restore.
3. You can restore a group from a backup set.

AIX Linux Solaris Windows

Supported Clients

Mac OS X AIX Linux Solaris This command is valid for all clients, except Mac OS X.

Windows This command is valid for all clients.

Syntax

```
>>-REStore GRoup--+---------+----source----+-------------+-----><
                  '-options-'               '-destination-'
```

Parameters

Mac OS X AIX Linux Solaris source

Mac OS X AIX Linux Solaris Specifies the virtual file space name and the group name on the server that you want to restore.

Windows source

Windows Specifies the virtual file space name (enclosed in braces) and the group name on the server that you want to restore.

destination

Specifies the path where you want to place the group or one or more group members. If you do not specify a destination, the client restores the files to their original location.

Windows tapeprompt	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris tapeprompt	AIX Linux Solaris Client user options file (dsm.opt) or command line.
todate	Command line only.
totime	Command line only.

Examples

AIX Linux Solaris Task

AIX Linux Solaris Restore all members in the `/virtfs/group1` group backup to their original location on the client system.

Command:

```
restore group /virtfs/group1
```

Windows Task

Windows Restore all members in the `virtfs\group1` group backup to their original location on the client system.

Command:

```
restore group {virtfs}\group1
```

AIX Linux Solaris Task

AIX Linux Solaris Display all groups within the `/virtfs` virtual file space. Use the showmembers option to display a list of group members from which you can select one or more to restore.

Command:

```
restore group /virtfs/
  * -pick -showmembers
```

Windows Task

Windows Display all groups within the `virtfs` virtual file space. Use the showmembers option to display a list of group members from which you can select one or more to restore.

Command:

```
restore group {virtfs}\
  * -pick -showmembers
```

AIX Linux Solaris Task

AIX Linux Solaris Display a list of groups within the `/virtfs` virtual file space from which you can select one or more groups to restore.

Command:

```
restore group /virtfs/* -pick
```

Windows Task

Windows Display a list of groups within the `virtfs` virtual file space from which you can select one or more groups to restore.

Command:

```
restore group {virtfs}\* -pick
```

AIX Linux Solaris Windows

Restore Image

The restore image command restores a file system or raw volume image that was backed up using the backup image command.

The restore obtains the backup image from the IBM Spectrum Protect™ server, or inside a backup set from the IBM Spectrum Protect server, when the backupsetname option is specified. This command can restore an active base image, or a point-in-time base image, with associated incremental updates.

Note:

1. Windows The account that runs the backup-archive client must have administrator authority to successfully perform any type of image restore.
2. AIX Linux Solaris Using the incremental option with the restore image command to perform a dynamic image backup is not supported.
3. If you use IBM Spectrum Protect HSM for Windows or IBM Spectrum Protect for Space Management, and you restore a file system image backup and plan to run reconciliation, you must restore the files that were backed up after the image backup. Otherwise, migrated files that were created after the image backup expire from the HSM archive storage on the IBM Spectrum Protect server.

You can use the verifyimage option with the restore image command to specify that you want to enable detection of bad sectors on the destination target volume. If bad sectors are detected on the target volume, teh client issues a warning message on the console and in the error log.

If bad sectors are present on the target volume, you can use the imagetofile option with the restore image command to specify that you want to restore the source image to a file. Later, you can use a data copy utility of your choice to transfer the image from the file to a disk volume.

AIX Linux Solaris Considerations:

- The API must be installed to use the restore image command.
- Solaris Image restore is not supported for the Sun QFS file system.
- Linux Image restore is not supported for GPFS™ file systems on Linux x86_64, Linux on POWER® and Linux on System z®.
- Linux On Linux systems, some file systems such as ext2, ext3, ext4, btrfs, and xfs use a universally unique identifier (UUID) to identify themselves to the operating system. If you create an image backup of such a volume and you restore it to a different location, you might have two volumes with the same UUID. If you use UUID to define your file systems in /etc/fstab, be aware that the backup-archive client might be unable to correctly mount the restored file system because the UUIDs conflict. To avoid this situation, restore the image to its original location. If you must restore it to a different location, change the UUID of either the original or restored volume before you mount the restored file system. Refer to the Linux documentation for instructions on how to change a UUID. You might also need to manually edit the /etc/fstab file so the original volume, the restored volume, or both volumes can be mounted.
- If you use the pick option, the following information is displayed for file system images that were backed up by the client:
  - Image Size
  - Stored Size - This value is the actual image size that is stored on the IBM Spectrum Protect server. The stored image on the server is the same size as the volume capacity.
  - File system type
  - Backup date and time
  - Management class that is assigned to image backups

    - Whether the image backup is an active or inactive copy
    - The image name
- If for some reason a restored image is corrupted, you can use the fsck tool to attempt to repair the image.

Windows Considerations:

- The IBM Spectrum Protect API must be installed to use the restore image command.
- You can restore an NTFS or ReFS file system to a FAT32 volume or vice versa.
- The destination volume to which you restore must exist and be the same size or larger than the source volume.
- The physical layout of the target volume (striped, mirrored) can differ.
- The target volume is overwritten with data contained in the image backup.
- You do not have to format a target volume before you restore an image backup that contains a file system.
- The client requires an exclusive lock to destination volume you are restoring. The client locks, restores, unlocks, unmounts, and mounts the volume during a restore operation. During the restore process, the destination volume is not available to other applications.
- If you use the pick option, the following information is displayed for file system images that are backed up by the client:
    - Image Size
    - Stored Size - This value is the actual image size that is stored on the server. The imagegapsize option can be set so only used blocks in a file system are backed up. So, the stored image size on the server might be smaller than the volume size. For online image backups, the stored image can be larger than the file system based on the size of the cache files.
    - File system type
    - Backup date and time
    - Management class that is assigned to image backup
    - Whether the image backup is an active or inactive copy
    - The image name
- If a restored image is corrupted, use the chkdsk utility to check for and repair any bad sectors or data inconsistencies (unless the restored volume is RAW).

Supported Clients

AIX Linux Solaris This option is valid for AIX®, Linux, and Oracle Solaris clients.

Windows This command is valid for all Windows clients.

Syntax

```
>>-REStore Image--+------------+--+- --sourcefilespec---+------->
                  '- --options-'   '- --"sourcefilespec"-'

>--+-----------------------+---------------------------------><
   '- --destinationfilespec-'
```

Parameters

sourcefilespec
Specifies the name of a source image file system to be restored. Only a single source image can be specified; you cannot use wildcard characters.

AIX Linux Solaris destinationfilespec
AIX Linux Solaris Specifies the name of an existing mounted file system or the path and file name to which the source file system is restored. The default is the original location of the file system.

Windows destinationfilespec
Windows Specifies the name of an existing mounted file system or the path and file name to which the source file system is restored. The default is the original location of the file system. You can restore an NTFS or ReFS file system to a FAT32 volume or vice versa.

Table 1. Restore Image command: Related options

Option	Where to use
backupsetname	Command line only.

Option	Where to use
AIX Linux Solaris dateformat	AIX Linux Solaris Client user option file (dsm.opt) or command line.
Windows dateformat	Windows Client option file (dsm.opt) or command line.
deletefiles	Command line only.
fromnode	Command line only.
AIX Linux Solaris fromowner	AIX Linux Solaris Command line only.
imagetofile	Command line only.
inactive	Command line only.
incremental	Command line only.
noprompt	Command line only.
pick	Command line only.
pitdate	Command line only.
pittime	Command line only.
AIX Linux Solaris timeformat	AIX Linux Solaris Client user option file (dsm.opt) or command line.
Windows timeformat	Windows Client option file (dsm.opt) or command line.
verifyimage	Command line only.

AIX Linux Solaris The restore image command does not define or mount the destination file space. The destination volume must exist, must be large enough to hold the source, and if it contains a file system, must be mounted. If an image backup contains a file system, and you restore them to a different location, be aware of the following points:

Windows The restore image command does not define or mount the destination file space. The destination volume must exist, must be large enough to hold the source, and if it contains a file system, must be mounted. The destination volume must be mapped to a drive letter. If an image backup contains a file system, and you restore them to a different location, be aware of the following points:

- If the destination volume is smaller than the source volume, the operation fails.
- AIX Linux Solaris If the destination volume is larger than the source, after the restore operation you lose the difference between the sizes. The lost space can be recovered by increasing the size of the volume, which also increases the size of the restored volume.
- Windows If the destination volume is larger than the source, after the restore operation you lose the difference between the sizes. If the destination volume is on a dynamic disk, the lost space can be recovered by increasing the size of the volume. Increasing the size of the volume also increases the size of the restored volume.

Examples

AIX Linux Solaris Task

AIX Linux Solaris Restore the `/home/test` directory over which the logical volume is mounted, to its original location.

Command: `dsmc rest image /home/test`

Windows Task

Windows Restore the `e:` drive to its original location.

Command: `dsmc rest image e:`

AIX Linux Solaris Task

AIX Linux Solaris Restore the `/home/proj` directory over which the logical volume is mounted, to its original location and apply the changes from the last incremental backup of the original image that is recorded on the server. The changes include deletion of files.

Command: `dsmc restore image /home/proj -incremental -deletefiles`

Windows Task

Windows Restore the `h:` drive to its original location and apply the changes from the last incremental backup of the original image that is recorded on the server. The changes include deletion of files.

Command: `dsmc restore image h: -incremental -deletefiles`

AIX Linux Solaris Task

AIX Linux Solaris Restore the `/usr` file system to its original location. Use the verifyimage option to enable detection of bad sectors on the target volume.

Command: `dsmc restore image /usr -verifyimage`

Windows Task

Windows Restore the `d:` drive to its original location. Use the verifyimage option to enable detection of bad sectors on the target volume.

Command: `dsmc restore image d: -verifyimage`

AIX Linux Solaris Task

AIX Linux Solaris If bad sectors present on the target volume, use the imagetofile option to restore the `/usr` file system to the `/home/usr.img` file to avoid data corruption.

Command: `dsmc restore image /usr /home/usr.img -imagetofile`

Windows Task

Windows If bad sectors present on the target volume, use the imagetofile option to restore the `d:` drive to the `e:\diskD.img` file to avoid data corruption.

Command: `dsmc restore image d: e:\diskD.img -imagetofile`

Windows Task

Windows Restore the `e:` drive from the backup set `weekly_backup_data.12345678` to its original location.

Command: `restore image e: -backupsetname=weekly_backup_data.12345678`

AIX Solaris Windows

Restore NAS

The restore nas command restores the image of a file system that belongs to a Network Attached Storage (NAS) file server. When you are using an interactive command-line session with a non-administrative ID, you are prompted for an administrator ID.

The NAS file server performs the outboard data movement. A server process performs the restore.

If you used the toc option with the backup nas command or the include.fs.nas option to save Table of Contents (TOC) information for each file system backup, you can use the QUERY TOC server command to determine the contents of a file system backup with the RESTORE NODE server command to restore individual files or directory trees. You can also use the web client to examine the entire file system tree and select files and directories to restore. If you do not save TOC information, you can still restore individual files or directory trees with the RESTORE NODE server command, if you know the fully qualified name of each file or directory and the image in which that object was backed up.

AIX Solaris Use the nasnodename option to specify the node name for the NAS file server. The NAS node name identifies the NAS file server to the IBM Spectrum Protect™ server. You must register the NAS node name at the server. Place the nasnodename option in your client system-options file (dsm.sys). The value in the client system-options file is the default, but this value can be overridden on the command line.

Windows Use the nasnodename option to specify the node name for the NAS file server. The NAS node name identifies the NAS file server to the IBM Spectrum Protect server. You must register the NAS node name at the server. Place the nasnodename option in your client options file (dsm.opt). The value in the client options file is the default, but this value can be overridden on the command line.

You can use the pick option to display a list of NAS images that are owned by the NAS node you specify. From this list, you can select one or more images to restore. If you select multiple images to restore with the pick option, do not use the monitor option or you serialize the restores. To start multiple restore processes simultaneously when you are restoring multiple images, do not specify monitor=`yes`.

Use the monitor option to specify whether you want to monitor a NAS file system image restore and display processing information on your screen.

Use the monitor process command to display a list of current restore processes for all NAS nodes for which your administrative user ID has authority. The administrative user ID should have at least client owner authority over both the NAS node and the client workstation node they are using either from command line or from the web.

Use the cancel process command to stop NAS restore processing.

AIX Solaris Regardless of client platform, NAS file system specifications use the forward slash (/) separator, as in this example: `/vol/vol0`.

Windows A NAS file system specification uses the following conventions:

- Regardless of client platform, NAS file system specifications use the forward slash (/) separator, as in this example: /vol/vol0.
- NAS file system designations on the command line require brace delimiters {} around the file system names, such as: {/vol/vol0}.

AIX Solaris Windows

Supported Clients

AIX Solaris This command is valid for AIX®, and Solaris clients only.

Windows This command is valid for all Windows clients.

Syntax

```
>>-REStore NAS--+------------+---- --sourcefilespec-------------->
                '- --options-'

>--+------------------------+---------------------------------><
   '- --destinationfilespec-'
```

Parameters

sourcefilespec
: Specifies the name of the NAS file system image you want to restore. This parameter is required unless you use the pick option to display a list of NAS images from which to choose. You cannot use wildcard characters when you specify the sourcefilespec.

destinationfilespec
: Specifies the name of an existing mounted file system on the NAS device over which you want to restore the image. This parameter is optional. The default is the original location of the file system on the NAS device.

Table 1. Restore NAS command: Related options

Option	Where to use
AIX Solaris dateformat	AIX Solaris Client user option file (dsm.opt) or command line.
Windows dateformat	Windows Client option file (dsm.opt) or command line.
inactive	Command line only.
mode	Command line only.
monitor	Command line only.
AIX Solaris nasnodename	AIX Solaris Client system options file (dsm.sys) or command line.
Windows nasnodename	Windows Client options file (dsm.opt) or command line.
AIX Solaris numberformat	AIX Solaris Client user option file (dsm.opt) or command line.
Windows numberformat	Windows Client option file (dsm.opt) or command line.
pick	Command line only.

Option	Where to use
pitdate	Command line only.
pittime	Command line only.
AIX Solaris timeformat	AIX Solaris Client user option file (dsm.opt) or command line.
Windows timeformat	Windows Client option file (dsm.opt) or command line.

Examples

AIX Solaris Task

AIX Solaris Restore the NAS file system image /vol/vol1 to the /vol/vol2 file system on the NAS file server called `nas1`.

Command: `restore nas -nasnodename=nas1 /vol/vol1 /vol/vol2`

Windows Task

Windows Restore the NAS file system image /vol/vol1 to the /vol/vol2 file system on the NAS file server called `nas1`.

Command: `restore nas -nasnodename=nas1 {/vol/vol1} {/vol/vol2}`

Task

Restore inactive NAS images.

Command: `restore nas -nasnodename=nas2 -pick -inactive`

Windows

Restore Systemstate

The restore systemstate command is deprecated for online system state restore operations.

Restriction:
You can no longer restore the system state on a system that is still online. Instead, use the ASR-based recovery method to restore the system state in offline Windows PE mode. For more information, see the following IBM Spectrum Protect wiki articles:

- Best Practices for Recovering Windows Server 2012 and Windows 8
- Best Practices for Recovering Windows Server 2012 R2 and Windows 8.1

If you try to restore the system state with the dsmc restore systemstate command, from the backup-archive client GUI, or from the web client, the following message is displayed:

```
ANS5189E Online SystemState restore has been deprecated. Please use offline
    WinPE method for performing system state restore.
```

Linux Windows

Restore VM

Use the restore vm command to restore a virtual machine that was previously backed up.

Windows

The restore VM command can be used to restore both Microsoft Hyper-V virtual machines and VMware virtual machines. The information for each type of restore is presented in its own heading. If you are restoring a virtual machine that is part of a Hyper-V setup, you can skip over the *Restore VM for VMware virtual machines* text. If you are restoring a VMware virtual machine, you do not need to read the *Restore VM for Hyper-V virtual machines* text.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect™ for Virtual Environments.

Linux Windows

Restore VM for VMware virtual machines

The Restore VM command can be used to restore VMware virtual machines or VMware virtual machine templates.

If you have the backup-archive client installed on a separate system that is configured as a vStorage backup server, you can restore full virtual machine backups to the ESX or ESXi server that they came from, or to a different server. To restore a full virtual machine backup to a different server, use the -host option. The backup-archive client copies the data from the IBM Spectrum Protect server over either the LAN or SAN. The client then writes the data directly to the ESX server, by using the transport method that is specified in the client options file.

Restoring a full virtual machine backup creates a new virtual machine; the configuration information and content of the new machine is identical to what it was when the backup occurred. All virtual machine disks are restored to the specified point-in-time, as virtual disks in the newly created virtual machine.

When you restore a specific disk, by using the :vmdk= syntax, an existing virtual machine is updated with the specified virtual disk data. Only the specified disks are restored to the existing virtual machine; other disks in the virtual machine are not altered. The existing virtual machine that you are restoring the disk to must be powered off before you initiate the restore operation.

To create a new virtual machine, specify the -vmname parameter and provide a name for the new virtual machine. The -vmname parameter creates a new virtual machine with a configuration that is identical to what it was when the backup occurred. If you also specify the :vmdk= syntax, data is restored to any disks that are included in the :vmdk= parameters; disks that are not included are restored, but only as unformatted disks that do not contain data.

Virtual machines are restored to their original resource pool, cluster, or folder if the containers exist. During a restore operation, if the destination target (a vCenter or ESXi host) does not have the required containers, the virtual machine is restored to the top-level default location on the target ESXi host. If you use the command-line client to restore a virtual machine, and if the virtual machine cannot be restored to its original inventory location, an informational message (ANS2091I) is displayed. If you use the Java™ GUI to restore a virtual machine, and if the virtual machine cannot be restored to its original inventory location, the informational message is not displayed, but the virtual machine is still restored to the top-level default location.

Data protection tags that were backed up with the run backup vm command are restored with the virtual machine. Data protection tags are used to exclude virtual machines from backups and to specify the retention policy of backups.

Windows Full virtual machine backups that were previously created by using VMware Consolidated Backup (VCB) can still be restored by using the original VCB restore steps. To restore full virtual machine backups that were created by VCB, see Restoring full VM backups that were created with VMware Consolidated Backup. If you use VCB to restore a virtual machine, use the VMware converter program on the client to move the restored files to a running state on a VMware server. If the backup-archive client is running in a virtual machine, and if you performed a file-level backup of the virtual machine's files with the version 7.1 or earlier client, you can restore the backup versions to the virtual machine by using the command-line interface or the Java GUI.

Supported Clients

Linux This command is valid on supported Linux clients that are installed on a vStorage backup server for a VMware virtual machine.

Windows This command is valid on supported Windows clients that are installed on a vStorage backup server for a VMware virtual machine.

Syntax

Parameters

Any parameter that contains spaces must be enclosed in quotation marks (" ").

sourcevmspec
Specifies the name of the virtual machine (or virtual machine template) that you want to restore.

VMNAme *timestamp
Specifies the new name for the virtual machine after it is restored, if you do not want to use the name specified by *sourcevmspec*.
You can use the * (asterisk) symbol as a wildcard to represent the name of the virtual machine that is restored. Placing valid characters before or after the asterisk can create a prefix or suffix in the name of the restored virtual machine.
The following characters are not supported in names of restored virtual machines: <q>:;'\"*?,<>/\\| . A restore command that includes unsupported characters will fail with error message ANS9117E.
VMWare does not support virtual machine names of greater than 80 characters in length.
A timestamp option, recording the date and time of the restore, can be appended to the name of the virtual machine that is restored. The option output uses the DATEFORMAT and TIMEFORMAT formats defined in the options file to determine how to specify the timestamp string. A dash is used as a delimiter in the dates returned by the timestamp parameters.
Note: This parameter is not valid for restoring VMware virtual machines backed up using VCB or if the FROM parameter specifies LOCAL.

DATACENTER
Specifies the name of the data center to restore the virtual machine to as it is defined in the vSphere vCenter. If the data center is contained in a folder, you must specify the -datacenter option when you restore the virtual machine and include the folder structure of the data center in the data center name. For example, the following syntax is valid:

```
-datacenter=folder_name/datacenter_name
```

When you restore a virtual machine by using the GUI, you must restore the virtual machine to a different location. If you restore to the original location, you cannot specify the folder name of the data center. Without a folder name to help locate the original data center, the restore operation fails.

Note: This parameter is not valid for restoring VMware virtual machines that were backed up using VCB.

HOST
Specifies the domain name of the ESX host server to restore to as it is defined in the vSphere vCenter.
This parameter is case-sensitive and must be the same value as the host name that is shown in the VMware vSphere Web Client. To confirm the host name in the vSphere Web client, select a host and click Manage > Networking > TCP/IP configuration > DNS.
Note: This parameter is not valid for restoring VMware virtual machines that were backed up using VCB.

DATASTORE
Specifies the VMware datastore to restore the virtual machine to. The datastore can be on a SAN, NAS, iSCSI device, or VMware virtual volume (VVOL). You can specify only one datastore when you restore a virtual machine. If you do not specify a datastore parameter, the virtual machine's VMDK file is restored to the datastore it was on when the backup was created.
Note: This parameter is not valid for restoring VMware virtual machines that were backed up using VCB.

Windows *destinationfilespec*
Windows This parameter is for VMware VCB restores only. It specifies the location where VCB full virtual machine image files are restored. If this option is not specified the vmbackdir option is used.

:vmdk=all-vmdk
This option specifies that all virtual disks (*.vmdk files) are included when the virtual machine is restored. This is the default.
Note: This parameter is not valid for restoring VMware virtual machines that were backed up using VCB.

:vmdk=cnfg
This option specifies that the virtual machine configuration information is restored. The configuration information is always restored when a new virtual machine is created. However, by default the configuration is not restored when you update an existing virtual machine with selected virtual disks.
Ordinarily, restoring configuration information to an existing virtual machine fails because the restored configuration information conflicts with the existing virtual machine configuration information. Use this option if the existing configuration file for a virtual machine on the ESX server has been deleted, and you want to use the backed up configuration to re-create it.
Note: This parameter is not valid for restoring VMware virtual machines that were backed up using VCB.

:vmdk=*disk label*
This option is used to specify the disk label of the virtual disks to include in the restore operation. You specify this option only if you want to selectively restore data from specific disks.
Note: On the Restore VM command, the label names of the vmdk files that you want to include (:vmdk= parameter) in a Restore VM operation must be specified as the English-language label name, as it is displayed in the output of the `Backup VM vmname -preview` command. Examples of the English vmdk labels are "Hard Disk 1", "Hard Disk 2", and so on.
Note: This parameter is not valid for restoring VMware virtual machines that were backed up using VCB.

:-vmdk=*disk label*

This option is used to specify the disk label of one or more virtual disks to exclude from the restore operation.
Note: On the Restore VM command, the label names of the vmdk files that you want to exclude (:-vmdk= parameter) from a Restore VM operation must be specified as the English-language label name, as it is displayed in the output of the `Backup VM vmname -preview` command. Examples of the English vmdk labels are "Hard Disk 1", "Hard Disk 2", and so on.
Note: This parameter is not valid for restoring VMware virtual machines that were backed up using VCB.

Table 1. Restore VM command: Related options when restoring VMware virtual machines

Option	Where to use
datacenter	Command line or options file. This parameter is not valid for restoring VMware virtual machines that were backed up using VCB.
datastore	Command line or options file. This parameter is not valid for restoring VMware virtual machines that were backed up using VCB.
host	Command line or options file. This parameter is not valid for restoring VMware virtual machines that were backed up using VCB.
inactive	Command line.
pick	Command line. This parameter is not valid for restoring VMware virtual machines that were backed up using VCB.
pitdate	Command line. This parameter is not valid for restoring VMware virtual machines that were backed up using VCB.
pittime	Command line. This parameter is not valid for restoring VMware virtual machines that were backed up using VCB.
Windows vmautostartvm This parameter is only valid when instantaccess is specified as the vmrestoretype value.	Windows Command line or client options file.
vmbackdir	Command line or client options file.
vmbackuplocation	Command line.
vmbackuptype	Command line or client options file.
vmdefaultdvportgroup	Command line or client options file
vmdefaultdvswitch	Command line or client options file
vmdefaultnetwork	Command line or client options file
vmdiskprovision This parameter is only valid when instantrestore is specified for the vmrestoretype value.	Command line or client options file.
Windows vmiscsiserveraddress This parameter is only valid when either instantaccess or instantrestore is specified for the vmrestoretype value.	Windows Command line or client options file.
vmmaxrestoresessions	Command line or client options file.
Windows vmrestoretype	Windows Command line.
Windows vmtempdatastore This parameter is only valid when instantrestore is specified for the vmrestoretype value.	Windows Command line or client options file.
vmvstortransport	Command line or client options file. This parameter is not valid for restoring VMware virtual machines that were backed up using VCB.

Examples

Windows Task

Windows To perform an instant restore or instant access operation from the command line, see Scenarios for running full VM instant access and full VM instant restore from the backup-archive client command line.

Task

Restore the most recent backup version of `myVM` to its original name. Use the VMware management interface to delete the original virtual machine, before you restore it using this syntax.

```
dsmc restore vm myvm
```

Task

Restore the most recent backup version of *myvm* to a new machine that is created with the name "Test Machine", and with the restore target for the data center, ESX host, and datastore all specified on the command.

```
dsmc restore vm myvm -vmname="Test Machine"
  -datacenter="myDatacenter" -host="myHostName"
   -datastore="myDatastore"
```

Task

Restore the most recent backup version of *myvm* with the new name *myvm_restored.*

```
dsmc restore vm myvm -vmname="*_restored"
  -datacenter="myDatacenter" -host="myHostName"
   -datastore="myDatastore"
```

Task

Restore the most recent backup version of *myvm* with a new name, showing date and time, similar to *myvm_03-22-2017_14-41-24.*

```
dsmc restore vm myvm -vmname="*_<timestamp>"
  -datacenter="myDatacenter" -host="myHostName"
   -datastore="myDatastore"
```

Task

Restore the most recent backup version of *myvm*. Restore to a data center named *mydatacenter*. The data center is within the vCenter; the relative path within the vCenter is dirA/datacenters/.

```
dsmc restore vm myvm -vmname="Test Machine"
  -datacenter="dirA/datacenters/myDatacenter"
  -host="myHostName" -datastore="myDatastore"
```

Task

Restore a virtual machine template back to the same location and name.

```
dsmc restore vm vmTemplateName
```

Task

Restore a virtual machine template to a new location.

```
dsmc restore vm vmTemplateName-vmname=newName
  -datastore=newDatastore -host=newHost
   -datacenter=newDatacenter
```

Task

Restore only Hard Disk 2 and Hard Disk 3 to the existing virtual machine that is named vm1.

```
dsmc restore vm "vm1:vmdk=Hard Disk 2:vmdk=Hard Disk 3"
```

Task

Restore all disks to the existing virtual machine named vm1, but do not restore the data from Hard Disk 4.

```
dsmc restore vm "vm1:-vmdk=Hard Disk 4"
```

Task

Restore only the data from hard Disk 1 to the existing virtual machine vm1; do not update any configuration information. Note: When you restore an existing virtual machine, the default behavior is to not update the configuration information.

```
dsmc restore vm "vm1:vmdk=Hard Disk 1:-vmdk=cnfg"
```

Task

Restore all disks to the existing virtual machine named vm1.

```
dsmc restore vm "vm1:vmdk=all-vmdk"
```

This command updates all virtual disks on an existing virtual machine, named vm1. Note that this action is different from the action that is performed by `dsmc restore vm vm1`, which creates a new virtual machine named vm1 (vm1 must not exist in order for `dsmc restore vm vm1` to succeed).

Task

Set a maximum of three sessions to be used for restore operations for virtual disks in the VM vm1:

```
dsmc restore vm vm1 -vmmaxrestoresessions=3
```

Important: For Windows virtual machines: If you attempt to run a full VM restore of an application protection backup that was created with 2 or more snapshot attempts, the system provider snapshot is present on the restored VM. As the application writes to the disk, the shadow storage space grows until it runs out of disk space.

In general, if application protection was used during a backup, use only application protection restore. When you restore the application, the volume is automatically reverted. However, if you must restore the full VM, you must either revert or delete the shadow copy.

After you restore the entire VM, verify that the restore was successful, and the data is not corrupted. If the data is not corrupted, delete the shadow copy. If the data is corrupted, revert the shadow copy to restore data integrity.

You can determine which shadow copy to delete or revert by looking for the dsmShadowCopyID.txt file in the root directory of each restored volume. This file contains the snapshot IDs of the shadow copies that were created during the snapshot attempts. You can use the diskshadow command delete shadows to delete these IDs, or the revert command to revert the shadow copy. After the delete or revert is completed, you can also delete the dsmShadowCopyID.txt file.

For more information, see INCLUDE.VMSNAPSHOTATTEMPTS.

Windows

Restore VM for Microsoft Hyper-V virtual machines

Use the Restore VM command to restore Hyper-V guests. You can restore Hyper-V guests to a local disk, a SAN-attached disk, to a cluster shared volume, or to a remote file server share. Remote file server shares must be on a Windows Server 2012 or later system.

If the virtual machine that you are restoring exists, the backup-archive client shuts it down and deletes all files that comprise the virtual machine. The client then restores it from the image that is stored on the IBM Spectrum Protect server. If the virtual machine is a member of a Windows Server 2012 cluster, the virtual machine is taken offline from the cluster, which stops the virtual machine. The files are then deleted, and the client restores it from the IBM Spectrum Protect backup.

Tip: Even though the client shuts down the virtual machine before it deletes it, manually shutting down the virtual machine before you run the Restore VM command is a good practice to follow to bring any in-progress application activities to an orderly stop. Then, use the Restore VM command to restore the virtual machine such that its content and configuration are identical to what it was when it was backed up.

Supported Clients

This command is valid on supported Windows clients that are installed on a Hyper-V host system.

Syntax

```
>>-REStore VM-- --sourcevmspec---------------------------------->

>--+-------------------------------------------------+---------->
   '- -targetpath=--path--+-----------------------+-'
                          '- -vmname=--new_vm_name-'

>--+----------------+-------------------------------------------><
   '-+------------+-'
     '- --options-'
```

Parameters

Any parameter that contains spaces must be enclosed in quotation marks (" ").
The *sourcevmspec* parameter is required. The other parameters are optional. Consider the following scenarios to determine the parameters to use:

- To restore the virtual machine to the original path using the original virtual machine name, use only the *sourcevmspec* parameter. The virtual machine is restored with its original VMware GUID.
- To restore the virtual machine to an alternate path using the original virtual machine name, use the *sourcevmspec* and -targetpath parameters. The virtual machine is restored to the specified path with a new VMware GUID. The virtual machine in the original path is not deleted.
- To restore the virtual machine to an alternate path using a new virtual machine name, use the *sourcevmspec*, -targetpath, and -vmname parameters. The virtual machine is restored to the specified path with the new name and a new VMware GUID. The virtual machine with the original name in the original path is not deleted.

The -vmname parameter is valid only for restoring virtual machines that were backed up by using `iffull` or `ifincremental` modes. This parameter is ignored for virtual machines that were backed up by using the `full` or `incremental` modes that were provided in previous product releases.

sourcevmspec
: Specifies the name of the virtual machine you want to restore. The virtual machine name is case-sensitive. You cannot use wildcards in the virtual machine name.

-targetpath=*path*
: Specifies the path that you want to restore the virtual machine to.
This parameter is required if the -vmname parameter is used and optional otherwise. Use this parameter to restore the virtual machine to an alternate path.

-vmname=*new_vm_name*
: Specifies a new name for the virtual machine. The name can contain 1-100 characters. The following characters are not valid: `\ / : ; , * ? " ' < > |`
This parameter requires the -targetpath parameter.

Table 2. Restore VM command: Related options when restoring Hyper-V virtual machines

Option	Where to use
inactive	Command line
pick	Command line

Examples

Task
: Restore the most recent backup version of a virtual machine named VM1 to the drive and path it was in when it was backed up.

```
dsmc restore vm VM1
```

Task
: Restore the most recent backup version of a virtual machine named vm1 to the drive and path it was in when it was backed up. Replace the existing virtual machine without prompting.

```
dsmc restore vm vm1 -replace=yes
```

Task
: Restore the backed up virtual machine named VM1 to a new name (vm2):

```
dsmc restore vm VM1 -VmName=vm2
```

Task

Restore the backed up virtual machine named vm1, and assign it a new name (vm2). Issue a prompt before overwriting vm2, if that virtual machine already exists.

```
dsmc restore vm vm1 -VmName=vm2 -replace=prompt
```

Task

Restore the virtual machine named vm1 to a specific drive and path, without renaming the virtual machine:

```
dsmc restore vm vm1 -targetpath="E:\New Path"
```

Task

Restore the virtual machine named vm1, but rename it as vm2 and restore it to a new path:

```
dsmc restore vm vm1 -VmName=vm2 -targetpath=F:\NewPath
```

Task

Use -pick and -inactive to show active and inactive backups for a virtual machine that is named vm1. You choose the backup to restore from a list:

```
dsmc restore vm vm1 -pick -inactive
```

Retrieve

The retrieve command obtains copies of archived files from the IBM Spectrum Protect™ server. You can retrieve specific files or entire directories.

Use the description option to specify the descriptions that are assigned to the files you want to retrieve.

Use the pick option to display a list of your archives from which you can select an archive to retrieve.

Retrieve the files to the same directory from which they were archived, or to a different directory. he backup-archive client uses the preservepath option with the subtree value as the default for restoring files.

Mac OS X Note: When a directory is retrieved, its modification date and time is set to the date and time of the retrieval, not to the date and time the directory had when it was archived. This is because the backup-archive client retrieves the directories first, then adds the files to the directories.

Windows Note:

1. When a directory is retrieved, its modification date and time is set to the date and time of the retrieve, not to the date and time the directory had when it was archived. This is because the backup-archive client retrieves the directories first, then adds the files to the directories.
2. An error occurs if you attempt to retrieve a file whose name is the same as the short name of an existing file. For example, if you attempt to retrieve a file you specifically named ABCDEF~1.DOC into the same directory where a file named abcdefghijk.doc exists, the retrieve fails because the Windows operating system equates the file named abcdefghijk.doc to a short name of ABCDEF~1.DOC. The retrieve function treats this as a duplicate file.
   If this error occurs, perform any of the following actions to correct it:
   - Retrieve the file with the short file name you specified to a different location.
   - Stop the retrieval, and change the name of the existing file.
   - Disable the short file name support on Windows.
   - Do not use file names that conflict with the short file naming convention. For example, do not use ABCDEF~1.DOC.

Windows The workstation name is part of the file name. Therefore, if you archive files on one workstation and you want to retrieve them to another workstation, you must specify a destination. This is true even if you are retrieving to the same physical workstation, but the workstation has a new name. For example, to retrieve the c:\doc\h2.doc file to its original directory on the workstation, named star, you would enter:

```
dsmc retrieve c:\doc\h2.doc \\star\c$\
```

The workstation named star has been renamed and the new name is meteor. To retrieve the c:\doc\h2.doc file to meteor, you would enter:

```
dsmc retrieve c:\doc\h2.doc \\meteor\c$\
```

You could also enter:

```
dsmc retrieve c:\doc\h2.doc \\star\c$\
```

You can enter the command in either of the preceding ways because if the workstation name is not included in the specification, the local workstation is assumed (meteor, in this case).

AIX Linux Solaris Mac OS X Windows

Supported Clients

This command is valid for all clients.

Mac OS X AIX Linux Solaris Mac OS X

Syntax

```
>>-RETrieve--+------------+--+- --sourcefilespec---+------------>
             '- --options-'  '- --"sourcefilespec"-'

>--+------------------------+---------------------------------><
   '- --destinationfilespec-'
```

Windows

Syntax

```
>>-RETrieve--+------------+-------------------------------------->
             '- --options-'

>--+- --sourcefilespec----------------------+------------------->
   '- --{--filespacename--}--sourcefilespec-'

>--+------------------------+---------------------------------><
   '- --destinationfilespec-'
```

Parameters

AIX Linux Solaris Mac OS X sourcefilespec

AIX Linux Solaris Mac OS X Specifies the path and file name that you want to retrieve. Use wildcard characters to specify a group of files or all the files in a directory.

Windows sourcefilespec

Windows Specifies the path and file name that you want to retrieve. Use wildcard characters to specify a group of files or all the files in a directory.

Note: If you include filespacename, do not include a drive letter in the file specification.

Windows {filespacename}

Windows Specifies the file space (enclosed in braces) on the server that contains the files you want to retrieve. This name is the drive label on the workstation drive from which the files were archived.

Use the file space name if the drive label name has changed, or if you are retrieving files that were archived from another node that had drive label names that are different from yours.

Note: You must specify a mixed or lowercase NTFS or ReFS file space name that is enclosed in quotation marks and braces. For example, *{"NTFSDrive"}*. Single quotation marks or quotation marks are valid in loop mode. For example: *{"NTFSDrive"}* and *{'NTFSDrive'}* are both valid. In batch mode, only single quotation marks are valid. The single quotation marks requirement is a restriction of the operating system.

AIX Linux Solaris Mac OS X destinationfilespec

AIX Linux Solaris Mac OS X Specifies the path and file name where you want the files to be written. If you do not specify a destination, the client restores the files to the original source path.

Note: If you do not specify a destination, the backup-archive client determines whether the original file system can be reached. If the original file system cannot be reached, the client does not restore the file.

AIX Linux Solaris This failure can also occur if you remove the virtualmountpoint option from the dsm.sys file. In this case, you can specify a different destination, or restore the original virtualmountpoint option to the dsm.sys file, restart the client, and try the command again.

Windows destinationfilespec

Windows Specifies the path and file name where you want the files to be written. If you do not specify a destination, the client restores the files to the original source path.

When you enter the destinationfilespec string, consider the following points:

- If the sourcefilespec names a single file, the destinationfilespec can be a file or a directory.
- If the sourcefilespec is wildcarded or if you specify the `subdir=yes` option, the destinationfilespec must be a directory and end with a directory delimiter (\).

Note: If the destination path or any part of it does not exist, the client creates it.

Examples

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Retrieve a single file named budget.

```
retrieve /home/devel/projecta/budget
```

Windows Task

Windows Retrieve a single file named budget.fin.

```
ret c:\devel\projecta\budget.fin
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Retrieve all files with an extension of .c from the /home/devel/projecta directory.

```
retrieve "/home/devel/projecta/*.c"
```

Windows Task

Windows Retrieve all files with an extension of .c from the c:\devel\projecta directory.

```
ret c:\devel\projecta\*.c
```

Windows Task

Windows Retrieve all files with a file extension of .c from the \devel\projecta directory on the winnt file space.

```
ret {winnt}\devel\projecta\*.c
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Retrieve all files in the /home directory.

```
retrieve /home/
```

Windows Task

Windows Retrieve all files in the c:\devel directory.

```
ret c:\devel\*
```

Windows Task

Windows Retrieve files from the abc file space proj directory.

```
ret {abc}\proj\*.*
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Retrieve all files with a file extension of .c from the /home/devel/projecta directory to the /home/newdevel/projectn/projecta directory. If the /projectn or the /projectn/projecta directory does not exist, it is created.

```
retrieve "/home/devel/projecta/*.c" /home/newdevel/projectn/
```

Windows Task

Windows Retrieve all files with a file extension of .c from the c:\devel\projecta directory to the c:\newdevel\projectn\projecta directory. If the \projectn or the \projectn\projecta directory does not exist, it is created.

```
ret c:\devel\projecta\*.c c:\newdevel\projectn\
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Retrieve files in the /user/project directory. Use the pick option.

```
ret "/user/project/*" -pick
```

Windows Task

Windows Retrieve files in the c:\project directory. Use the pick option.

```
ret c:\project\* -pick
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Retrieve all files that were archived from the /proj directory with the description "2012 survey results".

```
retrieve "/proj/*" -desc="2012 survey results"
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Retrieve archived file /home/devel/budget with description "my budget" to the /dev/rmt1 tape drive.

```
mkfifo fifo
dd if=fifo of=/dev/rmt1&
dsmc retrieve -replace=yes -description="mybudget"
/home/devel/budget fifo
```

Mac OS X Task

Mac OS X Retrieve a file from the renamed file space Jaguar_OLD to its original location. Enter both the source and destination as follows:

```
ret Jaguar_OLD/user5/Documents/myresume.doc /Users/user5/Documents/
```

Windows Task

Windows Retrieve a file from the renamed file space \\your-node\h$_OLD to its original location. Enter both the source and destination as follows:

```
ret \\your-node\h$_OLD\docs\myresume.doc h:\docs\
```

- Mac OS X Windows Retrieve archives from file spaces that are not Unicode-enabled
  If you want to retrieve archives from file spaces that were renamed by the Unicode-enabled client, you must specify the source on the server and a destination on the client.
- Windows Retrieve named streams
  The backup-archive client retrieves named streams on a file basis only.
- Windows Retrieve sparse files
  When retrieving sparse files to a non-NTFS or non-ReFS file system, set the server communication time-out value (IDLETIMEOUT) to the maximum value of 255 to avoid client session timeout.

Mac OS X Windows

Retrieve archives from file spaces that are not Unicode-enabled

If you want to retrieve archives from file spaces that were renamed by the Unicode-enabled client, you must specify the source on the server and a destination on the client.

Mac OS X This section applies to Mac OS X only. For example, assume that `Jaguar` is the name of your startup disk and you archive all of the .log files in the /Users/user5/Documents directory. Before the archive takes place, the server renames the file space to `Jaguar_OLD`. The archive places the data specified in the current operation into the Unicode-enabled file space named `/`. The new Unicode-enabled file space now contains only the Users/user5/Documents directory and the *.log files specified in the operation.

Mac OS X If you want to retrieve a file from the *renamed* (old) file space to its original location, you must enter both the source and destination as follows:

Windows If you want to retrieve archives from file spaces that were renamed by the Unicode-enabled client, you must specify the source on the server and a destination on the client. For example, you archived files from your H-disk, named \\your-node\h$ prior to installing the client. After the installation, you issue the following archive command:

```
arc h:\logs\*.log
```

Windows Before the archive takes place, the server renames the file space to `\\your-node\h$_OLD`. The archive continues placing the data specified in the current operation into the Unicode-enabled file space named `\\your-node\h$`. That file space now contains only the `\logs` directory and the `*.log` files. If you want to retrieve a file from the (old) *renamed* file space to its original location, you must enter both the source and destination as follows:

```
retrieve \\your-node\h$_OLD\docs\myresume.doc h:\docs\
```

Windows

Retrieve named streams

The backup-archive client retrieves named streams on a file basis only.

Directories in Windows systems can contain named streams. Named streams attached to a directory will always be overwritten (regardless of the value of the prompt option) during the retrieve.

Windows

Retrieve sparse files

When retrieving sparse files to a non-NTFS or non-ReFS file system, set the server communication time-out value (IDLETIMEOUT) to the maximum value of 255 to avoid client session timeout.

The following issues apply if more data is restored than the Microsoft disk quota allows:

- If the user who is performing the retrieve has a disk quota (for example, the user belongs to the Backup Operator Group), the backup-archive client does not retrieve any data that exceeds the disk quota of the retrieve user and displays a "Disk Full" message.
- If the user who is performing the retrieve does not have a disk quota (for example, the user belongs to the Administrator Group), the backup-archive client retrieves all data and transfers ownership of the files that exceed the disk quota of the original owner to the user who is performing the retrieve (in this case, the Administrator).

Schedule

The schedule command starts the client scheduler on your workstation. The client scheduler must be running before scheduled work can start.

AIX Linux Solaris Mac OS X **Authorized User:** The schedule command starts the client scheduler on your workstation. The client scheduler must be running before scheduled work can start.

Note:

1. The schedule command cannot be used if the managedservices option is set to `schedule`.
2. Mac OS X For Mac OSX only, to use the schedule command, specify managedservices `none` in the dsm.sys file.
3. This command is valid only on the initial command line. It is not valid in interactive mode or in a macro file.

Windows If the schedmode option is set to polling, the client scheduler contacts the server for scheduled events at the hourly interval you specified with the queryschedperiod option in your client options file (dsm.opt). If your administrator sets the queryschedperiod option for all nodes, that setting overrides the client setting.

AIX Linux Solaris Mac OS X If the schedmode option is set to polling, the client scheduler contacts the server for scheduled events at the hourly interval you specified with the queryschedperiod option in your client user-options file (dsm.opt). If your administrator sets the queryschedperiod option for all nodes, that setting overrides the client setting.

Windows If you are using TCP/IP communications, the server can prompt your workstation when it is time to run a scheduled event. To do so, set the schedmode option to prompted in the client options file (dsm.opt) or on the schedule command.

AIX Linux Solaris Mac OS X If you are using TCP/IP communications, the server can prompt your workstation when it is time to run a scheduled event. To do so, set the schedmode option to prompted in the client user-options file (dsm.opt) or on the schedule command.

Windows After you start the client scheduler, it continues to run and to start scheduled events until you pressCtrl+Break , restart the workstation, or turn off the workstation to end it.

AIX Linux Solaris Mac OS X Mac OS X You can use the sessioninitiation option with the schedule command to control whether the server or client initiates sessions through a firewall.

AIX Linux Solaris Mac OS X After you start the client scheduler, it continues to run and to start scheduled events until you press Ctrl+C, stop the scheduler process with the UNIX kill command, start the workstation again, or turn off the workstation to end it.

Mac OS X After you start the client scheduler, it continues to run and to start scheduled events until you press Ctrl+C, press the Q key twice, start the workstation again, or turn off the workstation to end it.

AIX Linux Solaris Mac OS X Windows Note: You *cannot* enter this command in interactive mode.
AIX Linux Solaris Mac OS X Windows

Supported Clients

This command is valid for all clients.

Syntax

```
>>-SCHedule--+------------+-------------------------------------><
            '- --options-'
```

Parameters

Table 1. Schedule command: Related options

Option	Where to use
Windows maxcmdretries	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X maxcmdretries	AIX Linux Solaris Mac OS X Client system options file (dsm.sys) or command line.
Windows password	Windows client options file (dsm.opt)
AIX Linux Solaris Mac OS X password	AIX Linux Solaris Mac OS X client user options file (dsm.opt)
Windows queryschedperiod	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X queryschedperiod	AIX Linux Solaris Mac OS X Client system options file (dsm.sys) or command line.
Windows retryperiod	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X retryperiod	AIX Linux Solaris Mac OS X Client system options file (dsm.sys) or command line.
Windows schedlogname	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X schedlogname	AIX Linux Solaris Mac OS X Client system options file (dsm.sys) or command line.
Windows schedmode	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X schedmode	AIX Linux Solaris Mac OS X Client system options file (dsm.sys) or command line.
Windows sessioninitiation	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X sessioninitiation	AIX Linux Solaris Mac OS X Client system options file (dsm.sys) or command line.
Windows tcpclientport	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X tcpclientport	AIX Linux Solaris Mac OS X Client system options file (dsm.sys) or command line.

Examples

Mac OS X Windows Task

Mac OS X Windows Start the client scheduler.

Command: `dsmc sch -password=notell`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X For AIX®: Start the scheduler at system bootup time by entering this command in the /etc/inittab file. Ensure that the ***passwordaccess*** option is set to *generate*.

Command: `tsm::once:/usr/bin/dsmc sched > /dev/null 2>&1 #TSM`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Interactively start the scheduler and keep it running in the background.

Command: `nohup dsmc sched 2> /dev/null &`

Windows When you run the schedule command, all messages that regard scheduled work are sent to the `dsmsched.log` file or to the file you specify with the schedlogname option in your client options file (dsm.opt). If you do not specify a directory path with the file name in the schedlogname option, the `dsmsched.log` resides in the current working directory.

AIX Linux Solaris Mac OS X When you run the schedule command, all messages that regard scheduled work are sent to the `dsmsched.log` file or to the file you specify with the schedlogname option in your client system-options file (dsm.sys). If you do not specify a directory path with the file name in the schedlogname option, the `dsmsched.log` resides in the current working directory, except for Mac OS X. For Mac OS X, the `dsmsched.log` resides in the `/Library/Logs/tivoli/tsm/` directory.

AIX Linux Solaris Mac OS X Windows Important: To prevent log write failures and process termination in certain cases, set the DSM_LOG environment variable to name a directory where default permissions allow the required access.

Selective

The selective command backs up files that you specify. If you damage or mislay these files, you can replace them with backup versions from the server.

When you run a selective backup, all the files are candidates for backup unless you exclude them from backup, or they do not meet management class requirements for serialization.

During a selective backup, copies of the files are sent to the server even if they did not change since the last backup - which can result in more than one copy of the same file on the server. If this occurs, you might not have as many different down-level versions of the file on the server as you intended. Your version limit might consist of identical files. To avoid this, use the incremental command to back up only new and changed files.

AIX Linux Solaris Mac OS X Windows You can selectively back up single files or directories. You can also use wildcard characters to back up groups of related files.

If you set the subdir option to yes when you back up a specific path and file, the client recursively backs up all subdirectories under that path, and any instances of the specified file that exist under any of those subdirectories.

During a selective backup, a directory path might be backed up, even if the specific file that was targeted for backup is not found. For example, the following command still backs up `dir1` and `dir2` even if the file `bogus.txt` does not exist.

Mac OS X

```
selective /Users/user1/Documents/dir1/bogus.txt
```

AIX Linux Solaris Mac OS X

```
selective "/dir1/dir2/bogus.txt"
```

Windows

```
selective c:\dir1\dir2\bogus.txt
```

If the selective command is retried because of a communication failure or session loss, the transfer statistics displays the number of bytes that the client attempts to transfer during *all* command attempts. Therefore, the statistics for bytes transferred might not match the file statistics, such as those for file size.

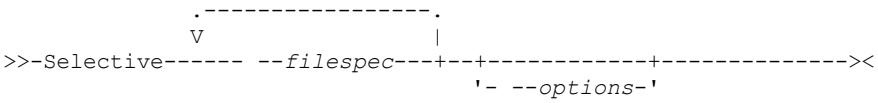
AIX Linux Solaris Mac OS X You can use the removeoperandlimit option to specify that the 20-operand limit is removed. If you specify the removeoperandlimit option with the selective command, the 20-operand limit is not enforced and is restricted only by available resources or other operating system limits.

AIX Linux Solaris Mac OS X Windows

Supported Clients

This command is valid for all clients.

Syntax



Parameters

filespec

Specifies the path and name of the file you want to back up. Use wildcard characters to include a group of files or to include all files in a directory.
To include multiple file specifications, separate each filespec with a space character. If multiple file specifications are included, and two or more of the specifications have common parent directories, then it is possible for the common directory objects to be backed up more than once. The conditions under which this behavior occurs are runtime-dependent, but the behavior itself has no adverse effects.

AIX Linux Mac OS X Solaris For example, if the filespec is /home/amr/ice.doc /home/amr/fire.doc, then /home and /home/amr might be backed up twice. The file objects, ice.doc and fire.doc, are backed up only once.

Windows For example if the filespec is C:\proposals\drafts\ice.doc C:\proposals\drafts\fire.doc, then C:\proposals and C:\proposals\drafts might be backed up twice. The file objects ice.doc and fire.doc are backed up only once.

If you want to avoid including the shared parent directory more than once, use separate, non-overlapping selective commands to back up each file specification.
AIX Linux Mac OS X Solaris If you back up a file system, include a trailing slash (/home/).
AIX Linux Mac OS X Solaris There is a limit of 20 operands. This limit prevents excessive sessions that are caused when wildcards are expanded by the UNIX shell command processor. You can prevent shell expansion from causing you to go over the 20-operand limit by placing quotation marks around file specifications that contain wildcards ("home/docs/*").
AIX Linux Mac OS X Solaris You can use the removeoperandlimit option to specify that the 20-operand limit is removed. If you specify the removeoperandlimit option, the 20-operand limit is not enforced and is restricted only by available resources or other operating system limits. For example, remove the 20 operand limit to backup 21 file specifications:

```
selective -removeoperandlimit filespec1 filespec2 ... filespec21
```

Windows If you back up a file system, include a trailing slash (C:\).
Windows You can specify as many file specifications as available resources or other operating system limits allow.
You can use the filelist option, instead of file specifications, to identify which files to include in this operation. However, these two methods are mutually exclusive. You cannot include file specification parameters and use the filelist option. If the filelist option is specified, any file specifications that are included are ignored.

Table 1. Selective command: Related options

Option	Where to use
Windows changingretries	Windows Client options file (dsm.opt) or command line.
AIX Linux Solaris Mac OS X changingretries	AIX Linux Solaris Mac OS X Client system options file (dsm.sys) or command line.

AIX Linux Solaris Mac OS X tapeprompt	AIX Linux Solaris Mac OS X Client user options file (dsm.opt) or command line.

Examples

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Back up the `proja` file in the `/home/devel` directory.

Command: `selective /home/devel/proja`

Windows Task

Windows Back up the `proja.dev` file in the `c:\devel` directory.

Command: `sel c:\devel\proja.dev`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Back up all files in the `/home/devel` directory whose file names begin with `proj`.

Command: `selective "/home/devel/proj*"`

Windows Task

Windows Back up all files in the `c:\devel` directory whose file names begin with `proj`.

Command: `sel c:\devel\proj*.*`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Back up all files in the `/home/devel` directory whose file names begin with `proj`. Back up the single file that is named `budget` in the `/user/home` directory.

Command: `selective "/home/devel/proj*" /user/home/budget`

Windows Task

Windows Back up all files in the `c:\devel` directory whose file names begin with `proj`. Back up all files with a file extension of `.fin` in the `c:\planning` directory.

Command: `sel c:\devel\proj* c:\planning\*.fin`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Back up the `/home` file system.

Command: `selective /home/ -subdir=yes`

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Assuming that you initiated a snapshot of the `/usr` file system and mounted the snapshot as `/snapshot/day1`, run a selective backup of the `/usr/dir1/sub1` directory tree from the local snapshot and manage it on the IBM Spectrum Protect™ server under the file space name `/usr`.

Command: `dsmc sel "/usr/dir1/sub1/*" -subdir=yes -snapshotroot=/snapshot/day1`

Windows Task

Windows Assuming that you initiated a snapshot of the `C:\` drive and mounted the snapshot as `\\florence\c$\snapshots\snapshot.0`, run a selective backup of the `c:\dir1\sub1` directory tree from the local snapshot and manage it on the IBM Spectrum Protect server under the file space name `C:\`.

Command: `dsmc sel c:\dir1\sub1\* -subdir=yes -snapshotroot=\\florence\c$\snapshots\snapshot.0`

- Windows Open file support
  If open file support is configured, the backup-archive client performs a snapshot backup or archive of files that are locked (or "in use") by other applications.
- Associate a local snapshot with a server file space
  Use the snapshotroot option with the selective command in conjunction with an independent software vendor application that provides a snapshot of a logical volume, to associate the data on the local snapshot with the real file space data that is stored on the IBM Spectrum Protect server. The snapshotroot option does not provide any facilities to take a volume snapshot, only to manage data created by a volume snapshot.

Windows

Open file support

If open file support is configured, the backup-archive client performs a snapshot backup or archive of files that are locked (or "in use") by other applications.

Use VSS as the snapshot provider; set snapshotproviderimage or snapshotproviderfs to VSS.

Note:

1. You can use the include.fs option to set snapshot options on a per file system basis.
2. Open file support is only available for local fixed volumes (mounted to either drive letters or volume mount points) formatted with NTFS or ReFS file systems. This support includes SAN-attached volumes that meet these requirements.
3. If the client is unable to create a snapshot, failover to non-OFS backup occurs; the same backup support that would be done if the OFS feature was not configured.
4. To enable open file support in a cluster environment, all systems in the cluster should have the OFS feature configured.

Associate a local snapshot with a server file space

Use the snapshotroot option with the selective command in conjunction with an independent software vendor application that provides a snapshot of a logical volume, to associate the data on the local snapshot with the real file space data that is stored on the IBM Spectrum Protect™ server. The snapshotroot option does not provide any facilities to take a volume snapshot, only to manage data created by a volume snapshot.

AIX AIX® only: You can perform a snapshot-based selective backup by specifying the option snapshotproviderfs=*JFS2*.

Set Access

The set access command gives users at other nodes access to your backup versions or archived copies.

You can also use the set access command to give users at other nodes access to your backup images.

You can give another user access to a specific file or image, multiple files or images, or all files in a directory. When you give access to another user, that user can restore or retrieve your objects. Specify in the command whether you are giving access to archives or backups.

Linux Windows For VMware virtual machines, you can give a user at another node access to the backups of a specific virtual machine.

When a node is exported to another IBM Spectrum Protect™ server, the access rules can change on the importing server. If an access rule is applied to all file spaces on the exporting server, the access rule on the importing server is restricted to only those file spaces that are imported. The file spaces are restricted in the access rule on the importing server for security reasons. Additionally, the access rules do not recognize the first occurrence of a wildcard character in the file specification when you

restore or retrieve. This means that if you restore or retrieve with a wildcard character in the file specification, subdirectories are ignored.

Tip: If you export a node to another IBM Spectrum Protect server, do not use a single wildcard character as the file specification in the access rule. Instead, create an access rule for each filespace.
Note: You cannot give access to both archives and backups using a single command.

Mac OS X | Windows When an existing file space is renamed during Unicode conversion, any access rules that are defined for the file space remain applicable to the original file space. However, new access rules must be defined to apply to the new Unicode file space.

Supported Clients

This command is valid for all clients.

Syntax

```
>>-SET Access--+- --Archive-+-----------------------------------><
               '- --Backup--'

>--+- --filespec----------------------+-- --node--+---------+--><
   +- --{--filespacename--}--filespec-+          '- --user-'
   +-image-fs-------------------------+
   '-TYPE=VM-- --vmname---------------'
```

Parameters

Archive
: Permits access to archived files or images.

Backup
: Permits access to backup versions of files or images.

AIX | Linux | Solaris | Mac OS X *filespec*

AIX | Linux | Solaris | Mac OS X Specifies the path, file, image, or directory to which your are giving access to another node or user. Use wildcard characters to specify a group of files or images, or all files in a directory; all objects in a directory branch; or all objects in a file system. Use a single asterisk "*" for the file spec to give access to all files or images owned by you and backed up on the server. When the command `set access backup "*" node` is entered, no check is made with the server; it is assumed you have at least one object backed up.

If you give access to a branch of the current working directory, you only need to specify the branch. If you give access to objects that are not in a branch of the current working directory, you must specify the complete path. The file spec to which you gave access must have at least one backup version or archive copy object (file or directory) on the server.

To specify all files in a named directory, enter `/home/mine/proj1/*` on the command line.

To give access to all objects below a certain level, use an asterisk, directory delimiter, and an asterisk at the end of your file spec. For example, to give access to all objects below `home/test`, use file spec `home/test/*/*`.

Important: Use of the form `/*/*` alone will not give access to objects in the named directory; only those in directories below the named directory are accessible.

The rules are essentially the same when considering the root directory. Enter `/*` on one set access command and `/*/*` on another if you want another user to have access to all files and directories in and below the root directory. The first `/*` gives access to all directories and all files in the root directory. The second `/*` allows access to all directories and files below the root directory.

For example:

- Your directory structure is multilevel: `/home/sub1/subsub1`.
- The `/home` directory contains the `h1.txt` and `h2.txt` files.
- The `/home/sub1` directory contains file `s1.htm`.
- The `/home/sub1/sub2` directory contains the `ss1.cpp` file.

To allow access to all files in the `/home/sub1/sub2` directory, enter:

```
set access backup /home/sub1/sub2/* * *
```

To allow access to only those files in the `/home` directory, enter:

```
set access backup /home/* * *
```

To allow access to all files in all directories in and below the `/home` directory, enter:

```
set access backup /home/* * *
set access backup /home/*/* * *
```

Windows *filespec*

Windows Specifies the path, file, image, or directory to which your are giving access to another node or user. Use wildcard characters to specify a group of files or images, or all files in a directory; all objects in a directory branch; or all objects in a drive. However, you cannot use a wildcard to specify all drives. Use a single asterisk "*" for the file spec to give access to all files or images owned by you and backed up on the server. When the command `set access backup "*" node` is entered, no check is made with the server; it is assumed you have at least one object backed up.

If you give access to a branch of the current working directory, you only need to specify the branch. If you give access to objects that are not in a branch of the current working directory, you must specify the complete path. The file spec to which you gave access must have at least one backup version or archive copy object (file or directory) on the server.

To specify all files in a named directory, enter `d:\test\mine\proj1\*` on the command line.

To give access to all objects below a certain level, use an asterisk, directory delimiter, and an asterisk at the end of your file spec. For example, to give access to all objects below `d:\test` use file spec `d:\test\*\*`.

Important: Use of the form `\*\*` alone will not give access to objects in the named directory; only those in directories below the named directory are accessible.

The rules are essentially the same when considering the root directory. Enter `\*` on one set access command and `\*\*` on another if you want another user to have access to all files and directories in and below the root directory. The first `\*` gives access to all directories and all files in the root directory. The second `\*` allows access to all directories and files below the root directory.

Note:

1. Use the file space name if the drive label name has changed.
2. If you include filespacename, do not include a drive letter in the file specification.

For example:

- Your directory structure is multilevel: `d:\test\sub1\subsub1`.
- The `d:\test` directory contains the `h1.txt` and `h2.txt` files.
- The `d:\test\sub1` directory contains file `s1.htm`.
- The `d:\test\sub1\sub2` directory contains the `ss1.cpp` file.

To allow access to all files in the `d:\test\sub1\sub2` directory, enter:

```
set access backup d:\test\sub1\sub2\* * *
```

To allow access to only those files in the `d:\test` directory, enter:

```
set access backup d:\test\* * *
```

To allow access to all files in all directories in and below the `d:\test` directory, enter:

```
set access backup d:\test\* * *
set access backup d:\test\*\* * *
```

Windows {filespacename}

Windows Specifies the file space name (enclosed in braces) on the server that contains the files to which you are giving access. This name is the drive label name on the workstation drive from which the file was backed up or archived. Use the file space name if the drive label name has changed.

image-fs

The name of the image file system to be shared. This can be specified as an asterisk (*) to allow access to all images owned by the user granting access.

Linux | Windows -TYPE=VM *vmname*

Linux Windows This parameter is required if you are using this command to provide another user with access to VMware virtual machine backups. The *vmname* option can be specified only if -TYPE=VM is specified; *vmname* is the name of the VMware virtual machine that you are permitting access to.

node

Specifies the client node of the user to whom you are giving access. Use wildcards to give access to more than one node with similar node names. Use an asterisk (*) to give access to all nodes.

AIX Linux Solaris Mac OS X user

AIX Linux Solaris Mac OS X This is an optional parameter that restricts access to the named user at the specified node. To allow any authorized user to access your backed up or archived data, specify root as the user.

Examples

Windows Task

Windows Give the user at node_2 authority to restore all files with an extension of `.c` from the `c:\devel\proja` directory.

```
set access backup c:\devel\proja\*.c node_2
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Give the user at `node_2` authority to restore the `budget` file from the `/home/user` directory.

```
set access backup /home/user/budget node_2
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Give `node_3` the authority to retrieve all files in the `/home/devel/proja` directory.

```
set ac archive /home/devel/proja/ node_3
```

Windows Task

Windows Give the user at `node_3` authority to retrieve all files in the `c:\devel` directory, but do not permit access to files in subdirectories of `c:\devel`, such as `c:\devel\proj`.

```
set access archive c:\devel\* node_3
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Give all nodes whose names end with `bldgb` the authority to restore all backup versions from directories with a file space name of `project`.

```
set ac b "{project}/*" "*bldgb"
```

Windows Task

Windows Give all nodes whose names end with `bldgb` the authority to restore all backup versions from all directories on the `d:` drive. The `d:` drive has the file space name of `project`.

```
set ac b {project}\*\* *bldgb
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Give any authorized user on node1 authority to retrieve all files in the /home/devel/projb directory.

```
set access archive /home/devel/projb/ node1 root
```

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X Give user serena at `node_5` authority to restore all images of the file space mounted on directory `/home/devel/proja`.

```
set acc backup "home/devel/proja/*/*" node_5 serena
```

Linux Windows Task

Linux Windows Give the node named myOtherNode the authority to restore files backed up by the VMware virtual machine named myTestVM.

```
set access backup -TYPE=VM myTestVM myOtherNode
```

Set Event

Using the set event command, you can specify the circumstances for when archived data is deleted.

You can use the set event command in the following ways:

- Prevent the deletion of data at the end of its assigned retention period (Deletion hold)
- Allow the expiration to take place, as defined by the archive copy group (Release a deletion hold)
- Start the expiration clock to run when a particular event occurs (Notify the server that an event occurred)

Objects that are affected can be specified with a standard file specification (including wildcards), a list of files whose names are in the file that is specified using the filelist option, or a group of archived files with the description specified with the description option.

Note: When only a <filespec> is used, all archived copies of files or folders that match the filespec are affected. If you want to affect certain versions of a file, use the -pick option and select from the displayed list.

Interaction with down-level servers

If the set event command is issued when the client is connected to a server that does not support event-based policy (previous to IBM Spectrum Protect™ 5.2.2), the command is rejected with an error message that indicates the current server does not support event-based policy.

Supported Clients

This command is valid for all clients.

Syntax

```
>>-SET Event---- -TYPE=--+-Hold--------------+------------------>
                         +-Release-----------+
                         '-Activateretention-'

>-- --<filespec>-- -- -filelist=<filespec>-- -- -description=--->

>-- -pick-----------------------------------------------------><
```

Parameters

TYPE=

Specifies the event type setting. This parameter must be specified.

hold

Prevents the object from being deleted regardless of expiration policy.

release

Allows normal event-controlled expiration to take place.

activateretention

Signals the server that the controlling event occurred and starts to run the expiration clock.

-pick

Provides a list of objects from which the user can select to apply the event.

The following options can also be used and serve their usual purpose:

- Dateformat
- Numberformat
- Noprompt
- Subdir
- Timeformat

Examples

AIX Linux Solaris Mac OS X Task

AIX Linux Solaris Mac OS X The following example displays the verbose and statistics output from the set event command `set event type=hold /home/accounting/ledgers/*05.books`, with objects rebound (as opposed to archived or some other notation).

```
Rebinding--> 274 /home/accounting/ledgers/
  jan05.books
Rebinding--> 290 /home/accounting/ledgers/
  feb05.books

```

Linux | Windows

Set Netappsvm

The set netappsvm command associates the logon credentials for a cluster management server, which are specified on the set password command, with a NetApp storage virtual machine, and the data storage virtual machine (SVM) name (data Vserver). You must enter this command before you can create a snapshot difference incremental backup of a clustered NetApp volume.

This command is typically entered only once. The parameters are stored and are reused the next time that you backup a clustered volume that is managed by the storage virtual machine. If you move an storage virtual machine to another cluster management server, you must reenter this command and specify the new cluster management server. If necessary, change the login credentials by using the set password command.

Supported clients

Linux This command is valid for Linux backup-archive clients that complete snapshot difference backups of clustered-data ONTAP-c-mode file-server volumes.

Windows This command is valid for Windows clients that perform snapshot difference backups of clustered-data ONTAP-c-mode file-server volumes.

Syntax

```
>>-SET NETAPPSVM--+-svm_hostname--cms_hostname-- svm_name-+---><
                  '- -remove--svm_hostname----------------'
```

Parameters

svm_hostname
Specifies the host name or IP address of the storage virtual machine that manages the volumes and logical interfaces (LIFs), for the volumes that you want to protect.

cms_hostname
Specifies the host name or IP address of the cluster management server. Specify the same host name that you specified for this cluster management server when you used the set password command to establish the login credentials.

svm_name
Specifies the name of the data SVM that manages the mounted volume. Contact the NetApp SVM administrator to obtain the data SVM name that is assigned to the virtual machine.

-remove *svm_hostname*
Disassociates the SVM from the cluster management server that it was previously associated with. Specify a SVM host-name

You can specify this parameter if you accidentally associated a storage virtual machine with a 7-mode file server. If you remove a 7-mode file server and then associate a cluster management server, set the logon credentials for the cluster management server by using the set password command.

Examples

Configure the credentials and access to a storage virtual machine:

```
set netappsvm svm_example.com cms_filer1.example.com svm_2
dsmc set password cms_filer1.example.com user_name password
```

Remove the associations that were created for the storage virtual machine:

```
set netappsvm -remove svm_example.com
```

AIX Linux Mac OS X Solaris Windows

Set Password

The set password command changes the IBM Spectrum Protect™ password for your workstation, or sets the credentials that are used to access another server.

If you omit the old and new passwords when you enter the set password command, you are prompted once for the old password and twice for the new password.

Passwords can be up to 63 character in length. Password constraints vary, depending on where the passwords are stored and managed, and depending on the version of the IBM Spectrum Protect server that your client connects to.

If your IBM Spectrum Protect server is at version 6.3.3 or later, and if you use an LDAP directory server to authenticate passwords

Use any of the following characters to create a password:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9 . ! @ # $ % ^ & * _ - + = ` ( )
| { } [ ] : ; < > , ? / ~
```

Passwords are case-sensitive and are subject to more restrictions that can be imposed by LDAP policies.

If your IBM Spectrum Protect server is at version 6.3.3 or later, and if you do not use an LDAP directory server to authenticate passwords

Use any of the following characters to create a password:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9 . ! @ # $ % ^ & * _ - + = ` ( )
| { } [ ] : ; < > , ? / ~
```

Passwords are stored in the IBM Spectrum Protect server database and are not case-sensitive.

If your IBM Spectrum Protect server is earlier than version 6.3.3

Use any of the following characters to create a password:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9
_ - & + .
```

Passwords are stored in the IBM Spectrum Protect server database and are not case-sensitive.

AIX Linux Mac OS X Solaris Windows Remember:

On the command line, enclose all parameters that contain one or more special characters in quotation marks. Without quotation marks, the special characters can be interpreted as shell escape characters, file redirection characters, or other characters that have significance to the operating system.

Windows

On Windows systems:

Enclose the command parameters in quotation marks (").

Command line example:

```
dsmc set password "t67@#$%^&" "pass2><w0rd"
```

AIX Linux Solaris

On AIX®, Linux, and Solaris systems:

Enclose the command parameters in single quotation marks (').

Command line example:

```
dsmc set password -type=vmguest 'Win 2012 SQL' 'tsml2dag\administrator' '7@#$%^&7'
```

Quotation marks are not required when you type a password with special characters in an options file.

Supported Clients

This command is valid for all clients.

The following parameters apply to VMware operations, which are available only if you are using the client as a data mover for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

- TYPE=DOMAIN
- TYPE=VM
- TYPE=VMGUEST

Syntax

```
>>-SET Password--+--------------+------------------------------>
                 '-oldpw--newpw-'

>--+-----------------------------------------+----------------->
   '-otherserver--otheruserid--otherpassword-'

   .-TYPE=TSM-----------.
>--+--------------------+-------------------------------------><
   +-TYPE=DOMAIN--------+
   +-TYPE=FASTBack------+
   +-TYPE=FILER---------+
   +-TYPE=VM------------+
   '-TYPE=VMGUEST ALLVM-'
```

Parameters

oldpw
: Specifies the current password for your workstation.

newpw
: Specifies the new password for your workstation.

other_server other_user_id other_password
: These three parameters specify the attributes that the client uses to access another server, such as a filer or an ESXi host.

  other_server
  : Specifies the host name or IP address of the server that the client can access to protect files.

  other_user_id
  : The user ID of an account on the server that the client uses to log on to the other server. The account must have the privileges that are necessary to perform the operations that are run after the user is logged on to the other server.

  other_password
  : The password that is associated with the user ID on the other server.

TYPE
: Specifies whether this password is for the backup-archive client or for another type of server.

  Use TYPE=TSM to specify the password for your backup-archive client. The default type is TYPE=TSM.

  Windows Use TYPE=DOMAIN to set the Windows domain administrator credentials to enable users to log in to a remote Windows proxy node (the file restore interface), for file restore operations. This option requires a license for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.
  Use the following format for the set password -type=domain command:

  ```
  set password -type=domain -validate administrator_name password
  ```

  where:

VALidate
: Validates the Windows domain administrator credentials before the credentials are stored. If the validation fails, the credentials are not stored, and users are not able to log in to the file restore interface. The validate parameter is valid only with the `TYPE=DOMAIN` parameter.

administrator_name
: Specifies the account name of a domain administrator. The account name must contain the Windows domain name and the administrator ID. The account name must be in the following format:

```
domain_name\administrator_ID
```

password
: Specifies the password that is associated with the specified domain administrator account.

For more information about configuration requirements for remote mount proxy nodes, see the IBM Spectrum Protect for Virtual Environments: Data Protection for VMware documentation.

Linux | Windows

Use `TYPE=FastBack`, on Linux and Windows clients, to store the Tivoli® Storage Manager FastBack credentials that are required for mounting and dismounting the FastBack volumes on the Windows FastBack Disaster Recovery Hub server.

The password file on the vStorage backup server must have either the Windows administrator ID for the VMware virtual center system, or the UNIX user ID for a specific ESX server. For a proxy backup for FastBack, the password file must contain the FastBack administrator ID and password. Here are some examples:

```
dsmc set password 192.0.2.24 admin admin 123 -type=fastback

dsmc set password 192.0.2.24 WORKGROUP:admin admin 123 -type=fastback

dsmc set password windserv administrator windpass4 -type=fastback
```

Important: You must define the user credentials that are required to mount and unmount FastBack volumes from a repository to the backup-archive client before you enter the backup-archive FastBack subcommand. Use the fbserver option to define the credentials.
Here is a brief description of the various configurations and credentials that you need:

- The backup-archive client is installed on a dedicated vStorage backup server. The client on the vStorage backup server must connect to multiple network share repositories.

Follow these steps for each of the network share repositories where the client is connected:

1. Configure the repository for remote network access from FastBack Manager. Refer to the Tivoli Storage Manager FastBack product documentation on IBM® Knowledge Center at http://www.ibm.com/support/knowledgecenter/SS9NU9/welcome.

   This step establishes a domain name, a network share user ID, and a network share password to connect remotely to the repository.

2. On the backup-archive client workstation, manually enter the following command:

   ```
   dsmc set password type=fastback FBServer domain:networkaccessuserid
      networkaccesspassword
   ```

   The fbserver option specifies the short host name of the FastBack server workstation. For the FastBack DR Hub, the fbserver option specifies the short name of the workstation where the DR Hub is installed.

   Networkaccessuserid is either the Windows administrator ID or the FastBack administration password.

   Domain is the domain name of the user ID.

   Networkaccesspassword is either the Windows administrator ID or the FastBack administration password.

3. These credentials are retrieved based on the short host name that you specify with the fbserver option.

Linux | Windows

Use `TYPE=FILER`, on Linux and Windows systems to specify that this password is for snapshot difference operations on a file server.

For TYPE=FILER, you must specify a file server name, and the user ID and the password that is used to access the file server. For example: `dsmc set password -type=filer myfiler filerid filerpasswd`.

When you specify TYPE=FILER, the password is stored in the password (TSM.sth) file without validating that the password is valid. Passwords that are stored with TYPE=FILER can be shared between client nodes. For example, a password that is stored by NODE_A can be used by NODE_B. Only one set of credentials is stored per file server.

Linux | Windows

Use TYPE=VM to set the password that is used to log on to an ESX or vCenter server.

```
dsmc SET PASSWORD -type=VM hostname administrator password
```

where:

hostname
Specifies the VMware VirtualCenter or ESX server that you want to back up, restore, or query. This host name must match the host name syntax that is used in the vmchost option. That is, if vmchost uses an IP address instead of a host name, this command must provide the IP address, and not a short host name or a fully qualified host name.

administrator
Specifies the account that is needed to log on to the vCenter or ESXi host.

password
Specifies the password that is associated with the login account that you specified for the vCenter or ESXi administrator.

Use the Preferences editor to set the vmchost, vmcuser, and vmcpw options.

You can also set the vmchost option in the client options file and then use the set password command to associate that host name with the administrator account and the administrative account password that is used to log on to that host. For example, `set password TYPE=VM myvmchost.example.com administrator_name administrator_password`.

Linux | Windows

Use TYPE=VMGUEST, on Linux and Windows clients, if you use the INCLUDE.VMTSMVSS option to protect a virtual machine. Use the following format for the set password command:

```
set password -type=vmguest guest_VM_name administrator password
```

where:

guest_VM_name
Specifies the name of the virtual machine guest that you want to protect.

administrator
Specifies the account that is needed to log on to the guest VM.

password
Specifies the password that is associated with the login account.

If you use the same credentials to log on to multiple virtual machines that are protected by the INCLUDE.VMTSMVSS option, you can set the password for the all of the virtual machines by specifying the ALLVM parameter. The ALLVM parameter causes the same credentials to be used when the client logs on to any guest that is included in an INCLUDE.VMTSMVSS option. The following command TYPE=TSM is an example of how to use ALLVM. In this example, the user name "Administrator" and the password "Password" are used to log on to any virtual machine that you included on an INCLUDE.VMTSMVSS option:

```
set password -type=vmguest ALLVM Administrator Password
```

You can also set a combination of shared and individual credentials. For example, if most virtual machines in your environment use the same credentials, but a few virtual machines use different credentials, you can use multiple set password commands to specify the credentials. For example, assume that most virtual machines use "Administrator1" as the login name and "Password1" as the password. Assume also that one virtual machine, named VM2, uses "Administrator2" as the login name and "Password2" as the password. The following commands are used to set the credentials for this scenario:

- `set password -type=vmguest ALLVM Administrator1 Password1` (sets credentials for most of the VMs).
- `set password -type=vmguest VM2 Administrator2 Password2` (sets unique credentials for VM2).

Examples

The following examples use the set password command.

AIX Linux Mac OS X Solaris Windows Task

AIX Linux Mac OS X Solaris Windows Change your password from `osecret` to `nsecret`.

```
set password osecret nsecret
```

AIX Linux Solaris Mac OS X Windows Task

AIX Linux Solaris Mac OS X Windows Set up a user ID and password for the root user on the file server `myFiler.example.com`.

```
dsmc set password -type=filer myFiler.example.com root

Please enter password for user id "root@myFiler.example.com": ******** Re-enter the password
for verification:******** ANS0302I Successfully done.
```

AIX Linux Solaris Mac OS X Windows Task

AIX Linux Solaris Mac OS X Windows Set up a user ID and password for the root user on the file server `myFiler.example.com`.

```
dsmc set password -type=filer myFiler.example.com root secret
```

Linux Windows Task

Linux Windows Set up a user ID and password for the FastBack server `myFastBackServer`. Use the -fbserver option in the archive fastback and backup fastback commands for the server name.

Linux `dsmc set password -type=FASTBack myFastBackServer myUserId 'pa$sword'` Windows `dsmc set password -type=FASTBack myFastBackServer myUserId "pa$sword"`

Important:

1. The `dsmc set password -type=fastback` command must be repeated on a dedicated client proxy workstation once for each FastBack repository where the backup-archive client is expected to connect.
2. For network share repositories, issue the `dsmc set password -type=fastback` command in this format: `dsmc set password -type=fastback myFBServer domainName:userId password`.

   The server name that is specified, which is `myFBServer` in this example, must match the name that you specify on the -fbserver option on a backup fastback or archive fastback command.

3. For the FastBack server or the FastBack Disaster Recovery Hub, the user ID and password that are specified must have FastBack administrator privileges. You must issue the `dsmc set password -type=fastback` command once for each FastBack Server branch repository on the FastBack DR Hub that the backup-archive client is expected to connect to.

Linux Task

Linux The backup-archive client is connecting to the FastBack server repository whose short host name is `myFBServer`. `user ID` is the FastBack network user ID that has read/write access to the repository share. `DOMAIN` is the domain to which the user ID belongs. `myNetworkPass` is the corresponding password for the user ID.

```
dsmc set password -type=fastback myFbServer DOMAIN:USERID myNetworkPass
```

Linux Task

Linux The backup-archive client is connecting to a repository on a DR Hub machine whose short host name is `myFbDrHub`. The user ID is the Windows administrator ID. `DOMAIN` is the domain to which the DR Hub machine belongs. `myNetworkPass` is the corresponding password for the administrator ID.

```
dsmc set password -type=fastback myFbDrHub DOMAIN:administrator adminPasswd
```

Windows Task

Windows Set up the Windows domain administrator credentials that are necessary for users to log in to the file restore interface and save the Windows domain credentials. In this example, the Windows domain in which all user accounts are registered is called `example_domain`. `Kev_the_admin` is the Windows domain administrator ID and `pas$word!` is the corresponding password for the administrator.

