: Specifies the name of the collocation group to display. To specify multiple names, use a wildcard character. This parameter is optional. The default is to display all collocation groups.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed. To display the members of the collocation group, you must specify FORMAT=DETAILED.

Display defined collocation groups

Display the collocation groups defined on the server. Issue the following command:

```
query collocgroup
```

```
Collocation Group Name         Collocation Group Description
-------------------------      ----------------------------
DEPT_ED                        Education department
GROUP1                         Low cap client nodes.
```

See Field descriptions for field descriptions.

Display detailed information for collocation groups

Display complete information about all collocation groups and determine which client nodes belong to which collocation groups. Issue the following command:

```
query collocgroup format=detailed
```

```
        Collocation Group Name: DEPT_ED
 Collocation Group Description: Education department
Last Update by (administrator): SERVER_CONSOLE
         Last Update Date/Time: 04/21/2013 10:59:03
   Collocation Group Member(s): EDU_1 EDU_7
           Filespace Member(s):

        Collocation Group Name: GROUP1
 Collocation Group Description: Low cap client nodes.
Last Update by (administrator): SERVER_CONSOLE
         Last Update Date/Time: 04/21/2013 10:59:16
   Collocation Group Member(s): CHESTER
           Filespace Member(s): alpha

        Collocation Group Name: GROUP1
 Collocation Group Description: Low cap client nodes.
Last Update by (administrator): SERVER_CONSOLE
         Last Update Date/Time: 04/21/2013 10:59:16
   Collocation Group Member(s): CHESTER
           Filespace Member(s): beta

        Collocation Group Name: GROUP1
 Collocation Group Description: Low cap client nodes.
Last Update by (administrator): SERVER_CONSOLE
         Last Update Date/Time: 04/21/2013 10:59:16
   Collocation Group Member(s): CHESTER
           Filespace Member(s): gamma
```

See Field descriptions for field descriptions.

Field descriptions

Collocation Group Name
: The name of the collocation group.

Collocation Group Description
: The description for the collocation group.

Last Update by (administrator)
: The name of the administrator that defined or most recently updated the collocation group.

Last Update Date/Time
: The date and time that an administrator defined or most recently updated the collocation group.

Collocation Group Member(s)
: The members of the collocation group.

Filespace Member(s)
: The file space or file spaces that are members of the collocation group. If there is more than one file space, each file space is displayed in a separate entry.

Related commands

Table 1. Commands related to QUERY COLLOCGROUP

Command	Description
DEFINE COLLOCGROUP	Defines a collocation group.
DEFINE COLLOCMEMBER	Adds a client node or file space to a collocation group.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DELETE COLLOCGROUP	Deletes a collocation group.
DELETE COLLOCMEMBER	Deletes a client node or file space from a collocation group.
MOVE NODEDATA	Moves data for one or more nodes, or a single node with selected file spaces.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY NODEDATA	Displays information about the location and size of data for a client node.
QUERY STGPOOL	Displays information about storage pools.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.
UPDATE COLLOCGROUP	Updates the description of a collocation group.
UPDATE STGPOOL	Changes the attributes of a storage pool.

AIX Linux Windows

QUERY CONTAINER (Query a container)

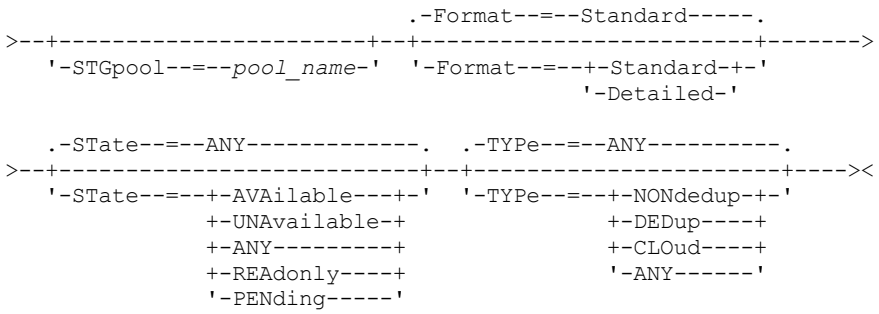
Use this command to display information about one or more containers.

Privilege class

Any administrator can issue this command.

Syntax

```
                    .-*--------------.
>>-Query CONTAINER--+----------------+-------------------------->
                    '-container_name-'
```



Parameters

container_name
: Specifies the name of the container. Specify one of the following values:

  *
  : Specifies that an asterisk (*) represents a wildcard character. Use wildcard characters such as an asterisk to match any characters. Alternatively, you can use a question mark (?) or a percent sign (%) to match exactly one character. If you specify an asterisk, all container names are displayed. This value is the default.

  container_name
  : Specifies the name of the container. The maximum length of the file name is 1024.

STGpool
: Specifies the name of the directory-container storage pool. This parameter is optional. The maximum length of the storage pool name is 30.

Format
: Specifies the level of detail of the query results. This parameter is optional. Specify one of the following values:

  Standard
  : Specifies that a summary of the information is displayed. This value is the default.

  Detailed
  : Specifies that detailed information is displayed.

STate
: Specifies the state of the container that is queried. This parameter is optional. Specify one of the following values:

  AVAilable
  : Specifies that only containers that are available are displayed.

  UNAvailable
  : Specifies that only containers that are not available are displayed. For example, a container might be unavailable if the header is corrupted or if the container cannot be opened.

  ANY
  : Specifies that containers in any state are displayed. This value is the default.

  REAdonly
  : Specifies that only containers in a read-only state are displayed. Data in the container can be read but data cannot be written to the container.

  PENding
  : Specifies that only containers in a pending state are displayed.

TYPe
: Specifies the type of container that is queried. This parameter is optional. Specify one of the following values:

  NONdedup
  : Displays containers that contain data that is not deduplicated. This type of data includes metadata, encrypted data, and data that is too small for data deduplication.

  DEDup
  : Displays containers that contain deduplicated data.

  CLOud
  : Displays containers that are stored in a cloud storage pool.

  ANY
  : Displays any type of container. This value is the default.

AIX Linux

Example: Display information about a container

See Field descriptions for field descriptions.

```
query container /Containers/09/0000000000000943.ncf

Container                              Storage       Container     State
                                       Pool Name     Type
-----------------------------------  ------------- ------------  ---------
/Containers/09/0000000000000943.ncf   STGPOOL1      Non Dedup     Available
```

Windows

Example: Display information about a container

See Field descriptions for field descriptions.

```
query container C:\abc\00\0000000000000005.ncf

Container                           Storage      Container   State
                                    Pool Name    Type
-------------------------------    -----------  ----------  ---------
C:\abc\00\0000000000000005.ncf     STGPOOL1     Non Dedup   Available
```

AIX Linux

Example: Display detailed information about a container

Display detailed information about containers that contain deduplicated data in storage pool STGPOOL1:

```
query container stgpool=STGPOOL1 type=dedup format=detail

                         Container: /abc/00/0000000000000001.dcf
                 Storage Pool Name: STGPOOL1
                    Container Type: Dedup
                             State: Available
                 Maximum size (MB): 40,960
                   Free Space (MB): 39,700
          Approx. Date Last Written: 11/10/2014 15:17:09
            Approx. Date Last Audit:
                        Cloud Type:
                         Cloud URL:
              Space Utilized (MB):
                     Object Count:
```

Windows

Example: Display detailed information about a container

Display detailed information about containers that contain deduplicated data in storage pool STGPOOL1:

```
query container stgpool=STGPOOL1 type=dedup format=detail

                         Container: C:\abc\00\0000000000000001.dcf
                 Storage Pool Name: STGPOOL1
                    Container Type: Dedup
                             State: Available
                 Maximum size (MB): 40,960
                   Free Space (MB): 39,700
          Approx. Date Last Written: 11/10/2014 15:17:09
            Approx. Date Last Audit:
                        Cloud Type:
                         Cloud URL:
              Space Utilized (MB):
                     Object Count:
```

Example: Display detailed information about containers that are stored in a cloud storage pool

Display detailed information about containers that are stored in the cloud storage pool CLOUDPOOL:

```
query container stgpool=CLOUDPOOL format=detail

                        Container: 7-64a1261000c811e58e8f005056c00008
                Storage Pool Name: CLOUDPOOL
                   Container Type: Cloud
                            State:
                  Free Space (MB):

        Approx. Date Last Written: 05/22/2015 14:36:57
          Approx. Date Last Audit:
                       Cloud Type: SWIFT
                        Cloud URL: http://cloudurl:5000/v2.0
            Space Utilized (MB): 7104
                   Object Count: 2472
```

Field descriptions

Container
: The name of the container.

Storage Pool Name
: The name of the storage pool.

Container Type
: The type of container.

State
: The state of the data in the container. The field can contain one of the following values:

  Available
  : The container is available for use.

  Unavailable
  : The container cannot be opened or validated.
  Tip: Issue the AUDIT CONTAINER command to validate the contents of the container.

  Read only
  : The container can be read but data cannot be written to the container.

  Pending
  : The container is pending deletion. When the value that is specified for the REUSEDELAY parameter expires on the DEFINE STGPOOL or UPDATE STGPOOL command, the container is deleted.

  This field does not apply to containers that are stored in cloud storage pools.

Maximum Size (MB)
: The maximum size of the container, in megabytes.

  This field does not apply to containers that are stored in cloud storage pools.

Free Space (MB)
: The total amount of free space that is available in the container, in megabytes.

  This field does not apply to containers that are stored in cloud storage pools.

Approx. Date Last Written
: The approximate date and time that data was written to the container.

Approx. Date Last Audit
: The approximate date and time that data was audited in the container.

Cloud Type
: If the container is stored in a cloud storage pool, the type of cloud platform.

Cloud URL
: If the container is stored in a cloud storage pool, the URL for accessing the on-premises private cloud or off-premises public cloud.

Space Utilized (MB)
: If the container is stored in a cloud storage pool, the amount of space that is used by the container in the on-premises private cloud or off-premises public cloud.

Object Count
: If the container is stored in a cloud storage pool, the number of objects that are managed by the on-premises private cloud or off-premises public cloud for the container.

Table 1. Commands related to QUERY CONTAINER

Command	Description
AUDIT CONTAINER	Audit a directory-container storage pool.
MOVE CONTAINER	Moves the contents of a storage pool container to another container.
QUERY DAMAGED	Displays information about damaged files.

QUERY CONTENT (Query the contents of a storage pool volume)

Use this command to display information about files in a storage pool volume, and the names of client files that link to a deduplicated group of files.

You can use this command to identify files that the server found to be damaged and files that were backed up to a copy storage pool or copied to an active-data pool. This command is useful when a volume is damaged or before you:

- Request the server to fix inconsistencies between a volume and the database
- Move files from one volume to another volume
- Delete a volume from a storage pool

Because this command can take a long time to run and the results can be large, consider using the COUNT parameter to limit the number of files displayed.

Note: Files that are cached in a disk volume and that are marked as damaged are not included in the results.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query CONtent--volume_name--+--------------------+----------->
                               '-NODE--=--node_name-'

>--+-------------------------------+--+------------------+------>
   '-FIlespace--=--file_space_name-'  '-COUnt--=--number-'

   .-Type--=--ANY--------------.  .-Format--=--Standard-----.
>--+---------------------------+--+-------------------------+--->
   '-Type--=--+-ANY-----------+-'  '-Format--=--+-Standard-+-'
              +-Backup-------+                  '-Detailed-'
              +-Archive------+
              '-SPacemanaged-'

                                    (1)
   .-DAmaged--=--ANY-----.  .-COPied------=--ANY-.
>--+--------------------+--+--------------------+-------------->
   '-DAmaged--=--+-ANY-+-'  '-COPied--=--+-ANY-+-'
                 +-Yes-+                 +-Yes-+
                 '-No--'                 '-No--'

   .-NAMEType--=--SERVER------.
>--+--------------------------+-------------------------------->
   '-NAMEType--=--+-SERVER--+-'
                  +-UNIcode-+
                  '-FSID----'

   .-CODEType--=--BOTH-----------.
>--+-----------------------------+------------------------------>
   '-CODEType--=--+-UNIcode----+-'
                  +-NONUNIcode-+
                  '-BOTH-------'

   .-FOLLOWLinks--=--No------------.
>--+-------------------------------+--------------------------><
   '-FOLLOWLinks--=--+-No--------+-'
                     +-Yes-------+
```

```
'-JUSTLinks-'
```

Notes:

1. Use this parameter only for volumes in primary storage pools.

Parameters

volume_name (Required)
: Specifies the volume to be queried.

NODE
: Specifies the backup-archive client or the IBM Spectrum Protect™ for Space Management associated with the file space to query. This parameter is optional. You can use wildcard characters to specify this name. If you do not specify a name, all backup-archive and IBM Spectrum Protect for Space Management clients are included.

FIlespace
: Specifies the file space to query. This parameter is optional. You can use wildcard characters to specify this name. File space names are case-sensitive. If you do not specify a file space name, all file spaces are included.

  For a server that has clients with Unicode support, you might need to have the server convert the file space name that you enter. For example, you might need to have the server convert the name that you enter from the server's code page to Unicode. See the NAMETYPE parameter for details. If you do not specify a file space name or specify only a single wildcard character for the name, you can use the CODETYPE parameter to limit the operation to Unicode file spaces or non-Unicode file spaces.

COUnt
: Specifies the number of files to be displayed. This parameter is optional. You can specify either a positive integer or a negative integer. If you specify a positive integer, *n*, the first `n` files are displayed. If you specify a negative integer, *-n*, the last `n` files are displayed in `reverse` order. You cannot specify COUNT=0. If you do not specify a value for this parameter, all files are displayed.

Type
: Specifies the types of files to query. This parameter is optional. The default value is ANY. If the volume that is being queried is assigned to an active-data pool, the only valid values are ANY and BACKUP. Possible values are:

  ANY
  : Specifies that all types of files in the storage pool volume are queried; backup versions of files, archived copies of files, and files that are migrated by IBM Spectrum Protect for Space Management clients from client nodes.

  Backup
  : Specifies that only backup files are queried.

  Archive
  : Specifies that only archive files are queried. This value is not valid for active-data pools.

  SPacemanaged
  : Specifies that only space-managed files (files that were migrated by an IBM Spectrum Protect for Space Management client) are queried. This value is not valid for active-data pools.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed. Unicode names are converted to the server code page.

  Detailed
  : Specifies that complete information is displayed. Unicode names are displayed in hexadecimal.

DAmaged
: Specifies criteria to restrict the query output based on whether files are marked as damaged. For purposes of this criteria, the server examines only physical files (a file that might be a single logical file or an aggregate that consists of logical files). This parameter is optional. The default value is ANY. Possible values are:

  ANY
  : Specifies that files are displayed regardless of whether the server found the files to be damaged.

  Yes
  : Specifies that only files that are marked as damaged are displayed. These are files in which the server found errors when a user attempted to restore, retrieve, or recall the file, or when an AUDIT VOLUME command was run.

  No

Specifies that only files not known to be damaged are displayed.

COPied
: Specifies criteria to restrict the query output based on whether files were backed up to a copy storage pool. Whether files are stored in an active-data pool does not affect the output. This parameter is optional. The default value is ANY. Possible values are:

  ANY
  : Specifies that files are displayed regardless of whether the files are backed up to a copy storage pool. Primary and cached file copies are displayed.

  Yes
  : Specifies that the files displayed are only those for which at least one usable backup copy exists in a copy storage pool. A file is not displayed if its copy in the copy storage pool is known to have errors. Cached file copies are not displayed because these files are never restored.

    Use COPIED=YES to identify primary files that can be restored using the RESTORE VOLUME or RESTORE STGPOOL command.

  No
  : Specifies that the files displayed are only those for which no usable backup copies exist in a copy storage pool. Cached file copies are not displayed because these files are never restored.

    Use COPIED=NO to identify primary files that cannot be restored using the RESTORE VOLUME or RESTORE STGPOOL command.

NAMEType
: Specify how you want the server to interpret the file space names that you enter. This parameter is useful when the server has clients with Unicode support. A backup-archive client with Unicode support is currently available only for Windows, Macintosh OS 9, Macintosh OS X, and NetWare. Use this parameter only when you specify a partly or fully qualified file space name.

  The default value is SERVER. Possible values are:

  SERVER
  : The server uses the server's code page to interpret the file space names.

  UNIcode
  : The server converts the file space names from the server code page to the UTF-8 code page. The success of the conversion depends on the actual characters in the names and the server's code page. Conversion can fail if the string includes characters that are not available in the server code page, or if the server has a problem accessing system conversion routines.

  FSID
  : The server interprets the file space names as their file space IDs (FSIDs).

CODEType
: Specify how you want the server to interpret the file space names that you enter. Use this parameter only when you enter a single wildcard character for the file space name.

  The default value is BOTH, which means that the file spaces are included regardless of code page type. Possible values are:

  UNIcode
  : Include file spaces that are only in Unicode.

  NONUNIcode
  : Include file spaces that are not only in Unicode.

  BOTH
  : Include file spaces regardless of code page type.

FOLLOWLinks
: Specifies whether to display only the files that are stored on the volume or only files that are linked to the volume. You can also display both stored files and linked files. The default is NO. Possible values are:

  No
  : Display only the files that are stored in the volume. Do not display files that have links to the volume.

  Yes
  : Display all files, including files that are stored on the volume and any files that have links to the volume.

  JUSTLinks

Display only the files that have links to the volume. Do not display files that are stored on the volume.

Example: Display the contents of a volume for a specific client node

Query the contents of a volume and limit the results to files backed up from the PEGASUS client node.

AIX | Linux For the volume /tsmstg/diskvol1.dsm, issue the command:

```
query content /tsmstg/diskvol1.dsm node=pegasus
 type=backup
```

Windows For the volume f:\tsmstg\diskvol1.dsm, issue the command:

```
query content f:\tsmstg\diskvol1.dsm node=pegasus
 type=backup
```

Results of the command include all logical files that make up any aggregate that is on the volume, even if the aggregate is stored on more than this volume. For aggregates, the query does not determine which logical files are actually stored on the volume for which the query is performed.