```
dsmc set password -type=domain -val "example_domain\Kev_the_admin" "pas$word!"
```

Linux Windows

Set Vmtags

The set vmtags command creates data protection tags and categories that can be added to VMware inventory objects. You can manage IBM Spectrum Protect™ backups of virtual machines in these VMware objects by specifying the tags with tools such as VMware vSphere PowerCLI Version 5.5 R2 or later.

This feature is available only if the client operates as a data mover for IBM Spectrum Protect for Virtual Environments: Data Protection for VMware.

If you are using the IBM Spectrum Protect vSphere Client plug-in to manage backups, you do not need to run the set vmtags command first. The tags and categories are created for you.

If you are writing scripts to apply these tags to VMware inventory objects, you need only to issue the set vmtags command once so that data protection tags are created before they are added to the VMware inventory.

You can manage virtual machine backups at the following VMware inventory object levels:

- Datacenter
- Folder (Host and Cluster folders and VM and Template folders)
- Host
- Host cluster
- Resource pool
- Virtual machine

For the list of supported tags, see "Supported data protection tags."

For tags that are related to schedules, the virtual machines must be in a protection set that is protected by a schedule. A protection set consists of the virtual machines in a container that is assigned the `Schedule (IBM Spectrum Protect)` tag.

After running the set vmtags command, you can assign the tags to VMware objects to manage the protection of virtual machines. For example, you can exclude or include virtual machines in scheduled backup services, specify the retention policy for backups, set the data consistency of snapshots, or select the virtual machine disks to protect.

If the data protection tags already exist, running the set vmtags command does not create the tags again.

If you are upgrading from a previous version of the data mover, running the set vmtags command again will create any new tags that are available in the new version of the data mover.

Requirements: Before you run the set vmtags command, ensure that the following requirements are met:

- VMware vCenter Server must be at Version 6.0 Update 1 or later.
- The vmchost option must be configured in the dsm.opt file on Windows data movers or dsm.sys file on Linux data movers. The user name and password that are associated with the vmchost value must also be set. If not already set, you can use the dsmc set password command to set the user name and password.

Supported clients

Linux This command is valid only on supported Linux x86_64 clients that are installed on a vStorage backup server that protects VMware assets.

Windows This command is valid on supported Windows 64-bit clients that are installed on a vStorage backup server that protects VMware assets.

Syntax

```
>>-SET VMTAGS-------------------------------------------------><
```

Parameters

No parameters are required for this command.

Examples

Task

Create data protection tags and categories that can be added to VMware inventory objects:

```
dsmc set vmtags
```

- Linux | Windows Data protection tagging overview
  To manage data protection of virtual machines, you can assign IBM Spectrum Protect tags to VMware inventory objects. You can assign tags to VMware objects by specifying data protection settings in the IBM Spectrum Protect vSphere Client plug-in of the vSphere Web Client. If you do not use the IBM Spectrum Protect vSphere Client plug-in, you can assign tags by using scripting tools such as VMware Power CLI.

Windows

IBM Spectrum Protect Client Service Configuration Utility

The following client services can be installed when you install the backup-archive client, or when you use the IBM Spectrum Protect™ Client Service Configuration Utility after the backup-archive client is installed:

- Backup-Archive Scheduler Service
- Client Acceptor Service
- Remote Client Agent Service
- Journal Engine Service

For more information about using the IBM Spectrum Protect Client Service Configuration Utility to install client services, see the related information about using the dsmcutil command.

- Windows Install the backup-archive scheduler service
  You can use either the backup-archive client GUI or the IBM Spectrum Protect Client Service Configuration Utility to install the scheduler.
- Windows dsmcutil command
  The IBM Spectrum Protect Client Service Configuration Utility, dsmcutil, can be used to install backup-archive client services on local and remote Windows workstations.

Related concepts:
dsmcutil command
Windows

Install the backup-archive scheduler service

You can use either the backup-archive client GUI or the IBM Spectrum Protect™ Client Service Configuration Utility to install the scheduler.

About this task

- From the backup-archive client GUI, click Utilities, and then click Setup Wizard. Select the Help me configure the Client Scheduler option.
- If you have an account that belongs to the Administrator/Domain Administrator group, you can use the IBM Spectrum Protect Client Service Configuration Utility to configure client services on both local and remote Windows workstations.

- Windows Using the Client Service Configuration Utility (Windows)
  This section provides the steps for using the Client Service Configuration Utility to automate backups, manage existing scheduler services, create a new scheduler, and associate a client acceptor to manage the scheduler.

Windows

dsmcutil command

The IBM Spectrum Protect™ Client Service Configuration Utility, dsmcutil, can be used to install backup-archive client services on local and remote Windows workstations.

You can use the dsmcutil command to install the following client services:

- Backup-Archive Scheduler Service
- Client Acceptor Service
- Remote Client Agent Service
- Journal Engine Service

The Client Service Configuration Utility must be run from an account that belongs to the Administrator/Domain Administrator group. The syntax for the command is as shown in the following text:

```
                          .-SCHEDuler---.
>>-dsmcutil-- --command--+-service-----+----------------------><
                         +-CAD---------+
                         +-JOURnal-----+
                         '-REMOTEagent-'
```

Note: Options that you specify with dsmcutil commands override option that you specify in your options file (dsm.opt).

The account that runs the utility must have the appropriate user rights for installing services and updating the Windows Registry on the target workstation.

If a remote workstation is specified, the account must be authorized to connect to the Windows Registry of the specified workstation.

Note: For the commands and options that are documented here, the minimum abbreviation that you can type is shown in uppercase letters.

- Windows Dsmcutil commands: Required options and examples
  Reference information for the dsmcutil commands and examples are provided.
- Windows Dsmcutil valid options
  This section lists the valid **dsmcutil** options that you can specify to use the scheduler service.

Configure the IBM Spectrum Protect client
Windows

Dsmcutil commands: Required options and examples

Reference information for the dsmcutil commands and examples are provided.

The INSTall command installs and configures backup-archive client services.

INSTall Scheduler

Installs and configures the IBM Spectrum Protect™ Scheduler Service.

These are the required INSTall command options:

- /name:*service_name*
- /password:*password*
- /clusternode:Yes | No (required if running the Microsoft Cluster Server (MSCS) or Veritas Cluster Server (VCS)).
- /clustername:*cluster_name* (required if running the MSCS or VCS).

Restriction: Do not specify a clustername of more than 64 characters. If you specify more than 64 characters and you are using Veritas Storage Foundation with High Availability or a Microsoft Cluster Server configuration, you might not be able to install or start the scheduler service.

The /clientdir:*client_dir* option can also be used, the default is the current directory.

The following files must exist in the directory specified by *client_dir*:

- dsmcsvc.exe

- dscenu.txt
- dsm.opt
- dsmntapi.dll
- tsmutil1.dll

Note: If the service is being installed on a remote workstation, the fully qualified client directory path should be relative to the target workstation. UNC names are not allowed for the local system account. Multiple services can be installed on the same workstation.
Tip: In the commands that are provided in the following examples, the default location of the client installation program (c:\program files\tivoli\tsm\baclient) is used. If you installed the client to a different location, replace the default path with your custom installation path. If the path contains a space, enclose the path in double quotation marks (for example, "c:\program files\tivoli\tsm\baclient").

Task

Install a scheduler service that is named `TSM Central Scheduler Service` on the local workstation. Start the service automatically at system boot time. All required files must reside in the current directory and the client options file must point to the IBM Spectrum Protect server where node ALPHA1 is defined with password `nodepw`. The server is contacted to verify that the specified node and password are valid. When the password is validated it is generated (encrypted) into the password store:
Command:

```
dsmcutil install scheduler /name:"TSM Central Scheduler Service"
/node:ALPHA1 /password:nodepw /autostart:yes
```

Task

Install a scheduler service named `TSM Central Scheduler Service` on remote workstation PDC. Start the service automatically at system boot time. The required scheduler service files and the specified options file must reside on the remote workstation in the `c:\program files\tivoli\tsm\baclient` directory. The password is encrypted into the password store. The IBM Spectrum Protect server is not contacted to validate the password.
Command:

```
dsmcutil install scheduler /name:"TSM Central Scheduler Service"
/machine:PDC /clientdir:"c:\program files\tivoli\tsm\baclient"
/optfile:"c:\program files\tivoli\tsm\baclient\dsm.opt"
/node:PDC /validate:no /autostart:yes /password:nodepassword
```

Task

Install a scheduler service named `TSM Central Scheduler Service` on remote workstation PDC. Start the service automatically at system boot time. The required scheduler service files and the specified options file must reside on the remote workstation in the `c:\program files\tivoli\tsm\baclient` directory. The password is encrypted into the password store. The IBM Spectrum Protect server residing at the specified TCP/IP host and port is contacted to validate the password.
Command:

```
dsmcutil install scheduler /name:"TSM Central Scheduler Service"
 /machine:PDC /clientdir:"c:\program files\tivoli\tsm\baclient"
 /optfile:"c:\program files\tivoli\tsm\baclient\dsm.opt"
 /node:PDC /autostart:yes /password:nodepassword
 /commmethod:tcpip /commserver:alpha1.example.com
 /commport:1521
```

Task

Install the `TSM Central Scheduler Service` on one node of a MSCS (or VCS) cluster. For *group-a* from workstation *node-1*, ensure that *node-1* currently owns *group-a* and then issue the following command.

Command:

Command:

```
dsmcutil install scheduler /name:"TSM Central Scheduler Service:
group-a" /clientdir:"c:\program files\tivoli\tsm\baclient"
/optfile:"c:\program files\tivoli\tsm\baclient\dsm.opt"
/node:mscs-cluster-group-a /password:n
/validate:no /autostart:yes /startnow:yes
/clusternode:yes /clustername:mscs-cluster
```

INSTall CAD

Installs and configures the Client Acceptor Service. Required options are:

- /name:*service_name*
- /node:*node_name*
- /password:*password*

Other valid options are:

- /optfile:*options_file*
- /httpport:*http_port*
- /webports:*web_ports*

Task

Install a Client Acceptor Service called `TSM CAD`. The client acceptor uses a node called *test* to connect to the IBM Spectrum Protect server. Use the options file `c:\program files\tivoli\tsm\baclient\dsm.opt` to connect to the server.

Command:

```
dsmcutil install cad /name:"TSM CAD" /node:test /password:test
/optfile:"c:\program files\tivoli\tsm\baclient\dsm.opt"
```

INSTall Journal

Installs a journaling engine service on all Windows clients. A journal database is created that stores information the client uses to determine which files are eligible for backup before an operation starts.

If necessary, you can use the nojournal option with the incremental command to specify that you want to perform a traditional full incremental backup.

The journaling engine service is named `TSM Journal Service` and uses the configuration file `tsmjbbd.ini` from the backup-archive client installation directory.

Note: The Journal Service is supported in a Microsoft Cluster Server environment. Multiple journal services can be installed by specifying unique pipe names using the JournalPipe journal config setting and client options.

There are no valid options for this command.

Task

Install the journal engine service (`TSM Journal Service`).

Command:

```
dsmcutil install journal
```

INSTall REMOTEAgent

Installs and configures a Remote Client Agent Service. Required options are:

- /name:*service_name*
- /node:*node_name*
- /password:*password*
- /partnername:*partner_service_name*

Other valid options are:

- /optfile:*options_file*

Task

Install a Remote Client Agent Service called `TSM AGENT`. The remote client agent uses a node called *test* to connect to the IBM Spectrum Protect server. The options file c:\program files\tivoli\tsm\baclient\dsm.opt is used to connect to. The partner client acceptor service is `TSM CAD`.

Command:

```
dsmcutil install remoteagent /name:"TSM AGENT" /node:test
/password:test /optfile:"c:\program files\tivoli\tsm\baclient\dsm.opt"
/partnername:"TSM CAD"
```

Note: Both the Remote Client Agent Service and the Client Acceptor Service must be installed to run the web client. The Client Acceptor Service must be installed before the Remote Client Agent Service. Use the /partnername: option to specify the name of the partner Client Acceptor Service.

REMove

Remove an installed Client Service. The required option is /name:*service_name*.

Task

Remove the specified scheduler service from the local workstation.
Command:

```
dsmcutil remove /name:"TSM Central Scheduler Service"
```

Task

Remove the journaling engine service (TSM Journal Service) from the local workstation.
Command:

```
dsmcutil remove /name:"TSM Journal Service"
```

UPDate

Updates Scheduler Service registry values. The required option for this command is /name:*service_name*, and the registry values to update. Other valid options are:

- /clientdir:*client_dir*
- /optfile::*options_file*
- /eventlogging:Yes | No
- /node:*node_name*
- /autostart:Yes | No
- /clusternode:Yes | No (required if running the MSCS or VCS).
- /clustername:*cluster_name* (required if running the MSCS or VCS).

Task

Update the client directory and options file for the specified scheduler service. All required client service files must reside in the specified directory.
Note: The communication options specified with the dsmcutil command here take precedence over those specified in the client options file.
Command:

```
dsmcutil update /name:"TSM Central Scheduler Service"
/clientdir:"c:\program files\tivoli\tsm\baclient"
/optfile:"c:\program files\tivoli\tsm\baclient\dsm.opt"
```

Task

Update the specified scheduler service to use the TCP/IP protocol to connect to the IBM Spectrum Protect server at the specified host name on the specified port.
Command:

```
dsmcutil update /name:"TSM Central Scheduler Service"
/commserver:nt1.example.com /commport:1521 /commmethod:
tcpip
```

UPDate CAD

Updates Client Acceptor Service registry values. The required option for this command is /name:*service_name*, and the registry values to update. Other valid options are:

- /node:*node_name*
- /password:*password*
- /optfile:*options_file*
- /httpport:*http_port*
- /webports:*web_ports*
- /cadschedname:*scheduler_name*

Task

Update the Client Acceptor Service to use the specified client password and options file. All required client service files must reside in the specified directory.

Command:

```
dsmcutil update cad /name:"TSM CAD" /password:test
/optfile:"c:\program files\tivoli\tsm\baclient\dsm.opt"
```

UPDate REMOTEAgent

Updates Remote Client Agent Service registry values. The required option for this command is /name:*service_name*, and the registry values to update. Other valid options are:

- /node:*node_name*
- /password:*password*
- /optfile:*options_file*
- /partnername:*partner_service_name*

Task

Update a Remote Client Agent Service called `TSM AGENT`. The remote client agent service uses a node called *test* to connect to the IBM Spectrum Protect server. The options file c:\program files\tivoli\tsm\baclient\dsm.opt is used to connect to the server. The partner client acceptor service is `TSM CAD`.

Command:

```
dsmcutil update remoteagent /name:"TSM AGENT" /node:test
/password:test /optfile:"c:\program files\tivoli\tsm\baclient\dsm.opt"
/partnername:"TSM CAD"
```

Query Scheduler

Query Scheduler Service registry values. Required options are: /name:*service_name*. Other valid options are:

- /machine:*machine_name*
- /clientdir
- /optfile
- /eventlogging
- /node
- /commmethod
- /commport
- /commserver
- /errorlog
- /schedlog

Note: Do not specify a value for the non-required options. The client returns option registry values for the scheduler service you specify.

Task

Query registry settings for the scheduler service you specify.

Command:

```
dsmcutil query /name:"TSM Central Scheduler Service"
```

Task

Query the client directory registry setting for the scheduler service you specify.

Command:

```
dsmcutil query /name:"TSM Central Scheduler Service"
```

Query CAD

Queries Client Acceptor Service registry values. The required option for this command is /name:*service_name*. Other valid options are:

- /machine:*machine_name*
- /node
- /optfile

- /httpport
- /webports
- /clientdir
- /partnername

Note: Do not specify a value for these options.

Task
: Query registry settings for the Client Acceptor Service you specify.
Command:

```
dsmcutil query cad /name:"TSM CAD"
```

Query Journal

Query the journaling engine service, `TSM Journal Service`, on a Windows system. There are no valid options for this command.

Task
: Query the journaling engine service, `TSM Journal Service`.
Command:

```
dsmcutil query journal
```

Query REMOTEAgent

Queries Remote Client Agent Service registry values. The required option for this command is /name:*service_name*. Other valid options are:

- /machine:*machine_name*
- /node
- /optfile
- /partnername
- /clientdir

Note: Do not specify a value for these options.

Task
: Query registry settings for the specified Remote Client Agent Service.
Command:

```
dsmcutil query remoteagent /name:"TSM AGENT"
```

List

Lists installed Client Services. There are no required options.

Task
: Locate and list the installed backup-archive client services on the local workstation.
Command:

```
dsmcutil list
```

Task
: List the installed backup-archive client services on remote workstation PDC.
Command:

```
dsmcutil list /MACHINE:PDC
```

START

Use the Start command to start a client service. The Start command requires the /name:*service_name* option.

Task
: Start the journaling engine service, `TSM Journal Service`.
Command:

```
dsmcutil start /name:"TSM Journal Service"
```

STOP

Use the Stop command to stop a client service. The Stop command requires the /name:*service_name* option.

Task
: Stop the journaling engine service, `TSM Journal Service`.
Command:

```
dsmcutil stop /name:"TSM Journal Service"
```

UPDATEPW

Generate an encrypted IBM Spectrum Protect password. The UPDATEPW command requires the /node:*node_name*, /password:*password*, and /commserver:*server_name* options. If the clusternode option is set to YES, the /optfile: parameter is also required.

Optionally, you can use the following options:

- /validate:Yes | No
- /clusternode:Yes | No (required if running the MSCS or VCS).
- /clustername:*cluster_name* (required if running the MSCS or VCS).
- /force:Yes | No
- /optfile: (for non-cluster operations)
- /commmethod:
- /commport:

The password is validated with the IBM Spectrum Protect server if /validate:Yes is specified. The password is updated on the server if you specify /updateonserver:Yes. If you specify this option, you must specify the current password with the /oldpassword: option.

Task
: Update the encrypted password for the specified node. Validate and update the password on the specified IBM Spectrum Protect server which resides on the specified TCP/IP hostname and port:
Command:

```
dsmcutil updatepw /node:alpha1 /commMethod:tcpip
/commServer:alpha1.example.com /commPort:1500
/password:newpw /oldpassword:oldpw /updateonserver:yes
/validate:yes /optfile:"c:\program files\tivoli\tsm\baclient\dsm.opt"
```

ADDACE

Grants access to the IBM Spectrum Protect backup-archive client password and the client SSL certificates for non-administrators.

Beginning with IBM Spectrum Protect Version 8.1.2, stricter access control is enforced for the IBM Spectrum Protect password storage on Windows operating systems. By default, only the Administrator, SYSTEM, or LocalSystem account has access to the password store and SSL certificates.

You can use the addace command to modify the access control list to allow additional users, such as non-administrative users, or processes such as the IBM Spectrum Protect Data Protection client processes to access the password store and SSL certificates.

The following options are required:

- -entity:*user* | *group*
- -object:ALL | *NODENAME* | *path*\TSM.* | *path*\spclient.*

Where:

user | *group*
: The Windows user or user group that is given read/write access to the password store.

ALL
: Grants access to all password files and SSL certificates in the subdirectories of the C:\ProgramData\Tivoli\TSM\baclient directory.

NODENAME

Grants access to all password files and SSL certificates that are found in the subdirectories of the C:\ProgramData\Tivoli\TSM\baclient\Nodes*nodename* directory.

path\TSM.* | *path*\spclient.*

For cluster passwords that can exist on a shared resource directory, grants access to the password files or certificate files in a specific directory for a node.

For more information about the secure password locations on Windows, see Secure password storage.
Tip: The dsmcutil deleteace command revokes access to password files and SSL certificates.

Task

After you installed and configured the backup-archive client as Administrator, you need to give Susan, a non-administrative user on your Windows system, access to the password files and SSL certificates on the client node `Alpha1`.
Command:

```
dsmcutil addace -entity:Susan -object:Alpha1
```

Task

A non-administrative user of IBM Spectrum Protect for Databases: Data Protection for Microsoft SQL Server configured the IBM Spectrum Protect passwords but the administrator also needs access to the passwords. The Data Protection for Microsoft SQL Server user grants access to the password files to the administrator by issuing the following command:
Command:

```
dsmcutil addace -entity:Administrator -object:all
```

Task

During a cluster configuration, the Windows administrator needs to give the cluster node `clusnode_A` access to the client SSL certificates.
Command:

```
dsmcutil addace -entity:Group_A
-object:C:\ProgramData\Tivoli\TSM\baclient\Nodes\clusnode_A\spclient.*
```

If the client certificates are not in the default location (C:\ProgramData\Tivoli\TSM\baclient\Nodes\clusnode_A\), they are located in the same directory as the dsm.opt file.

DELETEACE

Revokes access to the IBM Spectrum Protect backup-archive client password and the client SSL certificates for non-administrators.

You can use the deleteace command to modify the access control list to remove access to the password store and client certificates for users, such as non-administrative users or processes such as the IBM Spectrum Protect Data Protection client processes.

The following options are required:

- -entity:*user* | *group*
- -object:ALL | *NODENAME* | *path*\TSM.* | *path*\spclient.*

Where:

user | group

The Windows user or user group for which access to the password store and client certificates is removed.

ALL

Removes access to all password files and SSL certificates in the subdirectories of the C:\ProgramData\Tivoli\TSM\baclient directory.

NODENAME

Removes access to all password files and SSL certificates that are found in the subdirectories of the C:\ProgramData\Tivoli\TSM\baclient\Nodes*nodename* directory.

path\TSM.* | *path*\spclient.*

For cluster passwords that can exist on a shared resource directory, removes access to the password files or certificate files in a specific directory for a node.

For more information about the secure password locations on Windows, see Secure password storage.
Tip: The dsmcutil addace command grants access to password files and SSL certificates.

Task

Susan, a non-administrative user, left the company two days ago and the administrator must revoke access to the password files and SSL certificates on the client node `Alpha1`.
Command:

```
dsmcutil deleteace -entity:Susan -object:Alpha1
```

Task

Cluster node `clusnode_Z` is moved out of the cluster configuration and no longer needs to access to the client SSL certificates. Issue the following command to remove access for `clusnode_Z`.
Command:

```
dsmcutil deleteace -entity:Group_Z
-object:C:\ProgramData\Tivoli\TSM\baclient\Nodes\clusnode_Z\spclient.*
```

If the client certificates are not in the default location (C:\ProgramData\Tivoli\TSM\baclient\Nodes\clusnode_Z\), they are located in the same directory as the dsm.opt file.

Dsmcutil valid options

This section lists the valid **dsmcutil** options that you can specify to use the scheduler service.

About this task

/autostart:[Yes|No]
Specifies whether the Scheduler Service starts automatically at system boot time. The default is *No*.
/cadschedname:schedulername
Specifies the name of the scheduler service to manage with the client acceptor. Use this option when the ***managedservices*** option is set to *schedule* in the client options file dsm.opt. You can specify this option only with the client acceptor service.
/clientdir:clientdir
The fully qualified directory path where the Client Service files reside. This directory should be relative to the target workstation where the service is installed. UNC names are not allowed if the local system account is set to logon. The default is the current directory.
/clustername:clustername
This option replaces the ***/group*** option.

The ***/clustername*** option specifies the cluster name to which the system belongs. You can determine the cluster name in any of the following ways:

- On MSCS, run the MSCS command, CLUSTER /LIST, from the command line or use the Cluster Administrator utility. When the Cluster Administrator utility starts, it displays a tree-like structure with the cluster name at the top.
- On VCS, use the VCS Cluster Manager - Java™ Console or open the main.cf file in the %VCS_HOME%\config directory.
- On VCS, use the following command:

  ```
  haclus -display
  ```

Restriction: Do not specify a clustername of more than 64 characters. If you specify more than 64 characters and you are using Veritas Storage Foundation with High Availability or a Microsoft Cluster Server configuration, you might not be able to install or start the IBM Spectrum Protect™ scheduler service.

This option must be used with the ***/clusternode***:Yes option. This option must be specified when using the INSTALL command in a cluster environment. It must also be specified when using the UPDATE command to modify the cluster settings (***/clusternode*** and ***/clustername***).

This option can also be specified when using the UPDATEPW command in a cluster environment. Normally this is not required. However, if more than one scheduler service with different cluster settings are defined for a particular node, the utility cannot determine which settings are correct. In this case, correct the discrepancies between the services.

Alternatively, you can specify this option with ***/clusternode***:Yes and ***/force***:Yes, to force the utility to show or update the password with the specified cluster settings.

This option is not required if ***/clusternode***:No is specified.

/clusternode:Yes|No
Specifies whether to enable support for cluster resources. The default value is *No*. You must be running the MSCS or VCS to specify ***/clusternode***:Yes. This option must be specified when using the INSTALL command in a cluster environment. This option must also be specified when using the UPDATE command to modify the cluster settings (***/clusternode***, ***/clustername***).

This option can also be specified when using the UPDATEPW command in a cluster environment. Normally this is not required. However, if more than one scheduler service with different cluster settings are defined for a particular node, the utility cannot determine which settings are correct. In this case, correct the discrepancies between the services.

Alternatively, you can specify this option with ***/clustername*** and ***/force***:Yes, to force the utility to show or update the password with the specified cluster settings. If ***/clusternode***:No is specified, ***/clustername*** is not required.

/commmethod:protocol
Specifies client communications protocol to communicate with the IBM Spectrum Protect server. Valid protocols are: TCP/IP and Named Pipes. If you do not specify a value, the value is obtained from the client options file or set to the default client value. You can also use this option with the UPDATEPW command to specify a communication protocol to connect to a server when updating passwords.

/commport:serverport
Specifies the protocol specific IBM Spectrum Protect server port. For TCP/IP, this is the port on the specified hostname. If this option is not specified, the value is obtained from the client options file or set to the default client value. You can also use this option with the UPDATEPW command to specify a protocol specific server port to connect to for updating passwords.

/commserver:servername
Specifies the protocol specific IBM Spectrum Protect server name. Depending on the protocol used, this can be a TCP/IP hostname or a Named Pipes name. If not specified, the value is obtained from the client options file or set to the default client value.

This option can also be used with the UPDATEPW command to specify a protocol specific server name to connect to for updating passwords.

/copyfiles
Specifies that the service installation is copied to another location prior to installing the service. Use the ***/srcdir*** option to specify the fully qualified source path.

/errorlog:errorlog
Specifies the fully qualified name of the client error log.

/eventlogging:[Yes|No]
Turns detailed event logging on or off for the specified scheduler service. The default is *Yes*.

/force:[Yes|No]
This option can also be specified when using the UPDATEPW command in a cluster environment. Normally this is not required. However, if more than one scheduler service with different cluster settings is defined for a particular node, the utility cannot determine which settings are correct. In this case, correct the discrepancies between the services.

Alternatively, you can specify this option with ***/clusternode*** and ***/clustername*** (if ***/clusternode***:Yes is specified), to force the utility to show or update the password with the specified cluster settings.

/httpport:httpport
Specifies a TCP/IP port address for the web client.

/machine:machinename
Specifies the name of a remote workstation to connect to.

/name:servicename
Specifies the name of the Client service. The name must be quote delimited if it contains embedded spaces.

/node:nodename
Specifies the IBM Spectrum Protect node name the Client Service uses when connecting to the IBM Spectrum Protect server. Also used when displaying or updating the IBM Spectrum Protect password. The default is the workstation name.

/ntaccount:ntaccount
Specifies the Windows account which the service logs in as.

/ntdomain:ntdomain
Specifies the Windows domain which the service logs in as.

/ntpassword:ntpassword
Specifies the Windows password for the account under which the service logs in.
/oldpassword:oldpw
Current® IBM Spectrum Protect server password. Used in conjunction with the /updateonserver option when updating a password on the server.
/optfile:optionsfile
The fully qualified path of the client options file. This is the options file the specified Client Service uses to connect to the IBM Spectrum Protect server. The utility also uses the file to connect to the IBM Spectrum Protect server to validate and update passwords. Note that although this option overrides the default option file in the current directory (dsm.opt), the IBM Spectrum Protect API requires that a default option file exists in the current directory. UNC names are not allowed if the local system account is set to logon. The default is the dsm.opt file in the ***/clientdir*** directory.
/partnername:partner service name
This option is used when installing a Remote Client Agent Service to specify the partner Client Acceptor Service.
/password:password
The IBM Spectrum Protect password which is generated and encrypted.
/schedlog:schedlog
Specifies the fully qualified name of the client schedule log.
/srcdir:pathname
Use this option in conjunction with the ***/copyfiles*** option to specify the fully qualified source path to copy the service installation to another location prior to installing the service.
/startnow:[Yes|No]
Specifies whether dsmcutil starts the specified service after executing the command; the default is *Yes*. If you specify ***No***, you must start the service manually using the services control panel applet, or the NET START **name of the service**.
/updateonserver:[Yes|No]
Specifies whether the specified password is updated on the IBM Spectrum Protect server. Requires using the ***/oldpassword*** option.
/validate:[Yes|No]
Specifies whether to perform validation when displaying or updating the encrypted password. The default is *Yes*.
/webports: webports
Specifies the TCP/IP port number used by the Client Acceptor service and the web client agent service for communications with the web GUI.

  Updates to the IBM Spectrum Protect application programming interface (API) documentation can occur after the documentation is published in IBM® Knowledge Center.

API updates

Learn about new features and updates for the application programming interface (API) in IBM Spectrum Protect™ Version 8.1.

Release	New features and updates

Release	New features and updates
8.1.2	Enhanced client security settings Beginning in IBM Spectrum Protect Version 8.1.2, several changes are introduced in the backup-archive client to work with the IBM Spectrum Protect V8.1.2 server, which provides enhancements to improve the security between client and server communications. For more information, see Backup-archive client updates. The Trusted Communication Agent (TCA) is deprecated Due to the enhanced communication that is introduced in IBM Spectrum Protect V8.1.2, the Trusted Communication Agent (TCA) is no longer available. For more information, see: • Secure password storage • Enable non-root users to manage their own data Maintenance updates The API documentation has been updated to include maintenance updates.
8.1.0	IBM® Tivoli® Storage Manager is now IBM Spectrum Protect IBM Spectrum Protect Version 8.1 is the next generation of Tivoli Storage Manager. This new release represents more than a name change in the user interface and documentation. It is an evolution to a higher level of data protection that is designed to meet the complex demands of today's world. For more information, see Meet IBM Spectrum Protect. An administrative user ID is no longer created by default with the REGISTER NODE server command Beginning with IBM Spectrum Protect V8.1, the REGISTER NODE server command does not automatically create an administrative user ID that matches the node name. This product update is designed to optimize user authentication to a Lightweight Directory Access Protocol (LDAP) server. This product update does not affect existing client nodes, but can affect the process of registering new client nodes, including but not limited to nodes for IBM Spectrum Protect backup-archive clients. In some cases, you might have to create an administrative user ID when you register a node. You can create the administrative user ID by issuing the REGISTER NODE command and specifying the USERID parameter. For information about the types of clients that are affected, see technote 7048963. For more information about creating an administrative user ID, see Creating an administrative user with client owner authority. Discontinued support of client operating systems To take advantage of new product features, install the V8.1 backup-archive client and API on one of the supported operating systems. For the current list of supported operating systems, see technote 1243309. The following operating systems are no longer supported by the backup-archive client: • Windows 32-bit operating systems (client and API). • Windows Server 2008, Windows Server 2008 R2, Windows 7, and Windows 8 operating systems. • HP-UX operating systems. You can still use the IBM Spectrum Protect API on an HP-UX operating system. For installation instructions, see Installing the HP-UX Itanium 2 API. • Linux on Power Systems™ (big endian). You can still use the IBM Spectrum Protect API on Linux on Power Systems (big endian). For installation instructions, see Installing the API on Linux on Power Systems (Big Endian). • Solaris SPARC operating systems. You can still use the IBM Spectrum Protect API on Solaris SPARC operating systems. Instructions for installing the API are included in the topic, Installing the Oracle Solaris client.

Release notes for IBM Spectrum Protect Application Programming Interface Version 8.1

IBM Spectrum Protect™ Application Programming Interface (API) V8.1 is available. Read this document to find important installation information. You can also learn about product updates, compatibility issues, limitations, and known problems.

Contents

Description

The IBM Spectrum Protect API enables an application client to use storage management functions. The API includes function calls that you can use in an application to run the following operations:

- Start or end a session
- Assign management classes to objects before they are stored on a server
- Back up or archive objects to a server
- Restore or retrieve objects from a server
- Query the server for information about stored objects
- Manage file spaces
- Send retention events

The API is used by software developers to create new applications that work with IBM Spectrum Protect.

The publication entitled *IBM Spectrum Protect Using the Application Programming Interface* provides information about how to use the IBM Spectrum Protect API.

The IBM Spectrum Protect API is available on the following operating systems:

- HP-UX
- IBM® AIX®
- Linux
- Mac OS X
- Microsoft Windows 64-bit operating systems
- Oracle Solaris

For a list of the APARs that are fixed in this release, see technote 1993247.

Announcement

The announcement for the IBM Spectrum Protect V8.1 family of products includes the following information:

- Detailed product description, including a description of new functions
- Product-positioning statement
- Packaging and ordering details
- International compatibility information

To search for the product announcement, complete the following steps:

1. Go to the product announcement website.
2. In the Search for field, enter the product identifier (PID) for your product. The PID for IBM Spectrum Protect is 5725-W98.
3. In the Information Type field, select Announcement letters, and click Search.
4. From the Search in list, select Product Number.
5. Optional: In the Refine Your Search pane on the left side of the window, select the country where you reside.
6. In the Sort by section, select Newest first.

Compatibility with earlier versions

For compatibility with earlier versions, see IBM Spectrum Protect Server/Client Compatibility and Upgrade Considerations.

System requirements

Installing the API

For installation instructions, see Installing the API.

Updates, limitations, and known problems

Documentation updates, limitations, and known problems are documented as technotes in the Support knowledge base at the IBM Support Portal for IBM Spectrum Protect. As problems are discovered and resolved, IBM Software Support updates the knowledge base. By searching the knowledge base, you can find workarounds or solutions to problems.

Limitations and known problems
: For the limitations and known problems that affect the IBM Spectrum Protect V8.1 API, see technote 1993248.

Documentation updates
: For information that was not available at the time of publication, see the documentation updates at technote 7048957.

Readme files for IBM Spectrum Protect Version 8.1 Application Programming Interface fix packs

Readme files for the IBM Spectrum Protect™ Version 8.1 Application Programming Interface (API) fix packs are available in the Support knowledge base when there is a fix pack update.

View IBM Spectrum Protect Version 8.1 API fix pack readme files

Late-breaking documentation updates

Updates to the IBM Spectrum Protect™ application programming interface (API) documentation can occur after the documentation is published in IBM® Knowledge Center.

For late-breaking documentation updates, see technote 7048957 in the IBM Support Portal.

Installing the API

Information about installing the IBM Spectrum Protect™ application programming interface (API) is provided in the installation procedures for the backup-archive client.

- Installing the Tivoli Storage Manager backup-archive clients (UNIX, Linux, and Windows)

API overview

The IBM Spectrum Protect™ application program interface (API) enables an application client to use storage management functions.

The API includes function calls that you can use in an application to perform the following operations:

- Start or end a session
- Assign management classes to objects before they are stored on a server
- Back up or archive objects to a server
- Restore or retrieve objects from a server
- Query the server for information about stored objects
- Manage file spaces
- Send retention events

When you, as an application developer, install the API, you receive the files that an end user of an application needs:

- The API shared library.
- The messages file.
- The sample client options files.
- The source code for the API header files that your application needs.
- The source code for a sample application, and the makefile to build it.

For 64-bit applications, all compiles should be performed using compiler options that enable 64-bit support. For example, '-q64' should be used when building API applications on AIX®, and '-m64' should be used on Linux. See the sample make files for more information.

Important: When you install the API, ensure that all files are at the same level.

For information about installing the API, see Installing the IBM Spectrum Protect backup-archive clients.

References to UNIX and Linux include AIX, HP-UX, Linux, Mac OS X, and Oracle Solaris operating systems.

- Understanding configuration and options files
  Configuration and options files set the conditions and boundaries under which your session runs.
- Setting up the API environment
  The API uses unique environment variables to locate files. You can use different files for API applications from those that the backup-archive client uses. Applications can use the dsmSetup function call to override the values that the environment variables set.

Understanding configuration and options files

Configuration and options files set the conditions and boundaries under which your session runs.

You, an administrator, or an end user can set option values to:

- Set up the connection to a server
- Control which objects are sent to the server and the management class to which they are associated

You define options in one or two files when you install the API on your workstation.

On UNIX and Linux operating systems, the options reside in two options files:

- dsm.opt - the client options file
- dsm.sys - the client system options file

On other operating systems, the client options file (dsm.opt) contains all of the options.

Restriction: The API does not support the following backup-archive client options:

- autofsrename
- changingretries
- domain
- eventlogging
- groups

- subdir
- users
- virtualmountpoint

You also can specify options on the dsmInitEx function call. Use the option string parameter or the API configuration file parameter.

The same option can derive from more than one configuration source. When this happens, the source with the highest priority takes precedence. Table 1 lists the priority sequence.

Table 1. Configuration sources in order of decreasing priority

Priority	UNIX and Linux	Windows	Description
1	dsm.sys file (client system options)	not applicable	This file contains options that a system administrator sets only for UNIX and Linux. Tip: If your dsm.sys file contains server stanzas, ensure that the passwordaccess option specifies the same value (either prompt or generate) in each of the stanzas.
2	Option string (client options)	Option string (all options)	One of these options takes effect when it is passed as a parameter to a dsmInitEx call. The list can contain client options such as compressalways, servername (UNIX and Linux only), or tcpserveraddr (non-UNIX). With the API option string, an application client can make changes to the option values in the API configuration file and the client options file. For example, your application might query the end user if compression is required. Depending on the user responses, you can construct an API option string with this option and pass it into the call to dsmInitEx. For information about the API option string format, see dsmInitEx. You also can set this parameter to NULL. This indicates that there is no API option string for this session.
3	API configuration file (client options)	API configuration file (all options)	The values that you set in the API configuration file override the values that you set in the client options file. Set up the options in the API configuration file with values that are appropriate in the IBM Spectrum Protect™ session for the user. The values take effect when the API configuration file name is passed as a parameter in the dsmInitEx call. You also can set this parameter to NULL. This indicates that there is no API configuration file for this session.
4	dsm.opt file (client options)	dsm.opt file (all options)	On UNIX and Linux operating systems the dsm.opt file contains the user options only. On other operating systems, the dsm.opt file contains all options. To override the options in these files, follow the methods that are described in this table.

Related concepts:
Processing options

Setting up the API environment

The API uses unique environment variables to locate files. You can use different files for API applications from those that the backup-archive client uses. Applications can use the dsmSetup function call to override the values that the environment variables set.

Tip: On Windows, the default installation directory is: %SystemDrive%\Program Files\Common Files\Tivoli\TSM\api
Table 1 lists the API environment variables by operating system.

Table 1. API environment variables

Variables	UNIX and Linux	Windows

Variables	UNIX and Linux	Windows
DSMI_CONFIG	The fully-qualified name for the client options file (dsm.opt).	The fully-qualified name for the client options file (dsm.opt).
DSMI_DIR	Points to the path that contains the dsm.sys, en_US subdirectory, and any other national language support (NLS) language. The en_US subdirectory must contain dsmclientV3.cat.	Points to the path that contains dscenu.txt and any NLS message file.
DSMI_LOG	Points to the path for the dsierror.log file.	Points to the path for the dsierror.log file. If the client errorlogname option is set, the location specified by that option overrides the directory specified by DSMI_LOG.

Building and running the sample API application

The API package includes sample applications that demonstrate the API function calls in context. Install a sample application and review the source code to understand how you can use the function calls.

Select one of the following sample API application packages:

- The interactive, single-threaded application package (dapi*)
- The multithreaded application package (callmt*)
- The logical object grouping test application (dsmgrp*)
- The event-based retention policy sample application (callevnt)
- The deletion hold sample application (callhold)
- The data retention protection sample application (callret)
- The IBM Spectrum Protect™ data buffer sample program (callbuff)

To help you get started, review the procedure to build the sample dapismp sample application by your platform:

- For UNIX or Linux applications, see UNIX or Linux sample application source files.
- For Windows applications, see Windows 64-bit sample application.

The dapismp sample application creates its own data streams when backing up or archiving objects. It does not read or write objects to the local disk file system. The object name does not correspond to any file on your workstation. The "seed string" that you issue generates a pattern that can be verified when the object is restored or retrieved. Once you compile the sample application and run **dapismp** to start it, follow the instructions that display on your screen.

- UNIX or Linux sample application source files
  To build and run the sample UNIX or Linux sample application, you need to ensure you have certain source files. Once you build the sample application you can compile and run it.
- Windows 64-bit sample application
  To build and run the sample application for Microsoft Windows 64–bit systems, you must install the IBM Spectrum Protect API and ensure that you have certain source files.

UNIX or Linux sample application source files

To build and run the sample UNIX or Linux sample application, you need to ensure you have certain source files. Once you build the sample application you can compile and run it.

The files that are listed in Table 1 include the source files and other files that you need to build the sample application that is included with the API package.

Table 1. Files that you need to build the UNIX or Linux API sample application

File names		Description
README_api_enu		README file

File names		Description
dsmrc.h dsmapitd.h dsmapips.h dsmapifp.h release.h		Return codes header file Common type definitions header file Operating system-specific type definitions header file Function prototype header file Release values header file
dapibkup.c dapidata.h dapiinit.c dapint64.h dapint64.c dapipref.c dapiproc.c dapiproc.h	dapipw.c dapiqry.c dapirc.c dapismp.c dapitype.h dapiutil.h dapiutil.c	Modules for the command line-driven sample application
makesmp[64].*xxx*		Makefile to build dapismp for your operating system. The *xxx* indicates the operating system.
callmt1.c callmt2.c		Multi-threaded sample files
callmtu1.c callmtu2.c		Multi-threaded Unicode sample files
libApiDS.xx libApiDS64.xx, or libApiTSM64.xx		Shared library (the suffix is platform-dependent)
dsmgrp.c callevnt.c callhold.c callret.c callbuff.c dpsthread.c		Grouping sample files Event-based retention policy sample source code Deletion hold sample source code Data retention protection sample source code

- Building the UNIX or Linux sample application
  You build the dapismp sample API application by using a compiler for your operating system.

Windows 64-bit sample application

To build and run the sample application for Microsoft Windows 64–bit systems, you must install the IBM Spectrum Protect™ API and ensure that you have certain source files.

Restrictions:

- For best results, use dynamic loading. For an example, see the file dynaload.c and the implementation in the sample code.
- Files for the sample application are in the following directories:

  api64\obj
  : Contains the API sample program object files.

  api64\samprun
  : Contains the sample program dapismp. The sample program contains the execution directory.

- The DLL tsmapi64.dll is a 64-bit DLL.
- Use the Microsoft C/C++ Compiler Version 15 and the makefile makesmp64.mak to compile the API sample application dapismp. You might have to adjust the makefiles to fit your environment, specifically the library or the include directories.
- After you compile the application, run the sample application by issuing the command **dapismp** from the api64\samprun directory.
- Choose from the list of options displayed that are displayed. Ensure that you run the sign-on action before you run any other actions.
- Always prefix the file space, high-level, and low-level names with the correct path delimiter (\) when you enter the name, for example: \myfilespace. You must use this prefix even when you specify the asterisk (*) wildcard character.

For Windows operating systems, the source files that you must have to build the sample application are listed in Table 1. The sample application is included in the API package. For your convenience, a precompiled executable (dapismp.exe) is also included.

Table 1. Files for building the Windows 64-bit API sample application

File names	Description
api.txt	README file
tsmapi64.dll	API DLLs

Considerations for designing an application

When you design an application, you must have a broad understanding of many aspects of the API.

To gain an understanding of the API, review the following topics:

- Determining size limits
- Maintaining API version control
- Using multithreading
- Signals and signal handlers
- Starting or ending a session
- Object names and IDs
- Controlling access to password files
- Accessing objects as session owner
- Accessing objects across nodes and owners
- Managing file spaces
- Associating objects with management classes
- Expiration/deletion hold and release
- Querying the IBM Spectrum Protect system
- Sending data to a server
- Example flow diagrams for backup and archive
- File grouping
- State diagram summary for the IBM Spectrum Protect API

When you design your application, review the considerations in Table 1. Start structures with memset fields might change in subsequent releases. The stVersion value increments with each product enhancement.

Table 1. API Considerations for designing an application

Design item	Considerations
Setting locale	The application must set the locale before the API is called. To set the locale to the default value, add the following code to the application: `setlocale(LC_ALL,"");` To set the locale to another value, use the same call with the proper locale in the second parameter. Check for specifics in the documentation for each operating system that you are using.

Design item	Considerations
Session control	Apply the following guidelines to session control: • Assign a unique node name for each IBM Spectrum Protect backup-archive client and IBM Spectrum Protect API client product that you use. The following products are examples of these clients: ◦ IBM Spectrum Protect for Mail ◦ or IBM Spectrum Protect HSM for Windows • Use a consistent owner name across a backup and restore procedure. • Use the passwordaccess option to manage access to the protected password file. • Ensure that sessions for data movement end when the task is completed so that devices on the server are freed for use by other sessions. • To permit LAN-free data transfer, use the dsmSetup function call with the multithread flag set to on. • On AIX®, when you are using multithreaded applications or LAN-free, especially running on machines with multiple processors, set the environment variable AIXTHREAD_SCOPE to S in the environment before you start the application, for better performance and more solid scheduling. For example: `EXPORT AIXTHREAD_SCOPE=S` By setting AIXTHREAD_SCOPE to S, user threads that are created with default attributes are placed into system-wide contention scope. If a user thread is created with system-wide contention scope, the user thread is bound to a kernel thread and is scheduled by the kernel. The underlying kernel thread is not shared with any other user thread. For more information about this environment variable, see the following topic: Using multithreading • Ensure that only one thread in a session calls any API function at any time. Applications that use multiple threads with the same session handle must synchronize the API calls. For example, use a mutex to synchronize API calls: ◦ getTSMMutex() ◦ issue TSM API call ◦ releaseTSMMutex() Use this approach only when the threads share a handle. You can use parallel calls to API functions if the calls have different session handles. • Implement a threaded consumer/producer model for data movement. API calls are synchronous and the calls for dsmGetData function and dsmSendData function block until they are finished. By using a consumer/producer model, the application can read the next buffer during waiting periods for the network. Also, decoupling the data read/write and the network increases performance when there is a network bottleneck or delays. In general, the following holds: `Data thread <---> shared queue of buffers <---> communication thread (issue calls to the IBM Spectrum Protect API)` • Use the same session for multiple operations to avoid incurring an overhead. For applications that deal with many small objects, implement session-pooling so that the same session can be used across multiple small operations. An overhead is associated with opening and closing a session to the IBM Spectrum Protect server. The `dsmInit/dsmInitEX` call is serialized so even in a multithreaded application only one thread can sign on at any time. Also, during sign-on the API sends a number of one-time queries to the server so that the server can do all operations. These queries include policy, option, file spaces, and local configuration.

Design item	Considerations
Operation sequence	The IBM Spectrum Protect server locks file space database entries during some operations. The following rules apply when you are designing IBM Spectrum Protect API applications: • Queries lock the file space during the entire transaction. • The query lock can be shared with other query operations, so multiple query operations on the same file space can execute concurrently. • The following operations are used to modify the IBM Spectrum Protect server database (DB Chg): send, get, rename, update, and delete. • Completion of a DB Chg operation requires a file space lock during the database change at the end of the transaction. • Multiple DB Chg operations on the same file space can execute concurrently. There might be a delay while the sequence waits for the lock at the end transaction. • The query lock cannot be shared with DB Chg operations. A DB Chg operation delays the beginning of a query on the same file space, so design your applications to separate and serialize queries from DB Chg operations on the same file space.
Object naming	When you name objects, consider the following factors: • The specific object names are the high-level and low-level object names. If a unique identifier, such as a date stamp, is included in the name, then backup objects are always active. The objects expire only when they are marked inactive by the dsmDeleteObj function call. • The restore method for objects determines how to format the name for easy queries. If you plan to use a partial object restore (POR), you cannot use compression. To suppress compression, use the dsmSendObj objAttr objCompressed=bTrue function.
Object grouping	Group objects logically by using file spaces. A file space is a container on the server that provides a grouping category for the objects. The API queries all file spaces during the initial sign-on and also during queries, so the number of file spaces must be restricted. A reasonable assumption is that an application sets up 20 - 100 file spaces per node. The API can cater for more file spaces, but each file space incurs an overhead for the session. To create a more granular separation, use the `directory` object in the application.
Object handling	Do not store `objectID` values to use for future restores. These values are not guaranteed to be persistent during the life of the object. During a restore, pay special attention to the restore order. After the query, sort on this value before the restore. If you are using multiple types of serial media, then access the different types of media in separate sessions. For more information, see the following topic: Selecting and sorting objects by restore order
Management class	Consider how much control the application must have over the management class that is associated with the application objects. You can define include statements, or you can specify a name on the dsmSendObj function call.
Object size	IBM Spectrum Protect needs to know a size estimate for each object. Consider how your application estimates the size of an object. An overestimation of the object size is better than an underestimation.

- Determining size limits
  Certain data structures or fields in the API have size limits. These structures are often names or other text fields that cannot exceed a predetermined length.
- Maintaining API version control
  All APIs have some form of version control. The API version that you use in your application must be compatible with the version of the API library that is installed on the user workstation.
- Using multithreading
  The multithreaded API permits applications to create multiple sessions with the IBM Spectrum Protect server within the same process. The API can be entered again. Any calls can run in parallel from within different threads.
- Signals and signal handlers
  The application handles signals from the user or the operating system. If the user enters a CTRL+C keystroke sequence, the application must catch the signal and send dsmTerminate calls for each of the active threads. Then, call dsmCleanUp to exit. If sessions are not closed properly, unexpected results might occur on the server.

- Starting or ending a session
  IBM Spectrum Protect is a session-based product, and all activities must be performed within an IBM Spectrum Protect session. To start a session, the application starts the dsmInitEx call. This call must be performed before any other API call other than dsmQueryApiVersionEx, dsmQueryCliOptions, or dsmSetUp.
- Object names and IDs
  The IBM Spectrum Protect server is an object storage server whose primary function is to efficiently store and retrieve named objects. The object ID is unique for each object and remains with the object for the life of the object *except* when you use export or import.
- Accessing objects as session owner
  Each object has an owner name associated with it. The rules determining what objects are accessed depend on what owner name is used when a session is started. Use this session owner value to control access to the object.
- Accessing objects across nodes and owners
  Three function calls support cross-node, cross-owner access on the same platform: **dsmSetAccess**, **dsmDeleteAccess**, and **dsmQueryAccess**. These functions, along with the *-fromnode* and *-fromowner* string options that are passed on **dsmInitEx**, permit a complete cross-node query, restore and retrieve process through the API.
- Managing file spaces
  Because file spaces are important to the operation of the system, a separate set of calls is used to register, update, and delete file space identifiers. Before you can store any objects that are associated with a file space on the system, you must first register the file space with IBM Spectrum Protect.
- Associating objects with management classes
  A primary feature of IBM Spectrum Protect is the use of policies (management classes) to define how objects are stored and managed in IBM Spectrum Protect storage. An object is associated with a management class when the object is backed up or archived.
- Expiration/deletion hold and release
  You can hold deletion and expiration of specific archive objects in response to a pending or ongoing action that requires that particular data be held. In the event an action is initiated that might require access to data, that data must be available until the action is concluded and access to the data is no longer required as part of that process. After determining that the suspension is no longer required (released), normal deletion and expiration timing resumes per the original retention period.
- Querying the IBM Spectrum Protect system
  The API has several queries, such as management class query, that applications can use.
- Server efficiency
  Use these guidelines when you retrieve from, or send objects to, the IBM Spectrum Protect server.
- Sending data to a server
  The API permits application clients to send data or named objects and their associated data to IBM Spectrum Protect server storage.
- Set up the API to send performance data to the client performance monitor
  The client performance monitor is a component of the Tivoli® Storage Manager Administration Center that is used to display performance data that is collected by the API. The client performance monitor records and displays performance data for client backup, archive, and restore operations.
- Sending objects to the server
  Application clients can send data or named objects and their associated data to IBM Spectrum Protect storage by using the API backup and archive functions. The backup and archive components of the system permit use of different management procedures for data that is sent to storage.
- Data deduplication
  Data deduplication is a method of reducing storage needs by eliminating redundant data.
- Application failover
  When the IBM Spectrum Protect server becomes unavailable because of an outage, applications that use the API can automatically fail over to a secondary server for data recovery.
- Example flow diagrams for backup and archive
  The API is designed for straightforward logic flows and clear transitions between the various states of the application client. This clean state transition catches logic flaws and program errors early in the development cycle, greatly enhancing the quality and reliability of the system.
- File grouping
  The IBM Spectrum Protect API has a logical file grouping protocol that relates several individual objects together. You can reference and manage these groups as a logical group on the server. A logical group requires that all group members and the group leader belong to the same node and file space on the server.
- Receiving data from a server
  Application clients can receive data or named objects and their associated data from IBM Spectrum Protect storage by using the restore and retrieve functions. The restore function accesses objects that previously were backed up, and the retrieve function accesses objects that previously were archived.

- Updating and deleting objects on the server
  Your API applications can use the**dsmUpdateObj** or **dsmUpdateObjEx** function call to update objects that were archived or backed up. Use either call in the session state only, updating one object at a time. Use **dsmUpdateObjEx** to update any of several archive objects containing the same name.
- Logging events
  An API application can log event messages to central locations. The application can direct logging to the IBM Spectrum Protect server, the local machine, or both. The dsmLogEventEx function call is performed in a session. To view messages logged on the server, use the query actlog command through the administrative client.
- State diagram summary for the IBM Spectrum Protect API
  Once you review all the considerations for creating your own application with the IBM Spectrum Protect API, review this state diagram summary of an entire application.

Determining size limits

Certain data structures or fields in the API have size limits. These structures are often names or other text fields that cannot exceed a predetermined length.

The following fields are examples of data structures that have size limits:

- Application type
- Archive description
- Copy group destination
- Copy group name
- File space information
- Management class name
- Object owner name
- Password

These limits are defined as constants within the header file dsmapitd.h. Any storage allocation is based on these constants rather than on numbers that you enter. For more information, see API type definitions source files.

Maintaining API version control

All APIs have some form of version control. The API version that you use in your application must be compatible with the version of the API library that is installed on the user workstation.

The **dsmQueryApiVersionEx** should be the first API call that you enter when you use the API. This call performs the following tasks:

- Confirms that the API library is installed and available on the end user's system
- Returns the version level of the API library that the application accesses

The API is designed to be upwardly compatible. Applications that are written to older versions or releases of the API library operate correctly when you run a later version.

Determining the release of the API library is very important because some releases might have different memory requirements and data structure definitions. Downward compatibility is unlikely. See Table 1 for information about your platform.

Table 1. Platform compatibility information

Platform	Description
Windows	The message files must be at the same level as the library (DLL).
UNIX or Linux	The API library and the message files must be at the same level.

The **dsmQueryApiVersionEx** call returns the version of the API library that is installed on the end user workstation. You can then compare the returned value with the version of the API that the application client is using.

The API version number of the application client is entered in the compiled object code as a set of four constants defined in dsmapitd.h:

```
DSM_API_VERSION
DSM_API_RELEASE
DSM_API_LEVEL
DSM_API_SUB_LEVEL
```

See API type definitions source files.

The API version of the application client should be less than, or equal to, the API library that is installed on the user's system. Be careful about any other condition. You can enter the **dsmQueryApiVersionEx** call at any time, whether the API session has been started or not.

Data structures that the API uses also have version control information in them. Structures have version information as the first field. As enhancements are made to structures, the version number is increased. When initializing the version field, use the defined structure Version value in dsmapitd.h.

Figure 1 demonstrates the type definition of the structure, dsmApiVersionEx from the header file, dsmapitd.h. The example then defines a global variable that is named ***apiLibVer***. It also demonstrates how you can use it in a call to **dsmQueryApiVersionEx** to return the version of the end user's API library. Finally, the returned value is compared to the API version number of the application client.

Figure 1. An example of obtaining the version level of the API

```
typedef struct
{
        dsUint16_t stVersion;     /* Structure version               */
        dsUint16_t version;       /* API version                     */
        dsUint16_t release;       /* API release                     */
        dsUint16_t level;         /* API level                       */
        dsUint16_t subLevel;      /* API sub level                   */
} dsmApiVersionEx;

dsmApiVersionEx apiLibVer;

memset(&apiLibVer,0x00,sizeof(dsmApiVersionEx));
dsmQueryApiVersionEx(&apiLibVer);

/* check for compatibility problems */
dsInt16_t appVersion= 0, libVersion = 0;
  appVersion=(DSM_API_VERSION * 10000)+(DSM_API_RELEASE * 1000) +
               (DSM_API_LEVEL * 100) + (DSM_API_SUBLEVEL);
  libVersion = (apiLibVer.version * 10000) + (apiLibVer.release * 1000) +
                  (apiLibVer.level * 100) + (apiLibVer.subLevel);
   if (libVersion < appVersion)
   {
      printf("\n************************************************************\n");
      printf("The IBM Spectrum Protect API library is lower than the application version\n");
      printf("Install the current library version.\n");
      printf("************************************************************\n");
      return 0;
   }

printf("* API Library Version = %d.%d.%d.%d  *\n",
     apiLibVer.version,
     apiLibVer.release,
     apiLibVer.level,
     apiLibVer.subLevel);
```

Using multithreading

The multithreaded API permits applications to create multiple sessions with the IBM Spectrum Protect™ server within the same process. The API can be entered again. Any calls can run in parallel from within different threads.

Tip: When you run applications that assume a multithreaded API, use the **dsmQueryAPIVersionEx** call.

To run the API in multithreaded mode, set the *mtflag* value to DSM_MULTITHREAD on the **dsmSetUp** call. The **dsmSetUp** call must be the first call after the **dsmQueryAPIVersionEx** call. This call must return before any thread calls the **dsmInitEx** call. When all threads complete processing, enter a call to **dsmCleanUp**. The primary process should not end before all the threads complete processing. See callmt1.c in the sample application.

Restriction: The default for the API is single-thread mode. If an application does not call **dsmSetUp** with the *mtflag* value set to DSM_MULTITHREAD, the API permits only one session for each process.

Once **dsmSetUp** successfully completes, the application can begin multiple threads and enter multiple **dsmInitEx** calls. Each **dsmInitEx** call returns a handle for that session. Any subsequent calls on that thread for that session must use that handle value.

Certain values are process-wide, environmental variables (values that are set on **dsmSetUp**). Each **dsmInitEx** call parses options again. Each thread can run with different options by specifying an overwrite file or an options string on the **dsmInitEx** call. This enables different threads to go to different servers, or use different node names.

Recommendation: On HP, set the thread stack to 64K or greater. The default value of the thread stack (32K) might not be sufficient

To permit application users to have a LAN-free session, use **dsmSetUp** *mtFlag DSM_MULTITHREAD* in your application. This is necessary even if the application is single threaded. This flag activates the threading necessary for the IBM Spectrum Protect LAN-free interface.

Signals and signal handlers

The application handles signals from the user or the operating system. If the user enters a CTRL+C keystroke sequence, the application must catch the signal and send dsmTerminate calls for each of the active threads. Then, call dsmCleanUp to exit. If sessions are not closed properly, unexpected results might occur on the server.

The application requires signal handlers, such as SIGPIPE and SIGUSR1, for signals that cause the application to end. The application then receives the return code from the API. For example, to ignore SIGPIPE add the following instruction in your application: `signal(SIGPIPE, SIG_IGN)`. After this information is added, instead of the application exiting on a broken pipe, the proper return code is returned.

Starting or ending a session

IBM Spectrum Protect™ is a session-based product, and all activities must be performed within an IBM Spectrum Protect session. To start a session, the application starts the dsmInitEx call. This call must be performed before any other API call other than dsmQueryApiVersionEx, dsmQueryCliOptions, or dsmSetUp.

The dsmQueryCliOptions function can be called only before the dsmInitExcall. The function returns the values of important options, such as option files, compression settings, and communication parameters. The dsmInitEx call sets up a session with the server as indicated in the parameters that are passed in the call or defined in the options files.

The client node name, the owner name, and the password parameters are passed to the dsmInitEx call. The owner name is case-sensitive, but the node name and password are not. The application client nodes must be registered with the server before a session starts.

Each time an API application client starts a session with the server, the client application type is registered with the server. Always specify an operating system abbreviation for the application type value because this value is entered in the platform field on the server. The maximum string length is DSM_MAX_PLATFORM_LENGTH.

The dsmInitEx function call establishes the IBM Spectrum Protect session with the API configuration file and option list of the application client. The application client can use the API configuration file and option list to set a number of IBM Spectrum Protect options. These values override the values that are set in the user configuration files during installation. Users cannot change the options that the administrator defines. If the application client does not have a specific configuration file and option list, you can set both of these parameters to NULL. For more information about configuration files, see the following topic:

Understanding configuration and options files

The dsmInitEx function call establishes the IBM Spectrum Protect session, by using parameters that permit extended verification.

Check the dsmInitEx function call and the dsmInitExOut information return code. The administrator canceled the last session if the return code is okay (RC=ok) and the information return code (infoRC) is DSM_RC_REJECT_LASTSESS_CANCELED. To end the current session immediately, call dsmTerminate.

The dsmQuerySessOptions call returns the same fields as the dsmQueryCliOptions call. The call can be sent only within a session. The values reflect the client options that are valid during that session, from option files, and from any overrides from the dsmInitEx call.

After a session starts, the application can send a call to dsmQuerySessInfo to determine the server parameters that are set for this session. Items such as the policy domain and transaction limits are returned to the application with this call.

End sessions with a **dsmTerminate** call. Any connection with the server is closed and all resources that are associated with this session are freed.

For an example of starting and ending a session, see the following topic:

Figure 1

The example defines a number of global and local variables that are used in calls to dsmInitEx and dsmTerminate. The dsmInitEx call takes a pointer to `dsmHandle` as a parameter, while the dsmTerminate call takes the `dsmHandle` as a parameter. The example in Figure 2 displays the details of rcApiOut. The function rcApiOut calls the API function dsmRCMsg, which translates a return code into a message. The rcApiOut call then prints the message for the user. A version of rcApiOut is included in the API sample application. The dsmApiVersion function is a type definition that is found in the header file dsmapitd.h.

- Session security
  The IBM Spectrum Protect session-based system has security components that permit applications to start sessions in a secure manner. These security measures prohibit unauthorized access to the server and help to insure system integrity.
- Controlling access to password files
  To control access to the protected password files on UNIX and Linux systems, you can log on as an authorized user and set the passwordaccess option to generate.
- Creating an administrative user with client owner authority
  An administrative user with client owner authority can set parameters on the dsmInitEx function call to start sessions. This user can function as an "administrative user" with backup and restore authority for the defined nodes.

Session security

The IBM Spectrum Protect™ session-based system has security components that permit applications to start sessions in a secure manner. These security measures prohibit unauthorized access to the server and help to insure system integrity.

Every session that is started with the server must complete a sign-on process, requires a password. When the password is coupled with the node name of the client, it insures proper authorization when connecting to the server. The application client provides this password to the API to start the session.

Two methods of password processing are available: *passwordaccess=prompt* or *passwordaccess=generate*. If you use the *passwordaccess=prompt* option, you must include the password value on each **dsmInitEx** call. Or, you can supply the node name and owner name on the **dsmInitEx** call.

Passwords have expiration times associated with them. If a **dsmInitEx** call fails with a password-expired return code (DSM_RC_REJECT_VERIFIER_EXPIRED), the application client must enter the dsmChangePW call using the handle that is returned by **dsmInitEx**. This updates the password before the session can be established successfully. The example in Figure 3 demonstrates the procedure to change a password by using **dsmChangePW**. The login owner must use a root user ID or an authorized user ID to change the password.

The second method, *passwordaccess=generate*, encrypts and stores the password value in a file. The node name and owner name cannot be supplied on the **dsmInitEx** call, and the system default values are used. This protects the security of the password file. When the password expires, the generate parameter creates a new one and updates the password file automatically.

Tips:

1. If two different physical machines have the same IBM Spectrum Protect node name or multiple paths are defined on one node using several server stanzas, *passwordaccess=generate* might only work for the stanza which is used first after password expiration. During the first client-server contact, the user is prompted for the same password for each server stanza separately, and for each stanza, a copy of the password is stored separately. When the password expires, a new password is generated for the stanza which connects the first client-server contact. All subsequent attempts to connect via other server stanzas fail, because there is no logical link between their respective copies of the old password, and the updated copy generated by the stanza used first after password expiration. In this case, you must update the passwords prior to expiration or after expiration as a recovery from the situation, as follows:
   a. Run **dsmadmc** and update the password on the server.
   b. Run **dsmc -servername=stanza1** and use the new password to generate a proper entry.
   c. Run **dsmc -servername=stanza2** and use the new password to generate a proper entry.
2. For UNIX or Linux: Only the root user or an authorized user can change the password when using *passwordaccess=prompt*. Only the root user or an authorized user can start the password file when using *passwordaccess=generate*.
   Restriction: The options users and groups are not recognized.

An application can restrict user access by other means, such as setting access filters.

Applications that use multiple IP connections to a single IBM Spectrum Protect server should use the same node name and IBM Spectrum Protect client password for each session. Follow these steps to enable this support:

1. Define one IBM Spectrum Protect server stanza in the dsm.sys file.
2. For the connections not using the default IP address, specify the option values for *TCPserver* address and *TCPport* on the **dsmInitEx** call.

These values override the IP connection information, but the session still uses the same dsm.sys stanza node and password information.

Note: Nodes in a cluster share a single password.

printf("Enter your new password again:");
gets(new_pw2);
/* If new password entries don't match, try again or exit. */
/* If they do match, call dsmChangePW.                      */

rc = dsmChangePW(dsmHandle,current_pw,new_pw1);
if (rc)
{
   printf("*** Password change failed.  Rc =
}
else
{
   printf("*** Your new password has been accepted and updated.\n");
}
return 0;
```

Controlling access to password files

To control access to the protected password files on UNIX and Linux systems, you can log on as an authorized user and set the passwordaccess option to generate.

Procedure

Complete the following steps when you set the passwordaccess to generate:

1. Write the application with a call to dsmSetUp which passes *argv[0]*. The *argv[0]* contains the name of the application that calls the API. The application is permitted to run an authorized user; however, the administrator must decide on the login name for the authorized user.
2. Set the effective user ID bit (S bit) for the application executable to On. The owner of the application executable file can then become an authorized user and can create a password file, update passwords, and run applications. The owner of the application executable file must be the same as the user ID that runs the program. In the following example, *User* is `user1`, the name of the application executable file is `applA`, and `user1` has read/write permissions on the /home/user1 directory. The `applA` executable file has the following permissions:

   ```
   -rwsr-xr-x user1    group1   applA
   ```

3. Instruct the users of the application to use the authorized user name to log in. IBM Spectrum Protect™ verifies that the login ID matches the application executable owner before it permits access to the protected password file.
4. Set the passworddir option in the dsm.sys file to point to a directory where this user has read/write access. For example, enter the following line in the server stanza of the dsm.sys file:

   ```
   passworddir /home/user1
   ```

5. Create the password file and ensure that the authorized user owns the file.
6. Log on as `user1` and run `app1A`.
7. Call dsmSetUp and pass in *argv*.

Creating an administrative user with client owner authority

An administrative user with client owner authority can set parameters on the dsmInitEx function call to start sessions. This user can function as an "administrative user" with backup and restore authority for the defined nodes.

Procedure

To receive client owner authority, complete the following steps on the server:

1. Define the administrative user:

```
REGister Admin admin_name password
```

Where:

- *admin_name* is the administrative user name.
- *password* is the admin password.

2. Define the authority level. Users with system or policy authority also have client owner authority.

```
Grant Authority admin_name classes authority node
```

Where:

- *admin_name* is the administrative user.
- *classes* is the node.
- *authority* has one of the following levels of authority:
  - `owner`: full backup and restore authority for the node
  - `node`: single node
  - `domain`: group of nodes

3. Define access to a single node.

```
Register Node node_name password userid=user_id
```

Where:

- *node_name* is the client user node
- *password* is the client user node password
- *user_id* is the administrative user name

Results

When the application uses the administrative user, the dsmInitEx function is called with the userName and userNamePswd parameters.

```
dsmInitEx
            clientNodeName = NULL
            clientOwnerName = NULL
      clientPassword = NULL
      userName = 'administrative user' name
      userNamePswd = 'administrative user' password
```

You can set the passwordaccess option to generate or prompt. With either parameter, the userNamePswd value starts the session. When the session starts, any backup or restore process can occur for that node.

Object names and IDs

The IBM Spectrum Protect™ server is an object storage server whose primary function is to efficiently store and retrieve named objects. The object ID is unique for each object and remains with the object for the life of the object *except* when you use export or import.

To meet this requirement IBM Spectrum Protect has two main storage areas, database and data storage.

- The database contains all metadata, such as the name or attributes associated with objects.
- The data storage contains the object data. The data storage is actually a storage hierarchy that the system administrator defines. Data are efficiently stored and managed on either online or offline media, depending on cost and access needs.

Each object that is stored on the server has a name associated with it. The client controls the following key components of that name:

- File space name
- High-level name
- Low-level name
- Object type

When making decisions about naming objects for an application, you might need to use an external name for the full object names to the end user. Specifically, the end user might need to specify the object in an Include or Exclude statement when the application is run. The exact syntax of the object name in these statements is platform-dependent. On the Windows operating system, the drive letter associated with the file space rather than the file space name itself is used in the Include or Exclude statement.

The object ID value that was assigned when you created the object might not be the same as when you perform a restore process. Applications should save the object name and then query to obtain the current object ID before doing a restore.

- File space name
  The file space name is one of the most important storage components. It can be the name of a file system, disk drive, or any other high-level qualifier that groups related data together.
- High-level and low-level names
  Two other components of the object name are the high-level name qualifier and the low-level name qualifier. The high-level name qualifier is the directory path in which the object belongs, and the low-level name qualifier is the actual name of the object in that directory path.
- Object type
  The object type identifies the object as either a file or a directory. A file is an object that contains both attributes and binary data, and a directory is an object that contains only attributes.

File space name

The file space name is one of the most important storage components. It can be the name of a file system, disk drive, or any other high-level qualifier that groups related data together.

IBM Spectrum Protect™ uses the file space to identify the file system or disk drive on which the data are located. In this way, actions can be performed on all entities within a file space, such as querying all objects within a specified file space. Because the file space is such an important component of the IBM Spectrum Protect naming convention, you use special calls to register, update, query, and delete file spaces.

The server also has administrative commands to query the file spaces on any node in IBM Spectrum Protect storage, and delete them if necessary. All data stored by the application client must have a file space name associated with it. Select the name carefully to group similar data together in the system.

To avoid possible interference, an application client should select different file space names from those that a backup-archive client would use. The application client should publish its file space names so that end users can identify the objects for include-exclude statements, if necessary.

Note: On Windows platforms, a drive letter is associated with a file space. When you register or update a file space, you must supply the drive letter. Because the include-exclude list refers to the drive letter, you must keep track of each letter and its associated file space. In the sample program dapismp, the drive letter is set to "G" by default.

See Building and running the sample API application for more information on the sample programs.

High-level and low-level names

Two other components of the object name are the high-level name qualifier and the low-level name qualifier. The high-level name qualifier is the directory path in which the object belongs, and the low-level name qualifier is the actual name of the object in that directory path.

When the file space name, high-level name, and low-level name are concatenated, they must form a syntactically correct name on the operating system on which the client runs. It is not necessary for the name to exist as an object on the system or resemble the actual data on the local file system. However, the name must meet the standard naming rules to be properly processed by the **dsmBindMC** calls. See Understanding backup and archive objects for naming considerations that are related to policy management.

Object type

The object type identifies the object as either a file or a directory. A file is an object that contains both attributes and binary data, and a directory is an object that contains only attributes.

Table 1 shows what the application client would code is for object names by platform.

Table 1. Application object name examples by platform

Platform	Client code for object name
UNIX or Linux	/myfs/highlev/lowlev

Platform	Client code for object name
Windows	"myvol\\highlev\\lowlev" Note: On a Windows platform, a double backslash translates into a single backslash, because a backslash is the escape character. File space names start with a slash on the UNIX or Linux platform, but do not start with a slash on the Windows platform.

Accessing objects as session owner

Each object has an owner name associated with it. The rules determining what objects are accessed depend on what owner name is used when a session is started. Use this session owner value to control access to the object.

The session owner is set during the call to **dsmInitEx** in the *clientOwnerNameP* parameter. If you start a session with **dsmInitEx** owner name of *NULL* and you use *passwordaccess=prompt*, that session owner is handled with session (root or authorized user) authority. This is also true if you log in with a root user ID or an authorized user ID and you use *passwordaccess= generate*. During a session started in this manner, you can perform any action on any object that is owned by this node regardless of the actual owner of that object.

If a session is started with a specific owner name, the session can only perform actions on objects that have that object owner name associated with them. Backups or archives into the system all must have this owner name associated with them. Any queries performed return only the values that have this owner name associated with them. The object owner value is set during the **dsmSendObj** call in the **Owner** field of the **ObjAttr** structure. An owner name is case-sensitive. Table 1 summarizes the conditions under which a user has access to an object.

Table 1. Summary of user access to objects

Session owner	Object owner	User access
NULL (root, system owner)	" " (empty string)	Yes
NULL	Specific name	Yes
Specific name	" " (empty string)	No
Specific name	Same name	Yes
Specific name	Different name	No

Accessing objects across nodes and owners

Three function calls support cross-node, cross-owner access on the same platform: **dsmSetAccess**, **dsmDeleteAccess**, and **dsmQueryAccess**. These functions, along with the *-fromnode* and *-fromowner* string options that are passed on **dsmInitEx**, permit a complete cross-node query, restore and retrieve process through the API.

For example, User A on node A uses the **dsmSetAccess** function call to give access to its backups under the /db file space to User B from Node B. The access rule is displayed as:

ID	Type	Node	User	Path
1	Backup	Node B	User B	/db/*/*

When User B logs on at Node B, the option string to **dsmInitEx** is:

```
-fromnode=nodeA -fromowner=userA
```

These options are set for this session. Any queries access the file spaces, and files of Node A. Backups and archives are not permitted. Only query, restore, and retrieve processes are permitted from the file spaces for which User B has access. If the application tries to execute any operation using a **dsmBeginTxn** (for examples, backup or update) while signed in with a *-fromnode* or *-fromowner* option set, then the dsmBeginTxn fails with the return code DSM_RC_ABORT_NODE_NOT_AUTHORIZED. See the individual function calls and dsmInitEx for more information.
Tip: On UNIX and Linux you can specify *–fromowner=root* in the option string that is passed on the **dsmInitEx** function call. This permits non-root users access to files that the root owns if a set access was performed.

Use the *asnodename* option on the **dsmInitEx** option string with the appropriate function to back up, archive, restore, retrieve, query or delete data under the target node name on the IBM Spectrum Protect™ server. See Backing up multiple nodes with client node proxy support for information on enabling this option.

Managing file spaces

Because file spaces are important to the operation of the system, a separate set of calls is used to register, update, and delete file space identifiers. Before you can store any objects that are associated with a file space on the system, you must first register the file space with IBM Spectrum Protect™.

Use the dsmRegisterFS call to accomplish this task. For more information about object names and IDs, see Object names and IDs.

The file space identifier is the top-level qualifier in a three-part name hierarchy. Grouping related data together within a file space makes management of that data much easier. For example, either the application client or the IBM Spectrum Protect server administrator can delete a file space and all the objects within that file space.

File spaces also permit the application client to provide information about the file space to the server that the administrator can then query. This information is returned on the query in the qryRespFSData structure and includes the following file system information:

Type	Definition
fstype	The file space type. This field is a character string that the application client sets.
fsAttr[platform].fsInfo	A client information field that is used for client-specific data.
capacity	The total amount of space in the file space.
occupancy	The amount of space that is currently occupied in the file space.
backStartDate	The time stamp when the latest backup started (set by sending a dsmUpdateFS call).
backCompleteDate	The time stamp when the latest backup completed (set by sending a dsmUpdateFS call).

Using capacity and occupancy depends on the application client. Some applications might not need information about the size of the file space, in which case these fields can default to 0. For more information about querying file spaces, see Querying the IBM Spectrum Protect system.

After a file space is registered with the system, you can back up or archive objects at any time. To update the occupancy and the capacity fields of the file space after a backup or archive operation, call dsmUpdateFS. This call ensures that the values for the occupancy and capacity of the file system are current. You can also update the fsinfo, backupstart, and backupcomplete fields.

If you want to monitor your last backup dates, enter a dsmUpdateFS call before you start the backup. Set the update action to DSM_FSUPD_BACKSTARTDATE. This forces the server to set the backStartDate field of the file space to the current time. After the backup is complete for that file space, enter a dsmUpdateFS call with the update action that is set to DSM_FSUPD_BACKCOMPLETEDATE. This call creates a time stamp on the end of the backup.

If a file space is no longer needed, you can delete it with the dsmDeleteFS command. On a UNIX or Linux operating system, only the root user or authorized users can delete file spaces.

The examples in Figure 1 demonstrate how to use the three file space calls for UNIX or Linux. For an example of how to use the three file space calls for Windows, see the sample program code that is installed on your system.
Figure 1. An example of working with file spaces, Part 1

```
/*  Register the file space if it has not already been done.  */

dsInt16        rc;
regFSData     fsData;
char          fsName[DSM_MAX_FSNAME_LENGTH];
char          smpAPI[] = "Sample-API";

strcpy(fsName,"/home/tallan/text");
memset(&fsData,0x00,sizeof(fsData));
fsData.stVersion = regFSDataVersion;
fsData.fsName = fsName;
fsData.fsType = smpAPI;
strcpy(fsData.fsAttr.unixFSAttr.fsInfo,"Sample API FS Info");
fsData.fsAttr.unixFSAttr.fsInfoLength =
       strlen(fsData.fsAttr.unixFSAttr.fsInfo) + 1;
fsData.occupancy.hi=0;
fsData.occupancy.lo=100;
fsData.capacity.hi=0;
fsData.capacity.lo=300;
```

```
rc = dsmRegisterFS(dsmHandle,fsData);
if (rc == DSM_RC_FS_ALREADY_REGED) rc = DSM_RC_OK;  /* already done */
if (rc)
{
   printf("Filespace registration failed: ");
   rcApiOut(dsmHandle, rc);
   free(bkup_buff);
   return (RC_SESSION_FAILED);
}
```

Figure 2. An example of working with file spaces, Part 2

```
/* Update the file space. */

dsmFSUpd     updFilespace;         /* for update FS */

updFilespace.stVersion = dsmFSUpdVersion;
updFilespace.fsType = 0;             /* no change */
updFilespace.occupancy.hi = 0;
updFilespace.occupancy.lo = 50;
updFilespace.capacity.hi = 0;
updFilespace.capacity.lo = 200;
strcpy(updFilespace.fsAttr.unixFSAttr.fsInfo,
       "My update for filespace") ;
updFilespace.fsAttr.unixFSAttr.fsInfoLength =
       strlen(updFilespace.fsAttr.unixFSAttr.fsInfo);

updAction = DSM_FSUPD_FSINFO |
            DSM_FSUPD_OCCUPANCY |
            DSM_FSUPD_CAPACITY;

rc = dsmUpdateFS (handle,fsName,&updFilespace,updAction);
printf("dsmUpdateFS rc=%d\n", rc);
```

Figure 3. An example of working with file spaces, Part 3

```
/*  Delete the file space.  */

printf("\nDeleting file space
rc = dsmDeleteFS (dsmHandle,fsName,DSM_REPOS_ALL);
if (rc)
{
   printf("  FAILED!!! ");
   rcApiOut(dsmHandle, rc);
}
else printf("  OK!\n");
```

Associating objects with management classes

A primary feature of IBM Spectrum Protect™ is the use of policies (management classes) to define how objects are stored and managed in IBM Spectrum Protect storage. An object is associated with a management class when the object is backed up or archived.

This management class determines:

- How many versions of the object are kept if backed up
- How long to keep archive copies
- Where to insert the object in the storage hierarchy on the server

Management classes consist of both backup copy groups and archive copy groups. A copy group is a set of attributes that define the management policies for an object that is being backed up or archived. If a backup operation is being performed, the attributes in the backup copy group apply. If an archive operation is being performed, the attributes in the archive copy group apply.

The backup or archive copy group in a particular management class can be empty or NULL. If an object is bound to the NULL backup copy group, that object cannot be backed up. If an object is bound to the NULL archive copy group, the object cannot be archived.

Because the use of a policy is a very important component of IBM Spectrum Protect, the API requires that all objects sent to the server are first assigned a management class by using the **dsmBindMC** call. With IBM Spectrum Protect software, you can use an include-exclude list to affect management class binding. The **dsmBindMC** call uses the current Include-Exclude list to perform management class binding.

Include statements can associate a specific management class with a backup or archive object. Exclude statements can prevent objects from being backed up but not from being archived.

The API requires that **dsmBindMC** is called before you back up or archive an object. The **dsmBindMC** call returns a mcBindKey structure that contains information on management class and copy groups that are associated with the object. Check the copy group destination before proceeding with a send. When you send multiple objects in a single transaction, they must have the same copy group destination. The **dsmBindMC** function call returns the following information:

Table 1. Information returned on the dsmBindMC call

Information	Description
Management Class	The name of the management class that was bound to the object. The application client can send the **dsmBeginQuery** call to determine all attributes of this management class.
Backup Copy Group	Informs you if a backup copy group exists for this management class. If a backup operation is being performed and a backup copy group does not exist, this object cannot be sent to storage. You receive an error code if you attempted to send it using the **dsmSendObj** call.
Backup Copy Destination	This field identifies the storage pool to which the data is sent. If you are performing a multiple object backup transaction, all copy destinations within that transaction must be the same. If an object has a different copy destination than previous objects in the transaction, end the current transaction and begin a new transaction before you can send the object. You receive an error code if you attempt to send objects to different copy destinations within the same transaction.
Archive Copy Group	Informs you if an archive copy group exists for this management class. If an archive operation is being performed and an archive copy group does not exist, this object cannot be sent to storage. You receive an error code if you attempted to send it using the **dsmSendObj** call.
Archive Copy Destination	This field identifies the storage pool to which the data are sent. If you are performing a multiple object archive transaction, all copy destinations within that transaction must be the same. If an object has a different copy destination than previous objects in the transaction, end the current transaction and begin a new transaction before you send the object. You receive an error code if you attempt to send objects to different copy destinations within the same transaction.

Backup copies of an object can be rebound to a different management class if a subsequent back up with the same object name is done that uses a management class different than the original. For example, if you back up ObjectA and bind it to Mgmtclass1, and later you back up ObjectA and bind it to Mgmtclass2, the most current backup rebinds any inactive copies to Mgmtclass2. The parameters defined in Mgmtclass2 would now control all copies. However the data does not move if the destination is different.

You can also rebind backup copies to a different management class using the **dsmUpdateObj** or **dsmUpdateObjEx** call with the DSM_BACKUPD_MC action.

- Query management classes
  Applications can query management classes to determine what management classes are possible for a given node and to determine what the attributes are within the management class.

Deduplication option

Expiration/deletion hold and release

You can hold deletion and expiration of specific archive objects in response to a pending or ongoing action that requires that particular data be held. In the event an action is initiated that might require access to data, that data must be available until the action is concluded and access to the data is no longer required as part of that process. After determining that the suspension is no longer required (released), normal deletion and expiration timing resumes per the original retention period.

Before you begin

Verify that the server is licensed by issuing a test dsmRetentionEvent call:

1. Query for one object you want to hold and get the ID.
2. Issue the dsmBeginTxn, dsmRetentionEvent with Hold, and dsmEndTxn.
3. If the server is not licensed, you receive a vote of abort with reason code `DSM_RC_ABORT_LICENSE_VIOLATION`.

Restrictions:

1. You cannot issue more than one dsmRetentionEvent call in a single transaction.
2. You cannot issue a hold on an object that is already under hold.

Procedure

1. To hold objects, complete the following steps:
   a. Query the server for all the objects that you want to place under hold. Get the object ID for each object.
   b. Issue a dsmBeginTxn call, then issue a dsmRetentionEvent call with the list of objects, followed by a dsmEventType: eventHoldObj call. If the number of objects exceeds the value of maxObjPerTxn, use multiple transactions.
   c. Use the `qryRespArchiveData` response on the dsmGetNextQObj function call to confirm that the objects are put under hold. Check the value of `objHeld` in `qryRespArchiveData`.
2. To release objects from hold, complete the following steps:
   a. Query the server for all the objects that you want to release from hold. Get the object ID for each object.
   b. Issue a dsmBeginTxn call, then issue a dsmRetentionEvent call with the list of objects, followed by a dsmEventType: eventReleaseObj call. If the number of objects exceeds the value of `maxObjPerTxn`, use multiple transactions.
   c. Use the qryRespArchiveData response on the dsmGetNextQObj function call to confirm if the objects were released from hold. Check the value of objHeld in qryRespArchiveData.

- Archive data retention protection
  Data that is under the control of IBM Spectrum Protect™ cannot be modified by unauthorized agents, such as an individual or a program. This protection extends to preventing the deletion of data, such as archive objects, by any agent before the expiration of the retention period.

Querying the IBM Spectrum Protect™ system

The API has several queries, such as management class query, that applications can use.

Procedure

All queries that use the dsmBeginQuery call follow these steps:

1. Send the dsmBeginQuery call with the appropriate query type:
   - Backup
   - Archive
   - Active backed-up objects
   - File space
   - Management class

   The dsmBeginQuery call informs the API of the data format that is returned from the server. The appropriate fields can be placed in the data structures that are passed by the dsmGetNextQObj calls. The begin query call also permits the application client to set the scope of the query by properly specifying the parameters on the begin query call.
   Restriction: On UNIX or Linux systems, only the root user can query active backed-up objects. This query type is known as "fast path".
2. Enter the dsmGetNextQObj call to obtain each record from the query. This call passes a buffer that is large enough to hold the data that is returned from the query. Each query type has a corresponding data structure for the data returned. For example, a backup query type has an associated qryRespBackupData structure that is populated when the dsmGetNextQObj call is sent.
3. The dsmGetNextQObj call usually returns one of the following codes:
   - `DSM_RC_MORE_DATA`: Send the dsmGetNextQObj call again.
   - `DSM_RC_FINISHED`: There is no more data. Send the dsmEndQuery call.
4. Send the dsmEndQuery call. When all query data are retrieved or more query data are not needed, enter the dsmEndQuery call to end the query process. The API flushes any remaining data from the query stream and releases any resources that were used for the query.

Results

Figure 1 displays the state diagram for query operations.

Figure 1. State diagram for general queries

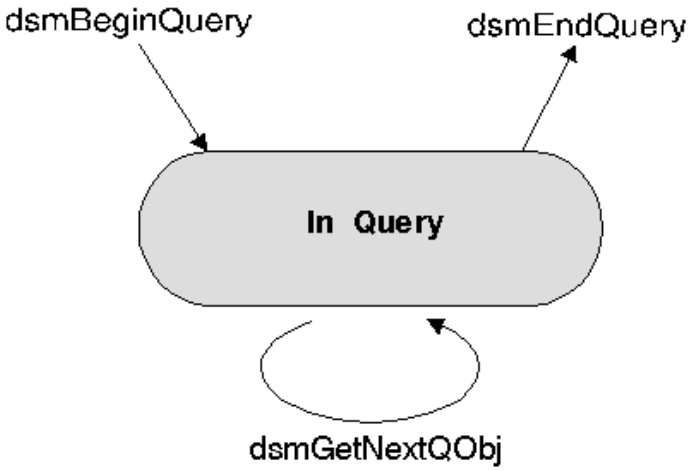

Figure 2 displays the flowchart for query operations.
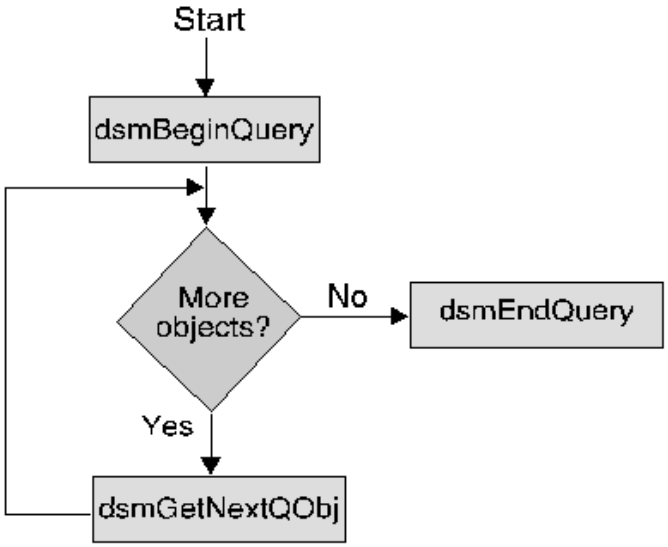
Figure 2. Flowchart for general queries



- Example of querying the system
  In this example a management class query prints out the values of all the fields in the backup and archive copy groups for a particular management class.

Server efficiency

Use these guidelines when you retrieve from, or send objects to, the IBM Spectrum Protect™ server.

- When you retrieve objects from the IBM Spectrum Protect server, follow these guidelines:
  - Retrieve data in the restore order that is provided by the IBM Spectrum Protect server. The restore order is especially important for tape devices, because retrieving data that is not ordered can result in tape rewinds and mounts.
  - Even when data is stored on a disk device, you can save time when the retrieves are ordered.
  - Perform as much work as possible in a single IBM Spectrum Protect server session.
  - Do not start and stop multiple sessions.
- When you send objects to the IBM Spectrum Protect server, follow these guidelines:
  - Send multiple objects in a single transaction.
  - Avoid sending one object per transaction, especially when the data is sent directly to a tape device. Part of the tape device transaction is to ensure that the data in the RAM buffers of the tape is written to media.

Sending data to a server

The API permits application clients to send data or named objects and their associated data to IBM Spectrum Protect™ server storage.

Tip: You can either back up or archive data. Perform all send operations within a transaction.

- The transaction model
  All data sent to IBM Spectrum Protect storage during a backup or archive operation is done within a transaction. A transaction model provides a high level of data integrity, but it does impose some restrictions that an application client must take into consideration.
- File aggregation
  IBM Spectrum Protect servers use a function that is called file aggregation. With file aggregation, all objects sent in a single transaction are stored together, which saves space and improves performance. You can still query and restore the objects separately.
- LAN-free data transfer
  The API can take advantage of LAN-free data transfer if the **dsmSetUp** option for multithreading is ON. The API returns the existence of a LAN-free destination in the **Query Mgmt Class** response structure **archDetailCG** or **backupDetailCG** field **bLanFreeDest**.
- Simultaneous-write operations
  You can configure IBM Spectrum Protect server storage pools to write simultaneously to a primary storage pool and copy storage pool or pools during a backup or archive. Use this configuration to create multiple copies of the object.
- Enhancing API performance
  You can use the tcpbuffsize and tcpnodelay client options and the DataBlk API parameter to enhance API performance.

The transaction model

All data sent to IBM Spectrum Protect™ storage during a backup or archive operation is done within a transaction. A transaction model provides a high level of data integrity, but it does impose some restrictions that an application client must take into consideration.

Start a transaction by a call to **dsmBeginTxn** or end a transaction by a call to **dsmEndTxn**. A single transaction is an atomic action. Data sent within the boundaries of a transaction is either committed to the system at the end of the transaction or rolled back if the transaction ends prematurely.

Transactions can consist of either single object sends or multiple object sends. To improve system performance by decreasing system overhead, send smaller objects in a multiple object transaction. The application client determines whether single or multiple transactions are appropriate.

Send all objects within a multiple object transaction to the same copy destination. If you need to send an object to a different destination than the previous object, end the current transaction and start a new one. Within the new transaction, you can send the object to the new copy destination.
Note: Objects that do not contain any bit data (*sizeEstimate=0*) are not checked for copy destination consistency.

IBM Spectrum Protect limits the number of objects that can be sent in a multiple object transaction. To find this limit, call **dsmQuerySessInfo** and examine the **maxObjPerTxn** field. This field displays the value of the *TXNGroupmax* option that is set on your server.

The application client must keep track of the objects sent within a transaction to perform retry processing or error processing if the transaction ends prematurely. Either the server or the client can stop a transaction at any time. The application client must be prepared to handle sudden transaction ends that it did not start.

File aggregation

IBM Spectrum Protect™ servers use a function that is called file aggregation. With file aggregation, all objects sent in a single transaction are stored together, which saves space and improves performance. You can still query and restore the objects separately.

To use this function, all of the objects in a transaction should have the same file space name. If the file space name changes within a transaction, the server closes the existing aggregated object and begins a new one.

LAN-free data transfer

The API can take advantage of LAN-free data transfer if the **dsmSetUp** option for multithreading is ON. The API returns the existence of a LAN-free destination in the **Query Mgmt Class** response structure **archDetailCG** or **backupDetailCG** field **bLanFreeDest**.

You can use LAN-free operations on platforms that are supported by the storage agent. Macintosh platform is excluded.

LAN-free information is provided in the following output structures. The out structure (**dsmEndGetDataExOut_t**) for **dsmEndGetData** includes the field, **totalLFBytesRecv**. This is the total number of LAN-free bytes that are received. The out structure (**dsmEndSendObjExOut_t**) for **dsmEndSendObjEx** includes the field, **totalLFBytesSent**. This is the total number of LAN-free bytes that were sent.

Related information:
LAN-free data movement: Storage agent overview

Simultaneous-write operations

You can configure IBM Spectrum Protect™ server storage pools to write simultaneously to a primary storage pool and copy storage pool or pools during a backup or archive. Use this configuration to create multiple copies of the object.

If a simultaneous-write operation fails, the return code on the **dsmEndTxn** function might be `DSM_RC_ABORT_STGPOOL_COPY_CONT_NO`, which indicates that the write to one of the copy storage pools failed, and the IBM Spectrum Protect storage pool option COPYCONTINUE was set to NO. The application terminates and the problem must be resolved by the IBM Spectrum Protect server administrator.

For more information about setting up simultaneous-write operations, see the IBM Spectrum Protect server documentation.

Enhancing API performance

You can use the tcpbuffsize and tcpnodelay client options and the DataBlk API parameter to enhance API performance.

Table 1 describes the actions that you can take to enhance the API performance.

Table 1. Backup-archive options and the API parameter that enhance performance

Backup-archive client options	**Description**
tcpbuffsize	Specifies the size of the TCP buffer. The default value is 31 KB. To enhance performance, set the value to 32 KB.
tcpnodelay	Specifies whether to send small buffers to the server rather than holding them. To enhance performance, set this option to *yes* for all platforms. This option is valid for Windows and AIX® only.
API parameter	**Description**
DataBlk	This parameter is used with the **dsmSendData** function call to determine the application buffer size. For best results, set the parameter as a multiple of the *tcpbuffsize* value that is specified with the tcpbuffsize minus 4 bytes. For example, set a value of 28 for this parameter when the value of tcpbuffsize is set to 32 KB.

Each dsmSendData call is synchronous and does not return until the data transferred to the API in the dataBlkPtr is flushed to the network. The API adds a 4-byte overhead to each transaction buffer that is placed on the network.

For example, when the transaction buffer size is 32 KB and the application DataBlk buffer size is 31 KB, then each application DataBlk buffer fits in a communications buffer and can be flushed immediately. However, if the application DataBlk buffer is exactly 32 KB, and because the API is adding 4 bytes per transaction buffer, two flushes are required; one of 32 KB and one of 4 bytes. Also, if you set the tcpnodelay option to no, flushing the 4 bytes might take up to 200 milliseconds.

Set up the API to send performance data to the client performance monitor

The client performance monitor is a component of the Tivoli® Storage Manager Administration Center that is used to display performance data that is collected by the API. The client performance monitor records and displays performance data for client backup, archive, and restore operations.

With performance monitoring enabled, you can display performance data that is collected by the API by using the performance monitor; the performance monitor is available in the Tivoli Storage Manager Administration Center. Starting with version 7.1, the Administration Center component is no longer included in Tivoli Storage Manager or IBM Spectrum Protect™ distributions. If you have an Administration Center that was installed with a previous server release, you can continue to use it to display performance data. If you do not already have an Administration Center installed, you can download the previously-released version from ftp://public.dhe.ibm.com/storage/tivoli-storage-management/maintenance/admincenter/v6r3/. For information about using the performance monitor, see the Tivoli Storage Manager Version 6.3 server documentation.

- Configuring client performance monitor options
  You enable IBM Spectrum Protect clients to use the performance monitor by specifying parameters in the client options file. You specify these options for each client that you want to monitor.

Sending objects to the server

Application clients can send data or named objects and their associated data to IBM Spectrum Protect™ storage by using the API backup and archive functions. The backup and archive components of the system permit use of different management procedures for data that is sent to storage.

The size estimate attribute is an estimate of the total size of the data object to send to the server. If the application does not know the exact object size, set the *sizeEstimate* to a higher estimate. If the estimate is smaller than the actual size, the IBM Spectrum Protect server uses extra resources to manage extra space allocations.

Tips:

- Be as accurate as is possible when you make this size estimate. The server uses this attribute for efficient space allocation and object placement within its storage resources.
- If the estimate is smaller than the actual size, a server with caching does not allocate extra space and stops the send.

You might encounter problems if the *sizeEstimate* is much too large. The server might not have enough space for the estimated size but does have space for the actual size; or the server might use slower devices.

You can back up or archive objects that are larger than two gigabytes in size. The objects can be either compressed or uncompressed.

To start a send operation, call **dsmSendObj**. If you have more data than you can send at one time, you can make repeated calls to **dsmSendData** to transfer the remainder of the information. Call **dsmEndSendObj** to complete the send operation.

- Understanding backup and archive objects
  The backup component of the IBM Spectrum Protect system supports several versions of named objects that are stored on the server.
- Compression
  Configuration options on a given node and the dsmSendObj objCompressed option, determine whether IBM Spectrum Protect compresses the object during a send. Also, objects with a sizeEstimate less than DSM_MIN_COMPRESS_SIZE are never compressed.
- Buffer copy elimination
  The buffer copy elimination function removes the copy of data buffers between an application and the IBM Spectrum Protect server, which results in better processor utilization. For maximum effect, use this approach in a LAN-free environment.
- API encryption
  Two methods are available to encrypt data: application-managed encryption and IBM Spectrum Protect client encryption.

Understanding backup and archive objects

The backup component of the IBM Spectrum Protect™ system supports several versions of named objects that are stored on the server.

Any object backed up to the server that has the same name as an object that is already stored on the server from that client is subject to version control. Objects are considered to be in active or inactive states on the server. The latest copy of an object on

the server that has not been deactivated is in the active state. Any other object with the same name, whether it is an older version or a deactivated copy, is considered inactive. Management class constructs define different management criteria. They are assigned to active and inactive objects on the server.

Table 1 lists the copy group fields that apply to active and inactive states:

Table 1. Backup copy group fields

Field	Description
VEREXISTS	The number of inactive versions if active versions exist.
VERDELETED	The number of inactive versions if active versions do not exist.
RETEXTRA	The number of days to keep inactive versions.
RETONLY	The number of days to keep the last inactive versions if active versions do not exist.

If backup versions each have a unique name, such as using a time stamp in the name, then versioning does not happen automatically: every object is active. Active objects never expire, so an application would be responsible for deactivating these with the **dsmDeleteObj** call. In this situation, the application would need the deactivated objects to expire as soon as possible. The user would define a backup copy group with VERDELETED=0 and RETONLY=0.

The archive component of the IBM Spectrum Protect system permits objects to be stored on the server with retention or expiration period controls instead of version control. Each object stored is unique, even though its name might be the same as an object already archived. Archive objects have a description field associated with the metadata that can be used during query to identify a specific object.

Every object on the IBM Spectrum Protect server is assigned a unique object ID. The persistence of the original value is not guaranteed during the life of an object (specifically, after an export or import). Therefore, an application should not query and save the original object ID for use on later restores. Rather, an application should save the object name and insert date. You can use this information during a restore to query objects and verify the insert date. Then, the current object ID can be used to restore the object.

Compression

Configuration options on a given node and the dsmSendObj objCompressed option, determine whether IBM Spectrum Protect™ compresses the object during a send. Also, objects with a sizeEstimate less than DSM_MIN_COMPRESS_SIZE are never compressed.

If the object is compressed already (objCompressed=bTrue), it is not compressed again. If it is not compressed, IBM Spectrum Protect decides whether to compress the object, based on the values of the compression option that is set by the administrator and that is set in the API configuration sources.

The administrator can change compression thresholds on the server by using the register node command (compression=yes, no, or client-determined). If this is client-determined, then the compression behavior is determined by the compression option value in the configuration sources.

Some types of data, such as data that is already compressed, might actually get bigger when processed with the compression algorithm. When this happens, the return code DSM_RC_COMPRESS_GREW is generated. If you realize that this might happen, but you want the send operation to continue anyway, tell the end users to specify the following option in their options file:

```
COMPRESSAlways Yes
```

If, during a dsmSendData function, with compression enabled, you get DSM_RC_COMPRESS_GREW return code, you might want to start over and send the object again without compression. To enforce this, set the dsmSendObj ObjAttr.objCompressed to bTrue.

Information about the actual compression behavior during a dsmSendObj is returned by the dsmEndSendObjEx call. objCompressed specifies if compression was done. totalBytesSent is the number of bytes sent by the application. totalCompressedSize is the number of bytes after compression. The dsmEndSendObjEx call also has a totalLFBytesSent field that contains the total bytes sent over LAN-free.

Attention: If your application plans to use partial object restore or retrieve, you cannot compress the data while sending it. To enforce this, set the dsmSendObj ObjAttr.objCompressed to bTrue.

- Compression type
  The type of compression that the client uses is determined by the combination of compression and client-side data deduplication that is used during backup or archive processing.

Buffer copy elimination

The buffer copy elimination function removes the copy of data buffers between an application and the IBM Spectrum Protect™ server, which results in better processor utilization. For maximum effect, use this approach in a LAN-free environment.

The buffers for data movement are allocated by IBM Spectrum Protect and a pointer is passed back to the application. The application places the data in the provided buffer, and that buffer is passed through the communication layers to the storage agent by using shared memory. The data is then moved to the tape device, which eliminates copies of data. This function can be used with either backup or archive operations.

Attention: When you use this method, pay extra attention to proper buffer handling and sizes of buffers. The buffers are shared between the components and any memory overwrite that is a result of a programming error results in severe errors.

The overall sequence of calls for backup/archive is as follows:

```
dsmInitEx (UseTsmBuffers = True, numTsmBuffers = [how many IBM Spectrum Protect
            -allocated buffers the application needs to allocate])
dsmBeginTxn
for each object in the txn
  dsmBindMC
    dsmSendObject
      dsmRequestBuffer
      dsmSendBufferData (sends and release the buffer used)
    dsmEndSendObjEx
dsmEndTxn
for each buffer still held
      dsmReleaseBuffer
dsmTerminate
```

The dsmRequestBuffer function can be called multiple times, up to the value that is specified by the numTsmBuffers option. An application can have two threads: a producer thread that fills buffers with data; and a consumer thread that sends those buffers to IBM Spectrum Protect with the dsmSendBufferData call. When a dsmRequestBuffer call is issued and the numTsmBuffers is reached, the dsmRequestBuffer call blocks until a buffer is released. The buffer release can happen by either calling dsmSendBufferData, which sends and releases a buffer or by calling dsmReleaseBuffer. For more information, see callbuff.c in the API sample directory.

If at any point there is a failure in the send, the application must release all the buffers that are held and terminate the session. For example:

```
  If failure
    for each data buffer held by application
      call dsmReleaseBuffer
  dsmTerminate
```

If an application calls dsmTerminate and a buffer is still held, the API does not exit. The following code is returned: `DSM_RC_CANNOT_EXIT_MUST_RELEASE_BUFFER`. If the application cannot release the buffer, the application must exit the process to force a cleanup.

- Buffer copy elimination and restore and retrieve
  The IBM Spectrum Protect server controls the amount of data to be placed in the buffer, based on tape access optimization with restore and retrieve. This method is not as beneficial to the application as the normal method of getting data. During prototyping, check the performance of the buffer copy elimination method and use this method only if you see a worthwhile improvement.

API encryption

Two methods are available to encrypt data: application-managed encryption and IBM Spectrum Protect™ client encryption.

Select and use only one of these methods to encrypt data. The methods are mutually exclusive and if you encrypt data by using both methods, you will be unable to restore or retrieve some data. For example, assume that an application uses application-managed encryption to encrypt object A, and then uses IBM Spectrum Protect client encryption to encrypt object B. During a

restore operation, if the application sets the option to use IBM Spectrum Protect client encryption and it tries to restore both objects, only object B can be restored; object A cannot be restored because it was encrypted by the application, not by the client.

Regardless of the encryption method that is used, the IBM Spectrum Protect must enable password authentication. By default, the server uses `SET AUTHENTICATION ON`.

The API uses either AES 128-bit or AES 256-bit encryption. AES 256-bit data encryption provides a higher level of data encryption than AES 128-bit data encryption. Files that are backed up by using AES 256-bit encryption cannot be restored with an earlier client. Encryption can be enabled with or without compression. If you use encryption, you cannot use the partial object restore and retrieve and buffer copy elimination functions.

- Application-managed encryption
  With application-managed encryption, the application provides the key password to the API (using key DSM_ENCRYPT_USER) and it is the application's responsibility to manage the key password.
- IBM Spectrum Protect client encryption
  IBM Spectrum Protect client encryption uses the key that is managed by the DSM_ENCRYPT_CLIENTENCRKEY value to protect your data. Client encryption is transparent to the application that is using the API, with the exception that partial object restore operations and retrieve operations are not possible for objects that were encrypted or compressed.

Application-managed encryption

With application-managed encryption, the application provides the key password to the API (using key DSM_ENCRYPT_USER) and it is the application's responsibility to manage the key password.

Attention: If the encryption key is not saved, and you forgot the key, your data is unrecoverable.

The application provides the key password in the dsmInitEx call and must provide the proper key password at restore time.

Attention: If the key password is lost, there is no way to restore the data.

The same key password must be used for backup and restore (or archive and retrieve) operations for the same object. This method does not have a dependency on the IBM Spectrum Protect™ server level. To set up this method, the application needs to follow these steps:

1. Set the bEncryptKeyEnabled variable to bTrue in the call to dsmInitEx, and set the encryptionPasswordP variable to point to a string with the encrypt key password.
2. Set the include.encrypt for the objects to encrypt. For example, to encrypt all data, set:

   ```
   include.encrypt /.../* (UNIX)
   ```

   and

   ```
   include.encrypt *\...\* (Windows)
   ```

   To encrypt the object /FS1/DB2/FULL, set:

   ```
   include.encrypt /FS1/DB2/FULL
   ```

3. Set ENCRYPTKEY=PROMPT|SAVE in the option string that is passed to the API in the dsmInitEx call on Windows. This option can also be set in dsm.opt (Windows) or dsm.sys (UNIX or Linux).

By default, the encryptkey option is set to prompt. This setting ensures that the key does not get stored automatically. If encryptkey save is specified, the key is stored by IBM Spectrum Protect on the local machine but then only one key can be valid for all IBM Spectrum Protect operations with the same node name.

After a send of an object, the dsmEndSendObjEx specifies whether an object was encrypted and which method was used. Possible values in the *encryptionType* field:

- DSM_ENCRYPT_NO
- DSM_ENCRYPT_USER
- DSM_ENCRYPT_CLIENTENCRKEY

The following table lists the API encryption types, prerequisites, and the functions that are available.

Table 1. API encryption types, prerequisites, and functions available

Type	Prerequisite	Function available

Type	Prerequisite	Function available
ENCRYPTIONTYPE	None	Set the ENCRYPTIONTYPE in the option string that is passed to the API in the dsmInitEx call on Windows. ENCRYPTIONTYPE=AES128 by default.
EncryptKey=save	None	API and backup-archive
EncryptKey=prompt	None	API and backup-archive
EncryptKey=generate	None	API and backup-archive
EnableClientEncryptKey	None	API only

Note: It is advised that the server has authentication turned ON. If authentication is turned OFF, the key is not encrypted, but the data is still encrypted. However, this is not recommended.

Table 2 shows how both Authorized Users and non-Authorized Users can encrypt or decrypt data during a backup or restore operation, depending on the value that is specified for the passwordaccess option. The TSM.PWD file must exist to perform the following authorized-user and non-authorized-user operations. The authorized user creates the TSM.PWD file and sets the encryptkey option to save and the passwordaccess option to generate.

Table 2. Encrypting or decrypting data with application managed key on UNIX or Linux

Operation	passwordaccess option	encryptkey option	Result
Authorized user backup	generate	save	Data encrypted.
	generate	prompt	Data encrypted if encryptionPasswordP contains an encryption password.
	prompt	save	Data encrypted if encryptionPasswordP contains an encryption password.
	prompt	prompt	Data encrypted if encryptionPasswordP contains an encryption password.
Authorized user restore	generate	save	Data encrypted.
	generate	prompt	Data encrypted if encryptionPasswordP contains an encryption password.
	prompt	save	Data encrypted if encryptionPasswordP contains an encryption password.
	prompt	prompt	Data encrypted if encryptionPasswordP contains an encryption password.
Non-authorized user backup	generate	save	Data encrypted.
	generate	prompt	Data encrypted if encryptionPasswordP contains an encryption password.
	prompt	save	Data encrypted if encryptionPasswordP contains an encryption password.
	prompt	prompt	Data encrypted if encryptionPasswordP contains an encryption password.
Non-authorized user restore	generate	save	Data encrypted.
	generate	prompt	Data encrypted if encryptionPasswordP contains an encryption password.
	prompt	save	data encrypted if encryptionPasswordP contains an encryption password.
	prompt	prompt	Data encrypted if encryptionPasswordP contains an encryption password.

IBM Spectrum Protect client encryption

IBM Spectrum Protect™ client encryption uses the key that is managed by the DSM_ENCRYPT_CLIENTENCRKEY value to protect your data. Client encryption is transparent to the application that is using the API, with the exception that partial object restore operations and retrieve operations are not possible for objects that were encrypted or compressed.

For both IBM Spectrum Protect client encryption and application-managed encryption, the encryption password refers to a string value that is used to generate the actual encryption key. The value for the encryption password option is 1-63 characters in length, but the key that is generated from it is always 8 bytes for 56 DES, 16 bytes for 128 AES, and 32 bytes for 256 AES.

Attention: If the encryption key is not available, data cannot be restored or retrieved. When you use ENABLECLIENTENCRYPTKEY for encryption, the encryption key is stored on the server database. For objects that use this method, the server database must exist and have the proper values for the objects for a proper restore. Ensure that you back up the server database frequently to prevent data loss.

This is the simpler method to implement, where one random encryption key is generated per session and it is stored on the IBM Spectrum Protect server with the object in the server database. During restore, the stored key is used for decryption. Using this method, the management of the key is the responsibility of IBM Spectrum Protect, and the application does not have to deal with the key at all. Because the key is stored in the server database, you must have a valid IBM Spectrum Protect database for a restore operation of an encrypted object. When the key is transmitted between the API and the server, it is also encrypted. The transmission of the key is secure, and when the key is stored in the IBM Spectrum Protect server database it is encrypted. The only time that the key is placed in the clear with the export data stream is when a node's data are exported between servers.

To enable IBM Spectrum Protect client encryption, complete the following steps:

1. Specify -ENABLECLIENTENCRYPTKEY=YES in the option string that is passed to the API on the dsmInitEx call or set the option in the system option file dsm.opt (Windows) or dsm.sys (UNIX or Linux).
2. Set the include.encrypt for the objects to encrypt. For example, to encrypt all data, set:

   ```
   include.encrypt /.../* (UNIX)
   ```

   and

   ```
   include.encrypt *\...\* (Windows)
   ```

   To encrypt the object /FS1/DB2/FULL, set:

   ```
   include.encrypt /FS1/DB2/FULL
   ```

Data deduplication

Data deduplication is a method of reducing storage needs by eliminating redundant data.

Overview

Two types of data deduplication are available on IBM Spectrum Protect™: *client-side data deduplication* and *server-side data deduplication*.

Client-side data deduplication is a data deduplication technique that is used on the backup-archive client to remove redundant data during backup and archive processing before the data is transferred to the IBM Spectrum Protect server. Using client-side data deduplication can reduce the amount of data that is sent over a local area network.

Server-side data deduplication is a data deduplication technique that is done by the server. The IBM Spectrum Protect administrator can specify the data deduplication location (client or server) to use with the DEDUP parameter on the REGISTER NODE or UPDATE NODE server command.

Enhancements

With client-side data deduplication, you can:

- Exclude specific files on a client from data deduplication.
- Enable a data deduplication cache that reduces network traffic between the client and the server. The cache contains extents that were sent to the server in previous incremental backup operations. Instead of querying the server for the existence of an extent, the client queries its cache.

  Specify a size and location for a client cache. If an inconsistency between the server and the local cache is detected, the local cache is removed and repopulated.

Note: For applications that use the IBM Spectrum Protect API, the data deduplication cache must not be used because of the potential for backup failures caused by the cache being out of sync with the IBM Spectrum Protect server. If multiple, concurrent backup-archive client sessions are configured, there must be a separate cache configured for each session.

- Enable both client-side data deduplication and compression to reduce the amount of data that is stored by the server. Each extent is compressed before it is sent to the server. The trade-off is between storage savings and the processing power that is required to compress client data. In general, if you compress and deduplicate data on the client system, you are using approximately twice as much processing power as data deduplication alone.

  The server can work with deduplicated, compressed data. In addition, backup-archive clients earlier than V6.2 can restore deduplicated, compressed data.

Client-side data deduplication uses the following process:

- The client creates extents. *Extents* are parts of files that are compared with other file extents to identify duplicates.
- The client and server work together to identify duplicate extents. The client sends non-duplicate extents to the server.
- Subsequent client data-deduplication operations create new extents. Some or all of those extents might match the extents that were created in previous data-deduplication operations and sent to the server. Matching extents are not sent to the server again.

Benefits

Client-side data deduplication provides several advantages:

- It can reduce the amount of data that is sent over the local area network (LAN).
- The processing power that is required to identify duplicate data is offloaded from the server to client nodes. Server-side data deduplication is always enabled for deduplication-enabled storage pools. However, files that are in the deduplication-enabled storage pools and that were deduplicated by the client, do not require additional processing.
- The processing power that is required to remove duplicate data on the server is eliminated, allowing space savings on the server to occur immediately.

Client-side data deduplication has a possible disadvantage. The server does not have whole copies of client files *until* you back up the primary storage pools that contain client extents to a non-deduplicated copy storage pool. (*Extents* are parts of a file that are created during the data-deduplication process.) During storage pool backup to a non-deduplicated storage pool, client extents are reassembled into contiguous files.

By default, primary sequential-access storage pools that are set up for data deduplication must be backed up to non-deduplicated copy storage pools before they can be reclaimed and before duplicate data can be removed. The default ensures that the server has copies of whole files at all times, in either a primary storage pool or a copy storage pool.

Important: For further data reduction, you can enable client-side data deduplication and compression together. Each extent is compressed before it is sent to the server. Compression saves space, but it increases the processing time on the client workstation.

The following options pertain to data deduplication:

- Deduplication
- Dedupcachepath
- Dedupcachesize
- Enablededupcache
- Exclude.dedup
- Include.dedup

- API client-side data deduplication
  Client-side data deduplication is used by the API on the backup-archive client, to remove redundant data during backup and archive processing before the data is transferred to the IBM Spectrum Protect server.
- Server-side data deduplication
  Server-side data deduplication is data deduplication that is performed by the server.

API client-side data deduplication

Client-side data deduplication is used by the API on the backup-archive client, to remove redundant data during backup and archive processing before the data is transferred to the IBM Spectrum Protect™ server.

Client-side data deduplication is used by the API, to remove redundant data during backup and archive processing before the data is transferred to the IBM Spectrum Protect server. Using client-side data deduplication can reduce the amount of data that is sent over a local area network. Using client-side data deduplication can also reduce the IBM Spectrum Protect server storage space.

When the client is enabled for client-side data deduplication, and you perform a backup or archive operation, the data is sent to the server as extents. The next time a backup or archive operation is performed, the client and server identify which data extents have already been backed up or archived, and send only the unique extents of data to the server.

For client-side data deduplication, the server and API must be at version 6.2 or later.

Before you use client-side data deduplication to back up or archive your files, the system must meet the following requirements:

- The client must have the deduplication option enabled.
- The server must enable the client for client-side data deduplication with the DEDUP=CLIENTORSERVER parameter on either the REGISTER NODE or UPDATE NODE command.
- The storage pool destination for the data must be a data deduplication-enabled storage pool. The data deduplication-enabled storage pool is file device type only.
- Ensure that the files are bound to the correct management class.
- A file can be excluded from client-side data deduplication processing. By default, all files are included.
- Files must be larger than 2 KB.
- The server can limit the maximum transaction size for data deduplication by setting the CLIENTDEDUPTXNLIMIT option on the server. See the server documentation information about this option.

If any of these requirements are not met, data is processed normally, with no client-side data deduplication.

Here are some data deduplication restrictions:

- LAN-free data movement and client-side data deduplication are mutually exclusive. If you enable both LAN-free data movement and client-side data deduplication, LAN-free data movement operations complete and client-side data deduplication is ignored.
- Encryption and client-side data deduplication are mutually exclusive. If you enable both encryption and client-side data deduplication, encryption operations complete and client-side data deduplication is ignored. Encrypted files, and files that are eligible for client-side data deduplication, can be processed in the same operation, but are done in separate transactions.
  Requirements:
  1. In any transaction, all files must be either included for data deduplication or excluded. If the transaction has mixed files, the transaction fails, and a return code of `DSM_RC_NEEDTO_ENDTXN` is returned by the API.
  2. Use storage device encryption together with client-side data deduplication. Because SSL is used in combination with client-side deduplication, there is no need for client encryption.
- The following functions are not available for client-side data deduplication:
  - IBM Spectrum Protect for Space Management (HSM) client
  - API shared buffer
  - NAS
  - Subfile backup
- Buffer copy elimination cannot be used with data transformations like compression, encryption, and data deduplication.
- If you use client-side deduplication, the API detects and fails (with RC=254) backups of file extents that are marked as expired on the server during sending data to the server. If you want to retry the operation, you need to include that programming in the calling application.
- Simultaneous-write operations on the server takes precedence over client-side data deduplication. If simultaneous-write operations are enabled, client-side data deduplication does not occur.
  Restriction: When client side data deduplication is enabled, the API cannot recover from a state where the server has run out of storage on the destination pool, even if there is a next pool defined. A stop reason code of DSM_RS_ABORT_DESTINATION_POOL_CHANGED is returned and the operation fails. There are two ways to recover from this situation:
  1. Ask the administrator to add more scratch volumes to the original filepool.
  2. Retry the operation with data deduplication disabled.

For even greater bandwidth savings, you can enable a local cache for data deduplication. The local cache saves queries from going to the IBM Spectrum Protect server. The default value for ENABLEDEDUPCACHE is NO, so that the cache is not out of sync with the server. If the cache is out of sync with the server, the application resends all data. If your application can retry on a failed transaction, and you want to use the local cache, set the ENABLEDEDUPCACHE option to YES in the dsm.opt (Windows) or dsm.sys (UNIX) file.

At the end of a restore, if *all* of the data was restored through the API, and the object was deduplicated by the client, an end-to-end digest is calculated and compared to the value calculated at backup time. If those values do not match, error DSM_RC_DIGEST_VALIDATION_ERROR is returned. If an application receives this error, the data is corrupt. This error can also be a result of a transient error on the network, so try the restore or retrieve again.

Here is an example of the query session command showing data deduplication information:

```
dsmQuerySessInfo Values:
Server Information:
Server name: SERVER1
Server Host: AVI
Server port: 1500
Server date: 2009/10/6 20:48:51
Server type: Windows
Server version: 6.2.0.0
Server Archive Retention Protection : NO
Client Information:
Client node type: API Test1
Client filespace delimiter: :
Client hl & ll delimiter: \
Client compression: Client determined (3u)
Client archive delete: Client can delete archived objects
Client backup delete: Client CANNOT delete backup objects
Maximum objects in multiple object transactions: 4096
Lan free Enabled: NO
Deduplication : Client Or Server
General session info:
Node: AVI
Owner:
API Config file:
```

Here is an example of the query management class command showing data deduplication information:

```
Policy Information:
Domain name: DEDUP
Policyset name: DEDUP
Policy activation date: 0/0/0 0:0:0
Default management class: DEDUP
Backup retention grace period: 30 days
Archive retention grace period: 365 days
Mgmt. Class 1:
Name: DEDUP
Description: dedup - values like standard
Backup CG Name: STANDARD
Frequency: 0
Ver. Data Exists: 2
Ver. Data Deleted: 1
Retain Extra Ver: 30
Retain Only Ver: 60
Copy Destination: AVIFILEPOOL
Lan free Destination: NO
Deduplicate Data: YES

Archive CG Name: STANDARD
Frequency: 10000
Retain versions: 365
Copy Destination: AVIFILEPOOL
Lan free Destination: NO
Retain Init : CREATE
Retain Minimum : 65534
Deduplicate Data: YES

Exclude files from data deduplication

You can choose to exclude backup or archive files from data deduplication.

To exclude files from data deduplication processing, follow these steps:

1. Set the exclude.dedup option for the objects to exclude.

   For example, to exclude all dedup data for UNIX systems, set:

   ```
   exclude.dedup /.../*
   ```

2. To exclude all dedup data for Windows systems, set:

   ```
   exclude.dedup *\...\*
   ```

Important: If an object is sent to a data deduplication pool, data deduplication occurs on the server, even if the object is excluded from client-side data deduplication.

Include files for data deduplication

You can choose to include backup or archive files for data deduplication.

To refine the list of files to be included, the include.dedup option can be used in combination with the exclude.dedup option.

By default, all eligible objects are included for data deduplication.

Here are some UNIX and Linux examples:

```
exclude.dedup /FS1/.../*

include.dedup /FS1/archive/*
```

Here are some Windows examples:

```
exclude.dedup E:\myfiles\...\*

include.dedup E:\myfiles\archive\*
```

Server-side data deduplication

Server-side data deduplication is data deduplication that is performed by the server.

The IBM Spectrum Protect™ administrator can specify the data deduplication location (client or server) to use with the DEDUP parameter on the REGISTER NODE or UPDATE NODE server command.

In a data deduplication-enabled storage pool (file pool), only one instance of a data extent is retained. Other instances of the same data extent are replaced with a pointer to the retained instance.

For more information about server-side data deduplication, see the IBM Spectrum Protect server documentation.

Application failover

When the IBM Spectrum Protect™ server becomes unavailable because of an outage, applications that use the API can automatically fail over to a secondary server for data recovery.

The IBM Spectrum Protect server that the client and API connects to during normal production processes is called the *primary server*. When the primary server is set up for node replication, that server is also known as the *source replication server*. The client node data on the source replication server can be replicated to the *target replication server*. This server is also known as the *secondary server*, and is the server that the client automatically fails over to when the primary server fails.

The client and API must be configured for automated client failover, and must connect to a version 7.1 (or later) server that replicates client node data. The configuration for the API is the same as the configuration for the backup-archive client.

During normal operations, connection information for the secondary server is automatically sent to the client from the primary server during the logon process. The secondary server information is automatically saved to the client options file.

Each time the client application logs on to the IBM Spectrum Protect server, it attempts to contact the primary server. If the primary server is unavailable, the application automatically fails over to the secondary server by using the secondary server information in the client options file. In failover mode, the application can query the secondary server and restore or retrieve replicated data.

You must back up the application at least one time to the primary server. The API can fail over to the secondary server to recover data only if the data from the client node was replicated from the primary server to the secondary server.

- Failover status information
  The API provides status information that applications can use to determine the failover status and the status of replicated client data on the secondary server.

Automated client failover configuration and use

Example flow diagrams for backup and archive

The API is designed for straightforward logic flows and clear transitions between the various states of the application client. This clean state transition catches logic flaws and program errors early in the development cycle, greatly enhancing the quality and reliability of the system.

For example, you cannot make a **dsmSendObj** call unless a transaction was started and a **dsmBindMC** call was previously made for the object that you are backing up.

Figure 1 displays the state diagram for performing backup or archive operations within a transaction. The arrow pointing from "In Send Object" to **dsmEndTxn** indicates that a **dsmEndTxn** call can be started after a call to **dsmSendObj** or **dsmSendData**. You might want to do this if an error condition occurred during the send of an object and you want to stop the entire operation. In this case, you must use a vote of DSM_VOTE_ABORT. In normal circumstances, however, call **dsmEndSendObj** before you end the transaction.

Figure 1. State diagram for backup and archive operations

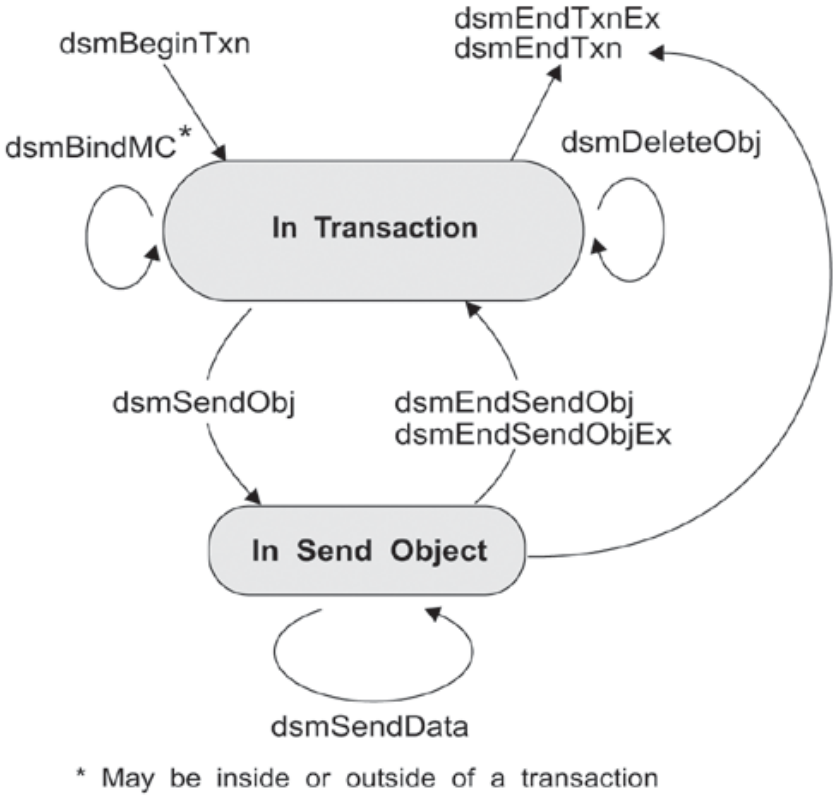

Figure 2 displays the flowchart for performing backup or archive operations within a transaction.

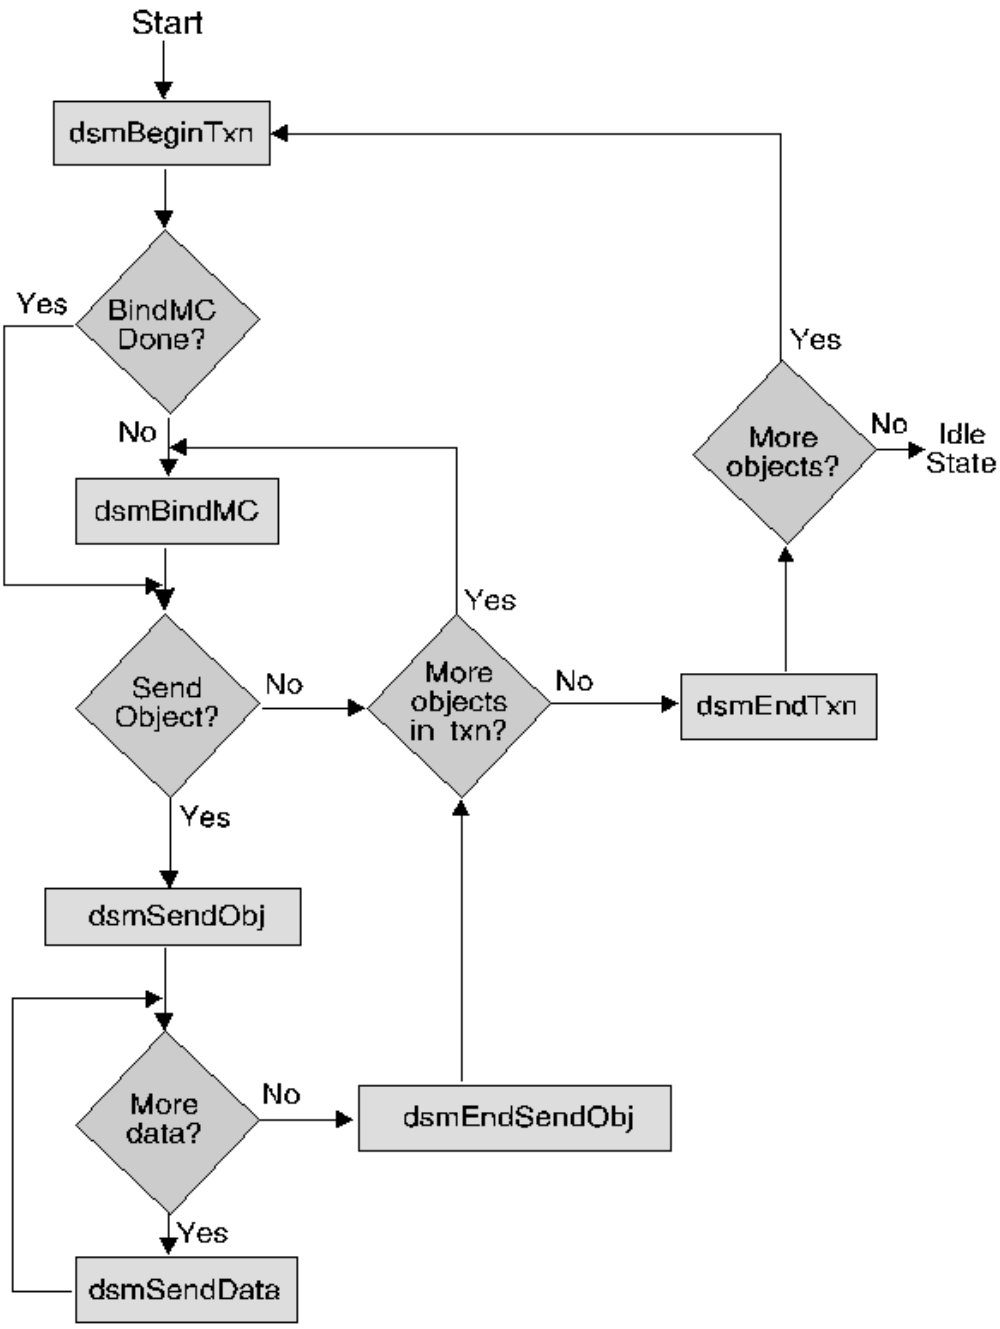
Figure 2. Flowchart for backup and archive operations



The primary feature in these two diagrams is the loop between the following API calls from within a transaction:

- **dsmBindMC**
- **dsmSendObj**
- **dsmSendData**
- **dsmEndSendObj**

The **dsmBindMC** call is unique in that you can start it from inside or outside of a transaction boundary. You can also start it from a different transaction, if required. The only requirement for the **dsmBindMC** call is that it is made prior to backing up or archiving an object. If the object that you are backing up or archiving is not associated with a management class, an error code is returned from **dsmSendObj**. In this situation, the transaction is ended by calling **dsmEndTxn** (this error condition is not shown in the flowchart).

The flowchart illustrates how an application would use multiple object transactions. It shows where decision points can be placed to determine if the object that is sent fits within the transaction or whether to start a new transaction.

- Code example of API functions that send data to IBM Spectrum Protect storage
  This example demonstrates the use of the API functions that send data to IBM Spectrum Protect™ storage. The **dsmSendObj** call appears inside a switch statement, so that different parameters can be called depending on whether a backup or archive operation is being performed.

File grouping

The IBM Spectrum Protect™ API has a logical file grouping protocol that relates several individual objects together. You can reference and manage these groups as a logical group on the server. A logical group requires that all group members and the group leader belong to the same node and file space on the server.

Each logical group has a group leader. If the group leader is deleted, the group is deleted. You cannot delete a member that is part of a group. Expiration of all members in a group is dependent on the group leader. For example, if a member is marked for expiration, the member does not expire unless the group leader expires. However, if a member is not marked for expiration, and the group leader is expired, then all members are expired.

File groups contain backup data only, and cannot contain archive data. Archive objects can use the **Archive Description** field to facilitate a type of grouping if required by an application.

The **dsmGroupHandler** call groups the operations. The **dsmGroupHandler** function must be called from within a transaction. Most group error conditions are caught on either the **dsmEndTxn**l or **dsmEndTxnEx** calls.

The `out` structure in **dsmEndTxnEx** includes a new field, **groupLeaderObjId**. This field contains the object ID of the group leader if a group was opened in that transaction. You can create a group across more than one transaction. A group is not committed, or saved, on the server until a close is performed. The **dsmGroupHandler** is an interface that can accept five different operations. They include:

- DSM_GROUP_ACTION_OPEN
- DSM_GROUP_ACTION_CLOSE
- DSM_GROUP_ACTION_ADD
- DSM_GROUP_ACTION_ASSIGNTO
- DSM_GROUP_ACTION_REMOVE

Table 1 lists the **dsmGroupHandler** function call actions:

Table 1. dsmGroupHanlder functions

Action	Description
OPEN	The OPEN action creates a group. The next object that is sent becomes the group leader. The group leader cannot have content. All objects after the first object become members that are added to the group. To create a group, open a group and pass in a unique string to identify the group. This unique identifier allows several groups with the same name to be opened. After the group is opened, the next object that is sent is the group leader. All other objects that are sent are group members.
CLOSE	The CLOSE action commits and saves an open group. To close the group, pass in the object name and the unique string that is used in the open operation. The application must check for open groups and, if necessary, close or delete the groups. A group is not committed or saved until the group is closed. A CLOSE action fails in the following conditions: • The group that you are trying to close has the same name as an existing open group. • A management class incompatibility exists between the current closed group and the new group to be closed of the same name. In this case, complete the following steps: 1. Query the previous closed group. 2. If the management class of the existing closed group is different from the management class associated with the current open group, issue a **dsmUpdateObject** with type DSM_BACKUPD_MC. This command updates the existing group to the new management class. 3. Issue the CLOSE action.
ADD	The ADD action appends an object to a group. All objects that are sent after the ADD action are assigned to the group.

Action	Description
ASSIGNTO	The ASSIGNTO action permits the client to assign objects that exist on the server to the declared peer group. This transaction sets up the PEER group relationship. The ASSIGNTO action is similar to the ADD action, with the following exceptions: • The ADD action applies to objects within an in-flight transaction. • The ASSIGNTO action applies to an object that is on the server.
REMOVE	The REMOVE action removes a member, or a list of members, from a group. A group leader cannot be removed from a group. A group member must be removed before the member can be deleted.

Use the following query types for group support:

- **qtBackupGroups**
- **qtOpenGroups**

The **qtBackupGroups** queries groups that are closed while **qtOpenGroups** queries groups that are open. The query buffer for the new types has fields for **groupLeaderObjId** and **objType**. The query performs differently depending on the values for these two fields. The following table includes some query possibilities:

Table 2. Examples of queries

groupLeaderObjId.hi	groupLeaderObjId.lo	objType	Result
0	0	NULL	Returns a list of all group leaders
grpLdrObjId.hi	grpLdrObjId.lo	0	Returns a list for all group members that are assigned to the specified group leader (**grpLdrObjId**).
grpLdrObjId.hi	grpLdrObjId.lo	objType	Returns a list by using **BackQryRespEnhanced3**, for each group member that is assigned to the specified group leader (**grpLdrObjId**), and matching the object type (**objType**).

The response structure (**qryRespBackupData**) from **dsmGetNextQObj** includes two fields for group support:

- **isGroupLeader**
- **isOpenGroup**

These fields are Boolean flags. The following example displays the creation of the group, adding members to the group, and closing the group to commit the group on the IBM Spectrum Protect server.

Figure 1. Example of pseudo-code that is used to create a group

```
dsmBeginTxn
        dsmGroupHandler (PEER, OPEN, leader, uniqueId)
        dsmBeginSendObj
                dsmEndSendObj
dsmEndTxnEx (With objId of leader)
Loop for multiple txns
{
        dsmBeginTxn
                dsmGroupHandler (PEER, ADD, member, groupLeaderObjID)
                Loop for multiple objects
                {
                        dsmBeginSendObj
                        Loop for data
                        {
                                dsmSendData
                        }
                        dsmEndSendObj
                }
        dsmEndTxn
}
dmBeginTxn
        dsmGroupHandler(CLOSE)
dsmEndTxn
```

For a code example, see the sample group program dsmgrp.c that is included in the API sampsrc directory.

Receiving data from a server

Application clients can receive data or named objects and their associated data from IBM Spectrum Protect™ storage by using the restore and retrieve functions. The restore function accesses objects that previously were backed up, and the retrieve function accesses objects that previously were archived.

Restriction: The API can only restore or retrieve objects that were backed up or archived using API calls.

Both restore and retrieve functions start with a query operation. The query returns different information depending on whether the data was originally backed up or archived. For instance, a query on backup objects returns information on whether an object is active or inactive, while a query on archive objects returns information such as object descriptions. Both queries return object IDs that are used to uniquely identify the object on the server.

- Partial object restore or retrieve
  The application client can receive only a portion of the object. This is called a partial object restore or a partial object retrieve.
- Restoring or retrieving data
  After a query is made and a session is established with the IBM Spectrum Protect server, you can run a procedure to restore or retrieve data.
- Example flow diagrams for restore and retrieve
  A state diagram and a flowchart can be used to illustrate how to perform restore or retrieve operations.
- Code example of receiving data from a server
  This example demonstrates using the API functions to retrieve data from IBM Spectrum Protect storage.

Partial object restore or retrieve

The application client can receive only a portion of the object. This is called a partial object restore or a partial object retrieve.

Attention: Partial restore or retrieve of compressed or encrypted objects produces unpredictable results.
Note: If you code your application to use a partial object restore or retrieve, you cannot compress the data while sending it. To enforce this, set *ObjAttr.objCompressed* to *bTrue*.
To perform a partial object restore or retrieve, associate the following two data fields with each object **GetList** entry:

offset
: The byte offset into the object from which to begin returning data.

length
: The number of object bytes to return.

Use DSM_MAX_PARTIAL_GET_OBJ to determine the maximum number of objects that can perform a partial object restore or retrieve for a specific **dsmBeginGetData** list.

The following data fields, used on the **dsmBeginGetData** call, determine what portion of the object is restored or retrieved:

- If both the offset and length are zero, the entire object is restored or retrieved from IBM Spectrum Protect™ storage.
- If the offset is greater than zero, but the length is zero, the object is restored or retrieved from the offset to the end.
- If the length is greater than zero, only the portion of the object from the offset for the specified length is restored or retrieved.

Restoring or retrieving data

After a query is made and a session is established with the IBM Spectrum Protect™ server, you can run a procedure to restore or retrieve data.

Procedure

To restore or retrieve data, complete the following steps:

1. Query the IBM Spectrum Protect server for either backup or archive data.
2. Determine the objects to restore or retrieve from the server.
3. Sort the objects on the Restore Order field.
4. Send the dsmBeginGetData call with the list of objects that you want to access.

5. Send the dsmGetObj call to obtain each object from the system. Multiple dsmGetData calls might be needed for each object to obtain all associated object data. Send the dsmEndGetObj call after all data for an object is obtained.
6. Send the dsmEndGetData call after all data for all objects is received, or to end the receive operation.

- Querying the server
  Before you begin any restore or retrieve operation, first query the IBM Spectrum Protect server to determine what objects you can receive from storage.
- Selecting and sorting objects by restore order
  After the backup or archive query is performed, the application client must determine which objects, if any, are to be restored or retrieved.
- Starting the dsmBeginGetData call
  After you select and sort the objects to receive, submit them to IBM Spectrum Protect for either a restore or retrieve operation. The **dsmBeginGetData** call begins a restore or retrieve operation. The objects are returned to the application client in the order you requested.
- Receiving each object to restore or retrieve
  After the dsmBeginGetData call is sent, you can perform a procedure to receive each object that is sent from the server.

Querying the server

Before you begin any restore or retrieve operation, first query the IBM Spectrum Protect™ server to determine what objects you can receive from storage.

To send the query, the application must enter the parameter lists and structures for the dsmBeginQuery call. The structure must include the file space that the query examines and pattern-match entries for the high-level and low-level name fields. If the session was initialized with a NULL owner name, you do not need to specify the owner field. However, if the session was initialized with an explicit owner name, only objects that are associated with that owner name are returned.

The point-in-time BackupQuery query provides a snapshot of the system at a specific time. By specifying a valid date, you can query all files that are backed up to that time. Even if an object has an active backup from a later date, point-in-time overrides an object state so that the previous inactive copy is returned. For more information, see the following example: pitDate.

A query returns all information that is stored with the object, in addition to the information in the following table.

Table 1. Query to the server return information

Field	Description
`copyId`	The `copyIdHi` and `copyIdLo` values provide an 8-byte number that uniquely identifies this object for this node in IBM Spectrum Protect storage. Use this ID to request a specific object from storage for restore or retrieve processing.
`restoreOrderExt`	The `restoreOrderExt` value provides a mechanism for receiving objects from IBM Spectrum Protect storage in the most efficient manner possible. Sort the objects to restore on this value to ensure that tapes are mounted only one time and are read from front to back.

You must keep some or all of the query information for later processing. Keep the `copyId` and `restoreOrderExt` fields because they are needed for the actual restore operation. You must also keep any other information needed to open a data file or identify a destination.

Call dsmEndQuery to finish the query operation.

Selecting and sorting objects by restore order

After the backup or archive query is performed, the application client must determine which objects, if any, are to be restored or retrieved.

Then you sort the objects in ascending order (low to high). This sorting is very important to the performance of the restore operation. Sorting the objects on the **restoreOrderExt** fields ensures that the data is read from the server in the most efficient order.

All data on disk is restored first, followed by data on media classes that require volume mounts (such as tape). The **restoreOrderExt** field also ensures that data on tape is read in order with processing starting at the front of a tape and progressing towards the end.

Properly sorting on the **restoreOrderExt** field means that duplicate tape mounts and unnecessary tape rewinds do not occur.

A non-zero value in the **restoreOrderExt**.top field correlates to a unique serial access device on the IBM Spectrum Protect™ server. Since a serial access device can only be used by one session / mount point at a time, the application should ensure that if it uses multiple sessions there are not concurrent restores with the same **restoreOrderExt**.top value. Otherwise the first session are able to access the objects, but other sessions wait until the first session terminates and the device becomes available.

The following example shows how to sort objects by using **Restore Order** fields.

Figure 1. Sorting objects with the restore order fields

```
typedef struct {
dsStruct64_t      objId;
dsUint160_t      restoreOrderExt;

}  SortOrder;               /* struct used for sorting */

    else
       return(EQUAL);
}
```

Starting the dsmBeginGetData call

After you select and sort the objects to receive, submit them to IBM Spectrum Protect™ for either a restore or retrieve operation. The **dsmBeginGetData** call begins a restore or retrieve operation. The objects are returned to the application client in the order you requested.

Complete the information for these two parameters in these calls:

mountWait
: This parameter tells the server whether the application client waits for offline media to be mounted in order to obtain data for an object, or whether that object should be skipped during processing of the restore or retrieve operation.

dsmGetObjListP
: This parameter is a data structure that contains the **objId** field which is a list of all object IDs that are restored or retrieved. Each **objId** is associated with a **partialObjData** structure that describes whether the entire **objId** or only a particular section of the object will be retrieved.

  Each **objId** is eight bytes in length, so a single restore or retrieve request can contain thousands of objects. The number of objects to request in a single call is limited to DSM_MAX_GET_OBJ or DSM_MAX_PARTIAL_GET_OBJ.

Receiving each object to restore or retrieve

After the dsmBeginGetData call is sent, you can perform a procedure to receive each object that is sent from the server.

About this task

The DSM_RC_MORE_DATA return code means that a buffer was returned and that you should call dsmGetData again. Check the DataBlk.numBytes for the actual number of returned bytes.

When you obtain all data for an object, you must send a dsmEndGetObj call. If more objects will be received, send dsmGetObj again.

If you want to stop the process, for example, to discard any remaining data in the restore stream for all objects that are not yet received, send the dsmEndGetData call. This call flushes the data from the server to the client. However, using this method might take time to complete. If you want to end a restore operation, use dsmTerminate to close the session.

Procedure

1. Send the dsmGetObj call to identify the object that you requested from the data stream and to obtain the first block of data that is associated with the object.
2. Send more dsmGetData calls, as necessary to obtain the remaining object data.

Example flow diagrams for restore and retrieve

A state diagram and a flowchart can be used to illustrate how to perform restore or retrieve operations.

The arrow pointing from "In Get Object" to **dsmEndGetData** indicates that you can send a **dsmEndGetData** call after a call to **dsmGetObj** or dsmGetData. You might need to do this if an error condition occurred while getting an object from IBM Spectrum Protect™ storage and you want to stop the operation. In normal circumstances, however, call **dsmEndGetObj** first.

Figure 1. State diagram for restore and retrieve operations

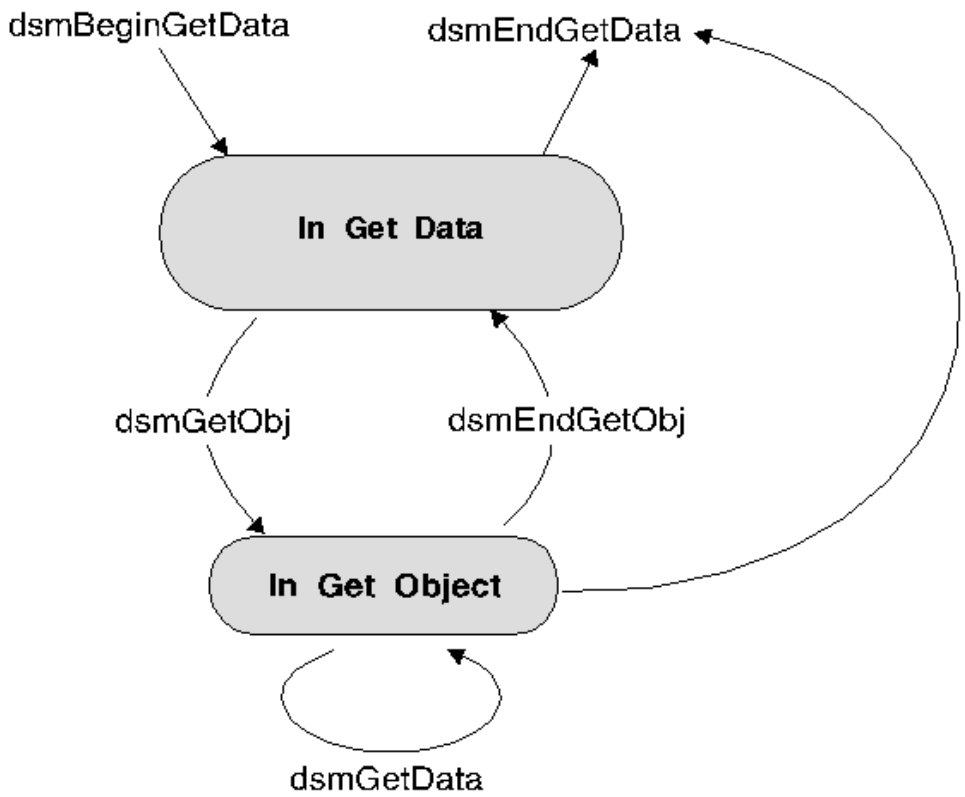

Figure 2 displays the flowchart for performing restore or retrieve operations.

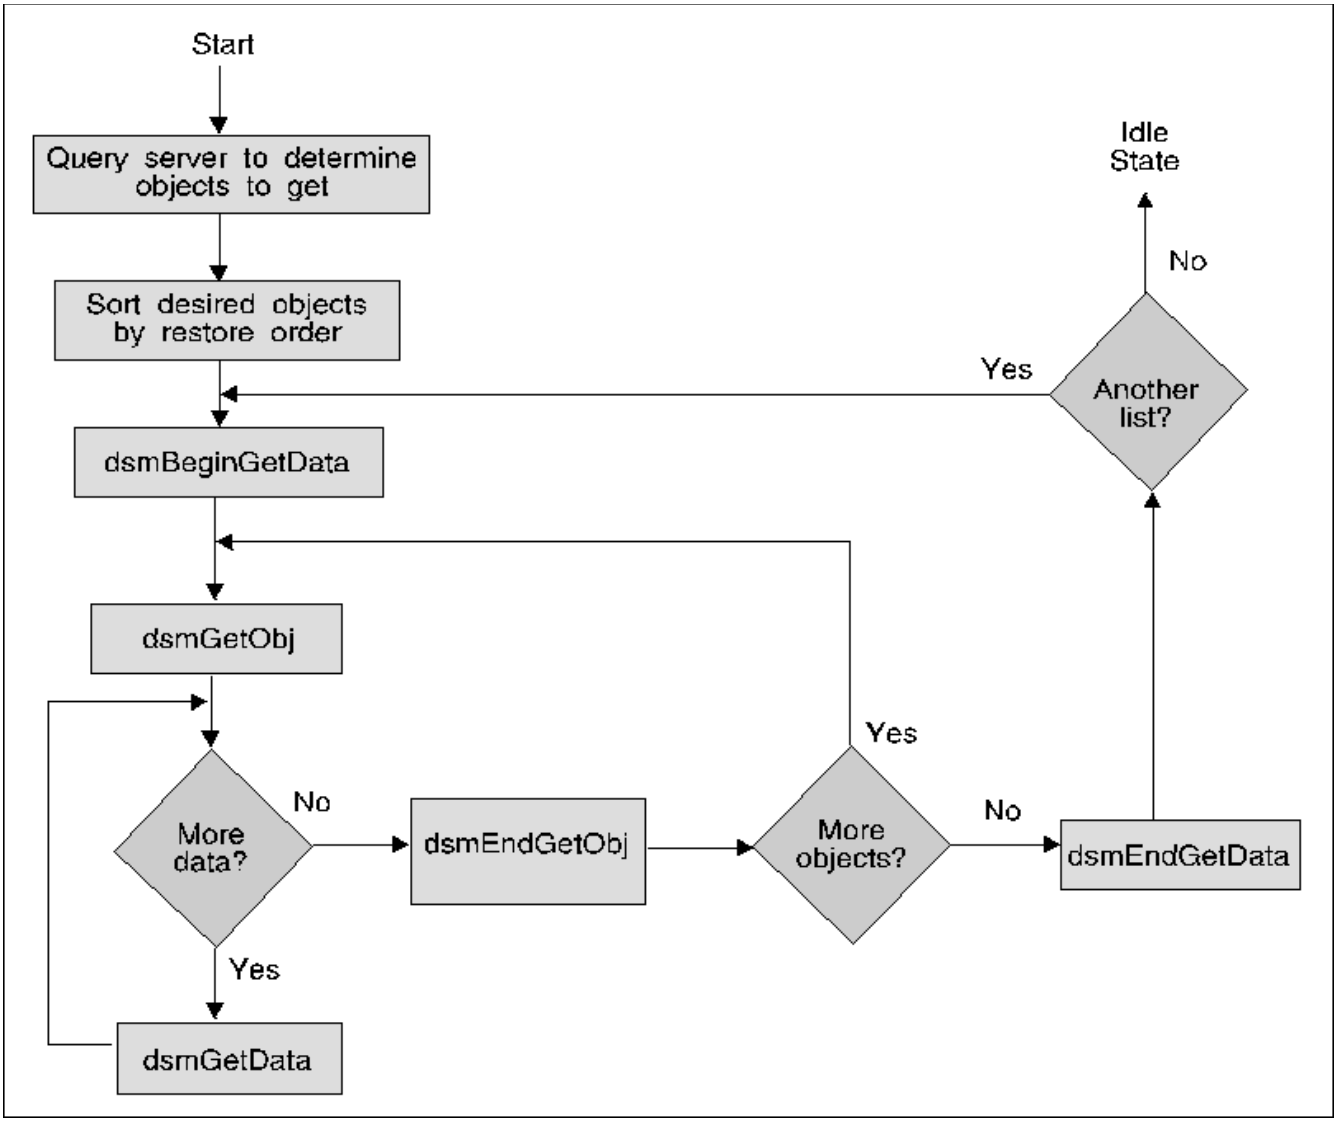
Figure 2. Flowchart for restore and retrieve operations



Code example of receiving data from a server

This example demonstrates using the API functions to retrieve data from IBM Spectrum Protect™ storage.

The **dsmBeginGetData** function call appears inside a switch statement, so that different parameters can be called depending on whether a restore or retrieve operation is being performed. The **dsmGetData** function call is called from inside a loop that repeatedly gets data from the server until a flag is set that permits the program execution to exit the loop.

Figure 1. An example of receiving data from a server

```
/* Call dsmBeginQuery and create a linked list of objects to restore. */
/* Process this list to create the proper list for the GetData calls. */
/* Set up the getList structure to point to this list.                */
/* This example is set up to perform a partial object retrieve.  To   */
/* retrieve only complete objects, set up:                            */
/*       getList.stVersion = dsmGetListVersion;                       */
/*       getList.partialObjData = NULL;                               */
dsmGetList getList;
getList.stVersion = dsmGetListPORVersion;   /* structure version      */
getList.numObjId  = items;              /* number of items in list   */
getList.objId     = (ObjID *)rest_ibuff;
                                  /* list of object IDs to restore  */
getList.partialObjData = (PartialObjData *) part_ibuff;
                                    /* list of partial object data  */
switch(get_type)
{
   case (Restore_Get) :
     rc = dsmBeginGetData(dsmHandle,bFalse,gtBackup,&getList);
```

```

       || (rc == DSM_RC_FINISHED))
   {
      if (rc == DSM_RC_MORE_DATA)
      {
         dataBlk.numBytes = 0;
         rc = dsmGetData(dsmHandle,&dataBlk);
      }
      else
         done = bTrue;
   }
   else
   {
      printf("*** dsmGetObj or dsmGetData failed: ");
      rcApiOut(dsmHandle, rc);
      done = bTrue;
   }
} /* while */
rc = dsmEndGetObj(dsmHandle);
/* check rc from dsmEndGetObj */
/* check rc from dsmEndGetData */
rc = dsmEndGetData(dsmHandle);
return 0;
```

Updating and deleting objects on the server

Your API applications can use the**dsmUpdateObj** or **dsmUpdateObjEx** function call to update objects that were archived or backed up. Use either call in the session state only, updating one object at a time. Use **dsmUpdateObjEx** to update any of several archive objects containing the same name.

To select an archive object, set the **dsmSendType** function call to **stArchive**.

- With **dsmUpdateObj**, only the latest archive object with the assigned name is updated.
- With **dsmUpdateObjEx**, any archived object can be updated by specifying the proper object ID.

For an archived object, the application can update the following fields:

- Description
- Object information
- Owner

To select a backup object, set **dsmSendType** to **stBackup**. For backed-up objects, only the active copy is updated.

For a backed-up object, the application can update the following fields:

- Management class
- Object information
- Owner

- Deleting objects from the server
  API applications can make calls to either delete objects that were archived or turn off objects that were backed up. Deleting

archived objects is dependent on the node authorization that was given when the administrator registered the node. Administrators can specify that nodes can delete archived objects.

Logging events

An API application can log event messages to central locations. The application can direct logging to the IBM Spectrum Protect™ server, the local machine, or both. The dsmLogEventEx function call is performed in a session. To view messages logged on the server, use the query actlog command through the administrative client.

Use the IBM Spectrum Protect client option, errorlogretention, to prune the client error log file if the application writes numerous client messages to the client log dsmLogType, either logLocal or logBoth.

For more information about IBM Spectrum Protect logs, see the IBM Spectrum Protect server documentation.

State diagram summary for the IBM Spectrum Protect API

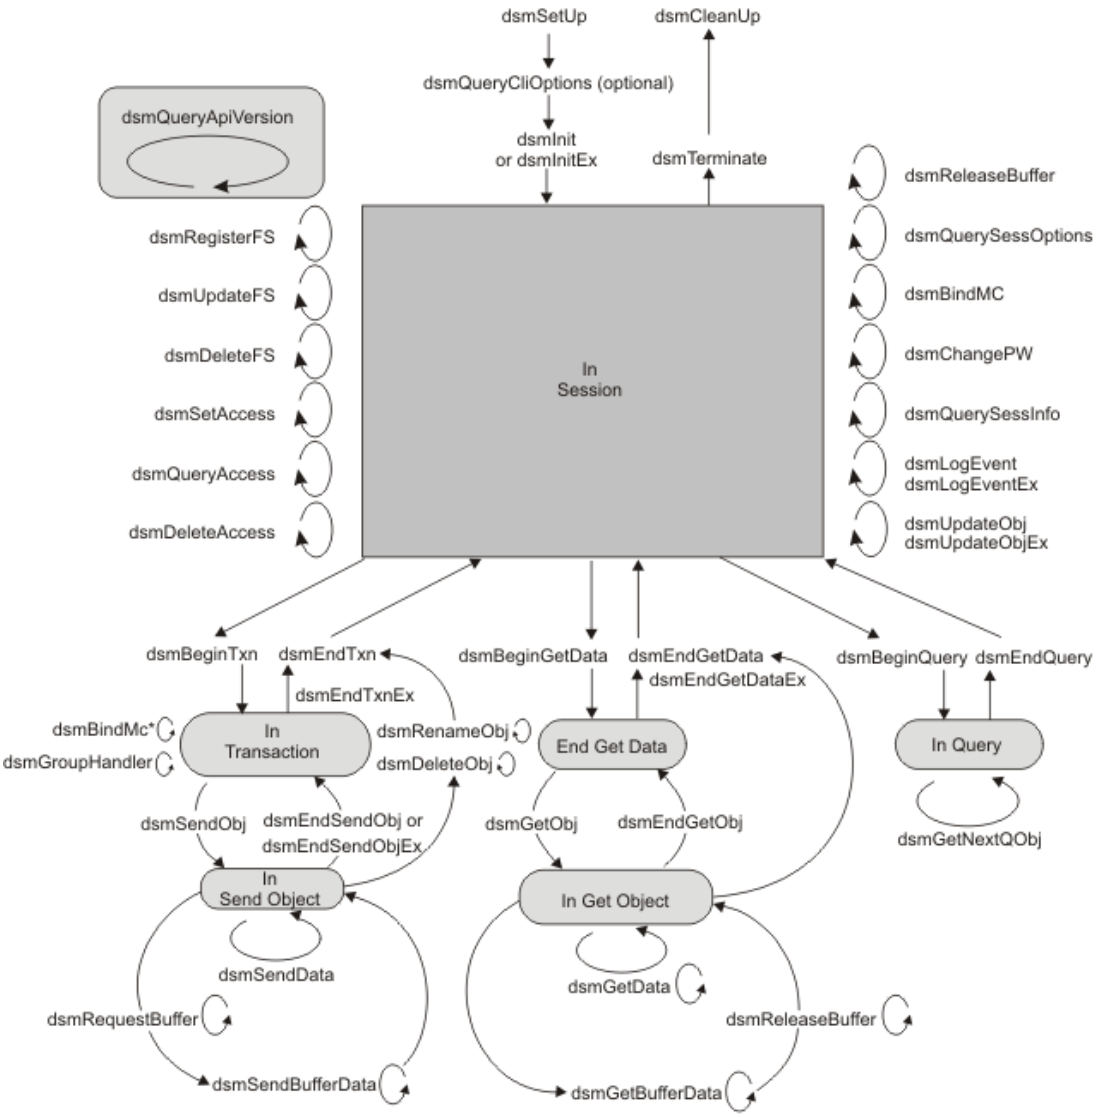
Once you review all the considerations for creating your own application with the IBM Spectrum Protect™ API, review this state diagram summary of an entire application.

Figure 1 contains the state diagram for the API. It contains all previously displayed state diagrams in addition to several other calls previously not displayed.

The points in this diagram include:

- Call **dsmQueryApiVersionEx** at any time. It has no state associated with it. See Figure 1 for an example.
- Call **dsmQueryCliOptions** before a **dsmInitEx** call only.
- Use **dsmRegisterFS**, **dsmUpdateFS**, and **dsmDeleteFS** to manage file spaces. These calls are made from within an idle session state. Use the **dsmBeginQuery** call to query file spaces. For more information about file space calls, see Managing file spaces.
- Send the **dsmBindMC** call from within an idle session state or from within a send object transaction state. See the example in Figure 1.
- Send the **dsmChangePW** call from within an idle session state.
  Note: If the **dsmInitEx** call returns with a password-expired return code, the **dsmChangePW** call must be made before you start a valid session. See Figure 3 for an example that uses **dsmChangePW**.
- If a call returns with an error, the state remains as it was. For example, if **dsmGetObj** returns with an error, the state remains In Get Data, and a call to **dsmEndGetObj** is a call sequence error.

Figure 1. Summary state diagram for the API



* Can be inside or outside of a transaction

Understanding interoperability

The API has two types of interoperability: between the backup-archive client and API applications and between different operating systems.

- Backup-archive client interoperability
  The backup-archive command line can access API objects to provide limited interoperability. API objects can only be viewed and accessed from the backup-archive command line client and cannot be viewed or accessed from any of the graphical interfaces. The backup-archive command-line client can only restore content of the file and nothing else, so you should only use it for a salvage type of operation.
- Operating system interoperability
  The IBM Spectrum Protect API supports cross-platform interoperability. Applications on a UNIX or Linux system can operate on file spaces and objects that are backed up from a Windows system. Similarly, a Windows system can operate on file spaces and objects that are backed up from a UNIX or Linux system.
- Backing up multiple nodes with client node proxy support
  Backups of multiple nodes which share storage can be consolidated to a common target node name on the IBM Spectrum

Protect server. This method is useful when the system that runs the backup can change over time, such as with a cluster. You can also use the asnodename option to restore data from a different system other than the one which ran the backup.

Backup-archive client interoperability

The backup-archive command line can access API objects to provide limited interoperability. API objects can only be viewed and accessed from the backup-archive command line client and cannot be viewed or accessed from any of the graphical interfaces. The backup-archive command-line client can only restore content of the file and nothing else, so you should only use it for a salvage type of operation.

The following command-line actions are provided:

- Delete archive
- Delete filespace
- Query
- Restore
- Retrieve
- Set access

The path information is actual directories for backup-archive client objects. In contrast, the API object path information might not have any relationship to existing directories: the path might be completely contrived. Interoperability does not change this aspect of these object types. To use this feature successfully, follow the restrictions and conventions.

Notes:

1. There is no interoperability between the backup-archive client and API objects stored on a retention protection server.
2. You cannot use the backup-archive client GUIs to access files that were stored using the API client. You can only use the command line to access these files.

- Naming your API objects
  Establish a consistent naming convention for API object names. The naming convention must cater for the file space name, the high-level qualifier, and the low-level qualifier. The file space name and high-level qualifiers can refer to actual directory names. Each object name can consist of more than one directory name that applies to the low-level qualifier.
- Backup-archive client commands you can use with the API
  You can use a subset of backup-archive client commands within an application. For example, you can view and manage objects that other users own either on the same node or on a different node.

Naming your API objects

Establish a consistent naming convention for API object names. The naming convention must cater for the file space name, the high-level qualifier, and the low-level qualifier. The file space name and high-level qualifiers can refer to actual directory names. Each object name can consist of more than one directory name that applies to the low-level qualifier.

For convenience, use the name of the object that is not prefixed with directory information as the low-level qualifier. For more information, see Object names and IDs.

File space names must be fully qualified when they are referred to from either the API or the backup-archive command line. For example, on a UNIX or Linux operating system, you register the following file spaces:

- `/a`
- `/a/b`

When you refer to `/a`, objects that are related only to file space `/a` are displayed. To view objects that are related to `/a/b`, you must specify `/a/b` as the file space name.

After you register both file spaces, if you back up object `b` into file space `/a`, then a query for `/a/b` continues to display objects that are related only to file space `/a/b`.

The exception to this restriction occurs in file space references when you attempt to query or delete file spaces with the API. In both cases, the file space names do not have to be fully qualified if you use a wildcard character. For example, `/a*` refers to both `/a` and `/a/b`.
Tip: If interoperability is important for you, then avoid file space names that overlap.

On Windows systems, enclose file space names in braces `{ }` for API objects when you access the objects from the backup-archive command line interface. Windows operating systems automatically place file space names in uppercase letters when you register or refer the names. However, this automatic function does not occur for the remainder of the object name specification. If you want full interoperability, place the high-level qualifier and the low-level qualifier in uppercase letters in the application when you back up API objects. If your application does not uppercase high-level qualifiers (directory names) and low-level qualifiers (file names) before it sends objects to the server, you will be unable to access the objects directly by name through the backup-archive client.

For example, if an object is stored on the server as {"FileSpacename"}\TEST\MYDIRNAME\file.txt, you cannot directly restore or query the file.txt object because your application did not uppercase the file name before the file was copied to the server. The only way to manipulate these objects is to use wildcard characters. For example, to query \TEST\MYDIRNAME\file.txt, a backup-archive client user must use wildcard characters for all parts of the object name that were not uppercased before they were sent to the server. The following command must be used to query this file.txt file:

```
dsmc query backup {"FileSpaceName"}\TEST\MYDIRNAME\*
```

If any other of the other qualifiers are also saved in lowercase text, those qualifiers must also be queried by using wildcards. For example, to query an object that is stored as {"FileSpaceName"}\TEST\mydirname\file.txt, use the following command:

```
dsmc query backup {"FileSpaceName"}\TEST\*\*
```

The examples that follow demonstrate these concepts. In both Windows and UNIX or Linux environments, you do not have to specify either the complete high-level or low-level qualifier. However, if you do not specify the complete qualifier, then you must use the wildcard character.

Platform	Example
Windows	To query all backed-up files in file space `MYFS`, enter the following string: `dsmc q ba "{MYFS}\*\*"` You must use at least one asterisk (*) for each of the high-level and low-level qualifiers.
UNIX or Linux	To query all backed-up files in file space `/A`, enter the following string: `dsmc q ba "/A/*/*"` You must use at least one asterisk (*) for each of the high-level and low-level qualifiers.

Backup-archive client commands you can use with the API

You can use a subset of backup-archive client commands within an application. For example, you can view and manage objects that other users own either on the same node or on a different node.

To view and manage objects that other users own either on the same node or on a different node, perform these steps:

1. Give access with the set access command.
2. Specify the owner and the node. Use the *fromowner* and *fromnode* options from the backup-archive command line to specify the owner and the node. For example:

   ```
   dsmc q ba "/A/*/*" -fromowner=other_owner -fromnode=other_node
   ```

Table 1 describes the commands that you can use with API objects.

Table 1. Backup-archive client commands you can use with API objects

Command	Description
Delete Archive	Archived files that the current user owns can be deleted. The set access command settings have no effect on this command.
Delete Filespace	The delete filespace command affects API objects.

Command	Description
Query	From the backup-archive command line, you can query backed up and archived API objects and objects that other users own, or that exist on other nodes. See Naming your API objects for information about querying API objects. Use the existing *–fromowner* option to query objects that a different user owns for which the set access permission has been given. Use the existing *–fromnode* option to query objects that exist on another node for which the set access permission has been given. For more information, see dsmInitEx.
Restore Retrieve	Note: Use these commands only for exception situations. API objects that are encrypted using the application managed key can be restored or retrieved if the encryption key is known or saved in the password file or registry. API objects encrypted by using transparent encryption cannot be restored or retrieved by using the backup-archive client. These commands return data as bit files that are created by using default file attributes. You can restore or retrieve API objects that other users own, or that are from a different node. The set access command determines which objects qualify.
Set Access	The set access command permits users to manage API objects that another user owns, or that are from another node.

Operating system interoperability

The IBM Spectrum Protect™ API supports cross-platform interoperability. Applications on a UNIX or Linux system can operate on file spaces and objects that are backed up from a Windows system. Similarly, a Windows system can operate on file spaces and objects that are backed up from a UNIX or Linux system.

About this task

By default, the names of objects from one UNIX system are compatible with the names of objects from other UNIX systems. By default, names of objects from Windows systems are not compatible with names of objects from UNIX systems. Several parameters control the naming of objects in IBM Spectrum Protect file spaces. If you set up an application appropriately, the names of objects can be used by applications that run on both Windows systems and UNIX systems. Use the same parameters to back up and restore objects.
Restriction: A Windows application that uses Unicode creates a file space that is not compatible with applications that run on UNIX systems.

Procedure

To achieve interoperability, complete the following setup tasks:

1. Establish a consistent naming convention. Select a character for the `dir` delimiter, such as forward slash (/) or backslash (\). Place the directory delimiter character in front of the file space name, the high-level qualifier, and the low-level qualifier.
2. When you call dsmInitEx, set the value of the dirDelimiter field to the directory delimiter character that you selected and set bCrossPlatform to bTrue.
3. Set the useUnicode flag to bFalse when you use the IBM Spectrum Protect interface. Unicode file names are not compatible with non-Unicode file names.

Backing up multiple nodes with client node proxy support

Backups of multiple nodes which share storage can be consolidated to a common target node name on the IBM Spectrum Protect™ server. This method is useful when the system that runs the backup can change over time, such as with a cluster. You can also use the asnodename option to restore data from a different system other than the one which ran the backup.

About this task

Use the asnodename option on the dsmInitEx option string to back up, archive, restore, and retrieve, query, or delete data under the target node name on the IBM Spectrum Protect server. You can also specify the asnodename option in the dsm.opt or dsm.sys file.

Restriction: Do not use target nodes as traditional nodes, especially if you encrypt your files before you back up to the server.

Procedure

To enable this option, complete the following steps:

1. Install the API client on all nodes in a shared data environment.
2. If not already registered, register each node with the IBM Spectrum Protect server. Register the common "target" node name to be shared by each of the agent nodes that are used in your shared data environment.
3. Register each of the agent nodes in the shared data environment with the server. The agent node name is used for authentication. Data is not stored by using the agent node name when the asnodename option is used.
4. Ask your administrator to grant proxy authority to all nodes in the shared environment to access the target node name on the IBM Spectrum Protect server, by using the grant proxynode command.
5. Use the query proxynode administrative client command to display the client nodes that have the authority to perform client operations on behalf of another node. This authority is granted by the grant proxynode command. Or use the dsmQuery command with the query type qtProxyNodeAuth to see the nodes to which this node can proxy.
6. If the application is using user encryption of data, not TSMENCRKEY, ensure that all nodes use the same encryption key. You must use the same encryption key for all files that are backed up in the shared node environment.

Related tasks:
Backing up data with client-node proxy support (UNIX and Linux systems)
Backing up data with client-node proxy support (Windows systems)

Using the API with Unicode

The IBM Spectrum Protect™ API supports Unicode UCS2, a fixed length, double-byte code page that has code points for all known code pages, such as Japanese, Chinese, or German. It supports as many as 65,535 unique code points.

Restriction: This feature is only available on Windows.

With Unicode, your application can back up and restore file names in any character set from the same machine. For example, on an English machine, you can back up and restore file names in any other language code page.

- When to use Unicode
  You can simplify your application that supports multiple languages by writing a Unicode application and by taking advantage of the IBM Spectrum Protect Unicode interface.
- Setting up Unicode
  To set up and use Unicode you must perform a particular procedure so the API registers a Unicode file space on the server and all file names in that file space become Unicode strings.

When to use Unicode

You can simplify your application that supports multiple languages by writing a Unicode application and by taking advantage of the IBM Spectrum Protect™ Unicode interface.

Use the IBM Spectrum Protect Unicode interface if any of the following conditions are true:

- If your application is already compiled for Unicode and it was converting to a multibyte character set (mbcs) before calling the IBM Spectrum Protect API.
- If you are writing a new application and want to enable your application to support Unicode.
- If your application uses a string passed to it from an operating system or other application that uses Unicode.

If you do not need Unicode, it is not necessary to compile your application again.

The API continues to support the dsm interface. The API SDK contains callmtu1.c and callmtu2.c sample programs that demonstrate how to use the Unicode API. Use **makemtu** to compile these programs.

Setting up Unicode

To set up and use Unicode you must perform a particular procedure so the API registers a Unicode file space on the server and all file names in that file space become Unicode strings.

Restriction: You cannot store Unicode and non-Unicode file names in the same file space.

1. Compile the code with the -DUNICODE flag.
2. All strings in your application must be wchar strings.
3. Follow the structures in the tsmapitd.h file, and the function definitions in the tsmapifp.h file for calls to the API.
4. Set the *useUnicode* flag to *bTrue* on the **tsmInitEx** function call. Any new file space is registered as a Unicode file space.

When you send data to previously registered, non-Unicode file spaces, the API continues to send file names as non-Unicode. Rename the old file spaces on the server to fsname_old and start a new Unicode file space for new data. The API restores non-Unicode data from the old file spaces. Use the **bIsUnicode** field in the **tsmQryRespFSData** structure that is returned on a query file space to determine whether or not a file space is Unicode.

Each **dsmXXX** function call has a matching **tsmXXX** function call. The difference between the two are the structures that are used. All **tsmXXX** function call structures have dsChar_t types for string values when they are compiled with the UNICODE flag. The dsChar_r maps to wchar. There is no other difference between these interfaces.
Restriction: Use either one interface or the other. Do not mix the **dsmXXX** function call and **tsmXXX** function call interfaces. Ensure that you use the IBM Spectrum Protect™ structures and IBM Spectrum Protect version definitions.

Some constants continue to be defined in the dsmapitd.h file, so you need both the dsmapitd.h and the tsmapitd.h files when you compile.

You can use the IBM Spectrum Protect interface on other operating systems, such as UNIX or Linux, but on these operating systems, the dsChar_t type maps to char because Unicode is supported on Windows operating systems. You can write only one variation of the application and compile on more than one operating system using the IBM Spectrum Protect interface. If you are writing a new application, use the IBM Spectrum Protect interface.

If you are upgrading an existing application:

1. Convert the **dsmXXX** function call structures and calls to the IBM Spectrum Protect interface.
2. Migrate existing file spaces.
3. Back up new file spaces with the *useUnicode* flag set to *true*.

Note: After you use a Unicode-enabled client to access a node, you cannot connect to the same node name with an older version of the API or with an API from another operating system. If your application uses cross-platform capability, do not use the Unicode flag. There is no cross-platform support between Unicode and non-Unicode operating systems.

When you enable the *useUnicode* flag, all string structures are treated as Unicode strings. On the server, only the following fields are true Unicode:

- File space name
- High level
- Low level
- Archive description

All remaining fields convert to mbcs in the local code page before they are sent to the server. Fields, such as nodename, are wchar strings. They must be valid in the current locale. For example, on a Japanese machine, you can back up files with Chinese names, but the node name must be a valid string in Japanese. The option file remains in the current code page. If you need to create a Unicode include-exclude list, use the *inclexcl* option with a file name and create a Unicode file with Unicode patterns in it.

Related reference:
Inclexcl option

API function calls

Table 1 provides an alphabetical list of the API function calls, a brief description and the location of more detailed information about the function call, which includes:

Element	Description
Purpose	Describes the function call.
Syntax	Contains the actual C code for the function call. This code is copied from the UNIX or Linux version of the dsmapifp.h header file. See API function definitions source file. This file differs slightly on other operating systems. Application programmers for other operating systems should check their version of the header file, dsmapifp.h, for the exact syntax of the API definitions.

Element	Description
Parameters	Describes each parameter in the function call, identifying it as either input (I) or output (O), depending on how it is used. Some parameters are designated as both input and output (I/O). The data types that are referenced in this section are defined in the dsmapitd.h header file. See API type definitions source files.
Return codes	Contains a list of the return codes that are specific to the function call. General system errors, such as communication errors, server problems, or user errors that might appear on any call are not listed. The return codes are defined in the dsmrc.h header file. See API return codes source file: dsmrc.h.

Table 1. API function calls

Function call and link	Description
dsmBeginGetData	Starts a restore or retrieve operation on a list of objects in storage.
dsmBeginQuery	Starts a query request to IBM Spectrum Protect™ for information.
dsmBeginTxn	Starts one or more transactions that begins a complete action. Either all of the actions succeed, or none succeed.
dsmBindMC	Associates, or binds, a management class to the object that is passed.
dsmChangePW	Changes an IBM Spectrum Protect password.
dsmCleanUp	This call is used if **dsmSetUp** was called.
dsmDeleteAccess	Deletes current authorization rules for backup versions or archived copies of your objects.
dsmDeleteFS	Deletes a file space from storage.
dsmDeleteObj	Turns off backup objects, or deletes archive objects in storage.
dsmEndGetData	Ends a **dsmBeginGetData** session that gets objects from storage.
dsmEndGetDataEx	Provides the total of LAN-free bytes that were sent.
dsmEndGetObj	Ends a **dsmGetObj** session that obtains data for a specified object.
dsmEndQuery	Signifies the end of a **dsmBeginQuery** action.
dsmEndSendObj	Indicates the end of data that is sent to storage.
dsmEndSendObjEx	Provides compression information and the number of bytes that were sent.
dsmEndTxn	Ends an IBM Spectrum Protect transaction.
dsmEndTxnEx	Provides group leader object ID information to use with the **dsmGroupHandlerfunction** call.
dsmGetData	Obtains a byte stream of data from IBM Spectrum Protect and place it in the caller's buffer.
dsmGetBufferData	Gets an IBM Spectrum Protect-allocated buffer of data from the IBM Spectrum Protect server.
dsmGetNextQObj	Gets the next query response from a previous **dsmBeginQuery** call and places it in the caller's buffer.
dsmGetObj	Obtains the requested object data from the data stream and places it in the caller's buffer.
dsmGroupHandler	Performs an action on a logical file group depending on the input that is given.
dsmInit	Starts an API session and connects the client to storage.
dsmInitEx	Starts an API session using the additional parameters that permit extended verification.
dsmLogEvent	Logs a user message to the server log file, to the local error log, or to both.
dsmLogEventEx	Logs a user message to the server log file, to the local error log, or to both.
dsmQueryAccess	Queries the server for all access authorization rules for either backup versions or archived copies of your objects.

Function call and link	Description
dsmQueryApiVersion	Performs a query request for the API library version that the application client accesses.
dsmQueryApiVersionEx	Performs a query request for the API library version that the application client accesses.
dsmQueryCliOptions	Queries important option values in the user's option files.
dsmQuerySessInfo	Starts a query request to IBM Spectrum Protect for information that is related to the operation of the specified session in **dsmHandle**.
dsmQuerySessOptions	Queries important option values that are valid in the specified session in **dsmHandle**.
dsmRCMsg	Obtains the message text that is associated with an API return code.
dsmRegisterFS	Registers a new file space with the server.
dsmReleaseBuffer	Returns an IBM Spectrum Protect-allocated buffer.
dsmRenameObj	Renames the high-level or low-level object name.
dsmRequestBuffer	Obtains an IBM Spectrum Protect-allocated buffer for buffer copy elimination.
dsmRetentionEvent	Sends a list of object IDs to the server with a retention event operation to be performed on these objects.
dsmSendBufferData	Sends data from an IBM Spectrum Protect-allocated buffer.
dsmSendData	Sends a byte stream of data to IBM Spectrum Protect via a buffer.
dsmSendObj	Starts a request to send a single object to storage.
dsmSetAccess	Gives other users, or nodes, access to backup versions or archived copies of your objects, access to all your objects, or access to a selective set.
dsmSetUp	Overwrites environment variable values.
dsmTerminate	Ends a session with the server and cleans up the IBM Spectrum Protect environment.
dsmUpdateFS	Updates a file space in storage.
dsmUpdateObj	Updates the objInfo information that is associated with an active backup object already on the server, or it updates archived objects.
dsmUpdateObjEx	Updates the objInfo information that is associated with a specific archive object even when there are multiple objects with same name, or it updates active backup objects.

- dsmBeginGetData
  The **dsmBeginGetData** function call starts a restore or retrieve operation on a list of objects in storage. This list of objects is contained in the **dsmGetList** structure. The application creates this list with values from the query that preceded a call to **dsmBeginGetData**.
- dsmBeginQuery
  The dsmBeginQuery function call starts a query request to the server for information about data, file spaces, and management classes.
- dsmBeginTxn
  The **dsmBeginTxn** function call begins one or more IBM Spectrum Protect transactions that begin a complete action; either all the actions succeed or none succeed. An action can be either a single call or a series of calls. For example, a **dsmSendObj** call that is followed by a number of **dsmSendData** calls can be considered a single action. Similarly, a **dsmSendObj** call with a **dataBlkPtr** that indicates a data area containing the object to back up is also considered a single action.
- dsmBindMC
  The **dsmBindMC** function call associates, or binds, a management class to the passed object. The object is passed through the include-exclude list that is pointed to in the options file. If a match is not found in the Include list for a specific management class, the default management class is assigned. The Exclude list can prevent objects from a backup but not from an archive.

- dsmChangePW
  The **dsmChangePW** function call changes an IBM Spectrum Protect password. On a multiple-user operating system such as UNIX or Linux, only the root user or the authorized user can use this call.
- dsmCleanUp
  The **dsmCleanUp** function call is used if **dsmSetUp** was called. The **dsmCleanUp** function call should be called after **dsmTerminate**. You cannot make any other calls after you call **dsmCleanUp**.
- dsmDeleteAccess
  The **dsmDeleteAccess** function call deletes current authorization rules for backup versions or archived copies of your objects. When you delete an authorization rule, you revoke the access a user has to any files that are specified by the rule.
- dsmDeleteFS
  The **dsmDeleteFS** function call deletes a file space from storage. To delete a file space, you must have the appropriate permissions that your IBM Spectrum Protect administrator gave you. To determine whether you have the necessary permissions, call **dsmQuerySessInfo**. This function call returns a data structure of type *ApiSessInfo*, that includes two fields, *archDel* and *backDel*.
- dsmDeleteObj
  The **dsmDeleteObj** function call inactivates backup objects, deletes backup objects, or it deletes archive objects in storage. The **dtBackup** type inactivates the currently active backup copy only. The **dtBackupID** type removes from the server whichever object ID is specified. Call this function from within a transaction.
- dsmEndGetData
  The **dsmEndGetData** function call ends a **dsmBeginGetData** session that obtains objects from storage.
- dsmEndGetDataEx
  The **dsmEndGetDataEx** function call provides the total of LAN-free bytes that were sent. It is an extension of the **dsmEndGetData** function call.
- dsmEndGetObj
  The **dsmEndGetObj** function call ends a **dsmGetObj** session that obtains data for a specified object.
- dsmEndQuery
  The **dsmEndQuery** function call signifies the end of a **dsmBeginQuery** action. The application client sends **dsmEndQuery** to complete a query. This call either is sent after all query responses are obtained through **dsmGetNextQObj**, or it is sent to end a query before all data are returned.
- dsmEndSendObj
  The **dsmEndSendObj** function call indicates the end of data that is sent to storage.
- dsmEndSendObjEx
  The **dsmEndSendObjEx** function call provides additional information regarding the number of bytes processed. The information includes: total bytes sent, compression information, lan-free bytes, and deduplication information.
- dsmEndTxn
  The dsmEndTxn function call ends an IBM Spectrum Protect transaction. Pair the dsmEndTxn function call with dsmBeginTxn to identify the call or set of calls that are considered a transaction. The application client can specify on the dsmEndTxn call whether the transaction must be committed or ended.
- dsmEndTxnEx
  The **dsmEndTxnEx** function call provides group leader object ID information for you to use with the **dsmGroupHandler** function call. It is an extension of the **dsmEndTxn** function call.
- dsmGetData
  The **dsmGetData** function call obtains a byte stream of data from IBM Spectrum Protect and places it in the caller's buffer. The application client calls **dsmGetData** when there is more data to receive from a previous **dsmGetObj** or **dsmGetData** call.
- dsmGetBufferData
  The **dsmGetBufferData** function call receives a byte stream of data from IBM Spectrum Protect through a buffer. After each call the application needs to copy the data and release the buffer through a call to **dsmReleaseBuffer**. If the number of buffers held by the application equals the numTsmBuffers specified in the **dsmInitEx** call, the **dsmGetBufferData** function blocks until a **dsmReleaseBuffer** is called.
- dsmGetNextQObj
  The dsmGetNextQObj function call gets the next query response from a previous dsmBeginQuery call and places the response in the caller buffer.
- dsmGetObj
  The **dsmGetObj** function call obtains the requested object data from the IBM Spectrum Protect data stream and places it in the caller's buffer. The **dsmGetObj** call uses the object ID to obtain the next object or partial object from the data stream.
- dsmGroupHandler
  The **dsmGroupHandler** function call performs an action on a logical file group depending on the input that is given. The client relates a number of individual objects together to reference and manage on the IBM Spectrum Protect server as a logical group.
- dsmInit
  The **dsmInit** function call starts an API session and connects the client to IBM Spectrum Protect storage. The application

client can have only one active session open at a time. To open another session with different parameters, use the **dsmTerminate** call first to end the current session.

- dsmInitEx
  The dsmInitEx function call starts an API session by using the additional parameters for extended verification.
- dsmLogEvent
  The **dsmLogEvent** function call logs a user message (ANE4991 I) to the server log file, to the local error log, or to both. A structure of type **logInfo** is passed in the call. This call must be performed while at **InSession** state inside a session. Do not perform it within a send, get, or query. To retrieve messages logged on the server, use the **query actlog** command through the administrative client.
- dsmLogEventEx
  The dsmLogEventEx function call logs a user message to the server log file, to the local error log, or to both. This call must be made while at an InSession state within a session. The call cannot be made within a send, get, or query call.
- dsmQueryAccess
  The **dsmQueryAccess** function call queries the server for all access authorization rules for either backup versions or archived copies of your objects. A pointer to an array of access rules is passed in to the call, and the completed array is returned. A pointer to the number of rules is passed in to indicate how many rules are in the array.
- dsmQueryApiVersion
  The **dsmQueryApiVersion** function call performs a query request for the API library version that the application client accesses.
- dsmQueryApiVersionEx
  The **dsmQueryApiVersionEx** function call performs a query request for the API library version that the application client accesses.
- dsmQueryCliOptions
  The **dsmQueryCliOptions** function call queries important option values in the user's option files. A structure of type **optStruct** is passed in the call and contains the information. This call is performed before **dsmInitEx** is called, and it determines the setup before the session.
- dsmQuerySessInfo
  The **dsmQuerySessInfo** function call starts a query request to IBM Spectrum Protect for information related to the operation of the specified session in **dsmHandle**. A structure of type **ApiSessInfo** is passed in the call, with all available session related information entered. This call is started after a successful **dsmInitEx** call.
- dsmQuerySessOptions
  The dsmQuerySessOptions function call queries important option values that are valid in the specified session in dsmHandle. A structure of type `optStruct` is passed in the call and contains the information.
- dsmRCMsg
  The dsmRCMsg function call obtains the message text that is associated with an API return code.
- dsmRegisterFS
  The **dsmRegisterFS** function call registers a new file space with the IBM Spectrum Protect server. Register a file space first before you can back up any data to it.
- dsmReleaseBuffer
  The **dsmReleaseBuffer** function returns a buffer to IBM Spectrum Protect. The application calls **dsmReleaseBuffer** after a **dsmGetDataEx** was called and the application has moved all the data out of the buffer and is ready to release it. **dsmReleaseBuffer** requires that **dsmInitEx** was called with the ***UseTsmBuffers*** set to *btrue* and a non-zero value was provided for *numTsmBuffers*. **dsmReleaseBuffer** should also be called if the application is about to call **dsmTerminate** and it still holds data buffers.
- dsmRenameObj
  The **dsmRenameObj** function call renames the high-level or low-level object name. For backup objects, pass in the current object name and changes either for high-level or low-level object names. For archive objects, pass in the current object file space name and object ID, and changes either for high-level or low-level object names. Use this function call within **dsmBeginTxn** and **dsmEndTxn** calls.
- dsmRequestBuffer
  The **dsmRequestBuffer** function returns a buffer to IBM Spectrum Protect. The application calls **dsmRequestBuffer** after a **dsmGetDataEx** was called and the application has moved all the data out of the buffer and is ready to release it.
- dsmRetentionEvent
  The **dsmRetentionEvent** function call sends a list of object IDs to the IBM Spectrum Protect server, with a retention event operation to be performed on these objects. Use this function call within **dsmBeginTxn** and **dsmEndTxn** calls.
- dsmSendBufferData
  The **dsmSendBufferData** function call sends a byte stream of data to IBM Spectrum Protect through a buffer that was provided in a previous **dsmReleaseBuffer** call. The application client can pass any type of data for storage on the server. Usually this data are file data, but it is not limited to file data. You can call **dsmSendBufferData** several times, if the byte stream of data that you are sending is large. Regardless of whether the call succeeds or fails, the buffer is released.
- dsmSendData
  The **dsmSendData** function call sends a byte stream of data to IBM Spectrum Protect through a buffer. The application

client can pass any type of data for storage on the server. Usually, these data are file data, but are not limited to such. You can call **dsmSendData** several times, if the byte stream of data that you want to send is large.

- dsmSendObj
  The **dsmSendObj** function call starts a request to send a single object to storage. Multiple **dsmSendObj** calls and associated **dsmSendData** calls can be made within the bounds of a transaction for performance reasons.
- dsmSetAccess
  The **dsmSetAccess** function call gives other users or nodes access to backup versions or archived copies of your objects, access to all your objects, or access to a selective set. When you give access to another user, that user can query, restore, or retrieve your files. This command supports wildcards for the following fields: *fs*, *hl*, *ll*, *node*, *owner*.
- dsmSetUp
  The **dsmSetUp** function call overwrites environment variable values. Call **dsmSetUp** before **dsmInitEx**. The values that were passed in the **envSetUp** structure overwrite any existing environment variables or defaults. If you specify NULL for a field, values are taken from the environment. If you do not set a value, the values are taken from the defaults.
- dsmTerminate
  The **dsmTerminate** function call ends a session with the IBM Spectrum Protect server and cleans up the IBM Spectrum Protect environment.
- dsmUpdateFS
  The dsmUpdateFS function call updates a file space in IBM Spectrum Protect storage. This update ensures that the administrator has a current record of your file space.
- dsmUpdateObj
  The **dsmUpdateObj** function call updates the meta information associated with an active backup or archive object already on the server. The application bit data is not affected. To update an object, you must give a specific non-wildcard name. To update an archived object, set the **dsmSendType** to **stArchive**. Only the latest named archive object is updated.
- dsmUpdateObjEx
  The **dsmUpdateObjEx** function call updates the meta information that is associated with an active backup or archive object that is on the server. The application bit data is not affected. To update an object, you must specify a non-wildcard name, or you can specify the object ID to update a specific archived object. You cannot use wildcard characters when specifying the name. To update a backup object, set the **dsmSendType** parameter to **stBackup**. To update an archived object, set the **dsmSendType** parameter to **stArchive**.

API return codes

dsmBeginGetData

The **dsmBeginGetData** function call starts a restore or retrieve operation on a list of objects in storage. This list of objects is contained in the **dsmGetList** structure. The application creates this list with values from the query that preceded a call to **dsmBeginGetData**.

The caller first must use the restore order fields that are obtained from the object query to sort the list that is contained in this call. This ensures that the objects are restored from storage in the most efficient way possible without rewinding or remounting data tapes.

When getting whole objects, the maximum *dsmGetList.numObjID* is DSM_MAX_GET_OBJ. When getting partial objects, the maximum is DSM_MAX_PARTIAL_GET_OBJ.

Follow the call to **dsmBeginGetData** with one or more calls to **dsmGetObj** to obtain each object within the list. After each object is obtained, or additional data for the object is not needed, the **dsmEndGetObj** call is sent.

When all objects are obtained, or the **dsmEndGetObj** is canceled, the **dsmEndGetData** call is sent. You then can start the cycle again.

Syntax

```
dsInt16_t dsmBeginGetData (dsUint32_t       dsmHandle,
   dsBool_t     mountWait,
   dsmGetType   getType,
   dsmGetList  *dsmGetObjListP);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous dsmInitEx call.

dsBool_t mountWait (I)

A Boolean true or false value indicates whether or not the application client waits for offline media to be mounted if the data that is needed is currently offline. If mountWait is true, the application waits for the server to mount the required media. The application waits until the media is mounted or the request is canceled.

dsmGetType getType (I)

An enumerated type consisting of gtBackup and gtArchive that indicates what type of object to get.

dsmGetList *dsmGetObjListP (I)

The structure that contains information about the objects or partial objects to restore or retrieve. The structure points to a list of object IDs and, in the case of a partial object restore or retrieve, a list of associated offsets and lengths. If your application uses the partial object restore or retrieve function, set the **dsmGetList.stVersion** field to **dsmGetListPORVersion**. In a partial object restore or retrieve, you cannot compress data while sending it. To enforce this, set **ObjAttr.objCompressed** to *bTrue*.

See Figure 1 and API type definitions source files for more information on this structure.

See Partial object restore or retrieve for more information on partial object restore or retrieve.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmBeginGetData

Return code	Explanation
DSM_RC_ABORT_INVALID_OFFSET (33)	The offset that was specified during a partial object retrieve is greater than the length of the object.
DSM_RC_ABORT_INVALID_LENGTH (34)	The length that was specified during a partial object retrieve is greater than the length of the object, or the offset in addition to the length extends past the end of the object.
DSM_RC_NO_MEMORY (102)	There is no RAM remaining to complete the request.
DSM_RC_NUMOBJ_EXCEED (2029)	The **dsmGetList.numObjId** is greater than DSM_MAX_GET_OBJ.
DSM_RC_OBJID_NOTFOUND (2063)	The object ID was not found. The object was not restored.
DSM_RC_WRONG_VERSION_PARM (2065)	The API version of the application client is different from the IBM Spectrum Protect™ library version.

dsmBeginQuery

The dsmBeginQuery function call starts a query request to the server for information about data, file spaces, and management classes.

Specifically, dsmBeginQuery can query:

- Archived data
- Backed-up data
- Active backed-up data
- File spaces
- Management classes

The query data that is returned from the call is obtained by one or more calls to dsmGetNextQObj. When the query is complete, the dsmEndQuery call is sent.

Syntax

```
dsInt16_t dsmBeginQuery  (dsUint32_t        dsmHandle,
   dsmQueryType  queryType,
   dsmQueryBuff  *queryBuffer);
```

Parameters

dsUint32_t dsmHandle (I)

The handle that associates this call with a previous dsmInitEx call.

dsmQueryType queryType (I)

Identifies the type of query to run. Assign one of the following options:

qtArchive

Queries archived objects.

qtBackup

Queries backed-up objects.

qtBackupActive

Queries active, backed-up objects only for the entire file space name that you pass. This query is called a "fast path" and is an efficient way to query active objects from storage.
Prerequisite: You must be logged on as a root user on a UNIX or Linux operating system.

qtFilespace

Queries registered file spaces.

qtMC

Queries defined management classes.

qtBackupGroups

Queries groups that are closed.

qtOpenGroups

Queries groups that are open.

qtProxyNodeAuth

Queries nodes to which this node can proxy.

qtProxyNodePeer

Queries peer nodes with the same target.

dsmQueryBuff *queryBuffer (I)

Identifies a pointer to a buffer that is mapped to a particular data structure. This structure is associated with the query type that you pass. These structures contain the selection criteria for each query type. Complete the fields in each structure to specify the scope of the query that you want to run. The `stVersion` field in each structure contains the structure version number.

The data structures and their related fields include the following items:

qryArchiveData

objName

The complete object name. You can use a wildcard character, such as an asterisk (*) or a question mark (?), in the high-level or low-level portion of the name. An asterisk matches zero or more characters, and a question mark matches one character. The objType field of objName can have one of the following values:

- `DSM_OBJ_FILE`
- `DSM_OBJ_DIRECTORY`
- `DSM_OBJ_ANY_TYPE`

For more information about high-level and low-level names, see the following topic: High-level and low-level names.

owner

The owner name of the object.

insDateLowerBound

The lower boundary for the insert date that the object was archived. To obtain the default lower boundary, set the year component to `DATE_MINUS_INFINITE`.

insDateUpperBound

The upper boundary for the insert date that the object was archived. To obtain the default upper boundary, set the year component to `DATE_PLUS_INFINITE`.

expDateLowerBound

The lower boundary for the expiration date. The default values for both expiration date fields are the same as for the insert date fields.

expDateUpperBound

The upper boundary for the expiration date.

descr

The archive description. Enter an asterisk (*) to search all descriptions.

qryBackupData

objName

The complete object name. You can use a wildcard character, such as an asterisk (*) or a question mark (?), in the high-level or low-level portion of the name. An asterisk matches zero or more characters, and a question mark matches one character. The objType field of objName can have one of the following values:

- `DSM_OBJ_FILE`
- `DSM_OBJ_DIRECTORY`
- `DSM_OBJ_ANY_TYPE`

For more information about high-level and low-level names, see the following topic: High-level and low-level names.

owner

The owner name of the object.

objState

You can query for one of the following object states:

- `DSM_ACTIVE`
- `DSM_INACTIVE`
- `DSM_ANY_MATCH`

pitDate

The point-in-time value. A query with this field returns the most recent object that is backed up before this date and time. The objState can be active or inactive. Objects that are deleted before the pitDate are not returned. For example:

```
Mon - backup ABC(1), DEF, GHI
Tue - backup ABC(2), delete DEF
Thr - backup ABC(3)
```

On Friday, call the query with a point-in-time value of Wednesday at 12:00:00 a.m. The call returns the following information:

```
 ABC(2) - an Inactive copy
 GHI    - an Active copy
```

The call does not return `DEF` because that object as deleted prior to the point-in-time value.

qryABackupData

objName

The complete object name. You can use a wildcard character, such as an asterisk (*) or a question mark (?), in the high-level or low-level portion of the name. An asterisk matches zero or more characters, and a question mark matches one character. The objType field of objName can have one of the following values:

- `DSM_OBJ_FILE`
- `DSM_OBJ_DIRECTORY`
- `DSM_OBJ_ANY_TYPE`

For more information about high-level and low-level names, see the following topic: High-level and low-level names.

qryFSData

fsName

Enter the name of a specific file space in this field, or enter an asterisk (*) to retrieve information about all registered file spaces.

qryMCData

mcName
Enter the name of a specific management class, or enter an empty string (" ") to retrieve information about all management classes.
Note: You cannot use an asterisk (*).

mcDetail
Determines whether information on the backup and archive copy groups of the management class is returned. The following values are valid:

- `bTrue`
- `bFalse`

qryBackupGroup:

groupType

The group type is `DSM_GROUPTYPE_PEER`.

fsName

The file space name.

owner

The owner ID.

groupLeaderObjId

The group leader object ID.

objType
The object type.

qryProxyNodeAuth:

targetNodeName

The target node name.

peerNodeName

The peer node name.

hlAddress

The peer address of the high-level name.

llAddress

The peer address of the low-level name.

qryProxyNodePeer:

targetNodeName

The target node name.

peerNodeName

The peer node name.

hlAddress

The peer address of the high-level name.

llAddress

The peer address of the low-level name.

Return codes

The following table describes the return codes for the dsmBeginQuery function call.

Table 1. Return codes for dsmBeginQuery

Return code	Return code number	Explanation
DSM_RC_NO_MEMORY	102	There is not enough memory to complete the request.
DSM_RC_FILE_SPACE_NOT_FOUND	124	The specified file space was not found.
DSM_RC_NO_POLICY_BLK	2007	Server policy information was not available.
DSM_RC_INVALID_OBJTYPE	2010	Invalid object type.
DSM_RC_INVALID_OBJOWNER	2019	Invalid object owner name.
DSM_RC_INVALID_OBJSTATE	2024	Invalid object condition.
DSM_RC_WRONG_VERSION_PARM	2065	The API version of the application client is different from the IBM Spectrum Protect™ library version.

dsmBeginTxn

The **dsmBeginTxn** function call begins one or more IBM Spectrum Protect™ transactions that begin a complete action; either all the actions succeed or none succeed. An action can be either a single call or a series of calls. For example, a **dsmSendObj** call that is followed by a number of **dsmSendData** calls can be considered a single action. Similarly, a **dsmSendObj** call with a **dataBlkPtr** that indicates a data area containing the object to back up is also considered a single action.

Try to group more than one object together in a single transaction for data transfer operations. Grouping objects results in significant performance improvements in the IBM Spectrum Protect system. From both a client and a server perspective, a certain amount of overhead is incurred by starting and ending each transaction.

There are limits to what you can perform within a single transaction. These restrictions include:

- A maximum number of objects that you can send or delete in a single transaction. This limit is located in the data that **dsmQuerySessInfo** returns in the *ApiSessInfo.maxObjPerTxn* field. This corresponds to the *TxnGroupMax* server option.
- All objects that are sent to the server (either backup or archive) within a single transaction must have the same copy destination that is defined in the management class binding for the object. This value is located in the data that **dsmBindMC** returns in the **mcBindKey.backup_copy_dest** or **mcBindKey.archive_copy_dest** fields.

With the API, either the application client can monitor and control these restrictions, or the API can monitor these restrictions. If the API is monitoring restrictions, appropriate return codes from the API calls inform the application client when one or more restrictions are reached.

Always match a **dsmBeginTxn** call with a **dsmEndTxn** call to optimize the set of actions within a pair of **dsmBeginTxn** and **dsmEndTxn** calls.

Syntax

```
dsInt16_t dsmBeginTxn  (dsUint32_t dsmHandle);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmBeginTxn

Return code	Explanation
DSM_RC_ABORT_NODE_NOT_AUTHORIZED (36)	FROMNODE or FROMOWNER is not allowed for TXN operations.

dsmBindMC

The **dsmBindMC** function call associates, or binds, a management class to the passed object. The object is passed through the include-exclude list that is pointed to in the options file. If a match is not found in the Include list for a specific management class, the default management class is assigned. The Exclude list can prevent objects from a backup but not from an archive.

The application client can use the parameters that are returned in the `mcBindKey` structure to determine if this object should be backed up or archived, or whether a new transaction must be started because of different copy destinations. See **dsmBeginTxn** for more information.

Call **dsmBindMC** before you call **dsmSendObj** because every object must have a management class associated with it. This call can be performed within a transaction or outside of a transaction. For example, within a multiple object transaction, if **dsmBindMC** indicates that the object has a different copy destination than the previous object, the transaction must be ended and a new transaction started. In this case, another **dsmBindMC** is not required because one has already been performed for this object.

Syntax

```
dsInt16_t dsmBindMC  (dsUint32_t       dsmHandle,
   dsmObjName  *objNameP,
   dsmSendType  sendType,
   mcBindKey   *mcBindKeyP);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

dsmObjName *objNameP (I)
A pointer to the structure that contains the file space name, high-level object name, low-level object name, and object type.

dsmSendType sendType (I)
Identifies whether this management class bind is performed for archive or backup sends. The possible values for this call include:

	Name	Description
	stBackup	A backup object
	stArchive	An archive object
	stBackupMountWait	A backup object
	stArchiveMountWait	An archive object

For the **dsmBindMC** call, `stBackup` and `stBackupMountWait` are equivalent, and `stArchive` and `stArchiveMountWait` are equivalent.

mcBindKey *mcBindKeyP (O)
This is the address of an `mcBindKey` structure where the management class information is returned. The application client can use the information that is returned here to determine if this object fits within a multiple object transaction, or to

perform a management class query on the management class that is bound to the object.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmBindMC

Return code	Explanation
DSM_RC_NO_MEMORY (102)	There is no RAM remaining to complete the request.
DSM_RC_INVALID_PARM (109)	One of the parameters that was passed has an invalid value.
DSM_RC_TL_EXCLUDED (185)	The backup object is excluded and cannot be sent.
DSM_RC_INVALID_OBJTYPE (2010)	Invalid object type.
DSM_RC_INVALID_SENDTYPE (2022)	Invalid send type.
DSM_RC_WRONG_VERSION_PARM (2065)	Application client API version is different from the IBM Spectrum Protect™ library version.

dsmChangePW

The **dsmChangePW** function call changes an IBM Spectrum Protect™ password. On a multiple-user operating system such as UNIX or Linux, only the root user or the authorized user can use this call.

On Windows operating systems, you can specify the password in the dsm.opt file. In this situation, **dsmChangePW** does not update the dsm.opt file. After the call to **dsmChangePW** is made, you must update the dsm.opt file separately.

This call must process successfully if **dsmInitEx** returns DSM_RC_VERIFIER_EXPIRED. The session ends if the **dsmChangePW** call fails in this situation.

If **dsmChangePW** is called for some other reason, the session remains open regardless of the return code.

Syntax

```
dsInt16_t dsmChangePW  (dsUint32_t   dsmHandle,
   char    *oldPW,
   char    *newPW);
```

Parameters

dsUint32_t dsmHandle (I)
: The handle that associates this call with a previous **dsmInitEx** call.

char *oldPW (I)
: The old password of the caller. The maximum length is DSM_MAX_VERIFIER_LENGTH.

char *newPW (I)
: The new password of the caller. The maximum length is DSM_MAX_VERIFIER_LENGTH.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmChangePW

Return code	Explanation
DSM_RC_ABORT_BAD_VERIFIER (6)	An incorrect password was entered.
DSM_RC_AUTH_FAILURE (137)	Authentication failure. Old password is incorrect.
DSM_RC_NEWPW_REQD (2030)	A value must be entered for the new password.
DSM_RC_OLDPW_REQD (2031)	A value must be entered for the old password.
DSM_RC_PASSWD_TOOLONG (2103)	The specified password is too long.

Return code	Explanation
DSM_RC_NEED_ROOT (2300)	The API caller must be a root user or an authorized user.

dsmCleanUp

The **dsmCleanUp** function call is used if **dsmSetUp** was called. The **dsmCleanUp** function call should be called after **dsmTerminate**. You cannot make any other calls after you call **dsmCleanUp**.

There are no return codes that are specific to this call.

Syntax

```
dsInt16_t DSMLINKAGE dsmCleanUp
    (dsBool_t        mtFlag);
```

Parameters

dsBool_t mtFlag (I)
: This parameter specifies that the API was used either in a single thread or a multithread mode. Possible values include:

  - DSM_SINGLETHREAD
  - DSM_MULTITHREAD

dsmDeleteAccess

The **dsmDeleteAccess** function call deletes current authorization rules for backup versions or archived copies of your objects. When you delete an authorization rule, you revoke the access a user has to any files that are specified by the rule.

When you use **dsmDeleteAccess**, you can only delete one rule at a time. Obtain the rule ID through the **dsmQueryAccess** command.

There are no return codes that are specific to this call.

Syntax

```
dsInt16_t DSMLINKAGE dsmDeleteAccess
             (dsUint32_t          dsmHandle,
              dsUint32_t          ruleNum) ;
```

Parameters

dsUint32_t dsmHandle (I)
: The handle that associates this call with a previous dsmInitEx call.

dsUint32_t ruleNum (I)
: The rule ID for the access rule that is deleted. This value is obtained from a **dsmQueryAccess** function call.

dsmDeleteFS

The **dsmDeleteFS** function call deletes a file space from storage. To delete a file space, you must have the appropriate permissions that your IBM Spectrum Protect™ administrator gave you. To determine whether you have the necessary permissions, call **dsmQuerySessInfo**. This function call returns a data structure of type *ApiSessInfo*, that includes two fields, *archDel* and *backDel*.

Note:

- On a UNIX or Linux operating system, only a root user or an authorized user can delete a file space.
- If the file space that you need to delete contains backup versions, you must have backup delete authority (***backDel*** = BACKDEL_YES). If the file space contains archive copies, you must have archive delete authority (*archDel* = ARCHDEL_YES). If the file space contains both backup versions and archive copies, you must have both types of delete authority.

- When using an archive manager server, a file space cannot actually be removed. This function call returns *rc=0* even though the file space was not actually deleted. The only way to verify that the file space has been deleted is to issue a filespace query to the server.
- The IBM Spectrum Protect server delete file-space function is a background process. If errors other than those detected before passing a return code happen, they are recorded in the IBM Spectrum Protect server log.

Syntax

```
dsInt16_t dsmDeleteFS  (dsUint32_t          dsmHandle,
   char           *fsName,
   unsigned char   repository);
```

Parameters

dsUint32_t dsmHandle (I)
: The handle that associates this call with a previous **dsmInitEx** call.

char *fsName (I)
: A pointer to the file space name to delete. The wildcard character is not permitted.

unsigned char repository (I)
: Indicates whether the file space to delete is a backup repository, archive repository, or both. The possible values for this field include:

```
DSM_ARCHIVE_REP     /* archive repository   */
DSM_BACKUP_REP      /* backup repository    */
DSM_REPOS_ALL       /* all repository types */
```

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmDeleteFS

Return code	Explanation
DSM_RC_ABORT_NOT_AUTHORIZED (27)	You do not have the necessary authority to delete the file space.
DSM_RC_INVALID_REPOS (2015)	Invalid value for repository.
DSM_RC_FSNAME_NOTFOUND (2060)	File space name not found.
DSM_RC_NEED_ROOT (2300)	API caller must be a root user.

dsmDeleteObj

The **dsmDeleteObj** function call inactivates backup objects, deletes backup objects, or it deletes archive objects in storage. The **dtBackup** type inactivates the currently active backup copy only. The **dtBackupID** type removes from the server whichever object ID is specified. Call this function from within a transaction.

See **dsmBeginTxn** for more information.

Before you send **dsmDeleteObj**, send the query sequence that is described in Querying the IBM Spectrum Protect system to obtain the information for **delInfo**. The call to **dsmGetNextQObj** returns a data structure named **qryRespBackupData** for backup queries or **qryRespArchiveData** for archive queries. These data structures contain the information that you need for **delInfo**.

The value of **maxObjPerTxn** determines the maximum number of objects that you can delete in a single transaction. To obtain this value, call **dsmQuerySessInfo**.

Tip: Your node must have the appropriate permission that your administrator set. To delete archive objects, you must have archive delete authority. You do not need backup delete authority to inactivate a backup object.

Syntax

```
dsInt16_t dsmDeleteObj  (dsUint32_t      dsmHandle,
   dsmDelType  delType,
   dsmDelInfo  delInfo)
```

Parameters

dsUint32_t dsmHandle (I)

The handle that associates this call with a previous **dsmInitEx** call.

dsmDelType delType (I)

Indicates what type of object (backup or archive) to delete. Possible values include:

	Name	Description
	dtArchive	The object to delete was previously archived.
	dtBackup	The object to inactivate was previously backed up.
	dtBackupID	The object to delete was previously backed up. Restriction: Using this **delType** with *objID* removes the backup object from the server. Only an owner of an object can delete it. You can delete any version (active or inactive) of an object. The server reconciles the versions. If you delete an active version of an object, the first inactive version becomes active. If you delete an inactive version of an object, all older versions will advance. The node must be registered with **backDel** permission.

dsmDelInfo delInfo (I)

A structure whose fields identify the object. The fields are different, depending on whether the object is a backup object or an archive object. The structure to inactivate a backup object, `delBack`, contains the object name and the object copy group. The structure for an archive object, `delArch`, contains the object ID.

The structure to remove a backup object, `delBackID`, contains the object ID.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmDeleteObj

Return code	Explanation
DSM_RC_FS_NOT_REGISTERED (2061)	File space name is not registered.
DSM_RC_WRONG_VERSION_PARM (2065)	Application client API version is different from the IBM Spectrum Protect™ library version.

dsmEndGetData

The **dsmEndGetData** function call ends a **dsmBeginGetData** session that obtains objects from storage.

The **dsmEndGetData** function call starts after all objects that you want to restore are processed, or ends the get process prematurely. Call **dsmEndGetData** to end a **dsmBeginGetData** session before you can continue other processing.

Depending on when **dsmEndGetData** is called, the API might need to finish processing a partial data stream before the process can be stopped. The caller, therefore, should not expect an immediate return from this call. Use **dsmTerminate** if the application needs to close the session and end the restore immediately.

There are no return codes that are specific to this call.

Syntax

```
dsInt16_t dsmEndGetData  (dsUint32_t dsmHandle);
```

Parameters

dsUint32_t dsmHandle (I)

The handle that associates this call with a previous **dsmInitEx** call.

dsmEndGetDataEx

The **dsmEndGetDataEx** function call provides the total of LAN-free bytes that were sent. It is an extension of the **dsmEndGetData** function call.

Syntax

There are no return codes that are specific to this call.

```
dsInt16_t dsmEndGetDataEx (dsmEndGetDataExIn_t * dsmEndGetDataExInP,
                           dsmEndGetDataExOut_t * dsmEndGetDataExOutP);
```

Parameters

dsmEndGetDataExIn_t *dsmEndGetDataExInP (I)
Passes the end get object dsmHandle that identifies the session and associates it with subsequent calls.

dsmEndGetDataExOut_t *dsmEndGetDataExOutP (O)
This structure contains this input parameter:

totalLFBytesRecv
The total LAN-free bytes that are received.

dsmEndGetObj

The **dsmEndGetObj** function call ends a **dsmGetObj** session that obtains data for a specified object.

Start the **dsmEndGetObj** call after an end of data is received for the object. This indicates that all data was received, or that no more data will be received for this object. Before you can start another **dsmGetObj** call, you must call **dsmEndGetObj**.

Depending on when **dsmEndGetObj** is called, the API might need to finish processing a partial data stream before the process can stop. Do not expect an immediate return from this call.

Syntax

```
dsInt16_t dsmEndGetObj  (dsUint32_t dsmHandle);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmEndGetObj

Return code	Explanation
DSM_RC_NO_MEMORY (102)	There is no RAM remaining to complete the request.

dsmEndQuery

The **dsmEndQuery** function call signifies the end of a **dsmBeginQuery** action. The application client sends **dsmEndQuery** to complete a query. This call either is sent after all query responses are obtained through **dsmGetNextQObj**, or it is sent to end a query before all data are returned.

Tip: IBM Spectrum Protect™ continues to send the query data from the server to the client in this case, but the API discards any remaining data.

Once a **dsmBeginQuery** is sent, a **dsmEndQuery** must be sent before any other activity can start.

There are no return codes that are specific to this call.

Syntax

```
dsInt16_t dsmEndQuery  (dsUint32_t dsmHandle);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

dsmEndSendObj

The **dsmEndSendObj** function call indicates the end of data that is sent to storage.

Enter the **dsmEndSendObj** function call to indicate the end of data from the **dsmSendObj** and **dsmSendData** calls. A protocol violation occurs if this is not performed. The exception to this rule is if you call **dsmEndTxn** to end the transaction. Doing this discards all data that was sent for the transaction.

Syntax

```
dsInt16_t dsmEndSendObj  (dsUint32_t dsmHandle);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmEndSendObj

Return code	Explanation
DSM_RC_NO_MEMORY (102)	There is no RAM remaining to complete this request.

dsmEndSendObjEx

The **dsmEndSendObjEx** function call provides additional information regarding the number of bytes processed. The information includes: total bytes sent, compression information, lan-free bytes, and deduplication information.

The dsmEndSendObjEx function call is an extension of the **dsmEndSendObj** function call.

Syntax

```
dsInt16_t dsmEndSendObjEx (dsmEndSendObjExIn_t  *dsmEndSendObjExInP,
                           dsmEndSendObjExOut_t *dsmEndSendObjExOutP);
```

Parameters

dsmEndSendObjExIn_t *dsmEndSendObjExInP (I)
This parameter passes the end send object dsmHandle that identifies the session and associates it with subsequent calls.
dsmEndSendObjExOut_t *dsmEndSendObjExOutP (O)
This parameter passes the end send object information:

	Name	Description
	totalBytesSent	The total number of bytes that are read from the application.
	objCompressed	A flag that displays if the object was compressed.
	totalCompressedSize	The total byte size after compression.
	totalLFBytesSent	The total LAN-free bytes that were sent.
	objDeduplicated	A flag that displays if the object was deduplicated by the API.

	Name	Description
	totalDedupSize	Total bytes sent after deduplication.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmEndSendObjEx

Return code	Explanation
DSM_RC_NO_MEMORY (102)	There is no RAM remaining to complete this request.

dsmEndTxn

The dsmEndTxn function call ends an IBM Spectrum Protect™ transaction. Pair the dsmEndTxn function call with dsmBeginTxn to identify the call or set of calls that are considered a transaction. The application client can specify on the dsmEndTxn call whether the transaction must be committed or ended.

Perform all of the following calls within the bounds of a transaction:

- **dsmSendObj**
- **dsmSendData**
- **dsmEndSendObj**
- **dsmDeleteObj**

Syntax

```
dsInt16_t dsmEndTxn (dsUint32_t   dsmHandle,
   dsUint8_t    vote,
   dsUint16_t  *reason);
```

Parameters

dsUint32_t dsmHandle (I)
: The handle that associates this call with a previous dsmInitEx call.

dsUint8_t vote (I)
: Indicates whether the application client commits all the actions that are done between the previous dsmBeginTxn call and this call. The following values are possible:

```
DSM_VOTE_COMMIT     /* commit current transaction    */
DSM_VOTE_ABORT      /* roll back current transaction */
```

Use `DSM_VOTE_ABORT` only if your application finds a reason to stop the transaction.

dsUint16_t *reason (O)
: If the call to dsmEndTxn ends with an error, or the value of `vote` is not agreed to, this parameter has a reason code that indicates why the vote failed. The return code for the call might be zero, and the reason code might be non-zero. Therefore, the application client must always check for errors on both the return code and the reason (`if (rc || reason)`) before you can assume a successful completion.

If the application specifies a vote of `DSM_VOTE_ABORT`, the reason code is `DSM_RS_ABORT_BY_CLIENT (3)`. See API return codes source file: dsmrc.h for a list of the possible reason codes. Numbers 1 through 50 in the return codes list are reserved for the reason codes. If the server ends the transaction, the return code is `DSM_RC_CHECK_REASON_CODE`. In this case, the reason value contains more information on the cause of the abort.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmEndTxn

Return code	Explanation

Return code	Explanation
DSM_RC_ABORT_CRC_FAILED (236)	The CRC that was received from the server does not match the CRC that was calculated by the client.
DSM_RC_INVALID_VOTE (2011)	The value that was specified for `vote` is not valid.
DSM_RC_CHECK_REASON_CODE (2302)	The transaction was aborted. Check the reason field.
DSM_RC_ABORT_STGPOOL_COPY_CONT_NO (241)	The write to one of the copy storage pools failed, and the IBM Spectrum Protect storage pool option COPYCONTINUE is set to NO. The transaction terminates.
DSM_RC_ABORT_RETRY_SINGLE_TXN (242)	This abort code indicates that the current transaction was aborted because of a problem during a store operation. The problem can be resolved by sending each file in an individual transaction. This error is typical in the following circumstances: • The next storage pool has a different copy storage pool list. • The operation is switched to this pool in the middle of a transaction. .

dsmEndTxnEx

The **dsmEndTxnEx** function call provides group leader object ID information for you to use with the **dsmGroupHandler** function call. It is an extension of the **dsmEndTxn** function call.

Syntax

```
dsInt16_t dsmEndTxnEx (dsmEndTxnExIn_t *dsmEndTxnExInP
                       dsmEndTxnExOut_t *dsmEndTxnExOutP);
```

Parameters

dsmEndTxnExIn_t *dsmEndTxnExInP (I)
This structure contains the following parameters:

dsmHandle
The handle that identifies the session and associates it with subsequent IBM Spectrum Protect™ calls.

dsUint8_t vote (I)
Indicates whether or not the application client commits all the actions that are done between the previous dsmBeginTxn call and this call. The possible values are:

```
DSM_VOTE_COMMIT     /* commit current transaction    */
DSM_VOTE_ABORT      /* roll back current transaction */
```

Use `DSM_VOTE_ABORT` only if your application has found a reason to stop the transaction.

dsmEndTxnExOut_t *dsmEndTxnExOutP (O)
This structure contains the following parameters:

dsUint16_t *reason (O)
If the call to **dsmEndTxnEx** ends with an error or the value of *vote* is not agreed to, this parameter has a reason code indicating why the vote failed.
Tip: The return code for the call might be zero, and the reason code might be non-zero. Therefore, the application client must always check for errors on both the return code and the reason (`if (rc || reason)`) before you can assume a successful completion.

If the application specifies a vote of DSM_VOTE_ABORT, the reason code is DSM_RS_ABORT_BY_CLIENT (3). See API return codes source file: dsmrc.h for a list of the possible reason codes. Numbers 1 through 50 in the return codes list are reserved for the reason codes. If the server ends the transaction, the return code is DSM_RC_CHECK_REASON_CODE. In this case, the reason value contains more information on the cause of the abort.

groupLeaderObjId
The group leader object ID that is returned when the DSM_ACTION_OPEN flag is used with the **dsmGroupHandler** call.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmEndTxnEx

Return code	Explanation
DSM_RC_INVALID_VOTE (2011)	The value that was specified for vote is invalid.
DSM_RC_CHECK_REASON_CODE (2302)	The transaction was aborted. Check the reason field.
DSM_RC_ABORT_STGPOOL_COPY_CONT_NO (241)	The write to one of the copy storage pools failed, and the IBM Spectrum Protect storage pool option COPYCONTINUE was set to NO. The transaction terminates.
DSM_RC_ABORT_RETRY_SINGLE_TXN (242)	During a simultaneous-write operation, an object in the transaction is going to a destination with different copy storage pools. End the current transaction and send each object again in its own transaction.

dsmGetData

The **dsmGetData** function call obtains a byte stream of data from IBM Spectrum Protect™ and places it in the caller's buffer. The application client calls **dsmGetData** when there is more data to receive from a previous **dsmGetObj** or **dsmGetData** call.

Syntax

```
dsInt16_t dsmGetData  (dsUint32_t   dsmHandle,
   DataBlk *dataBlkPtr);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.
DataBlk *dataBlkPtr (I/O)
Points to a structure that includes both a pointer to the buffer for the data that is received and the size of the buffer. On return, this structure contains the number of bytes that is actually transferred. See API type definitions source files for the type definition.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmGetData

Return code	Explanation
DSM_RC_ABORT_INVALID_OFFSET (33)	The offset that was specified during a partial object retrieve is greater than the length of the object.
DSM_RC_ABORT_INVALID_LENGTH (34)	The length that was specified during a partial object retrieve is greater than the length of the object, or the offset in addition to the length extends beyond the end of the object.
DSM_RC_FINISHED (121)	Finished processing. The last buffer was received. Check `numBytes` for the amount of data and then call IBM Spectrum ProtectdsmEndGetObj.
DSM_RC_NULL_DATABLKPTR (2001)	Datablock pointer is null.
DSM_RC_ZERO_BUFLEN (2008)	Buffer length is zero for datablock pointer.
DSM_RC_NULL_BUFPTR (2009)	Buffer pointer is null for datablock pointer.

Return code	Explanation
DSM_RC_WRONG_VERSION_PARM (2065)	The application client's API version is different from the IBM Spectrum Protect library version.
DSM_RC_MORE_DATA (2200)	There is more data to get.

dsmGetBufferData

The **dsmGetBufferData** function call receives a byte stream of data from IBM Spectrum Protect™ through a buffer. After each call the application needs to copy the data and release the buffer through a call to **dsmReleaseBuffer**. If the number of buffers held by the application equals the numTsmBuffers specified in the **dsmInitEx** call, the **dsmGetBufferData** function blocks until a **dsmReleaseBuffer** is called.

Syntax

```
dsInt16_t   dsmGetBufferData    (getDatatExIn_t         *dsmGetBufferDataExInP,
                                 getDataExOut_t         *dsmGetBufferDataExOutP) ;
```

Parameters

getDataExIn_t * dsmGetBufferDataExInP (I)
This structure contains the following input parameter.

dsUint32_t dsmHandle
The handle that identifies the session and associates it with a previous **dsmInitEx** call.

getDataExOut_t * dsmGetBufferDataExOutP (0)
This structure contains the following output parameters.

dsUint8_t tsmBufferHandle(0)
The handle that identifies the buffer received.
char *dataPtr(0)
The address to which the data was written.
dsUint32_t numBytes(0)
Actual number of bytes written by IBM Spectrum Protect.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmGetBufferData

Return code	Explanation
DSM_RC_BAD_CALL_SEQUENCE (2041)	The call was not issued in the proper state.
DSM_RC_OBJ_ENCRYPTED (2049)	This function cannot be used for encrypted objects.
DSM_RC_OBJ_COMPRESSED (2048)	This function cannot be used for compressed objects.
DSM_RC_BUFF_ARRAY_ERROR (2045)	A buffer array error occurred.

dsmGetNextQObj

The dsmGetNextQObj function call gets the next query response from a previous dsmBeginQuery call and places the response in the caller buffer.

The dsmGetNextQObj call is called one or more times. Each time the function is called, either a single query record is retrieved, or an error or a `DSM_RC_FINISHED` reason code is returned. If `DSM_RC_FINISHED` is returned, there is no more data to process. When all query data is retrieved, or if no more query data is needed, send the dsmEndQuery call to end the query process.

The dataBlkPtr parameter must point to a buffer that is defined with the qryResp*Data structure type. The context in which dsmGetNextQObj is called determines the type of structure that is entered on the query response.

Syntax

```
dsInt16_t dsmGetNextQObj (dsUint32_t   dsmHandle,
   DataBlk *dataBlkPtr);
```

Parameters

dsUint32_t dsmHandle (I)

The handle that associates this call with a previous dsmInitEx call.

DataBlk *dataBlkPtr (I/O)

Points to a structure that includes both a pointer to the buffer for the data to be received and the size of the buffer. This buffer is the qryResp*Data response structure. On return, this structure contains the number of bytes that is transferred. The structure that is associated with each type of query is described in the following table. For more information about the type definition of DataBlk, see the following topic: API type definitions source files.

Table 1. DataBlk pointer structure

Query	Response structure	Fields of special interest
qtArchive	qryRespArchiveData	sizeEstimate Contains the value that is passed on a previous dsmSendObj call. mediaClass Can have a value of `MEDIA_FIXED` if the object is on disk, or `MEDIA_LIBRARY` if the object is on tape. clientDeduplicated Indicates whether this object is deduplicated by the client.
qtBackup	qryRespBackupData	restoreOrderExt Is of type `dsUint16_t`. Sort on this field when several objects are restored on a dsmBeginGetData call. An example of sorting code for this call is in the API sample, `dapiqry.c`. For a sorting example, see the following topic: Figure 1. sizeEstimate Contains the value that is passed on a previous dsmSendObj call. mediaClass Can have a value of `MEDIA_FIXED` if the object is on disk or `MEDIA_LIBRARY` if the object is on tape. clientDeduplicated Indicates whether this object is deduplicated by the client.
qtBackupActive	qryARespBackupData	
qtBackupGroups	qryRespBackupData	dsBool_t isGroupLeader If true, signifies this object is a group leader.
qtOpenGroups	qryRespBackupData	dsBool_t isOpenGroup; If true, signifies this group is open and not complete.

Query	Response structure	Fields of special interest
qtFilespace	qryRespFSData	backStartDate Contains the server time stamp when the file space is updated with the backStartDate action. backCompleteDate Contains the server time stamp when the file space is updated with the backCompleteDate action. lastReplStartDate Contains the time stamp for the last time that replication was started on the server. lastReplCmpltDate Contains the time stamp for the last time that replication was completed, even if there was a failure. lastBackOpDateFromServer Contains the last store time stamp that was saved on the server. lastBackOpDateFromLocal Contains the last store time stamp that was saved on the client.
qtMC	qryRespMCData qryRespMCDetailData	
qtProxyNodeAuth	qryRespProxyNodeData targetNodeName peerNodeName hlAddress llAddress	
qtProxyNodePeer	qryRespProaxyNodeData targetNodeName peerNodeName hlAddress llAddress	

Return codes

The following table describes the return codes for the dsmGetNextQObj function call.

Table 2. Return codes for the dsmGetNextQObj function call

Return code	Return code number	Description
DSM_RC_ABORT_NO_MATCH	2	No match for the query was requested.
DSM_RC_FINISHED	121	Finished processing (start dsmEndQuery). There is no more data to process.
DSM_RC_UNKNOWN_FORMAT	122	The file that IBM Spectrum Protect™ attempted to restore or retrieve has an unknown format.
DSM_RC_COMM_PROTOCOL_ERROR	136	Communication protocol error.
DSM_RC_NULL_DATABLKPTR	2001	Pointer is not pointing to a data block.
DSM_RC_INVALID_MCNAME	2025	Invalid management class name.
DSM_RC_BAD_CALL_SEQUENCE	2041	The sequence of calls is invalid.
DSM_RC_WRONG_VERSION_PARM	2065	The version of the application client API is different from the IBM Spectrum Protect library version.
DSM_RC_MORE_DATA	2200	There is more data to get.

Return code	Return code number	Description
DSM_RC_BUFF_TOO_SMALL	2210	Buffer is too small.

dsmGetObj

The **dsmGetObj** function call obtains the requested object data from the IBM Spectrum Protect™ data stream and places it in the caller's buffer. The **dsmGetObj** call uses the object ID to obtain the next object or partial object from the data stream.

The data for the indicated object is placed in the buffer to which **DataBlk** points. If more data is available, you must make one or more calls to **dsmGetData** to receive the remaining object data until a return code of DSM_RC_FINISHED is returned. Check the `numBytes` field in **DataBlk** to see whether any data remains in the buffer.

Objects should be asked for in the order that they were listed on the **dsmBeginGetData** call in the **dsmGetList** parameter. The exception is when the application client needs to pass over an object in the data stream to get to an object later in the list. If the object that is indicated by the object ID is not the next object in the stream, the data stream is processed until the object is located, or the stream is completed. Use this feature with care, because it might be necessary to process and discard large amounts of data to locate the requested object.

Requirement: If **dsmGetObj** returns a failure code (NOT FINISHED or MORE_DATA), the session must be terminated to stop the restore operation. This is especially important when you use encryption and receive a RC_ENC_WRONG_KEY. You must start a new session with the proper key.

Syntax

```
dsInt16_t dsmGetObj (dsUint32_t dsmHandle,
   ObjID    *objIdP,
   DataBlk  *dataBlkPtr);
```

Parameters

dsUint32_t dsmHandle (I)
: The handle that associates this call with a previous **dsmInitEx** call.

ObjID *objIdP (I)
: A pointer to the ID of the object to restore.

DataBlk *dataBlkPtr (I/O)
: A pointer to the buffer where the restored data are placed.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmGetObj

Return code	Explanation
DSM_RC_ABORT_INVALID_OFFSET (33)	The offset that is specified during a partial object retrieve is greater than the length of the object.
DSM_RC_ABORT_INVALID_LENGTH (34)	The length that is specified during a partial object retrieve is greater than the length of the object, or the offset in addition to the length extends past the end of the object.
DSM_RC_FINISHED (121)	Finished processing (start **dsmEndGetObj**).
DSM_RC_WRONG_VERSION_PARM (2065)	Application client's API version is different from the IBM Spectrum Protect library version.
DSM_RC_MORE_DATA (2200)	There is more data to get.
RC_ENC_WRONG_KEY (4580)	The key provided in the **dsmInitEx** call, or the saved key, does not match the key that was used to encrypt this object. Terminate the session and provide the proper key.

dsmGroupHandler

The **dsmGroupHandler** function call performs an action on a logical file group depending on the input that is given. The client relates a number of individual objects together to reference and manage on the IBM Spectrum Protect™ server as a logical group.

For more information, see File grouping.

Syntax

```
dsInt16_t dsmGroupHandler (dsmGroupHandlerIn_t   *dsmGroupHandlerInP,
                           dsmGroupHandlerOut_t  *dsmGroupHandlerOutP);
```

Parameters

dsmGroupHandlerIn_t *dsmGroupHandlerInP (I)
Passes group attributes to the API.

groupType
The type of the group. Values include:

- DSM_GROUPTYPE_PEER - peer group

actionType
The action to be executed. Values include:

- DSM_GROUP_ACTION_OPEN - creates a new group
- DSM_GROUP_ACTION_CLOSE - commits and saves an open group
- DSM_GROUP_ACTION_ADD - appends to a group
- DSM_GROUP_ACTION_ASSIGNTO - assigns to another group
- DSM_GROUP_ACTION_REMOVE- removes a member from a group

memberType.
The group type of the object. Values include:

- DSM_MEMBERTYPE_LEADER - group leader
- DSM_MEMBERTYPE_MEMBER - group member

*uniqueGroupTagP
A unique string ID that is associated with a group.
leaderObjId
The Object ID for the group leader.
*objNameP
A pointer to the object name of the group leader.
memberObjList
A list of objects to remove or assign.

dsmGroupHandlerOut_t *dsmGroupHandlerOutP (O)
Passes the address of the structure that the API completes. The structure version number is returned.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmGroupHandler

Return code	Explanation
DSM_RC_ABORT_INVALID_GROUP_ACTION (237)	An invalid operation was attempted on a group leader or member.

dsmInit

The **dsmInit** function call starts an API session and connects the client to IBM Spectrum Protect™ storage. The application client can have only one active session open at a time. To open another session with different parameters, use the **dsmTerminate** call first to end the current session.

To permit cross-node query and restore or retrieve, use the *-fromnode* and *-fromowner* string options. See Accessing objects across nodes and owners for more information.

Syntax

```
dsInt16_t  dsmInit  (dsUint32_t        *dsmHandle,
   dsmApiVersion *dsmApiVersionP,
   char          *clientNodeNameP,
   char          *clientOwnerNameP,
   char          *clientPasswordP,
   char          *applicationType,
   char          *configfile,
   char          *options);
```

Parameters

dsUint32_t *dsmHandle (O)
: The handle that identifies this initialization session and associates it with subsequent IBM Spectrum Protect calls.

dsmApiVersion *dsmApiVersionP (I)
: A pointer to the data structure identifying the version of the API that the application client is using for this session. The structure contains the values of the three constants, DSM_API_VERSION, DSM_API_RELEASE, and DSM_API_LEVEL, that are set in the dsmapitd.h file. A previous call to **dsmQueryApiVersion** must be performed to ensure that compatibility exists between the application client API version and the version of the API library that is installed on the user's workstation.

char *clientNodeNameP (I)
: This parameter is a pointer to the node for the IBM Spectrum Protect session. All sessions must have a node name associated with them. The constant, DSM_MAX_NODE_LENGTH, in the dsmapitd.h file sets the maximum size that is permitted for a node name.

  The node name is not case-sensitive.

  If this parameter is set both to NULL and *passwordaccess* is set to *prompt*, the API attempts to obtain the node name first from the options string that was passed. If it is not there, the API then attempts to obtain the node name from the configuration file or options files. If these attempts to find the node name fail, the UNIX or Linux API uses the system host name, while APIs on other operating systems return the DSM_RC_REJECT_ID_UNKNOWN code.

  This parameter must be NULL if the *passwordaccess* option in the dsm.sys file is set to *generate*. The API uses the system host name.

char *clientOwnerNameP (I)
: This parameter is a pointer to the owner of the IBM Spectrum Protect session. If the operating system on which the session starts is a multi-user operating system, an owner name of NULL (the root user) has the authority to back up, archive, restore, or retrieve any objects belonging to the application, regardless of the owner of the object.

  The owner name is case-sensitive.

  This parameter must be NULL if the *passwordaccess* option in the dsm.sys file is set to *generate*. The API then uses the login user ID.

  Note: On a multi-user operating system, if *passwordaccess* is set to *prompt*, it is not necessary for the owner name to match the active user ID of the session running the application.

char *clientPasswordP (I)
: This parameter is a pointer to the password of the node on which the IBM Spectrum Protect session runs. The DSM_MAX_VERIFIER_LENGTH constant in the dsmapitd.h file sets the maximum size that is permitted for a password.

  The password is not case-sensitive.

  Except when the password file is first started, the value of this parameter is ignored if *passwordaccess* is set to *generate*.

char *applicationType (I)
: This parameter identifies the application that is running the session. The application client defines the value.

  Each time an API application client starts a session with the server, the application type (or platform) of the client is updated on the server. We recommend that the application type value contain an operating system abbreviation because this value is entered in the **platform** field on the server. The maximum string length is DSM_MAX_PLATFORM_LENGTH.

  To see the current value of the application type, call **dsmQuerySessInfo**.

char *configfile (I)

This parameter points to a character string that contains the fully-qualified name of an API configuration file. Options specified in the API configuration file override their specification in the client options file. Options files are defined when IBM Spectrum Protect (client or API) is installed.

char *options (I)

Points to a character string that can contain user options such as:

- *Compressalways*
- *Servername* (UNIX or Linux only)
- *TCPServeraddr*
- *Fromnode*
- *Fromowner*
- *EnableClientEncryptKey*

The application client can use the option list to override the values of these options that the configuration file sets.

The format of the options is:

1. Each option that is specified in the option list begins with a dash (-) and is followed by the option keyword.
2. The keyword, in turn, is followed by an equal sign (=) and then followed by the option parameter.
3. If the option parameter contains a blank space, enclose the parameter with single or double quotes.
4. If more than one option is specified, separate the options with blanks.

If options are NULL, values for all options are taken from the user options file or the API configuration file.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmInit

Return code	Explanation
DSM_RC_ABORT_SYSTEM_ERROR (1)	The server has detected a system error and has notified the clients.
DSM_RC_REJECT_VERIFIER_EXPIRED (52)	Password has expired and must be updated.
DSM_RC_REJECT_ID_UNKNOWN (53)	Could not find the node name.
DSM_RC_AUTH_FAILURE (137)	There was an authentication failure.
DSM_RC_NO_STARTING_DELIMITER (148)	There is no starting delimiter in pattern.
DSM_RC_NEEDED_DIR_DELIMITER (149)	A directory delimiter is needed immediately before and after the "match directories" meta-string ("...") and one was not located.
DSM_RC_NO_PASS_FILE (168)	The password file is not available.
DSM_RC_UNMATCHED_QUOTE (177)	An unmatched quote is in the option string.
DSM_RC_NLS_CANT_OPEN_TXT (0610)	Unable to open the message text file.
DSM_RC_INVALID_OPT (400)	An entry in the option string is invalid.
DSM_RC_INVALID_DS_HANDLE (2014)	Invalid DSM handle.
DSM_RC_NO_OWNER_REQD (2032)	Owner parameter must be NULL when *passwordaccess* is set to *generate*.
DSM_RC_NO_NODE_REQD (2033)	Node parameter must be NULL when *passwordaccess* is set to *generate*.
DSM_RC_WRONG_VERSION (2064)	The API version for the application client has a higher value than the IBM Spectrum Protect version.
DSM_RC_PASSWD_TOOLONG (2103)	The password that was specified is too long.
DSM_RC_NO_OPT_FILE (2220)	A configuration file could not be located.
DSM_RC_INVALID_KEYWORD (2221)	A keyword that was specified in an options string is invalid.
DSM_RC_PATTERN_TOO_COMPLEX (2222)	The include-exclude pattern is too complex for IBM Spectrum Protect to interpret.
DSM_RC_NO_CLOSING_BRACKET (2223)	There is no closing bracket in the pattern.

Return code	Explanation
DSM_RC_INVALID_SERVER (2225)	For a multi-user environment, the server in the system configuration file was not found.
DSM_RC_NO_HOST_ADDR (2226)	Not enough information to connect to host.
DSM_RC_MACHINE_SAME (2227)	The nodename that is defined in the options file cannot be the same as the system host name.
DSM_RC_NO_API_CONFIGFILE (2228)	Cannot open the configuration file.
DSM_RC_NO_INCLEXCL_FILE (2229)	The include-exclude file was not found.
DSM_RC_NO_SYS_OR_INCLEXCL (2230)	Either the dsm.sys file or the include-exclude file was not found.

Processing options

dsmInitEx

The dsmInitEx function call starts an API session by using the additional parameters for extended verification.

Syntax

```
dsInt16_t  dsmInitEx   (dsUint32_t        *dsmHandleP,
                        dsmInitExIn_t     *dsmInitExInP,
                        dsmInitExOut_t    *dsmInitExOutP) ;
```

Parameters

dsUint32_t *dsmHandleP (O)
The handle that identifies this initialization session and associates it with subsequent IBM Spectrum Protect™ calls.

dsmInitExIn_t *dsmInitExInP
This structure contains the following input parameters:

dsmApiVersion *dsmApiVersionP (I)
This parameter is a pointer to the data structure that identifies the version of the API that the application client is using for this session. The structure contains the values of the four constants, DSM_API_VERSION, DSM_API_RELEASE, DSM_API_LEVEL, and DSM_API_SUBLEVEL that are set in the dsmapitd.h file. Call dsmQueryApiVersionEx and verify that the API version of the application client and the version of the API library that is installed on the user's workstation is compatible.

char *clientNodeNameP (I)
This parameter is a pointer to the node for the IBM Spectrum Protect session. All sessions must be associated with a node name. The DSM_MAX_NODE_LENGTH constant in the dsmapitd.h file sets the maximum size for a node name.

The node name is not case-sensitive.

If this parameter is set to NULL, and passwordaccess is set to prompt, the API attempts to obtain the node name first from the options string that was passed. If it is not there, the API then attempts to obtain the node name from the configuration file or options files. If these attempts to find the node name fail, the UNIX or Linux API uses the system host name, while the APIs from other operating systems return `DSM_RC_REJECT_ID_UNKNOWN`.

This parameter must be NULL if the passwordaccess option in the dsm.sys file is set to generate. The API then uses the system host name.

char *clientOwnerNameP (I)
This parameter is a pointer to the owner of the IBM Spectrum Protect session. If the operating system is a multi-user platform, an owner name of NULL (the root user) has the authority to back up, archive, restore, or retrieve any objects that belong to the application, regardless of the owner of the object.

The owner name is case-sensitive.

This parameter must be NULL if the passwordaccess option in the dsm.sys file is set to generate. The API then uses the login user ID.

Tip: On a multi-user platform, if passwordaccess is set to prompt, it is not necessary for the owner name to match the active user ID of the session that is running the application.

char *clientPasswordP (I)
A pointer to the password of the node on which the IBM Spectrum Protect session runs. The DSM_MAX_VERIFIER_LENGTH constant in the dsmapitd.h file sets the maximum size that is allowed for a password.

The password is not case-sensitive.

Except when the password file is first started, the value of this parameter is ignored if passwordaccess is set to generate.

char *userNameP;
A pointer to the administrative user name that has client authority for this node.

char *userPasswordP;
A pointer to the password for the userName parameter, if a value is supplied.

char *applicationType (I)
Identifies the application that is running the IBM Spectrum Protect session. The application client identifies the value.

Each time an API application client starts a session with the server, the application type (or operating system) of the client is updated on the server. The value is entered in the platform field on the server. Consider using an operating system ID in the value. The maximum string length is defined in the DSM_MAX_PLATFORM_LENGTH constant.

To view the current value of the application type, call dsmQuerySessInfo.

char *configfile (I)
Points to a character string that contains the fully qualified name of an API configuration file. Options that are specified in the API configuration file override their specification in the client options file. Options files are defined when IBM Spectrum Protect (client or API) is installed.

char *options (I)
Points to a character string that can contain user options such as:

- Compressalways
- Servername (UNIX and Linux systems only)
- TCPServeraddr (not for UNIX systems)
- Fromnode
- Fromowner

The application client can use the options list to override the values of these options that the configuration file sets.

Options have the following format:

1. Each option that is specified in the option list begins with a dash (-) and is followed by the option keyword.
2. The keyword is followed by an equal sign (=) and then the option parameter.
3. If the option parameter contains a blank space, enclose the parameter with single or double quotation marks.
4. If more than one option is specified, separate the options with blanks.

If options are NULL, the values for all options are taken from the user options file or the API configuration file.

dirDelimiter
The directory delimiter that is prefixed on the file space, high-level or low-level names. You must specify the dirDelimiter parameter only if the application overrides the system defaults. In a UNIX or Linux environment, the default is forward slash (/). In a Windows environment, the default is backslash (\).

useUnicode
A Boolean flag that indicates whether Unicode is enabled. The useUnicode flag must be false to achieve cross-platform interoperability between UNIX and Windows systems.

bCrossPlatform
A Boolean flag that must be set (bTrue) to achieve cross-platform interoperability between UNIX and Windows systems. When the bCrossPlatform flag is set, the API ensures that the file spaces are not Unicode and that the application does not use Unicode. A Windows application that uses Unicode is not compatible with applications that use non-Unicode encodings. The bCrossPlatform flag must not be set for a Windows application that uses Unicode.

UseTsmBuffers
Indicates whether to use buffer copy elimination.

numTsmBuffers
Number of buffers when `useTsmBuffers=bTrue`.

bEncryptKeyEnabled
Indicates whether encryption with application-managed key is used.
encryptionPasswordP
The encryption password.
Restriction: When `encryptkey=save`, if an encrypt key exists, the value that is specified in the encryptionPasswordP is ignored.
dsmAppVersion *appVersionP (I)
This parameter is a pointer to the data structure that identifies the version information of the application that is starting an API session. The structure contains the values of the four constants, applicationVersion, applicationRelease, applicationLevel, and applicationSubLevel, which are set in the tsmapitd.h file.

dsmInitExOut_t *dsmInitExOut P
This structure contains the output parameters.

dsUint32_t *dsmHandle (0)
The handle that identifies this initialization session and associates it with subsequent API calls.
infoRC
Additional information about the return code. Check both the function return code and the value of infoRC. An infoRC value of DSM_RC_REJECT_LASTSESS_CANCELED (69), the IBM Spectrum Protect indicates that the administrator canceled the last session.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmInitEx

Return code	Explanation
DSM_RC_ABORT_SYSTEM_ERROR (1)	The IBM Spectrum Protect server detected a system error and notified the clients.
DSM_RC_REJECT_VERIFIER_EXPIRED (52)	Password expired and must be updated. The next call must be dsmChangePW with the handle returned on this call.
DSM_RC_REJECT_ID_UNKNOWN (53)	Cannot not find the node name.
DSM_RC_TA_COMM_DOWN (103)	The communications link is down.
DSM_RC_AUTH_FAILURE (137)	There was an authentication failure.
DSM_RC_NO_STARTING_DELIMITER (148)	There is no starting delimiter in pattern.
DSM_RC_NEEDED_DIR_DELIMITER (149)	A directory delimiter is needed immediately before and after the "match directories" meta-string ("..."), but was not found.
DSM_RC_NO_PASS_FILE (168)	The password file is not available.
DSM_RC_UNMATCHED_QUOTE (177)	An unmatched quotation mark is in the option string.
DSM_RC_NLS_CANT_OPEN_TXT (0610)	Unable to open the message text file.
DSM_RC_INVALID_OPT (2013)	An entry in the option string is invalid.
DSM_RC_INVALID_DS_HANDLE (2014)	Invalid DSM handle.
DSM_RC_NO_OWNER_REQD (2032)	Owner parameter must be NULL when passwordaccess is set to generate.
DSM_RC_NO_NODE_REQD (2033)	Node parameter must be NULL when passwordaccess is set to generate.
DSM_RC_WRONG_VERSION (2064)	Application client's API version has a higher value than the IBM Spectrum Protect version.
DSM_RC_PASSWD_TOOLONG (2103)	The specified password is too long.
DSM_RC_NO_OPT_FILE (2220)	No configuration file is found.
DSM_RC_INVALID_KEYWORD (2221)	A keyword that is specified in an options string is invalid.
DSM_RC_PATTERN_TOO_COMPLEX (2222)	Include-exclude pattern too complex to be interpreted by IBM Spectrum Protect.
DSM_RC_NO_CLOSING_BRACKET (2223)	There is no closing bracket in the pattern.