```
Node Name     Type  Filespace     FSID  Client's Name for File
                    Name
-----------   ----  ----------    ----  ----------------------
PEGASUS       Bkup  \\pegasus\e$    1   \UNI_TEST\ SM01.DAT
PEGASUS       Bkup  \\pegasus\e$    1   \UNI_TEST\ SM02.DAT
```

See Field descriptions for field descriptions.

Example: Display detailed information for a tape volume

Query the contents of the tape volume named WPD001. Display only files that are backed up by the node MARK, and files that are either stored on the volume or linked to the volume. Display only the first four files on the volume.

```
query content wpd001 node=mark count=4 type=backup followlinks=yes
 format=detailed

                         Node Name: MARK
                              Type: Bkup
                   Filespace Name: \\mark\e$
        Hexadecimal Filespace Name:
                              FSID: 1
            Client's Name for File: \UNI_TEST\ SM01.DAT
Hexadecimal Client's Name for File:
                      Aggregated?: 1/3
                      Stored Size: 2,746
                   Segment Number:
                     Cached Copy?: No
                           Linked: No
                  Fragment Number:

                         Node Name: MARK
                              Type: Bkup
                   Filespace Name: \\mark\e$
        Hexadecimal Filespace Name:
                              FSID: 1
            Client's Name for File: \UNI_TEST\ SM02.DAT
Hexadecimal Client's Name for File:
                      Aggregated?: 2/3
                      Stored Size: 2,746
                   Segment Number:
                     Cached Copy?: No
                           Linked: No
                  Fragment Number: 2

                         Node Name: MARK
                              Type: Bkup
                   Filespace Name: \\mark\e$
        Hexadecimal Filespace Name:
                              FSID: 1
            Client's Name for File: \UNI_TEST\ SM03.DAT
Hexadecimal Client's Name for File:
                      Aggregated?: 3/3
```

```
      Stored Size: 2,746
    Segment Number:
      Cached Copy?: No
            Linked: No
  Fragment Number: 3
```

See Field descriptions for field descriptions.

Field descriptions

Node Name
: The node to which the file belongs.

Type
: The type of file: archive (Arch), backup (Bkup), or space-managed (SpMg) by an IBM Spectrum Protect for Space Management client.

Filespace Name
: The file space to which the file belongs.

  File space names can be in a different code page or locale than the server. If they are, the names in the Operations Center and the administrative command-line interface might not be displayed correctly. Data is backed up and can be restored normally, but the file space name or file name might be displayed with a combination of invalid characters or blank spaces.

  If the file space name is Unicode-enabled, the name is converted to the server code page for display. The success of the conversion depends on the operating system, the characters in the name, and the server code page. Conversion can be incomplete if the string includes characters that are not available in the server code page or if the server cannot access system conversion routines. If the conversion is incomplete, the name might contain question marks, blanks, unprintable characters, or ellipses (...).

Hexadecimal Filespace Name
: The file space to which the file belongs. If the file space name is in Unicode, the name is displayed in hexadecimal format.

FSID
: The file space ID (FSID) for the file space. The server assigns a unique FSID when a file space is first stored on the server.

Client's Name for File
: The client's name for the file.

  File space names and file names that can be in a different code page or locale than the server do not display correctly in the Operations Center or the administrative command-line interface. The data itself is backed up and can be restored properly, but the file space or file name might display with a combination of invalid characters or blank spaces. The results of the conversion for characters that are not supported by the current code page depends on the operating system. For names that IBM Spectrum Protect is able to partially convert, you might see question marks (??), blanks, unprintable characters, or "...". These characters indicate to the administrator that files do exist.

Hexadecimal Client's Name for File
: The client's name for the file that is displayed in hexadecimal format.

Aggregated?
: Whether the file is a logical file that is stored as part of an aggregate. If the file is part of an aggregate, the sequence of this file within the aggregate and the total number of logical files in the aggregate are displayed. Results of the command include all logical files that make up any aggregate that is on the volume, even if the aggregate is stored on more than this volume. The query does not determine which logical files are actually stored on the volume for which the query is performed.

  If the file is not part of an aggregate, the field displays "no".

Stored Size
: The size of the physical file, in bytes. If the file is a logical file that is stored as part of an aggregate, this value indicates the size of the entire aggregate.

Segment Number
: For volumes in sequential-access storage pools, specifies whether the physical file (either a single logical file or an aggregate of logical files) is stored across multiple volumes. For example, if the logical file is stored in an aggregate that spans two volumes, the segment number indicates `1/2` (the first part of the physical file is stored on the volume) or `2/2` (the second part of the physical file is stored on the volume). If the segment number is `1/1`, the physical file is completely stored on the volume. For volumes in random-access storage pools, no value is displayed for this field.

Cached Copy?
: Whether the physical file is a cached copy of a file migrated to the next storage pool. If the file is part of an aggregate, this value pertains to the aggregate.

Linked
: Indicates whether the file is stored on the volume or whether the file is linked to the volume.

Fragment Number
: Specifies the fragment number. If the fragment number is blank, it is either the first fragment or not a fragment.

Related commands

Table 1. Commands related to QUERY CONTENT

Command	Description
BACKUP STGPOOL	Backs up a primary storage pool to a copy storage pool.
COPY ACTIVEDATA	Copies active backup data.
DEFINE VOLUME	Assigns a volume to be used for storage within a specified storage pool.
DELETE VOLUME	Deletes a volume from a storage pool.
RESTORE STGPOOL	Restores files to a primary storage pool from copy storage pools.
RESTORE VOLUME	Restores files stored on specified volumes in a primary storage pool from copy storage pools.
UPDATE VOLUME	Updates the attributes of storage pool volumes.

AIX | Linux | Windows

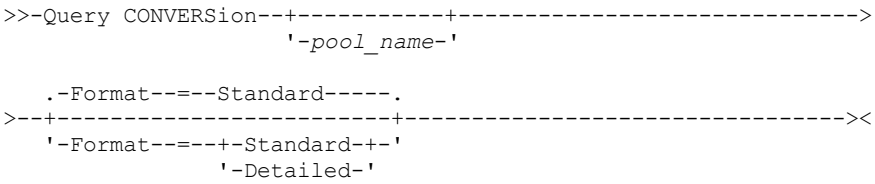
QUERY CONVERSION (Query conversion status of a storage pool)

Use this command to display information about a conversion operation. You can convert a primary storage pool that uses a FILE type device class or a virtual tape library (VTL) to a directory-container storage pool.

Privilege class

To issue this command, you must have restricted storage privilege.

Syntax



Parameters

pool_name
: Specifies the source storage pool to query. This parameter is optional. If you do not specify a value for this parameter, information is displayed for all storage pools.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Specify one of the following values:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed.

Example: Display conversion information for all storage pools

Display conversion information for all storage pools. See Field descriptions for field descriptions.

```
query conversion

Source Storage  Target Storage  Starting   Total       Last
    Pool              Pool      Amount     Converted   Converted
------------  ---------------  ---------  ----------  ----------
FILEPOOL         CTR             3 GB       3 GB         3 GB
FPOOL            CTR             333 MB     333 MB       267 MB
```

Example: Display detailed about storage pool conversion

Display detailed information about storage pool conversion. See Field descriptions for field descriptions.

```
query conversion format=detailed

    Source Storage Pool: FILEPOOL
    Target Storage Pool: CTR
      Maximum Processes: 4
               Duration: 60 minutes
      Starting Amount: 333 MB
      Total Converted: 333 MB
       Last Converted: 333 MB
      Start Date/Time: 03/24/2016 13:22:32
```

Field descriptions

Source Storage Pool
: The name of the storage pool that is being converted.

Target Storage Pool
: The name of the destination storage pool, where the converted data will be stored.

Maximum Processes
: Specifies the maximum number of conversion processes.

Duration
: Specifies the length of time, in minutes, for conversion.

Starting Amount
: The starting amount of data to convert, in megabytes (MB), gigabytes (GB), or terabytes (TB).

Total Converted
: The total amount of data that is converted, in megabytes (MB), gigabytes (GB), or terabytes (TB).

Last Converted
: The amount of data, in megabytes (MB), gigabytes (GB), or terabytes (TB), that is converted during this conversion process.

Start Date/Time
: The time and date that the CONVERT STGPOOL command was first issued for the storage pool.

Related commands

Table 1. Commands related to QUERY CONVERSION

Command	Description
CONVERT STGPOOL	Convert a storage pool to a directory-container storage pool.
QUERY CLEANUP	Query the cleanup status of a source storage pool.

QUERY COPYGROUP (Query copy groups)

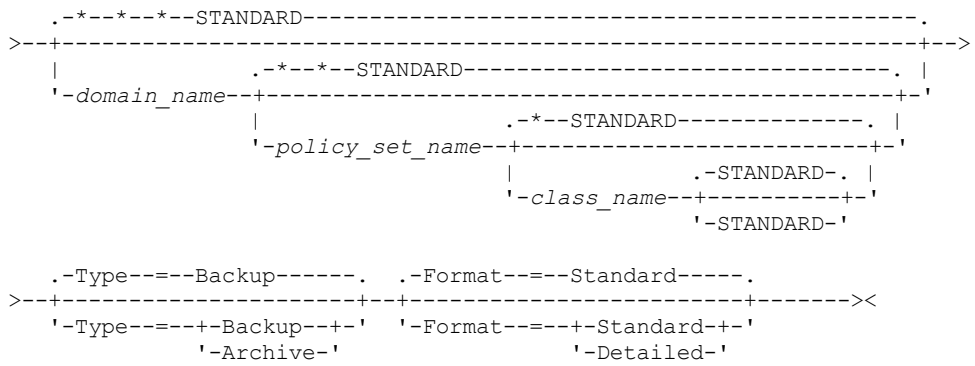
Use this command to display information about one or more copy groups.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query COpygroup-----------------------------------------------><
```



Parameters

domain_name
: Specifies the policy domain that is associated with the copy group to query. This parameter is optional. You can use wildcard characters to specify names. If you do not specify a value for this parameter, all policy domains are queried. You must specify this parameter when querying an explicitly named copy group.

policy_set_name
: Specifies the policy set associated with the copy group to query. This parameter is optional. You can use wildcard characters to specify names. If you do not specify a value for this parameter, all policy sets are queried. You must specify this parameter when querying an explicitly named copy group.

class_name
: Specifies the management class that is associated with the copy group to query. This parameter is optional. You can use wildcard characters to specify names. If you do not specify a value for this parameter, all management classes are queried. You must specify this parameter when querying an explicitly named copy group.

STANDARD
: Specifies the name of the copy group. This parameter is optional. The name of the copy group must be STANDARD. The default is STANDARD.

Type
: Specifies the type of copy group to be queried. This parameter is optional. The default value is BACKUP. Possible values are:

  Backup
  : Specifies that you want to query backup copy groups.

  Archive
  : Specifies that you want to query archive copy groups.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed.

Example: Display information about the default backup copy group

Display information about the default backup copy group in the ENGPOLDOM engineering policy domain. Issue the following command:

```
query copygroup engpoldom * *
```

The following data shows the output from the query. It shows that the ACTIVE policy set contains two backup copy groups that belong to the MCENG and STANDARD management classes.

```
Policy     Policy     Mgmt       Copy     Versions  Versions Retain   Retain
Domain     Set        Class      Group    Data      Data     Extra    Only
Name       Name       Name       Name     Exists    Deleted  Versions Version
---------- --------   --------   -------  --------  -------  -------  -------
ENGPOLDOM  ACTIVE     MCENG      STANDARD  5         4         90      600
ENGPOLDOM  ACTIVE     STANDARD   STANDARD  2         1         30      60
```

```
ENGPOLDOM STANDARD  MCENG      STANDARD  5          4         90       600
ENGPOLDOM STANDARD  STANDARD   STANDARD  2          1         30       60
ENGPOLDOM TEST      STANDARD   STANDARD  2          1         30       60
```

Example: Display detailed information on one backup copy group

Display complete information on the backup copy group assigned to the ACTIVEFILES management class in the VACATION policy set of the EMPLOYEE_RECORDS policy domain. Issue the command:

```
query copygroup employee_records vacation
activefiles format=detailed
```

Example: Display information on the backup copy group in the STANDARD management class and policy set

From a managed server, display complete information on the backup copy group assigned to the STANDARD management class in the STANDARD policy set of the ADMIN_RECORDS policy domain. Issue the command:

```
query copygroup admin_records
standard standard format=detailed

                 Policy Domain Name: ADMIN_RECORDS
                    Policy Set Name: STANDARD
                    Mgmt Class Name: STANDARD
                    Copy Group Name: STANDARD
                    Copy Group Type: Backup
               Versions Data Exists: 2
              Versions Data Deleted: 1
              Retain Extra Versions: 30
                Retain Only Version: 60
                          Copy Mode: Modified
                 Copy Serialization: Shared Static
                     Copy Frequency: 0
                  Copy Destination: BACKUPPOOL
Table of Contents (TOC) Destination:
     Last Update by (administrator): $$CONFIG_MANAGER$$
              Last Update Date/Time: 2002.10.02 17.51.49
                   Managing profile: ADMIN_INFO
                    Changes Pending: Yes
```

Example: Display information on an archive copy group

From a managed server, display complete information on the archive copy group STANDARD that is assigned to the MCLASS1 management class in the SUMMER policy set of the PROG1 policy domain. Issue the command:

```
query copygroup prog1 summer mclass1
type=archive format=detailed

                 Policy Domain Name: PROG1
                    Policy Set Name: SUMMER
                    Mgmt Class Name: MCLASS1
                    Copy Group Name: STANDARD
                    Copy Group Type: Archive
                     Retain Version: 730
               Retention Initiation: Creation
                  Minimum Retention:
                 Copy Serialization: Shared Static
                     Copy Frequency: Cmd
                          Copy Mode: Absolute
                  Copy Destination: ARCHPOOL
     Last Update by (administrator): $$CONFIG_MANAGER$$
              Last Update Date/Time: 2002.10.02 17.42.49
                   Managing profile: ADMIN_INFO
```

Example: Display information on the copy group for a NAS backup

Query the copy group for the NAS backup. Issue the command:

```
query copygroup nasdomain
type=backup
```

```
                  Policy Domain Name: NASDOMAIN
                     Policy Set Name: ACTIVE
                     Mgmt Class Name: STANDARD
                     Copy Group Name: STANDARD
                     Copy Group Type: Backup
                 Versions Data Exists: 2
                Versions Data Deleted: 1
                Retain Extra Versions: 30
                  Retain Only Version: 60
                            Copy Mode: Modified
                   Copy Serialization: Shared Static
                       Copy Frequency: 0
                    Copy Destination: NASPOOL
Table of Contents (TOC) Destination: BACKUPPOOL
     Last Update by (administrator): SERVER_CONSOLE
               Last Update Date/Time: 10/02/2002 12:16:52
                    Managing profile:
                     Changes Pending: Yes
```

Field descriptions

Policy Domain Name
: The name of the policy domain.

Policy Set Name
: The name of the policy set.

Mgmt Class Name
: The name of the management class.