Return code	Explanation
DSM_RC_INVALID_SERVER (2225)	For a multi-user environment, the server in the system configuration file was not found.
DSM_RC_NO_HOST_ADDR (2226)	Not enough information to connect to the host.
DSM_RC_MACHINE_SAME (2227)	The node name that is defined in the options file cannot be the same as the system host name.
DSM_RC_NO_API_CONFIGFILE (2228)	Cannot open the configuration file.
DSM_RC_NO_INCLEXCL_FILE (2229)	The include-exclude file was not found.
DSM_RC_NO_SYS_OR_INCLEXCL (2230)	Either the dsm.sys or the include-exclude file was not found.

Processing options

dsmLogEvent

The **dsmLogEvent** function call logs a user message (ANE4991 I) to the server log file, to the local error log, or to both. A structure of type **logInfo** is passed in the call. This call must be performed while at **InSession** state inside a session. Do not perform it within a send, get, or query. To retrieve messages logged on the server, use the **query actlog** command through the administrative client.

See the summary state diagram, Figure 1.

Syntax

```
dsInt16_t dsmLogEvent
     (dsUint32_t    dsmHandle,
     logInfo        *logInfoP);
```

Parameters

dsUint32_t dsmHandle(I)
The handle that associates this call with a previous **dsmInitEx** call.
logInfo *logInfoP (I)
Passes the message and destination. The application client is responsible for allocating storage for the structure. The fields in the **logInfo** structure are:

message
The text of the message to be logged. This must be a null-ended string. The maximum length is DSM_MAX_RC_MSG_LENGTH.
dsmLogtype
Specifies where to log the message. Possible values include: **logServer**, **logLocal**, **logBoth**.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmLogEvent

Return code	Explanation
DSM_RC_STRING_TOO_LONG (2120)	The message string is too long.

dsmLogEventEx

The dsmLogEventEx function call logs a user message to the server log file, to the local error log, or to both. This call must be made while at an InSession state within a session. The call cannot be made within a send, get, or query call.

Summary state diagram: For an overview of the session interactions, see the summary state diagram in the following topic:

Figure 1

The severity determines the IBM Spectrum Protect™ message number. To view messages that are logged on the server, use the query actlog command through the administrative client. Use the IBM Spectrum Protect client option, errorlogretention, to prune the client error log file if the application generates numerous client messages written to the client log, dsmLogType either logLocal or logBoth. For more information, see the IBM Spectrum Protect server documentation.

Syntax

```
extern dsInt16_t DSMLINKAGE  dsmLogEventEx(
       dsUint32_t            dsmHandle,
       dsmLogExIn_t          *dsmLogExInP,
       dsmLogExOut_t         *dsmLogExOutP
);
```

Parameters

dsUint32_t dsmHandle(I)
: The handle that associates this call with a previous dsmInitEx call.

dsmLogExIn_t *dsmLogExInP
: This structure contains the input parameters.

  dsmLogSeverity severity;
  : This parameter is the event severity. The possible values are:

    ```
    logSevInfo,       /* information ANE4990 */
    logSevWarning,    /* warning     ANE4991 */
    logSevError,      /* Error       ANE4992 */
    logSevSevere      /* severe      ANE4993 */
    ```

  char appMsgID[8];
  : This parameter is a string to identify the specific application message. A suitable format is three characters that are followed by four numbers, for example: DSM0250.

  dsmLogType logType;
  : This parameter specifies where to direct the event. The parameter has the following possible values:

    - logServer
    - logLocal
    - logBoth

  char *message;
  : This parameter is the text of the event message to log. The text must be a null-ended string. The maximum length is DSM_MAX_RC_MSG_LENGTH.
    Restriction: Messages that go to the server must be in English. Non-English messages do not display correctly.

dsmLogExOut_t *dsmLogExOutP
: This structure contains the output parameters. Currently, there are no output parameters.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmLogEventEx

Return code	Explanation
DSM_RC_STRING_TOO_LONG (2120)	The message string is too long.

dsmQueryAccess

The **dsmQueryAccess** function call queries the server for all access authorization rules for either backup versions or archived copies of your objects. A pointer to an array of access rules is passed in to the call, and the completed array is returned. A pointer to the number of rules is passed in to indicate how many rules are in the array.

There are no return codes that are specific to this call.

Syntax

```
dsInt16_t DSMLINKAGE dsmQueryAccess
                    (dsUint32_t            dsmHandle),
                     qryRespAccessData     **accessListP,
                     dsUint16_t            *numberOfRules) ;
```

Parameters

dsUint32_t dsmHandle (I)

The handle that associates this call with a previous **dsmInitEx** call.

qryRespAccessData **accessListP (O)

A pointer to an array of `qryRespAccessData` elements that the API library allocates. Each element corresponds to an access rule. The number of elements in the array is returned in the **numberOfRules** parameter. The information that is returned in each `qryRespAccessData` element includes the following:

	Name	Description
	ruleNumber	The ID for the access rule. This identifies the rule for deletion.
	AccessType	The backup or archive type.
	Node	The node on which you gave access.
	Owner	The user to whom you gave access.
	objName	The high-level, or low-level file space descriptors.

dsUint32_t *numberOfRules (O)

Returns the number of rules in the `accessList` array.

dsmQueryApiVersion

The **dsmQueryApiVersion** function call performs a query request for the API library version that the application client accesses.

All updates to the API are made in an upward-compatible format. Any application client with an API version or release less than, or equal to, the API library on the end user's workstation operates without change. Be aware before you proceed that should the **dsmQueryApiVersion** call return a version or version release older than that of the application clients, some API calls might be enhanced in a manner that is not supported by the end user's older version of the API.

The application API version number is stored in the dsmapitd.h header file as constants DSM_API_VERSION, DSM_API_RELEASE, and DSM_API_LEVEL.

There are no return codes that are specific to this call.

Syntax

```
void dsmQueryApiVersion  (dsmApiVersion *apiVersionP);
```

Parameters

dsmApiVersion *apiVersionP (O)

This parameter is a pointer to the structure that contains the API library version, release, and level components. For example, if the library is version 1.1.0, then, after returning from the call, the fields of the structure contain the following values:

```
dsmApiVersionP->version  = 1
dsmApiVersionP->release  = 1
dsmApiVersionP->level    = 0
```

dsmQueryApiVersionEx

The **dsmQueryApiVersionEx** function call performs a query request for the API library version that the application client accesses.

All updates to the API are made in an upward-compatible format. Any application client that has an API version or release less than or equal to the API library on the end user's workstation operates without change. See Summary of Code Changes in the README_api_enu file for exceptions to upward compatibility. If the **dsmQueryApiVersionEx** call returns a version or version release that is different from that of the application client, be aware before you proceed that some API calls might be enhanced in a manner that is not supported by the end user's older version of the API.

The application API version number is stored in the dsmapitd.h header file as constants DSM_API_VERSION, DSM_API_RELEASE, DSM_API_LEVEL, and DSM_API_SUBLEVEL.

There are no return codes that are specific to this call.

Syntax

```
void dsmQueryApiVersionEx (dsmApiVersionEx *apiVersionP);
```

Parameters

dsmApiVersionEx *apiVersionP (O)

This parameter is a pointer to the structure that contains the API library's version, release, level, and sublevel components. For example, if the library is Version 5.5.0.0, then, after returning from the call, the fields of the structure contain the following values:

- `ApiVersionP->version = 5`
- `ApiVersionP->release = 5`
- `ApiVersionP->level = 0`
- `ApiVersionP->subLevel = 0`

dsmQueryCliOptions

The **dsmQueryCliOptions** function call queries important option values in the user's option files. A structure of type **optStruct** is passed in the call and contains the information. This call is performed before **dsmInitEx** is called, and it determines the setup before the session.

There are no return codes that are specific to this call.

Syntax

```
dsInt16_t dsmQueryCliOptions
    (optStruct     *optstructP);
```

Parameters

optStruct *optstructP (I/O)

This parameter passes the address of the structure that the API completes. The application client is responsible for allocating storage for the structure. On successful return, the appropriate information is entered in the fields in the structure.

The following information is returned in the **optStruct** structure:

	Name	Description
	dsmiDir	The value of the environment DSMI_DIR variable.
	dsmiConfig	The client option file as specified by the DSMI_CONFIG environment variable.
	serverName	The name of the IBM Spectrum Protect™ server.
	commMethod	The communication method selected. See the #defines for DSM_COMM_* in the dsmapitd.h file.
	serverAddress	The address of the server that is based on the communication method.
	nodeName	The client node (machine) name.
	compression	This field provides information regarding the compression option.
	passwordAccess	The values are: *bTrue* for generate, and *bFalse* for prompt.

Related concepts:
Processing options

dsmQuerySessInfo

The **dsmQuerySessInfo** function call starts a query request to IBM Spectrum Protect™ for information related to the operation of the specified session in **dsmHandle**. A structure of type **ApiSessInfo** is passed in the call, with all available session related information entered. This call is started after a successful **dsmInitEx** call.

The information that is returned in the **ApiSessInfo** structure includes the following:

- Server information: port number, date and time, and type
- Client defaults: application type, delete permissions, delimiters, and transaction limits
- Session information: login ID, and owner
- Policy data: domain, active policy set, and retention grace period

See API type definitions source files for information about the content of the structure that is passed and each field within it.

Syntax

```
dsInt16_t dsmQuerySessInfo  (dsUint32_t         dsmHandle,
   ApiSessInfo   *SessInfoP);
```

Parameters

dsUint32_t dsmHandle (I)
: The handle that associates this call with a previous **dsmInitEx** call.

ApiSessInfo *SessInfoP (I/O)
: This parameter passes the address of the structure that the API enters. The application client is responsible for allocating storage for the structure and for completing the field entries that indicate the version of the structure that is used. On successful return, the fields in the structure are completed with the appropriate information. The adsmServerName is the name that is given in the **define server** command on the IBM Spectrum Protect server. If the archiveRetentionProtection field is true, the server is enabled for retention protection.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmQuerySessInfo

Return code	Explanation
DSM_RC_NO_SESS_BLK (2006)	No server session block information.
DSM_RC_NO_POLICY_BLK (2007)	No server policy information available.
DSM_RC_WRONG_VERSION_PARM (2065)	Application client's API version is different from the IBM Spectrum Protect library version.

dsmQuerySessOptions

The dsmQuerySessOptions function call queries important option values that are valid in the specified session in dsmHandle. A structure of type `optStruct` is passed in the call and contains the information.

This call is started after a successful dsmInitEx call. The values that are returned might be different from the values returned on a dsmQueryCliOptions call, depending on values that are passed to the dsmInitEx call, primarily optString, and optFile. For information about option precedence, see Understanding configuration and options files.

There are no return codes that are specific to this call.

Syntax

```
dsInt16_t dsmQuerySessOptions
    (dsUint32_t    dsmHandle,
```

```
    optStruct      *optstructP);
```

Parameters

dsUint32_t dsmhandle(I)
: The handle that associates this call with a previous dsmInitEx call.

optStruct *optstructP (I/O)
: This parameter passes the address of the structure that the API completes. The application client is responsible for allocating storage for the structure. On successful return, the fields in the structure are completed with the appropriate information.

The information returned in the optStruct structure is:

	Name	Description
	dsmiDir	The value of the DSMI_DIR environment variable.
	dsmiConfig	The dsm.opt file that the DSMI_CONFIG environment variable specifies.
	serverName	The name of the IBM Spectrum Protect™ server stanza in the options file.
	commMethod	The communication method that was selected. See the #defines for DSM_COMM_* in the dsmapitd.h file.
	serverAddress	The address of the server that is based on the communication method.
	nodeName	The name of the client's node (machine).
	compression	The value of the compression option (bTrue=on and bFalse=off).
	compressAlways	The value of the compressalways option (bTrue=on and bFalse=off).
	passwordAccess	Value bTrue for generate, and bFalse for prompt.

Related concepts:
Processing options

dsmRCMsg

The dsmRCMsg function call obtains the message text that is associated with an API return code.

The **msg** parameter displays the message prefix return code in parentheses ( ), followed by the message text. For example, a call to dsmRCMsg might return the following:

```
ANS0264E (RC2300) Only root user can execute dsmChangePW or dsmDeleteFS.
```

For some languages where characters are different in ANSII and OEM code pages, it might be necessary to convert strings from ANSII to OEM before printing them out (for example, Eastern European single-byte character sets). The following is an example:

```
   dsmRCMsg(dsmHangle, rc, msgBuf);
   #ifdef WIN32
   #ifndef WIN64
   CharToOemBuff(msgBuf, msgBuf, strlen(msgBuf));
   #endif
   #endif
   printf("
```

Syntax

```
dsInt16_t dsmRCMsg  (dsUint32_t       dsmHandle,
   dsInt16_t        dsmRC,
   char         *msg);
```

Parameters

dsUint32_t dsmHandle (I)
: The handle that associates this call with a previous dsmInitEx call.

dsInt16_t dsmRC (I)
: The API return code of the associated message text. The API return codes are listed in the dsmrc.h file. See API return codes source file: dsmrc.h for more information.

char *msg (O)
This parameter is the message text that is associated with the return code, dsmRC. The caller is responsible for allocating enough space for the message text.

The maximum length for **msg** is defined as DSM_MAX_RC_MSG_LENGTH.

On platforms that have National Language Support and a choice of language message files, the API returns a message string in the national language.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmRCMsg

Return code	Explanation
DSM_RC_NULL_MSG (2002)	The **msg** parameter for dsmRCMsg call is a NULL pointer.
DSM_RC_INVALID_RETCODE (2021)	Return code that was passed to **dsmRCMsg** call is an invalid code.
DSM_RC_NLS_CANT_OPEN_TXT (0610)	Unable to open the message text file.

dsmRegisterFS

The **dsmRegisterFS** function call registers a new file space with the IBM Spectrum Protect™ server. Register a file space first before you can back up any data to it.

Application clients should not use the same file space names that a backup-archive client would use.

- On UNIX or Linux, run the **df** command for these names.
- On Windows, these names are generally the volume labels that are associated with the different drives on your system.

Syntax

```
dsInt16_t dsmRegisterFS  (dsUint32_t         dsmHandle,
   regFSData     *regFilespaceP);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.
regFSData *regFilespaceP (I)
This parameter passes the name of the file space and associated information that you need to register with the IBM Spectrum Protect server.
Tip: The *fstype* field includes the prefix, **"API:".** All file space queries display this string. For example, if the user passes *myfstype* for *fstype* in **dsmRegisterFS**, the actual value string on the server is returned as `API:myfstype` when queried. This prefix distinguishes API objects from backup-archive objects.

The usable area for **fsInfo** is now DSM_MAX_USER_FSINFO_LENGTH.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmRegisterFS

Return code	Explanation
DSM_RC_INVALID_FSNAME (2016)	Invalid file space name.
DSM_RC_INVALID_DRIVE_CHAR (2026)	Drive letter is not an alphabetic character.
DSM_RC_NULL_FSNAME (2027)	Null file space name.
DSM_RC_FS_ALREADY_REGED (2062)	File space is already registered.

Return code	Explanation
DSM_RC_WRONG_VERSION_PARM (2065)	Application client's API version is different from the IBM Spectrum Protect library version.
DSM_RC_FSINFO_TOOLONG (2106)	File space information is too long.

dsmReleaseBuffer

The **dsmReleaseBuffer** function returns a buffer to IBM Spectrum Protect™. The application calls **dsmReleaseBuffer** after a **dsmGetDataEx** was called and the application has moved all the data out of the buffer and is ready to release it. **dsmReleaseBuffer** requires that **dsmInitEx** was called with the ***UseTsmBuffers*** set to *btrue* and a non-zero value was provided for *numTsmBuffers*. **dsmReleaseBuffer** should also be called if the application is about to call **dsmTerminate** and it still holds data buffers.

dsmReleaseBufferSyntax

```
dsInt16_t  dsmReleaseBuffer  (releaseBufferIn_t     *dsmReleaseBufferInP,
                              releaseBufferOut_t    *dsmReleaseBufferOutP) ;
```

Parameters

releaseBufferIn_t * dsmReleaseBufferInP (I)
This structure contains the following input parameters.

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.
dsUint8_t tsmBufferHandle(I)
The handle that identifies this buffer.
char *dataPtr(I)
The address to which the application is written.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmReleaseBuffer

Return code	Explanation
DSM_RC_BAD_CALL_SEQUENCE	The call was not issued in the proper state.
DSM_RC_INVALID_TSMBUFFER	The handle or the value of **dataPtr** are invalid.
DSM_RC_BUFF_ARRAY_ERROR	A buffer array error occurred.

dsmRenameObj

The **dsmRenameObj** function call renames the high-level or low-level object name. For backup objects, pass in the current object name and changes either for high-level or low-level object names. For archive objects, pass in the current object file space name and object ID, and changes either for high-level or low-level object names. Use this function call within **dsmBeginTxn** and **dsmEndTxn** calls.

The merge flag determines whether or not a duplicate backup object name is merged with the existing backups. If the new name corresponds to an existing object and merge is true, the current object is converted to the new name and it becomes the active version of the new name while the existing active object that had that name becomes the top most inactive copy of the object. If the new name corresponds to an existing object and merge is false, the function then returns the return code, DSM_RC_ABORT_DUPLICATE_OBJECT.

Restrictions:

- Only the owner of the object can rename it.
- The dsmRenameObj function is not supported if data retention protection is enabled on the IBM Spectrum Protect™ server or if you are connected to the IBM Spectrum Protect for Data Retention server.

The **dsmRenameObj** function call tests for these merge conditions:

- The current **dsmObjName** object and the new high-level or low-level object must match on owner, copy group, and management class.
- The current **dsmObjName** must have been backed up more recently than the currently active object with the new name.
- There must be only an active copy of the current **dsmObjName** with no inactive copies.

Syntax

```
dsInt16_t dsmRenameObj  (dsmRenameIn_t     *dsmRenameInP,
                         dsmRenameOut_t    *dsmRenameOutP);
```

Parameters

dsUint32_t dsmHandle (I)
: The handle that associates this call with a previous **dsmInitEx** call.

dsmRenameIn_t *dsmRenameInP
: This structure contains the input parameters.

  dsUint8_t repository (I);
  : This parameter indicates whether the file space to delete is in the backup repository or the archive repository.

  dsmObjName *objNameP (I);
  : This parameter is a pointer to the structure that contains the current file space name, high-level object name, low-level object name, and object type.

  char newHl [DSM_MAX_HL_LENGTH + 1];
  : This parameter specifies the new high-level name.

  char newLl [DSM_MAX_LL_LENGTH + 1];
  : This parameter specifies the new low-level name.

  dsBool_t merge;
  : This parameter determines whether or not a backup object is merged with duplicate named objects. The values are either true or false.

  ObjID;
  : The object ID for archive objects.

dsmRenameOut_t *dsmRnameOutP
: This structure contains the output parameters.
  Note: There are no output parameters.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmRenameObj

Return code	Explanation
DSM_RC_ABORT_MERGE_ERROR (45)	Server detected a merge error.
DSM_RC_ABORT_DUPLICATE_OBJECT (32)	Object already exists and merge is false.
DSM_RC_ABORT_NO_MATCH (2)	Object not found.
DSM_RC_REJECT_SERVER_DOWNLEVEL (58)	The IBM Spectrum Protect server must be at V3.7.4.0 or later for this function to work.

dsmRequestBuffer

The **dsmRequestBuffer** function returns a buffer to IBM Spectrum Protect™. The application calls **dsmRequestBuffer** after a **dsmGetDataEx** was called and the application has moved all the data out of the buffer and is ready to release it.

dsmReleaseBuffer requires that **dsmInitEx** was called with the *UseTsmBuffers* set to *btrue* and a non-zero value was provided for *numTsmBuffers*. **dsmReleaseBuffer** should also be called if the application is about to call **dsmTerminate** and it still holds IBM Spectrum Protect buffers.

Syntax

```
dsInt16_t  dsmRequestBuffer   (getBufferIn_t      *dsmRequestBufferInP,
                               getBufferOut_t     *dsmRequestBufferOutP) ;
```

Parameters

getBufferIn_t * dsmRequestBufferInP (I)
This structure contains the following input parameter:

dsUint32_t dsmHandle
The handle that identifies the session and associates it with a previous **dsmInitEx** call.

getBufferOut_t *dsmRequestBufferOut P (0)
This structure contains the output parameters.

dsUint8_t tsmBufferHandle(0)
The handle that identifies this buffer.
char *dataPtr(0)
The address to which application is written.
dsUint32_t *bufferLen(0)
Maximum number of bytes that can be written to this buffer.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmRequestBuffer

Return code	Explanation
DSM_RC_BAD_CALL_SEQUENCE (33)	The call was not issued in the proper state.
DSM_RC_SENDDATA_WITH_ZERO_SIZE (34)	If the object being sent is 0 length, no calls to **dsmReleaseBuffer** are allowed.
DSM_RC_BUFF_ARRAY_ERROR (121)	A valid buffer could not be obtained.

dsmRetentionEvent

The **dsmRetentionEvent** function call sends a list of object IDs to the IBM Spectrum Protect™ server, with a retention event operation to be performed on these objects. Use this function call within **dsmBeginTxn** and **dsmEndTxn** calls.

Note: The server must be at version 5.2.2.0 or later for this function to work.

The maximum number of objects in a call is limited to the value of *maxObjPerTxn* that is returned in the *ApisessInfo* structure from a **dsmQuerySessInfo** call.

Only an owner of an object can send an event on that object.

The following events are possible:

eventRetentionActivate
Can be issued only for objects that are bound to an event based management class. Sending this event activates the event for this object and the state of the retention for this object changes from DSM_ARCH_RETINIT_PENDING to DSM_ARCH_RETINIT_STARTED.
eventHoldObj
This event issues a retention or deletion hold on the object so that, until a release is issued, the object is not expired and cannot be deleted.
eventReleaseObj
This event can only be issued for an object that has a value of DSM_ARCH_HELD_TRUE in the *objectHeld* field and removes the hold on the object resuming the original retention policy.

Before you send *dsmRetentionEvent*, send the query sequence that is described in Querying the IBM Spectrum Protect system to obtain the information for the object. The call to **dsmGetNextQObj** returns a data structure named **qryRespArchiveData** for

archive queries. This data structure contains the information that is needed for **dsmRetentionEvent**.

Syntax

```
extern dsInt16_t DSMLINKAGE dsmRetentionEvent(
  dsmRetentionEventIn_t          *ddsmRetentionEventInP,
  dsmRetentionEventOut_t         *dsmRetentionEventOutP
   );
```

Parameters

dsmRetentionEventIn_t *dsmRetentionEventP
: This structure contains the following input parameters:

  dsUint16_t stVersion;
  : This parameter indicates the structure version.

  dsUint32_t dsmHandle (I)
  : The handle that associates this call with a previous dsmInitEx call.

  dsmEventType_t evenType (I);
  : This parameter indicates the event type. See the beginning of this section for the meaning of these possible values: **eventRetentionActivate**, **eventHoldObj**, **eventReleaseObj**

  dsmObjList_t objList;
  : This parameter indicates a list of object IDs to signal.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmRetentionEvent

Return code	Explanation
DSM_RC_ABORT_NODE_NOT_AUTHORIZED (36)	The node or user does not have proper authority.
DSM_RC_ABORT_TXN_LIMIT_EXCEEDED (249)	Too many objects in the transaction.
DSM_RC_ABORT_OBJECT_ALREADY_HELD (250)	Object is already held, cannot issue another hold.
DSM_RC_REJECT_SERVER_DOWNLEVEL (58)	The server must be at V5.2.2.0 or later for this function to work.

dsmSendBufferData

The **dsmSendBufferData** function call sends a byte stream of data to IBM Spectrum Protect™ through a buffer that was provided in a previous **dsmReleaseBuffer** call. The application client can pass any type of data for storage on the server. Usually this data are file data, but it is not limited to file data. You can call **dsmSendBufferData** several times, if the byte stream of data that you are sending is large. Regardless of whether the call succeeds or fails, the buffer is released.

Restriction: When you use the *useTsmBuffers* option, even if an object is included for compression, the object is not compressed.

Syntax

```
dsInt16_t  dsmSendBufferData   (sendBufferDataIn_t        *dsmSendBufferDataExInP,
                                sendBufferDataOut_t       *dsmSendBufferDataOutP) ;
```

Parameters

sendBufferDataIn_t * dsmSendBufferDataInP (I)
: This structure contains the following input parameters.

  dsUint32_t dsmHandle (I)
  : The handle that associates this call with a previous **dsmInitEx** call.

  dsUint8_t tsmBufferHandle(I)
  : The handle that identifies the buffer to send.

  char *dataPtr(I)
  : The address to which application data was written.

dsUint32_t numBytes(I)
The actual number of bytes written by the application (should always be less than the value provided in **dsmReleaseBuffer**).

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmSendBufferData

Return code	Explanation
DSM_RC_BAD_CALL_SEQUENCE (2041)	The call was not issued in the proper state.
DSM_RC_INVALID_TSMBUFFER (2042)	The handle or the value of **dataPtr** are invalid.
DSM_RC_BUFF_ARRAY_ERROR (2045)	A buffer array error occurred.
DSM_RC_TOO_MANY_BYTES (2043)	The value of *numBytes* is bigger than the size of the buffer provided in the **dsmReleaseBuffer** call.

dsmSendData

The **dsmSendData** function call sends a byte stream of data to IBM Spectrum Protect™ through a buffer. The application client can pass any type of data for storage on the server. Usually, these data are file data, but are not limited to such. You can call **dsmSendData** several times, if the byte stream of data that you want to send is large.

Restriction: The application client cannot reuse the buffer that is specified in **dsmSendData** until the **dsmSendData** call returns.
Tip: If IBM Spectrum Protect returns code 157 (DSM_RC_WILL_ABORT), start a call to **dsmEndSendObj** and then to **dsmEndTxn** with a vote of DSM_VOTE_COMMIT. The application then receives return code 2302 (DSM_RC_CHECK_REASON_CODE) and passes the reason code back to the application user. This informs the user why the server is ending the transaction.

Syntax

```
dsInt16_t dsmSendData  (dsUint32_t   dsmHandle,
   DataBlk *dataBlkPtr);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.
DataBlk *dataBlkPtr (I/O)
This parameter points to a structure that includes both a pointer to the buffer from which the data are to be sent, as well as the size of the buffer. On return, this structure contains the number of bytes that is actually transferred. See API type definitions source files for the type definition.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmSendData

Return code	Explanation
DSM_RC_NO_COMPRESS_MEMORY (154)	Insufficient memory available to perform data compression or expansion.
DSM_RC_COMPRESS_GREW (155)	During compression the compressed data grew in size compared to the original data.
DSM_RC_WILL_ABORT (157)	An unknown and unexpected error occurred, causing the transaction to halt.
DSM_RC_WRONG_VERSION_PARM (2065)	Application client's API version is different than the IBM Spectrum Protect library version.
DSM_RC_NEEDTO_ENDTXN (2070)	Need to end the transaction.

Return code	Explanation
DSM_RC_OBJ_EXCLUDED (2080)	The include-exclude list excludes the object.
DSM_RC_OBJ_NOBCG (2081)	The object has no backup copy group and will not be sent to the server.
DSM_RC_OBJ_NOACG (2082)	The object has no archive copy group and is not sent to the server.
DSM_RC_SENDDATA_WITH_ZERO_SIZE (2107)	The object cannot send data with a zero byte *sizeEstimate*.

dsmSendObj

The **dsmSendObj** function call starts a request to send a single object to storage. Multiple **dsmSendObj** calls and associated **dsmSendData** calls can be made within the bounds of a transaction for performance reasons.

The **dsmSendObj** call processes the data for the object as a byte stream passed in memory buffers. The **dataBlkPtr** parameter in the **dsmSendObj** call permits the application client to either:

- Pass the data and the attributes (the attributes are passed through the **objAttrPtr**) of the object in a single call.
- Specify part of the object data through the **dsmSendObj** call and the remainder of the data through one or more **dsmSendData** calls.

Alternatively, the application client can specify only the attributes through the **dsmSendObj** call and specify the object data through one or more calls to **dsmSendData**. For this method, set **dataBlkPtr** to NULL on the **dsmSendObj** call.
Tip: For certain object types, byte stream data might not be associated with the data; for example, a directory entry with no extended attributes.

Before **dsmSendObj** is called, a preceding **dsmBindMC** call must be made to properly bind a management class to the object that you want to back up or archive. The API keeps this binding so that it can associate the proper management class with the object when it is sent to the server. If you permit the management class that is bound on a **dsmSendObj** call to default for an object type of directory (DSM_OBJ_DIRECTORY), the default might not be the default management class. Instead, the management class with the greatest retention time is used. If more than one management class exists with this retention time, the first one that is encountered is used.

Follow all object data that is sent to storage with a **dsmEndSendObj** call. If you do not have object data to send to the server, or all data was contained within the **dsmSendObj** call, start a **dsmEndSendObj** call before you can start another **dsmSendObj** call. If multiple data sends were required through the **dsmSendData** call, the **dsmEndSendObj** follows the last send to indicate the state change.

Tip: If IBM Spectrum Protect™ returns code 157 (DSM_RC_WILL_ABORT), start a call to **dsmEndTxn** with a vote of DSM_VOTE_COMMIT. The application receives return code 2302 (DSM_RC_CHECK_REASON_CODE) and passes the reason code back to the application user. This informs the user why the server is ending the transaction.

If the reason code is 11 (DSM_RS_ABORT_NO_REPOSIT_SPACE), it is possible that the *sizeEstimate* is too small for the actual amount of data. The application needs to determine a more accurate *sizeEstimate* and send the data again.

Syntax

```
dsInt16_t dsmSendObj   (dsUint32_t       dsmHandle,
   dsmSendType  sendType,
   void        *sendBuff,
   dsmObjName  *objNameP,
   ObjAttr     *objAttrPtr,
   DataBlk     *dataBlkPtr);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

dsmSendType sendType (I)
This parameter specifies the type of send that is being performed. Possible values include:

	Name	Description
	stBackup	A backup object that is sent to the server.

	Name	Description
	stArchive	An archive object that is sent to the server.
	stBackupMountWait	A backup object for which you want the server to wait until the necessary device, such as a tape, is mounted.
	stArchiveMountWait	An archive object for which you want the server to wait until the necessary device, such as a tape, is mounted.

Note: Use the **MountWait** types if there is any possibility that your application user might send data to a tape.

void *sendBuff (I)

This parameter is a pointer to a structure that contains other information specific to the **sendType** on the call. Currently, only a **sendType** of **stArchive** has an associated structure. This structure is called **sndArchiveData** and it contains the archive description.

dsmObjName *objNameP (I)

This parameter is a pointer to the structure that contains the file space name, high-level object name, low-level object name, and object type. See Object names and IDs for more information.

ObjAttr *objAttrPtr (I)

This parameter passes object attributes of interest to the application. See API type definitions source files for the type definition.

The attributes are:

- **owner** refers to the owner of the object. Determining whether the owner is declared to be a specific name or an empty string is important when getting the object back from IBM Spectrum Protect storage. See Accessing objects as session owner for more information.
- **sizeEstimate** is a best estimate of the total size of the data object to send to the server. Be as accurate as possible on this size, because the server uses this attribute for efficient space allocation and object placement within its storage resources.
  If the size estimate that you specified is significantly smaller than the actual number of bytes that are sent, the server might have difficulty allocating enough space and end the transaction with a reason code of 11 (DSM_RS_ABORT_NO_REPOSIT_SPACE).
  Note: The size estimate is for the total size of the data object in bytes.

  Objects with a size smaller than DSM_MIN_COMPRESS_SIZE do not compress.

  If your object has no bit data (only the attribute information from this call), the **sizeEstimate** should be zero.
  Note: Starting with Version 5.1.0, the copy destination within a transaction is not checked for consistency on zero-length objects.
- **objCompressed** is a Boolean value that states whether or not the object data have already been compressed.

  If the object is compressed (object *compressed=bTrue*), IBM Spectrum Protect does not try to compress it again. If it is not compressed, IBM Spectrum Protect decides whether to compress the object, based on the values of the compression option set by the administrator and set in the API configuration sources.

  If your application plans to use partial object restore or retrieve, you cannot compress the data while sending it. To enforce this, set *ObjAttr.objCompressed* to *bTrue*.

- **objInfo** saves information about the particular object.
  Restriction: Information is not stored here automatically. When this attribute is used, you must set the attribute, *objInfoLength*, to show the length of *objInfo*.
- **mcNameP** contains the name of a management class that overrides the management class that is obtained from **dsmBindMC**.
- **disableDeduplication** is a Boolean value. When it is set to true, this object is not deduplicated by the client.

DataBlk *dataBlkPtr (I/O)

This parameter points to a structure that includes both a pointer to the buffer of data that is to be backed up or archived and the size of that buffer. This parameter applies to **dsmSendObj** only. If you want to begin sending data on a subsequent **dsmSendData** call, rather than on the **dsmSendObj** call, set the buffer pointer in the DataBlk structure to NULL. On return, this structure contains the number of bytes that is actually transferred. See API type definitions source files for the type definition.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmSendObj

Return code	Explanation
DSM_RC_NO_COMPRESS_MEMORY (154)	Insufficient memory available to perform data compression or expansion.
DSM_RC_COMPRESS_GREW (155)	During compression, the compressed data grew in size compared to the original data.
DSM_RC_WILL_ABORT (157)	An unknown and unexpected error occurred, causing the transaction to be halted.
DSM_RC_TL_NOACG (186)	The management class for this file does not have a valid copy group for the send type.
DSM_RC_NULL_OBJNAME (2000)	Null object name.
DSM_RC_NULL_OBJATTRPTR (2004)	Null object attribute pointer.
DSM_RC_INVALID_OBJTYPE (2010)	Invalid object type.
DSM_RC_INVALID_OBJOWNER (2019)	Invalid object owner.
DSM_RC_INVALID_SENDTYPE (2022)	Invalid send type.
DSM_RC_WILDCHAR_NOTALLOWED (2050)	Wildcard characters not allowed.
DSM_RC_FS_NOT_REGISTERED (2061)	File space not registered.
DSM_RC_WRONG_VERSION_PARM (2065)	Application client's API version is different from the IBM Spectrum Protect library version.
DSM_RC_NEEDTO_ENDTXN (2070)	Need to end transaction.
DSM_RC_OBJ_EXCLUDED (2080)	The include-exclude list excluded the object.
DSM_RC_OBJ_NOBCG (2081)	The object has no backup copy group, and it is not sent to the server.
DSM_RC_OBJ_NOACG (2082)	The object has no archive copy group, and it is not sent to the server.
DSM_RC_DESC_TOOLONG (2100)	Description is too long.
DSM_RC_OBJINFO_TOOLONG (2101)	Object information is too long.
DSM_RC_HL_TOOLONG (2102)	High-level qualifier is too long.
DSM_RC_FILESPACE_TOOLONG (2104)	File space name is too long.
DSM_RC_LL_TOOLONG (2105)	Low-level qualifier is too long.
DSM_RC_NEEDTO_CALL_BINDMC (2301)	**dsmBindMC** must be called first.

dsmSetAccess

The **dsmSetAccess** function call gives other users or nodes access to backup versions or archived copies of your objects, access to all your objects, or access to a selective set. When you give access to another user, that user can query, restore, or retrieve your files. This command supports wildcards for the following fields: *fs*, *hl*, *ll*, *node*, *owner*.

Note: You cannot give access to both backup versions and archive copies by using a single command. You must specify either backup or archive.

Syntax

```
dsInt16_t DSMLINKAGE dsmSetAccess
        (dsUint32_t          dsmHandle,
         dsmSetAccessType    accessType,
         dsmObjName          *objNameP,
         char                *node,
         char                *owner);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

dsmAccessType accessType (I)

This parameter specifies the type of objects for which you want to give access. Possible values include:

	Name	Description
	atBackup	Specifies that access is being set to backup objects.
	atArchive	Specifies that the access is being set for archive objects.

dsmObjName *objNameP (I)

This parameter is a pointer to the structure that contains the file space name, the high-level object name, and the low-level object name.

Note: To specify all file spaces, use an asterisk (*) for the file space name.

char *node (I)

This parameter is a pointer to the node name for which access is given. For any node, specify an asterisk (*).

char *owner (I)

This parameter is a pointer to the user name on the node to which you gave access. For all users, specify an asterisk (*).

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmSetAccess

Return code	Explanation
DSM_RC_INVALID_ACCESS_TYPE (2110)	Invalid access type specified.
DSM_RC_FILE_SPACE_NOT_FOUND (124)	Specified file space was not found on the server.
DSM_RC_QUERY_COMM_FAILURE (2111)	Communication error during server query.
DSM_RC_NO_FILES_BACKUP (2112)	No files were backed up for this file space.
DSM_RC_NO_FILES_ARCHIVE (2113)	No files were archived for this file space.
DSM_RC_INVALID_SETACCESS (2114)	Invalid formulation of set access.

dsmSetUp

The **dsmSetUp** function call overwrites environment variable values. Call **dsmSetUp** before **dsmInitEx**. The values that were passed in the **envSetUp** structure overwrite any existing environment variables or defaults. If you specify NULL for a field, values are taken from the environment. If you do not set a value, the values are taken from the defaults.

Requirements:

1. If you use **dsmSetUp**, always call **dsmTerminate** before **dsmCleanUp**.
2. API instrumentation can only be activated if the testflag INSTRUMENT: API is set in the configuration file and the **dsmSetUp** or **dsmCleanUp** calls are used in the application.

Syntax

```
dsInt16_t DSMLINKAGE dsmSetUp
        (dsBool_t    mtFlag,
         envSetUp    *envSetUpP);
```

Parameters

dsBool_t mtFlag (I)

This parameter specifies if the API will be used in a single thread, or a multithread mode. Values include:

```
DSM_SINGLETHREAD
DSM_MULTITHREAD
```

Requirement: The multithread flag must be on for LAN-free data transfer to occur.

envSetUp *envSetUpP(I)

This parameter is a pointer to the structure that holds the overwrite values. Specify NULL if you do not want to override existing environment variables. The fields in the **envSetUp** structure include:

	Name	Description
	dsmiDir	A fully-qualified directory path that contains a message file on UNIX or Linux. It also specifies the dsm.sys directories.
	dsmiConfig	The fully-qualified name of the client options file.
	dsmiLog	The fully-qualified path of the error log directory.
	argv	Pass the argv[0] name of the calling program if the application must run with authorized user authority. See Controlling access to password files for more information.
	logName	The file name for an error log if the application does not use dsierror.log.
	inclExclCaseSensitive	Indicates whether include/exclude rules are case-sensitive or case-insensitive. This parameter can be used on Windows only, it is ignored elsewhere.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmSetUp

Return code	Explanation
DSM_RC_ACCESS_DENIED (106)	Access to the specified file or directory is denied.
DSM_RC_INVALID_OPT (0400)	An invalid option was found.
DSM_RC_NO_HOST_ADDR (0405)	The TCPSERVERADDRESS for this server is not defined in the server name stanza in the system options file.
DSM_RC_NO_OPT_FILE (0406)	The options file specified by filename cannot be found.
DSM_RC_MACHINE_SAME (0408)	The NODENAME defined in the options file cannot be the same as the system *HostName*.
DSM_RC_INVALID_SERVER (0409)	The system options file does not contain the SERVERNAME option.
DSM_RC_INVALID_KEYWORD (0410)	An invalid option keyword was found in the **dsmInitEx** configuration file, the option string, dsm.sys, or dsm.opt.
DSM_RC_PATTERN_TOO_COMPLEX (0411)	The include or exclude pattern issued is too complex to be accurately interpreted by IBM Spectrum Protect™.
DSM_RC_NO_CLOSING_BRACKET (0412)	The include or exclude pattern is incorrectly constructed. The closing bracket is missing.
DSM_RC_NLS_CANT_OPEN_TXT (0610)	The system is unable to open the message text file.
DSM_RC_NLS_INVALID_CNTL_REC (0612)	The system is unable to use the message text file.
DSM_RC_NOT_ADSM_AUTHORIZED (0927)	You must be the authorized user to have multithreading and *passwordaccess* generate.
DSM_RC_NO_INCLEXCL_FILE (2229)	The include-exclude file was not found.
DSM_RC_NO_SYS_OR_INCLEXCL (2230)	Either the dsm.sys or the include-exclude file was not found.

dsmTerminate

The **dsmTerminate** function call ends a session with the IBM Spectrum Protect™ server and cleans up the IBM Spectrum Protect environment.

Syntax

There are no return codes that are specific for this call.

```
dsInt16_t dsmTerminate (dsUint32_t dsmHandle);
```

Parameters

dsUint32_t dsmHandle (I)
: The handle that associates this call with a previous **dsmInitEx** call.

dsmUpdateFS

The dsmUpdateFS function call updates a file space in IBM Spectrum Protect™ storage. This update ensures that the administrator has a current record of your file space.

Syntax

```
dsInt16_t dsmUpdateFS  (dsUint32_t      dsmHandle,
   char          *fs,
   dsmFSUpd      *fsUpdP,
   dsUint32_t     fsUpdAct);
```

Parameters

dsUint32_t dsmHandle (I)
: The handle that associates this call with a previous dsmInitEx call.

char *fs (I)
: This parameter is a pointer to the file space name.

dsmFSUpd *fsUpdP (I)
: This parameter is a pointer to the structure that has the correct fields for the update that you want. Complete only those fields that need updating.

dsUint32_t fsUpdAct (I)
: A 2-byte bit map that indicates which of the fields to update. The bit masks have the following values:

  - DSM_FSUPD_FSTYPE
  - DSM_FSUPD_FSINFO
    Tip: For Windows operating systems, the drive letter value from dsmDOSAttrib is also updated when FSINFO is selected.
  - DSM_FSUPD_OCCUPANCY
  - DSM_FSUPD_CAPACITY
  - DSM_FSUPD_BACKSTARTDATE
  - DSM_FSUPD_BACKCOMPLETEDATE

  For a description of these bit masks, see the DSM_FSUPD definitions in the following topic: API type definitions source files.

Return codes

The following table lists return codes for the dsmUpdateFS function call.

Table 1. Return codes for dsmUpdateFS

Return code	Return code number	Description
DSM_RC_FS_NOT_REGISTERED	2061	File space name is not registered.
DSM_RC_WRONG_VERSION_PARM	2065	The API version of the application client is different from the IBM Spectrum Protect library version.
DSM_RC_FSINFO_TOOLONG	2106	File space information is too long.

dsmUpdateObj

The **dsmUpdateObj** function call updates the meta information associated with an active backup or archive object already on the server. The application bit data is not affected. To update an object, you must give a specific non-wildcard name. To update an archived object, set the **dsmSendType** to **stArchive**. Only the latest named archive object is updated.

You can only start the **dsmUpdateObj** call in the session state; it cannot be called inside a transaction because it performs its own transaction. And, you can update only one object at a time.

Restriction: On a UNIX or Linux operating system, if you change the owner field, you cannot query or restore the object unless you are the root user.

Syntax

```
dsInt16_t  dsmUpdateObj
   (dsUint32_t      dsmHandle,
    dsmSendType     sendType,
    void           *sendBuff,
    dsmObjName     *objNameP,
    ObjAttr        *objAttrPtr,  /* objInfo */
    dsUint16_t      objUpdAct);  /* action bit vector */
```

Parameters

The field descriptions are the same as those in **dsmSendObj**, with the following exceptions:

dsmObjName *objNameP (I)
: You cannot use a wildcard.

ObjAttr *objAttrPtr (I)
: The **objCompressed** field is ignored for this call.

  Other differences are:

  - **owner**. If you specify a new **owner** field, the owner changes.
  - **sizeEstimate**. If you specify a non-zero value it should be the actual amount of data sent, in bytes. The value is stored in the IBM Spectrum Protect™ metadata for future use.
  - **objInfo**. This attribute contains the new information to be placed in the **objInfo** field. Set the **objInfoLength** to the length of the new **obiInfo**.

dsUint16_t objUpdAct
: The bit masks and possible actions for **objUpdAct** are:

  DSM_BACKUPD_MC
  : Updates the management class for the object.

  DSM_BACKUPD_OBJINFO
  : Updates **objInfo**, **objInfoLength**, and **sizeEstimate**.

  DSM_BACKUPD_OWNER
  : Updates the owner of the object.

  DSM_ARCHUPD_DESCR
  : Updates the **Description** field. Enter the value for the new description through the **SendBuff** parameter. See the sample program for proper use.

  DSM_ARCHUPD_OBJINFO
  : Updates **objInfo**, **objInfoLength**, and **sizeEstimate**.

  DSM_ARCHUPD_OWNER
  : Updates the owner of the object.

Return codes

The return code numbers are provided in parentheses ( ).

Table 1. Return codes for dsmUpdateObj

Return code	Explanation
DSM_RC_INVALID_ACTION (2232)	Invalid action.
DSM_RC_FS_NOT_REGISTERED (2061)	File space not registered.
DSM_RC_BAD_CALL_SEQUENCE (2041)	Sequence of calls is invalid.
DSM_RC_WILDCHAR_NOTALLOWED (2050)	Wildcard characters are not allowed.
DSM_RC_ABORT_NO_MATCH (2)	Previous query does not match.

dsmUpdateObjEx

The **dsmUpdateObjEx** function call updates the meta information that is associated with an active backup or archive object that is on the server. The application bit data is not affected. To update an object, you must specify a non-wildcard name, or you can specify the object ID to update a specific archived object. You cannot use wildcard characters when specifying the name. To update a backup object, set the **dsmSendType** parameter to **stBackup**. To update an archived object, set the **dsmSendType** parameter to **stArchive**.

You can only start the **dsmUpdateObjEx** call in the session state; it cannot be called inside a transaction because it performs its own transaction. You can update only one object at a time.

Restriction: On a UNIX or Linux operating system, if you change the owner field, you cannot query or restore the object unless you are the root user. Only the current active version of a backup object can be updated.

Syntax

```
dsInt16_t  dsmUpdateObjEx
   (dsmUpdateObjExIn_t   *dsmUpdateObjExInP,
    dsmUpdateObjExOut_t  *dsmUpdateObjExOutP);
```

Parameters

dsmUpdateObjExIn_t *dsmUpdateObjExInP
: This structure contains the following input parameters:

  dsUint16_t stVersion (I)
  : The current version of the structure that is used.

  dsUint32_t dsmHandle (I)
  : The handle that associates this call with a previous **dsmInitEx** call.

  dsmSendType sendType (I)
  : The type of send that is being performed. The value can be:

    stBackup
    : A backup object that is sent to the server.

    stArchive
    : An archive object that is sent to the server.

  dsmObjName *objNameP (I)
  : A pointer to the structure that contains the filespace name, high-level object name, low-level object name, and object type. You cannot use a wildcard.

  ObjAttr *objAttrPtr (I)
  : Passes object attributes to the application. The values that are updated depend on the flags in the **objUpdAct** field. The **objCompressed** attribute is ignored for this call.

    The attributes are:

    - **owner** changes the owner if a new name is entered.
    - **sizeEstimate** is the actual amount of data that is sent in bytes. The value is stored in the IBM Spectrum Protect™ meta data for future use.
    - **objCompressed** is a Boolean value that states whether or not the object data have already been compressed.
    - **objInfo** is an attribute that contains the new information to be placed in the **objInfo** field. Set the **objInfoLength** to the length of the new **objInfo**.
    - **mcNameP** contains the name of a management class that overrides the management class that is obtained from **dsmBindMC**.

  dsUint32_t objUpdAct
  : Specifies the bit masks and actions for **objUpdAct** are:

    DSM_BACKUPD_MC
    : Updates the management class for the object.

    DSM_BACKUPD_OBJINFO
    : Updates the information object (**objInfo**), the length of the information object (**objInfoLength**), and the amount of data that is sent (**sizeEstimate**) for the backup object.

    DSM_BACKUPD_OWNER

Updates the owner for the backup object.

DSM_ARCHUPD_DESCR
Updates the **Description** field for the archive object. Enter the value for the new description through the **sendBuff** parameter.

DSM_ARCHUPD_OBJINFO
Updates the information object (**objInfo**), the length of the information object (**objInfoLength**), and the amount of data that is sent (**sizeEstimate**) for the archive object.

DSM_ARCHUPD_OWNER
Updates the owner of the archive object.

ObjID archObjId
Specifies the unique object ID for a specific archive object. Because multiple archive objects can have the same name, this parameter identifies a specific one. You can obtain the object ID by using a query archive call.

dsmUpdateObjExOut_t *dsmUpdateObjExOutP
This structure contains the output parameter:

dsUint16_t stVersion (I)
The current version of the structure that is used.

Return codes

The return code numbers are provided in parentheses ( ) in the following table.

Table 1. Return codes for dsmUpdateObjEx

Return code	Explanation
DSM_RC_INVALID_ACTION (2012)	Invalid action.
DSM_RC_FS_NOT_REGISTERED (2061)	File space not registered.
DSM_RC_BAD_CALL_SEQUENCE (2041)	Sequence of calls is invalid.
DSM_RC_WILDCHAR_NOTALLOWED (2050)	Wildcard characters are not allowed.
DSM_RC_ABORT_NO_MATCH (2)	Previous query does not match.

API return codes source file: dsmrc.h

The dsmrc.h header file contains all return codes that the API can return to an application.

The information that is provided here contains a point-in-time copy of the dsmrc.h file that is distributed with the API. View the file in the API distribution package for the latest version.

API type definitions source files

This appendix contains structure definitions, type definitions, and constants for the API. The first header files, dsmapitd.h and tsmapitd.h, illustrate the definitions that are common to all operating systems.

The second header file, dsmapips.h, provides an example of definitions that are specific to a particular operating system; in this example, the Windows platform.

The third header file, release.h, includes the version and release information.

The information that is provided here contains a point-in-time copy of the files that are distributed with the API. View the files in the API distribution package for the latest version.

API function definitions source file

This appendix contains the dsmapifp.h header file, so you can see the function definitions for the API.

Note: DSMLINKAGE is defined differently for each operating system. See the definitions in the dsmapips.h file for your specific operating system.

The information that is provided here contains a point-in-time copy of the files that are distributed with the API. View the files in the API distribution package for the latest version.

Developing solutions with the application programming interface

Teljesítmény

A kiszolgáló és az ügyfelek teljesítményére számos tényező van hatással, beleértve az operációs rendszereket, a rendszerhardvert, a hálózati konfigurációkat, a tárolóeszközök típusait, valamint az ügyfélfájlok méretét és számát. A felsorolt tényezők közötti interakciók a teljesítmény optimalizálását bonyolult feladattá tehetik.

Ez a kiadás nem tartalmazza a teljesítmény összetevő frissített változatát. A teljesítmény dokumentációt a következő helyen találja: 8.1.0 változat.

Hibaelhárítás

A problémák diagnosztizálásához és elhárításához rendelkezésre állnak hibaelhárító eljárások.

Ez a kiadás nem tartalmazza a hibaelhárítási összetevő frissített változatát. A hibaelhárítási dokumentációt a 8.1.0 változat tartalmazza.

Messages, return codes, and error codes

Explanations and suggested actions are available for messages that are issued by IBM Spectrum Protect™ components.

- Introduction to messages
- IBM Global Security Kit return codes
  The server and client use the IBM Global Security Kit (GSKit) for SSL (Secure Sockets Layer) processing between the server and the backup-archive client. Some messages that are issued for SSL processing include GSKit return codes.
- ANE: Client events logged to the server
- ANR: Server common and platform-specific messages

- ANS: Client messages
- API return codes
- I/O error code descriptions in server messages
- Device error codes in the AIX system error log
- Troubleshooting (V8.1.0 is the most recent publication)

Introduction to messages

Messages, error codes, and return codes are issued by the IBM Spectrum Protect™ server and clients.

Messages and codes can appear on the server console, the administrative client, an operator terminal, the administrative graphical user interface, the backup-archive client, or the hierarchical storage managment client (HSM client).

IBM Spectrum Protect provides an activity log to help the administrator track server activity and monitor the system. The activity log contains messages generated by the server, and is stored in the database. The server automatically deletes messages from the activity log after they have passed the specified retention period. Any messages sent to the server console are stored in the activity log. Examples of the types of messages stored in the activity log include:

- When client sessions start or end
- When migration starts or ends
- When backed up files are expired from server storage
- Any output generated from background processes

Some messages have no explanations and are not published. The client can send statistics to the server providing information about a backup or restore. These statistics are informational messages that can be enabled or disabled to the various event logging receivers. These messages are not published.

- IBM Spectrum Protect server and client messages format
- Interpreting return code messages

Related tasks:
Using the activity log (V7.1.1)

IBM Spectrum Protect server and client messages format

IBM Spectrum Protect™ server and client messages consist of the following elements:

- A three-letter prefix. Messages have different prefixes to help you identify the IBM Spectrum Protect component that issues the message. Typically, all messages for a component have the same prefix. Sometimes a component issues messages with two or three different prefixes.

  For example, backup-archive clients issue messages with the ANS prefix. Backup-archive client events that are logged to the server have the ANE prefix. Server common and server platform-specific messages have the ANR prefix.

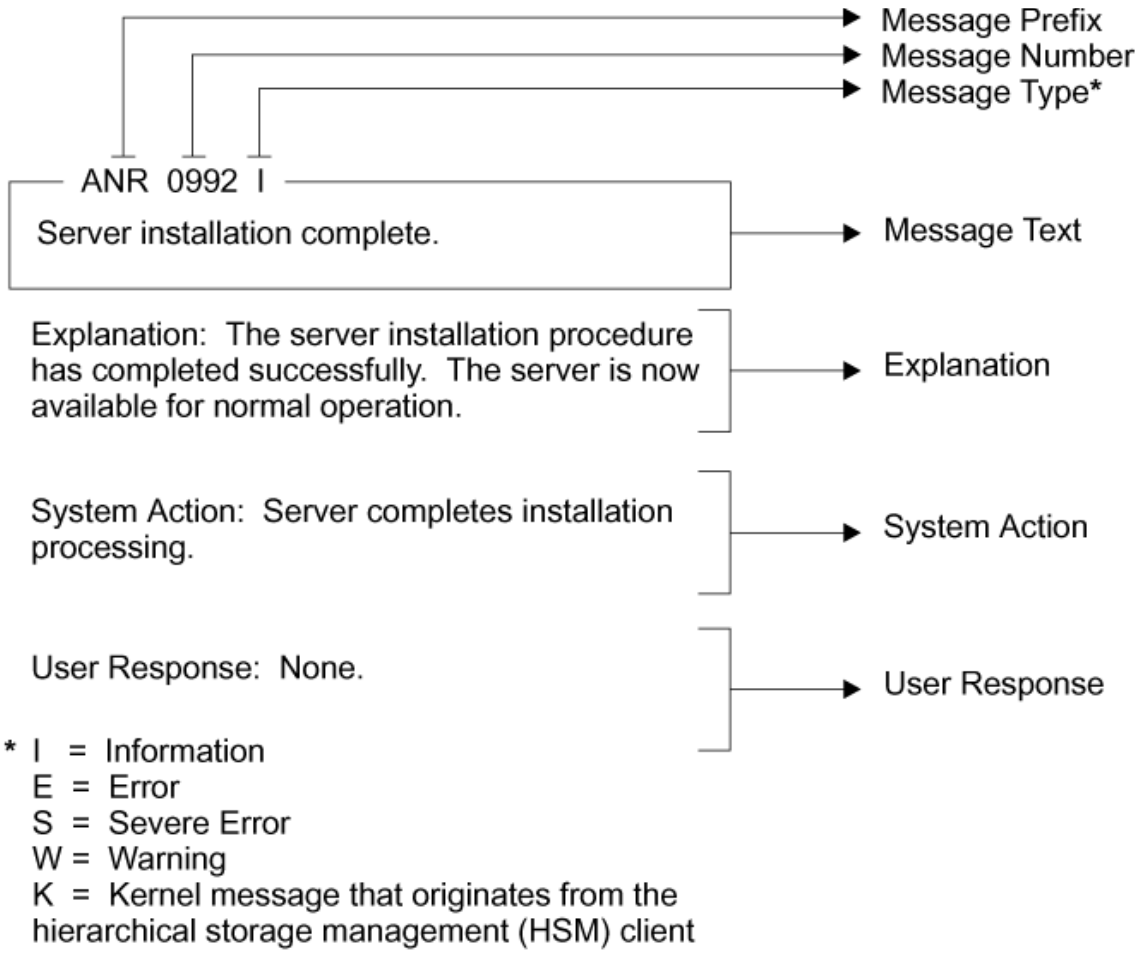
- A numeric message identifier.
- A one-letter severity code. The following codes indicate the severity of the action that generated the message:

Code	Severity	Meaning
S	Severe	The product or a product function cannot continue. User response is required.
E	Error	An error is encountered during processing. Processing might stop. User response might be required.
W	Warning	Processing continues, but problems might occur later as a result of the warning.
I	Information	Processing continues. User response is not necessary.

- Message text that is displayed on screen and written to message logs.
- Explanation, System Action, and User Response texts. These texts elaborate on the message text, and are available in the product messages publications and in the command line help.

The following image presents a typical IBM Spectrum Protect server message.

The callouts identify each element of the message.



Message variables in the message text appear in italics.

Interpreting return code messages

Many different commands can generate the same *return code*. The following examples are illustrations of two different commands issued that result in the same return code; therefore, you must read the *descriptive message* for the command.

In these examples, two different commands yield the same return code, but they also return descriptive messages that are unique to each command. The two commands are `q event standard dddd` and `def vol cstg05 primary`. Both yield a generic message with return code:

```
ANS5102I: Return Code 11.
```

But the first command also yields a descriptive message:

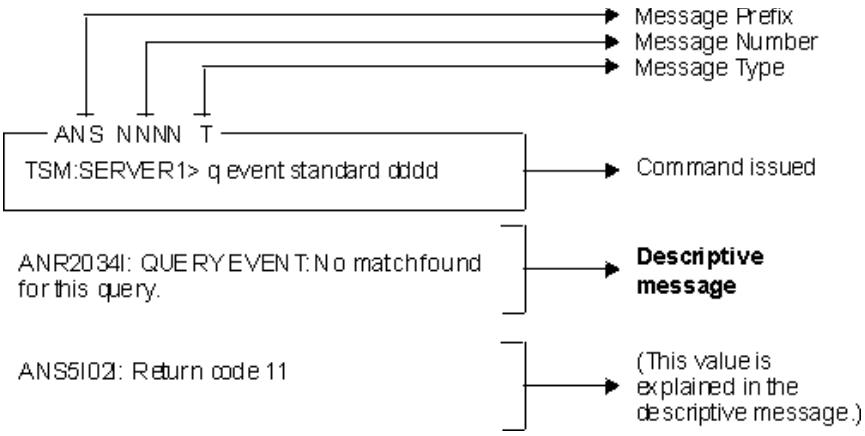
```
ANR2034I: QUERY EVENT: No match found for this query.
```

And the second command also yields a unique, descriptive message:

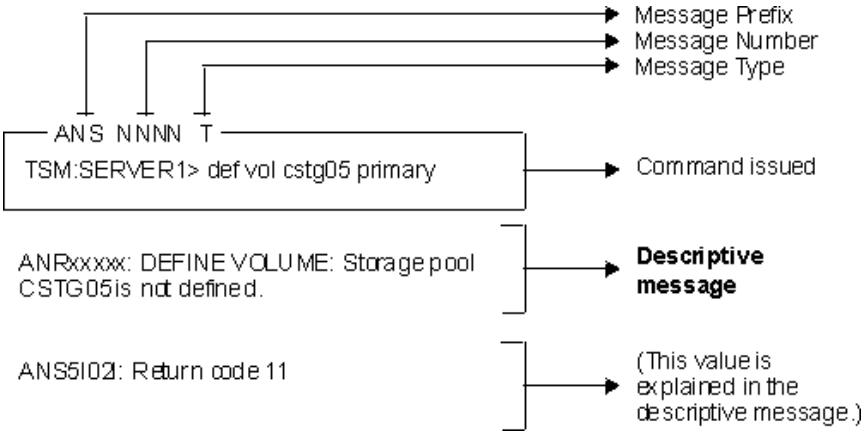
```
ANRxxxx: DEFINE VOLUME: Storage pool CSTG05 is not defined.
```

- Example one for QUERY EVENT command
- Example two for DEFINE VOLUME command

Example one for QUERY EVENT command



Example two for DEFINE VOLUME command



ANE messages

ANE messages are issued by the server. All messages with the ANE prefix are client events logged to the server.

- ANE messages list

ANR messages

ANR messages are issued by the server. Some ANR messages are common to all operating systems, and some are specific to a single operating system.

- ANR messages list

ANS 0000-9999 messages

ANS messages with message numbers in the range 0000-9999 are issued by the following IBM Spectrum Protect™ clients:

- Administrative clients
- Application programming interface clients
- Backup–archive clients
- IBM Spectrum Protect for Space Management (HSM) clients

A list of new and changed messages since the previous product modification level is available in the client_message.chg file in the product installation directory. The lists of new and changed client messages for V8.1.2 and later are also available in the IBM developerWorks wiki.

- ANS messages list

API return codes

IBM Spectrum Protect™ V8.1.2 API return codes are listed. The format of the return codes is described.

In addition, some messages that are issued for SSL processing include GSKit return codes. See IBM Global Security Kit return codes for details.

- API return code format
- API return codes

API return code format

This section explains the API (Application Programming Interface) return code format. For each return code, the following information is provided:

- The return code number. This number corresponds to the number in the **dsmrc.h** header file.
- The severity code. This letter is an indication of the severity that generated the return code. The severity codes and their meanings are:

S	Severe error	Processing cannot continue.
E	Error	Processing cannot continue.
W	Warning	Processing can continue, but problems might develop later. You should be cautious.
I	Information	Processing continues. User response is not necessary.

- The symbolic name. This name corresponds to the definition in the header file, **dsmrc.h**. *Always use the symbolic name for a return code in your application rather than the return code number.*
- The explanation. This field explains the circumstances under which this return code might be generated.
- The system action. This field describes what action IBM Spectrum Protect™ is going to take in response to the return code.
- The user response. This field explains how you should respond to the system action.

Many of the return codes describe errors that cause processing to stop. You can send a message to the end user that describes the problem and suggest a course of action. To identify different messages, use these return code values or develop your own numbering system.

API return codes

IBM Spectrum Protect™ V8.1.2 API return codes are listed in ascending numeric order. The complete return code is documented.

- -452 E
  DSM_RC_SHM_NOTAUTH Insufficient authority to connect to the shared memory region
- -451 E
  DSM_RC_SHM_FAILURE An error occurred using the Shared Memory protocol
- -450 E
  DSM_RC_SHM_TCPIP_FAILURE Session rejected: TCP/IP connection failure for Shared Memory
- -190 E
  DSM_RC_NP_ERROR Session rejected: Named Pipes connection failure.
- -057 E
  DSM_RC_TCPIP_LOADFAILURE The TCP/IP load function failed.
- -056 E
  DSM_RC_TCPIP_DLL_LOADFAILURE An error occurred while loading a library.
- -055 E
  DSM_RC_WINSOCK_MISSING The TCP/IP WINSOCK.DLL file cannot be found.
- -054 E
  DSM_RC_NETWORK_UNREACHABLE The specified TCP/IP host name is unreachable
- -053 E
  DSM_RC_BAD_HOST_NAME An invalid TCP/IP address was specified.
- -052 E
  DSM_RC_CONN_REFUSED An attempt to establish a TCP/IP connection was rejected by the host
- -051 E
  DSM_RC_CONN_TIMEDOUT The attempt to establish a TCP/IP connection timed out before the connection was made.

- -050 E
  DSM_RC_TCPIP_FAILURE Session rejected: TCP/IP connection failure.
- 0000 I
  DSM_RC_OK Successfully done.
- 0001 E
  DSM_RC_ABORT_SYSTEM_ERROR This operation cannot continue due to an error on the IBM Spectrum Protect server. See your IBM Spectrum Protect server administrator for assistance.
- 0002 E
  DSM_RC_ABORT_NO_MATCH No objects on server match query
- 0003 E
  DSM_RC_ABORT_BY_CLIENT Client ended transaction
- 0004 W
  DSM_RC_ABORT_ACTIVE_NOT_FOUND An active backup version could not be found.
- 0005 E
  DSM_RC_ABORT_NO_DATA The IBM Spectrum Protect server has no data for the object.
- 0006 E
  DSM_RC_ABORT_BAD_VERIFIER You entered an incorrect password.
- 0007 E
  DSM_RC_ABORT_NODE_IN_USE Node in use
- 0008 E
  DSM_RC_ABORT_EXPDATE_TOO_LOW Expiration date must be greater than today's date
- 0009 W
  DSM_RC_ABORT_DATA_OFFLINE The requested data is offline.
- 0010 E
  DSM_RC_ABORT_EXCLUDED_BY_SIZE Object too large for server limits
- 0011 E
  DSM_RC_ABORT_NO_REPOSIT_SPACE Server out of data storage space
- 0012 E
  DSM_RC_ABORT_MOUNT_NOT_POSSIBLE Server media mount not possible
- 0013 E
  DSM_RC_ABORT_SIZESTIMATE_EXCEED Size estimate exceeded
- 0014 E
  DSM_RC_ABORT_DATA_UNAVAILABLE File data currently unavailable on server
- 0015 E
  DSM_RC_ABORT_RETRY Unexpected retry request. The IBM Spectrum Protect server found an error while writing the data.
- 0016 E
  DSM_RC_ABORT_NO_LOG_SPACE The server does not have enough recovery log space to continue the current operation
- 0017 E
  DSM_RC_ABORT_NO_DB_SPACE The server does not have enough database space to continue the current operation
- 0018 E
  DSM_RC_ABORT_NO_MEMORY The server does not have enough memory to continue the current operation.
- 0020 E
  DSM_RC_ABORT_FS_NOT_DEFINED The specified file space does not exist on the server. The file space might have been deleted by another client or an administrator.
- 0021 S
  DSM_RC_ABORT_NODE_ALREADY_DEFED Open Registration failed because the specified node name is defined in the server
- 0022 S
  DSM_RC_ABORT_NO_DEFAULT_DOMAIN Open Registration failed because no default domain exists
- 0023 S
  DSM_RC_ABORT_INVALID_NODENAME Open Registration failed because an invalid node name was specified
- 0024 S
  DSM_RC_ABORT_INVALID_POL_BIND A policy management problem has occurred on the IBM Spectrum Protect server.
- 0024 E
  DSM_RC_ABORT_NO_INVALID_POL_BIND An object in the transaction has been bound to an invalid management class.
- 0025 E
  DSM_RC_ABORT_DEST_NOT_DEFINED Server problem: Destination not defined.
- 0026 S
  DSM_RC_ABORT_WAIT_FOR_SPACE The IBM Spectrum Protect server does not currently have space in the storage pool for this file. This may be a temporary condition.
- 0027 E
  DSM_RC_ABORT_NOT_AUTHORIZED The file space cannot be deleted because this node does not have permission to

delete archived or backed up data.

- 0028 E
  DSM_RS_ABORT_RULE_ALREADY_DEFED 'Access rule' Access Rule already defined for node 'node'. Old rule must be deleted before new one can be defined.
- 0029 S
  DSM_RC_ABORT_NO_STOR_SPACE_STOP Server out of data storage space
- 0030 E
  DSM_RC_ABORT_LICENSE_VIOLATION The operation is not permitted due to server licenses values.
- 0032 E
  DSM_RC_ABORT_DUPLICATE_OBJECT A duplicate object was found, operation cannot complete.
- 0033 E
  DSM_RC_ABORT_INVALID_OFFSET partialObjOffset value for partial object retrieve is invalid.
- 0034 E
  DSM_RC_ABORT_INVALID_LENGTH partialObjLength value for partial object retrieve is invalid.
- 0036 E
  DSM_RC_END_NODE_NOT_AUTHORIZED The node or user does not have proper authority to perform this operation
- 0041 E
  DSM_RC_ABORT_EXCEED_MAX_MP This node has exceeded its maximum number of mount points.
- 0045 E
  DSM_RC_ABORT_MERGE_ERROR The specified objects failed the merge test.
- 0047 E
  DSM_RC_ABORT_INVALID_OPERATION An invalid operation was attempted on a node
- 0048 E
  DSM_RC_ABORT_STGPOOL_UNDEFINED The specified target storage pool is not defined.
- 0049 E
  DSM_RC_ABORT_INVALID_DATA_FORMAT A target storage pool does not have the correct data format for the given node type.
- 0050 E
  DSM_RC_ABORT_DATAMOVER_UNDEFINED No associated data mover is defined for the given node.
- 0051 E
  DSM_RC_REJECT_NO_RESOURCES Session rejected: All server sessions are currently in use
- 0052 E
  DSM_RC_REJECT_VERIFIER_EXPIRED The session is rejected. Your password has expired.
- 0053 E
  DSM_RC_REJECT_ID_UNKNOWN Session rejected: User ID is incorrect, does not have admin authority, or is not known by the server
- 0054 E
  DSM_RC_REJECT_DUPLICATE_ID Session rejected: Duplicate ID entered
- 0055 E
  DSM_RC_REJECT_SERVER_DISABLED Session rejected: Server disabled.
- 0056 E
  DSM_RC_REJECT_CLOSED_REGISTER The server is not configured to allow open registration
- 0057 S
  DSM_RC_REJECT_CLIENT_DOWNLEVEL Session rejected: Downlevel client code version
- 0058 S
  DSM_RC_REJECT_SERVER_DOWNLEVEL Session rejected: Downlevel server code version
- 0059 E
  DSM_RC_REJECT_ID_IN_USE Session Rejected: The specified node name is currently in use
- 0061 E
  DSM_RC_REJECT_ID_LOCKED Session Rejected: The specified node name is currently locked.
- 0062 S
  DSM_RC_SIGNONREJECT_LICENSE_MAX SLM LICENSE EXCEEDED: The client licenses for IBM Spectrum Protect are exceeded. See your system administrator.
- 0063 E
  DSM_RC_REJECT_NO_MEMORY Session Rejected: The server does not have enough memory to allow a connection to be established.
- 0064 E
  DSM_RC_REJECT_NO_DB_SPACE Session Rejected: The server does not have enough database space to allow a connection to be established.
- 0065 E
  DSM_RC_REJECT_NO_LOG_SPACE Session Rejected: The server does not have enough recovery log space to allow a connection to be established.

- 0066 E
  DSM_RC_REJECT_INTERNAL_ERROR The session is rejected. The IBM Spectrum Protect server has an internal error.
- 0067 S
  DSM_RC_SIGNONREJECT_INVALID_CLI Session Rejected: The server is not licensed for this platform type. See your system administrator.
- 0068 E
  DSM_RC_CLIENT_NOT_ARCHRETPROT The session is rejected. The server does not allow a signon of a client that is not archive-retention protection enabled.
- 0069 E
  DSM_RC_SESSION_CANCELED Session Rejected: The session was canceled by the server administrator.
- 0073 E
  DSM_RC_REJECT_INVALID_NODE_TYPE An inconsistency was detected between the client node and the node that is registered to the IBM Spectrum Protect server.
- 0074 E
  DSM_RC_REJECT_INVALID_SESSIONINIT Server does not allow client-initiated connections for this node.
- 0075 E
  DSM_RC_REJECT_WRONG_PORT Wrong server port.
- 0079 E
  DSM_RC_CLIENT_NOT_SPMRETPROT The session is rejected. The server does not allow a signon of a client that is not enabled for space-management retention-protection.
- 0101 W
  DSM_RC_USER_ABORT The operation was stopped by the user.
- 0102 E
  DSM_RC_NO_MEMORY file name(line number)The operating system refused a IBM Spectrum Protect request for memory allocation.
- 0104 E
  DSM_RC_FILE_NOT_FOUND File not found during Backup, Archive or Migrate processing
- 0105 E
  DSM_RC_PATH_NOT_FOUND The specified directory path 'pathname' could not be found.
- 0106 E
  DSM_RC_ACCESS_DENIED Access to the specified file or directory is denied
- 0106 E
  DSM_RC_ACCESS_DENIED The specified file is being used by another process
- 0107 E
  DSM_RC_NO_HANDLES No file handles available
- 0108 E
  DSM_RC_FILE_EXISTS The file exists and cannot be overwritten.
- 0109 E
  DSM_RC_INVALID_PARM Invalid parameter was found.
- 0110 E
  DSM_RC_INVALID_HANDLE An invalid file handle was passed; system error.
- 0111 E
  DSM_RC_DISK_FULL Processing stopped; Disk full condition
- 0113 E
  DSM_RC_PROTOCOL_VIOLATION Protocol violation
- 0114 E
  DSM_RC_UNKNOWN_ERROR An unknown system error has occurred from which IBM Spectrum Protect cannot recover.
- 0115 E
  DSM_RC_UNEXPECTED_ERROR An unexpected error occurred.
- 0116 E
  DSM_RC_FILE_BEING_EXECUTED File is in use; Write permission denied.
- 0117 E
  DSM_RC_DIR_NO_SPACE No more files can be restored or retrieved since the destination directory is full.
- 0118 E
  DSM_RC_LOOPED_SYM_LINK Too many symbolic links were detected while resolving name
- 0119 E
  DSM_RC_FILE_NAME_TOO_LONG The file name is too long and can not be processed by IBM Spectrum Protect
- 0120 E
  DSM_RC_FILE_SPACE_LOCKED File system is locked by system
- 0121 I
  DSM_RC_FINISHED The operation is finished.

- 0122 E
  DSM_RC_UNKNOWN_FORMAT The file has an unknown format.
- 0123 E
  DSM_RC_NO_AUTHORIZATION Not authorized to restore the other node's data.
- 0124 E
  DSM_RC_FILE_SPACE_NOT_FOUND File space 'filespace-name' does not exist
- 0125 E
  DSM_RC_TXN_ABORTED Transaction aborted
- 0126 E
  DSM_RC_SUBDIR_AS_FILE IBM Spectrum Protect cannot build a directory path because a file exists with the same name as the directory.
- 0127 E
  DSM_RC_PROCESS_NO_SPACE Disk space limit for this process reached
- 0128 E
  DSM_RC_PATH_TOO_LONG Destination directory path length exceeds system maximum
- 0129 E
  DSM_RC_NOT_COMPRESSED File is not compressed; System failure.
- 0130 E
  DSM_RC_TOO_MANY_BITS File compressed on a different client machine that has more memory
- 0131 E
  DSM_RC_COMPRESSED_DATA_CORRUPTED The compressed file is corrupted and cannot be expanded correctly.
- 0131 S
  DSM_RC_SYSTEM_ERROR An internal program error occurred.
- 0132 E
  DSM_RC_NO_SERVER_RESOURCES The IBM Spectrum Protect server is out of resources.
- 0133 E
  DSM_RC_FS_NOT_KNOWN The file space for domain 'domain-name' could not be found on the IBM Spectrum Protect server.
- 0134 E
  DSM_RC_NO_LEADING_DIRSEP The objName field has no leading directory separator.
- 0135 E
  DSM_RC_WILDCARD_DIR Wildcards are not allowed in the objName directory path.
- 0136 E
  DSM_RC_COMM_PROTOCOL_ERROR The session is rejected: There was a communications protocol error.
- 0137 E
  DSM_RC_AUTH_FAILURE Session rejected: Authentication failure
- 0138 E
  DSM_RC_TA_NOT_VALID The dsmtca execution/owner permissions are invalid.
- 0139 S
  DSM_RC_KILLED Process killed.
- 0145 S
  DSM_RC_WOULD_BLOCK The dsmtca would block the operation.
- 0146 S
  DSM_RC_TOO_SMALL The area for the include/exclude pattern is too small.
- 0147 S
  DSM_RC_UNCLOSED There is no closing bracket in the pattern.
- 0148 S
  DSM_RC_NO_STARTING_DELIMITER Include/Exclude pattern must start with a directory delimiter
- 0149 S
  DSM_RC_NEEDED_DIR_DELIMITER A beginning or ending directory delimiter is missing from the Include/Exclude pattern.
- 0151 S
  DSM_RC_BUFFER_OVERFLOW The data buffer overflowed.
- 0154 E
  DSM_RC_NO_COMPRESS_MEMORY Insufficient memory for file compression/expansion
- 0155 T
  DSM_RC_COMPRESS_GREW Compressed Data Grew
- 0156 E
  DSM_RC_INV_COMM_METHOD An unsupported communications method was specified.
- 0157 S
  DSM_RC_WILL_ABORT The transaction will be aborted.
- 0158 E
  DSM_RC_FS_WRITE_LOCKED Destination file or directory is write locked

- 0159 I
  DSM_RC_SKIPPED_BY_USER A file was skipped during a restore operation because the file is off line and the application has chosen not to wait for a tape mount.
- 0160 E
  DSM_RC_TA_NOT_FOUND Unable to find the dsmtca module.
- 0162 E
  DSM_RC_FS_NOT_READY File system/drive not ready
- 0164 E
  DSM_RC_FIO_ERROR File input/output error
- 0165 E
  DSM_RC_WRITE_FAILURE File write error
- 0166 E
  DSM_RC_OVER_FILE_SIZE_LIMIT File exceeds system/user file limits
- 0167 E
  DSM_RC_CANNOT_MAKE Cannot make file/directory
- 0168 E
  DSM_RC_NO_PASS_FILE Password file is not available.
- 0169 E
  DSM_RC_VERFILE_OLD PASSWORDACCESS is GENERATE, but password needed for server 'server-name'. Either the password is not stored locally, or it was changed at the server.
- 0173 E
  DSM_RC_INPUT_ERROR The process is running in a non-interactive mode, but requires user input.
- 0174 E
  DSM_RC_REJECT_PLATFORM_MISMATCH Session rejected: Node type mismatch
- 0175 E
  DSM_RC_TL_NOT_FILE_OWNER Not file owner
- 0177 S
  DSM_RC_UNMATCHED_QUOTE Quotes are not matched
- 0184 E
  DSM_RC_TL_NOBCG The management class for this file does not have a valid backup copy group. This file will not be backed up.
- 0185 W
  DSM_RC_TL_EXCLUDED File 'file-namefile-namefile-name' excluded by Include/Exclude list
- 0186 E
  DSM_RC_TL_NOACG The management class for this file does not have a valid archive copy group. This file will not be archived.
- 0187 E
  DSM_RC_PS_INVALID_ARCHMC Invalid management class entered
- 0188 S
  DSM_RC_NO_PS_DATA Either the node does not exist on the server or there is no active policy set for the node.
- 0189 S
  DSM_RC_PS_INVALID_DIRMC The management class assigned to directories does not exist.
- 0190 S
  DSM_RC_PS_NO_CG_IN_DIR_MC There is no backup copy group in the management class used for directories.
- 0231 E
  DSM_RC_ABORT_MOVER_TYPE Unknown Remote Mover type
- 0232 E
  DSM_RC_ABORT_ITEM_IN_USE An Operation for the requested node and file space is already in progress.
- 0233 E
  DSM_RC_ABORT_LOCK_CONFLICT System resource in use
- 0234 E
  DSM_RC_ABORT_SRV_PLUGIN_COMM_ERROR Server plugin communication error
- 0235 E
  DSM_RC_ABORT_SRV_PLUGIN_OS_ERROR Server plugin detected unsupported NAS filer operating system.
- 0236E
  DSM_RC_ABORT_CRC_FAILED The CRC received from the Server does not match the CRC calculated by the client.
- 0237E
  DSM_RC_ABORT_INVALID_GROUP_ACTION An invalid operation was attempted on a group leader or group member.
- 0238E
  DSM_RC_ABORT_DISK_UNDEFINED Remote disk not defined.
- 0239E
  DSM_RC_ABORT_BAD_DESTINATION Input destination does not match expected destination.

- 0240E
  DSM_RC_ABORT_DATAMOVER_NOT_AVAILABLE Data mover is not available.
- 0241E
  DSM_RC_ABORT_STGPOOL_COPY_CONT_NO Operation failed because the copy continue option was set to NO.
- 0242E
  DSM_RC_ABORT_RETRY_SINGLE_TXN Transaction failed because of a problem during a store operation.
- 0245 E
  DSM_RC_ABORT_PATH_RESTRICTED The current client configuration does not comply with the value of the DATAWRITEPATH or DATAREADPATH server option for this node.
- 0247 E
  DSM_RC_ABORT_INSERT_NOT_ALLOWED This server does not support backup operations.
- 0248 E
  DSM_RC_ABORT_DELETE_NOT_ALLOWED Deleting this object: "fshlll" is not allowed.
- 0249 E
  DSM_RC_ABORT_TXN_LIMIT_EXCEEDED The number of objects in this transaction exceed TXNGROUPMAX values.
- 0250 E
  DSM_RC_ABORT_OBJECT_ALREADY_HELD fshlll is already under hold.
- 0292 E
  DSM_RC_TCA_FORK_FAILED Error starting the dsmtca or dsmenc process.
- 0295 E
  DSM_RC_TCA_INVALID_REQUEST The IBM Spectrum Protect dsmtca received an invalid request.
- 0296 E
  DSM_RC_TCA_NOT_ROOT This action requires IBM Spectrum Protect administrative authority on this system.
- 0297 E
  DSM_RC_TCA_SEMGET_ERROR Error allocating semaphores.
- 0298 E
  DSM_RC_TCA_SEM_OP_ERROR Error setting semaphore value or waiting on semaphore.
- 0400 E
  DSM_RC_INVALID_OPT An invalid option was found during option parsing.
- 0405 E
  DSM_RC_NO_HOST_ADDR TCPSERVERADDRESS not defined for this server in the System Options File
- 0406 S
  DSM_RC_NO_OPT_FILE Options file 'file-name' could not be found, or it cannot be read.
- 0408 E
  DSM_RC_MACHINE_SAME A virtual node name must not equal either a node name or the system host name.
- 0409 E
  DSM_RC_INVALID_SERVER Server name not found in System Options File
- 0410 E
  DSM_RC_INVALID_KEYWORD An invalid option keyword was found during option parsing.
- 0411 S
  DSM_RC_PATTERN_TOO_COMPLEX The include or exclude pattern cannot be parsed.
- 0412 S
  DSM_RC_NO_CLOSING_BRACKET Include/Exclude pattern is missing a closing bracket
- 0426 E
  DSM_RC_CANNOT_OPEN_TRACEFILE Initialization functions cannot open the trace file specified.
- 0427 E
  DSM_RC_CANNOT_OPEN_LOGFILE Initialization functions cannot open the error log file specified.
- 0600 E
  DSM_RC_DUP_LABEL A duplicate volume label exists. The operation cannot continue.
- 0601 E
  DSM_RC_NO_LABEL The drive has no label. The operation cannot continue.
- 0610 E
  DSM_RC_NLS_CANT_OPEN_TXT Unable to open message text file.
- 0611 E
  DSM_RC_NLS_CANT_READ_HDR Unable to use message text file.
- 0612 E
  DSM_RC_NLS_INVALID_CNTL_REC Unable to use message text file.
- 0613 E
  DSM_RC_NLS_INVALID_DATE_FMT Invalid value for DATEFORMAT specified.
- 0614 E
  DSM_RC_NLS_INVALID_TIME_FMT Invalid value for TIMEFORMAT specified.