Copy Group Name
: The name of the copy group. This name is always STANDARD.

Copy Group Type
: The type of the copy group.

Versions Data Exists
: The maximum number of backup versions to retain for files that are currently on the client file system.

Versions Data Deleted
: The maximum number of backup versions to retain for files that have been deleted from the client file system after being backed up using IBM Spectrum Protect™.

Retain Extra Versions
: The number of days to retain a backup version after that version becomes inactive.

Retain Only Version
: The number of days to retain the last backup version of a file that has been deleted from the client file system.

Copy Serialization
: Whether a file can be in use during an archive operation.

Copy Frequency
: The copy frequency of the copy group. For archive copy groups, this value is always CMD.

Copy Mode
: Specifies that files in the copy group are archived regardless of whether they have been modified. For archive copy groups, this value is always ABSOLUTE.

Copy Destination
: The name of the storage pool where the server initially stores files associated with this archive copy group.

Table of Contents (TOC) Destination
: The name of the primary storage pool in which TOCs are initially stored for image backup operations in which TOC generation is requested.

Last Update by (administrator)
: The name of the administrator or server that most recently updated the copy group. If this field contains $$CONFIG_MANAGER$$, the copy group is associated with a domain that is managed by the configuration manager.

Last Update Date/Time
: The date and time when the copy group was most recently defined or updated.

Managing Profile
: The profile or profiles to which the managed server subscribed to get the definition of this policy copy group.

Changes Pending
: Whether or not changes are being made but not activated. Once the changes are activated, the field resets to No.

Related commands

Table 1. Commands related to QUERY COPYGROUP

Command	Description
DEFINE COPYGROUP	Defines a copy group for backup or archive processing within a specified management class.
DELETE COPYGROUP	Deletes a backup or archive copy group from a policy domain and policy set.
UPDATE COPYGROUP	Changes one or more attributes of a copy group.

AIX Linux Windows

QUERY DAMAGED (Query damaged data in a directory-container or cloud-container storage pool)

Use this command to display information about damaged data extents in a directory-container or cloud-container storage pool. Use this command together with the AUDIT CONTAINER command to determine a recovery method for the damaged data.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query DAMaged--pool_name-------------------------------------->

   .-Type--=--Status---------------.
>--+-------------------------------+-------------------------><
   '-Type--=--+-INVentory--------+-'
              +-Node--| A |------+
              '-CONTAiner--| A |-'

A (Additional filter by node name)

|--+------------------------+-----------------------------------|
   '-Nodename--=--node_name-'
```

Parameters

pool_name (Required)
: Specifies the name of the directory-container or cloud storage pool.

Type
: Specifies the type of information to display. This parameter is optional. Specify one of the following values:

  Status
  : Specifies that information is displayed about damaged data extents. For cloud storage pools, orphaned extents are also displayed. This is the default.

  Node
  : Specifies that information about the number of damaged files per node is displayed.

  INVentory
  : Specifies that inventory information for each damaged file is displayed.

  CONTAiner
  : Specifies that the containers that contain damaged data extents or cloud orphaned extents are displayed. For directory-container storage pools, storage pool directories are also displayed.

Nodename
: Specifies that damaged file information for a single node is displayed.
  Restriction: You cannot specify this parameter if the TYPE=CONTAINER or TYPE=STATUS parameter is specified.

Example: Display status information about damaged or orphaned data extents

Display information about the status of damaged data extents that are stored in a container.

```
query damaged pool1 type=status

Storage Pool     Non-Dedup Data    Dedup Data     Cloud Orphaned
Name             Extent Count      Extent Count   Extent Count
---------------  -------------     ----------     -------------
POOL1                  58               145
```

For cloud storage pools, the number of orphaned extents is also displayed.

```
Storage Pool     Non-Dedup Data    Dedup Data     Cloud Orphaned
Name             Extent Count      Extent Count   Extent Count
---------------  -------------     ----------     -------------
POOL1                  65               238            18
```

Example: Display information about a damaged file for a node type

Display information about damaged files that are stored in a node.

```
query damaged pool1 type=node

Node Name      Number of
               Damaged Files
-------------  -----------------
POOL1                  37
```

Example: Display information about a damaged file for an inventory type

Display information about damaged files that are stored in an inventory.

```
query damaged pool2 type=inventory

       Client's Name for File: /data/files/10.out
                         Type: Bkup
                    Node Name: NODE1
               Filespace Name: /data/space
                        State: Available
               Insertion time: 01/19/2015 16:01:35
                    Object ID: 2073
```

Example: Display information about a damaged file for a container type

Display information about damaged files that are stored in a container.

```
query damaged pool3 type=container

         Directory ID: 1
            Directory: /abc/space/container1
            Container: /abc/space/container1/00/0000000000000022.dcf
                State: Unavailable
```

For cloud containers, only the name of the container is displayed.

```
         Directory ID:
            Directory:
            Container: ibmsp.12520ae05b4011e613320a0027000000/
                       001-10006a3278bc34f0e4118a850090fa3dcb48/
                       00000000000001.ncf
                State:
```

For local storage, the following information about a damaged container is displayed.

```
                Directory ID: 1
                   Directory: localdirectory
                   Container: localdirectory/00/00000000000011.ncf
                       State: Unavailable
```

Field descriptions

Client's Name for File (TYPE=INVENTORY only)
: The name of the file.

Cloud Orphaned Extent Count (TYPE=STATUS only)

The number of orphaned extents in a cloud storage pool. Extents are considered orphaned if they do not have a corresponding database entry.

Container (TYPE=CONTAINER only)
The name of the container.

Deduplicated Extent Count (TYPE=STATUS only)
The number of damaged extents in the storage pool for deduplicated data.
Directory (TYPE=CONTAINER only)
The name of the storage pool directory.
Directory ID (TYPE=CONTAINER only)
The identification number of the storage pool directory.

Filespace Name (TYPE=INVENTORY only)
The name of file space.

Insertion time (TYPE=INVENTORY only)
The date and time that the object was stored on the server.

Node Name (TYPE=INVENTORY or TYPE=NODE only)
The name of the node.
Non-Deduplicated Extent Count (TYPE=STATUS only)
The number of damaged extents in the storage pool for data that is not deduplicated, such as metadata and client-encrypted data.

Number of Damaged Files (TYPE=NODE only)
The number of damaged files per node.

Object ID (TYPE=INVENTORY only)
The identification number of the object.

State (TYPE=INVENTORY or TYPE=CONTAINER only)
The state of the data in either the inventory or the container, depending on the type of data you are querying. The field can contain one of the following values:

Active
The version of the file in the inventory is active. There can be only one active version of the file in the inventory.
Inactive
The version of the file in the inventory is inactive. There can be multiple inactive versions of the file in the inventory.
Available
The state of the container is available.
Unavailable
The state of the container is unavailable. For example, a container might be unavailable if the header is corrupted or if the container cannot be opened.
Read-Only
The container is in a read-only state. Data in the container can be read, but data cannot be written to the container.
Pending
The container is pending deletion. The contents of the container were moved to a different container, and the container is ready to be deleted.

Type (TYPE=INVENTORY only)
The type of data in the file.

Table 1. Commands related to QUERY DAMAGED

Command	Description
AUDIT CONTAINER	Audit a directory-container storage pool.
QUERY CLEANUP	Query the cleanup status of a source storage pool.
QUERY CONTAINER	Displays information about a container.
REMOVE DAMAGED	Removes damaged data from a source storage pool.

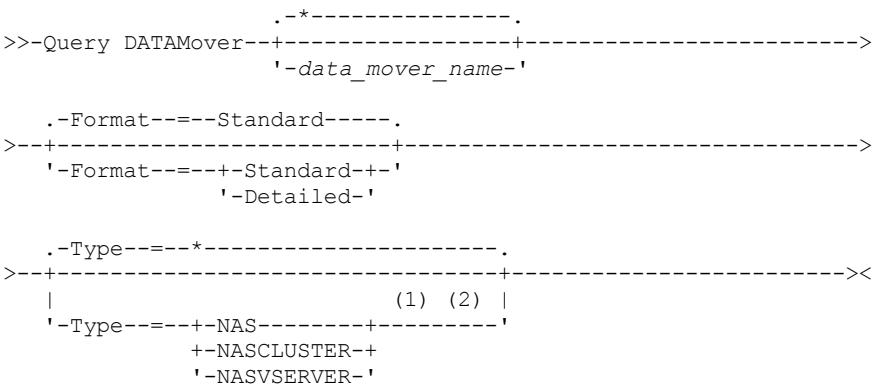
QUERY DATAMOVER (Display data mover definitions)

Use this command to display data mover definitions.

Privilege class

Any administrator can issue this command.

Syntax



Notes:

1. You must specify the TYPE parameter if `FORMAT=DETAILED`.
2. You can specify `TYPE=NASCLUSTER` and `TYPE=NASVSERVER` only on an AIX, Linux, or Windows operating system.

Parameters

data_mover_name
: Specifies the name of the data mover to display. You can specify multiple names with a wildcard character. The default displays all data movers.

Format
: Specifies how the information is displayed. This parameter is optional. The default is STANDARD.

  Standard
  : Specifies that name and address information is displayed.

  Detailed
  : Specifies that complete information is displayed.

Type
: Specifies the type of data mover to be displayed. If you specify `FORMAT=DETAILED`, you must specify a value for the TYPE parameter.

  NAS
  : Specifies a NAS file server.

  AIX Linux Windows NASCLUSTER
  : AIX Linux Windows Specifies a clustered NAS file server.

  AIX Linux Windows NASVSERVER
  : AIX Linux Windows Specifies a virtual storage device within a cluster.

Example: Display information about all data movers

Display the data movers on the server. Issue the command:

```
query datamover
```

```
Data Mover Name    Data Mover Type     Online
-------------      -------------       ------
 NASMOVER1              NAS               Yes
 NASMOVER2              NAS                No
```

See Field descriptions for field descriptions.

Example: Display information about one data mover

Display partial information about data mover DATAMOVER6. Issue the command:

```
query datamover datamover6 type=nas
```

```
 Source Name      Type           Online
-------------     -------        ------
DATAMOVER6        NAS            Yes
```

See Field descriptions for field descriptions.

Example: Display detailed information about one data mover

Display detailed information about data mover DATAMOVER6. The TYPE parameter is required when FORMAT=DETAILED. Issue the command:

```
query datamover datamover6 format=detailed type=nas
```

```
               Data Mover Name:   DataMover6
               Data Mover Type:   NAS
                    IP Address:   198.51.100.0
           TCP/IP Port Number:   10000
                     User Name:   NDMPadmin
     Storage Pool Data Format:   NDMPDUMP
                         Online:   Yes
Last Update by (administrator):   ADMIN
        Last Update Date/Time:   05/23/2015 09:26:33
```

See Field descriptions for field descriptions.

AIX | Linux | Windows

Example: Display detailed information about a clustered NAS data mover

Display detailed information about a clustered NAS data mover that is named CLUSTERA. Issue the following command:

```
query datamover clustera format=detailed type=nascluster
```

```
               Data Mover Name:   CLUSTERA
               Data Mover Type:   NASCLUSTER
                    IP Address:   192.0.2.255
           TCP/IP Port Number:   10000
                     User Name:   ndmp
     Storage Pool Data Format:   NETAPPDUMP
                         Online:   Yes
Last Update by (administrator):   ADMIN
        Last Update Date/Time:   04/28/2015 09:26:33
```

See Field descriptions for field descriptions.

Field descriptions

Data Mover Name
: Specifies the name of the data mover.

Data Mover Type
: Specifies the type of the data mover.

IP Address
: Specifies the IP address of the data mover.

TCP/IP Port Number
: Specifies the TCP port number for the data mover.

User Name
: Specifies the user ID that the server uses to access the data mover.

Storage Pool Data Format
: Specifies the data format that is used by the data mover.

Online
: Specifies whether the data mover is online and available for use.

Last Update by (administrator)
: Specifies the ID of the administrator who completed the last update.

Last Update Date/Time
: Specifies the date and time when the last update occurred.

Related commands

Table 1. Commands related to QUERY DATAMOVER

Command	Description
DEFINE DATAMOVER	Defines a data mover to the IBM Spectrum Protect server.
DELETE DATAMOVER	Deletes a data mover.
UPDATE DATAMOVER	Changes the definition for a data mover.

QUERY DB (Display database information)

Use this command to display information about the database.

Privilege class

Any administrator can issue this command.

Syntax

```
             .-Format--=--Standard-----.
>>-Query DB--+-------------------------+----------------------><
             '-Format--=--+-Standard-+-'
                          '-Detailed-'
```

Parameters

Format
: Specifies how the information is displayed. This parameter is optional. The default is STANDARD. The following values are possible:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed.

Example: Display summary statistics about the database

Display statistical information about the database. Issue the command:

```
query db
```

```
Database Name  Total Pages  Usable Pages  Used Pages  Free Pages
-------------  -----------  ------------  ----------  ----------
       TSMDB1       32,776        32,504      24,220       8,284
```

See Field descriptions for field descriptions.

Example: Display detailed database information

Display detailed statistical information about the database. Issue the command:

```
query db format=detailed
```

```
                  Database Name: TSM_DB2
  Total Space of File System (MB): 1,748,800
   Space Used on File System (MB): 2,304,355
      Space Used by Database (MB): 448
        Free Space Available (MB): 235,609
                     Total Pages: 32,776
```

```
                    Usable Pages: 32,504
                      Used Pages: 24,220
                      Free Pages: 8,284
              Buffer Pool Hit Ratio: 99.3
              Total Buffer Requests: 204,121
                     Sort Overflows: 0
            Package Cache Hit Ratio: 89.8
     Last Database Reorganization: 05/25/2009 16:44:06
           Full Device Class Name: FILE
Number of Database Backup Streams: 4
     Incrementals Since Last Full: 0
   Last Complete Backup Date/Time: 05/18/2009 22:55:19
        Compress Database Backups: Yes
    Protect Master Encryption Key: No
```

See Field descriptions for field descriptions.

Field descriptions

Database Name
: The name of the database that is defined and configured for use by the IBM Spectrum Protect™ server.

AIX Linux Total Space of File System (MB)
: AIX Linux The total space, in megabytes, of the file systems in which the database is located.

Windows Total Space of File System (MB)
: Windows The total space, in megabytes, of the drives on which the database is located.

Space Used on File System (MB)
: The amount of database space, in megabytes, that is in use.

Space Used by Database (MB)
: The size of the database, in megabytes. The value does not include any temporary table space. The size of the database is calculated from the amount of space that is used on the file system containing the database.

Free Space Available (MB)
: The amount of database space, in megabytes, that is not in use.

Total Pages
: The total number of pages in the table space.

Usable Pages
: The number of usable pages in the table space.

Used Pages
: The number of used pages in the table space.

Free Pages
: The total number of free pages in all table spaces. The IBM Spectrum Protect database has up to 10 table spaces.

Buffer Pool Hit Ratio
: The total hit ratio percent.

Total Buffer Requests
: The total number of buffer pool data logical reads and index logical reads since the last time the database was started or since the database monitor was reset.

Sort Overflows
: The total number of sorts that ran out of the sort heap and might have required disk space for temporary storage.

Package Cache Hit Ratio
: A percentage that indicates how well the package cache is helping to avoid reloading packages and sections for static SQL from the system catalogs. It also indicates how well the package cache is helping to avoid recompiling dynamic SQL statements. A high ratio indicates that it is successful in avoiding these activities.

Last Database Reorganization
: The last time that the database manager completed an automatic reorganization activity.

Full Device Class Name
: The name of the device class that is used for full database backups.

Number of Database Backup Streams
: The number of concurrent data movement streams that were used during the database backup.

Incrementals Since Last Full
: The number of incremental backups that were completed since the last full backup.

Last Complete Backup Date/Time
: The date and time of the last full backup.

Compress Database Backups
: Specifies whether database backups are compressed.

Protect Master Encryption Key

Specifies whether database backups include a copy of the server master encryption key.

Related commands

Table 1. Commands related to QUERY DB

Command	Description
BACKUP DB	Backs up the IBM Spectrum Protect database to sequential access volumes.
EXTEND DBSPACE	Adds directories to increase space for use by the database.
QUERY DBSPACE	Displays information about the storage space defined for the database.

QUERY DBSPACE (Display database storage space)

Use this command to display information about the directories used by the database to store data.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-QUERY DBSpace-----------------------------------------------><
```

Parameters

None.