- 0615 E
  DSM_RC_NLS_INVALID_NUM_FMT Invalid value for NUMBERFORMAT specified.
- 0620 E
  DSM_RC_LOG_CANT_BE_OPENED Unable to open error log file.
- 0621 E
  DSM_RC_LOG_ERROR_WRITING_TO_LOG The log file cannot be written to.
- 0622 E
  DSM_RC_LOG_NOT_SPECIFIED The log file name was not specified.
- 0927 E
  DSM_RC_NOT_ADSM_AUTHORIZED Only a IBM Spectrum Protect authorized user can perform this Action.
- 961 E
  DSM_RC_DIRECT_STORAGE_AGENT_UNSUPPORTED Direct connection to the Storage Agent is not allowed.
- 963 E
  DSM_RC_FS_NAMESPACE_DOWNLEVEL The long namespace has been removed from the local file space. If you wish to proceed with the backup/archive operation, rename your file space on the server.
- 0996 E
  DSM_RC_SERVER_DOWNLEVEL_FUNC The IBM Spectrum Protect server is downlevel and does not support the requested function. See error log for version information.
- 0997 E
  DSM_RC_STORAGEAGENT_DOWNLEVEL The IBM Spectrum Protect Storage Agent is downlevel and does not support the requested function. See error log for version information.
- 0998 E
  DSM_RC_SERVER_AND_SA_DOWNLEVEL The IBM Spectrum Protect Server and IBM Spectrum Protect Storage agent are downlevel and do not support the requested function. See error log for version information.
- 1376 E
  DSM_RC_DIGEST_VALIDATION_ERROR Error processing 'filespace namepath-namefile-name'; end-to-end digest validation failed.
- 2000 E
  DSM_RC_NULL_OBJNAME The object name pointer is NULL.
- 2001 E
  DSM_RC_NULL_DATABLKPTR The data block pointer is NULL.
- 2002 E
  DSM_RC_NULL_MSG msg parameter for dsmRCMsg is a NULL pointer.
- 2004 E
  DSM_RC_NULL_OBJATTRPTR The object attribute pointer is NULL.
- 2006 E
  DSM_RC_NO_SESS_BLK There is no server session information.
- 2007 E
  DSM_RC_NO_POLICY_BLK There is no server policy information.
- 2008 E
  DSM_RC_ZERO_BUFLEN The dataBlk bufferLen value is zero.
- 2009 E
  DSM_RC_NULL_BUFPTR The dataBlk bufferPtr is NULL.
- 2010 E
  DSM_RC_INVALID_OBJTYPE The objType is invalid.
- 2011 E
  DSM_RC_INVALID_VOTE The dsmEndTxn vote is invalid.
- 2012 E
  DSM_RC_INVALID_ACTION The update action is invalid.
- 2014 E
  DSM_RC_INVALID_DS_HANDLE There was an error in the IBM Spectrum Protect API internals.
- 2015 E
  DSM_RC_INVALID_REPOS The repository type is invalid.
- 2016 E
  DSM_RC_INVALID_FSNAME Filespace name should start with the directory delimiter.
- 2017 E
  DSM_RC_INVALID_OBJNAME The object name is either an empty string or has no leading delimiter.
- 2018 E
  DSM_RC_INVALID_LLNAME Low level qualifier of the object name should start with the directory delimiter.
- 2019 E
  DSM_RC_INVALID_OBJOWNER The object owner is invalid.

- 2020 E
  DSM_RC_INVALID_ACTYPE The dsmBindMC sendType is invalid.
- 2021 E
  DSM_RC_INVALID_RETCODE no text available for this return code.
- 2022 E
  DSM_RC_INVALID_SENDTYPE The dsmSendObj sendType is invalid.
- 2023 E
  DSM_RC_INVALID_PARAMETER The dsmDeleteObj delType is invalid.
- 2024 E
  DSM_RC_INVALID_OBJSTATE The query Backup objState is invalid.
- 2025 E
  DSM_RC_INVALID_MCNAME The management class name was not found.
- 2026 E
  DSM_RC_INVALID_DRIVE_CHAR The drive letter is not an alphabetic character.
- 2027 E
  DSM_RC_NULL_FSNAME The Register Filespace name is NULL.
- 2028 E
  DSM_RC_INVALID_HLNAME High level qualifier of the object name should start with the directory delimiter.
- 2029 E
  DSM_RC_NUMOBJ_EXCEED The number of objects on dsmBeginGetData exceeds DSM_MAX_GET_OBJ | DSM_MAX_PARTIAL_GET_OBJ.
- 2030 E
  DSM_RC_NEWPW_REQD The new password value is NULL or blank.
- 2031 E
  DSM_RC_OLDPW_REQD The old password value is NULL or blank.
- 2032 E
  DSM_RC_NO_OWNER_REQD On dsmInit, the owner is not allowed to establish a session when PASSWORDACCESS=generate.
- 2033 E
  DSM_RC_NO_NODE_REQD On dsmInit, the node is not allowed when PASSWORDACCESS=generate.
- 2034 E
  DSM_RC_KEY_MISSING The key file is missing.
- 2035 E
  DSM_RC_KEY_BAD The key file content is invalid.
- 2041 E
  DSM_RC_BAD_CALL_SEQUENCE The sequence of calls is invalid.
- 2042 E
  DSM_RC_INVALID_TSMBUFFER The tsmBuffHandle is invalid, or the value of dataPtr is invalid.
- 2043 E
  DSM_RC_TOO_MANY_BYTES The number of bytes copied into the tsmBuffer is larger than the allowed value.
- 2044 E
  DSM_RC_MUST_RELEASE_BUFFER dsmTerminate cannot finish because the application is holding on to 1 or more tsmBuffers.
- 2045 E
  DSM_RC_BUFF_ARRAY_ERROR An internal error occurred in the tsmBuffer array.
- 2046 E
  DSM_RC_INVALID_DATABLK When using useTsmBuffers, dataBlk must be NULL in calls to dsmSendObj and dsmGetObj.
- 2047 E
  DSM_RC_ENCR_NOT_ALLOWED Encryption is not allowed when using useTsmBuffers.
- 2048 E
  DSM_RC_OBJ_COMPRESSED This object cannot be restored/retrieved using useTsmBuffers, because it is compressed.
- 2049 E
  DSM_RC_OBJ_ENCRYPTED This object cannot be restored/retrieved using useTsmBuffers, because it is encrypted.
- 2050 E
  DSM_RC_WILDCHAR_NOTALLOWED On dsmSendObj, wildcards are not allowed for the objName.
- 2051 E
  DSM_RC_POR_NOT_ALLOWED When using useTsmBuffers, a restore/retrieve with partial object restore is not allowed.
- 2052 E
  DSM_RC_NO_ENCRYPTION_KEY No encryption key was found. If you are using -encryptkey=prompt make sure there is a value in the encryptionPasswordP field and that bEncryptKeyEnabled is set to true.
- 2053 E
  DSM_RC_ENCR_CONFLICT Conflicting encryption key options have been specified.

- 2060 E
  DSM_RC_FSNAME_NOTFOUND The filespace to delete/set access cannot be found.
- 2061 E
  DSM_RC_FS_NOT_REGISTERED On dsmSendObj, dsmDeleteObj, or dsmUpdateFS the filespace is not registered.
- 2062 W
  DSM_RC_FS_ALREADY_REGED On dsmRegisterFS the filespace is already registered.
- 2063 E
  DSM_RC_OBJID_NOTFOUND On dsmBeginGetData the objID is NULL.
- 2064 E
  DSM_RC_WRONG_VERSION On dsmInit, the caller API version is different than the IBM Spectrum Protect library version.
- 2065 E
  DSM_RC_WRONG_VERSION_PARM The caller's structure version is different than the IBM Spectrum Protect library version.
- 2070 E
  DSM_RC_NEEDTO_ENDTXN Issue dsmEndTxn and then begin a new transaction session.
- 2080 E
  DSM_RC_OBJ_EXCLUDED The backup or archive object is excluded from processing.
- 2081 E
  DSM_RC_OBJ_NOBCG The backup object does not have a copy group.
- 2082 E
  DSM_RC_OBJ_NOACG The archive object does not have a copy group.
- 2090 E
  DSM_RC_APISYSTEM_ERROR Memory used by the IBM Spectrum Protect API has been corrupted.
- 2100 E
  DSM_RC_DESC_TOOLONG The sendObj Archive description is too long.
- 2101 E
  DSM_RC_OBJINFO_TOOLONG The sendObj ObjAttr.objInfo is too long.
- 2102 E
  DSM_RC_HL_TOOLONG The sendObj dsmObjName.hl is too long.
- 2103 E
  DSM_RC_PASSWD_TOOLONG The password, or encryptionPassword string provided is too long.
- 2104 E
  DSM_RC_FILESPACE_TOOLONG The sendObj dsmObjName.fs is too long.
- 2105 E
  DSM_RC_LL_TOOLONG The sendObj dsmObjName.ll is too long.
- 2106 E
  DSM_RC_FSINFO_TOOLONG On RegisterFS or UpdateFS the fsAttr's fsInfo is too long.
- 2107 E
  DSM_RC_SENDDATA_WITH_ZERO_SIZE Cannot Send data with a zero byte sizeEstimate.
- 2110 E
  DSM_RC_INVALID_ACCESS_TYPE The dsmSetAccess access Type is invalid.
- 2111 E
  DSM_RC_QUERY_COMM_FAILURE Communications error with server during object query
- 2112 E
  DSM_RC_NO_FILES_BACKUP No files have been previously backed up for this filename/filespace.
- 2113 E
  DSM_RC_NO_FILES_ARCHIVE No files have been previously archived for this filename/filespace.
- 2114 E
  DSM_RC_INVALID_SETACCESS Invalid format for Set Access command.
- 2120 E
  DSM_RC_STRING_TOO_LONG The following message was too long to log to the server: 'shortened message with message number'
- 2200 I
  DSM_RC_MORE_DATA On dsmGetNextQObj or dsmGetData there is more available data.
- 2210 E
  DSM_RC_BUFF_TOO_SMALL The dataBlk buffer is too small for the query response.
- 2228 E
  DSM_RC_NO_API_CONFIGFILE The configuration file specified on dsmInit cannot be opened.
- 2229 E
  DSM_RC_NO_INCLEXCL_FILE The Include/Exclude definition file was not found.
- 2230 E
  DSM_RC_NO_SYS_OR_INCLEXCL Either the dsm.sys file was not found, or the Inclexcl file specified in dsm.sys was not

found.

- 2231 E
  DSM_RC_REJECT_NO_POR_SUPPORT Partial Object Retrieve is not supported on this server.
- 2300 E
  DSM_RC_NEED_ROOT Only a UNIX root user can execute dsmChangePW or dsmDeleteFS.
- 2301 E
  DSM_RC_NEEDTO_CALL_BINDMC You must issue dsmBindMC before dsmSendObj.
- 2302 I
  DSM_RC_CHECK_REASON_CODE The dsmEndTxn vote is ABORT, so check the reason field.
- 2400 E
  DSM_RC_ALMGR_OPEN_FAIL License file could not be opened.
- 2401 E
  DSM_RC_ALMGR_READ_FAIL Read failure on the license file.
- 2402 E
  DSM_RC_ALMGR_WRITE_FAIL Write failure on the license file.
- 2403 E
  DSM_RC__ALMGR_DATA_FMT Data in the license file is not in a valid format.
- 2404 E
  DSM_RC_ALMGR_CKSUM_BAD The checksum in the license file does not match the licenseregistration string.
- 2405 E
  DSM_RC_ALMGR_TRIAL_EXPRD This is an expired try and buy license.
- 4580 E
  DSM_RC_ENC_WRONG_KEY Error processing 'filespace namepath-namefile-name'; invalid encryption key.
- 4582 E
  DSM_RC_ENC_NOT_AUTHORIZED User is not authorized to encrypt file-space namedirectory_pathfile_name.
- 4584 E
  DSM_RC_ENC_TYPE_UNKOWN Error processing 'filespace namepath-namefile-name': unsupported encryption type.
- 4600 E
  DSM_RC_CLUSTER_INFO_LIBRARY_NOT_LOADED CLUSTERNODE is set to YES but the Cluster Information Daemon is notstarted.
- 4601 E
  DSM_RC_CLUSTER_LIBRARY_INVALID CLUSTERNODE is set to YES but the cluster load library is not valid.
- 4602 E
  DSM_RC_CLUSTER_LIBRARY_NOT_LOADED CLUSTERNODE is set to YES but the cluster software is not availableon this system.
- 4603 E
  DSM_RC_CLUSTER_NOT_MEMBER_OF_CLUSTER CLUSTERNODE is set to YES but this machine is not a member of acluster.
- 4604 E
  DSM_RC_CLUSTER_NOT_ENABLED CLUSTERNODE is set to YES but the cluster service is not enabledon this system.
- 4605 E
  DSM_RC_CLUSTER_NOT_SUPPORTED The CLUSTERNODE option is not supported on this system.
- 4606 E
  DSM_RC_CLUSTER_UNKNOWN_ERROR An unexpected error (retcode) occurred while the program was trying to obtain the cluster name from the system.
- 5200 E
  DSM_RC_ABORT_CERTIFICATE_NOT_FOUND The remote node is not properly configured on the IBM Spectrum Protect server.
- 5702 E
  DSM_RC_PROXY_REJECT_NO_RESOURCES Proxy Rejected: The IBM Spectrum Protect server has run out of memory.
- 5705 E
  DSM_RC_PROXY_REJECT_DUPLICATE_ID Proxy Rejected: The ASNODENAME and NODENAME options have the same value.
- 5710 E
  DSM_RC_PROXY_REJECT_ID_IN_USE Proxy Rejected: The node name you specified in the ASNODENAME option is locked.
- 5717 E
  DSM_RC_PROXY_REJECT_INTERNAL_ERROR Proxy Rejected: The server has an internal error.
- 5722 E
  DSM_RC_PROXY_REJECT_NOT_AUTHORIZED Proxy Rejected: Proxy authority has not been granted to this node.
- 5746 E
  DSM_RC_PROXY_INVALID_FROMNODE The ASNODENAME option is not valid with the FROMNODE option.
- 5748 E
  DSM_RC_PROXY_INVALID_CLUSTER The ASNODENAME option cannot be used with the CLUSTERNODE option.

- 5749 E
  DSM_RC_PROXY_INVALID_FUNCTION The operation that is being attempted cannot be invoked using the ASNODENAME option.
- 5801 E
  DSM_RC_CRYPTO_ICC_ERROR Unexpected error in cryptography library.

-452 E DSM_RC_SHM_NOTAUTH Insufficient authority to connect to the shared memory region

Explanation

The user issuing the command does not have authority to connect to the shared memory segment. When the shared memory segment is created by the server, it will be owned by the effective uid of the server process (dsmserv). Only processes running under this uid or root will be allowed to connect to the segment (and thus to the server).

System action

The session is rejected and processing stops.

User response

Run the command under the uid of the processing running dsmserv, if possible. Otherwise contact your system administrator for further help.

-451 E DSM_RC_SHM_FAILURE An error occurred using the Shared Memory protocol

Explanation

An error has occurred while reading or writing data through the Shared Memory communications protocol.

System action

IBM Spectrum Protect cannot complete the requested operation.

User response

Check the trace log for additional information and retry the operation. If the problem continues, see your system administrator for further help.

-450 E DSM_RC_SHM_TCPIP_FAILURE Session rejected: TCP/IP connection failure for Shared Memory

Explanation

An attempt to connect to the local server using the Shared Memory protocol has failed during initial TCP/IP communications. This error can occur if the server is not listening on the correct port, or if the server is down.

System action

Session rejected. Processing stopped.

User response

Retry the operation, or wait until the server comes back up and retry the operation. If the problem continues, see your system administrator for further help.

-190 E DSM_RC_NP_ERROR Session rejected: Named Pipes connection failure.

Explanation

An attempt to connect to the server using Named Pipes communications failed. This might have occurred if an incorrect NAMEDPIPENAME was specified in the options files or if your system administrator canceled a backup operation.

System action

Processing stopped.

User response

Retry the operation, or wait until the server comes back up and retry the operation. Ensure that the value specified on the NAMEDPIPENAME option is the same as the one used by the server. If the problem continues, contact your system administrator for further help.

-057 E DSM_RC_TCPIP_LOADFAILURE The TCP/IP load function failed.

Explanation

An error occurred while locating a function. The TCP/IP load function failed.

System action

Processing stopped.

User response

Verify your TCP/IP installation.

-056 E DSM_RC_TCPIP_DLL_LOADFAILURE An error occurred while loading a library.

Explanation

An error occurred while loading a library. The TCP/IP DLL load failed.

System action

Processing stopped.

User response

Verify your TCP/IP installation.

-055 E DSM_RC_WINSOCK_MISSING The TCP/IP WINSOCK.DLL file cannot be found.

Explanation

The TCP/IP WINSOCK.DLL file cannot be found.

System action

Processing stopped.

User response

Verify your TCP/IP installation.

-054 E DSM_RC_NETWORK_UNREACHABLE The specified TCP/IP host name is unreachable

Explanation

The TCP/IP host name specified in the TCPSERVERADDRESS statement cannot be reached.

System action

Processing stopped.

User response

Check your options file for the correct TCPSERVERADDRESS statement. See your administrator for the correct name of the server.

-053 E DSM_RC_BAD_HOST_NAME An invalid TCP/IP address was specified.

Explanation

The TCP/IP address specified by the IBM Spectrum Protect client's TCPSERVERADDRESS setting could not be found on the network. Common reasons for this error include:

- The TCPSERVERADDRESS client option specifies the wrong TCP/IP address for the IBM Spectrum Protect server".
- The machine that hosts the IBM Spectrum Protect server is not on the network.
- A network problem is preventing the IBM Spectrum Protect client from reaching the machine that hosts the IBM Spectrum Protect server.

System action

processing stops.

User response

Verify that the TCPSERVERADDRESS and TCPPORT settings have the correct values for your IBM Spectrum Protect server. Use your operating system's "ping" (or similar) utility to ensure that your machine can locate the machine that hosts the IBM Spectrum Protect server across the network. Try the operating again. If the problem persists, ask your IBM Spectrum Protect administrator for further assistance.

-052 E DSM_RC_CONN_REFUSED An attempt to establish a TCP/IP connection was rejected by the host

Explanation

An attempt to establish a TCP/IP connection was rejected by the server.

System action

Processing stopped.

User response

The server was not fully initialized, is not currently running, was not enabled for TCP/IP communications, or an incorrect TCP/IP port number was specified. If the problem continues, see your system administrator.

-051 E DSM_RC_CONN_TIMEDOUT The attempt to establish a TCP/IP connection timed out before the connection was made.

Explanation

The Object of the connection attempt failed to respond within the the allotted wait time. In the case of the B/A client, this message is preceded in dsmerror.log by message ANS5216E that gives details of the connection that failed. The condition may be temporary.

System action

processing stops.

User response

- Restart the IBM Spectrum Protect client and retry the operation.
- Check the client options file and verify that TCPSERVERADDRESS and TCPPORT specify the correct TCP/IP address and port number for your IBM Spectrum Protect server.
- Verify that network connectivity exists between the IBM Spectrum Protect client machine and the IBM Spectrum Protect server machine.
- If the problem persists, see your IBM Spectrum Protect administrator for further assistance.

-050 E DSM_RC_TCPIP_FAILURE Session rejected: TCP/IP connection failure.

Explanation

An attempt to connect to the server using TCP/IP communications failed. This can be a result of incorrect TCP/IP option settings in your client options file. This error can also occur if the LAN connection went down or if your system administrator canceled a backup operation.

System action

Session rejected. Processing stopped.

User response

Retry the operation, or wait until the server comes back up and retry the operation. If the problem continues, see your system administrator for further help.

0000 I DSM_RC_OK Successfully done.

Explanation

The operation successfully completed.

System action

None.

User response

None.

0001 E DSM_RC_ABORT_SYSTEM_ERROR This operation cannot continue due to an error on the IBM Spectrum Protect server. See your IBM Spectrum Protect server administrator for assistance.

Explanation

The IBM Spectrum Protect server encountered an error condition that prevents the IBM Spectrum Protect client operation from continuing. Your IBM Spectrum Protect server administrator can review the IBM Spectrum Protect server activity log for more details about the error.

System action

Processing stopped.

User response

Contact your IBM Spectrum Protect server administrator for assistance. The administrator can review the IBM Spectrum Protect server activity log for further information about the conditions that lead to this error.

0002 E DSM_RC_ABORT_NO_MATCH No objects on server match query

Explanation

No objects on the server match the query operation being performed. If this object is part of a backupset generated on a node, and the node name is changed on the server, any backup set objects that were generated prior to the name change will not match the new node name.

System action

Processing stopped.

User response

Ensure the names are properly entered. If the object is part of a backupset generated prior to a node name change, ensure that the node name is the same as the node for which the backup set was generated.

0003 E DSM_RC_ABORT_BY_CLIENT Client ended transaction

Explanation

The client system ended the operation with the server and ended the current transaction.

System action

Processing stopped.

User response

Restart the session.

0004 W DSM_RC_ABORT_ACTIVE_NOT_FOUND An active backup version could not be found.

Explanation

An attempt was made to expire an object, but the IBM Spectrum Protect server was unable to find an active backup version of the object. This message is preceded by message ANS1228E which specifies the object name.

For instance, this message could be issued if two separate client processes are backing up the same file system at the same time. If one of the processes expires a file, then the IBM Spectrum Protect server will make that file inactive. If the second process subsequently attempts to expire that same file, the IBM Spectrum Protect server will not find an active version of the file, so the second process will issue this message for that file.

System action

The object is not expired. Processing continues with the next object.

User response

- Review the console output, schedule log, or error log and locate the ANS1228E message that immediately precedes this message. ANS1228E will identify the object that could not be expired.
- Examine the conditions under which the problem occurred and assess whether those conditions explain the occurrence of this message. For example, this message could appear if multiple instances of the client were attempting to back up the file system concurrently.

- If the reason this message occurred can not be determined and the message occurs when the operation is tried again, then contact IBM support for further assistance. Also try searching for this message number on http://www.ibm.com for possible solutions.

0005 E DSM_RC_ABORT_NO_DATA The IBM Spectrum Protect server has no data for the object.

Explanation

IBM Spectrum Protect tried to do a restore or retrieve on an object that has no data associated with it. If a corrective action is possible, it is with the IBM Spectrum Protect server.

System action

IBM Spectrum Protect ends the current operation.

User response

Ask the IBM Spectrum Protect administrator to check the IBM Spectrum Protect activity log for any messages related to this error that might help identify the problem.

0006 E DSM_RC_ABORT_BAD_VERIFIER You entered an incorrect password.

Explanation

You entered an incorrect current password or you entered a new password that does not fulfill the password length requirements set on the server.

System action

Processing stops.

User response

Retry the session with the correct password. If this fails or you have forgotten your password, ask the IBM Spectrum Protect administrator to assign a new password.

0007 E DSM_RC_ABORT_NODE_IN_USE Node in use

Explanation

The node you are running on is in use by another operation on the server. This might be from another client or from some activity on the server.

System action

Processing stopped.

User response

Retry the operation, or see your system administrator to see what other operations are running for your node.

0008 E DSM_RC_ABORT_EXPDATE_TOO_LOW Expiration date must be greater than today's date

Explanation

Archive expiration date is too low, the date must be greater than today's date.

System action

IBM Spectrum Protect canceled the current operation.

User response

Retry archiving the file with an expiration date that is higher than today's date.

0009 W DSM_RC_ABORT_DATA_OFFLINE The requested data is offline.

Explanation

For the restore or retrieve operation, one or more of the requested files must be recalled from offline storage media (generally tape). The wait time depends on your site's offline storage management policies.

System action

IBM Spectrum Protect waits for offline storage media to become available and then continues.

User response

None.

0010 E DSM_RC_ABORT_EXCLUDED_BY_SIZE Object too large for server limits

Explanation

The object is too large. The configuration of the server does not have any data storage space that accepts the object.

System action

File skipped.

User response

See your system administrator to determine the maximum file (object) size for which your site's server is configured.

0011 E DSM_RC_ABORT_NO_REPOSIT_SPACE Server out of data storage space

Explanation

The server does not have any space available to store the object.

System action

Processing Ends.

User response

You can take any of the following actions:

- Request the system administrator to add space to the storage pool.
- For IBM Spectrum Protect client, set COMPRESSALWAYS=NO and COMPRESSIon=YES in the options file (DSM.OPT), then the file will be resent uncompressed if it grows during compression.
- For API Applications, consult the application's documentation for recommendations regarding compression.
- Turn off disk caching in the disk storage pool, and issue MOVE DATA commands to each disk pool volume to clear out the cached bitfiles.

0012 E DSM_RC_ABORT_MOUNT_NOT_POSSIBLE Server media mount not possible

Explanation

Server media mount not possible. The server timed out waiting for a mount of an offline volume.

System action

File skipped.

User response

Retry later when server volumes can be mounted. Ensure that the MAXNUMMP (maximum number of mount points) defined on the server for this node is greater than 0.

0013 E DSM_RC_ABORT_SIZESTIMATE_EXCEED Size estimate exceeded

Explanation

The total amount of data for a backup or archive operation exceeds the estimated size originally sent to the server for allocating data storage space. This happens when many files are growing by large amounts while the backup or archive operation is in session.

System action

Processing stopped.

User response

Retry the operation. If the problem continues, check what other processes are running on the client machine that are generating large amounts of data. Disable those operations while the backup or archive operation is taking place.

0014 E DSM_RC_ABORT_DATA_UNAVAILABLE File data currently unavailable on server

Explanation

The file data is currently unavailable on the server. A retrieve or restore operation was attempted. Possible causes are:

- Data was corrupted at the server
- Server found a read error
- File is temporarily involved in a reclaim operation at the server
- Server requested a tape volume that was marked unavailable.

System action

Processing stopped.

User response

Retry the operation. If the problem continues, see your system administrator to determine the problem from the server console or the activity log. Check whether any requests were made for a tape volume that was unavailable. A tape volume may be marked unavailable if prior read errors were encountered or the volume is checked out of the tape library.

0015 E DSM_RC_ABORT_RETRY Unexpected retry request. The IBM Spectrum Protect server found an error while writing the data.

Explanation

None.

System action

If the current operation supports another attempt, the client tries the operation again. Otherwise, processing stops.

User response

None.

0016 E DSM_RC_ABORT_NO_LOG_SPACE The server does not have enough recovery log space to continue the current operation

Explanation

The server ran out of recovery log space.

System action

Processing ends.

User response

This error is a temporary problem. Retry later or see your system administrator.

0017 E DSM_RC_ABORT_NO_DB_SPACE The server does not have enough database space to continue the current operation

Explanation

The server ran out of database space.

System action

Processing ends.

User response

See your system administrator.

0018 E DSM_RC_ABORT_NO_MEMORY The server does not have enough memory to continue the current operation.

Explanation

The server ran out of memory.

System action

Processing ends.

User response

This is a temporary problem. Retry later or see your system administrator.

0020 E DSM_RC_ABORT_FS_NOT_DEFINED The specified file space does not exist on the server. The file space might have been deleted by another client or an administrator.

Explanation

The specified file space does not exist on the server. Your system administrator deleted the file space or another client using your client's node name deleted it.

System action

Current operation has been cancelled.

User response

Check the file space name to see if it is correct, and retry the operation.

0021 S DSM_RC_ABORT_NODE_ALREADY_DEFED Open Registration failed because the specified node name is defined in the server

Explanation

Open registration failed because a node is defined in the server with the same name.

System action

Current operation has been cancelled.

User response

Retry with another node name.

0022 S DSM_RC_ABORT_NO_DEFAULT_DOMAIN Open Registration failed because no default domain exists

Explanation

Open registration failed because a default policy domain does not exist for you to place your node.

System action

Current operation has been cancelled.

User response

See your system administrator.

0023 S DSM_RC_ABORT_INVALID_NODENAME Open Registration failed because an invalid node name was specified

Explanation

Open registration failed because the specified node name contains invalid characters.

System action

Current operation has been cancelled.

User response

Retry with another node name that does not have any invalid characters.

0024 S DSM_RC_ABORT_INVALID_POL_BIND A policy management problem has occurred on the IBM Spectrum Protect server.

Explanation

The client error log and IBM Spectrum Protect server activity log may contain additional information about this error.

System action

Processing is stops.

User response

Try the operation again. If the problem persists, examine the client error log and IBM Spectrum Protect server activity log for additional information about this error. If the problem cannot be resolved, then obtain a SERVICE trace that captures the problem and contact IBM technical support for additional assistance. Your IBM Spectrum Protect administrator can help you configure the trace.

0024 E DSM_RC_ABORT_NO_INVALID_POL_BIND An object in the transaction has been bound to an invalid management class.

Explanation

One of the objects in the transaction is bound to a management class that is not part of this node's policy, or the management class type is not supported for this client level.

System action

The current operation ends.

User response

Make sure all objects are bound to a valid management class, or upgrade the client to the proper level.

0025 E DSM_RC_ABORT_DEST_NOT_DEFINED Server problem: Destination not defined.

Explanation

Server problem: Destination not defined.

System action

Processing stopped.

User response

Have your service representative check the error log.

0026 S DSM_RC_ABORT_WAIT_FOR_SPACE The IBM Spectrum Protect server does not currently have space in the storage pool for this file. This may be a temporary condition.

Explanation

This message is typically issued when the storage pool in which the data is being placed does not have sufficient space to store the data, but the space will be available soon. For example, a storage pool migration might free up sufficient space to store the data.

System action

Current operation has been cancelled.

User response

Try the operation at a later time. If this fails, contact the IBM Spectrum Protect administrator and request more storage pool space.

0027 E DSM_RC_ABORT_NOT_AUTHORIZED The file space cannot be deleted because this node does not have permission to delete archived or backed up data.

Explanation

You cannot delete the file space data unless your IBM Spectrum Protect administrator has authorized your node to do so. Authorization permits you to delete backup data, archive data, or both.

System action

Delete processing fails.

User response

Use the DSMC QUERY SESSION command to verify your authorization. Ask your IBM Spectrum Protect administrator to provide the necessary authorization or to delete the file space for you.

0028 E DSM_RS_ABORT_RULE_ALREADY_DEFED '*Access rule*' Access Rule already defined for node '*node*'. Old rule must be deleted before new one can be defined.

Explanation

You are trying to define authorization for the specified node, which already has authorization defined.

System action

IBM Spectrum Protect did not redefine authorization for the specified node.

User response

Update the authorization, or delete the old rule and define a new one, or use the current authorization.

0029 S DSM_RC_ABORT_NO_STOR_SPACE_STOP Server out of data storage space

Explanation

The server does not have space available to store the object.

System action

Processing Ends.

User response

Report to your system administrator that a storage pool on the server is full.

0030 E DSM_RC_ABORT_LICENSE_VIOLATION The operation is not permitted due to server licenses values.

Explanation

The node or user is trying to perform an operation that either exceeds license values, or is not licensed.

System action

The session is rejected or the transaction is cancelled, ending the current operation.

User response

See your system administrator.

0032 E DSM_RC_ABORT_DUPLICATE_OBJECT A duplicate object was found, operation cannot complete.

Explanation

A duplicate object was found, operation cannot complete.

System action

The requested operation failed.

User response

Try the operation with a different file specification.

0033 E DSM_RC_ABORT_INVALID_OFFSET partialObjOffset value for partial object retrieve is invalid.

Explanation

The partialObjOffset value for partial object retrieve is invalid.

System action

The system returns to the calling procedure.

User response

Specify a valid value.

0034 E DSM_RC_ABORT_INVALID_LENGTH partialObjLength value for partial object retrieve is invalid.

Explanation

partialObjLength value for partial object retrieve is invalid.

System action

The system returns to the calling procedure.

User response

Specify a valid value.

0036 E DSM_RC_END_NODE_NOT_AUTHORIZED The node or user does not have proper authority to perform this operation

Explanation

The node or user does not have proper authority to perform this operation.

System action

The transaction is ended.

User response

Check the authority for the specified object.

0041 E DSM_RC_ABORT_EXCEED_MAX_MP This node has exceeded its maximum number of mount points.

Explanation

Either no tape or sequential disk mount points are permitted for this operation, or the maximum number of mount points allowed are already in use. The operation can not be completed. The IBM Spectrum Protect administrator defines the maximum number of mount points with the MAXNUMMP property of your node definition.

System action

The object is skipped

User response

If you are performing any other operations that might be using mount points, wait until those operations are complete, then try the failed operation again. Otherwise contact your IBM Spectrum Protect administrator for further assistance

0045 E DSM_RC_ABORT_MERGE_ERROR The specified objects failed the merge test.

Explanation

The specified objects failed the merge test, operation cannot complete.

System action

The requested operation failed.

User response

See documentation for the merge test parameters.

0047 E DSM_RC_ABORT_INVALID_OPERATION An invalid operation was attempted on a node

Explanation

The operation is not valid.

System action

Current operation has ended.

User response

Contact your system administrator for more information.

0048 E DSM_RC_ABORT_STGPOOL_UNDEFINED The specified target storage pool is not defined.

Explanation

The storage pool is not defined.

System action

Current operation has ended.

User response

Contact your system administrator for more information.

0049 E DSM_RC_ABORT_INVALID_DATA_FORMAT A target storage pool does not have the correct data format for the given node type.

Explanation

none

System action

Current operation has ended.

User response

Contact your system administrator for more information.

0050 E DSM_RC_ABORT_DATAMOVER_UNDEFINED No associated data mover is defined for the given node.

Explanation

none

System action

Current operation has ended.

User response

Contact your system administrator for more information.

0051 E DSM_RC_REJECT_NO_RESOURCES Session rejected: All server sessions are currently in use

Explanation

IBM Spectrum Protect has all available sessions in use and cannot accept a new one at this time.

System action

Current operation has been cancelled.

User response

Retry the operation. If the problem continues, see your system administrator to increase the number of concurrently active sessions to the server.

0052 E DSM_RC_REJECT_VERIFIER_EXPIRED The session is rejected. Your password has expired.

Explanation

The password for IBM Spectrum Protect user ID has expired. It can be either IBM Spectrum Protect node name password or administrative user ID password or both.

System action

Current operation has been cancelled. You are not allowed to connect to the server until the password is updated.

User response

Update your password. It may require updating the node name password or the corespondent administrative ID password or both. You may use the SET PASSWORD command, or have the IBM Spectrum Protect administrator update your node or your administrative ID.

0053 E DSM_RC_REJECT_ID_UNKNOWN Session rejected: User ID is incorrect, does not have admin authority, or is not known by the server

Explanation

The user ID, which is either IBM Spectrum Protect node name or administrative user ID, is not known by the server. Possible reasons for this include:

- Your node name is not registered with the IBM Spectrum Protect server
- The node name is correct but does not have a corresponding administrative ID with the same name and client owner authority
- you are attempting to access a file that was migrated to a different node.

System action

Current operation has been cancelled.

User response

Do the following checks:

- Check that your IBM Spectrum Protect user ID is entered correctly.
- Check the administrative ID associated with your IBM Spectrum Protect node and verify that the IBM Spectrum Protect node name has a matching administrative ID with client owner authority for the node. If it does not, your IBM Spectrum Protect administrator needs to create it.
- Check that the server is using closed registration and that your node name is registered with the server.

- If attempting to access a migrated file, your node name must be the same node that migrated the file.

0054 E DSM_RC_REJECT_DUPLICATE_ID Session rejected: Duplicate ID entered

Explanation

Another process using this node name is active with the server.

System action

IBM Spectrum Protect cannot connect to the server. Current operation has been cancelled.

User response

If you are running a UNIX-based system, ensure that another process is not active with IBM Spectrum Protect under the same name. Also, ensure that your node name is unique to the server so that it cannot be used by another person. See your system administrator to identify the owner of that node name.

0055 E DSM_RC_REJECT_SERVER_DISABLED Session rejected: Server disabled.

Explanation

The server is in a disabled state and cannot be accessed for normal activity.

System action

Current operation has been cancelled.

User response

On the IBM Spectrum Protect server, run the ENABLE SESSIONS administrative command. Try the operation again after the server returns to an enabled state. If the problem continues, see your system administrator.

0056 E DSM_RC_REJECT_CLOSED_REGISTER The server is not configured to allow open registration

Explanation

No authorization. Registration is required by your system administrator. The server is not configured to allow open registration.

System action

Session not started.

User response

You must obtain a IBM Spectrum Protect node and password from your system administrator.

0057 S DSM_RC_REJECT_CLIENT_DOWNLEVEL Session rejected: Downlevel client code version

Explanation

The server version and your client version do not match. The client code is downlevel.

System action

Current operation has been cancelled.

User response

See your system administrator to see what version of IBM Spectrum Protect to run for your location.

0058 S DSM_RC_REJECT_SERVER_DOWNLEVEL Session rejected: Downlevel server code version

Explanation

The server version and your client version do not match. The server code is downlevel.

System action

Current operation has been cancelled.

User response

See your system administrator to see what version of IBM Spectrum Protect to run for your location.

0059 E DSM_RC_REJECT_ID_IN_USE Session Rejected: The specified node name is currently in use

Explanation

The node name you specified is in use on the server.

System action

Session was not started.

User response

The server is probably performing a task that prevents your node from establishing a session. Retry later or check with your system administrator.

0061 E DSM_RC_REJECT_ID_LOCKED Session Rejected: The specified node name is currently locked.

Explanation

The node name you specified is currently locked on the server.

System action

Session was not started.

User response

Check with your system administrator to find out why your node name is locked.

0062 S DSM_RC_SIGNONREJECT_LICENSE_MAX SLM LICENSE EXCEEDED: The client licenses for IBM Spectrum Protect are exceeded. See your system administrator.

Explanation

Adding a new enrollment will exceed the product license count for IBM Spectrum Protect.

System action

Execution of the client enrollment or connection request ends.

User response

See your system administrator.

0063 E DSM_RC_REJECT_NO_MEMORY Session Rejected: The server does not have enough memory to allow a connection to be established.

Explanation

The server does not have enough memory to allow your client to establish a connection with the server.

System action

Session was not started.

User response

Retry later or see your system administrator.

0064 E DSM_RC_REJECT_NO_DB_SPACE Session Rejected: The server does not have enough database space to allow a connection to be established.

Explanation

The server ran out of database space.

System action

Session was not started.

User response

See your system administrator.

0065 E DSM_RC_REJECT_NO_LOG_SPACE Session Rejected: The server does not have enough recovery log space to allow a connection to be established.

Explanation

The server ran out of recovery log space.

System action

Session was not started.

User response

This error is a temporary problem. Retry later or see your system administrator.

0066 E DSM_RC_REJECT_INTERNAL_ERROR The session is rejected. The IBM Spectrum Protect server has an internal error.

Explanation

The client cannot establish a connection to the IBM Spectrum Protect server because of an internal server error.

System action

The session was not started.

User response

Notify your IBM Spectrum Protect administrator of this error.

0067 S DSM_RC_SIGNONREJECT_INVALID_CLI Session Rejected: The server is not licensed for this platform type. See your system administrator.

Explanation

The server is not licensed for the requesting client type.

System action

Execution of the client enrollment or connection request ends.

User response

See your system administrator.

0068 E DSM_RC_CLIENT_NOT_ARCHRETPROT The session is rejected. The server does not allow a signon of a client that is not archive-retention protection enabled.

Explanation

The client cannot establish a connection to the server because the server is enabled for archive-retention protection enabled and the client is not.

System action

The session is not started.

User response

See your system administrator.

0069 E DSM_RC_SESSION_CANCELED Session Rejected: The session was canceled by the server administrator.

Explanation

The server administrator canceled the current client session.

System action

Execution of the client connection request ends.

User response

See your system administrator.

0073 E DSM_RC_REJECT_INVALID_NODE_TYPE An inconsistency was detected between the client node and the node that is registered to the IBM Spectrum Protect server.

Explanation

The user has probably coded the node option incorrectly. For instance, the node that is registered to the IBM Spectrum Protect server might be a type of NAS, but the node is actually a non-NAS client.

System action

Operation ends.

User response

Ensure that the node name is correct in the client options file. Make sure to use a node of type NAS only with the nasnodename option.

0074 E DSM_RC_REJECT_INVALID_SESSIONINIT Server does not allow client-initiated connections for this node.

Explanation

The node is not allowed to initiate connections due to the configuration parameters for this node on the server. Server is able to initiate connections to the client scheduler running in prompted mode.

System action

The IBM Spectrum Protect operation ends.

User response

Contact your systems administrator to enable client-initiated sessions for your node or update the SESSIONINITIATION option and run the client scheduler.

0075 E DSM_RC_REJECT_WRONG_PORT Wrong server port.

Explanation

You were trying to open a backup/archive client session on the server port set up for administrative sessions only.

System action

The IBM Spectrum Protect operation ends.

User response

Contact your systems administrator and/or use the correct values for TCP port and TCP Admin Port.

0079 E DSM_RC_CLIENT_NOT_SPMRETPROT The session is rejected. The server does not allow a signon of a client that is not enabled for space-management retention-protection.

Explanation

The client cannot establish a connection to the server because the server is enabled for space-management retention-protection and the client is not.

System action

The session is not started.

User response

See your system administrator.

0101 W DSM_RC_USER_ABORT The operation was stopped by the user.

Explanation

The operation was stopped at the request of the user. This usually occurs when the 'Q' key is pressed two times.

System action

Processing stopped.

User response

None.

0102 E DSM_RC_NO_MEMORY *file name*(*line number*)The operating system refused a IBM Spectrum Protect request for memory allocation.

Explanation

IBM Spectrum Protect requires access to memory in order to store information as processing proceeds. In this case, more memory was requested than the operating system would allocate. Possible reasons include:

- The system is low on memory.
- The process in which the program runs has exceeded the maximum allocated memory.
- Some other error condition occurred. No memory is available.

System action

IBM Spectrum Protect cannot complete the requested operation.

User response

Close all unneeded applications and try the operation again. If the operation still fails, try dividing the task into several smaller units. For example, if a file specification contains several high-level directories, run the IBM Spectrum Protect task serially for each directory. If the IBM Spectrum Protect task is an incremental backup, use the option "-memoryefficientbackup=yes".

For UNIX systems that support resource limits, you can check if the memory resource limit is too low by entering the following command: `ulimit -a`

Based on the resulting data, you can ask the UNIX system root user to increase the resource limit above the current default limit. The UNIX system root user has the authority to increase resource limits.

0104 E DSM_RC_FILE_NOT_FOUND File not found during Backup, Archive or Migrate processing

Explanation

The file being processed for backup, archive or migrate no longer exists on the client. Another process deleted the file before it could be backed up, archived or migrated by IBM Spectrum Protect.

System action

File skipped.

User response

None.

0105 E DSM_RC_PATH_NOT_FOUND The specified directory path '*pathname*' could not be found.

Explanation

An invalid or unreachable directory path was specified.

System action

Processing stopped.

User response

Try the operation again using a valid directory path.

0106 E DSM_RC_ACCESS_DENIED Access to the specified file or directory is denied

Explanation

Access to the specified file or directory is denied. You tried to read from or write to a file and you do not have access permission for either the file or the directory.

System action

Processing stopped.

User response

Ensure that you specified the correct file or directory name, correct the permissions, or specify a new location.

0106 E DSM_RC_ACCESS_DENIED The specified file is being used by another process

Explanation

The specified file is being used by another process. You tried to read from or write to a file that is currently being used by another process.

System action

Processing stopped.

User response

Ensure that you specified the correct file or directory name, correct the permissions, or specify a new location.

0107 E DSM_RC_NO_HANDLES No file handles available

Explanation

All file handles for your system are currently in use. No more are available.

System action

Processing stopped.

User response

Either free some file handles by ending other processes, or modify your system setup to allow for more files to be open at the same time.

0108 E DSM_RC_FILE_EXISTS The file exists and cannot be overwritten.

Explanation

The file being restored or retrieved exists and cannot be overwritten due to lack of authority or access permissions.

System action

The file is skipped.

User response

Verify that you have sufficient access permissions to overwrite the file, then try the operation again. If the problem persists, contact your system administrator or IBM Spectrum Protect administrator for further assistance.

0109 E DSM_RC_INVALID_PARM Invalid parameter was found.

Explanation

The system encountered an internal program error due to an invalid parameter.

System action

The system returns to the calling procedure.

User response

Ask your service representative to check the error log.

0110 E DSM_RC_INVALID_HANDLE An invalid file handle was passed; system error.

Explanation

An internal system error occurred: A file operation failed because of an invalid file handle.

System action

processing stops.

User response

Try the operation again. If the failure persists, obtain a service trace that captures the problem and contact IBM technical support for additional assistance. Your IBM Spectrum Protect administrator can help you configure the trace.

0111 E DSM_RC_DISK_FULL Processing stopped; Disk full condition

Explanation

No more files can be restored or retrieved because the destination disk is full.

System action

Processing stopped.

User response

Free up disk space, or restore or retrieve the file to another disk.

0113 E DSM_RC_PROTOCOL_VIOLATION Protocol violation

Explanation

A communications protocol error occurred. The communication subsystem is not properly defined or is itself in error.

System action

Processing Ends.

User response

Verify that the communication processes are operating properly, and then retry the operation.

0114 E DSM_RC_UNKNOWN_ERROR An unknown system error has occurred from which IBM Spectrum Protect cannot recover.

Explanation

An unknown error occurred. This might be a low-level system or communication error from which IBM Spectrum Protect cannot recover.

System action

Processing stops.

User response

Try the operation again. If the problem persists, review the IBM Spectrum Protect error log for any related messages. Obtain a service trace that captures the problem and contact IBM technical support for additional assistance. Your IBM Spectrum Protect administrator can help you configure the trace.

0115 E DSM_RC_UNEXPECTED_ERROR An unexpected error occurred.

Explanation

This is usually caused by a low-level system error or communication error from which IBM Spectrum Protect cannot recover.

System action

Processing stopped.

User response

Examine the client error log for any additional messages that might be related to this problem. Try the operation again. If the problem persists, contact IBM Spectrum Protect technical support for further assistance.

0116 E DSM_RC_FILE_BEING_EXECUTED File is in use; Write permission denied.

Explanation

The current file cannot be opened to write to because it is currently being run by another operation.

System action

File skipped.

User response

Stop the operation that is running the file and retry the operation, or restore or retrieve the file to a different name or directory.

0117 E DSM_RC_DIR_NO_SPACE No more files can be restored or retrieved since the destination directory is full.

Explanation

No more files can be restored or retrieved since the destination directory is full.

System action

Processing stopped.

User response

Free up disk space, or restore or retrieve the file to another disk.

0118 E DSM_RC_LOOPED_SYM_LINK Too many symbolic links were detected while resolving name

Explanation

While trying to resolve the file name, too many symbolic links were found.

System action

File skipped.

User response

Ensure that you do not have a looping symbolic link for the file.

0119 E DSM_RC_FILE_NAME_TOO_LONG The file name is too long and can not be processed by IBM Spectrum Protect

Explanation

The size limit for file names may vary by operating system. The most common limit is 256 characters. The file name being processed exceeds the limit supported by IBM Spectrum Protect on this system.

System action

The file is skipped.

User response

Enter HELP FILE SPEC or see the client manual for the operating system on which you are receiving this error. The "File specification syntax" section of the manual explains file name lengths supported by IBM Spectrum Protect.

0120 E DSM_RC_FILE_SPACE_LOCKED File system is locked by system

Explanation

File system cannot be accessed because it is locked by the system.

System action

The operation cannot be completed.

User response

See your system administrator.

0121 I DSM_RC_FINISHED The operation is finished.

Explanation

The operation is finished.

System action

The system returns to the calling procedure.

User response

Proceed with next function call.

0122 E DSM_RC_UNKNOWN_FORMAT The file has an unknown format.

Explanation

The process tried to restore or retrieve a file, but it had an unknown format.

System action

The file is skipped.

User response

The file was either backed up by another application, or the data is invalid. If the file belongs to this system, try the operation again. If the problem persists, contact IBM technical support for further assistance.

0123 E DSM_RC_NO_AUTHORIZATION Not authorized to restore the other node's data.

Explanation

The client is not authorized to restore the other node's data.

System action

The system returns to the calling procedure.

User response

Get authorization from the other node.

0124 E DSM_RC_FILE_SPACE_NOT_FOUND File space '*filespace-name*' does not exist

Explanation

The specified file space (domain) is incorrect or does not exist on the machine.

System action

Processing stopped.

User response

Retry the operation specifying an existing domain (drive letter or file system name).

0125 E DSM_RC_TXN_ABORTED Transaction aborted

Explanation

The current transaction between the server and the client stopped. A server, client, or communication failure cannot be recovered.

System action

Current operation has been cancelled.

User response

Retry the operation. If the problem continues, see your system administrator to isolate the problem.

0126 E DSM_RC_SUBDIR_AS_FILE IBM Spectrum Protect cannot build a directory path because a file exists with the same name as the directory.

Explanation

None

System action

Processing stopped.

User response

Remove or rename the file that has the same name as the directory. Alternatively, you can restore the directory to a different location.

0127 E DSM_RC_PROCESS_NO_SPACE Disk space limit for this process reached

Explanation

The disk space allocated for the client owner is full.

System action

Processing stopped.

User response

Free up disk space and retry the restore or retrieve operation.

0128 E DSM_RC_PATH_TOO_LONG Destination directory path length exceeds system maximum

Explanation

The path name specified plus the path name in the restored file name combine to create a name whose length exceeds the system maximum.

System action

Processing stopped.

User response

Specify a destination path that, when combined, is less than the system maximum.

0129 E DSM_RC_NOT_COMPRESSED File is not compressed; System failure.

Explanation

A file that was flagged as compressed was not compressed, and the system failed.

System action

Processing stopped.

User response

See your system administrator to report this problem. This error is a system failure.

0130 E DSM_RC_TOO_MANY_BITS File compressed on a different client machine that has more memory

Explanation

You are trying to restore a file that was backed up and compressed on another client workstation that had more memory than your client workstation. You cannot restore this file. When the file is restored, it is expanded and your workstation does not have enough memory.

System action

Current operation has been cancelled.

User response

Obtain a machine with more memory and retry the operation.

0131 E DSM_RC_COMPRESSED_DATA_CORRUPTED The compressed file is corrupted and cannot be expanded correctly.

Explanation

The compressed file cannot be expanded correctly due to one of the following reasons:

- There is a problem on the tape.
- There is a communications problem.
- The compressed file was corrupted on the IBM Spectrum Protect Server.

System action

File skipped.

User response

1) The compressed file is corrupted because there is a problem on the tape. To know if this is the problem, please issue the following command on the IBM Spectrum Protect Server: audit volume <volume_name> fix=no If there is any problem reported, you could move the data from that volume to a new one (see command MOVE DATA) and try again the restore. 2) There are communications problems between the IBM Spectrum Protect Server and the IBM Spectrum Protect Client and the results is that

the file is corrupted during the transmission. If you use a gigabit Ethernet adapter on the Server please upgrade the card driver (AIX platform) or add provided by SUN suggested changes to some system network options which have resolved this problem (SUN platform). 3) Please verify with your network support if during the restore there are no any problems between the IBM Spectrum Protect Client/Server that is originating the file corruption.

0131 S DSM_RC_SYSTEM_ERROR An internal program error occurred.

Explanation

An unexpected condition was encountered and the operation can not continue. This might be a programming error.

System action

processing stops.

User response

Try the operation again. If the problem persists, contact your IBM Spectrum Protect administrator or IBM technical support for further assistance.

0132 E DSM_RC_NO_SERVER_RESOURCES The IBM Spectrum Protect server is out of resources.

Explanation

A lack of a storage resource or a maximum value condition does not allow any new activity.

System action

Current operation has been cancelled.

User response

Try the operation again at a later time. If the problem continues, contact your IBM Spectrum Protect administrator to isolate what resource is unavailable. The IBM Spectrum Protect administrator can check the IBM Spectrum Protect server activity log for messages that might explain the problem.

0133 E DSM_RC_FS_NOT_KNOWN The file space for domain '*domain-name*' could not be found on the IBM Spectrum Protect server.

Explanation

The specified file space was expected to be found on the server, but it no longer exists. It is possible that a command was issued to delete the file space from the server while the current operation was in progress.

System action

IBM Spectrum Protect processing stops.

User response

Try the operation again. If the problem recurs, check the error log for any other messages that might indicate a reason for the failure. Try to correct any indicated problems, then try the operation again. If the problem persists, contact IBM technical support

for further assistance.

0134 E DSM_RC_NO_LEADING_DIRSEP The objName field has no leading directory separator.

Explanation

The objName field does not have a leading directory separator.

System action

The system returns to the calling procedure.

User response

Correct the value for the objName.

0135 E DSM_RC_WILDCARD_DIR Wildcards are not allowed in the objName directory path.

Explanation

Wildcards are not allowed in the objName directory path.

System action

The system returns to the calling procedure.

User response

Correct the value for the objName.

0136 E DSM_RC_COMM_PROTOCOL_ERROR The session is rejected: There was a communications protocol error.

Explanation

An unexpected network message was received by the client. This could be caused by network problems or a programming error.

System action

The current operation has been cancelled.

User response

Verify that your communication path is functioning properly and try the operation again. If the problem persists, contact your IBM Spectrum Protect administrator for further assistance.

0137 E DSM_RC_AUTH_FAILURE Session rejected: Authentication failure

Explanation

Authentication failure. You entered an incorrect user id or password.

System action

Current operation has been cancelled.

User response

Enter your correct user id and password. If you cannot remember the correct user id or password, see your system administrator to have new credentials assigned for your node name.

0138 E DSM_RC_TA_NOT_VALID The dsmtca execution/owner permissions are invalid.

Explanation

The dsmtca execution/owner permissions are invalid.

System action

Processing stopped.

User response

Have your system administrator check the installation instructions for the client to ensure that the dsmtca permissions are set correctly.

0139 S DSM_RC_KILLED Process killed.

Explanation

Processing stopped. This is a programming failure and the client program ends.

System action

Processing stopped.

User response

Retry the operation. If the problem continues, contact your system administrator.

0145 S DSM_RC_WOULD_BLOCK The dsmtca would block the operation.

Explanation

The dsmtca blocks the operation. This is a programming failure and the client program ends.

System action

Processing stopped.

User response

Retry the operation. If the problem continues, contact your system administrator.

0146 S DSM_RC_TOO_SMALL The area for the include/exclude pattern is too small.

Explanation

The area for the include/exclude pattern is too small. This is a programming failure and the client program ends.

System action

Processing stopped.

User response

Retry the operation. If the problem continues, contact your system administrator.

0147 S DSM_RC_UNCLOSED There is no closing bracket in the pattern.

Explanation

There is no closing bracket in the pattern. This is a programming failure and the client program ends.

System action

Processing stopped.

User response

Retry the operation. If the problem continues, contact your system administrator.

0148 S DSM_RC_NO_STARTING_DELIMITER Include/Exclude pattern must start with a directory delimiter

Explanation

The include or exclude pattern must start with a directory delimiter.

System action

Processing stopped.

User response

Correct the syntax for the pattern.

0149 S DSM_RC_NEEDED_DIR_DELIMITER A beginning or ending directory delimiter is missing from the Include/Exclude pattern.

Explanation

1. The include/exclude pattern has a '...' without a beginning or ending directory delimiter.
2. For Windows, the drive seperator is not immediately followed by a directory delimiter.

System action

Processing stopped.

User response

Correct the syntax for the pattern.

0151 S DSM_RC_BUFFER_OVERFLOW The data buffer overflowed.

Explanation

The data buffer overflowed. This is a programming failure and the client program ends.

System action

Processing stopped.

User response

Retry the operation. If the problem continues, contact your system administrator.

0154 E DSM_RC_NO_COMPRESS_MEMORY Insufficient memory for file compression/expansion

Explanation

Not enough memory is available to do data compression or expansion. For a restore or retrieve, the file cannot be recalled from the server until more storage is made available. For a backup or archive, try running without compression if storage cannot be made available.

System action

Processing stopped.

User response

Free up extra storage for the operation to continue, or run the backup or archive process without compression enabled.

0155 T DSM_RC_COMPRESS_GREW Compressed Data Grew

Explanation

The size of the file after compression is greater than the size of the file before compressed.

System action

Even though the size of the file increased, the file is compressed.

User response

None.

0156 E DSM_RC_INV_COMM_METHOD An unsupported communications method was specified.

Explanation

None.

System action

processing stops.

User response

Specify a communications interface that is supported by the IBM Spectrum Protect client on your operating system. See the IBM Spectrum Protect client manual for your operating system for further information on configuring IBM Spectrum Protect client communications.

0157 S DSM_RC_WILL_ABORT The transaction will be aborted.

Explanation

The server encountered an error and will abort the transaction.

System action

The transaction will be aborted. The reason code is passed on the dsmEndTxn call.

User response

Issue the dsmEndTxn with a vote of DSM_VOTE_COMMIT and examine the reason code.

0158 E DSM_RC_FS_WRITE_LOCKED Destination file or directory is write locked

Explanation

The file or directory being restored or retrieved from the server cannot be written to because the destination is write locked. Another operation might have the file open and will not allow it to be updated.

System action

File skipped.

User response

Either determine which operation has the file write locked, or restore the file to another name or location.

0159 I DSM_RC_SKIPPED_BY_USER A file was skipped during a restore operation because the file is off line and the application has chosen not to wait for a tape mount.

Explanation

A file was skipped during a restore operation because the file is off line and the application has chosen not to wait for a tape mount.

System action

File skipped.

User response

Verify the application sets the mountWait value correctly on dsmBeginGetData.

0160 E DSM_RC_TA_NOT_FOUND Unable to find the dsmtca module.

Explanation

IBM Spectrum Protect was unable to find the dsmtca module in the specified directory.

System action

Processing ends.

User response

Make sure the dsmtca module is in the directory specified by DSMI_DIR.

0162 E DSM_RC_FS_NOT_READY File system/drive not ready

Explanation

The file system/drive was not ready for access.

System action

Processing stopped.

User response

Ensure that the drive is available , and then retry the operation.

0164 E DSM_RC_FIO_ERROR File input/output error

Explanation

An error was found while reading from or writing to the file.

System action

File or file system is skipped.

User response

Check your system to ensure that it is operating properly. For OS/2, run CHKDSK /F for the failing drive which can be found in dsmerror.log.

0165 E DSM_RC_WRITE_FAILURE File write error

Explanation

An error was found while writing to the file.

System action

File skipped.

User response

Check your system to ensure that it is operating properly.

0166 E DSM_RC_OVER_FILE_SIZE_LIMIT File exceeds system/user file limits

Explanation

A file being restored or retrieved exceeds system set limits for this user.

System action

File skipped.

User response

Ensure that the system limits are set properly.

0167 E DSM_RC_CANNOT_MAKE Cannot make file/directory

Explanation

The directory path for files being restored or retrieved cannot be created.

System action

File skipped.

User response

Ensure that you have the proper authorization to create the directory for file being restored or retrieved. Make sure that you have write access.

0168 E DSM_RC_NO_PASS_FILE Password file is not available.

Explanation

The file containing the stored password for the specified *server-name* is unavailable.

System action

Processing ends.

User response

The root user must set and store a new password.

0169 E DSM_RC_VERFILE_OLD PASSWORDACCESS is GENERATE, but password needed for server '*server-name*'. Either the password is not stored locally, or it was changed at the server.

Explanation

Either the password is not stored locally, or it was changed at the server.

System action

IBM Spectrum Protect prompts you for the password if IBM Spectrum Protect is running in the foreground.

User response

If IBM Spectrum Protect was running as a background process, issue any IBM Spectrum Protect command from the foreground. Enter the password in answer to the prompt. Then try your background IBM Spectrum Protect command again.

0173 E DSM_RC_INPUT_ERROR The process is running in a non-interactive mode, but requires user input.

Explanation

This process requires keyboard input, but non-interactive processes are unable to read input from keyboard.

System action

processing stops.

User response

Perform the following actions to resolve this error:

- Run the product in interactive mode.
- Ensure your password is set correctly.

0174 E DSM_RC_REJECT_PLATFORM_MISMATCH Session rejected: Node type mismatch

Explanation

Your node name is associated with a different type of operating system and cannot be used on this system.

System action

Current operation has been cancelled.

User response

If you need a new node name, see your system administrator to assign a new one to you. Generally, you have a unique node name for each machine and operating system pair that requires access to the server.

0175 E DSM_RC_TL_NOT_FILE_OWNER Not file owner

Explanation

The file cannot be backed up because the client is not the file owner.

System action

The file is skipped.

User response

None.

0177 S DSM_RC_UNMATCHED_QUOTE Quotes are not matched

Explanation

The quotes specified in the pattern are not the same and do not make a set.

System action

Processing stopped.

User response

Correct the pattern by using matching quotes in the syntax.

0184 E DSM_RC_TL_NOBCG The management class for this file does not have a valid backup copy group. This file will not be backed up.

Explanation

The management class for this file does not have a backup copy group specified. This file will not be backed up.

System action

Processing stopped.

User response

Add a valid backup copy group to the management class, and then retry the operation.

0185 W DSM_RC_TL_EXCLUDED File '*file-namefile-namefile-name*' excluded by Include/Exclude list

Explanation

You can not back up, archive, or migrate files that are excluded.

System action

The file can not be processed.

User response

If the file is intentionally excluded, then this message can be ignored. Otherwise modify the include/exclude list, restart the client, and try the operation again. Contact your IBM Spectrum Protect administrator for further assistance.

0186 E DSM_RC_TL_NOACG The management class for this file does not have a valid archive copy group. This file will not be archived.

Explanation

The management class for this file does not have an archive copy group specified. This file will not be archived.

System action

Processing stopped.

User response

Add a valid archive copy group to the management class, and then retry the operation.

0187 E DSM_RC_PS_INVALID_ARCHMC Invalid management class entered

Explanation

You entered an invalid management class.

System action

Requested operation is not possible.

User response

Retry the operation using a valid management class.

0188 S DSM_RC_NO_PS_DATA Either the node does not exist on the server or there is no active policy set for the node.

Explanation

This error occurs when you try to access another node's data. Either the node is not registered with the IBM Spectrum Protect server, or there is no active policy set for the node.

System action

Processing stops.

User response

Verify that the node whose data you are trying to access is registered with the IBM Spectrum Protect server. If you have more than one IBM Spectrum Protect server, make sure you are connecting to the correct server, then try the operation again. If the problem persists, contact your IBM Spectrum Protect administrator for further assistance.

0189 S DSM_RC_PS_INVALID_DIRMC The management class assigned to directories does not exist.

Explanation

The management class named on the DIRMC option does not exist in your assigned policy set on the server. The error log contains an entry showing the invalid management class name.

System action

processing stops.

User response

Remove the current DIRMC option from the client options file, then run DSMC QUERY MGMTCLASS -DETAIL to view information about available management classes. Make sure the management class you select has a backup copy group. If you have more than one IBM Spectrum Protect server, make sure you are connecting to the correct server. If you are unable to find a suitable management class, contact your IBM Spectrum Protect administrator for further assistance.

0190 S DSM_RC_PS_NO_CG_IN_DIR_MC There is no backup copy group in the management class used for directories.

Explanation

The DIRMC option names a management class that contains no backup copy group.

System action

processing stops.

User response

Remove the current DIRMC option from the client options file, then run DSMC QUERY MGMTCLASS -DETAIL to view information about available management classes. Make sure the management class you select has a backup copy group. If you have more

than one IBM Spectrum Protect server, make sure you are connecting to the correct server. If you are unable to find a suitable management class, contact your IBM Spectrum Protect administrator for further assistance.

0231 E DSM_RC_ABORT_MOVER_TYPE Unknown Remote Mover type

Explanation

The specified Remote Mover type is unknown.

System action

Current operation has ended.

User response

Contact your system administrator for more information.

0232 E DSM_RC_ABORT_ITEM_IN_USE An Operation for the requested node and file space is already in progress.

Explanation

A request has been made to use a data mover to perform an operation for the indicated node and file space. Since an operation for this node and file space is already in progress, the new operation cannot be performed.

System action

Current operation has ended.

User response

Retry the operation at a later time.

0233 E DSM_RC_ABORT_LOCK_CONFLICT System resource in use

Explanation

A required resource is in use by another command or process.

System action

Current operation has ended.

User response

Retry the operation at a later time.

0234 E DSM_RC_ABORT_SRV_PLUGIN_COMM_ERROR Server plugin communication error

Explanation

Communication between a server plugin module and a NAS filer failed.

System action

Current operation has ended.

User response

Contact your system administrator for more information.

0235 E DSM_RC_ABORT_SRV_PLUGIN_OS_ERROR Server plugin detected unsupported NAS filer operating system.

Explanation

A plugin module detected that a NAS filer is running an unsupported operating system or operating system level.

System action

Current operation has ended.

User response

Contact your system administrator for more information.

0236E DSM_RC_ABORT_CRC_FAILED The CRC received from the Server does not match the CRC calculated by the client.

Explanation

The server sent a CRC for a buffer. The client calculated a CRC for the same buffer. These did not match. The mismatch indicates a communication failure.

System action

In some cases, the client can indicate the failure to the server and retry the operation.

User response

Check the trace log for additional information and retry the operation. If the problem persists, contact your system administrator.

0237E DSM_RC_ABORT_INVALID_GROUP_ACTION An invalid operation was attempted on a group leader or group member.

Explanation

An invalid operation was attempted on a logical group.

System action

The current operation stops.

User response

Retry a valid operation.

0238E DSM_RC_ABORT_DISK_UNDEFINED Remote disk not defined.

Explanation

An operation was attempted on a remote disk that is not defined.

System action

The current operation stops.

User response

Define the proper remote disk.

0239E DSM_RC_ABORT_BAD_DESTINATION Input destination does not match expected destination.

Explanation

Input destination does not match expected destination.

System action

The current operation stops.

User response

Retry operation with proper destination.

0240E DSM_RC_ABORT_DATAMOVER_NOT_AVAILABLE Data mover is not available.

Explanation

Data mover is not available.

System action

The current operation stops.

User response

Retry operation with a proper Data mover.

0241E DSM_RC_ABORT_STGPOOL_COPY_CONT_NO Operation failed because the copy continue option was set to NO.

Explanation

Operation failed because the copy continue option was set to NO.

System action

The current operation stops.

User response

This abort code indicates that a store operation, like backup or archive failed because the copy continue option was set to NO. The sysadmin will need to resolve the problem on the server end.

0242E DSM_RC_ABORT_RETRY_SINGLE_TXN Transaction failed because of a problem during a store operation.

Explanation

Transaction failed because of a problem during a store operation. This error is typical when the next storage pool has a different copy storage pool list and we switch to this pool in the middle of a transaction.

System action

Transaction is aborted.

User response

Resend objects in separate transactions.

0245 E DSM_RC_ABORT_PATH_RESTRICTED The current client configuration does not comply with the value of the DATAWRITEPATH or DATAREADPATH server option for this node.

Explanation

The values of the DATAWRITEPATH and DATAREADPATH server options specify where the client is allowed to send data, and where data is read from. The values for the specified node name should correspond with the client configuration. For example, you will get this error message if DATAWRITEPATH contains a LAN value and the client is configured to use LAN-free protocol, or vice versa.

System action

Processing stopped.

User response

Check the client, server, and storage agent logs to determine why the client was not able to send data LAN-free. Make sure the client configuration and server options are compatible.

0247 E DSM_RC_ABORT_INSERT_NOT_ALLOWED This server does not support backup operations.

Explanation

This server only supports archive operations, backup is not allowed.

System action

The current operation ends.

User response

Use only archive operations with this server.

0248 E DSM_RC_ABORT_DELETE_NOT_ALLOWED Deleting this object: "*fshlll*" is not allowed.

Explanation

The object is either under a hold and cannot be deleted, or it is on a retention-protection enabled server and has not expired.

System action

The object is skipped and processing continues.

User response

Check the status of the object through a query to see if it is held, or when it expires.

0249 E DSM_RC_ABORT_TXN_LIMIT_EXCEEDED The number of objects in this transaction exceed TXNGROUPMAX values.

Explanation

There are too many objects in this transaction.

System action

The current operation ends.

User response

Try the operation again with fewer objects in the transaction, or increase the TXNGROUPMAX value on the server.

0250 E DSM_RC_ABORT_OBJECT_ALREADY_HELD *fshlll* is already under hold.

Explanation

One of the objects in the transaction The specified object is already under hold, and it cannot be placed under a new hold.

System action

The current operation ends. This object is skipped and processing continues.

User response

Issue a query to see the status of the objects, and try the operation again, without the object that is already held.

0292 E DSM_RC_TCA_FORK_FAILED Error starting the dsmtca or dsmenc process.

Explanation

An error has occurred starting the dsmtca or dsmenc process; specifically, the `fork()` function has failed.

System action

Processing ends.

User response

Probable system error. If the problem persists, restart the workstation.

0295 E DSM_RC_TCA_INVALID_REQUEST The IBM Spectrum Protect dsmtca received an invalid request.

Explanation

The dsmtca or dsmenc process was invoked by the backup-archive client and received an unknown request argument in the call.

System action

Processing ends.

User response

It is possible that the dsmtca or dsmenc process was mistakenly invoked by a process other than the backup-archive client. If that is not the case, then this is an internal error. If the problem recurs, contact your IBM service representative.

0296 E DSM_RC_TCA_NOT_ROOT This action requires IBM Spectrum Protect administrative authority on this system.

Explanation

An activity has been attempted that must be performed by the IBM Spectrum Protect administrator (for example, open registration, file space delete or password update).

System action

Processing ends.

User response

If the activity is required, the administrator for this system must perform it.

0297 E DSM_RC_TCA_SEMGET_ERROR Error allocating semaphores.

Explanation

An error has occurred because the semaphores you are attempting to allocate have become insufficient.

System action

Processing ends.

User response

Ask your system administrator for assistance, and possibly increase the number of semaphores in your system.

0298 E DSM_RC_TCA_SEM_OP_ERROR Error setting semaphore value or waiting on semaphore.

Explanation

An error has occurred while attempting to set or wait on a semaphore.

System action

Processing ends.

User response

Probable system error. If the problem persists, restart the workstation.

0400 E DSM_RC_INVALID_OPT An invalid option was found during option parsing.

Explanation

An invalid option was found.

System action

The system returns to the calling procedure.

User response

Verify the options in dsm.opt, dsm.sys, and the options string. Check the error log for more details about the error. on the AS/400 platform, verify the options in *LIB/QOPTIBM Spectrum Protect(APIOPT).

0405 E DSM_RC_NO_HOST_ADDR TCPSERVERADDRESS not defined for this server in the System Options File

Explanation

The TCPSERVERADDRESS for this server is not defined in the server name stanza in the system options file.

System action

IBM Spectrum Protect initialization fails and the program ends.

User response

See the IBM Spectrum Protect administrator for your system, and make sure that the server to which you are trying to connect, has a valid TCPSERVERADDRESS defined in the system options file.

0406 S DSM_RC_NO_OPT_FILE Options file '*file-name*' could not be found, or it cannot be read.

Explanation

Common reasons for this error include:

- The default options file does not exist.
- You specified the -OPTFILE option when starting the IBM Spectrum Protect client, but the options file you provided does not exist.
- The DSM_CONFIG (or DSMI_CONFIG if you are using the IBM Spectrum Protect API) environment variable specifies an options file that does not exist.
- You specified the -OPTFILE option when starting the IBM Spectrum Protect client, but the options file that you provided is not in the standard file encoding of the system. For example, on Windows the expected file encoding is ANSI.
- You specified the -OPTFILE option when starting the IBM Spectrum Protect client, but the options file that you provided does not have appropriate read permissions for the user that is running the operation.

System action

IBM Spectrum Protect client processing stops.

User response

Make sure that the options file you want to use exists, it has the read rights set for the user that is running the operation, and it is in the standard file encoding of the system. For example, on Windows the expected file encoding is ANSI. Review the configuration information in the IBM Spectrum Protect client manual specific to your operating system. If the problem persists, ask your IBM Spectrum Protect administrator for further assistance.

0408 E DSM_RC_MACHINE_SAME A virtual node name must not equal either a node name or the system host name.

Explanation

A VIRTUALNODENAME option was entered with a name the same as either a NODENAME option or the system host name.

System action

Initialization fails and the program ends.

User response

If the virtual node name entered was the same as the host name, remove the virtual node name option. If it was the same as the node name option, you can remove either one, depending upon the intended usage. Node name is used to assign an alternate name to your system. Virtual node name is used to access another system's server data.

0409 E DSM_RC_INVALID_SERVER Server name not found in System Options File

Explanation

The system options file does not contain the SERVERNAME option.

System action

IBM Spectrum Protect initialization fails and the program ends.

User response

See the IBM Spectrum Protect administrator for your system, and make sure that the system options file contains the server name.

0410 E DSM_RC_INVALID_KEYWORD An invalid option keyword was found during option parsing.

Explanation

An invalid option keyword was found in the dsmInit configuration file, the option string, dsm.sys, or dsm.opt.

System action

The system returns to the calling procedure.

User response

Correct the spelling of the option keywords. Verify that the dsmInit configuration file only has a subset of the dsm.sys options. Check the error log for more details about the error.

0411 S DSM_RC_PATTERN_TOO_COMPLEX The include or exclude pattern cannot be parsed.

Explanation

The pattern is formatted incorrectly or is too complex to be interpreted.

System action

Processing stopped.

User response

Verify that the include or exclude pattern is specified correctly. If the pattern is correct, then contact IBM technical support for further assistance.

0412 S DSM_RC_NO_CLOSING_BRACKET Include/Exclude pattern is missing a closing bracket

Explanation

The include or exclude pattern is incorrectly constructed. The closing bracket is missing.

System action

Processing stopped.

User response

Correct the syntax for the pattern.

0426 E DSM_RC_CANNOT_OPEN_TRACEFILE Initialization functions cannot open the trace file specified.

Explanation

The file could not be opened during initialization. The specified path might be incorrect. It is also possible that the current user does not have permission to write to the tracefile in the directory specified. It is also possible that no space is available at the tracefile location.

System action

Processing stops.

User response

Make sure the tracefile option points to a valid path and that the user has proper permissions to write to the specified file.

0427 E DSM_RC_CANNOT_OPEN_LOGFILE Initialization functions cannot open the error log file specified.

Explanation

The error log file could not be opened during initialization. The specified path may be incorrect. It is also possible that the current user does not have permission to write to the logfile in the directory specified. It is also possible that no space is available at the given logfile location.

System action

Processing terminates.

User response

Make sure the logfile option points to a valid path and that the user has proper permissions to write to the file specified.

0600 E DSM_RC_DUP_LABEL A duplicate volume label exists. The operation cannot continue.

Explanation

For removable media, IBM Spectrum Protect uses the volume label as the file space name. To prevent data from different volumes being stored in the same file space on the IBM Spectrum Protect server, backup or archive of removable media volumes having duplicate volume labels is not allowed.

System action

The requested operation does not run.

User response

Change the volume labels on the removable media volumes so that there are no duplicate labels. Then restart IBM Spectrum Protect and try the operation again.

0601 E DSM_RC_NO_LABEL The drive has no label. The operation cannot continue.

Explanation

Backup or archive of removable media requires that the media have a volume label. An attempt was made to back up or archive data on a removable volume that has no label.

System action

The requested operation does not run.

User response

Create a volume label on the removable media, then try the operation again.

0610 E DSM_RC_NLS_CANT_OPEN_TXT Unable to open message text file.

Explanation

The system is unable to open the message txt file (dscenu.txt or dsmclientV3.cat for AIX). On the AS/400 platform this file is QANSAPI/QAANSENU(TXT).

System action

The system returns to the calling procedure.

User response

Verify that the dscenu.txt file is in the directory pointed to by DSMI_DIR. For AIX, verify that the dsmclientV3.cat file has a symbolic link to /usr/lib/nls/msg/<locale>/dsmclientV3.cat .

0611 E DSM_RC_NLS_CANT_READ_HDR Unable to use message text file.

Explanation

The system is unable to use the message text file (dscenu.txt or dsmclientV3.cat for AIX) because of an invalid header. On the AS/400 platform this file is QANSAPI/QAANSENU(TXT).

System action

The system returns to the calling procedure.

User response

Install the message text file again.

0612 E DSM_RC_NLS_INVALID_CNTL_REC Unable to use message text file.

Explanation

The system is unable to use the message txt file (dscenu.txt or dsmclientV3.cat for AIX) because of an invalid control record. On the AS/400 platform this file is QANSAPI/QAANSENU(TXT).

System action

The system returns to the calling procedure.

User response

Install the message text file again.

0613 E DSM_RC_NLS_INVALID_DATE_FMT Invalid value for DATEFORMAT specified.

Explanation

An invalid value is specified for DATEFORMAT.

System action

The system returns to the calling procedure.

User response

Specify a valid value.

0614 E DSM_RC_NLS_INVALID_TIME_FMT Invalid value for TIMEFORMAT specified.

Explanation

An invalid value is specified for TIMEFORMAT.

System action

The system returns to the calling procedure.

User response

Specify a valid value.

0615 E DSM_RC_NLS_INVALID_NUM_FMT Invalid value for NUMBERFORMAT specified.

Explanation

An invalid value is specified for NUMBERFORMAT.

System action

The system returns to the calling procedure.

User response

Specify a valid value.

0620 E DSM_RC_LOG_CANT_BE_OPENED Unable to open error log file.

Explanation

The system is unable to open the error log file.

System action

The system returns to the calling procedure.

User response

Verify the DSMI_LOG value and access permission. On the AS/400 platform, verify the value specified for ERRORLOGNAME in the API options file.

0621 E DSM_RC_LOG_ERROR_WRITING_TO_LOG The log file cannot be written to.

Explanation

There was an error writing to the log file.

System action

The system returns to the calling procedure.

User response

Verify the DSMI_LOG value and access permission. on the AS/400 platform, verify the value specified for ERRORLOGNAME in the API options file.

0622 E DSM_RC_LOG_NOT_SPECIFIED The log file name was not specified.

Explanation

The system is unable to open the error log file.

System action

The system returns to the calling procedure.

User response

Verify the DSMI_LOG value and access permission. On the AS/400 platform, verify the value specified for ERRORLOGNAME in the API options file.

0927 E DSM_RC_NOT_ADSM_AUTHORIZED Only a IBM Spectrum Protect authorized user can perform this Action.

Explanation

User must be a IBM Spectrum Protect authorized user to perform this action. User is not password authorized and this action requires authorization.

System action

Processing stopped.

User response

User must be root user, or user must be the owner of the executable and the set effective user id bit is set to 'on' ('s' bit).

961 E DSM_RC_DIRECT_STORAGE_AGENT_UNSUPPORTED Direct connection to the Storage Agent is not allowed.

Explanation

You cannot connect directly to the Storage Agent.

System action

Processing stopped.

User response

To perform Lanfree operations using the Storage Agent, specify the ENABLELANFREE option in your options file, and restart the process.

963 E DSM_RC_FS_NAMESPACE_DOWNLEVEL The long namespace has been removed from the local file space. If you wish to proceed with the backup/archive operation, rename your file space on the server.

Explanation

The process has detected that the server namespace is NTW:LONG, but the local volume does not have long name support. If you would like to back up the volume using the short names, rename the file space on the server. If you would like to back up using long names, add the long namespace support back to the volume in question.

System action

Processing stopped.

User response

Add the long namespace support to the volume or rename(remove) the corresponding server file space.

0996 E DSM_RC_SERVER_DOWNLEVEL_FUNC The IBM Spectrum Protect server is downlevel and does not support the requested function. See error log for version information.

Explanation

The function being used requires a more current IBM Spectrum Protect Server.

System action

The operation fails.

User response

Upgrade your IBM Spectrum Protect Server to a level that supports this function. See error log for version information.

0997 E DSM_RC_STORAGEAGENT_DOWNLEVEL The IBM Spectrum Protect Storage Agent is downlevel and does not support the requested function. See error log for version information.

Explanation

The function being used requires a more current IBM Spectrum Protect Storage Agent.

System action

The operation fails.

User response

Upgrade your IBM Spectrum Protect Storage Agent to a level that supports this function. See error log for version information.

0998 E DSM_RC_SERVER_AND_SA_DOWNLEVEL The IBM Spectrum Protect Server and IBM Spectrum Protect Storage agent are downlevel and do not support the requested function. See error log for version information.

Explanation

The function being used requires a more current IBM Spectrum Protect Server and IBM Spectrum Protect Storage agent

System action

The operation fails.

User response

Upgrade your IBM Spectrum Protect Server and IBM Spectrum Protect Storage agent to a level that supports this function. See error log for version information.

1376 E DSM_RC_DIGEST_VALIDATION_ERROR Error processing '*filespace namepath-namefile-name*'; end-to-end digest validation failed.

Explanation

Cryptographic digest of the restored or retrieved data did not match the digest generated during the backup or archive operation. Possible causes are a transmission error, data corruption, or a hash collision.

System action

Processing stops

User response

Try the restore operation again. If the problem persists, contact IBM technical support for additional assistance.

2000 E DSM_RC_NULL_OBJNAME The object name pointer is NULL.

Explanation

There is no value provided for the object name pointer.

System action

The system returns to the calling procedure.

User response

Provide an address for the dsmObjName structure.

2001 E DSM_RC_NULL_DATABLKPTR The data block pointer is NULL.

Explanation

There is no value provided for the data block pointer.

System action

The system returns to the calling procedure.

User response

Provide an address for the DataBlk structure.

2002 E DSM_RC_NULL_MSG msg parameter for dsmRCMsg is a NULL pointer.

Explanation

The message parameter for dsmRCMsg is a NULL pointer.

System action

The system returns to the calling procedure.

User response

Allocate enough space for the message parameter.

2004 E DSM_RC_NULL_OBJATTRPTR The object attribute pointer is NULL.

Explanation

There is no value provided for the object attribute pointer.

System action

The system returns to the calling procedure.

User response

Provide an address for the ObjAttr structure.

2006 E DSM_RC_NO_SESS_BLK There is no server session information.

Explanation

The server did not respond with the session information.

System action

The system returns to the calling procedure.

User response

Verify the server status.

2007 E DSM_RC_NO_POLICY_BLK There is no server policy information.

Explanation

The server did not respond with the policy information.

System action

The system returns to the calling procedure.

User response

Verify the server policy definitions.

2008 E DSM_RC_ZERO_BUFLEN The dataBlk bufferLen value is zero.

Explanation

The value for the dataBlk bufferLen is zero.

System action

The system returns to the calling procedure.

User response

Provide a non-zero value for the bufferLen.

2009 E DSM_RC_NULL_BUFPTR The dataBlk bufferPtr is NULL.

Explanation

There is no value provided for the dataBlk bufferPtr.

System action

The system returns to the calling procedure.

User response

Provide an address for the bufferPtr.

2010 E DSM_RC_INVALID_OBJTYPE The objType is invalid.

Explanation

The value for the objType is invalid.

System action

The system returns to the calling procedure.

User response

The value for dsmObjName.objType must be:

- DSM_OBJ_FILE or DSM_OBJ_DIRECTORY for Backup, or
- DSM_OBJ_FILE for Archive.

2011 E DSM_RC_INVALID_VOTE The dsmEndTxn vote is invalid.

Explanation

The dsmEndTxn vote is invalid.

System action

The system returns to the calling procedure.

User response

The vote must be DSM_VOTE_COMMIT or DSM_VOTE_ABORT.

2012 E DSM_RC_INVALID_ACTION The update action is invalid.

Explanation

The dsmUpdateFS or dsmUpdateObj action is invalid.

System action

The system returns to the calling procedure.

User response

Correct the action value. Valid values are defined in dsmapitd.h and documented in our Using the API book.

2014 E DSM_RC_INVALID_DS_HANDLE There was an error in the IBM Spectrum Protect API internals.

Explanation

The system encountered an error in the API internals.

System action

The system returns to the calling procedure.

User response

Shut down the process and retry the operation. Verify that any previous dsmInit calls were cleaned up and terminated by a dsmTerminate call. If the problem continues, contact your system administrator or service representative.

2015 E DSM_RC_INVALID_REPOS The repository type is invalid.

Explanation

The repository type is invalid.

System action

The system returns to the calling procedure.

User response

For dsmDeleteFS the repository must be one of the following:

- DSM_ARCHIVE_REP
- DSM_BACKUP_REP
- DSM_REPOS_ALL.

2016 E DSM_RC_INVALID_FSNAME Filespace name should start with the directory delimiter.

Explanation

The filespace name is invalid.

System action

The system returns to the calling procedure.

User response

Filespace name should start with the directory delimiter.

2017 E DSM_RC_INVALID_OBJNAME The object name is either an empty string or has no leading delimiter.

Explanation

The object name is invalid because of an empty string or there is no leading delimiter.

System action

The system returns to the calling procedure.

User response

Verify the format of the dsmObjName full path.

2018 E DSM_RC_INVALID_LLNAME Low level qualifier of the object name should start with the directory delimiter.

Explanation

The low level qualifier for the object name is invalid.

System action

The system returns to the calling procedure.

User response

Start the low level qualifier of the object name with the directory delimiter.

2019 E DSM_RC_INVALID_OBJOWNER The object owner is invalid.

Explanation

The object owner must be either the root user, or the object owner must be the same as the session owner.

System action

The system returns to the calling procedure.

User response

Verify the session owner and object owner.

2020 E DSM_RC_INVALID_ACTYPE The dsmBindMC sendType is invalid.

Explanation

The dsmBindMC sendType is invalid.

System action

The system returns to the calling procedure.

User response

The sendType must be one of the following:

- stBackup
- stArchive
- stBackupMountWait
- stArchiveMountWait

2021 E DSM_RC_INVALID_RETCODE no text available for this return code.

Explanation

The dsmRC parameter for dsmRCMsg is an unsupported return code.

System action

The system returns to the calling procedure.

User response

Specify a valid value.

2022 E DSM_RC_INVALID_SENDTYPE The dsmSendObj sendType is invalid.

Explanation

The dsmSendObj sendType is invalid.

System action

The system returns to the calling procedure.

User response

The sendType must be one of the following:

- stBackup
- stArchive
- stBackupMountWait
- stArchiveMountWait

2023 E DSM_RC_INVALID_PARAMETER The dsmDeleteObj delType is invalid.

Explanation

The dsmDeleteObj delType is invalid.

System action

The system returns to the calling procedure.

User response

The delType must be dtBackup or dtArchive.

2024 E DSM_RC_INVALID_OBJSTATE The query Backup objState is invalid.

Explanation

The query Backup objState is invalid.

System action

The system returns to the calling procedure.

User response

The qryBackupData.objState must be one of the following:

- DSM_ACTIVE
- DSM_INACTIVE
- DSM_ANY_MATCH

2025 E DSM_RC_INVALID_MCNAME The management class name was not found.

Explanation

A query or send operation is unable to find the management class name.

System action

The system returns to the calling procedure.

User response

Verify the management class name.

2026 E DSM_RC_INVALID_DRIVE_CHAR The drive letter is not an alphabetic character.

Explanation

The drive letter is not an alphabetic character. This return code is valid on Microsoft Windows only.

System action

The system returns to the calling procedure.

User response

Verify that the drive designation is an alphabetic character. The referenced field is dsmDosFSAttrib.driveLetter.

2027 E DSM_RC_NULL_FSNAME The Register Filespace name is NULL.

Explanation

There is no value provided for the Register Filespace name.

System action

The system returns to the calling procedure.

User response

Provide a filespace name on dsmRegisterFS.

2028 E DSM_RC_INVALID_HLNAME High level qualifier of the object name should start with the directory delimiter.

Explanation

The high level qualifier for the object name is invalid.

System action

The system returns to the calling procedure.

User response

High level qualifier of the object name should start with the directory delimiter.

2029 E DSM_RC_NUMOBJ_EXCEED The number of objects on dsmBeginGetData exceeds DSM_MAX_GET_OBJ | DSM_MAX_PARTIAL_GET_OBJ.

Explanation

The number of objects (numObjId) specified on the dsmBeginGetData call exceeds DSM_MAX_GET_OBJ | DSM_MAX_PARTIAL_GET_OBJ.

System action

The system returns to the calling procedure.

User response

Check the number of objects before calling dsmBeginGetData. If it is greater than DSM_MAX_GET_OBJ | DSM_MAX_PARTIAL_GET_OBJ, then issue multiple Get call sequences.

2030 E DSM_RC_NEWPW_REQD The new password value is NULL or blank.

Explanation

There is no value provided for new password.

System action

The system returns to the calling procedure.

User response

Provide a new password on dsmChangePW.

2031 E DSM_RC_OLDPW_REQD The old password value is NULL or blank.

Explanation

There is no value provided for old password.

System action

The system returns to the calling procedure.

User response

Provide an old password on dsmChangePW.

2032 E DSM_RC_NO_OWNER_REQD On dsmInit, the owner is not allowed to establish a session when PASSWORDACCESS=generate.

Explanation

PASSWORDACCESS=GENERATE establishes a session with the current login user as the owner. The application should set clientOwnerNameP to NULL when PASSWORDACCESS=GENERATE is in effect.

System action

The system returns to the calling procedure. Whether the application can continue processing depends on how the application handles the error.

User response

This message applies to applications that utilize the IBM Spectrum Protect API, and is intended primarily for the vendor of the application for which the message is issued. Depending on the application, this could be a configuration issue.

Consult the documentation for the application and verify that the application is configured correctly. If the problem persists, contact the application vendor for further assistance.

2033 E DSM_RC_NO_NODE_REQD On dsmInit, the node is not allowed when PASSWORDACCESS=generate.

Explanation

PASSWORDACCESS=generate establishes a session with the current hostname as the node.

System action

The system returns to the calling procedure.

User response

When using PASSWORDACCESS=generate, set clientNodeNameP to NULL.

2034 E DSM_RC_KEY_MISSING The key file is missing.

Explanation

The key file for Data Protection for Oracle cannot be found.

System action

The system returns to the calling procedure.

User response

Ensure that you have ordered the Data Protection for Oracle, and install the key file.

2035 E DSM_RC_KEY_BAD The key file content is invalid.

Explanation

The key file content for Data Protection for Oracle is invalid.

System action

The system returns to the calling procedure.

User response

Ensure that you have ordered the Data Protection for Oracle, and install the key file.

2041 E DSM_RC_BAD_CALL_SEQUENCE The sequence of calls is invalid.

Explanation

Then API requires function calls to be made in a specific sequence. The function calls were not made in the expected sequence. The error can be triggered by the following issues:

- An error in the network.
- A bug in the IBM Spectrum Protect API.
- A bug in the IBM Spectrum Protect server.
- A bug in the application (IBM or third party) that uses the IBM Spectrum Protect API.

System action

The system returns to the calling procedure.

User response

An end user can respond in the following ways:

- Check the network for errors.
- Look for clues in the IBM Spectrum Protect server activity log file, client side dsierror.log log file, and log files that are specific to the problem application.
- Search the IBM support pages for APARs that match the problem. The support site is at IBM Spectrum Protect Support Portal
- If the API application is developed by a third party (not IBM), search that third party's support pages for known issues that match the problem.

If none of the above actions resolve the problem, report the problem to the vendor of the application that uses the IBM Spectrum Protect API.

A developer of an application that uses the IBM Spectrum Protect API must investigate the reason for the problem, including reviewing the IBM Spectrum Protect API state diagram. The IBM Spectrum Protect API state diagram is in the product documentation at IBM Spectrum Protect product documentation

2042 E DSM_RC_INVALID_TSMBUFFER The tsmBuffHandle is invalid, or the value of dataPtr is invalid.

Explanation

An invalid value for a handle or dataPtr has been passed into the API.

System action

The system returns to the calling procedure.

User response

There is a problem with the calling application. Verify the values of the tsmBuffHandle and dataptr passed to the API.

2043 E DSM_RC_TOO_MANY_BYTES The number of bytes copied into the tsmBuffer is larger than the allowed value.

Explanation

An invalid number of bytes was copied to a tsmBuffer.

System action

The system returns to the calling procedure.

User response

There is a problem with the calling application. Verify the number of bytes copied into the tsmBuffer.

2044 E DSM_RC_MUST_RELEASE_BUFFER dsmTerminate cannot finish because the application is holding on to 1 or more tsmBuffers.

Explanation

An application is trying to terminate a session, but is still holding some tsmBuffers.

System action

The system returns to the calling procedure.

User response

The application must return all buffers for this session by calling tsmReleaseBuffer, and then issue dsmTerminate.

2045 E DSM_RC_BUFF_ARRAY_ERROR An internal error occurred in the tsmBuffer array.

Explanation

An internal API buffer array error occurred.

System action

The system returns to the calling procedure.

User response

Try the operation again. If the problem continues, contact your system administrator or service representative.

2046 E DSM_RC_INVALID_DATABLK When using useTsmBuffers, dataBlk must be NULL in calls to dsmSendObj and dsmGetObj.

Explanation

The value for dataBlk must be NULL when using useTsmBuffers.

System action

The system returns to the calling procedure.

User response

There is a problem with the calling application. Contact your application provider

2047 E DSM_RC_ENCR_NOT_ALLOWED Encryption is not allowed when using useTsmBuffers.

Explanation

useTsmBuffers does not support encryption.

System action

The system returns to the calling procedure.

User response

Try the operation again, without using useTsmBuffers, or disable encryption for this operation.

2048 E DSM_RC_OBJ_COMPRESSED This object cannot be restored/retrieved using useTsmBuffers, because it is compressed.

Explanation

useTsmBuffers does not support compression.

System action

The system returns to the calling procedure.

User response

Try the operation again, without using useTsmBuffers.

2049 E DSM_RC_OBJ_ENCRYPTED This object cannot be restored/retrieved using useTsmBuffers, because it is encrypted.

Explanation

useTsmBuffers does not support encryption.

System action

The system returns to the calling procedure.

User response

Try the operation again, without using useTsmBuffers.

2050 E DSM_RC_WILDCHAR_NOTALLOWED On dsmSendObj, wildcards are not allowed for the objName.

Explanation

On dsmSendObj, wildcards are not allowed for the objName.

System action

The system returns to the calling procedure.

User response

Provide a fs, hl, and ll on the dsmObjName.

2051 E DSM_RC_POR_NOT_ALLOWED When using useTsmBuffers, a restore/retrieve with partial object restore is not allowed.

Explanation

useTsmBuffers does not support partial object restore.

System action

The system returns to the calling procedure.

User response

Make sure the calling application is either using Partial object restore or useTsmBuffers.

2052 E DSM_RC_NO_ENCRYPTION_KEY No encryption key was found. If you are using -encryptkey=prompt make sure there is a value in the encryptionPasswordP field and that bEncryptKeyEnabled is set to true.

Explanation

There was no encryption key found in the password file, or no key was provided by the application.

System action

The system returns to the calling procedure.

User response

If you are using -encryptkey=prompt, make sure there is a value in encryptionPasswordP and that bEncryptKeyEnabled is set to true.

2053 E DSM_RC_ENCR_CONFLICT Conflicting encryption key options have been specified.

Explanation

When using the ENABLEENCRYPTKEY option, the parameter bEncryptKeyEnabled for the IBM Spectrum Protect API dsmInitExIn_t and tsmInitExIn_t structures cannot be set to bTrue.

System action

The system returns to the calling procedure.

User response

Either remove the ENABLEENCRYPTKEY option from the options file, or set the parameter bEncryptKeyEnabled to bFalse in the program using the IBM Spectrum Protect API.

2060 E DSM_RC_FSNAME_NOTFOUND The filespace to delete/set access cannot be found.

Explanation

The filespace to delete cannot be found.

System action

The system returns to the calling procedure.

User response

Verify the filespace name.

2061 E DSM_RC_FS_NOT_REGISTERED On dsmSendObj, dsmDeleteObj, or dsmUpdateFS the filespace is not registered.

Explanation

On dsmSendObj, dsmDeleteObj, or dsmUpdateFS, the filespace is not registered.

System action

The system returns to the calling procedure.

User response

Verify the filespace name.

2062 W DSM_RC_FS_ALREADY_REGED On dsmRegisterFS the filespace is already registered.

Explanation

On dsmRegisterFS the filespace is already registered.

System action

The system returns to the calling procedure.

User response

Verify the filespace name.

2063 E DSM_RC_OBJID_NOTFOUND On dsmBeginGetData the objID is NULL.

Explanation

On dsmBeginGetData, the objID is NULL.

System action

The system returns to the calling procedure.

User response

Verify the following:

- The dsmGetList is not NULL.
- Each objID is not NULL.
- The dsmGetList numObjId is not zero.

2064 E DSM_RC_WRONG_VERSION On dsmInit, the caller API version is different than the IBM Spectrum Protect library version.

Explanation

On dsmInit, the caller API version is later than the IBM Spectrum Protect library version.

System action

The system returns to the calling procedure.

User response

Install the latest IBM Spectrum Protect API library.

2065 E DSM_RC_WRONG_VERSION_PARM The caller's structure version is different than the IBM Spectrum Protect library version.

Explanation

The caller's structure version is different than the IBM Spectrum Protect library version.

System action

The system returns to the calling procedure.

User response

Ensure that the stVersion field is set with the value in the header file. Recompile the application with the latest header files.

2070 E DSM_RC_NEEDTO_ENDTXN Issue dsmEndTxn and then begin a new transaction session.

Explanation

This transaction must be ended and a new one must be started due to one of the following reasons:

- The destination changed.
- The byte limit is exceeded
- The maximum number of objects is exceeded.

System action

The system returns to the calling procedure.

User response

Issue dsmEndTxn and start a new transaction session.

2080 E DSM_RC_OBJ_EXCLUDED The backup or archive object is excluded from processing.

Explanation

The backup or archive object is excluded from processing.

System action

The system returns to the calling procedure.

User response

Verify the objName and Exclude lists.

2081 E DSM_RC_OBJ_NOBCG The backup object does not have a copy group.

Explanation

The backup object does not have a copy group.

System action

The system returns to the calling procedure.

User response

Verify server policy definitions.

2082 E DSM_RC_OBJ_NOACG The archive object does not have a copy group.

Explanation

The archive object does not have a copy group.

System action

The system returns to the calling procedure.

User response

Verify server policy definitions.

2090 E DSM_RC_APISYSTEM_ERROR Memory used by the IBM Spectrum Protect API has been corrupted.

Explanation

Memory used by the IBM Spectrum Protect API has been corrupted.

System action

The system returns to the calling procedure.

User response

Retry the operation. If the problem continues, contact your system administrator or service representative.

2100 E DSM_RC_DESC_TOOLONG The sendObj Archive description is too long.

Explanation

The sendObj Archive description is too long.

System action

The system returns to the calling procedure.

User response

The sndArchiveData.descr string must be less than or equal to DSM_MAX_DESCR_LENGTH.

2101 E DSM_RC_OBJINFO_TOOLONG The sendObj ObjAttr.objInfo is too long.

Explanation

The sendObj ObjAttr.objInfo is too long.

System action

The system returns to the calling procedure.

User response

The objInfo field must be less than or equal to DSM_MAX_OBJINFO_LENGTH.

2102 E DSM_RC_HL_TOOLONG The sendObj dsmObjName.hl is too long.

Explanation

The sendObj dsmObjName.hl is too long.

System action

The system returns to the calling procedure.

User response

The hl field must be less than or equal to DSM_MAX_HL_LENGTH.

2103 E DSM_RC_PASSWD_TOOLONG The password, or encryptionPassword string provided is too long.

Explanation

The value provided for password or encryptionPassword is too long.

System action

The system returns to the calling procedure.

User response

The password or encrypionPassword field must be less than DSM_MAX_VERIFIER_LENGTH.

2104 E DSM_RC_FILESPACE_TOOLONG The sendObj dsmObjName.fs is too long.

Explanation

The sendObj dsmObjName.fs is too long.

System action

The system returns to the calling procedure.

User response

The fs field must be less than or equal to DSM_MAX_FS_LENGTH.

2105 E DSM_RC_LL_TOOLONG The sendObj dsmObjName.ll is too long.

Explanation

The sendObj dsmObjName.ll is too long.

System action

The system returns to the calling procedure.

User response

The ll field must be less than or equal to DSM_MAX_LL_LENGTH.

2106 E DSM_RC_FSINFO_TOOLONG On RegisterFS or UpdateFS the fsAttr's fsInfo is too long.

Explanation

On RegisterFS or UpdateFS the fsAttr's fsInfo is too long.

System action

The system returns to the calling procedure.

User response

The fsInfo field must be less than or equal to DSM_MAX_FSINFO_LENGTH.

2107 E DSM_RC_SENDDATA_WITH_ZERO_SIZE Cannot Send data with a zero byte sizeEstimate.

Explanation

You cannot send data for an object with size estimate = 0.

System action

The system returns to the calling procedure.

User response

Set size estimate greater than 0 in dsmSendObj.

2110 E DSM_RC_INVALID_ACCESS_TYPE The dsmSetAccess access Type is invalid.

Explanation

The dsmSetAccess accessType is invalid.

System action

The system returns to the calling procedure.

User response

The accessType must be one of the following:

- atBackup
- atArchive

2111 E DSM_RC_QUERY_COMM_FAILURE Communications error with server during object query

Explanation

An unexpected communications error occurred during an object query to the server.

System action

Processing stopped.

User response

Verify that communications are active between the client and server machines. Server outages, processor outages, and communication controller outages can cause this error.

2112 E DSM_RC_NO_FILES_BACKUP No files have been previously backed up for this filename/filespace.

Explanation

You tried to set access to files when no files for the specified filename, drive or file system were previously backed up.

System action

Processing stopped.

User response

Ensure that the correct drive or file system was specified and that files are backed up for you to set access.

2113 E DSM_RC_NO_FILES_ARCHIVE No files have been previously archived for this filename/filespace.

Explanation

You tried to set access to files when no files for the specified filename, drive or file system were previously archived.

System action

Processing stopped.

User response

Ensure that the correct drive or file system was specified and that files are archived for you to set access.

2114 E DSM_RC_INVALID_SETACCESS Invalid format for Set Access command.

Explanation

The SET ACCESS command must have at least three operands, the first of which must be either BACKUP or ARCHIVE. A validly formed file specification must follow.

System action

Processing stopped, the command is not executed.

User response

Use the HELP SET ACCESS command for complete details of usage, then enter the SET ACCESS command using the correct syntax.

2120 E DSM_RC_STRING_TOO_LONG The following message was too long to log to the server: '*shortened message with message number*'

Explanation

The message text and inserts are too large to send to the server in the available internal buffer.

System action

The *message number* message is written to the local client error log, then shortened and sent to the server as a part of this message. The message is reduced in length by substituting '...' in the middle of the original message.

User response

The message referred to has been shortened, but describes the error that occurred. See the documentation for that message for more information.

2200 I DSM_RC_MORE_DATA On dsmGetNextQObj or dsmGetData there is more available data.

Explanation

On dsmGetNextQObj or dsmGetData there is more available data.

System action

The system returns to the calling procedure.

User response

Call the function again.

2210 E DSM_RC_BUFF_TOO_SMALL The dataBlk buffer is too small for the query response.

Explanation

The dataBlk buffer is too small for the query response.

System action

The system returns to the calling procedure.

User response

On dsmGetNextQObj ensure that the dataBlk buffer is at least as big as the query response structure.

2228 E DSM_RC_NO_API_CONFIGFILE The configuration file specified on dsmInit cannot be opened.

Explanation

The configuration file specified on dsmInit cannot be opened.

System action

The system returns to the calling procedure.

User response

Verify the file name.

2229 E DSM_RC_NO_INCLEXCL_FILE The Include/Exclude definition file was not found.

Explanation

The Include/Exclude definition file was not found.

System action

The system returns to the calling procedure.

User response

Verify the file name on the Inclexcl option.

2230 E DSM_RC_NO_SYS_OR_INCLEXCL Either the dsm.sys file was not found, or the Inclexcl file specified in dsm.sys was not found.

Explanation

Either the dsm.sys file was not found, or the Inclexcl file specified in dsm.sys was not found.

System action

The system returns to the calling procedure.

User response

The dsm.sys file must be in the directory referenced by the environment variable DSMI_DIR. Verify the file name on the Inclexcl option in the dsm.sys file.

2231 E DSM_RC_REJECT_NO_POR_SUPPORT Partial Object Retrieve is not supported on this server.

Explanation

The IBM Spectrum Protect server specified by the user does not support partial object retrieve.

System action

The system returns to the calling procedure.

User response

Specify a IBM Spectrum Protect server which supports the partial object retrieve function.

2300 E DSM_RC_NEED_ROOT Only a UNIX root user can execute dsmChangePW or dsmDeleteFS.

Explanation

Only a UNIX root user can execute dsmChangePW or dsmDeleteFS.

System action

The system returns to the calling procedure.

User response

Run this program as a root user.

2301 E DSM_RC_NEEDTO_CALL_BINDMC You must issue dsmBindMC before dsmSendObj.

Explanation

You must issue dsmBindMC before dsmSendObj.

System action

The system returns to the calling procedure.

User response

Modify your program.

2302 I DSM_RC_CHECK_REASON_CODE The dsmEndTxn vote is ABORT, so check the reason field.

Explanation

After a dsmEndTxn call, the transaction is aborted by either the server or client with a DSM_VOTE_ABORT and the reason is returned.

System action

The system returns to the calling procedure.

User response

Check the reason field for the code which explains why the transaction has been aborted.

2400 E DSM_RC_ALMGR_OPEN_FAIL License file could not be opened.

Explanation

The license file was not found, or could not be opened because of permissions or the file is corrupted.

System action

The system returns to the calling procedure.

User response

Check permissions on file. See if the license file is in the correct place.

2401 E DSM_RC_ALMGR_READ_FAIL Read failure on the license file.

Explanation

The license file was not found, or could not be opened because of permissions, or the file is corrupted.

System action

The system returns to the calling procedure.

User response

Check permissions on file. See if the license file is in the correct place.

2402 E DSM_RC_ALMGR_WRITE_FAIL Write failure on the license file.

Explanation

The license file was not found, or could not be opened because of permissions or the file is corrupted.

System action

The system returns to the calling procedure.

User response

Check permissions on file. See if license file is in the correct place.

2403 E DSM_RC__ALMGR_DATA_FMT Data in the license file is not in a valid format.

Explanation

The license file is not valid.

System action

The system returns to the calling procedure.

User response

User needs to obtain a new license.

2404 E DSM_RC_ALMGR_CKSUM_BAD The checksum in the license file does not match the licenseregistration string.

Explanation

The registration string is not valid.

System action

The system returns to the calling procedure.

User response

User needs to obtain a new license.

2405 E DSM_RC_ALMGR_TRIAL_EXPRD This is an expired try and buy license.

Explanation

The registration string is not valid.

System action

The system returns to the calling procedure.

User response

User needs to obtain a new license.

4580 E DSM_RC_ENC_WRONG_KEY Error processing '*filespace namepath-namefile-name*'; invalid encryption key.

Explanation

The key you entered does not match the key that was used to encrypt the file during backup. The file can not be restored unless the matching key is entered.

System action

processing stops.

User response

Try the restore operation again and provide the correct key.

4582 E DSM_RC_ENC_NOT_AUTHORIZED User is not authorized to encrypt *file-space namedirectory_pathfile_name*.

Explanation

The user is not authorized to encrypt the file. Normally, only a IBM Spectrum Protect authorized user or a root user can use IBM Spectrum Protect encryption. However, a certain combination of PASSWORDACCESS and ENCRYPTKEY options may allow encryption operations by a non-authorized user.

System action

The file is not backed up or restored.

User response

Log in as a root or IBM Spectrum Protect authorized user and try the operation again. See IBM Spectrum Protect Backup-Archive Client Installation and User's Guide for the correct usage of the ENCRYPTKEY option.

4584 E DSM_RC_ENC_TYPE_UNKOWN Error processing '*filespace namepath-namefile-name*': unsupported encryption type.

Explanation

The files you are trying to restore or retrieve have been backed up or archived by a later version of the IBM Spectrum Protect client. The file encryption method is not supported by the current client.

System action

Object skipped.

User response

Restore or retrieve the file with the most recent version of the IBM Spectrum Protect client.

4600 E DSM_RC_CLUSTER_INFO_LIBRARY_NOT_LOADED CLUSTERNODE is set to YES but the Cluster Information Daemon is not started.

Explanation

The HACMP Cluster Information Daemon must be started in order to specify the CLUSTERNODE option.

System action

Processing ends.

User response

Start the HACMP Cluster Information Dameon.

4601 E DSM_RC_CLUSTER_LIBRARY_INVALID CLUSTERNODE is set to YES but the cluster load library is not valid.

Explanation

The load library that the operating system provides to obtain the cluster name is not valid. A possible cause is an out-of-date load library which does not contain the proper routines this product expects.

System action

Processing ends.

User response

Ensure that the latest cluster software is installed on the system.

4602 E DSM_RC_CLUSTER_LIBRARY_NOT_LOADED CLUSTERNODE is set to YES but the cluster software is not available on this system.

Explanation

The load library that the operating systems provides to obtain the cluster name is not available on this system.

System action

Processing ends.

User response

Ensure that the cluster software is installed on the system.

4603 E DSM_RC_CLUSTER_NOT_MEMBER_OF_CLUSTER CLUSTERNODE is set to YES but this machine is not a member of a cluster.

Explanation

This machine is not a member of a cluster node. Possible causes are that the cluster service has not been configured correctly, or that the cluster is in the process of initialization.

System action

Processing ends.

User response

Ensure that the cluster software is configured properly. If the cluster is in the process of initialization, retry the operation at a later time.

4604 E DSM_RC_CLUSTER_NOT_ENABLED CLUSTERNODE is set to YES but the cluster service is not enabled on this system.

Explanation

The cluster service has not been enabled on this system.

System action

Processing ends.

User response

Enable the cluster service on the system.

4605 E DSM_RC_CLUSTER_NOT_SUPPORTED The CLUSTERNODE option is not supported on this system.

Explanation

This option is not supported on this system.

System action

Processing ends.

User response

Disable the CLUSTERNODE option in the local options file.

4606 E DSM_RC_CLUSTER_UNKNOWN_ERROR An unexpected error (*retcode*) occurred while the program was trying to obtain the cluster name from the system.

Explanation

An unknown error occurred while the program was trying to obtain the cluster name from the cluster service. The error code is the reason code provided directly from the cluster service being used in this operating system environment.

System action

Processing ends.

User response

Consult the documentation for your clustering software for an explanation of the reason code. Insure that your clustering service is operational, then try the IBM Spectrum Protect operation again.

5200 E DSM_RC_ABORT_CERTIFICATE_NOT_FOUND The remote node is not properly configured on the IBM Spectrum Protect server.

Explanation

The remote node is not properly configured on the IBM Spectrum Protect server.

System action

Processing stopped.

User response

Ensure that the remote node is properly configured and connected to the IBM Spectrum Protect server by using TLS. This validates the remote node configuration and ensures that the information that is related to the remote node is sent to the server.

5702 E DSM_RC_PROXY_REJECT_NO_RESOURCES Proxy Rejected: The IBM Spectrum Protect server has run out of memory.

Explanation

There is not enough memory available to allow this operation to continue.

System action

Current operation has been cancelled.

User response

Try the operation again. If the problem continues, see your system administrator to increase the amount of memory of the server.

5705 E DSM_RC_PROXY_REJECT_DUPLICATE_ID Proxy Rejected: The ASNODENAME and NODENAME options have the same value.

Explanation

The ASNODENAME and NODENAME options cannot have the same value.

System action

The current operation is cancelled.

User response

Use the ASNODENAME option only to access another node. It is not necessary to set the ASNODENAME option to access your own node. Remove the ASNODENAME option from your option file unless you are actually trying to access a node that you have been granted authority to access with the administrative command "`Grant Proxynode`".

5710 E DSM_RC_PROXY_REJECT_ID_IN_USE Proxy Rejected: The node name you specified in the ASNODENAME option is locked.

Explanation

The IBM Spectrum Protect administrator has locked the node you specified as the ASNODENAME option.

System action

The IBM Spectrum Protect operation ends.

User response

The IBM Spectrum Protect server administrator must unlock the node before you can access it. Try the operation later, or check with your IBM Spectrum Protect administrator.

5717 E DSM_RC_PROXY_REJECT_INTERNAL_ERROR Proxy Rejected: The server has an internal error.

Explanation

The client cannot proxy to the node named by the ASNODENAME option because of an internal server error.

System action

Current operation has been cancelled.

User response

See your system administrator immediately.

5722 E DSM_RC_PROXY_REJECT_NOT_AUTHORIZED Proxy Rejected: Proxy authority has not been granted to this node.

Explanation

The node has not been granted proxy authority to access the node named by the ASNODENAME option. The IBM Spectrum Protect administrator must first grant proxy authority.

System action

The IBM Spectrum Protect operation ends.

User response

The IBM Spectrum Protect server administrator must grant proxy authority for this node. See the administrator command "Grant Proxynode".

5746 E DSM_RC_PROXY_INVALID_FROMNODE The ASNODENAME option is not valid with the FROMNODE option.

Explanation

None.

System action

Processing stops.

User response

Remove the ASNODENAME option from the options file or do not use the FROMNODE option.

5748 E DSM_RC_PROXY_INVALID_CLUSTER The ASNODENAME option cannot be used with the CLUSTERNODE option.

Explanation

None.

System action

Processing stops.

User response

Remove the ASNODENAME option and retry the operation.

5749 E DSM_RC_PROXY_INVALID_FUNCTION The operation that is being attempted cannot be invoked using the ASNODENAME option.

Explanation

None.

System action

Processing stops.

User response

Remove the ASNODENAME option and retry the operation.

5801 E DSM_RC_CRYPTO_ICC_ERROR Unexpected error in cryptography library.

Explanation

There was an unexpected error in the cryptography library. See the error log for more information.

System action

processing stops.

User response

Check the error log for ANS1467E to determine the cause of failure. Verify you IBM Spectrum Protect client is installed properly. If needed, reinstall client and/or API. If the problem still exists, contact IBM Spectrum Protect technical support.

Descriptions of I/O codes in server messages

IBM Spectrum Protect™ messages can contain input/output (I/O) codes. The codes can be operation codes, completion codes, additional sense codes (ASC), and additional sense code qualifier (ASCQ) codes.

Code descriptions are provided for I/O error messages from the IBM Spectrum Protect server for all supported operating systems.

Code

Description

OP

I/O operation that failed. These values can be displayed:

- READ
- WRITE
- FSR (forward space record)
- RSR (reverse space record)
- FSF (forward space file)
- RSF (reverse space file)
- WEOF (write end of file mark)
- OFFL (rewind and unload the tape)
- FLUSH (flush)
- GET_MEDIUM_INFO (get medium information)
- LOCATE (locate)
- QRYLBP (query logical block protection)
- RDBLKID (read block ID)
- SETLBP (set logical block protection)
- SETMODE (set mode)
- REW (rewind)
- SPACEEOD (space end of data)
- TESTREADY (test drive ready)

CC

I/O completion code. This value is returned by the device driver to the server when an error occurs. For a list of completion codes, see Completion code and operation code values overview. For information about tape library system calls and error descriptions for the library I/O control requests, see technote S7002972.

KEY

Byte 2 of the sense bytes from the error. The following lists some definitions:

0 = no additional sense bytes available
1 = recovered error
2 = not ready
3 = medium error
4 = hardware error
5 = incorrect request
6 = unit attention (for example, a SCSI bus reset)
7 = data protect
8 = blank check
9 = vendor specific
A = copy canceled
B = canceled command
C = obsolete
D = volume overflow
E = miscompare
F = reserved

ASC/ASCQ
: ASC and ASCQ codes are bytes 12 and 13 of the sense bytes. The drive or library reference manual provided with the device contains tables explaining the values of the KEY, ASC, and ASCQ fields. Descriptions of standard ASC and ASCQ codes provides additional information about standard values of ASC and ASCQ codes.

Operating system error codes
: When a command fails, the operating system returns an error number. To determine what the error codes mean, take the following action:

  - On AIX®, HP-UX, and Solaris, platforms, view the errno.h file in the /usr/include/sys directory. This file provides definitions for error codes.
  - On Linux platforms, view the errno-base.h and errno.h files in the /usr/include/asm-generic directory. These files provides definitions for codes.
  - On Windows platforms, contact Microsoft Support for help with error messages.

- Completion code and operation code values overview
  IBM Spectrum Protect messages can contain device driver completion codes from the device drivers.
- Descriptions of standard ASC and ASCQ codes
  Standard ASC and ASCQ codes are described.

Completion code and operation code values overview

IBM Spectrum Protect™ messages can contain device driver completion codes from the device drivers.

- Device drivers completion codes: Common codes
  IBM Spectrum Protect device drivers provide completion codes that are common to all device classes.
- Device drivers completion codes: Media changers
  IBM Spectrum Protect device drivers provide completion codes that are specific to media changer devices.
- Device drivers completion codes: Tape drives
  IBM Spectrum Protect device drivers provide completion codes that are specific to tape drives.

Device drivers completion codes: Common codes

IBM Spectrum Protect™ device drivers provide completion codes that are common to all device classes.

The following table shows common completion code values for IBM Spectrum Protect device drivers. Each entry provides a description for the I/O error message and the recommended action. After completing the recommended action, try the failing operation again.

Table 1. Completion code values common to all device classes

Decimal	Hexadecimal	Description	Recommended action
200	X'C8'	The device indicated a failure condition, but sense data was unavailable.	Try the failing operation again.
201	X'C9'	The device driver failed.	Contact IBM Spectrum Protect Support.

Decimal	Hexadecimal	Description	Recommended action
202	X'CA'	The device EEPROM failed.	Test the device. Service the device if necessary.
203	X'CB'	Manual intervention is required.	Correct the problem on the device. The problem can be a stuck tape, dirty heads, or a jammed library arm.
204	X'CC'	The system recovered from an I/O error; for your information only.	No action necessary.
205	X'CD'	The SCSI adapter failed.	Check for loose cables, bent pins, bad cables, bad SCSI adapters, improper termination, or bad terminators.
206	X'CE'	A general SCSI failure occurred.	Check for loose cables, bent pins, bad cables, bad SCSI adapters, improper termination, or bad terminators.
207	X'CF'	The device cannot perform the requested action.	Ensure that the device is on and ready. Ensure that the drive was defined appropriately with the DEFINE DRIVE command. Ensure that the device class was defined appropriately with the DEFINE DEVCLASS command.
208	X'D0'	The command stopped.	Contact IBM Spectrum Protect Support.
209	X'D1'	A failure is detected in the device microcode.	Check the microcode level of the drive. Contact the drive manufacturer and request the latest level.
210	X'D2'	The device was reset due to device power-up, SCSI bus reset, or manual tape load/eject.	Try the failing operation again.
211	X'D3'	The SCSI bus is busy.	Ensure that the SCSI IDs are correctly assigned to the correct device, and the device is not being accessed by another process.
212	X'D4'	Persistent reservation is not supported on this device.	No action is necessary.
213	X'D5'	A persistent reservation operation failed.	Reset the device and try the operation again. If the problem persists, contact IBM Spectrum Protect Support.

Device drivers completion codes: Media changers

IBM Spectrum Protect™ device drivers provide completion codes that are specific to media changer devices.

The following table shows completion code values for IBM Spectrum Protect device drivers for media changers. Each entry provides a description for the I/O error message and the recommended action. After performing the recommended action, try the failing operation again.

Table 1. Completion code values for media changers

Decimal	Hexadecimal	Description	Recommended action
300	X'12C'	Cartridge entry/exit error	Check the entry/exit ports for a jammed volume.
301	X'12D'	Cartridge load failure	Check the drive for jammed volumes. On AIX®, display the errpt to check for hardware errors.

Decimal	Hexadecimal	Description	Recommended action
302	X'12E'	Cartridge in failed drive	Check the drive for jammed volumes. On AIX, display the errpt to check for hardware errors.
303	X'12F'	Carousel not loaded	Ensure that the carousel is correctly in place and the door is shut.
304	X'130'	Changer failure	On AIX, display the errpt to check for hardware errors.
305	X'131'	Drive failure	Ensure that the heads are clean. On AIX, display the errpt to check for hardware errors.
306	X'132'	Drive or media failure	Ensure that the heads are clean. On AIX, display the errpt to check for hardware errors.
307	X'133'	Entry/exit failure	Check the tape library interface for hardware errors. If there are no errors, contact IBM Spectrum Protect Support.
308	X'134'	Entry/exit port not present	Check the tape library interface for hardware errors. If there are no errors, contact IBM Spectrum Protect Support.
309	X'135'	Library audit error	Ensure that there are no jammed volumes. It is possible that the library audit is failing due to hardware errors. On AIX, display the errpt to check for hardware errors.
310	X'136'	Library full	Check for jammed volumes. Ensure that the volumes are not rearranged. If the library is not full, start the AUDIT LIBRARY command.
311	X'137'	Media export	Check the tape library interface for hardware errors. If there are no errors, contact IBM Spectrum Protect Support.
312	X'138'	Slot failure	Ensure that nothing is jammed in the slot.
313	X'139'	Slot or media failure	Ensure that the volume is not jammed in the slot and that the volumes are not rearranged. If the problem persists, start the AUDIT LIBRARY command.
314	X'13A'	The source slot or drive was empty in an attempt to move a volume	Ensure that the volumes are not rearranged. If the problem persists, start the AUDIT LIBRARY command.
315	X'13B'	The destination slot or drive was full in an attempt to move a volume	Ensure that the volumes are not rearranged, or that a volume is not stuck in the drive. If problem persists, start the AUDIT LIBRARY command.
316	X'13C'	Cleaner cartridge installed	Contact IBM Spectrum Protect support.
317	X'13D'	Media not ejected	Ensure that the volumes are not rearranged, or that a volume is not stuck in the drive. If problem persists, start the AUDIT LIBRARY command.
318	X'13E'	I/O port not configured	Contact IBM Spectrum Protect Support.
319	X'13F'	First destination empty	Ensure that the volumes are not rearranged. If problem persists, start the AUDIT LIBRARY command.
320	X'140'	No inventory information	Start the AUDIT LIBRARY command.

Decimal	Hexadecimal	Description	Recommended action
321	X'141'	Read element status mismatch	Ensure that host bus adapter drivers and firmware are at current levels. Check the tape library interface for hardware errors. If there are no errors, contact IBM Spectrum Protect Support.
322	X'142'	Initialize range failed	Check the tape library interface for hardware errors. If there are no errors, contact IBM Spectrum Protect Support.

Device drivers completion codes: Tape drives

IBM Spectrum Protect™ device drivers provide completion codes that are specific to tape drives.

The following table shows completion code values for IBM Spectrum Protect device drivers for tape drives. Each entry provides a description for the I/O error message and the recommended action. After trying the recommended action, try the failing operation again.

Table 1. Completion code values for tape drives

Decimal	Hexadecimal	Description	Recommended action
400	X'190'	Physical end of media encountered	Ensure that the heads are clean on the drive.
401	X'191'	End of data detected	Contact IBM Spectrum Protect Support.
402	X'192'	Media corrupted	Ensure that the heads are clean. Ensure that the media is not physically damaged and has not reached the end of life as specified by the media manufacturer.
403	X'193'	Media failure	Ensure that the heads are clean. Ensure that the media is not physically damaged and has not reached the end of life as specified by the media manufacturer.
404	X'194'	Media incompatibility	Ensure that the correct length and type of media is being used.
406	X'196'	Sector that is requested is invalid	Internal server error. Contact IBM Spectrum Protect Support.
407	X'197'	Write protect	Ensure that the volume is not write protected.
408	X'198'	Clean the media and the drive	Clean the drive heads with a cleaning cartridge.
409	X'199'	Media fault	Ensure that the heads are clean. Ensure that the media is not physically damaged and has not reached the end of life as specified by the media manufacturer.
410	X'19A'	Cleaning complete	Try the failing operation again.
411	X'19B'	Logical end of media encountered	ContactIBM Spectrum Protect Support.
412	X'19C'	Media not present in drive	Ensure that the media is correctly positioned in the drive. If problem persists, start the AUDIT LIBRARY command.
413	X'19D'	Encountered the beginning of the media	Contact IBM Spectrum Protect Support.
414	X'19E'	Erase failure	Clean the drive heads.
415	X'19F'	Attempted to overwrite written WORM media	Internal server error. ContactIBM Spectrum Protect Support.

Decimal	Hexadecimal	Description	Recommended action
416	X'1A0'	An incorrect length block was read.	Ensure that the heads are clean. On AIX®, display the errpt to check for hardware errors.
417	X'1A1'	Open read only	Contact IBM Spectrum Protect Support.
418	X'1A2'	Open write only	Contact IBM Spectrum Protect Support.
419	X'1A2'	Media scan failed	Clean the drive and media.
420	X'1A4'	Logical write protect	Ensure that the heads are clean. Check operating system error logs for hardware errors. Verify that the write protect tab is off. Turn off SAN tape acceleration or set CHECKTAPEPOS to OFF or TSMonly.
422	X'1A6'	Cleaning is required	Clean the tape drive.
423	X'1A7'	Media error	Check operating system error logs for hardware errors. Check for bad media.
424	X'1A8'	Encryption-related error occurred	Check your encryption setting on your device class and tape drive.
425	X'1A9'	Decryption-related error occurred	Check your encryption setting on your device class and tape drive.
425	X'1AA'	An external, encryption-related error occurred	Check the encryption setting on your device class and tape drive.
426	X'1AB'	A CRC mismatch occurred	Ensure that the media has not reached the end of life as specified by the media manufacturer. Try the operation again.

Descriptions of standard ASC and ASCQ codes

Standard ASC and ASCQ codes are described.

The ASC and ASCQ codes are bytes 12 and 13 for SCSI-2 devices. On Windows systems, these codes are displayed in the Windows Event Log, but the information is in different bytes.

See server message ANR8300E or ANR8302E for the recommended action.

The following table provides standard descriptions for some ASC and ASCQ codes. Each value has a prefix of 0x, which indicates that it is a hexadecimal constant. Note that descriptions vary among devices. For an accurate description of ASC and ASCQ codes for any device, see the documentation that comes with the device.

Table 1. Descriptions of standard ASC and ASCQ codes

ASC	ASCQ	Description
0x00	0x00	No additional sense
0x00	0x01	Filemark detected
0x00	0x02	End-of-medium detected
0x00	0x03	Setmark detected
0x00	0x04	Beginning of medium
0x00	0x05	End of data
0x00	0x06	I/O process terminated
0x02	0x00	No seek complete
0x03	0x00	Device write fault
0x03	0x01	No write current

ASC	ASCQ	Description
0x03	0x02	Excessive write errors
0x04	0x00	Logical unit not ready
0x04	0x01	Becoming ready
0x04	0x02	Not ready, initializing command required
0x04	0x03	Not ready, manual intervention required
0x04	0x04	Not ready, formatting
0x05	0x00	No response to select
0x06	0x00	No reference position found
0x07	0x00	Multiple devices selected
0x08	0x00	Communication failure
0x08	0x01	Communication timeout
0x08	0x02	Communication parity error
0x09	0x00	Track following error
0x0A	0x00	Error log overflow
0x0C	0x00	Write error
0x11	0x00	Unrecovered read error
0x11	0x01	Read retries exhausted
0x11	0x02	Error too long to correct
0x11	0x03	Multiple read errors
0x11	0x08	Incomplete block read
0x11	0x09	No gap found
0x11	0x0A	Miscorrected error
0x14	0x00	Recorded entity not found
0x14	0x01	Record not found
0x14	0x02	Filemark/setmark not found
0x14	0x03	End-of-data not found
0x14	0x04	Block sequence error
0x15	0x00	Random positioning error
0x15	0x01	Mechanical positioning error
0x15	0x02	Read positioning error
0x17	0x00	No error correction applied
0x17	0x01	Recovered with retries
0x17	0x02	Recovered with positive head offset
0x17	0x03	Recovered with negative head offset
0x18	0x00	ECC applied
0x1A	0x00	Parameter list length error
0x1B	0x00	Synchronous data transfer error
0x20	0x00	Invalid operation code
0x21	0x00	Block out of range
0x21	0x01	Invalid element address

ASC	ASCQ	Description
0x24	0x00	Invalid field in CDB
0x25	0x00	LUN not supported
0x26	00	Invalid field in parameter list
0x26	0x01	Parameter not supported
0x26	0x02	Parameter value invalid
0x26	0x03	Threshold parameters not supported
0x27	0x00	Write protected
0x28	0x00	Not-ready to ready
0x28	0x01	Import/export element accessed
0x29	0x00	Power-on, reset, bus reset
0x2A	0x00	Parameters changed
0x2A	0x01	Mode parameters changed
0x2A	0x02	Log parameters changed
0x2B	0x00	Copy cannot run
0x2C	0x00	Command sequence error
0x2D	0x00	Overwrite error on update
0x2F	0x00	Command cleared by initiator
0x30	0x00	Incompatible media
0x30	0x01	Media unknown format
0x30	0x02	Media incompatible format
0x30	0x03	Cleaning cartridge installed
0x31	0x00	Media format corrupted
0x33	0x00	Tape length error
0x37	0x00	Rounded parameter
0x39	0x00	Saving parameters not supported
0x3A	0x00	Medium not present
0x3B	0x00	Sequential positioning error
0x3B	0x01	Positioning error at BOT
0x3B	0x02	Positioning error at EOT
0x3B	0x08	Reposition error
0x3B	0x0D	Medium destination element full
0x3B	0x0E	Medium source element empty
0x3D	0x00	Invalid bits in message
0x3E	0x00	LUN not self-configured
0x3F	0x00	Operating conditions changed
0x3F	0x01	Microcode changed
0x3F	0x02	Changed operating definition
0x3F	0x03	Inquiry data changed
0x3F	0x0E	Reported LUNs data changed
0x43	0x00	Message error

ASC	ASCQ	Description
0x44	0x00	Internal target failure
0x45	0x00	Select/reselect failure
0x46	0x00	Unsuccessful soft reset
0x47	0x00	SCSI parity error
0x48	0x00	Initiator detected message received
0x49	0x00	Invalid message error
0x4A	0x00	Command phase error
0x4B	0x00	Data phase error
0x4C	0x00	LUN failed self-configuration
0x4E	0x00	Overlapped commands attempt
0x50	0x00	Write append error
0x50	0x01	Write append position error
0x50	0x02	Position error (timing)
0x51	0x00	Erase failure
0x52	0x00	Cartridge fault
0x53	0x00	Load/media eject failed
0x53	0x01	Unload tape failure
0x53	0x02	Media removal prevented
0x5A	0x00	Operator state changed
0x5A	0x01	Operator media removal
0x5A	0x02	Operator write protect
0x5A	0x03	Operator write permit

Device error codes in the AIX system error log

Some device error codes are logged in the AIX® system error log.

ADSM_DD_LOG1 (0xAC3AB953)
DEVICE DRIVER SOFTWARE ERROR

This error is logged by the IBM Spectrum Protect™ device driver when a problem is suspected in the IBM Spectrum Protect device driver software. If the IBM Spectrum Protect device driver issues a SCSI I/O command with an illegal operation code, the command fails and the error is logged with this identifier. Report this error immediately to IBM Spectrum Protect Support.

Detail Data: Sense Data

The sense data contains information that can determine the cause of the error. Report all data in the error entry to IBM Spectrum Protect Support.

ADSM_DD_LOG2 (0x5680E405)

HARDWARE/COMMAND-ABORTED ERROR

This error is logged by the IBM Spectrum Protect device driver when the device reports a hardware error or stop-command error in response to a SCSI I/O command.

Detail Data: Sense Data

The sense data contains information that can determine which hardware component failed and why. To interpret the sense data for a particular device, refer to the SCSI specification manual for the device.

ADSM_DD_LOG3 (0x461B41DE)
MEDIA ERROR

This error is logged by the IBM Spectrum Protect device driver when a SCSI I/O command fails because of corrupted or incompatible media, or because a drive requires cleaning.

Detail Data: Sense Data

The sense data contains information that can determine the cause of the error. To interpret the sense data for a particular device, refer to the SCSI specification manual for the device.

ADSM_DD_LOG4 (0x4225DB66)
TARGET DEVICE GOT UNIT ATTENTION

This error is logged by the IBM Spectrum Protect device driver after receiving certain UNIT ATTENTION notifications from a device. UNIT ATTENTIONs are informational and usually indicate that some state of the device changed. For example, this error would be logged if the door of a library device was opened and then closed. Logging this event indicates that the activity occurred and that the library inventory might be changed.

Detail Data: Sense Data

The sense data contains information that describes the reason for the UNIT ATTENTION. To interpret the sense data for a particular device, see the SCSI specification manual for the device.

ADSM_DD_LOG5 (0xDAC55CE5)
PERMANENT UNKNOWN ERROR

This error is logged by the IBM Spectrum Protect device driver after receiving an unknown error from a device in response to a SCSI I/O command. If the error persists, report it to IBM Spectrum Protect support personnel.

Detail Data: Sense Data

The sense data consists of information that can determine the cause of the error. Report all data in the error entry to IBM Spectrum Protect Support.

ADSM_DD_LOG6 (0xBC539B26)
WARNING OR INFORMATIONAL MESSAGE FOR TARGET DEVICE

This error is logged by the IBM Spectrum Protect device driver after receiving a warning or informational message from a device in response to a SCSI I/O command. These informational messages might not be an indication of a problem. If the message persists, report it to IBM Spectrum Protect Support.

Detail Data: Sense Data

The sense data consists of information that can determine the reason for the message. Report all data in the entry to IBM Spectrum Protect Support.

IBM Global Security Kit return codes

The server and client use the IBM Global Security Kit (GSKit) for SSL (Secure Sockets Layer) processing between the server and the backup-archive client. Some messages that are issued for SSL processing include GSKit return codes.

GSKit is automatically installed or updated during IBM Spectrum Protect™ installation and provides the following libraries:

- GSKit SSL
- GSKit Key Management API

- IBM Crypto for C (ICC)

The tsmdiag utility reports the GSKit level that is installed on your system, or you can use one of the following methods:

- For Windows, issue the following commands:

  ```
  regedit /e gskitinfo.txt "HKEY_LOCAL_MACHINE\software\ibm\gsk8\"
  notepad gskitinfo.txt
  ```

  CAUTION:
  You can damage the system registry if you use regedit incorrectly.
- For the 64-bit AIX® server, issue the following command from the command line: `gsk8ver_64`

See Table 1 for the GSKit SSL return codes.

The server uses the GSKit Key Management API to automatically create the key management database and server private and public keys. Some messages that are issued for this processing might include GSKit Key Management return codes. See Table 2 for the key management return codes.

Table 1. IBM Global Security Kit SSL general return codes

Return code (hex)	Return code (decimal)	Constant	Explanation
0x00000000	0	GSK_OK	The task completes successfully. Issued by every function call that completes successfully.
0x00000001	1	GSK_INVALID_HANDLE	The environment or SSL handle is not valid. The specified handle was not the result of a successful `open()` function call.
0x00000002	2	GSK_API_NOT_AVAILABLE	The dynamic link library (DLL) was unloaded and is not available (occurs on Microsoft Windows systems only).
0x00000003	3	GSK_INTERNAL_ERROR	Internal error. Report this error to IBM Software Support.
0x00000004	4	GSK_INSUFFICIENT_STORAGE	Insufficient memory is available to complete the operation.
0x00000005	5	GSK_INVALID_STATE	The handle is not in a valid state for operation, such as completing an `init()` operation on a handle twice.
0x00000006	6	GSK_KEY_LABEL_NOT_FOUND	Specified key label is not found in key file.
0x00000007	7	GSK_CERTIFICATE_NOT_AVAILABLE	Certificate is not received from the partner.
0x00000008	8	GSK_ERROR_CERT_VALIDATION	Certificate validation error.
0x00000009	9	GSK_ERROR_CRYPTO	Error processing cryptography.
0x0000000a	10	GSK_ERROR_ASN	Error validating ASN fields in certificate.
0x0000000b	11	GSK_ERROR_LDAP	Error connecting to user registry.
0x0000000c	12	GSK_ERROR_UNKNOWN_ERROR	Internal error. Report this error to IBM Software Support.
0x0000000d	13	GSK_INVALID_PARAMETER	Invalid parameter.
0x0000000e	14	GSK_ERROR_UNEXPECTED_INT_EXCEPTION	Invalid parameter. Report this error to IBM Software Support.
0x00000065	101	GSK_OPEN_CIPHER_ERROR	Internal error. Report this error to IBM Software Support.
0x00000066	102	GSK_KEYFILE_IO_ERROR	I/O error reading the key file.
0x00000067	103	GSK_KEYFILE_INVALID_FORMAT	The key file does not have a valid internal format. Recreate the key file.
0x00000068	104	GSK_KEYFILE_DUPLICATE_KEY	The key file has two entries with the same key.

Return code (hex)	Return code (decimal)	Constant	Explanation
0x00000069	105	GSK_KEYFILE_DUPLICATE_LABEL	The key file has two entries with the same label.
0x0000006a	106	GSK_BAD_FORMAT_OR_INVALID_PASSWORD	The key file password is used as an integrity check. Either the key file is corrupted or the password ID is incorrect.
0x0000006b	107	GSK_KEYFILE_CERT_EXPIRED	The default key in the key file has an expired certificate.
0x0000006c	108	GSK_ERROR_LOAD_GSKLIB	An error occurred loading one of the GSK dynamic link libraries. Check that GSK was installed correctly.
0x0000006d	109	GSK_PENDING_CLOSE_ERROR	Indicates that a connection is trying to be made in a GSK environment after the GSK_ENVIRONMENT_ CLOSE_OPTIONS was set to GSK_DELAYED_ ENVIRONMENT_CLOSE and gsk_environment_close() function was called.
0x000000c9	201	GSK_NO_KEYFILE_PASSWORD	Both the password and the stash-file name were not specified. The key file is not initialized.
0x000000ca	202	GSK_KEYRING_OPEN_ERROR	Unable to open the key file. Either the path was specified incorrectly or the file permissions did not allow the file to be opened.
0x000000cb	203	GSK_RSA_TEMP_KEY_PAIR	Unable to generate a temporary key pair. Report this error to IBM Software Support.
0x000000cc	204	GSK_ERROR_LDAP_NO_SUCH_OBJECT	A user name object was specified that is not found.
0x000000cd	205	GSK_ERROR_LDAP_INVALID_CREDENTIALS	A password that is used for an LDAP (lightweight directory access protocol) query is not correct.
0x000000ce	206	GSK_ERROR_BAD_INDEX	An index into the Fail Over list of LDAP servers was not correct.
0x000000cf	207	GSK_ERROR_FIPS_NOT_SUPPORTED	This installation of GSKit does not support FIPS mode of operation.
0x0000012d	301	GSK_CLOSE_FAILED	Indicates that the GSK environment close request was not properly managed. Cause is most likely due to a gsk_secure_socket*() command that is attempted after a gsk_close_environment() call.
0x00000191	401	GSK_ERROR_BAD_DATE	The system date was not set to a valid value.
0x00000192	402	GSK_ERROR_NO_CIPHERS	The SSLv2 and the SSLv3 are not enabled.
0x00000193	403	GSK_ERROR_NO_CERTIFICATE	The required certificate was not received from the partner.
0x00000194	404	GSK_ERROR_BAD_CERTIFICATE	The received certificate was formatted incorrectly.
0x00000195	405	GSK_ERROR_UNSUPPORTED_CERTIFICATE_TYPE	The received certificate type was not supported.
0x00000196	406	GSK_ERROR_IO	An I/O error occurred on a data read or write operation.
0x00000197	407	GSK_ERROR_BAD_KEYFILE_LABEL	The specified label in the key file is not found.

Return code (hex)	Return code (decimal)	Constant	Explanation
0x00000198	408	GSK_ERROR_BAD_KEYFILE_PASSWORD	The specified key file password is incorrect. The key file cannot be used. The key file also might be corrupt.
0x00000199	409	GSK_ERROR_BAD_KEY_LEN_FOR_EXPORT	In a restricted cryptography environment, the key size is too long to be supported.
0x0000019a	410	GSK_ERROR_BAD_MESSAGE	An incorrectly formatted SSL message was received from the partner.
0x0000019b	411	GSK_ERROR_BAD_MAC	The message authentication code (MAC) was not successfully verified.
0x0000019c	412	GSK_ERROR_UNSUPPORTED	Unsupported SSL protocol or unsupported certificate type.
0x0000019d	413	GSK_ERROR_BAD_CERT_SIG	The received certificate contained an incorrect signature.
0x0000019e	414	GSK_ERROR_BAD_CERT	Incorrectly formatted certificate is received from the partner.
0x0000019f	415	GSK_ERROR_BAD_PEER	Did not receive a valid SSL protocol from the partner.
0x000001a0	416	GSK_ERROR_PERMISSION_DENIED	Report this error to IBM Software Support.
0x000001a1	417	GSK_ERROR_SELF_SIGNED	The self-signed certificate is not valid.
0x000001a2	418	GSK_ERROR_NO_READ_FUNCTION	The `read()` failed. Report this error to IBM Software Support.
0x000001a3	419	GSK_ERROR_NO_WRITE_FUNCTION	The `write()` failed. Report this error to IBM Software Support.
0x000001a4	420	GSK_ERROR_SOCKET_CLOSED	The partner closed the socket before the protocol completed.
0x000001a5	421	GSK_ERROR_BAD_V2_CIPHER	The specified V2 cipher is not valid.
0x000001a6	422	GSK_ERROR_BAD_V3_CIPHER	The specified V3 cipher is not valid.
0x000001a7	423	GSK_ERROR_BAD_SEC_TYPE	Report this error to IBM Software Support.
0x000001a8	424	GSK_ERROR_BAD_SEC_TYPE_COMBINATION	Report this error to IBM Software Support.
0x000001a9	425	GSK_ERROR_HANDLE_CREATION_FAILED	The handle cannot be created. Report this error to IBM Software Support.
0x000001aa	426	GSK_ERROR_INITIALIZATION_FAILED	Initialization failed. Report this internal error to service.
0x000001ab	427	GSK_ERROR_LDAP_NOT_AVAILABLE	Not able to access the specified user registry when a certificate is being validated.
0x000001ac	428	GSK_ERROR_NO_PRIVATE_KEY	The specified key did not contain a private key.
0x000001ad	429	GSK_ERROR_PKCS11_LIBRARY_NOTLOADED	A failed attempt was made to load the specified PKCS11 shared library.
0x000001ae	430	GSK_ERROR_PKCS11_TOKEN_LABELMISMATCH	The PKCS #11 driver failed to find the token that is specified by the caller.
0x000001af	431	GSK_ERROR_PKCS11_TOKEN_NOTPRESENT	A PKCS #11 token is not present in the slot.
0x000001b0	432	GSK_ERROR_PKCS11_TOKEN_BADPASSWORD	The password/pin to access the PKCS #11 token is not valid.
0x000001b1	433	GSK_ERROR_INVALID_V2_HEADER	The SSL header received was not a properly formatted SSLv2 header.

Return code (hex)	Return code (decimal)	Constant	Explanation
0x000001b2	434	GSK_CSP_OPEN_ERROR	Cannot open the hardware-based cryptographic service provider. Either the CSP name is not specified correctly or a failed attempt was made to access the specified CSP certificate store.
0x000001b3	435	GSK_CONFLICTING_ATTRIBUTE_SETTING	Attribute setting conflict between PKCS11, CMS key database, and Microsoft Crypto API.
0x000001b4	436	GSK_UNSUPPORTED_PLATFORM	The requested function is not supported on the platform that the application is running. For example, the Microsoft Crypto API is not supported on platforms other than Windows 2000.
0x000001b6	438	GSK_ERROR_INCORRECT_SESSION_TYPE	Incorrect value is returned from the reset session type callback function. Only GSKit `gsk_sever_session`, `gsk_sever_session_with_cl_auth`, or `gsk_sever_session_with_cl_auth_crit` is allowed.
0x000001f5	501	GSK_INVALID_BUFFER_SIZE	The buffer size is negative or zero.
0x000001f6	502	GSK_WOULD_BLOCK	Used with nonblocking I/O. Refer to the nonblocking section for usage.
0x00000259	601	GSK_ERROR_NOT_SSLV3	SSLv3 is required for `reset_cipher()`, and the connection uses SSLv2.
0x0000025a	602	GSK_MISC_INVALID_ID	A valid ID was not specified for the `gsk_secure_soc_misc()` function call.
0x000002bd	701	GSK_ATTRIBUTE_INVALID_ID	The function call does not have a valid ID. This issue might also be caused by specifying an environment handle when a handle for an SSL connection should be used.
0x000002be	702	GSK_ATTRIBUTE_INVALID_LENGTH	The attribute has a negative length, which is not valid.
0x000002bf	703	GSK_ATTRIBUTE_INVALID_ENUMERATION	The enumeration value is not valid for the specified enumeration type.
0x000002c0	704	GSK_ATTRIBUTE_INVALID_SID_CACHE	A parameter list that is not valid for replacing the SID cache routines.
0x000002c1	705	GSK_ATTRIBUTE_INVALID_NUMERIC_VALUE	When a numeric attribute is set, the specified value is not valid for the specific attribute that is being set.
0x000002c2	706	GSK_CONFLICTING_VALIDATION_SETTING	Conflicting parameters were set for additional certificate validation.
0x000002c3	707	GSK_AES_UNSUPPORTED	The AES cryptographic algorithm is not supported.
0x000002c4	708	GSK_PEERID_LENGTH_ERROR	The PEERID does not have the correct length.
0x000002c5	709	GSK_CIPHER_INVALID_WHEN_FIPS_MODE_OFF	The particular cipher is not allowed when FIPS mode of operation is off.
0x000002c6	710	GSK_CIPHER_INVALID_WHEN_FIPS_MODE_ON	No approved FIPS ciphers are selected in FIPS mode of operation.
0x00000641	1601	GSK_TRACE_STARTED	The trace started successfully.
0x00000642	1602	GSK_TRACE_STOPPED	The trace stopped successfully.

Return code (hex)	Return code (decimal)	Constant	Explanation
0x00000643	1603	GSK_TRACE_NOT_STARTED	No trace file was previously started, so it cannot be stopped.
0x00000644	1604	GSK_TRACE_ALREADY_STARTED	Trace file is started, so it cannot be restarted.
0x00000645	1605	GSK_TRACE_OPEN_FAILED	Trace file cannot be opened. The first parameter of `gsk_start_trace()` must be a valid full path file name.

Table 2. IBM Global Security Kit key management return codes

Return code (hex)	Return code (decimal)	Constant	Explanation
0x00000000	0	GSK_OK	The task completes successfully. This message is issued by every function call that completes successfully.
0x00000001	1	GSK_INVALID_HANDLE	The environment or SSL handle is not valid. The specified handle was not the result of a successful open() function call.
0x00000002	2	GSK_API_NOT_AVAILABLE	The DLL (dynamic link library) was unloaded and is not available (occurs on Microsoft Windows systems only).
0x00000003	3	GSK_INTERNAL_ERROR	Internal error. Report this error to IBM Software Support.
0x00000004	4	GSK_INSUFFICIENT_STORAGE	Insufficient memory is available to complete the operation.
0x00000005	5	GSK_INVALID_STATE	The handle is in an incorrect state for operation, such as completing an init() operation on a handle twice.
0x00000006	6	GSK_KEY_LABEL_NOT_FOUND	Specified key label is not found in key file.
0x00000007	7	GSK_CERTIFICATE_NOT_AVAILABLE	Certificate is not received from the partner.
0x00000008	8	GSK_ERROR_CERT_VALIDATION	Certificate validation error.
0x00000009	9	GSK_ERROR_CRYPTO	Error processing cryptography.
0x0000000a	10	GSK_ERROR_ASN	Error validating ASN fields in certificate.
0x0000000b	11	GSK_ERROR_LDAP	Error connecting to user registry.
0x0000000c	12	GSK_ERROR_UNKNOWN_ERROR	Internal error. Report this error to IBM Software Support.
0x00000065	101	GSK_OPEN_CIPHER_ERROR	Internal error. Report this error to IBM Software Support.
0x00000066	102	GSK_KEYFILE_IO_ERROR	I/O error reading the key file.
0x00000067	103	GSK_KEYFILE_INVALID_FORMAT	The key file has an internal format that is not valid. Recreate key file.
0x00000068	104	GSK_KEYFILE_DUPLICATE_KEY	The key file has two entries with the same key.

Return code (hex)	Return code (decimal)	Constant	Explanation
0x00000069	105	GSK_KEYFILE_DUPLICATE_LABEL	The key file has two entries with the same label.
0x0000006a	106	GSK_BAD_FORMAT_OR_INVALID_ PASSWORD	The key file password is used as an integrity check. Either the key file is corrupted or the password ID is incorrect.
0x0000006b	107	GSK_KEYFILE_CERT_EXPIRED	The default key in the key file has an expired certificate.
0x0000006c	108	GSK_ERROR_LOAD_GSKLIB	An error occurred while one of the GSK dynamic link libraries is loaded. Check GSK was installed correctly.
0x0000006d	109	GSK_PENDING_CLOSE_ERROR	This message indicates that a connection is trying to be made in a GSK environment after the GSK_ENVIRONMENT_ CLOSE_OPTIONS was set to GSK_DELAYED_ ENVIRONMENT_CLOSE and gsk_environment_close() function was called.
0x000000c9	201	GSK_NO_KEYFILE_PASSWORD	Both the password and the stash-file name were not specified, so the key file is not initialized.
0x000000ca	202	GSK_KEYRING_OPEN_ERROR	Unable to open the key file. Either the path was specified incorrectly or the file permissions did not allow the file to be opened.
0x000000cb	203	GSK_RSA_TEMP_KEY_PAIR	Unable to generate a temporary key pair. Report this error to IBM Software Support.
0x000000cc	204	GSK_ERROR_LDAP_NO_SUCH_OBJECT	A user name object was specified that is not found.
0x000000cd	205	GSK_ERROR_LDAP_INVALID_ CREDENTIALS	A Password that is used for an LDAP query is not correct.
0x000000ce	206	GSK_ERROR_BAD_INDEX	An index into the Fail Over list of LDAP servers was not correct.
0x000000cf	207	GSK_ERROR_FIPS_NOT_SUPPORTED	This installation of GSKit does not support FIPS mode of operation.
0x0000012d	301	GSK_CLOSE_FAILED	Indicates that the GSK environment close request was not properly managed. Cause is most likely due to attempting a gsk_secure_socket*() command after a gsk_close_environment() call.
0x00000191	401	GSK_ERROR_BAD_DATE	The system date was set to a value that is not valid.
0x00000192	402	GSK_ERROR_NO_CIPHERS	SSLv2 and SSLv3 are not enabled.
0x00000193	403	GSK_ERROR_NO_CERTIFICATE	The required certificate was not received from the partner.

Return code (hex)	Return code (decimal)	Constant	Explanation
0x00000194	404	GSK_ERROR_BAD_CERTIFICATE	The received certificate was formatted incorrectly.
0x00000195	405	GSK_ERROR_UNSUPPORTED_ CERTIFICATE_TYPE	The received certificate type was not supported.
0x00000196	406	GSK_ERROR_IO	An I/O error occurred on a data read-or-write operation.
0x00000197	407	GSK_ERROR_BAD_KEYFILE_LABEL	The specified label in the key file is not found.
0x00000198	408	GSK_ERROR_BAD_KEYFILE_PASSWORD	The specified key file password is incorrect. The key file cannot be used. The key file might also be corrupt.
0x00000199	409	GSK_ERROR_BAD_KEY_LEN_ FOR_EXPORT	In a restricted cryptography environment, the key size is too long to be supported.
0x0000019a	410	GSK_ERROR_BAD_MESSAGE	An incorrectly formatted SSL message was received from the partner.
0x0000019b	411	GSK_ERROR_BAD_MAC	The MAC was not successfully verified.
0x0000019c	412	GSK_ERROR_UNSUPPORTED	Unsupported SSL protocol or unsupported certificate type.
0x0000019d	413	GSK_ERROR_BAD_CERT_SIG	The received certificate contained an incorrect signature.
0x0000019e	414	GSK_ERROR_BAD_CERT	Incorrectly formatted certificate is received from the partner.
0x0000019f	415	GSK_ERROR_BAD_PEER	An SSL protocol that is not valid is received from the partner.
0x000001a0	416	GSK_ERROR_PERMISSION_DENIED	Report this error to IBM Software Support.
0x000001a1	417	GSK_ERROR_SELF_SIGNED	The self-signed certificate is not valid.
0x000001a2	418	GSK_ERROR_NO_READ_FUNCTION	The read() failed. Report this error to IBM Software Support.
0x000001a3	419	GSK_ERROR_NO_WRITE_FUNCTION	The write() failed. Report this error to IBM Software Support.
0x000001a4	420	GSK_ERROR_SOCKET_CLOSED	The partner closed the socket before the protocol completed.
0x000001a5	421	GSK_ERROR_BAD_V2_CIPHER	The specified V2 cipher is not valid.
0x000001a6	422	GSK_ERROR_BAD_V3_CIPHER	The specified V3 cipher is not valid.
0x000001a7	423	GSK_ERROR_BAD_SEC_TYPE	Report this error to IBM Software Support.
0x000001a8	424	GSK_ERROR_BAD_SEC_TYPE_ COMBINATION	Report this error to IBM Software Support.
0x000001a9	425	GSK_ERROR_HANDLE_CREATION_ FAILED	The handle is not created. Report this error to IBM Software Support.
0x000001aa	426	GSK_ERROR_INITIALIZATION_FAILED	Initialization failed. Report this internal error to service.

Return code (hex)	Return code (decimal)	Constant	Explanation
0x000001ab	427	GSK_ERROR_LDAP_NOT_AVAILABLE	Unable to access the specified user registry when a certificate is being validated
0x000001ac	428	GSK_ERROR_NO_PRIVATE_KEY	The specified key did not contain a private key.
0x000001ad	429	GSK_ERROR_PKCS11_LIBRARY_ NOTLOADED	A failed attempt was made to load the specified PKCS11 shared library.
0x000001ae	430	GSK_ERROR_PKCS11_TOKEN_ LABELMISMATH	The PKCS #11 driver failed to find the token that is specified by the caller.
0x000001af	431	GSK_ERROR_PKCS11_TOKEN_ NOTPRESENT	A PKCS #11 token is not present in the slot.
0x000001b0	432	GSK_ERROR_PKCS11_TOKEN_ BADPASSWORD	The password/pin to access the PKCS #11 token is incorrect.
0x000001b1	433	GSK_ERROR_INVALID_V2_HEADER	The SSL header received was not a properly formatted SSLv2 header.
0x000001b2	434	GSK_CSP_OPEN_ERROR	Could not open the hardware-based cryptographic service provider (CSP). Either the CSP name is not specified correctly or a failed attempt was made to access the specified CSP certificate store.
0x000001b3	435	GSK_CSP_OPEN_ERROR	Some conflicting attributes for SSL operation were defined.
0x000001b4	436	GSK_CSP_OPEN_ERROR	The Microsoft Crypto API is only supported on Microsoft Windows 2000 with Service Pack 2 applied.
0x000001b5	437	GSK_CSP_OPEN_ERROR	System is running in IPv6 mode without setting a PEERID.
0x000001f5	501	GSK_INVALID_BUFFER_SIZE	The buffer size is negative or zero.
0x000001f6	502	GSK_WOULD_BLOCK	Used with nonblocking I/O. Refer to the nonblocking section for usage.
0x00000259	601	GSK_ERROR_NOT_SSLV3	SSLv3 is required for reset_cipher(), and the connection uses SSLv2.
0x0000025a	602	GSK_MISC_INVALID_ID	An ID that is not valid was specified for the gsk_secure_soc_misc() function call.
0x000002bd	701	GSK_ATTRIBUTE_INVALID_ID	The function call has an ID that is not valid. This issue might also be caused by specifying an environment handle when a handle for an SSL connection should be used.
0x000002be	702	GSK_ATTRIBUTE_INVALID_LENGTH	The attribute has a negative length, which is not valid.
0x000002bf	703	GSK_ATTRIBUTE_INVALID_ ENUMERATION	The enumeration value is not valid for the specified enumeration type.

Return code (hex)	Return code (decimal)	Constant	Explanation
0x000002c0	704	GSK_ATTRIBUTE_INVALID_SID_CACHE	A parameter list that is not valid for replacing the SID cache routines.
0x000002c1	705	GSK_ATTRIBUTE_INVALID_ NUMERIC_VALUE	When a numeric attribute is set, the specified value is not valid for the specific attribute that is being set.
0x000002c2	706	GSK_CONFLICTING_VALIDATION_ SETTING	Conflicting parameters were set for additional certificate validation.
0x000002c3	707	GSK_AES_UNSUPPORTED	The AES cryptographic algorithm is not supported.
0x000002c4	708	GSK_PEERID_LENGTH_ERROR	The PEERID does not have the correct length.
0x000002c5	709	GSK_CIPHER_INVALID_WHEN_FIPS_MODE_OFF	The particular cipher is not allowed when FIPS mode of operation is off.
0x000002c6	710	GSK_CIPHER_INVALID_WHEN_FIPS_MODE_ON	No approved FIPS ciphers are selected in FIPS mode of operation.
0x00000641	1601	GSK_TRACE_STARTED	The trace started successfully.
0x00000642	1602	GSK_TRACE_STOPPED	The trace stopped successfully.
0x00000643	1603	GSK_TRACE_NOT_STARTED	No trace file was previously started so it cannot be stopped.
0x00000644	1604	GSK_TRACE_ALREADY_STARTED	Trace file is started so it cannot be started again.
0x00000645	1605	GSK_TRACE_OPEN_FAILED	Trace file cannot be opened. The first parameter of gsk_start_trace() must be a valid, full-path file name.

Szószedet

Ez a szószedet a IBM Spectrum Protect és a IBM Spectrum Protect Snapshot rendszer, továbbá kapcsolódó termékeik kifejezéseit, valamint meghatározásait tartalmazza.

A szószedet a következő kereszthivatkozásokat tartalmazza:

- A *Lásd* az olvasót egy nem preferált kifejezésről a preferált kifejezésre, vagy a rövidítésről a teljesen kiírt kifejezésre lépteti át.
- *Lásd még*: kapcsolódó vagy hasonló kifejezésekre utal.

Az egyéb kifejezéseket és meghatározásokat az IBM® terminológiai webhelyen találja.

A B C D E F G H I J K L M N O P R S T U V W Z

A

abszolút mód
: A tárolókezelésben azon biztonságimásolat-csoportosítási üzemmód, amely meghatározza, hogy a fájlokat vagy könyvtárakat akkor is növekményes biztonsági mentéssel kell kezelni, ha azok a legutóbbi mentés óta nem módosultak. Lásd még: mód, módosított mód.

ACK
: Lásd: nyugtázás.

ACL
: Lásd: hozzáférés-felügyeleti lista.

adatáthelyező

Eszköz, amely a kiszolgáló részére végrehajtja az adatok áthelyezését. A hálózatra csatlakozó tároló (NAS) fájlkiszolgáló az adatáthelyezők egyike.

adatbázis-mentési sorozat
Az adatbázis egy teljes biztonsági mentése, valamint legfeljebb 32 növekményes mentés a teljes biztonsági mentés óta. Minden egyes futtatott teljes biztonsági mentés új adatbázis-mentési sorozatot kezd. Az egyes mentési sorozatokat egy-egy szám azonosítja. Lásd még: adatbázis-pillanatkép, teljes biztonsági mentés.

adatbázis-pillanatkép
Az egész adatbázisról a helyszínről elvihető adathordozóra készített teljes biztonsági mentés. Az adatbázis-pillanatkép létrehozásakor az aktuális adatbázis-mentési sorozat nem kerül megszakításra. Az adatbázis-pillanatképhez nem tartozhatnak növekményes adatbázismentések. Lásd még: adatbázis-mentési sorozat, teljes biztonsági mentés.

adathordozó-kiszolgáló
Program z/OS környezetben, amely a z/OS rendszertől eltérő operációs rendszereken futó IBM Spectrum Protect kiszolgálóknak biztosít hozzáférést z/OS lemez- és szalagtárolókhoz.

adatkettőzés-megszüntetés
Lásd: adatkettőzés-megszüntetés.

adatkettőzés megszüntetése
A tárolási igények csökkentési módszere, amely a redundáns adatok kiküszöbölésére épít. A tárolási adathordozó csak az adatok egy példányát őrzi meg. Ekkor a megőrzött példányra irányuló mutató lép ugyanazon adatok egyéb példányai helyébe. Lásd még: belső adatkettőzés-megszüntetés, utófeldolgozási adatkettőzés-megszüntetés.

adatkezelő kiszolgáló
Az ügyfélleltár számára metaadat-információkat gyűjtő, valamint a tárolóügynök részére a helyi hálózaton tranzakciókat kezelő kiszolgáló. Az adatkezelő kiszolgáló tájékoztatja a tárolóügynököt a megfelelő könyvtárattribútumokról, valamint a célkötet azonosítójáról.

adatközpont
Virtualizált környezetben hosztokat, fürtöket, hálózatokat és adattárolókat magában foglaló tároló.

adattároló
Virtualizált környezetben az a hely, ahol a virtuális gép adatai kerülnek tárolásra.

adattároló-kezelési alkalmazásprogramozási felület (DSMAPI)
Függvények és szemantikai elemek készlete, amely képes végrehajtani a fájlokra vonatkozó események megfigyelését, valamint a fájlokban lévő adatok kezelését és karbantartását. HSM környezetben a DSMAPI események segítségével értesíti az adatkezelési alkalmazásokat a fájlokra vonatkozó műveletekről, tetszőleges attribútuminformációkat tárol a fájlokkal együtt, támogatja a fájlokban található felügyelt területeket, valamint a DSMAPI hozzáférési jogaival vezérli a fájlobjektumok elérését.

adminisztrációs munkamenet
Azon időszak, amelynek során az adminisztrátori felhasználói azonosító az adminisztrációs feladatok végrehajtása érdekében kommunikál a kiszolgálóval. Lásd még: ügyfélcsomópont-munkamenet, munkamenet.

adminisztrációs ügyfélprogram
Fájlkiszolgálón, munkaállomáson vagy nagyszámítógépen futó program, amelyet az adminisztrátorok a kiszolgáló felügyeletére és megfigyelésére használnak. Lásd még: mentési-archiválási ügyfél.

adminisztrációsjogosultság-osztály
Lásd: jogosultságosztály.

adminisztrációsparancs-ütemezés
Adatbázisrekord, amely az adminisztrációs parancsok tervezett feldolgozását írja le az adott időszakban. Lásd még: központi ütemező, ügyfélütemezés, ütemezés.

adminisztrátor
Adminisztrációs feladatokért, például a hozzáférési jogosultságok és a tartalmak kezelésért felelős személy. Az adminisztrátorok jogosultságszinteket is adományozhatnak a felhasználóknak.

aktív fájlrendszer
Az a fájlrendszer, amelyet tárhelykezeléssel láttak el. A tárhelykezelés esetén az aktív fájlrendszerhez kapcsolódó feladatok közé tartozik az automatikus átállítás, az összeegyeztetés, a szelektív átállítás és a visszahívás. Lásd még: inaktív fájlrendszer.

aktív irányelvkészlet
Az irányelvtartományhoz rendelt összes ügyfélcsomópont által jelenleg használt irányelvszabályokat tartalmazó aktivált irányelvkészlet. Lásd még: irányelvtartomány, irányelvkészlet.

aktív változat
A tárolt fájl legújabb biztonsági másolata. A fájlok aktív változatát addig nem lehet törölni, amíg a biztonsági mentési folyamat azt észleli, hogy a felhasználó újabb változatra cserélte az adott fájlt, vagy törölte azt a fájlkiszolgálóról, illetve a munkaállomásról. Lásd még: biztonsági mentési változat, inaktív változat.

aktívadat-tároló
Tárolókészlet-kötetek nevesített készlete, amely csak az ügyfél biztonsági mentési adatainak aktív változatát tartalmazza. Lásd még: kiszolgálótároló, tárolókészlet, tárolókészlet-kötet.

aktiválás

Az irányelvkészletek tartalmának érvényesítése, majd azok aktív irányelvkészletté tétele.

alapértelmezett kezelési osztály
: Az irányelvkészlethez rendelt kezelési osztály. Ez az osztály a mentett vagy archivált fájlok szabályozásához kerül felhasználásra, ha az adott fájl a befoglalási-kizárási lista révén nincs kifejezetten konkrét kezelési osztályhoz társítva.

alkalmazásügyfél
: A rendszeren egy alkalmazás védelme érdekében telepített program. A kiszolgáló biztonsági mentési szolgáltatásokat nyújt az alkalmazásügyfélnek.

alkalmazkodó részfájlmentés
: Olyan biztonsági mentés, amely az egész fájl helyett csak a fájl megváltozott részeit küldi át a kiszolgálóra. Az alkalmazkodó részfájlmentés csökkenti a hálózati forgalmat, valamint növeli a biztonsági mentés sebességét.