Example: Display database storage space information

Display information about database storage space. Issue the command:

```
query dbspace
```

AIX | Linux

```
Location            Total Space of     Used Space on     Free Space
                    File System (MB)   File System (MB)  Available (MB)
-----------------   ----------------   ---------------   --------------
/tsmdb001           1,748,800          1,513,191.125     117,804.422
/tsmdb002           1,748,800          1,513,191.125     117,804.422
```

Windows

```
Location            Total Space of     Used Space on     Free Space
                    File System (MB)   File System (MB)  Available (MB)

e:\tsm\db002        1,748,800          1,513,191.125     117,804.422
```

See Field descriptions for field descriptions.

Field descriptions

Location

Specifies the locations of database directories.

AIX Total Space of File System (MB)

AIX The total amount of space, in megabytes, of the file system in which the database is located.

Windows Total Space of File System (MB)

Windows The total amount of space, in megabytes, of the drives on which the database is located.

Used Space on File System (MB)

The amount of storage space, in megabytes, that is in use.

AIX Linux When you run the QUERY DBSPACE command, the value in the output might be greater than the value that is obtained by running the df system command. The output from the df system command does not include the amount of space that is reserved for the root user.

Linux If you run the df system command, the default percentage of space that is reserved for the root user is 5%. You can change this default value.

Free Space Available (MB)
The amount of space, in megabytes, that is not in use.

Windows Free Space Available (MB)
Windows The amount of space remaining on the drive where the directory is located.

>--+------------------+--+----------------------+-------------><
   '-ENDTime---=--time-'  '-ALLSTats---=--+-Yes-+-'
                                         '-No--'
```

Parameters

pool_name
: Specifies the name of the directory-container storage pool whose data is contained in the data deduplication statistics. This parameter is optional. If you do not specify a value for this parameter, all storage pools are displayed. You can specify up to 30 characters for the storage pool name. If you specify more than 30 characters, the command fails.
Restriction: You can specify directory-container storage pools or cloud storage pools only.

node_name
: Specifies the name of the client node whose data is contained in the data deduplication statistics. This parameter is optional. If you do not specify a value for this parameter, all nodes are displayed. You can specify up to 64 characters for the node name. If you specify more than 64 characters, the command fails.

filespace_name or FSID
: Specifies the names of one or more file spaces that contain the data to be included in the data deduplication statistics. This parameter is optional. You can use wildcard characters to specify this name. If you do not specify a value for this parameter, all file spaces are displayed. You can specify more than one file space by separating the names with commas and no intervening spaces.
For a server that has clients with support for file spaces that are in Unicode format, you can enter either a file space name or a file space identifier (FSID). If you enter a file space name, you might need to have the server convert the file space name that you enter. For example, you might need to have the server convert the name that you enter from the server's code page to Unicode.
Restrictions: The following restrictions apply to file space names and FSIDs:

  - You must specify a node name if you specify a file space name.
  - Do not mix file space names and FSIDs in the same command.

Format
: Specifies how the information is displayed. This parameter is optional. Specify one of the following values:

  Standard
  : Specifies that partial information is displayed for the specified data deduplication sets. This is the default.

  Detailed
  : Specifies that complete information is displayed for the specified data deduplication sets.

CODEType
: Specify what type of file spaces to include in the operation. The default value is BOTH, which specifies that file spaces are included regardless of code page type. Use this parameter only when you enter a single wildcard character for the file space name. Specify one of the following values:

  UNIcode
  : Include file spaces that are in Unicode format.

  NONUNIcode
  : Include file spaces that are not in Unicode format.

  BOTH
  : Include file spaces regardless of code page type. This is the default.

NAMEType
: Specify how you want the server to interpret the file space names that you enter. This parameter is useful when the server has clients with support for file spaces that are in Unicode format. You can use this parameter for IBM Spectrum Protect™ clients that use Windows, NetWare, or Macintosh OS X operating systems.
Use this parameter only when you enter a node name and a file space name or FSID.
Restriction: When you specify this parameter, the file space name cannot contain a wildcard.

  Specify one of the following values:

  SERVER
  : The server uses the server's code page to interpret the file space names. This is the default.

  UNIcode

The server converts the file space name that is entered from the server code page to the UTF-8 code page. The success of the conversion depends on the actual characters in the name and the server's code page. Conversion can fail if the string includes characters that are not available in the server code page, or if the server cannot access system conversion routines.

FSID

The server interprets the file space names as their FSIDs.

BEGINDate

Specifies the start date to query data deduplication statistics. This parameter is optional. You can use this parameter with the BEGINTIME parameter to specify a range for the date and time. If you specify a begin date without a begin time, the time is at 12:00 a.m. (midnight) on the date you specify.

Restriction: You can specify this parameter only when you specify the ALLSTATS=YES parameter.

Specify one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date.	09/15/2015
TODAY	The current date.	TODAY
TODAY-days or-days	The current date minus days specified.	TODAY -3 or -3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include records that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include records that were active on the 10th day of the current month.

BEGINTime

Specifies the start time to query the data deduplication statistics. This parameter is optional. You can use this parameter with the BEGINDATE parameter to specify a range for the date and time. If you specify a begin time without a begin date, the date is the current date at the time you specify.

Restriction: You can specify this parameter only when you specify the ALLSTATS=YES parameter.

Specify one of the following values:

Value	Description	Example
HH:MM:SS	A specific time.	10:30:08
NOW	The current time.	NOW
NOW+HH:MM or +HH:MM	The current time plus hours and minutes specified.	NOW+02:00 or +02:00.
NOW-HH:MM or-HH:MM	The current time minus hours and minutes specified.	NOW-02:00 or –02:00.

ENDDate

Specifies the end date to query data deduplication statistics. This parameter is optional. You can use this parameter with the ENDTIME parameter to specify a range for the date and time. If you specify an end date without an end time, the time is at 11:59:59 p.m. on the specified end date.

Restriction: You can specify this parameter only when you specify the ALLSTATS=YES parameter.

Specify one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1999
TODAY	The current date	TODAY
TODAY-days or -days	The current date minus days specified.	TODAY -3 or -3.

Value	Description	Example
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include records that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include records that were active on the 10th day of the current month.

ENDTime

Specifies the end time of the range to query the data deduplication statistics. This parameter is optional. You can use this parameter with the ENDDATE parameter to specify a range for the date and time. If you specify an end time without an end date, the date is the current date at the time you specify.
Restriction: You can specify this parameter only when you specify the ALLSTATS=YES parameter.
Specify one of the following values:

Value	Description	Example
HH:MM:SS	A specific time.	10:30:08
NOW	The current time.	NOW
NOW+HH:MM or +HH:MM	The current time plus hours and minutes on the specified end date	NOW+02:00 or +02:00.
NOW-HH:MM or -HH:MM	The current time minus hours and minutes on the specified end date	NOW-02:00 or -02:00.

ALLSTats

Specifies whether to display all data deduplication statistics or only the most recently generated data deduplication statistics. This parameter is optional. Specify one of the following values:

No
: Displays only data deduplication statistics that were most recently generated for each node and file space.

Yes
: Displays all data deduplication statistics.

Example: View data deduplication statistics in standard format

Display data deduplication statistics for a storage pool that is named POOL1. The data deduplication statistics are for node NODE1 and the statistics from 8 May 2015 are displayed. See Field descriptions for field descriptions.

```
query dedupstats pool1 node1 begindate=05/08/2015

                      Date/Time: 05/05/2015 15:15:23
                Storage Pool Name: POOL1
                      Node Name: NODE1
                 Filespace Name: \\fs1\a1
                           FSID: 41
                           Type: Bkup
        Total Saving Percentage: 86.62
      Total Data Protected (MB): 311
```

Example: View detailed data deduplication statistics

Display detailed information for data deduplication for a storage pool that is named POOL1.

```
query dedupstats pool1 format=detailed

                      Date/Time: 05/05/2015 15:15:23
                Storage Pool Name: POOL1
                      Node Name: NODE1
                 Filespace Name: \\fs1\a1
```

```
                            FSID: 41
                            Type: Bkup
         Total Data Protected (MB): 47,646
             Total Space Used (MB): 10,139
            Total Space Saved (MB): 37,507
          Total Saving Percentage: 78.72
            Deduplication Savings: 21,278,892,501
         Deduplication Percentage: 42.59
     Non-Deduplicated Extent Count: 1,658
Non-Deduplicated Extent Space Used: 732,626
               Unique Extent Count: 189,791
          Unique Extent Space Used: 23,385,014,635
               Shared Extent Count: 178,712
      Shared Extent Data Protected: 26,575,010,669
          Shared Extent Space Used: 5,267,815,421
               Compression Savings: 5,267,815,421
         Compression Percentage: 62.93
        Compressed Extent Count: 352,498
      Uncompressed Extent Count: 17,663
      Encryption Extent Space Used: 52,901,672
             Encryption Percentage: 100.00
           Encrypted Extent Count: 188
         Unencrypted Extent Count: 0
```

Field descriptions

Date/Time
: Displays the time and date that the data deduplication statistics are generated.

Storage Pool Name
: The name of the storage pool.

Node Name
: The name of the client node whose data is contained in the data deduplication statistics.

Filespace Name
: The name of the file space.

FSID
: The name of the file space identifier.

Type
: The type of data. The following values are possible:

  Arch
  : Data that has been archived.

  Bkup
  : Data that has been backed up.

  SpMg
  : Data that has been migrated from an IBM Spectrum Protect for Space Management client.

Total Data Protected (MB)
: The logical amount of data, in megabytes, that is protected in the storage pool before data deduplication and compression. This value represents the sum of the Total Space Used (MB) and Total Space Saved (MB) values.

Total Space Used (MB)
: The total amount of used space in the storage pool, in megabytes. This value is the physical amount of data that is backed up after data deduplication and compression.

Total Space Saved (MB)
: The total amount of space, in megabytes, of data that is removed from the storage pool because of data deduplication and compression. This value represents the sum of the Deduplication Savings and Compression Savings values.

Total Saving Percentage
: The percentage of data that is removed from the storage pool because of compression and data deduplication.

Deduplication Savings
: The amount of used space that is saved in the storage pool because of data deduplication.

Deduplication Percentage
: The percentage of data that is removed from the storage pool because of data deduplication.

Non-Deduplicated Extent Count
: The number of data extents that are not deduplicated in the storage pool.

Non-Deduplicated Extent Space Used

The amount of space that is used by data extents that are not deduplicated in the storage pool. This value applies to containers that have a .ncf file type and that do not have deduplicated data.
Tip: Data extents that are not deduplicated consist of the following data or file types:

- File metadata.
- Files that are less than 2 KB.
- Files that use client encryption.

Unique Extent Count
The number of data extents that are not shared by a node.
Unique Extent Space Used
The amount of space in the storage pool that is not shared by a node. This value applies to containers that have a .dcf file type and that do not have deduplicated data.
Shared Extent Count
The number of data extents that are used multiple times by the same node or by different nodes because of data deduplication.
Shared Extent Data Protected
The amount of space in the storage pool that is protected by shared data extents before data deduplication.
Shared Extent Space Used
The amount of space in the storage pool that is used by shared data extents after data deduplication.
Compression Savings
The amount of used space that is saved in the storage pool because of compression after data deduplication.
Compression Percentage
The percentage of data that is removed from the storage pool because of compression.
Compressed Extent Count
The number of data extents that are compressed.
Uncompressed Extent Count
The number of data extents that are uncompressed.
Encryption Extent Space Used
The amount of space in the storage pool that is used by encrypted data extents.
Encryption Percentage
The percentage of encrypted data in the storage pool.
Encrypted Extent Count
The number of data extents that are encrypted.
Unencrypted Extent Count
The number of data extents that are not encrypted.

Related commands

Table 1. Commands related to QUERY DEDUPSTATS

Command	Description
DELETE DEDUPSTATS	Deletes data deduplication statistics.
GENERATE DEDUPSTATS	Generates data deduplication statistics.

QUERY DEVCLASS (Display information on one or more device classes)

Use this command to display information on one or more device classes.

Privilege class

Any administrator can issue this command.

Syntax

```
                  .-*-----------------.
>>-Query DEVclass--+-------------------+------------------------>
                   '-device_class_name-'

   .-Format--=--Standard-----.
>--+------------------------+-------------------------------><
```

```
   '-Format--=--+-Standard-+-'
                '-Detailed-'
```

Parameters

device_class_name
: Specifies the name of the device class to be queried. This parameter is optional. You can use wildcard characters to specify this name. All matching device classes are displayed. If you do not specify a value for this parameter, all device classes are displayed.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed for the specified device class.

  Detailed
  : Specifies that complete information is displayed for the specified device class.

Example: List all device classes

Display information on all device classes.

```
query devclass
```

AIX Linux Windows

```
Device       Device     Storage  Device Format  Est/Max  Mount
Class        Access        Pool  Type           Capacity Limit

See Field descriptions for field descriptions.

Field descriptions

Device Class Name
: The name of the device class.

Device Access Strategy
: How data is written to the device class.

Storage Pool Count
: The number of storage pools that are assigned to the device class.

Device Type
: The device type of the device class.

Format
: The recording format.

Est/Max Capacity (MB)
: The estimated or maximum capacity of a volume that is associated with the device class.

Mount Limit
: The maximum number of sequential access volumes that can be mounted concurrently or specifies that DRIVES is the mount limit.

Mount Wait (min)
: The maximum number of minutes to wait for a sequential access volume to be mounted.

Mount Retention (min)
: The number of minutes to retain an idle sequential access volume before dismounting it.

Label Prefix
: The high-level qualifier of the data set name that the server writes into the sequential access media labels.

Windows Drive Letter
: Windows The drive letter for a removable file.

Library
: The name of the defined library object that contains the drives that are used by the device class.

Directory
: The directory or directories for a shared FILE device class.

Server Name
: The name of a defined server.

Retry Period
: The interval over which the server attempts to contact a target server if communications failure is suspected.

Retry Interval
: How often the retries are done within a retry period.

Shared
: Whether this FILE device class is shared between the server and one or more storage agents.

High-level Address
: The IP address of the device in dotted decimal format.

Minimum Capacity
: The minimum capacity of a volume that is associated with the device class.

WORM
: Whether this drive is a write once, read many (WORM) device.

Drive Encryption
: Whether drive encryption is allowed. This field applies only to volumes in a storage pool that is associated with a device type of 3592, LTO, or ECARTRIDGE.

Scaled Capacity
: The percentage of the media capacity that can be used to store data.

AIX Linux Primary Allocation (MB)
: AIX Linux For FILE device classes that represent storage that is managed by a z/OS® media server. Specifies the initial amount of space that is dynamically allocated when a new volume is opened.

AIX Linux Secondary Allocation (MB)
: AIX Linux For FILE device classes that represent storage that is managed by a z/OS media server. Specifies the amount of space by which a file volume is extended when space that is already allocated to the file volume is used up.

AIX Linux Compression
: AIX Linux For tape device classes that represent storage that is managed by a z/OS media server. Specifies whether the data is compressed.

AIX Linux Retention
: AIX Linux For tape device classes that represent storage that is managed by a z/OS media server. Specifies the number of days to retain the tape, if retention is used.

AIX Linux Protection
: AIX Linux For tape device classes that represent storage that is managed by a z/OS media server. Specifies whether the volumes are protected by the RACF program.

AIX Linux Expiration Date
: AIX Linux For tape device classes that represent storage that is managed by a z/OS media server. Specifies the expiration date that is placed on the tape labels for this device class, if expiration is used.

AIX Linux Unit
: AIX Linux For tape device classes that represent storage that is managed by a z/OS media server. Specifies the esoteric unit name for the group of tape devices.

Logical Block Protection
: Specifies whether logical block protection is enabled and, if it is, the mode. Possible values are Read/Write, Write-only, and No. You can use logical block protection only with the following types of drives and media:

  - IBM® LTO5 and later
  - IBM 3592 Generation 3 drives and later with 3592 Generation 2 media and later
  - Oracle StorageTek T10000C and T10000D drives

Last Update by (administrator)
: The administrator that made the last update to the device class.

Last Update Date/Time
: The date and time of the last update.

Related commands

Table 1. Commands related to QUERY DEVCLASS

Command	Description

Command	Description
DEFINE DEVCLASS	Defines a device class.
AIX Linux DEFINE DEVCLASS (z/OS media server)	AIX Linux Defines a device class to use storage managed by a z/OS media server.
DEFINE SERVER	Defines a server for server-to-server communications.
DELETE DEVCLASS	Deletes a device class.
QUERY DIRSPACE	Displays information about FILE directories.
QUERY SERVER	Displays information about servers.
UPDATE DEVCLASS	Changes the attributes of a device class.
AIX Linux UPDATE DEVCLASS (z/OS media server)	AIX Linux Changes the attributes of a device class for storage managed by a z/OS media server.