Általános elnevezési megállapodás (UNC)
: Az egyesített kiszolgáló- és hálózatnév. Ezek a nevek együtt azonosítják az erőforrást a tartományban.

Általános párhuzamos fájlrendszer (GPFS)
: Nagy teljesítményű osztott lemezes fájlrendszer, amely képes a fürtözött rendszerkörnyezetben adathozzáférést biztosítani a csomópontokról. Lásd még: információséletciklus-kezelés.

Általánosan egyedi azonosító (UUID)
: 128 bites numerikus azonosító, amelynek segítségével biztosítható, hogy két összetevő ne rendelkezzen egyező azonosítóval. Lásd még: globálisan egyedi azonosító.

archív másolat
: Kiszolgálótárolóban archivált fájl vagy fájlcsoport.

archív másolatcsoport
: Irányelvobjektum, amely archivált fájlok előállítását, célmeghatározását és lejáratát vezérlő attribútumokat tartalmaz. Lásd még: másolatcsoport.

archiválás
: Programok, adatok vagy fájlok másolása egy másik tárolási adathordozóra, általában hosszú távú tárolás vagy védelem céljából. Lásd még: lekérés.

archívummegtartási türelmi időszak
: Azon napok száma, ameddig a tárolókezelő megőriz egy archivált fájlt, amikor a kiszolgáló nem képes újra összerendelni a fájlt egy megfelelő kezelési osztállyal. Lásd még: összerendelés.

árnyékkötet
: A kötet pillanatképéből tárolt adatok. A pillanatkép akkor is elkészíthető, miközben a rendszer alkalmazásai folytatják az adatok kiírását a kötetekre.

árnyékmásolat
: A kötet pillanatképe. A pillanatkép akkor is elkészíthető, miközben a rendszer alkalmazásai folytatják az adatok kiírását a kötetekre.

árva csonkfájl
: Az a fájl, amelyhez nem található átállított fájl azon a kiszolgálón, amellyel az ügyfélcsomópont a tárhelykezelési szolgáltatások igénybevétele érdekében felveszi a kapcsolatot. Például a csonkfájl akkor válhat árvává, amikor az ügyfél rendszerbeállítás-fájlja úgy módosul, hogy egy olyan kiszolgálóhoz kell csatlakoznia, amely eltér a fájl átállítási helyéül szolgáló kiszolgálótól.

átállít
: Adatok áthelyezése egy másik helyre, illetve alkalmazások áthelyezése egy másik számítógéprendszerre.

átállítás
: Az adatok egyik számítógéprendszerről a másikra való áthelyezésének folyamata, vagy egy alkalmazás áthelyezése egy másik számítógéprendszerre.

átállítási feladat
: Az átállítani kívánt fájlok, valamint az átállítás után az eredeti fájlokon végrehajtani kívánt műveletek meghatározása. Lásd még: feladatfájl, küszöbérték szerinti átállítás.

átállítási küszöbérték
: Tárolókészletek vagy fájlrendszerek százalékos arányként kifejezett magas és alacsony kapacitásértékei, amelyekre beállítható az átállítás elindítása és leállítása.

átállított fájl
: A helyi fájlrendszerből a tárolóba másolt fájl. UNIX vagy Linux rendszereken futó HSM ügyfelek esetén a csonkfájl lép a fájl helyébe a helyi fájlrendszeren. Windows rendszereken a csonkfájl létrehozása választható. Lásd még: fájlállapot, előzetesen átállított fájl, rezidens fájl, csonkfájl.

áteresztőképesség
: A tárolókezelésben azon munkaterhelés byte-jainak összesített száma a többletterhelés nélkül, amely részt vesz a biztonsági mentésben vagy visszaállításban, osztva az eltelt idővel.

átlátszó visszahívás
: Az átállított fájlok munkaállomásra vagy fájlkiszolgálóra történő automatikus visszahívásához használt folyamat, amelyre a fájlok elérésekor kerül sor. Lásd még: szelektív visszahívás.

Átvitelvezérlési protokoll/Internet protokoll (TCP/IP)

Ipari szabványnak számító, nyilvános kommunikációsprotokoll-készlet, amely megbízható átfogó kapcsolatokat biztosít a különböző típusú összekapcsolt hálózatok feletti alkalmazások között. Lásd még: kommunikációs módszer.

AutoFS
: Lásd: automatikusan beillesztett fájlrendszer.

automatikus átállítás
: A fájlok helyi fájlrendszerről a tárolóba való automatikus áthelyezésére szolgáló folyamat, amely a munkaállomás root felhasználója által kiválasztott paraméterekre és beállításokra épül. Lásd még: igény szerinti átállítás, küszöbérték szerinti átállítás.

automatikus észlelés
: Az adatbázisban lévő meghajtók vagy könyvtárak sorozatszámát abban az esetben észlelő, jelentő és frissítő szolgáltatás, amikor meghatározásra került a helyi kiszolgálóról származó útvonal.

automatikusan beillesztett fájlrendszer (AutoFS)
: Automatikus beillesztést végző démon által felügyelt fájlrendszer. Az automatikus beillesztést végző démon egy megadott könyvtárútvonalat figyel, majd automatikusan beilleszti a fájlrendszert az adatok eléréséhez.

B

beágyazott tömörítés
: A tárterület csökkentésének módja. A program eltávolítja az ismétlődő karaktereket, szóközöket, karakterláncokat vagy bináris adatokat, és egy tárolókészletbe írja azokat. Lásd még: tömörítés.

beállításfájl
: Feldolgozási beállításokat tartalmazó fájl. Lásd még: ügyfél rendszerbeállítás-fájlja, ügyfél felhasználóibeállítás-fájlja.

becsült kapacitás
: A tárolókészlet rendelkezésre álló területe megabyte-ban.

bedolgozó
: Külön telepíthető szoftvermodul, amely funkciókkal egészíti ki a meglévő programokat, alkalmazásokat vagy felületeket.

befoglalási-kizárási fájl
: Utasításokat tartalmazó fájl, amelyekkel meghatározhatók a biztonsági mentésben szerepeltetendő fájlok, valamint a biztonsági mentéshez vagy archiváláshoz használandó társított kezelési osztályok. Lásd még: befoglalási-kizárási lista.

befoglalási-kizárási lista
: Beállítások felsorolása, amelyek befoglalják vagy kizárják a biztonsági mentéshez kiválasztott fájlokat. A kizárási beállítás a biztonsági mentésben szerepeltetni nem kívánt fájlokat azonosítja. A befoglalási beállítások a kizárási szabályok alól mentesülő fájlokat azonosítják, illetve kezelési osztályt rendelnek a fájlokhoz vagy fájlok csoportjához a biztonsági mentési vagy archiválási szolgáltatások esetében. Lásd még: befoglalási-kizárási fájl.

beillesztés várakozási időtartama
: Azon percek maximális száma, ameddig a kiszolgáló várakozik a soros elérésű kötet beillesztési kérésének teljesítésére, mielőtt visszavonná a kérést.

beillesztési korlát
: Azon kötetek maximális száma, amelyek egyidejűleg érhetők el ugyanabból az eszközosztályból. A beillesztési korlát határozza meg a beillesztési pontok maximális számát. Lásd még: beillesztési pont.

beillesztési pont
: Logikai meghajtó, amelyen keresztül a kötetek hozzáférhetők a soros elérésű eszközosztályban. A cserélhető adathordozó eszköztípus - például a szalagok - esetén a beillesztési pont a logikai meghajtóhoz társított logikai meghajtó. A fájl eszköztípus esetén a beillesztési pont az I/O adatfolyamhoz társított logikai meghajtó. Lásd még: beillesztési korlát.

beillesztésmegtartási időszak
: Azon percek maximális száma, ameddig a kiszolgáló megőrzi a nem használt beillesztett soros elérésű adathordozó-kötetet, mielőtt elvégezné annak lecsatlakoztatását.

belső adatkettőzés-megszüntetés
: A tárolási igények csökkentési módszere, amely a redundáns adatok kiküszöbölésére épít. Az adatkettőzés megszüntetésére az adatok tároló típusú tárolókészletbe való kiírásakor kerül sor. Lásd még: adatkettőzés-megszüntetés, utófeldolgozási adatkettőzés-megszüntetés.

bevezető adatok
: Az átállított fájlok kezdetéről származó azon adatbyte-ok, amelyek a helyi fájlrendszeren a fájlnak megfelelő csonkfájlban kerülnek tárolásra. A bevezető adatok csonkfájlban tárolt mennyisége a megadott csonkmérettől függ.

biztonsági mentési változat
: Az ügyfélcsomópont által a tárolóban mentett fájl vagy könyvtár. A tárolóban több biztonsági mentési változat is létezhet, de csak egy biztonsági mentési változat számít aktív változatnak. Lásd még: aktív változat, másolatcsoport, inaktív változat.

biztonságimásolat-csoport
: Irányelvobjektum, amely a fájlok biztonsági mentési változatainak előállítását, célmeghatározását és lejáratát vezérlő attribútumokat tartalmaz. A biztonságimásolat-csoport egy kezelési osztályhoz tartozik. Lásd még: másolatcsoport.

biztonságimentés-megtartási türelmi időszak

Azon napok száma, ameddig a tárolókezelő megőriz egy biztonságimentés-változatot, miután a kiszolgáló nem képes újra összerendelni a fájlt egy megfelelő kezelési osztállyal.

C

CAD
: Lásd: ügyfélfogadó démon.

cél
: Másolatcsoport- vagy kezelésiosztály-attribútum, amely azon elsődleges tárolókészletet határozza meg, amelyben az ügyfélfájl mentésre, archiválásra vagy átállításra kerül. Lásd még: másolat-tárolókészlet.

célcsomópont
: Ügyfélcsomópont, amely számára más (ügynökcsomópontoknak nevezett) ügyfélcsomópontok megbízotti jogosultságot adományoztak. A megbízotti jogosultság lehetővé teszi az ügynökcsomópontoknak a biztonsági mentéshez és visszaállításhoz hasonló műveletek célcsomópont nevében történő végrehajtását. Az adatokat a célcsomópont birtokolja.

csomag
: Az adatkommunikáció terén bináris számjegyek adat- és vezérlőjeleket is tartalmazó sorozata, amely egy összetett egészként kerül átvitelre és -váltásra.

csomópont
: Az a fájlkiszolgáló vagy munkaállomás, amelyen a mentési-archiválási ügyfélprogram telepítésre került, és amelyet bejegyeztek a kiszolgálóhoz.

csomópontjogosultság-osztály
: Jogosultságosztály, amely felhatalmazza az adminisztrátort egy adott ügyfélcsomóponthoz tartozó mentési-archiválási ügyfelek, vagy az irányelvtartomány valamennyi ügyfelének távoli elérésére. Lásd még: jogosultságosztály.

csomópontnév
: A munkaállomások, fájlkiszolgálók vagy számítógépek kiszolgálón való azonosítására szolgáló egyedi név.

csonk
: Hivatkozás a Windows fájlrendszerben, amelyet a hierarchikus tárolókezelési (HSM) ügyfél hoz létre az átállított fájlokhoz, és átlátszó felhasználó-hozzáférést tesz lehetővé. A csonk az átállított fájl ritka fájlábrázolása csatolt újraértelmezési ponttal.

csonkfájl
: Az eredeti fájl helyébe lépő fájl a helyi fájlrendszerben, amikor a fájl átállításra kerül a tárolóba. A csonkfájl tartalmazza az átállított fájl kiszolgálótárolóból való visszahívásához szükséges információkat. További információkat is magában foglal, amelyek segítségével kiküszöbölhető az átállított fájl visszahívásának igénye. Lásd még: átállított fájl, rezidens fájl.

csonkfájl mérete
: Az eredeti fájl helyébe lépő fájl mérete a helyi fájlrendszerben, amikor a fájl átállításra kerül a kiszolgálótárolóba. A csonkfájlok számára megadott méret határozza meg, hogy mennyi bevezető adat tárolható a csonkfájlokban. A csonkfájlméret alapértéke a fájlrendszer számára megadott blokkméret mínusz 1 byte.

csoportos mentés
: Legalább egy fájlterületről származó fájlok listáját tartalmazó csoport biztonsági mentése.

D

démon
: Felügyelet nélküli futó program, amely folyamatos vagy ismétlődő funkciókat, például hálózatfelügyelet lát el.

dinamikus sorbafejtés
: Másolatsorosítás, amelynek keretében a fájlok vagy mappák attól függetlenül mentésre vagy archiválsára kerülnek az első kísérletben, hogy azok módosulnak-e a mentés vagy archiválás során. Lásd még: osztott dinamikus sorbafejtés, osztott statikus sorbafejtés, statikus sorbafejtés.

DRM
: Lásd: katasztrófa utáni helyreállítás kezelője.

DSMAPI
: Lásd: adattároló-kezelési alkalmazásprogramozási felület.

E

EA
: Lásd: kiterjesztett attribútum.

EB
: Lásd: exabyte.

EFS
: Lásd: Titkosított fájlrendszer.

egyedi postafiók-visszaállítás
: Lásd: postafiók-visszaállítás.

előfizetés
: Tárolási környezetben azon előfizetők azonosításának folyamata, amelyekhez a profilok terjesztésre kerülnek. Lásd még: vállalati konfiguráció, felügyelt kiszolgáló.

előzetes átállítás
: Az átállításra alkalmas fájlok kiszolgálótárolóba való átmásolásának folyamata, amely az eredeti fájlt érintetlenül hagyja a helyi fájlrendszerben.

előzetes átállítás százalékos aránya
: Tárhelykezelési beállítás, amely azt vezérli, hogy a fájlrendszer következő alkalmas jelöltjei előzetesen átállításra kerülnek-e a küszöbérték vagy igény szerinti átállítást követve.

előzetesen átállított fájl
: A kiszolgálótárolóba másolt, de a helyi fájlrendszerben csonkfájllal nem helyettesített fájl. A fájl azonos másolata a helyi fájlrendszerben és a kiszolgálótárolóban egyaránt megtalálható. Az előzetesen átállított fájlok tárhelykezeléssel ellátott UNIX és Linux fájlrendszerekben fordulnak elő. Lásd még: fájlállapot, átállított fájl, rezidens fájl.

előzetesen átállított fájlok adatbázisa
: Adatbázis, amely a kiszolgálótárolóba előzetesen átállított fájlokkal kapcsolatban tartalmaz információkat.

elsődleges tárolókészlet
: Megnevezett kötetek vagy tárolók készlete, amelyet a kiszolgáló a fájlok biztonsági mentési változatainak, a fájlok archív másolatainak, valamint az ügyfélcsomópontokról átállított fájloknak a tárolására használ. Lásd még: másolat-tárolókészlet, kiszolgálótároló, tárolókészlet, tárolókészlet-kötet.

elsődleges telephely
: Fizikai vagy virtuális telephely, amelyet hardver-, hálózati és tároló-erőforrások alkotnak. Az éles műveletek jellemzően az elsődleges telephelyen futnak. Az adatok replikálhatók egy másodlagos telephelyre, katasztrófa utáni helyreállítási és átállási műveletekhez. Lásd még: másodlagos telephely.

érvényesítés
: Az irányelvkészlet ellenőrzése olyan állapotok meghatározásáért, amelyek problémákat okozhatnak, ha az adott irányelvkészlet válik az aktív irányelvkészletté. Például az érvényesítési folyamat ellenőrzi, hogy az irányelvkészlet tartalmaz-e egy alapértelmezett kezelési osztályt.

esemény
: Feladat vagy rendszer jelentőségteljes eseménye. Az esemény lehet egy művelet befejeződése vagy meghiúsulása, felhasználói művelet vagy egy folyamat állapotának megváltozása. Lásd még: vállalati naplózás, fogadó.

eseménykiszolgáló
: Az a kiszolgáló, amelyre más kiszolgálók eseményeket küldhetnek naplózás céljából. Az eseménykiszolgáló továbbítja az eseményeket a küldő kiszolgáló eseményeire felkészített fogadóknak.

eseményrekord
: Az események tényleges állapotát és eredményeit leíró adatbázisrekord.

eszközkonfigurációs fájl
: 1. Kiszolgáló esetén az a fájl, amely a meghatározott eszközosztályok, valamint egyes kiszolgálók esetén a meghatározott könyvtárak és meghajtók információit tartalmazza. Ezek az információk az adatbázisban található eszközkonfigurációs információk példányai.
2. Tárolóügynök esetén az a fájl, amely a tárolóügynök nevét és jelszavát, valamint a SAN-hoz csatolt könyvtárakat, valamint a tárolóügynök által használt meghajtókat kezelő kiszolgálóval kapcsolatos információkat tartalmazza.

eszközosztály
: Tárolóeszközök csoportjára vonatkozó jellemzők megnevezett készlete. Minden egyes eszközosztály egyedi névvel rendelkezik, és a lemez, fájl, optikai lemez vagy szalag eszköztípust képviseli.

exabyte (EB)
: A processzor esetében valós és virtuális tárolókapacitás, illetve csatornamennyiség: 2 a 60. hatványon, azaz 1 152 921 504 606 846 976 byte. A lemeztároló kapacitása és kommunikációs mennyiség esetén 1 000 000 000 000 000 000 byte.

F

fájlállapot
: Azon fájlok tárhelykezelési módja, amelyek tárhelykezeléssel ellátott fájlrendszerben helyezkednek el. A fájlok három állapotban lehetnek: rezidens, előzetesen átállított vagy átállított. Lásd még: átállított fájl, előzetesen átállított fájl, rezidens fájl.

fájlélettartam
: Az átállítási prioritás megállapítása céljából a fájlhoz való legutóbbi hozzáférés óta eltelt napok száma.

fájleszköz típusa
: Eszköztípus, amely a soros elérésű fájlok használatát határozza meg kötetekként a lemeztárolóban.

fájlhozzáférés időpontja
: AIX, UNIX vagy Linux rendszereken a fájlhoz való legutóbbi hozzáférés időpontja.

fájlkiszolgáló
: Kijelölt számítógép és annak helyi hálózatra csatlakozó perifériás tárolóeszközei, amelyek a felhasználók által a hálózaton megosztott programokat és fájlokat tárolják.

fájlrendszer-átállító (FSM)
: Kernelbővítmény, amely elfog minden fájlrendszeri műveletet, valamint biztosítja a szükséges tárhelykezelési támogatást. Ha nincs szükség tárhelykezelési támogatásra, a műveletet átadja az operációs rendszernek, amely végrehajtja normál funkcióit. A fájlrendszer-átállítót a rendszer akkor illeszti be a fájlrendszerben, ha azt tárhelykezeléssel látják el.

fájlrendszerállapot
: Azon fájlrendszer tárolókezelési módja, amely a hierarchikus tárolókezelési (HSM) ügyfél telepítési helyéül szolgáló munkaállomáson található. A fájlrendszerek a következő állapotok egyikében lehetnek: natív, aktív, inaktív vagy globális inaktív.

fájlterület
: A kiszolgálótároló logikai területe, amely egy ügyfélcsomópont által egyetlen logikai partícióról, fájlrendszerből vagy virtuális beillesztési pontról mentett vagy archivált fájlok csoportját tartalmazza. Az ügyfélcsomópontok képesek visszaállítani, lekérni vagy törölni fájlterületeiket a kiszolgálótárolóból. A kiszolgálótárolóban az egyetlen fájlterülethez tartozó fájlok nem szükségképpen kerülnek együtt tárolásra.

fájlterület-azonosító (FSID)
: Egyedi numerikus azonosító, amelyet a kiszolgáló rendel a fájlterülethez, amikor tárolja azt a kiszolgálótárolóban.

feladatfájl
: Előállított fájl, amely az átállítási feladat konfigurációs információit tartalmazza. A fájl XML formátumú, amely a Windows ügyfél grafikus felhasználói felületéhez kapcsolódó hierarchikus tárolókezelési (HSM) ügyfélben hozható létre és szerkeszthető. Lásd még: átállítási feladat.

felhőtároló típusú tárolókészlet
: Tárolókészlet, amelyet a kiszolgáló felhőtárolóban való adattárolásra használ. A felhőtároló helyben vagy távol is elhelyezkedhet. Lásd még: tároló típusú tárolókészlet, könyvtár típusú tárolókészlet, tárolókészlet.

felügyelt kiszolgáló
: Legalább egy profilra való előfizetés segítségével a konfigurációkezelőtől konfigurációs információkat fogadó kiszolgáló. A konfigurációs információk közé tartozhatnak az objektum-, például irányelv- vagy ütemezésmeghatározások. Lásd még: konfigurációkezelő, vállalati konfiguráció, profil, előfizetés.

felügyelt objektum
: Meghatározás a felügyelt kiszolgáló adatbázisában, amelyet a konfigurációkezelő terjesztett a felügyelt kiszolgálóra. Amikor a felügyelt kiszolgáló előfizet egy profilra, az adott profilhoz társított valamennyi objektum felügyelt objektummá válik a felügyelt kiszolgáló adatbázisában.

felülvizsgálat
: A kiszolgáló által birtokolt információk, valamint a rendszer tényleges állapota közötti logikai ellentmondások ellenőrzése. A tárolókezelő olyan elemek információit képes felülvizsgálni, mint a kötetek, a könyvtárak és licencek. Például amikor a tárolókezelő felülvizsgál egy kötetet, akkor a kiszolgáló ellenőrzi az adatbázisban tárolt, mentett vagy archivált fájlok információi, valamint a kiszolgálótárolóban az egyes biztonsági mentési változatokhoz vagy archív másolatokhoz társított tényleges adatok közötti ellentmondásokat.

fizikai fájl
: Legalább egy tárolókészletben elhelyezett fájl, amely egyetlen logikai fájlt, vagy logikai fájlok összesítésként egybecsomagolt csoportját foglalja magában. Lásd még: összesítés, logikai fájl, fizikai foglaltság.

fizikai foglaltság
: A tárolókészletben található fizikai fájlok által felhasznált területmennyiség. Ez a terület magában foglalja a logikai fájlok összesítésekből való törlésekor létrehozott használaton kívüli területet is. Lásd még: logikai fájl, logikai foglaltság, fizikai fájl.

fogadó
: Kiszolgálólerakat, amely az eseményekként jelentkező kiszolgáló- és ügyfélüzenetek naplóját tartalmazza. A fogadó például egy fájlkilépési pont, felhasználói kilépési pont, vagy a kiszolgálókonzol- és tevékenységnapló lehet. Lásd még: esemény.

FSID
: Lásd: fájlterület-azonosító.

FSM
: Lásd: fájlrendszer-átállító.

fuzzy biztonsági mentés
: A fájlok azon biztonsági mentési változata, amely esetleg nem pontosan tükrözi a fájlok jelenlegi tartalmát, mivel a fájlok biztonsági mentésére azok módosításával egyidejűleg került sor.

fuzzy másolat
: A fájlok azon biztonsági mentési változata vagy archív másolata, amely esetleg nem pontosan tükrözi a fájlok eredeti tartalmát, mivel azok biztonsági mentésére vagy archiválására a fájlok módosítása közben került sor.

G

GB
: Lásd: gigabyte.

gigabyte (GB)
: A processzortároló, a valós és virtuális tárterület, illetve a csatornakötet esetén: kettő a 30. hatványon, azaz 1 073 741 824 byte. A lemeztároló kapacitása és a kommunikációs mennyiség esetén 1 000 000 000 byte.

globális inaktív állapot
: Minden tárhelykezeléssel ellátott fájlrendszer állapota, ha a tárhelykezelést globálisan leállították az ügyfélcsomópont esetében.

globális név (WWN)
: 64 bites, előjel nélküli egyedi névazonosító.

globálisan egyedi azonosító (GUID)
: Algoritmus alapján meghatározott szám, amely egyedien azonosítja a rendszer egyik egyedét. Lásd még: Általánosan egyedi azonosító.

GPFS
: Lásd: Általános párhuzamos fájlrendszer.

GPFS csomópontkészlet
: GPFS fájlrendszerek beillesztett, meghatározott csoportja.

GUID
: Lásd: globálisan egyedi azonosító.

gyakoriság
: A másolatcsoportok attribútuma, amely napokban határozza meg a növekményes biztonsági mentések közötti minimális időtartamot.

gyorsítótárba helyezés
: A fájlok másodpéldányának kötetlen elérésű adathordozóra helyezése, amikor a kiszolgáló a hierarchia másik tárolókészletébe állítja át az adott fájlt.

gyorsítótárfájl
: A Logikaikötet-pillanatkép ügynök által létrehozott logikai kötet pillanatképe. A blokkok közvetlenül azelőtt kerülnek mentésre, hogy a képmentés során megtörténne azok módosítása, valamint logikai tárolási egységeiket a rendszer gyorsítótárfájlokba mentené.

H

hálózati adatátviteli sebesség
: Az átvitt byte-ok összesített számát az adatátviteli idővel elosztva kiszámítható sebességérték. Ez a sebesség például az adatok hálózati átvitelével töltött időnek felelhet meg.

Hálózati adatkezelési protokoll (NDMP)
: Protokoll, amely lehetővé teszi a hálózatitároló-kezelési alkalmazásoknak az NDMP protokollal kompatibilis fájlkiszolgálók biztonsági mentésének és helyreállításának vezérlését, szállító által beszerzett szoftverek adott fájlkiszolgálón való telepítése nélkül.

Hálózati alapvető be-/kimeneti rendszer
: Lásd: NetBIOS.

hálózatra csatlakozó tároló típusú fájlkiszolgáló (NAS fájlkiszolgáló)
: Fájlkiszolgálási funkciókra optimalizált operációs rendszerrel rendelkező kijelölt tárolóeszköz. A NAS fájlkiszolgáló a csomópont és az adatáthelyező jellemzőivel egyaránt rendelkezhet.

helyettesítő karakter
: Különleges karakter, például csillag (*) vagy kérdőjel (?), amely legalább egy karakter ábrázolására használható. A helyettesítő karakter helyébe bármely karakter vagy karakterhalmaz behelyettesíthető.

helyi
: 1. Eszközök, fájlok vagy rendszerek esetén azok kommunikációs vonal alkalmazása nélkül, közvetlenül a felhasználói rendszerről való elérése.
2. Hierarchikus tárolókezelési termékek esetén az áthelyezni kívánt átállított fájlok céljára vonatkozik. Lásd még: távoli.

helyi árnyékkötet
: Lemeztárolási alrendszeren honosított árnyékköteteken tárolt adatok.

helyi hálózat (LAN)
: Hálózat, amely több eszközt csatlakoztat egy korlátozott területen (például egyetlen épületben vagy épületegyüttesben), és amelyet egy nagyobb hálózathoz lehet csatlakoztatni.

helyreállítási napló

Az adatbázisba kiírandó frissítések naplója. A napló segítségével helyreállítás végezhető a rendszer- és adathordozó-hibák után. A helyreállítási napló az aktív (naplótükröt is tartalmazó) és archív naplóból tevődik össze.

helyreállítási telephely
: Lásd: másodlagos telephely.

hibanapló
: Adathalmaz vagy fájl, amely egy termékkel vagy rendszerrel kapcsolatos hibainformációk rögzítésére szolgál.

hierarchikus tárolókezelés (HSM)
: Funkció, amely automatikusan végzi a lemezen és/vagy szalagon található adatok terjesztését és kezelését, a tárolási hierarchia szintjeiként véve figyelembe ezen és egyéb lehetséges típusú eszközöket, ahol a hierarchia a gyors, költséges eszközöktől a lassabb, olcsóbb és valószínűleg cserélhető eszközökig terjed. A célkitűzései közé tartozik az adat-hozzáférési idő minimálisra csökkentése, valamint a rendelkezésre álló adathordozó-kapacitás maximális kihasználása. Lásd még: hierarchikus tárolókezelési ügyfél, visszahívás, tárolási hierarchia.

hierarchikus tárolókezelési ügyfél (HSM ügyfél)
: Ügyfélprogram, amely a kiszolgálóval működik együtt a rendszer hierarchikus tárolókezelésének (HSM) biztosításában. Lásd még: hierarchikus tárolókezelés, kezelési osztály.

hitelesítési szabály
: Meghatározás, amelynek segítségével egy másik felhasználó visszaállíthat vagy lekérhet fájlokat a tárolóból.

hozzáférés-felügyeleti lista (ACL)
: A számítógépes biztonság terén azon objektumokhoz társított lista, amely az adott objektumhoz hozzáférő összes alanyt, valamint az ő hozzáférési jogaikat azonosítja.

hozzáférési mód
: A tárolókészletek vagy tárolókötetek attribútuma, amely azt határozza meg, hogy a kiszolgáló képes-e írni az adott tárolókészletbe vagy tárolókötetbe, illetve képes-e olvasni abból.

HSM
: Lásd: hierarchikus tárolókezelés.

HSM ügyfél
: Lásd: hierarchikus tárolókezelési ügyfél.

I

i-node
: Belső adatszerkezet, amely az egyedi fájlokat írja le AIX, UNIX és Linux rendszereken. Egy i-node a fájl csomópontját, típusát, tulajdonosát és helyét tartalmazza.

i-node száma
: A fájlrendszer egy adott i-node fájlját meghatározó szám.

ideiglenes kötet
: Címkével ellátott kötet, amely üres vagy nem tartalmaz érvényes adatokat, nincs meghatározva és felhasználás céljából elérhető. Lásd még: kötet.

időtúllépés
: Időtartam, amely egy esemény bekövetkezése vagy végrehajtása céljából kiosztásra kerül, és amelynek elteltével a rendszer megszakítja a műveletet.

igény szerinti átállítás
: Az a folyamat, amely az aktív hierarchikus tárolókezeléssel (HSM) rendelkező fájlrendszer helyhiányos állapotára való reagáláshoz kerül felhasználásra. A fájlok addig a kiszolgálótárolóra kerülnek átállításra, amíg a területfelhasználás a fájlrendszer számára beállított alacsony küszöbérték szintjére nem csökken. Ha a magas és az alacsony küszöbérték azonos, akkor egy fájl kerül átállításra. Lásd még: automatikus átállítás, szelektív átállítás, küszöbérték szerinti átállítás.

ILM
: Lásd: információséletciklus-kezelés.

inaktív fájlrendszer
: Olyan fájlrendszer, amely esetében a tárhelykezelés leállításra került. Lásd még: aktív fájlrendszer.

inaktív változat
: A fájlok azon biztonsági mentési változata, amely nem a legújabb biztonsági mentési változat, vagy már nem létezik az ügyfélrendszerben. Az inaktív biztonsági mentési változatok a fájlhoz rendelt kezelési osztály alapján alkalmasak a lejárati feldolgozásra. Lásd még: aktív változat, biztonsági mentési változat.

indítási ablak
: Azon időszak, amelyben az ütemezést el kell indítani.

információséletciklus-kezelés (ILM)
: Irányelvalapú fájlkezelési rendszer tároló- és fájlkészletek számára. Lásd még: Általános párhuzamos fájlrendszer.

IP cím
: Eszköz vagy logikai egység egyedi címe a hálózaton, amely az Internet protokoll szabványát alkalmazza.

irányelvjogosultság-osztály

Jogosultságosztály, amely felhatalmazza az adminisztrátort az irányelvobjektumok kezelésére, az ügyfélcsomópontok regisztrálására, valamint az ügyfélcsomópontok ügyfélműveleteinek ütemezésére. A jogosultság adott irányelvtartományokra korlátozható. Lásd még: jogosultságosztály.

irányelvkészlet
Szabályok csoportja az irányelvtartományban. A szabályok határozzák meg, hogy miként történik az adatok vagy tároló-erőforrások automatikus kezelése az irányelvtartományban található ügyfélcsomópontok számára. A szabályokat kezelési osztályok tartalmazhatják. Lásd még: aktív irányelvkészlet, kezelési osztály.

irányelvtartomány
Az irányelv-felhasználók csoportosítása legalább egy irányelvkészlet segítségével, amelyek a felhasználókhoz tartozó adat- vagy tároló-erőforrásokat kezelik. A felhasználók az irányelvtartományhoz társított ügyfélcsomópontok. Lásd még: aktív irányelvtartomány, tartomány.

J

jelszó-előállítás
A régi jelszó lejárata esetén az a folyamat, amely új jelszót hoz létre és tárol a titkosított jelszófájlban. A jelszó automatikus előállítása megelőzi a jelszavakhoz kapcsolódó felszólítás kiadását.

jogosult felhasználó
A munkaállomáson található ügyfél adminisztrációs jogosultságával rendelkező felhasználó. Ez a felhasználó megváltoztathatja a jelszavakat, nyílt regisztrációkat hajthat végre, valamint törölheti a fájlterületeket.

jogosultság
Objektumok, erőforrások vagy funkciók elérésére vonatkozó jog. Lásd még: jogosultságosztály.

jogosultságosztály
Az adminisztrátornak adományozott jogosultsági szint. A jogosultságosztály határozza meg az adminisztrátor által végrehajtható adminisztrációs feladatokat. Lásd még: jogosultság, csomópontjogosultság-osztály, operátorjogosultság-osztály, irányelvjogosultság-osztály, tárolójogosultság-osztály, rendszerjogosultság-osztály.

jogosultságszabály
Meghatározás, amely egy másik felhasználónak engedélyezi a felhasználó fájljainak tárolóból való visszaállítását vagy lekérését.

K

katasztrófa utáni helyreállítás kezelője (DRM)
A kiszolgálóhoz tartozó katasztrófa utáni helyreállítási terv elkészítéséhez és használatához segítséget nyújtó funkció.

katasztrófa utáni helyreállítási terv
A katasztrófa utáni helyreállítás kezelője (DRM) által létrehozott fájl, amely katasztrófa esetén a számítógéprendszerek helyreállítási módjával, valamint a bizonyos helyreállítási feladatok végrehajtása érdekében futtatható parancsfájlokkal kapcsolatban tartalmaz információkat. A fájl a kiszolgáló által használt szoftverekkel és hardverekkel, valamint a helyreállítási adathordozó helyével kapcsolatban foglal magában információkat.

KB
Lásd: kilobyte.

képfájl
Fájlrendszer vagy nyers logikai kötet, amelynek biztonsági mentése egyetlen objektumként megy végbe.

képfájlmentés
A teljes fájlrendszer vagy nyers logikai kötet biztonsági mentése egyetlen objektumként.

kezelési osztály
Irányelvobjektum, amelyet a felhasználók az egyes fájlokhoz rendelhetnek annak megadása érdekében, hogy a kiszolgáló miként kezeli az adott fájlt. A kezelési osztály egy biztonságimásolat-csoportot, archív másolatcsoportot és tárhelykezelési attribútumokat tartalmazhat. Lásd még: összerendelés, másolatcsoport, hierarchikus tárolókezelési ügyfél, irányelvkészlet, újbóli összerendelés.

kiinduló fájlrendszer
Az a fájlrendszer, amelyből a fájl átállításra került. A fájl visszahívásakor az a kiinduló fájlrendszerébe tér vissza.

kilobyte (KB)
A processzortároló, a valós és virtuális tárterület, illetve a csatornakötet esetén: 2 a 10. hatványon, azaz 1024 byte. A lemeztároló kapacitása és a kommunikációs mennyiség esetén 1000 byte.

kiszolgáló
Szoftverprogram vagy számítógép, amely szolgáltatásokat nyújt más szoftverprogramoknak vagy számítógépeknek. Lásd még: ügyfél.

kiszolgáló által rákérdezett ütemezési mód
Ügyfél-/kiszolgálókommunikációs eljárás, ahol a kiszolgáló akkor lép kapcsolatba az ügyfélcsomóponttal, ha feladatokat kell végrehajtani. Lásd még: ügyfél-lekérdezési ütemezési mód.

kiszolgálóbeállítás-fájl

Különféle kiszolgálóműveleteket vezérlő beállításokat tartalmazó fájl. Ezek a beállítások olyan elemeket érintenek, mint a kommunikáció, az eszközök és a teljesítmény.

kiszolgálótároló
: A kiszolgáló által használt elsődleges, másolási és aktívadat-tárolási készletek, amelyek segítségével a felhasználó fájlok tárolása zajlik, például a biztonsági mentési változatok, az archív másolatok, és a hierarchikus tárolókezelési ügyfélcsomópontokról átállított (területkezelt) fájlok esetében. Lásd még: aktívadat-tároló, tároló típusú tárolókészlet, másolat-tárolókészlet, elsődleges tárolókészlet, tárolókészlet-kötet, kötet.

kiterjesztés
: Az adatbázis vagy a helyreállítási napló információinak tárolására használható elérhető terület részarányának növelése.

kiterjesztett attribútum (EA)
: Fájlokhoz vagy könyvtárakhoz társított név-érték párok. A kiterjesztett attribútumok három osztálya létezik: felhasználói, rendszer- és megbízható attribútumok.

kizárás
: A fájlok befoglalási-kizárási listán való azonosításának folyamata. Ez a folyamat megakadályozza, hogy a fájlok mentésre vagy átállításra kerüljenek minden alkalommal, amikor a felhasználó vagy az ütemezés növekményes vagy szelektív biztonsági mentési műveletet végez. A fájlok kizárhatók a biztonsági mentési és/vagy tárhelykezelési folyamatból.

kizárási-befoglalási lista
: Lásd: befoglalási-kizárási lista.

kommunikációs módszer
: Az a módszer, amellyel az ügyfél és a kiszolgáló információkat cserél. Lásd még: Átvitelvezérlési protokoll/Internet protokoll.

kommunikációs protokoll
: Meghatározott felületek készlete, amely engedélyezi a számítógépek egymással folytatott kommunikációját.

konfigurációkezelő
: Kiszolgáló, amely konfigurációs információkat, például irányelveket és ütemezéseket terjeszt a felügyelt kiszolgálóknak azok profilja szerint. A konfigurációs információk irányelveket és ütemezéseket foglalhatnak magukban. Lásd még: vállalati konfiguráció, felügyelt kiszolgáló, profil.

könyvtár
: 1. Lecsatlakoztatható rögzített adathordozó, például egy mágneslemez vagy -szalag lerakata.
  2. Legalább egy meghajtóból, és (a könyvtártípustól függően) valószínűleg olyan robotikus eszközökből álló gyűjtemény, amelyek segítségével elérhetők a tárolókötetek.

könyvtárkezelő
: Eszközműveleteket vezérlő kiszolgáló abban az esetben, amikor több tárolókezelési kiszolgáló osztozik egy tárolóeszközön. Lásd még: könyvtárügyfél.

könyvtártároló típusú tárolókészlet
: Tárolókészlet, amelyet a kiszolgáló tárolókészlet-könyvtárakban való adattárolásra használ. A könyvtártároló típusú tárolókészletben tárolt adatok belső vagy ügyféloldali adatkettőzés-megszüntetést alkalmazhatnak. Lásd még: felhőtároló típusú tárolókészlet, tároló típusú tárolókészlet, tárolómásolat típusú tárolókészlet, tárolókészlet.

könyvtárügyfél
: A másik tárolókezelési kiszolgáló által felügyelt könyvtár eléréséhez kiszolgálók közötti kommunikációt használó kiszolgáló. Lásd még: könyvtárkezelő.

kötet
: Különálló tárolóegység a lemezen, szalagon vagy egyéb adatrögzítési hordozón, amely támogatja az azonosító és paraméterlista valamilyen formáját, például a kötetcímke vagy a be-/kimeneti vezérlés használatát. Lásd még: ideiglenes kötet, kiszolgálótároló, tárolókészlet, tárolókészlet-kötet.

Kötet árnyékmásolata szolgáltatás (VSS)
: Microsoft alkalmazásprogramozási felületek (API) készlete, amelynek segítségével a kötetek árnyékmásolatainak biztonsági mentése, a fájlok - köztük az összes nyitott fájl - pontos másolatai stb. hozhatók létre.

kötettörténetfájl
: A kiszolgáló által az adatbázis biztonsági mentéseihez, valamint az adminisztrátori, csomópont-, irányelv- vagy kiszolgálóadatok exportálásához használt kötetekkel kapcsolatos információkat tartalmazó fájl. A fájl továbbá a hozzáadott, újrafelhasznált vagy törölt soros hozzáférésű tárolókészlet-kötetekkel kapcsolatban is rendelkezik információkkal. Ezek az információk a kiszolgáló-adatbázisban rögzített kötetinformációk másolatai.

központi ütemező
: Az adminisztrátor számára ügyfélműveletek és adminisztrációs parancsok ütemezését engedélyező funkció. A műveletek úgy ütemezhetők, hogy azok rendszeres időközönként, vagy egy adott dátumon menjenek végbe. Lásd még: adminisztrációsparancs-ütemezés, ügyfélütemezés.

különleges fájl
: AIX, UNIX vagy Linux rendszereken a rendszer eszközeit meghatározó fájl, vagy a folyamatok által létrehozott ideiglenes fájlok. A különleges fájlok három alaptípusa létezik: elsőnek be, elsőnek ki (FIFO), blokk és karakter.

külső könyvtár
A tárolókezelési rendszertől eltérő adathordozó-kezelő rendszer által felügyelt meghajtók gyűjteménye.
küszöbérték szerinti átállítás
A fájlok helyi fájlrendszerből a kiszolgálótárolóba való áthelyezésének folyamata, amely a fájlrendszer számára meghatározott magas és alacsony küszöbértékekre épül. Lásd még: automatikus átállítás, igény szerinti átállítás, átállítási feladat, szelektív átállítás.
kvóta
1. AIX, UNIX vagy Linux rendszereken futó HSM esetén a fájlrendszerből a kiszolgálótárolóba átállítható és előzetesen átállítható adatmennyiségre vonatkozó (megabyte-ban megadott) korlát.
2. Windows rendszereken futó HSM esetén a visszahívott fájlok által lefoglalt területre vonatkozó, felhasználó által megadott korlát.

L

LAN
Lásd: helyi hálózat.
LAN nélküli adatáthelyezés
Az ügyféladatok áthelyezése az ügyfélrendszer és a tárolóhálózaton (SAN) található tárolóeszköz között, kihagyva a helyi hálózatot.
LAN nélküli adatátvitel
Lásd: LAN nélküli adatáthelyezés.
lap
Meghatározott területegység a tárolási adathordozón vagy adatbáziskötetben.
lejárat
A fájlok, adathalmazok vagy objektumok törlés céljából való azonosításának folyamata, mivel elérkezett azok lejárati dátuma vagy megtartási időszakuk véget ért.
lejáró fájl
Átállított vagy előzetesen átállított fájl, amely lejárat és a tárolóból való eltávolítás céljából került megjelölésre. Ha a csonkfájlok vagy az előzetesen átállított fájlok eredeti példánya törlésre kerül a helyi fájlrendszerből, vagy végbemegy az előzetesen átállított fájlok eredeti példányának frissítése, akkor a megfelelő átállított vagy előzetesen átállított fájl az összeegyeztetés következő futtatásakor lesz lejárat céljából megjelölve.
lekérés
Archivált információk átmásolása felhasználás céljából a tárolókészletből a munkaállomásra. A lekérési művelet nem befolyásolja a tárolókészletben lévő archív változatot. Lásd még: archiválás.
LOFS
Lásd: visszahurkolásos virtuális fájlrendszer.
logikai fájl
Legalább egy kiszolgáló-tárolókészletben önmagában vagy egy összesítés részeként tárolt fájl. Lásd még: összesítés, fizikai fájl, fizikai foglaltság.
logikai foglaltság
A tárolókészletben szereplő logikai fájlok által használt terület. Ez a terület nem tartalmazza azt a használaton kívüli területet, amely akkor kerül létrehozásra, amikor logikai fájlokat törölnek az összesítési fájlokból, így kisebb lehet a fizikai foglaltságnál. Lásd még: fizikai foglaltság.
logikai kötet
A fizikai kötet fájlrendszert tartalmazó része.
logikai kötet biztonsági mentése
A fájlrendszer vagy logikai kötet egyetlen objektumként történő biztonsági mentése.
logikaiegység-szám (LUN)
A SCSI szabványban azon eszközök megkülönböztetésére használt egyedi azonosító, amelyek mindegyike egy logikai egység (LU).
Logikaikötet-pillanatkép ügynök (LVSA)
Pillanatkép-szolgáltatóként viselkedni képes szoftver, amely az online képfájlmentés során létrehozza a logikai kötet pillanatképét.
LUN
Lásd: logikai egységszám.
LVSA
Lásd: Logikaikötet-pillanatkép ügynök.

M

makrófájl

Legalább egy olyan IBM Spectrum Protect adminisztrációs parancsot tartalmazó fájl, amelyet csak a MACRO paranccsal lehet egy adminisztrációs ügyfélből futtatni. Lásd még: IBM Spectrum Protect parancsfájl.

másodlagos telephely
: Fizikai vagy virtuális telephely, amelyet hardver-, hálózati és az elsődleges telephely igényeit támogató tároló-erőforrások alkotnak. Amikor az elsődleges telephelyen meghibásodás történik, akkor a műveletek a másodlagos telephelyen folytatódhatnak. Lásd még: elsődleges telephely.

másolat-tárolókészlet
: Elsődleges tárolókészletekben található fájlok másolatait tartalmazó kötetek megnevezett készlete. A másolat-tárolókészletek csak az elsődleges tárolókészletekben tárolt adatok biztonsági mentéséhez kerülnek felhasználásra. A másolat-tárolókészletek nem lehetnek biztonságimásolat-csoportok, archív másolatcsoportok vagy kezelési osztályok céljai (területkezelt fájlok esetén). Lásd még: cél, elsődleges tárolókészlet, kiszolgálótároló, tárolókészlet, tárolókészlet-kötet.

másolatcsoport
: Olyan attribútumokat tartalmazó irányelvobjektum, amelyek a biztonsági mentési változatok vagy archív másolatok előállítási módját, kezdeti elhelyezését, valamint lejáratának idejét vezérlik. A másolatcsoport egy kezelési osztályhoz tartozik. Lásd még: archív másolatcsoport, biztonságimásolat-csoport, biztonsági mentési változat, kezelési osztály.

másolatmentés
: Teljes biztonsági mentés, amelynek keretében a tranzakciós naplófájlok törlésére nem kerül sor, így az nem zavarja meg a növekményes vagy különbségi mentést használó biztonsági mentési eljárásokat.

maximális átviteli egység (MTU)
: Az adott fizikai adathordozón egyetlen keretben elküldhető legnagyobb fizikai blokk. Például az Ethernet esetében a maximális átviteli egység 1500 byte.

MB
: Lásd: megabyte.

megabyte (MB)
: A processzortároló, a valós és virtuális tárterület, illetve a csatornakötet esetén: 2 a 20. hatványon, azaz 1 048 576 byte. A lemeztároló kapacitása és a kommunikációs mennyiség esetén 1 000 000 byte.

megbízható kommunikációs ügynök (TCA)
: A bejelentkezési jelszó protokollját kezelő program abban az esetben, amikor az ügyfelek jelszó-előállítást alkalmaznak.

megtartás
: Napokban mért időmennyiség, ameddig a mentett vagy archivált fájlokat a törlés előtt a rendszer megőrzi a tárolókészletben. A másolatcsoport-attribútumok és a tartományhoz tartozó alapértelmezett megtartási türelmi időszak határozza meg a megtartást.

mentési-archiválási ügyfél
: Munkaállomáson vagy fájlkiszolgálón futó program, amely a fájlok biztonsági mentését, archiválását, visszaállítását és lekérését teszi lehetővé a felhasználók számára. Lásd még: adminisztrációs ügyfél.

mentési készlet
: A mentési-archiválási ügyfél számára előállított biztonsági mentési fájlok aktív változataiból álló hordozható, egyesített csoport.

mentésikészlet-gyűjtemény
: Egyidejűleg létrehozott, valamint azonos mentésikészletnévvel, kötetnevekkel, leírással és eszközosztályokkal rendelkező mentési készletek csoportja. A kiszolgáló azok csomópontnevével, mentésikészletnevével és fájltípusával azonosítja a gyűjteményben az egyes mentési készleteket.

metaadatok
: Az adatok jellemzőit bemutató - leíró - adatok.

mintaillesztési karakter
: Lásd: helyettesítő karakter.

mód
: Másolatcsoport-attribútum, amely meghatározza, hogy el kell végezni az utolsó biztonsági mentése óta nem módosult fájlok biztonsági mentését. Lásd még: abszolút mód, módosított mód.

módosított mód
: A tárolókezelésben azon biztonságimásolat-csoportosítási üzemmód, amely meghatározza, hogy a fájlokat vagy könyvtárakat csak akkor kell növekményes biztonsági mentéssel kezelni, ha azok a legutóbbi mentés óta módosultak. A fájl vagy könyvtár akkor számít módosultnak, ha megváltozott annak dátuma, mérete, tulajdonosa vagy jogosultságai. Lásd még: abszolút mód, mód.

MTU
: Lásd: maximális átviteli egység.

munkaállomás
: Terminál vagy személyi számítógép, amelyen a felhasználó alkalmazásokat futtathat, és amely általában egy nagyszámítógéphez vagy hálózathoz csatlakozik.

munkamenet

Logikai vagy virtuális kapcsolat két állomás, szoftverprogram vagy eszköz között a hálózaton, amely lehetővé teszi a két elem kommunikációját és adatcseréjét a munkamenet időtartama alatt. Lásd még: adminisztrációs munkamenet.

munkamenet erőforrás-felhasználása
Az ügyfélmunkamenet során felhasznált vagy lekért idő, processzoridő és terület mennyisége.

N

Nagle-algoritmus
A kisebb csomagok egyesítése, valamint azok együttes küldése révén a TCP/IP hálózatok torlódását csökkentő algoritmus.

naplóalapú biztonsági mentés
Windows és AIX ügyfelek biztonsági mentésének módszere, amely a változásértesítési mechanizmust használja fel a fájlokban a növekményes biztonsági mentési teljesítmény javításához, csökkentve a fájlrendszer teljes elemzésének igényét.

naplódémon
AIX, UNIX és Linux rendszereken a fájlrendszerekben található fájlokhoz kapcsolódó módosítási tevékenységet nyomon követő program.

naplószolgáltatás
Microsoft Windows rendszerben a fájlrendszerekben található fájlokhoz kapcsolódó módosítási tevékenységet nyomon követő program.

NAS csomópont
Ügyfélcsomópont, amely egy hálózatra csatlakozó tároló (NAS) típusú fájlkiszolgáló. A NAS csomópont adatait egy hálózati adatkezelési protokoll (NDMP) által vezérelt NAS fájlkiszolgáló viszi át. A NAS csomópontot NAS fájlkiszolgáló-csomópontnak is szokás nevezni.

NAS fájlkiszolgáló
Lásd: hálózatra csatlakozó tároló típusú fájlkiszolgáló.

NAS fájlkiszolgáló-csomópont
Lásd: NAS csomópont.

natív fájlrendszer
Fájlrendszer, amely a fájlkiszolgálóhoz helyileg igen, azonban a tárhelykezeléshez nem került hozzáadásra. A hierarchikus tárolókezelési (HSM) ügyfél nem biztosít tárhelykezelési szolgáltatásokat a fájlrendszernek.

natív formátum
A kiszolgáló által közvetlenül a tárolókészletbe írt adatok formátuma. Lásd még: nem natív adatformátum.

NDMP
Lásd: Hálózati adatkezelési protokoll.

nem natív adatformátum
A kiszolgáló által a műveletekhez használt formátumtól eltérő, a tárolókészletbe kiírt adatokra jellemző formátum. Lásd még: natív formátum.

NetBIOS (Hálózati alapvető be-/kimeneti rendszer)
Hálózatok és személyi számítógépek szabványos felülete, amely a helyi hálózatokban üzenet-, nyomtatókiszolgáló- és fájlkiszolgáló-funkciók biztosítására szolgál. A NetBIOS felületet igénybe vevő alkalmazásoknak nem szükséges a LAN adatkapcsolat-vezérlési (DLC) protokolljainak részleteit kezelniük.

nevesített adatcsatorna
A folyamatközi kommunikáció egy típusa, amely lehetővé teszi az üzenetfolyamok átadását a partnerfolyamatok - például egy ügyfél és egy kiszolgáló - között.

növekményes biztonsági mentés
A fájlok vagy könyvtárak biztonsági mentési, illetve a lapok adatbázisbeli másolási folyamata, amikor az új, illetve a legutóbbi teljes vagy növekményes biztonsági mentés óta módosult elemek kerülnek feldolgozásra. Lásd még: szelektív biztonsági mentés.

nyers logikai kötet
A fizikai kötet nem kiosztott blokkokból álló, naplózott fájlrendszer- (JFS) meghatározással nem rendelkező része. A logikai kötet csak alacsony szintű I/O funkciókon keresztül elérhető el olvasás/írás céljából.

nyílt regisztráció
Regisztrációs folyamat, amelyben a felhasználók regisztrálhatják a kiszolgálóval munkaállomásaikat ügyfélcsomópontokként. Lásd még: zárt regisztráció.

nyilvántartás
Lerakat, amely hozzáférési és konfigurációs információkat tartalmaz a felhasználók, rendszerek és szoftverek számára.

nyugtázás (ACK)
Nyugtázási karakterek átvitele az adatátvitelre adott pozitív válaszként.

O

offline kötetmentés

Biztonsági mentés, amelynek keretében a kötet zárolt, így más rendszeralkalmazások nem tudják azt a biztonsági mentési művelet során elérni.

online kötetmentés
: Biztonsági mentés, amelynek keretében a kötetet más rendszeralkalmazások is elérhetik a biztonsági mentési művelet során.

operátorjogosultság-osztály
: Jogosultságosztály, amely felhatalmazza az adminisztrátort a kiszolgáló letiltására vagy leállítására, a kiszolgáló engedélyezésére, a kiszolgálófolyamatok megszakítására, valamint a cserélhető adathordozók kezelésére. Lásd még: jogosultságosztály.

osztott dinamikus sorbafejtés
: Sorbafejtési érték, amely meghatározza, hogy a fájlt nem szabad biztonsági mentési vagy archiválási műveletben használni, ha az a művelet során módosul. A mentési-archiválási ügyfél több alkalommal tesz kísérletet a biztonsági mentési vagy archiválási műveletre; ha a fájl minden kísérlet ideje alatt módosul, akkor a mentési-archiválási ügyfél az utolsó kísérlet keretében végzi el a fájl biztonsági mentését vagy archiválását. Lásd még: dinamikus sorbafejtés, sorbafejtés, osztott statikus sorbafejtés, statikus sorbafejtés.

osztott könyvtár
: Több tárolókezelő kiszolgáló által használt könyvtáreszköz.

osztott statikus sorbafejtés
: Másolatcsoport-sorbafejtési érték, amely meghatározza, hogy a biztonsági mentési vagy archiválási művelet során a fájlt nem lehet módosítani. Az ügyfél több alkalommal tesz kísérletet a művelet ismételt végrehajtására. Ha a fájl minden próbálkozáskor használatban van, akkor a rendszer a fájl biztonsági mentését vagy archiválását nem végzi el. Lásd még: dinamikus sorbafejtés, sorbafejtés, osztott dinamikus sorbafejtés, statikus sorbafejtés.

összeegyeztetés
: Az eredeti adatlerakat és az adatok biztonsági mentés céljából történő tárolására szolgáló nagyobb rendszer közötti következetesség biztosításának folyamata. Az adatok biztonsági mentés céljából történő tárolására szolgáló nagyobb rendszerekre példák a tárolókiszolgálók vagy egyéb tárolórendszerek. Az összeegyeztetési folyamat során a már szükségtelenként azonosított adatok eltávolításra kerülnek.

összerendelés
: A fájlok társítása a kezelési osztályok nevével. Lásd még: archívummegtartási türelmi időszak, kezelési osztály, újbóli összerendelés.

összerendezés
: Az a folyamat, amely a tárolókészletben minimális számú soros elérésű köteten tartja az összes olyan adatot, amely egy együgyfeles fájlterülethez, egyetlen ügyfélcsomóponthoz, vagy ügyfélcsomópontok egy csoportjához tartozik. Az összerendezés nagy mennyiségű adat visszaállításakor képes csökkenteni a kötelezően elérendő kötetek számát.

összerendezési csoport
: Olyan ügyfélcsomópontok felhasználó által megadott csoportja, amelyek adatai az összerendezési folyamat révén minimális számú köteten kerülnek tárolásra.

összesítés
: Legalább egy tárolókészletben tárolt objektum, amely egybecsomagolt logikai fájlok adott csoportját tartalmazza. Lásd még: logikai fájl, fizikai fájl.

összesített adatátviteli sebesség
: Teljesítménystatisztika, amely az adott művelet feldolgozása során másodpercenként átvitt byte-ok átlagos számát jelzi.

P

IBM Spectrum Protect parancsfájl
: IBM Spectrum Protect adminisztrációs parancsok sorozata, amelyek a IBM Spectrum Protect kiszolgáló adatbázisában kerülnek tárolásra. A parancsfájl bármely felületről futtatható a kiszolgálón. A parancsfájl a parancsparaméterek és feltételes funkciók behelyettesítési értékeit is magában foglalhatja. Lásd még: makrófájl, parancsfájl.

parancsfájl
: Parancsok fájlban egyesített sorozata, amely a fájl futtatásakor egy adott funkciót hajt végre. A parancsfájlok értelmezésére futásuk közben kerül sor. Lásd még: IBM Spectrum Protect parancsfájl.

párbeszéd
: Két program közötti kapcsolat egy olyan munkamenet keretében, amely a tranzakció feldolgozása során lehetővé teszi számukra az egymással folytatott kommunikációt.

pillanatkép
: Képfájlmentési típus, amely a kötet adott időpontbeli nézetét tartalmazza.

postafiók-visszaállítás
: Funkció, amely Microsoft Exchange Server adatokat állít vissza (IBM Data Protection for Microsoft Exchange biztonsági mentésekből) a postafiók vagy postafiókelemek szintjén.

profil

Konfigurációs információk megnevezett csoportja, amely a felügyelt kiszolgáló előfizetése esetén a konfigurációkezelő terjeszthet. A konfigurációs információk közé tartozhatnak a regisztrált adminisztrátori azonosítók, irányelvek, ügyfélütemezések, ügyfélbeállítás-készletek, adminisztrációs ütemezések, tárolókezelő-parancsfájlok, kiszolgáló- és kiszolgálócsoport-meghatározások. Lásd még: konfigurációkezelő, vállalati konfiguráció, felügyelt kiszolgáló.

profiltársítás
: A konfigurációkezelő esetében a profil és az objektum, például egy irányelvtartomány között meghatározott kapcsolat. A profiltársítások adják meg a profilra előfizetett felügyelt kiszolgálóra terjesztett konfigurációs információkat.

R

regisztrálás
: A kiszolgáló elérésére képes ügyfélcsomópont vagy adminisztrátori azonosító meghatározása.

rendszerjogosultság-osztály
: Jogosultságosztály, amely minden kiszolgálóparancs kiadására felhatalmazza az adminisztrátort. Lásd még: jogosultságosztály.

részleges fájlvisszahívási mód
: Visszahívási mód, amelynek hatására a hierarchikus tárolókezelési (HSM) funkció csak az átállított fájl egy részét olvassa be a tárolóból, a fájlhoz hozzáférő alkalmazás által kért módon.

rezidens fájl
: Windows rendszeren a helyi fájlrendszer egyik teljes fájlja, amely átállított fájl is lehet, mivel átállított másolata létezhet a kiszolgálótárolóban. UNIX vagy Linux rendszeren a helyi fájlrendszer egyik teljes fájlja, amely nem került átállításra vagy előzetesen átállításra, vagy visszahívták azt a kiszolgálótárolóból, majd elvégezték a fájl módosítását.

ritka fájl
: Az általa tartalmazott adatoknál nagyobb méretben létrehozott fájl, amely üres területet hagy az adatok jövőbeli hozzáadására.

root felhasználó
: Korlátozások nélkül tevékenykedő rendszerfelhasználó. A root felhasználó rendelkezik az adminisztrációs feladatok végrehajtásához szükséges különleges jogokkal és felhatalmazásokkal.

S

SAN
: Lásd: tárolóhálózat.

sérült fájl
: Fizikai fájl, amelyben a rendszer olvasási hibákat észlelt.

sorbafejtés
: A biztonsági mentés vagy archiválás feldolgozása során módosított fájlok kezelésének folyamata. Lásd még: osztott dinamikus sorbafejtés, osztott statikus sorbafejtés, statikus sorbafejtés.

SSL
: Lásd: Védett socket réteg.

stabilizált fájlterület
: A kiszolgálón igen, az ügyfélen azonban nem létező fájlterület.

statikus sorbafejtés
: Másolatcsoport-sorbafejtési érték, amely meghatározza, hogy a biztonsági mentési vagy archiválási művelet során a fájlt nem lehet módosítani. Ha az első kísérlet alatt a fájl használatban van, akkor a mentési-archiválási ügyfél nem tudja elvégezni a fájl biztonsági mentését vagy archiválását. Lásd még: dinamikus sorbafejtés, sorbafejtés, osztott dinamikus sorbafejtés, osztott statikus sorbafejtés.

szakasz
: Sorok csoportja a fájlokban, amelyek együttesen egy közös funkciót képviselnek, vagy a rendszer adott részét határozzák meg. A szakaszokat általában üres sorok vagy kettőspontok választják el egymástól, valamint minden szakasz rendelkezik névvel.

szalagkönyvtár
: Berendezések és szolgáltatások készlete, amelyek támogatják egy telepítés szalagkörnyezetét. A szalagkönyvtár a szalagtároló rack szekrényeket, az automatikus szalagbeillesztési mechanizmusokat, a szalagos meghajtók készletét és az adott meghajtókra szerelt kapcsolódó szalagkötetek halmazát foglalhatja magában.

szalagkötet-előtag
: A fájlnév magas szintű minősítője vagy a szabványos szalagcímke adatkészletneve.

szelektív átállítás
: A felhasználó által kiválasztott fájlok helyi fájlrendszerből a kiszolgálótárolóba való másolásának, majd a helyi fájlrendszerben a fájlok csonkfájlokkal való helyettesítésének folyamata. Lásd még: igény szerinti átállítás, küszöbérték szerinti átállítás.

szelektív biztonsági mentés

Az ügyféltartományból származó adott fájlok vagy könyvtárak biztonsági mentésének folyamata. A mentett fájlok a befoglalási-kizárási listán ki nem zárt fájlokat jelentik. A fájloknak kötelező megfelelniük az egyes fájlokhoz társított kezelési osztály biztonságimásolat-csoportjában található sorbafejtési követelménynek. Lásd még: növekményes biztonsági mentés.

szelektív visszahívás
: A felhasználó által kiválasztott fájlok kiszolgálótárolóból a helyi fájlrendszerbe való másolásának folyamata. Lásd még: visszahívás, átlátszó visszahívás.

T

tárhelykezelés
: Lásd: hierarchikus tárolókezelés.

tárolási egység
: Az adatok kettőzésmegszüntetési folyamata során létrehozott fájlrész. Az ismétlődések azonosítása érdekében a tárolási egységek kerülnek összehasonlításra más fájltárolási egységekkel.

tárolási hierarchia
: Elsődleges tárolókészletek adminisztrátor által meghatározott logikai sorrendje. A sorrend jellemzően a tárolókészlet által használt eszközök sebességére és kapacitására épül. A tárolási hierarchia a következő tárolókészlet megadásával szabható meg a tárolókészlet-meghatározásban. Lásd még: tárolókészlet.

tároló
: Adattárolási hely, például egy fájl, könyvtár vagy eszköz. Lásd még: tároló típusú tárolókészlet.

tároló típusú tárolókészlet
: Elsődleges tárolókészlet, amelyet a kiszolgáló adatok tárolására használ. Az adatok fájlrendszeri könyvtárakban vagy felhőtárolókban található tárolókban kerülnek tárolásra. Az adatokban szükség szerint megszüntetésre kerülnek a kettőzések, ahogy a kiszolgáló kiírja azokat a tárolókészletbe. Lásd még: cloud-container storage pool, container, könyvtártároló típusú tárolókészlet.

tárolóhálózat (SAN)
: Az adott környezetre szabott kijelölt tárolóhálózat, amely kiszolgálókat, rendszereket, tárolási termékeket, hálózatkezelési termékeket, szoftvereket és szolgáltatásokat egyesít.

tárolójogosultság-osztály
: Jogosultságosztály, amely jogosultságot biztosít az adminisztrátornak a kiszolgálóhoz tartozó tároló-erőforrások kiosztási és használati módjának felügyeletéhez, például az adatbázis, a helyreállítási napló és a kiszolgálótároló megfigyeléséhez. Lásd még: jogosultságosztály.

tárolókészlet
: Tárolókötetek vagy tárolók készlete, amely az ügyféladatok tárolásához felhasznált célnak felel meg. Lásd még: active-data pool, felhőtároló típusú tárolókészlet, másolat tárolókészlet, könyvtártároló típusú tárolókészlet, elsődleges tárolókészlet, tároló hierarchia.

tárolókészlet-kötet
: A tárolókészlethez rendelt kötet. Lásd még: aktívadat-tároló, másolat-tárolókészlet, elsődleges tárolókészlet, kiszolgálótároló, kötet.

tárolómásolat típusú tárolókészlet
: Tárolókészlet, amelyet egy kiszolgáló könyvtártároló típusú tárolókészletekből származó kiterjedések másolatainak tárolásához használ. A másolatok a könyvtártároló típusú tárolókészletben keletkezett sérülések javítására szolgálnak. A tárolómásolat típusú tárolókészlet szekvenciális adathordozót, például szalagot használ. Lásd még: könyvtártároló típusú tárolókészlet.

tárolómező
: Az Amazon Simple Storage Service (Amazon S3) által használt felhőtároló típusú tároló.

tárolóügynök
: Program, amely az ügyféladatok biztonsági mentését és visszaállítását közvetlenül lehetővé teszi a tárolóhálózathoz (SAN) csatlakoztatott tárolóba/tárolóból.

társítás
: Az ügyfélcsomópont és az ügyfélütemezés között meghatározott kapcsolat. A társítás az ütemezés nevét, az ütemezés irányelvtartományának nevét, valamint az ütemezett műveleteket végrehajtó ügyfélcsomópont nevét azonosítja.

tartomány
: Legalább egy olyan irányelvkészlettel rendelkező ügyfélcsomópontok csoportosítása, amely adatokat vagy tároló-erőforrásokat kezel az ügyfélcsomópontok számára. Lásd még: irányelvtartomány.

távoli
: Hierarchikus tárolókezelési termékek esetén az áthelyezni kívánt átállított fájlok kiindulópontjára vonatkozik. Lásd még: helyi.

TCA
: Lásd: megbízható kommunikációs ügynök.

TCP/IP

Lásd: Átvitelvezérlési protokoll/Internet protokoll.

teljes biztonsági mentés
: Az egész kiszolgáló-adatbázis biztonsági mentésének folyamata. A teljes biztonsági mentések egy-egy új adatbázis-mentési sorozatot kezdenek. Lásd még: adatbázis-mentési sorozat, adatbázis-pillanatkép, növekményes biztonsági mentés.

terhelési partíció (WPAR)
: Egyetlen operációsrendszer-példányon belüli partíció.

területfigyelő démon
: A területfelhasználást minden aktív tárhelykezeléssel rendelkező fájlrendszerben ellenőrző démon, amely automatikusan elindítja a küszöbérték szerinti átállítást, ha a fájlrendszer területfelhasználása eléri vagy meghaladja a magas küszöbértéket.

területkezelt fájl
: A hierarchikus tárolókezelési (HSM) ügyfél által az ügyfélcsomópontról átállított fájl. A HSM ügyfél igény szerint hívja vissza a fájlt az ügyfélcsomópontra.

tevékenységnapló
: A kiszolgáló által előállított normál tevékenységüzeneteket rögzítő napló. Ezen üzenetek közé tartoznak a kiszolgáló és az ügyfél működésével kapcsolatos információk, például a munkamenetek kezdő időpontja, vagy az eszköz I/O hibák.

Titkosított fájlrendszer (EFS)
: Fájlrendszeri szintű titkosítást használó fájlrendszer.

tömörítés
: Az a funkció, amely eltávolítja az ismétlődő karaktereket, szóközöket, karaktersorozatokat vagy bináris adatok a feldolgozás alatt álló adatokból, majd a karaktereket vezérlőkarakterekkel helyettesíti. A tömörítés csökkenti az adatok esetében szükséges tárolóterület mennyiségét. Lásd még beágyazott tömörítés.

törlésjelző objektum
: A törölt objektumok attribútumainak részhalmaza. A törlésjelző objektum megadott időtartamig kerül megőrzésre, az adott időtartam végén pedig a rendszer véglegesen törli azt.

tükrözés
: Ugyanazon adatok egyidejűleg több lemezre való írásának folyamata. Az adatok tükrözése védelmet nyújt az adatbázison vagy a helyreállítási naplón belüli adatvesztéssel szemben.

U

UCS-2
: 2 byte-os (16 bites) kódolási séma, amely az ISO/IEC 10646-1-es specifikációjára épül. Az UCS-2 a megvalósítás három szintjét határozza meg: 1. szint - A kódolt elemek egyesítése nem engedélyezett; 2. szint - A kódolt elemek egyesítése csak thai, ind, héber és arab nyelv esetén engedélyezett; 3. szint - A kódolt elemek bármely egyesítése engedélyezett.

újbóli összerendelés
: A fájlok valamennyi mentett változatának társítása egy új kezelésiosztály-névhez. Például az aktív biztonsági mentési változattal rendelkező fájl újbóli összerendelésére akkor kerül sor, amikor a fájl újabb változatáról készül biztonsági mentés másik kezelésiosztály-társítással. Lásd még: összerendelés, kezelési osztály.

UNC
: Lásd: Általános elnevezési megállapodás.

Unicode
: Karakterkódolási szabvány, amely a világ általános nyelvein írt szövegek, valamint számos klasszikus és történelmi szöveg cseréjét, feldolgozását és megjelenítését támogatja.

Unicode támogatással rendelkező fájlterület
: Unicode szabványt követő névvel rendelkező fájlterület, amely a többnyelvű munkaállomásokon bármely területi beállítással kompatibilis.

UTF-8
: Unicode átalakítási formátum, 8 bites kódolással, amelyet a meglévő ASCII-alapú rendszerekkel való egyszerű használatra terveztek. Az UTF-8 formátumú adatok CCSID értéke: 1208.

utófeldolgozási adatkettőzés-megszüntetés
: A tárolási igények csökkentési módszere, amely a redundáns adatok kiküszöbölésére épít. Az adatok először kiírásra kerülnek a tárolókészletbe, a rendszer azonosítja a megkettőzött adatokat, majd visszanyeri a területet a tárolókészletben. Lásd még: adatkettőzés-megszüntetés, belső adatkettőzés-megszüntetés.

útvonal
: Objektum, amely egy:egy kapcsolatot határoz meg a forrás és a cél között. Az útvonal segítségével a forrás eléri a célt. Az adatok a forrástól a célhoz áramolhatnak, és vissza. A forrásra példa az adatáthelyező (például a hálózatra csatlakozó tároló [NAS] típusú fájlkiszolgáló), a célra pedig a szalagos meghajtó.

UUID
: Lásd: Általánosan egyedi azonosító.

ügyfél

A kiszolgálóról szolgáltatásokat kérő szoftverprogram vagy számítógép. Lásd még: kiszolgáló.

ügyfél-lekérdezési ütemezési mód
: Műveleti módszer, amelyben az ügyfél lekérdezi a munkát a kiszolgálóról. Lásd még: kiszolgáló által rákérdezett ütemezési mód.

ügyfél felhasználóibeállítás-fájlja
: A rendszeren található ügyfél által használt feldolgozási beállítások készletét tartalmazó fájl. A készlet magában foglalhat olyan beállításokat, amelyek az ügyfél által csatlakoztatott kiszolgálókat határozzák meg, valamint amelyek a biztonsági mentési, archiválási, hierarchikus tárolókezelési és ütemezési műveleteket befolyásolják. Ezt a fájl dsm.opt fájlnak is szokás nevezni. AIX, UNIX vagy Linux rendszerek esetén lásd még: ügyfél rendszerbeállítás-fájlja. Lásd még: ügyfél rendszerbeállítás-fájlja, beállításfájl.

ügyfél rendszerbeállítás-fájlja
: AIX, UNIX vagy Linux rendszerű ügyfeleken használt fájl, amely a szolgáltatásokért csatlakoztatandó kiszolgálókat azonosító feldolgozási beállítások készletét tartalmazza. Ez a fájl meghatározza továbbá a biztonsági mentés, archiválás, hierarchikus tárolókezelés és ütemezés kommunikációs módszereit, valamint beállításait is. Lásd még: ügyfél felhasználóibeállítás-fájlja, beállításfájl.

ügyfél/kiszolgáló
: Osztott adatfeldolgozás esetén az együttműködés modelljére vonatkozik, amelynek keretében az egyik számítógépen található program kérést küld egy másik számítógépen lévő programnak, majd megvárja annak válaszát. A kérést küldő programot ügyfélnek, a válaszolót kiszolgálónak szokás nevezni.

ügyfélbeállítás-fájl
: Szerkeszthető fájl, amely a kiszolgálót és a kommunikációs módszert azonosítja, valamint biztosítja a biztonsági mentés, archiválás, hierarchikus tárolókezelés és ütemezés konfigurációját.

ügyfélbeállítás-készlet
: Beállítások csoportja, amelyek a kiszolgálón kerültek meghatározásra, és amelyeket az ügyfélbeállítás-fájlokkal együtt az ügyfélcsomópontokon használnak fel.

ügyfélcsomópont
: Az a fájlkiszolgáló vagy munkaállomás, amelyen a mentési-archiválási ügyfélprogram telepítésre került, és amelyet bejegyeztek a kiszolgálóhoz.

ügyfélcsomópont-munkamenet
: Az a munkamenet, amelynek keretében az ügyfélcsomópont a biztonsági mentési, visszaállítási, archiválási, átállítási vagy visszahívási kérések végrehajtása érdekében kommunikál a kiszolgálóval. Lásd még: adminisztrációs munkamenet.

ügyfélfogadó
: A webes ügyfelekhez tartozó Java™ kisalkalmazást a webböngészőknek kiszolgáló szolgáltatás. Windows rendszereken az ügyfélfogadó szolgáltatásként kerül telepítésre és futtatásra. AIX, UNIX és Linux rendszereken az ügyfélfogadó démonként kerül futtatásra.

ügyfélfogadó démon (CAD)
: Lásd: ügyfélfogadó.

ügyféltartomány
: A meghajtók, fájlrendszerek vagy kötetek azon készlete, amelyet a felhasználó az adatok mentési-archiválási ügyféllel történő biztonsági mentése vagy archiválása céljából választ ki.

ügyfélütemezés
: Adatbázisrekord, amely az ügyfélműveletek tervezett feldolgozását írja le az adott időszakban. Az ügyfélműveletek közé tartozhatnak a következők: biztonsági mentési, archiválási, visszaállítási vagy lekérési műveletek, az ügyfél operációs rendszeri parancsai, illetve makrók. Lásd még: adminisztrációsparancs-ütemezés, központi ütemező, ütemezés.

ügynökcsomópont
: Ügyfélcsomópont, amelynek megbízotti jogosultságot adományoztak azért, hogy műveleteket hajtson végre egy másik ügyfélcsomópont (a célcsomópont) nevében.

ütemezés
: Adatbázisrekord, amely a feldolgozandó ügyfélműveleteket vagy adminisztrációs parancsokat írja le. Lásd még: adminisztrációsparancs-ütemezés, ügyfélütemezés.

ütemezési mód
: A kiszolgáló és az ügyfélcsomópont ütemezési műveletének típusa, amely két ütemezési lehetőséget támogat: az ügyfél-lekérdezési és a kiszolgáló által rákérdezett ütemezési módot.

V

vállalati konfiguráció
: A kiszolgálók azon beállításának módszere, amelynek révén az adminisztrátorok a kiszolgálók közötti kommunikáció segítségével más kiszolgálókra terjeszthetik a kiszolgálók egyikének konfigurációját. Lásd még: konfigurációkezelő, felügyelt kiszolgáló, profil, előfizetés.

vállalati naplózás

Az események egyik kiszolgálóról a kijelölt eseménykiszolgálóra való küldésének folyamata. Az eseménykiszolgáló továbbítja az eseményeket a kijelölt fogadóknak, például a felhasználói kilépési pontoknak. Lásd még: esemény.

változat
: A kiszolgálótárolóban található fájl biztonsági másolata. A fájlok legújabb biztonsági másolata az aktív változat. Ugyanazon fájl korábbi példányai inaktív változatok. A kiszolgáló által megőrzött változatok számát a kezelési osztályban szereplő másolatcsoport-attribútumok határozzák meg.

Védett socket réteg (SSL)
: Biztonsági protokoll, amely adatvédelmet nyújt a kommunikáció számára. Az SSL segítségével az ügyfél-/kiszolgálóalkalmazások olyan módon kommunikálhatnak, amelyet a lehallgatás, illetéktelen módosítás és üzenethamisítás megakadályozására terveztek.

védett telephely
: Lásd: elsődleges telephely.

véglegesítési pont
: Azon időpont, amikor az adatokat következetesnek lehet tekinteni.

véletlenszerűvé tétel
: A különböző ügyfelekhez tartozó ütemezési kezdési időpontok terjesztési folyamata az ütemezés indítási ablakának megadott százalékos arányán belül.

virtuális beillesztési pont
: Az adott fájlrendszer virtuális fájlrendszerként meghatározott könyvtárága. A virtuális fájlrendszer biztonsági mentése saját fájlterületén megy végbe a kiszolgálón. Míg a kiszolgáló különálló fájlrendszerként dolgozza fel a virtuális beillesztési pontot, addig az ügyfél operációs rendszere nem így tesz.

virtuális fájlterület
: A hálózatra csatlakozó tároló (NAS) típusú fájlrendszerben található könyvtárak ábrázolása az adott könyvtárhoz vezető elérési útvonalként.

virtuális kötet
: Archív fájl a célkiszolgálón, amely egy sorrendi adathordozó-kötetet ábrázol a forráskiszolgáló számára.

visszaállítás
: Információk másolása felhasználás céljából azok biztonsági mentési helyéről az aktív tárolóhelyre. Például információk másolása a kiszolgálótárolóból az ügyfél-munkaállomásra.

visszahívás
: Az átállított fájlok kiinduló fájlrendszerbe való visszamásolása a kiszolgálótárolóból a hierarchikus tárolókezelési ügyféllel. Lásd még: szelektív visszahívás.

visszahurkolásos virtuális fájlrendszer (LOFS)
: Fájlrendszer, amely úgy kerül létrehozásra, hogy a könyvtárat egy másik helyi könyvtár fölött illesztenek be - ez a beillesztés feletti beillesztés technikája. A LOFS fájlrendszert automatikus beillesztő segítségével is elő lehet állítani.

visszanyerés
: A több soros elérésű kötetből származó maradék adatok kevesebb, új soros elérésű kötetekben való egyesítésének folyamata.

visszanyerési küszöbérték
: A soros elérésű adathordozó-kötetnek kötelezően előírt terület százalékos aránya, amelynek elérésekor a kiszolgáló visszanyerheti a kötetet. A terület a fájlok lejárata vagy törlése esetén válik visszanyerhetővé.

VSS
: Lásd: Kötet árnyékmásolata forduljon.

VSS azonnali visszaállítás
: Művelet, amely visszaállítja az adatokat a helyi pillanatképből. A pillanatkép a helyi árnyékköteten található VSS biztonsági mentés. A visszaállítási művelet hardverrel segített visszaállítási módszer segítségével (például FlashCopy művelettel) kéri le az adatokat.

VSS biztonsági mentés
: Biztonsági mentési művelet, amely a Microsoft Kötet árnyékmásolata szolgáltatás (VSS) technológiáját használja. A biztonsági mentési művelet online pillanatképet (adott időpontbeli következetes másolatot) állít elő. Ez a másolat helyi árnyékköteteken vagy kiszolgálótárolóban helyezhető el.

VSS gyors visszaállítás
: Művelet, amely visszaállítja az adatokat a helyi pillanatképből. A pillanatkép a helyi árnyékköteten található VSS biztonsági mentés. A visszaállítási művelet fájlszintű másolási módszer segítségével kéri le az adatokat.

VSS kiírt biztonsági mentés
: Biztonsági mentési művelet, amely a Microsoft által fejlesztett Kötet árnyékmásolata szolgáltatás (VSS) (alternatív rendszerre telepített) hardverszolgáltatójával helyezi át az adatokat a kiszolgálóra. A biztonsági mentési művelet ezen típusa az éles rendszerről egy másikra helyezi át a biztonsági mentés által jelentett terhelést.

VSS visszaállítás
: Funkció, amely a Microsoft által fejlesztett Kötet árnyékmásolata szolgáltatás (VSS) szoftverszolgáltatóját veszi igénybe a kiszolgálótárolóban található pillanatképek visszaállításához. Ezeket a pillanatképeket a VSS biztonsági mentés készítette, és eredeti helyükre kerülnek visszaállításra.

W

WPAR
: Lásd: terhelési partíció.

WWN
: Lásd: globális név.

Z

zárt regisztráció
: Regisztrációs folyamat, amelyben csak adminisztrátor regisztrálhat a kiszolgálóval munkaállomásokat ügyfélcsomópontokként. Lásd még: nyílt regisztráció.