QUERY DIRSPACE (Query storage utilization of FILE directories)

Use this command to display information about free space in the directories associated with a device class with a device type of FILE.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query DIRSPace--+-------------------+----------------------><
                   '-device_class_name-'
```

Parameters

device_class_name
: Specifies the name of the device class to be queried. This parameter is optional. You can use wildcard characters to specify this name. All matching device classes of device type FILE are displayed. If you do not specify a value for this parameter, all device classes of device type FILE are displayed.

Example: List FILE type device classes

Display information for all device classes with a device type of FILE. In the following example the unit M is equivalent to megabytes, and the unit G is equivalent to gigabytes.

```
query dirspace
```

Windows

```
Device       Directory                     Estimated   Estimated
Class                                       Capacity   Available
-----------  ----------------------------  ----------  ----------
DBBKUP       /This/is/a/large/directory      13,000 M     5,543 M
DBBKUP       /This/is/directory2            13,000 M     7,123 M
DBBKUP2      /This/is/a/huge/directory        2,256 G     2,200 G
```

Windows

```
Device       Directory                     Estimated   Estimated
Class                                       Capacity   Available
-----------  ----------------------------  ----------  ----------
DBBKUP       G:\This\is\a\large\directory    13,000 M     5,543 M
DBBKUP       G:\This\is\directory2           13,000 M     7,123 M
DBBKUP2      G:\This\is\a\huge\directory       2,256 G     2,200 G
```

Field descriptions

Device Class Name
: The name of the device class.

Directory
: The path of the directory located on the server.

Estimated Capacity
: The estimated total capacity for the directory.

Estimated Available
: The estimated remaining available space for the directory.

Related commands

Table 1. Commands related to QUERY DIRSPACE

Command	Description
DEFINE DEVCLASS	Defines a device class.
DELETE DEVCLASS	Deletes a device class.
QUERY DEVCLASS	Displays information about device classes.
UPDATE DEVCLASS	Changes the attributes of a device class.

QUERY DOMAIN (Query a policy domain)

Use this command to display information on one or more policy domains.

Privilege class

Any administrator can issue this command.

Syntax

```
                .-*-----------.  .-Format--=--Standard-----.
>>-Query DOmain--+-------------+--+------------------------+--><
                 '-domain_name-'  '-Format--=--+-Standard-+-'
                                               '-Detailed-'
```

Parameters

domain_name
: Specifies the policy domain to query. This parameter is optional. You can use wildcard characters to specify names. If you do not specify a value for this parameter, all policy domains are displayed.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed.

Example: Display a summary of policy domains

Display partial information for all policy domains on the server. Issue the command:

```
query domain
```

```
Policy       Activated    Activated     Number of    Description
Domain       Policy       Default      Registered
Name         Set          Mgmt              Nodes
                          Class
```

```
---------    ---------    ---------    ----------    -----------------
EMPLOYEE-    VACATION     ACTIVEFI-             6    Employee Records
 _RECORDS                  LES                       Domain
PROG1                                           0    Programming Group
                                                      Test Domain
PROG2                                           0    Programming Group
                                                      Test Domain
STANDARD     STANDARD     STANDARD              1    Installed default
                                                      policy domain
```

See Field descriptions for field descriptions.

Example: Display the list of active-data pools

Display the active-data pool list. Issue the command:

```
query domain format=detailed
```

```
              Policy Domain Name: STANDARD
           Activated Policy Set: STANDARD
           Activation Date/Time: 05/16/2006 16:18:05
          Days Since Activation: 15
    Activated Default Mgmt Class: STANDARD
      Number of Registered Nodes: 1
                     Description: Installed default policy domain.
 Backup Retention (Grace Period): 30
Archive Retention (Grace Period): 365
  Last Update by (administrator): SERVER_CONSOLE
          Last Update Date/Time: 05/31/2006 15:17:48
               Managing profile:
                Changes Pending: Yes
          Active Data Pool List: ADPPOOL
```

See Field descriptions for field descriptions.

Field descriptions

Policy Domain Name
: The name of the policy domain.

Activated Policy Set
: The name of the policy set that was last activated in the domain.

  The definitions in the last activated policy set and the ACTIVE policy set are not necessarily identical. When you activate a policy set, the server copies the contents of the policy set to the policy set with the special name ACTIVE. The copied definitions in the ACTIVE policy set can be modified only by activating another policy set. You can modify the original policy set without affecting the ACTIVE policy set. Therefore, definitions in the policy set that was last activated might not be the same as those in the ACTIVE policy set.

Activation Date/Time
: The date and time that the policy set was activated.

Days Since Activation
: The number of days since the policy set was activated.

Activated Default Mgmt Class
: The assigned default management class for the policy set.

Number of Registered Nodes
: The number of client nodes registered to the policy domain.

Description
: The description of the policy domain.

Backup Retention (Grace Period)
: The number of days to retain inactive backup versions of files when any of the following conditions occur:

  - A file is rebound to a new management class, but neither the new management class nor default management class contains a backup copy group.
  - The management class to which a file is bound no longer exists, and the default management class does not contain a backup copy group.

- The backup copy group is deleted from the management class to which a file is bound and the default management class does not contain a backup copy group.

Archive Retention (Grace Period)
: The number of days to retain an archive file that meets either of the following conditions:

- The management class to which a file is bound no longer exists, and the default management class does not contain an archive copy group.
- The archive copy group is deleted from the management class to which a file is bound and the default management class does not contain an archive copy group.

Last Update by (administrator)
: The administrator that defined or most recently updated the policy domain. If this field contains $$CONFIG_MANAGER$$, the policy domain is associated with a profile that is managed by the configuration manager.

Last Update Date/Time
: When the administrator defined or most recently updated the policy domain.

Managing Profile
: The profile or profiles to which the managed server subscribed to get the definition of this policy domain.

Changes Pending
: Whether or not changes are being made but not activated. Once the changes are activated, the field resets to No.

Active Data Pool List
: The list of active-data pools in the domain.

Related commands

Table 1. Commands related to QUERY DOMAIN

Command	Description
COPY DOMAIN	Creates a copy of a policy domain.
DEFINE DOMAIN	Defines a policy domain that clients can be assigned to.
DELETE DOMAIN	Deletes a policy domain along with any policy objects in the policy domain.
UPDATE DOMAIN	Changes the attributes of a policy domain.

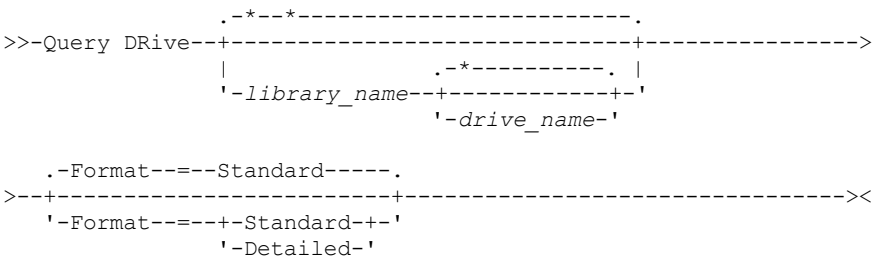
QUERY DRIVE (Query information about a drive)

Use this command to display information about the drives associated with a library.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

library_name
: Specifies the name of the library where the queried drive is located. This parameter is optional. You can use a wildcard character to specify this name.

You must specify a value for this parameter if you specify a drive name.

drive_name
: Specifies the name assigned to the drive. This parameter is optional. You can use a wildcard character to specify this name. If you specify a drive name, you must also specify a *library_name*.

Format
: Specifies how the information is displayed. This parameter is optional. The default is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed for the drive.

  Detailed
  : Specifies that complete information is displayed for the drive.

Example: List drives associated with the server

Display information about all drives associated with the server. Issue the command:

```
query drive
```

```
Library    Drive     Device    Online
Name       Name      Type
--------   ------    --------  -----
LIB1       DRIVE01   3590       Yes
LIB2       DRIVE02   3590       Yes
```

See Field descriptions for field descriptions.

Example: Display detailed information on a specific drive and library

Display detailed information about the drive named DRIVE02 that is associated with the library LIB2. Issue the command:

```
query drive lib2 drive02 format=detailed
```

```
                              Library Name: LIB2
                                Drive Name: DRIVE02
                               Device Type: 3590
                                   On-Line: Yes
                               Drive State: Empty
                              Allocated to:
             Last Update by (administrator): ADMIN
                       Last Update Date/Time: 02/29/2002 09:26:23
Cleaning Frequency (Gigabytes/ASNEEDED/NONE): NONE
```

See Field descriptions for field descriptions.

Field descriptions

Library Name
: The name of the library to which the drive is assigned.

Drive Name
: The name assigned to the drive.

Device Type
: The device type as specified in the associated device class. The server must have a path defined from the server to the drive in order to determine the true device type. As long as there is a path defined from the server to the drive, the server will display the true device type of the drive even if there are other paths defined to this drive. Exceptions to this occur if the device type is remote or unknown.

  REMOTE
  : The server does not have a path to the device. The only defined paths to the device are from data movers.

  UNKNOWN
  : No path exists.

  Tip: Review the output of the QUERY PATH command to determine if the desired paths are defined. If they are not defined, define those desired paths using the DEFINE PATH command. Also, if using a data mover device, review the output of the QUERY DATAMOVER command to determine the type of the data mover device. If you are using a path from the server to a drive, the device type of the device class and the drive need to match. If you are using a path from a data mover device to a

drive, review the documentation for your type of data mover to ensure the device type of the device class is compatible with the type of data mover device.

On-Line
: Specifies the status of the drive:

  Yes
  : The drive is online and available for server operations.

  No
  : The drive is offline and was put in this state by an administrator updating the status.

  Unavailable Since
  : Specifies that the drive has been unavailable since *mm/dd/yy hh:mm:ss*. Output shows the time the server marked the drive as unavailable.

  Polling Since
  : Specifies that the server is polling the drive because the drive stopped responding. Output shows the time the server detected a problem and began polling. The server polls a drive before stating it is unavailable. The time output follows the format: mm/dd/yy hh:mm:ss.

Read Formats
: The read formats for the drive.

Write Formats
: The write formats for the drive.

Element
: The element number for the drive.

Drive State
: This specifies the current state of this particular drive based on the result of the last SCSI command to the drive or library. The server tracks the state of the drive to improve its selection of a drive for an operation and its drive recovery operations. The values are:

  Unavailable
  : The drive is not available to the library for operations.

  Empty
  : The drive is empty and ready for operations.

  Loaded
  : The drive is currently loaded, and the server is performing operations to the drive.

  Unloaded
  : The media has been ejected from the drive.

  Reserved
  : The drive is reserved for a mount request.

  Unknown
  : The drive begins in drive state unknown as a result of being defined, as a result of server initialization, or as a result of having its status updated to online.

Volume Name
: The volume name for the drive.

Allocated To
: The name of the library client that is currently using the drive. This applies to shared SCSI libraries only; the field is left blank for all other libraries.

WWN
: The World Wide Name for the drive.

Last Update by (administrator)
: Who performed the last update to the drive.

Last Update Date/Time
: The date and time when the last update occurred.

Cleaning Frequency (Gigabytes/ASNEEDED/NONE)
: How often the server activates drive cleaning. This value can be the number of gigabytes, ASNEEDED, or NONE.

Related commands

Table 1. Commands related to QUERY DRIVE

Command	Description
AUDIT LIBRARY	Ensures that an automated library is in a consistent state.

Command	Description
DEFINE DRIVE	Assigns a drive to a library.
DEFINE LIBRARY	Defines an automated or manual library.
DEFINE PATH	Defines a path from a source to a destination.
DELETE DRIVE	Deletes a drive from a library.
DELETE LIBRARY	Deletes a library.
QUERY LIBRARY	Displays information about one or more libraries.
UPDATE DRIVE	Changes the attributes of a drive.

QUERY DRMEDIA (Query disaster recovery media)

Use this command to display information about database backup volumes, and volumes in copy storage pools, container-copy storage pools, and active-data storage pools. You can also use the command to create a file of executable commands to process the volumes.

The processing of volumes by this command depends on what the volumes are used for:

Backups of the server database
: To control whether the command processes database backup volumes, use the SOURCE parameter. The command can process volumes that are used for full plus incremental or snapshot database backups. You cannot specify virtual volumes (backup objects that are stored on another server). You can change volumes through each state, or you can use the TOSTATE parameter and skip states to simplify the movements.

Copy storage pools
: The QUERY DRMEDIA command always processes eligible copy storage-pool volumes.

Container-copy storage pools
: By default, volumes in container-copy storage pools are not eligible for processing by the QUERY DRMEDIA command. To process container-copy storage pool volumes, you must issue the SET DRMCOPYCONTAINERSTGPOOL command first, or specify the COPYCONTAINERSTGPOOL parameter on the QUERY DRMEDIA command.

Active-data storage pools
: By default, volumes in active-data storage pools are not eligible for processing by the QUERY DRMEDIA command. To process active-data pool volumes, you must issue the SET DRMACTIVEDATASTGPOOL command first, or specify the ACTIVEDATASTGPOOL parameter on the QUERY DRMEDIA command.

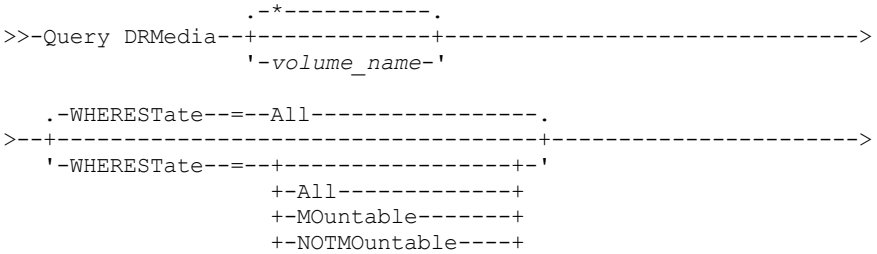
If you are using an external library and have moved a volume to the NOTMOUNTBLE state using the MOVE DRMEDIA command, the QUERY DRMEDIA command might still report the volume state as MOUNTABLE if it detects that the volume is in the library. Refer to the external library documentation for information about the procedures that you should follow when you use the MOVE DRMEDIA and the QUERY DRMEDIA commands.

Privilege class

To issue this command, you must have one of the following privilege classes:

- *If the CMD parameter is NOT specified:* operator or system privilege.
- *If the CMD parameter is specified and the REQSYSAUTHOUTFILE server option is set to NO:* operator, unrestricted storage, or system privilege.
- *If the CMD parameter is specified and the REQSYSAUTHOUTFILE server option is set to YES (the default):* system privilege.

Syntax



Parameters

volume_name
: Specifies the names of the volumes to be queried. You can use wildcard characters to specify multiple names. This parameter is optional. The server looks for matching names among the following eligible volumes:

  - Database backup volumes, as selected by the SOURCE parameter of this command.
  - Copy storage pool volumes from copy storage pools specified by the COPYSTGPOOL parameter. If you do not use the COPYSTGPOOL parameter, the server queries volumes from copy storage pools previously specified by the SET DRMCOPYSTGPOOL command.
  - Active-data storage pool volumes from active-data storage pools specified by the ACTIVEDATASTGPOOL parameter. If you do not use the ACTIVEDATASTGPOOL parameter, the server queries volumes from active-data storage pools that were previously specified by the SET DRMACTIVEDATASTGPOOL command.
  - Container-copy storage pool volumes from container-copy storage pools specified by the COPYCONTAINERSTGPOOL parameter. If you do not use the COPYCONTAINERSTGPOOL parameter, the server queries volumes from container-copy storage pools that were previously specified by the SET DRMCOPYCONTAINERSTGPOOL command.

  Other parameters can also limit the results of the query.

WHERE State
: Specifies the state of volumes to be processed. This parameter is optional. The default is ALL. Possible values are:

  All
  : Specifies all volumes in all states.

  MOuntable
  : Volumes in this state contain valid data and are accessible for onsite processing.

  NOTMOuntable
  : Volumes in this state are onsite, contain valid data, and not accessible for onsite processing.

  COUrier
  : Volumes in this state are being moved to an offsite location.

  VAult
  : Volumes in this state are offsite, contain valid data, and are not accessible for onsite processing.

VAULTRetrieve
Volumes in this state are located at the offsite vault, do not contain valid data, and can be moved back onsite for reuse or disposal:

- A copy storage pool volume is considered to be in the VAULTRETRIEVE state if it has been empty for at least the number of days specified with the REUSEDELAY parameter on the DEFINE STGPOOL command.
- A database backup volume is considered to be in the VAULTRETRIEVE state if it is associated with a database backup series that was expired based on the value specified using the SET DRMDBBACKUPEXPIREDAYS command.

Important: When you issue QUERY DRMEDIA WHERESTATE=VAULTRETRIEVE, the server dynamically determines which volumes can be moved back onsite for reuse or disposal. Therefore, to ensure that you identify all volumes that are in a VAULTRETRIEVE state, issue QUERY DRMEDIA WHERESTATE=VAULTRETRIEVE without the BEGINDATE, ENDDATE, BEGINTIME or ENDTIME parameters. The `Last Update Date/Time` field in the output for QUERY DRMEDIA WHERESTATE=VAULTRETRIEVE displays the date and time that a volume was moved to the VAULT state, not VAULTRETRIEVE.

COURIERRetrieve
Volumes in this state are being moved back to the onsite location.

REmote
Volumes in this state contain valid data and are located at the offsite remote server.

BEGINDate
Specifies the beginning date used to select volumes. This parameter is optional. Volumes are considered eligible if the MOVE DRMEDIA command has changed the volume to its current state on or after the specified date. The default is the earliest date for which volume information exists.
You can specify the date using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY-days *or* -days	The current date minus days specified. The maximum number of days is 9999.	TODAY-7 *or* -7. To query volumes beginning with records changed to their current state a week ago, you can specify BEGINDATE=TODAY-7 or BEGINDATE=-7.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

ENDDate
Specifies the ending date used to select volumes. This parameter is optional. Volumes are considered eligible if the MOVE DRMEDIA command has changed the volume to its current state on or before the specified date. The default is the current date.
You can specify the date using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY-days *or* -days	The current date minus days specified. The maximum number of days is 9999.	TODAY-7 *or* -7. To query volumes beginning with records changed to their current state a week ago, you can specify BEGINDATE=TODAY-7 or BEGINDATE=-7.

Value	Description	Example
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

BEGINTime

Specifies the beginning time used to select volumes. This parameter is optional. Volumes are considered eligible if the MOVE DRMEDIA command has changed the volume to its current state on or after the specified time and date. The default is midnight (00:00:00) on the date specified with the BEGINDATE parameter.

You can specify the time using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time on the specified begin date	12:33:28
NOW	The current time on the specified begin date	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes on the specified begin date	NOW+03:00 *or* +03:00. If you issue QUERY DRMEDIA command at 9:00 with BEGINTIME=NOW+03:00 or BEGINTIME=+03:00. The server displays volumes that were changed to their current state at 12:00 on the begin date that you specify.
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes on the specified begin date	NOW-03:30 *or* -03:30. If you issue QUERY DRMEDIA command at 9:00 with BEGINTIME=NOW-03:30 or BEGINTIME=-03:30. The server displays volumes that were changed to their current state at 5:30 on the begin date that you specify.

ENDTime

Specifies the ending time used to select volumes. This parameter is optional. Volumes are considered eligible if the MOVE DRMEDIA command has changed the volume to its current state on or before the specified time and date. The default is 23:59:59.

You can specify the time using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time on the specified end date	10:30:08
NOW	The current time on the specified end date	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes on the specified end date	NOW+03:00 *or* +03:00. If you issue QUERY DRMEDIA command at 9:00 with ENDTIME=NOW+03:00 or ENDTIME=+03:00, IBM Spectrum Protect™ processes volumes that were changed to their current state at 12:00 on the end date you specify.

Value	Description	Example
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes on the specified end date	NOW-03:30 *or* -03:30 If you issue QUERY DRMEDIA command at 9:00 with ENDTIME=NOW-03:00 or ENDTIME=-03:00, IBM Spectrum Protect processes volumes that were changed to their current state at 6:00 on the end date you specify.

COPYstgpool
Specifies the name of the copy storage pool whose volumes are to be processed. This parameter is optional. You can use wildcard characters to specify this name. The copy storage pools specified with this parameter override those specified with the SET DRMCOPYSTGPOOL command.

If this parameter is not specified, the server selects the storage pools as follows:

- If the SET DRMCOPYSTGPOOL command was previously issued with valid copy storage pool names, the server processes only those storage pools.
- If the SET DRMCOPYSTGPOOL command has not been issued, or if all of the copy storage pools have been removed using the SET DRMCOPYSTGPOOL command, the server processes all copy storage pool volumes in the specified state (ALL, MOUNTABLE, NOTMOUNTABLE, COURIER, VAULT, VAULTRETRIEVE, COURIERRETRIEVE, or REMOTE).

Source
Specifies whether any database backup volumes are selected. This parameter is optional. The default is DBBACKUP. Possible values are:

DBBackup
Full and incremental database backup volumes are selected.
DBSnapshot
Snapshot database backup volumes are selected.
DBNone
No database backup volumes are selected.

ACTIVEDatastgpool
Specifies the name of the active-data storage pool whose volumes are to be processed. This parameter is optional. You can use wildcard characters to specify this name. The active-data storage pools that are specified with this parameter override those specified with the SET DRMACTIVEDATASTGPOOL command.

If this parameter is not specified, the server selects the storage pools as follows:

- If the SET DRMACTIVEDATASTGPOOL command was previously issued with valid active-data storage pool names, the server processes only those storage pools.
- If the SET DRMACTIVEDATASTGPOOL command has not been issued, or all of the active-data storage pools have been removed using the SET DRMACTIVEDATASTGPOOL command, the server processes all active-data storage pool volumes in the specified state (ALL, NOTMOUNTABLE, COURIER, VAULT, VAULTRETRIEVE, COURIERRETRIEVE, or REMOTE). Volumes in the MOUNTABLE state are not processed.

COPYCONtainerstgpool
Specifies the name of the container-copy storage pool whose volumes are to be processed. This parameter is optional. You can use wildcard characters to specify this name. The container-copy storage pools that are specified using this parameter override those that are specified using the SET DRMCOPYCONTAINERSTGPOOL command.

If this parameter is not specified, the server selects the storage pools as follows:

- If the SET DRMCOPYCONTAINERSTGPOOL command was previously issued with names of valid container-copy storage pools, the server processes only those storage pools.
- If the SET DRMCOPYCONTAINERSTGPOOL command has not been issued, or if all container-copy storage pools were removed using the SET DRMCOPYCONTAINERSTGPOOL command, the server processes all container-copy pool volumes based on the value that is specified by the WHERESTATE parameter. If the parameter is set to a value of ALL, NOTMOUNTABLE, COURIER, VAULT, VAULTRETRIEVE, COURIERRETRIEVE, or REMOTE, the volumes are processed. If the value is set to MOUNTABLE, the volumes are not processed.

Format
Specifies the information to be displayed. This parameter is optional. The default is STANDARD. Possible values are:

Standard
Specifies that partial information is displayed.
Detailed
Specifies that detailed information is displayed.
Cmd
Specifies that executable commands are built for the selected volumes. If you specify FORMAT=CMD, you must also specify the CMD parameter.

WHERELOcation
Specifies the location of the volumes to be queried. This parameter is optional. The maximum length of the location is 255 characters. Enclose the text in quotation marks if it contains any blank characters. If you specify a target server name, the disaster recovery manager displays all database backup volumes and copy storage pool volumes located on the target server.

CMd
Specifies the creation of executable commands to process the volume name and location obtained by this command. This parameter is optional. You must enclose the command specification in quotation marks. The maximum length of this parameter is 255 characters. The disaster recovery manager writes the commands to a file specified by the CMDFILENAME parameter or the SET DRMCMDFILENAME command, or generated by the QUERY DRMEDIA command. If the command length is greater than 240 characters, it is split into multiple lines and continuation characters (+) are added. You may need to alter the continuation character according to the product that runs the commands.

If you do not specify the FORMAT=CMD parameter, this command will not create any command lines.

string
The command string. The string must not include embedded quotation marks. For example, this is a valid CMD parameter:

```
cmd="checkin libvol lib8mm &vol status=scratch"
```

This is an example of a CMD parameter that is *not* valid:

```
cmd=""checkin libvolume lib8mm" &vol status=scratch""
```

substitution
Specifies a substitution variable to tell QUERY DRMEDIA to substitute a value for the variable. The variables are not case-sensitive, and must not contain blank spaces after the ampersand (&). The possible variables are:

&VOL
A volume name variable.
&LOC
A volume location.
&VOLDSN
The name of the file the server writes into the sequential access media labels. An example of a copy storage pool tape volume file name using the default prefix TSM is TSM.BFS. An example of a database backup tape volume file name using a prefix TSM310 defined with the device class is TSM310.DBB.
&NL
The new line character. When &NL is specified, QUERY DRMEDIA command splits the command at the &NL variable and does not append a continuation character. You must specify the proper continuation character before the &NL if one is required. If the &NL is not specified and the command line is greater than 240 characters, the line is split into multiple lines and continuation characters (+) are added.

AIX Linux CMDFilename
AIX Linux Specifies the fully qualified name of the file to contain the commands specified with CMD parameter. This parameter is optional.

If you do not specify a name with the SET DRMCMDFILENAME command, the server creates a file name by appending `exec.cmds` to the absolute directory path name of the IBM Spectrum Protect instance directory. If you specify a null string (" "), the commands are displayed on the console only. You can redirect the commands to a file using the redirection character for the operating system.

If the operation fails after the command file is created, the file is not deleted.

Windows CMDFilename

Windows Specifies the fully qualified name of the file to contain the commands specified with CMD parameter. This parameter is optional.

If you do not specify a file name with the SET DRMCMDFILENAME command, the server creates a file name by appending `exec.cmd` to the directory that represents this instance of the server (typically the directory where the IBM Spectrum Protect server was originally installed). If you specify a null string (""), the commands are displayed on the console only. You can redirect the commands to a file by using > or >> provided by the system. The disaster recovery manager allocates the file name specified or generated. If the file exists, the disaster recovery manager tries to use it and any existing data is overwritten.

If the operation fails after the command file is created, the file is not deleted.

APPend

Specifies whether to overwrite any existing contents of the command file or append the commands to the file. This parameter is optional. The default is NO. Possible values are:

No

The disaster recovery manager overwrites the contents of the file.

Yes

The disaster recovery manager appends the commands to the file.

Example: List volumes to be sent to offsite storage

Display all volumes to be given to a courier for offsite storage.

```
query drmedia wherestate=notmountable
format=standard
```

```
Volume Name      State           Last Update           Automated
                                 Date/Time             LibName
---------------  --------------  --------------------  ---------
TAPE01           Not mountable    01/20/1998 14:25:22
DBTP01           Not mountable    01/20/1998 14:25:22
DBTP03           Not mountable    01/20/1998 14:31:53
```

See Field descriptions for field descriptions.

Example: Display information on volumes at the vault

Display detailed information about all volumes at the vault.

```
query drmedia wherestate=vault format=detailed
```

```
                    Volume Name: DBTP02
                          State: Vault
          Last Update Date/Time: 01/20/1998 13:29:02
                       Location: Ironmnt
                    Volume Type: DBBackup
          Copy Storage Pool Name:
   Active-Data Storage Pool Name: TSMACTIVEPOOL
               Automated LibName:
```

See Field descriptions for field descriptions.

Field descriptions

Volume Name

The name of the database backup or copy storage pool volume.

State

The state of the volume.

Last Update Date/Time

The date and time that the volume state was last updated. For volumes in the VAULTRETRIEVE state, this field displays the date and time that a volume was moved to the VAULT state, not VAULTRETRIEVE. The server does not "update" volumes to VAULTRETRIEVE. At the time the QUERY DRMEDIA command is issued, the server dynamically determines whether the data in copy storage pool volumes and database backup volumes is no longer valid and whether the volume can be brought back onsite for reuse or disposal.

Location
: The Location field is displayed when the volume is not mountable or when it's not in the library. The Location field is empty if the volume is mountable and is in the library.

Volume Type
: The type of volume. Possible values are:

  DBBackup
  : A full or incremental database backup volume.

  DBSnapshot
  : A database snapshot backup volume.

  CopyStgPool
  : A copy storage pool volume.

  ContcopyStgPool
  : A container-copy storage pool volume.

Copy Storage Pool Name
: For a copy storage pool volume, the name of the copy storage pool.

Active Data Storage Pool Name
: For an active-data storage pool volume, the name of the active-data storage pool.

Container-Copy Storage Pool Name
: For a container-copy storage pool volume, the name of the container-copy storage pool.

Automated LibName
: The name of the automated library if the volume is in a library.

Related commands

Table 1. Commands related to QUERY DRMEDIA

Command	Description
BACKUP DB	Backs up the IBM Spectrum Protect database to sequential access volumes.
BACKUP STGPOOL	Backs up a primary storage pool to a copy storage pool.
CHECKOUT LIBVOLUME	Checks a storage volume out of an automated library.
MOVE DRMEDIA	Moves DRM media onsite and offsite.
QUERY DRMSTATUS	Displays DRM system parameters.
SET DRMACTIVEDATASTGPOOL	Specifies that active-data storage pools are managed by DRM.
AIX Linux Windows SET DRMCOPYCONTAINERSTGPOOL	Specifies the container-copy storage pools that are used in DRM commands.
SET DRMCOPYSTGPOOL	Specifies that copy storage pools are managed by DRM.
SET DRMDBBACKUPEXPIREDAYS	Specifies criteria for database backup series expiration.
SET DRMCMDFILENAME	Specifies a file name for containing DRM executable commands.
SET DRMFILEPROCESS	Specifies whether the MOVE DRMEDIA or QUERY DRMEDIA command processes files associated with a device type of file.

QUERY DRMSTATUS (Query disaster recovery manager system parameters)

Use this command to display information about the system parameters defined for disaster recovery manager (DRM).

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query DRMSTatus-----------------------------------------><
```

Parameters

None.

Example: Display DRM system parameter information

Display information about the DRM system parameters:

```
query drmstatus
```

```
              Recovery Plan Prefix:
         Plan Instructions Prefix:
       Replacement Volume Postfix: @
            Primary Storage Pools: PRIM1 PRIM2
               Copy Storage Pools: COPY*
        Active-Data Storage Pools: TSMACTIVEPOOL
     Container-Copy Storage Pools: COPYCNTRPOOL
      Not Mountable Location name: Local
                     Courier Name: Fedex
                  Vault Site Name: Ironmnt
  DB Backup Series expiration days: 30 Day(s)
Recovery Plan File Expiration Days: 30 Days(s)
                     Check Label?: No
         Process FILE Device Type?: No
                  Command file name:
```

Field descriptions

Recovery Plan Prefix
: User-specified prefix portion of the file name for the recovery plan file.

Plan Instructions Prefix
: User-specified prefix portion of the file names for the server recovery instructions files.

Replacement Volume Postfix
: The character added to the end of the replacement volume names in the recovery plan file.

Primary Storage Pools
: The primary storage pools that are eligible for processing by the PREPARE command. If this field is blank, all primary storage pools are eligible.

Copy Storage Pools
: The copy storage pools that are eligible for processing by the MOVE DRMEDIA, PREPARE, and QUERY DRMEDIA commands. If this field is blank, all copy storage pools are eligible.

Active-Data Storage Pools
: The active-data pools that are eligible for processing by the MOVE DRMEDIA, PREPARE, and QUERY DRMEDIA commands. If this field is blank, active-data pools are not eligible.

Container-Copy Storage Pools
: The container-copy storage pools that are eligible for processing by the MOVE DRMEDIA, PREPARE, and QUERY DRMEDIA commands. If this field is blank, container-copy storage pools are not eligible.

Not Mountable Location Name
: The name of the offsite location where the media to be shipped are stored.

Courier Name
: The name of the courier used to carry the media to the vault.

Vault Site Name
: The name of the vault where the media is stored.

DB Backup Series Expiration Days
: The minimum number of days that must elapse since a database series has been created before it is eligible to be expired. See the SET DRMDBBACKUPEXPIREDAYS command for information about the criteria that must be met for database backup series expiration.

Recovery Plan File Expiration Days
: The minimum number of days that must elapse since a recovery plan file, stored on a target server, has been created before it is eligible to be expired. See the SET DRMRPFEXPIREDAYS command for information about the criteria that must be met for recovery plan file expiration.

Check Label?

Whether media labels are read for sequential media volumes checked out by the MOVE DRMEDIA command. Possible values are Yes or No.

Process FILE Device Type?

Whether MOVE DRMEDIA or QUERY DRMEDIA commands process database backup and copy storage pool volumes associated with a device class with a FILE device type. Possible values are Yes or No.

Command File Name

The full path file name that contains the executable commands generated by the MOVE DRMEDIA or QUERY DRMEDIA command.

Related commands

Table 1. Commands related to QUERY DRMSTATUS

Command	Description
MOVE DRMEDIA	Moves DRM media onsite and offsite.
PREPARE	Creates a recovery plan file.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
SET DRMCHECKLABEL	Specifies whether IBM Spectrum Protect should read volume labels during MOVE DRMEDIA command processing.
SET DRMACTIVEDATASTGPOOL	Specifies that active-data storage pools are managed by DRM.
AIX Linux Windows SET DRMCOPYCONTAINERSTGPOOL	Specifies the container-copy storage pools that are used in DRM commands.
SET DRMCOPYSTGPOOL	Specifies that copy storage pools are managed by DRM.
SET DRMCMDFILENAME	Specifies a file name for containing DRM executable commands.
SET DRMCOURIERNAME	Specifies the name of the courier for the disaster recovery media.
SET DRMDBBACKUPEXPIREDAYS	Specifies criteria for database backup series expiration.
SET DRMFILEPROCESS	Specifies whether the MOVE DRMEDIA or QUERY DRMEDIA command processes files associated with a device type of file.
SET DRMINSTRPREFIX	Specifies the prefix portion of the path name for the recovery plan instructions.
SET DRMPLANVPOSTFIX	Specifies the replacement volume names in the recovery plan file.
SET DRMPLANPREFIX	Specifies the prefix portion of the path name for the recovery plan.
SET DRMPRIMSTGPOOL	Specifies that primary storage pools are managed by DRM.
SET DRMRPFEXPIREDAYS	Set criteria for recovery plan file expiration.
SET DRMVAULTNAME	Specifies the name of the vault where DRM media is stored.
SET DRMNOTMOUNTABLENAME	Specifies the location name of the DRM media to be sent offsite.

QUERY ENABLED (Query enabled events)

Use this command to display either a list of enabled events or a list of disabled events, whichever is shorter.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query--ENabled--+-CONSOLE--------+--------------------------->
                   +-ACTLOG---------+
                   +-EVENTSERVER----+
                   +-FILE-----------+
                   +-FILETEXT-------+
                   |            (1) |
                   +-NTEVENTLOG-----+
                   |        (2)     |
                   +-SYSLOG---------+
                   +-TIVOLI---------+
                   '-USEREXIT-------'

>--+---------------------------+-----------------------------><
   +-NODEname--=--node_name-----+
   '-SERVername--=--server_name-'
```

Notes:

1. This parameter is only available for the Windows operating system.
2. This parameter is only available for the Linux operating system.

Parameters

receiver
: Specifies a type of receiver for enabled events. This is a required parameter. Valid values are:

  ACTLOG
  : Specifies the IBM Spectrum Protect™ activity log as a receiver.

  CONSOLE
  : Specifies the standard server console as a receiver.

  EVENTSERVER
  : Specifies the event server as a receiver.

  FILE
  : Specifies a user file as a receiver. Each logged event is a record in the file and a person cannot read each logged event easily.

  FILETEXT
  : Specifies a user file as a receiver. Each logged event is a fixed-size, readable line.

  Windows NTEVENTLOG
  : Windows Specifies the Windows application log as a receiver.

  Linux SYSLOG
  : Linux Specifies the Linux system log as a receiver.

  TIVOLI
  : Specifies the Tivoli Management Environment (TME) as a receiver.

  USEREXIT
  : Specifies a user-written routine to which IBM Spectrum Protect writes information as a receiver.

NODEname
: Specifies a node name to be queried. You can specify NODENAME or SERVERNAME. If neither parameter is specified, the query is for events enabled for the server running this command.

SERVername
: Specifies a server name to be queried. You can specify NODENAME or SERVERNAME. If neither parameter is specified, the query is for events enabled for the server running this command.

Example: Query the server for console events

Query the server for server events that are enabled for the console. There are 10000 possible server events. Either a list of enabled events or disabled events is displayed (whichever list is shorter).

```
query enabled console

9998 events are enabled for the CONSOLE receiver.  The
following events are DISABLED for the CONSOLE receiver:

ANR8409, ANR8410
```

Related commands

Table 1. Commands related to QUERY ENABLED

Command	Description
BEGIN EVENTLOGGING	Starts event logging to a specified receiver.
DISABLE EVENTS	Disables specific events for receivers.
ENABLE EVENTS	Enables specific events for receivers.
END EVENTLOGGING	Ends event logging to a specified receiver.
QUERY EVENTRULES	Displays information about rules for server and client events.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

QUERY EVENT (Query scheduled and completed events)

Use this command to display the status of scheduled events. The time and date parameters allow you to limit the query to events that were scheduled to occur within the specified times and dates. Limiting the output to events whose scheduled start times fall within a date and time range also minimizes the time it takes to process this query.

The command syntax differs for queries that apply to scheduled client operations and to scheduled administrative commands.

Table 1. Commands related to QUERY EVENT

Command	Description
DEFINE SCHEDULE	Defines a schedule for a client operation or an administrative command.
DELETE EVENT	Deletes event records before a specified date and time.
QUERY ACTLOG	Displays messages from the server activity log.
SET EVENTRETENTION	Specifies the number of days to retain records for scheduled operations.
SET RANDOMIZE	Specifies the randomization of start times within a window for schedules in client-polling mode.

- QUERY EVENT (Display client schedules)
  Use the QUERY EVENT command to display scheduled and completed events for selected clients.
- QUERY EVENT (Display administrative event schedules)
  Use the QUERY EVENT command to display scheduled and completed events for selected administrative command schedules.

QUERY EVENT (Display client schedules)

Use the QUERY EVENT command to display scheduled and completed events for selected clients.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query EVent--domain_name--schedule_name---------------------->

   .-Type--=--Client-.
>--+-----------------+--+-------------------------+------------->
                       |           .-,---------.  |
                       |           V           |  |
                       '-Nodes--=----node_name-+-'
```

```
   .-BEGINDate--=--current_date-.  .-BEGINTime--=--00:00-.
>--+----------------------------+--+--------------------+------>
   '-BEGINDate--=--date---------'  '-BEGINTime--=--time--'

   .-ENDDate--=--end_date-.  .-ENDTime--=--23:59-.
>--+--------------------+--+------------------+-------------->
   '-ENDDate--=--date-----'  '-ENDTime--=--time--'

   .-EXceptionsonly--=--No------.
>--+--------------------------+------------------------------>
   '-EXceptionsonly--=--+-No--+-'
                        '-Yes-'

   .-Format--=--Standard-----.
>--+-------------------------+-------------------------------><
   '-Format--=--+-Standard-+-'
                '-Detailed-'
```

Parameters

domain_name (Required)
: Specifies the name of the policy domain to which the schedules belong. You can use a wildcard character to specify this name.

schedule_name (Required)
: Specifies the name of the schedule for which events are displayed. You can use a wildcard character to specify this name.

Type=Client
: Specifies that the query displays events for client schedules. This parameter is optional. The default is CLIENT.

Nodes
: Specifies the name of the client node that belongs to the specified policy domain for which events are displayed. You can specify multiple client nodes by separating the names with commas and no intervening spaces. You can use wildcard characters to specify nodes. If you do not specify a client name, events display for all clients that match the domain name and the schedule name.

BEGINDate
: Specifies the beginning date of the time range for events to be displayed. All events scheduled to start during this time are displayed. This parameter is optional. The default is the current date.
  You can specify the date using one of the values below:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY+days **or** +days	The current date plus days specified. The maximum number of days you can specify is 9999.	TODAY +3 **or** +3.
TODAY-days **or** -days	The current date minus days specified	TODAY-7 **or** -7. To query events scheduled to start during the past seven days, specify BEGINDATE=TODAY-7 ENDDATE=TODAY or BEGINDATE=-7 ENDDATE=TODAY.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM

Value	Description	Example
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

BEGINTime

Specifies the beginning time of the range for events to be displayed. All events scheduled to start during this time are displayed. This parameter is optional. The default value is 00:00.

You can specify the time using one of the values below:

Value	Description	Example
HH:MM:SS	A specific time on the specified begin date	10:30:08
NOW	The current time on the specified begin date	NOW
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes on the specified begin date	NOW+03:00 **or** +03:00. If you issue this command at 9:00 to query events scheduled to start 3 hours from now, you can specify either BEGINTIME=NOW+03:00 or BEGINTIME=+03:00. IBM Spectrum Protect™ displays events at 12:00 on the specified begin date.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes on the specified begin date	NOW-04:00 **or** -04:00. If you issue this command at 9:00 to query events scheduled to start during the last 4 hours, you can specify either BEGINTIME=NOW-04:00 ENDTIME=NOW or BEGINTIME=-04:00 ENDTIME=NOW. IBM Spectrum Protect displays events at 5:00 on the specified begin date.

ENDDate

Specifies the ending date of the time range for events to be displayed. All events that were schedule to start during this time are displayed. This parameter is optional. The default is the value used for the BEGINDATE.

You can specify the date using one of the values below:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY+days **or** +days	The current date plus days specified. The maximum number of days you can specify is 9999.	TODAY +3 **or** +3.
TODAY-days **or** -days	The current date minus days specified	TODAY-8 **or** -8. To query events scheduled to start during a one-week period that ended yesterday, you can specify either BEGINDATE=TODAY-8 ENDDATE=TODAY-1 or BEGINDATE=-8 ENDDATE=-1.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM

Value	Description	Example
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

ENDTime

Specifies the ending time of the range for events to be displayed. All events that were scheduled to start during this time are displayed. This parameter is optional. The default value is 23:59.
You can specify the time using one of the values below:

Value	Description	Example
HH:MM:SS	A specific time on the specified end date	10:30:08
NOW	The current time on the specified end date	NOW
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes on the specified end date	NOW+03:00 **or** +03:00. If you issue this command at 9:00 to query events scheduled to start 3 hours from now, you can specify either BEGINTIME=NOW ENDTIME=NOW+03:00 or BEGINTIME=NOW ENDTIME=+03:00.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes on the specified end date	NOW-04:00 **or** -04:00

EXceptionsonly

Specifies the type of information you want on scheduled or completed events. This parameter is optional. The default is NO. You can specify one of the following values:

No
: Specifies that the information on past and projected events is displayed.

Yes
: Specifies that the events that failed or did not process as scheduled are displayed.

Format

Specifies how information displays. This parameter is optional. The default is STANDARD. The following values are possible:

Standard
: Specifies that partial information for events displays.

Detailed
: Specifies that complete information for events displays.

Display partial information for unsuccessful events

Display partial information for all events that are scheduled for DOMAIN1 that did not run successfully. Limit the search to the client named JOE. Limit the events that are displayed to events that were scheduled to occur from February 11, 2001 (02/11/2001) to February 12, 2001 (02/12/2001).

```
query event domain1 * nodes=joe begindate=02/11/2001
enddate=02/12/2001 exceptionsonly=yes

Scheduled Start      Actual Start          Schedule  Node    Status
                                            Name     Name
-------------------- --------------------  --------- ----   ---------
02/11/1999 01:00:00  02/11/1999 01:13:55   BACK1      JOE   Failed
02/12/1999 01:00:00                        DAILYBKP   JOE   Missed
```

See Field descriptions for field descriptions.

Display partial information for scheduled events for a client

Display complete information for all events that are scheduled for processing. Use the start time as 10 days previous to today, and the finish includes today.

```
query event * * begindate=today-10 enddate=today
```

```

```

Field descriptions

Policy Domain Name
Specifies the name of the policy domain to which the schedule is assigned.

Schedule Name
Specifies the name of the schedule that initiated this event.

Node Name
Specifies the client that is scheduled to perform the operation.

Scheduled Start
Specifies the scheduled starting date and time for the event.

Actual Start
Specifies the date and time at which the client began processing the scheduled operation. No information is displayed if the scheduled operation has not started.

Completed
Specifies the date and time the scheduled event is completed.

Status
Specifies the status of the event at the time the QUERY EVENT command is issued. The following values are possible:

Completed
Specifies that the scheduled event is completed.

Failed
Specifies that the client reports a failure when you run the scheduled operation and successive retries failed.

Failed - no restart
Specifies an intermediate status, when a client session is interrupted by a communications error or timeout on the server. This status can be changed to a final status of "Completed" or "Failed" when the event completes.

Future
Specifies that the beginning of the startup window for the event is in the future. This status also indicates that an event record has not been created for this event.

In Progress
Specifies that the scheduled event is running and has not yet reported the completion state to the server.

Periodically check the status for completion of the scheduled event. If this status is not updated in a reasonable amount of time, review your client dsmsched.log and dsmerror.log to determine why the client did not report the outcome of this event to the server. If the scheduled backup failed, rerun the scheduled event or perform a manual incremental backup to ensure the data backup.

Missed
Specifies that the scheduled startup window for this event passed and the schedule did not begin.

Pending
Specifies that the QUERY EVENT command was issued during the startup window for the event, but processing the scheduled operation did not begin.

Restarted
Specifies that the client has tried to process the scheduled operation again.

Severed
Specifies that the communications with the client is severed before the event can complete.

Started
Specifies that the event has begun processing.

Uncertain
Specifies that the state of the event cannot be determined. The server specifies `Uncertain` if the QUERY EVENT command does not find an event record. An event record is not found if the record was deleted or if the server was unavailable during the scheduled startup window (the schedule was never started). Records with Uncertain status are not stored in the database. If you do not want these records to display, either specify EXCEPTIONSONLY=YES or delete the schedule if it is no longer needed.

Attention: When a scheduled operation is processing, and is not restarted within its specified duration, the Status field shows `Started`. If the operation continues beyond the specified duration, no event record is created. If a query is issued after the specified duration has passed, the Status shows as `Failed` even if the operation is still running. After the operation completes, an event record is created, and a subsequent query shows the result in the Status field.

Result
Specifies the return code that indicates whether the schedule processed successfully. If the return code is a value other than 0, examine the server activity log and the client's error log and schedule log.

Return code	Explanation
0	All operations were completed successfully.

Return code	Explanation
4	The operation was completed, but some files were not processed.
8	The operation was completed with at least one warning message.
12	The operation was completed with at least one error message. The count of error messages does not include notifications about skipped files.
-99	The operation failed because the session between the client and the server ended for an unknown reason. It is unknown whether the client can reconnect to the server to complete the schedule event.

If a schedule has ACTION=COMMAND as a parameter, and the command is not an IBM Spectrum Protect command, the command can produce other values in the Result field.

Reason
: Specifies the reason for the return code.

QUERY EVENT (Display administrative event schedules)

Use the QUERY EVENT command to display scheduled and completed events for selected administrative command schedules.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query EVent--schedule_name--Type--=--Administrative---------->

   .-BEGINDate--=--current_date-.  .-BEGINTime--=--00:00-.
>--+-------------------------+--+---------------------+------>
   '-BEGINDate--=--date-------'  '-BEGINTime--=--time--'

   .-ENDDate--=--begin_date-.  .-ENDTime--=--23:59-.
>--+----------------------+--+------------------+------------>
   '-ENDDate--=--date-------'  '-ENDTime--=--time--'

   .-EXceptionsonly--=--No------.
>--+--------------------------+------------------------------>
   '-EXceptionsonly--=--+-No--+-'
                        '-Yes-'

   .-Format--=--Standard-----.
>--+-----------------------+--------------------------------><
   '-Format--=--+-Standard-+-'
                '-Detailed-'
```

Parameters

schedule_name (Required)
: Specifies the name of the schedule for which events display. You can use wildcard characters to specify names.

Type=Administrative (Required)
: Specifies that the query displays events for administrative command schedules.

BEGINDate
: Specifies the beginning date of the time range for events to be displayed. All events scheduled to start during this time are displayed. This parameter is optional. The default is the current date.
You can specify the date using one of the values below:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY

Value	Description	Example
TODAY+days **or** +days	The current date plus days specified. The maximum number of days you can specify is 9999.	TODAY +3 **or** +3.
TODAY-days **or** -days	The current date minus days specified	TODAY-7 **or** -7. To query events scheduled to start during the past seven days, specify BEGINDATE=TODAY-7 ENDDATE=TODAY or BEGINDATE=-7 ENDDATE=TODAY.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

BEGINTime

Specifies the beginning time of the range for events to be displayed. All events scheduled to start during this time are displayed. This parameter is optional. The default value is 00:00.

You can specify the time using one of the values below:

Value	Description	Example
HH:MM:SS	A specific time on the specified begin date	10:30:08
NOW	The current time on the specified begin date	NOW
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes on the specified begin date	NOW+03:00 **or** +03:00. If you issue this command at 9:00 to query events scheduled to start 3 hours from now, you can specify either BEGINTIME=NOW+03:00 or BEGINTIME=+03:00. IBM Spectrum Protect™ displays events at 12:00 on the specified begin date.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes on the specified begin date	NOW-04:00 **or** -04:00. If you issue this command at 9:00 to query events scheduled to start during the last 4 hours, you can specify either BEGINTIME=NOW-04:00 ENDTIME=NOW or BEGINTIME=-04:00 ENDTIME=NOW. IBM Spectrum Protect displays events at 5:00 on the specified begin date.

ENDDate

Specifies the ending date of the time range for events to be displayed. All events that were schedule to start during this time are displayed. This parameter is optional. The default is the value used for the BEGINDATE.

You can specify the date using one of the values below:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY+days **or** +days	The current date plus days specified. The maximum number of days you can specify is 9999.	TODAY +3 **or** +3.

Value	Description	Example
TODAY-days **or** -days	The current date minus days specified	TODAY-8 **or** -8. To query events scheduled to start during a one-week period that ended yesterday, you can specify either BEGINDATE=TODAY-8 ENDDATE=TODAY-1 or BEGINDATE=-8 ENDDATE=-1.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

ENDTime

Specifies the ending time of the range for events to be displayed. All events that were scheduled to start during this time are displayed. This parameter is optional. The default value is 23:59.
You can specify the time using one of the values below:

Value	Description	Example
HH:MM:SS	A specific time on the specified end date	10:30:08
NOW	The current time on the specified end date	NOW
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes on the specified end date	NOW+03:00 **or** +03:00. If you issue this command at 9:00 to query events scheduled to start 3 hours from now, you can specify either BEGINTIME=NOW ENDTIME=NOW+03:00 or BEGINTIME=NOW ENDTIME=+03:00.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes on the specified end date	NOW-04:00 **or** -04:00

EXceptionsonly

Specifies the type of information you want on scheduled or completed events. This parameter is optional. The default is NO. You can specify one of the following values:

No
: Specifies that the information on past and projected events is displayed.

Yes
: Specifies that the events that failed or did not process as scheduled are displayed.

Format

Specifies how the information displays. This parameter is optional. The default value is STANDARD. Possible values are:

Standard
: Specifies that partial information for events displays.

Detailed
: Specifies that complete information for events displays.

Example: List events for a specific administrative schedule

Display partial information for all events scheduled for an administrative schedule named DOSADMIN. Limit the query to events that are scheduled for March 30, 1999 (03/30/1999). Issue the command:

```
query event dosadmin type=administrative
begindate=03/30/1999
enddate=03/30/1999
```

```
Scheduled Start      Actual Start          Schedule Status
                                           Name
-------------------- --------------------  --------- ---------
03/30/1999 00:00:00  03/30/1999 00:00:01   DOSADMIN  Completed
03/30/1999 04:00:00  03/30/1999 04:00:01   DOSADMIN  Completed
03/30/1999 12:00:00                        DOSADMIN  Future
03/30/1999 16:00:00                        DOSADMIN  Future
```

Field descriptions

Scheduled Start
: Specifies the scheduled starting date and time for the event.

Actual Start
: Specifies the date and time at which the client began processing the scheduled operation. No information displays if the schedule has not started executing.

Schedule Name
: Specifies the name of the schedule that initiated this event.

Status
: For administrative commands or scripts that specify WAIT=YES, the status of a scheduled event is STARTED until the operation specified by the command or script is completed. The final status of the scheduled event depends on the return code of the operation. However, if WAIT=YES and if the schedule is running a script that specifies PREVIEW=YES, the final status is COMPLETED, unless the script contained a syntax error.

  For administrative commands or scripts that specify WAIT=NO, the status of a scheduled event is COMPLETED if the scheduled command or script started. The success of the schedule is independent of the success of the operation performed by the command or script.

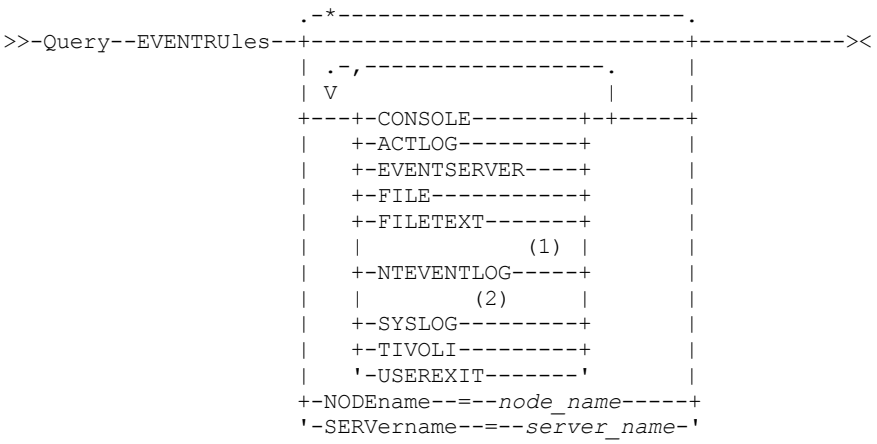
QUERY EVENTRULES (Query rules for server or client events)

Use this command to display the history of events that are enabled or disabled by a specified receiver for the server or for a client node.

Privilege class

Any administrator can issue this command.

Syntax



Notes:

1. This parameter is only available for the Windows operating system.
2. This parameter is only available for the Linux operating system.

Parameters

receivers

Specifies the name of one or more receivers for enabled events. This parameter is optional.

You can use a wildcard character to specify all receivers.

Valid values are:

CONSOLE
: Specifies the standard console as a receiver.

ACTLOG
: Specifies the IBM Spectrum Protect™ activity log as a receiver.

EVENTSERVER
: Specifies the event server as a receiver.

FILE
: Specifies a user file as a receiver. Each logged event is a record in the file and a person cannot read each logged event easily.

FILETEXT
: Specifies a user file as a receiver. Each logged event is a fixed-size, readable line.

Windows NTEVENTLOG
: Windows Specifies the Windows application log as a receiver.

Linux SYSLOG
: Linux Specifies the Linux system log as a receiver.

TIVOLI
: Specifies the Tivoli Management Environment (TME) as a receiver.

USEREXIT
: Specifies a user-written routine to which IBM Spectrum Protect writes information as a receiver.

NODEname
: Specifies a node name to be queried. You can use a wildcard character to specify a name. You can specify NODENAME or SERVERNAME. If neither parameter is specified, the query is for event rules for the server running this command.

SERver
: Specifies a server name to be queried. You can use a wildcard character to specify a name. You can specify NODENAME or SERVERNAME. If neither parameter is specified, the query is for event rules for the server running this command.

Example: Display the history of client events for the server console

Display the history of client events enabled or disabled for the server console and activity log receivers.

```
query eventrules console,actlog nodename=*
```

```
Date/Time            Client Event Rules
-------------------- ----------------------------------------------
05/29/97 13:39:58    ENABLE EVENTS CONSOLE ANE4001 NODENAMES=JEE
05/30/97 13:46:25    DISABLE EVENTS ACTLOG ANE4962 NODENAMES=JEE
05/30/97 13:46:25    DISABLE EVENTS ACTLOG ANE4963 NODENAMES=JEE
05/30/97 13:46:25    DISABLE EVENTS ACTLOG ANE4965 NODENAMES=JEE
05/30/97 13:46:25    DISABLE EVENTS ACTLOG ANE4966 NODENAMES=JEE
05/30/97 13:46:25    DISABLE EVENTS ACTLOG ANE4967 NODENAMES=JEE
05/30/97 13:46:25    DISABLE EVENTS ACTLOG ANE4968 NODENAMES=JEE
05/30/97 14:24:20    ENABLE EVENTS CONSOLE ANE4015 NODENAMES=RON
05/30/97 14:24:50    ENABLE EVENTS CONSOLE ANE4026 NODENAMES=DONNA
05/30/97 14:25:59    ENABLE EVENTS CONSOLE ANE4015 NODENAMES=DONNA
```

Example: Display the history of client events for all receivers

Display the history of server events enabled or disabled for all receivers.

```
query eventrules
```

```
Date/Time            Server Event Rules
-------------------- ----------------------------------------------
05/22/97 14:35:13    ENABLE EVENTS CONSOLE ANR2578
05/30/97 14:29:31    ENABLE EVENTS CONSOLE ANR0272
05/30/97 14:31:46    ENABLE EVENTS USEREXIT ANR0130
05/30/97 14:31:54    ENABLE EVENTS USEREXIT ANR0131
05/30/97 14:50:28    ENABLE EVENTS USEREXIT ANR0266
```

Field descriptions

Date/Time
: Specifies the date and time when the event was enabled or disabled.

Client Event Rules
: Specifies client events that were enabled or disabled for the specified receivers.

Server Event Rules
: Specifies server events that were enabled or disabled for the specified receivers.

Related commands

Table 1. Commands related to QUERY ENABLED

Command	Description
BEGIN EVENTLOGGING	Starts event logging to a specified receiver.
DISABLE EVENTS	Disables specific events for receivers.
ENABLE EVENTS	Enables specific events for receivers.
END EVENTLOGGING	Ends event logging to a specified receiver.
QUERY ENABLED	Displays enabled or disabled events for a specific receiver.

QUERY EVENTSERVER (Query the event server)

Use this command to display the name of the event server.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query EVENTSERVer-------------------------------------------><
```

Example: Display the event server name

Display the name of the event server.

```
query eventserver
```

```
ANR1669I Server EVENT is defined as the event server.
```

Related commands

Table 1. Commands related to QUERY EVENTSERVER

Command	Description
BEGIN EVENTLOGGING	Starts event logging to a specified receiver.
DEFINE EVENTSERVER	Defines a server as an event server.
DEFINE SERVER	Defines a server for server-to-server communications.
DELETE EVENTSERVER	Deletes reference to the event server.
DELETE SERVER	Deletes the definition of a server.
END EVENTLOGGING	Ends event logging to a specified receiver.

QUERY EXPORT (Query for active or suspended export operations)

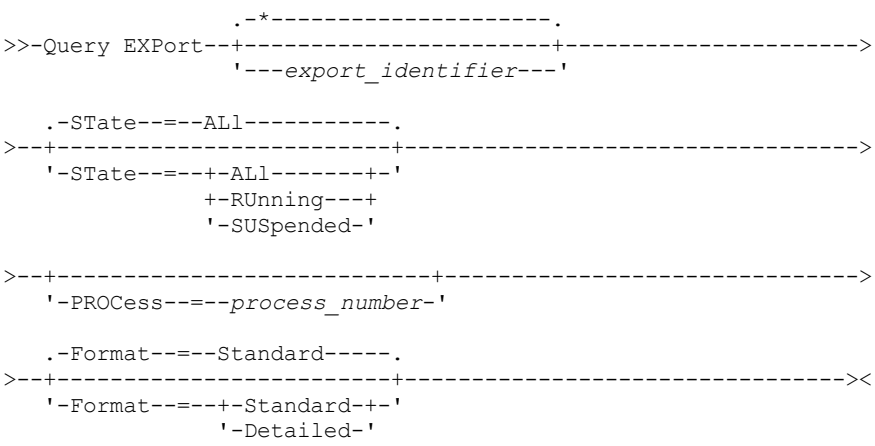
Use this command to list all restartable export operations. A restartable export is a server-to-server export operation whose FILEDATA value is not NONE. Only active server-to-server export operations that can be suspended are displayed.

Any EXPORT NODE or EXPORT SERVER operation with FILEDATA=NONE are not displayed. Additionally, the QUERY EXPORT command does not show export operations where the target device is either sequential media or virtual volumes.

Privilege class

An administrator can issue this command.

Syntax



Parameters

export_identifier
: This optional parameter is the unique string identifier for the server-to-server export operation. Wildcard characters can be used to specify this name, and all matching export operations are queried. If you do not specify a value for this parameter and you also do not specify a PROCESS identifier, then all export operations are queried.

STate
: This optional parameter queries the state of the valid server-to-server export operations. The default value is ALL. The possible values are:

  ALl
  : Lists all running and suspended server-to-server export operations.

  RUnning
  : Lists all active server-to-server export operations that are identifying eligible files or exporting files to the target server.

  SUSpended
  : Lists all suspended server-to-server export operations. These suspended operations stopped running because of a failure or by the SUSPEND EXPORT command being issued.

PROCess
: This optional parameter specifies the number of a running server-to-server export operation that you want to query. If PROCESS is specified, IBM Spectrum Protect™ only displays the running server-to-server export operation associated with the process number. If PROCESS is not specified, IBM Spectrum Protect displays information on all server-to-server export operations. You cannot specify this parameter if you specify an export identifier or if you specify the STATE parameter with a value of SUSPENDED.

Format
: This optional parameter specifies how the information is displayed. The default value is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed for the specified export operations.

  Detailed
  : When specified, displays all available information for the export operations.

Example: Display running and suspended export operations

List information for all currently running and suspended export operations. Issue the following command:

```
query export state=all

Export          Start Time    State       Process   Command
Identifier                                ID
-------------   -----------   ---------   --------  ------------------
MYEXPORTNODE    01/24/2007    Suspended      --     Export NODE
                10:30:03                            me,you,them
                                                    filespace=c$
                                                    nametype=unicode
                                                    filedata=all
                                                    durunits=indefinite
                                                    toserver=athens
                                                    exportid=MYEXPORTNODE

                                                    durunits=indefinite
                                                    toserver=athens
                                                    exportid=EXPORT_HOME_DIRS

EXPORT_NODE_    01/25/2007    Running Not    --     Export NODE n5,n6,n7
0001            14:30:33      Suspendible          filespace=d$
                                                    nametype=unicode
                                                    filedata=archive
                                                    durunits=indefinite
                                                    toserver=athens
```

See Field descriptions for field descriptions.

Example: Display information about a running export operation

List information for the currently running export operation with process number "7." Issue the following command:

```
query export process=7

Export          Start Time   State    Process   Command
Identifier                                      ID
----------      ----------   ------   -------   --------
MYEXPORTNODE    01/24/2007   Running    7       Export NODE
                10:30:03                        me,you,them
                                                filespace=c$
                                                nametype=unicode
                                                filedata=all
                                                toserver=athens
                                                exportid=MYEXPORTNODE
```

See Field descriptions for field descriptions.

Example: Display detailed information about all suspended export operations

List information for all currently suspended export operations. Issue the following command:

```
query export state=suspended format=detailed

             Export Identifier: MyExportNode
                    Start Time: 01/24/2007 10:30:03
                         State: Suspended
                    Process Id: --
                       Command: Export NODE m* filespace=c$
                                 nametype=unicode
                                 filedata=all durunits=indefinite
                                 toserver=athens
                         Phase: File list complete. Exporting
                                 eligible files
           Total Running Time: 3 Days 0 Hours 24 Minutes

```

See Field descriptions for field descriptions.

Field descriptions

Export identifier
: The unique identifier assigned to this server-to-server export operation.

Start time
: The time and date that this export operation was first initiated.

State
: The current state of this export operation. The value is one of the following:

  Running - Not Suspendible

The operation is active and is transmitting definitions to the target server. The process cannot be suspended, and if the process fails while in this state, you cannot restart it.

Running
: The operation is active and is either searching for eligible files or transmitting file data to the target server.

Running - Suspend in Progress
: The operation is in the process of being suspended as a result of a SUSPEND EXPORT command. The export operation is fully suspended when all of the data from the export operation is saved. An export operation in this state does not respond to the following commands:

- CANCEL PROCESS
- CANCEL EXPORT
- RESTART EXPORT
- SUSPEND EXPORT

Suspended
: The operation stopped running due to a failure or was suspended with the SUSPEND EXPORT command.

Process ID
: The process ID for the export operation when the status is either "Initializing" or "Running".

Command
: The full command issued to start this server-to-server export.

Phase
: The current step that the operation is performing. The possible phases are shown in the order in which they are performed:

Creating definitions on target server
: The operation is exporting definitions. The process cannot be suspended. Should the process fail in this phase, it cannot be restarted.

Identifying and exporting eligible files
: The operation is building a list of eligible files for export. Some files may also be transmitted to the target during this phase. A process in this phase can be suspended. Should the process fail in this phase, it can be restarted.

File list complete. Exporting eligible files
: The operation has completed building the list of eligible files for export and it is now transmitting the files to the target. A process in this phase can be suspended. Should the process fail in this phase, it can be restarted.

Total running time
: The overall running time for this server-to-server export operation. For example, if this operation started and was then suspended and restarted two times, this value is the total running time of all three active processes of the export operation.

Current® process running time
: The running time of the active process of a server-to-server export operation. No value is displayed for a suspended operation because no active process exists.

Export operation restart count
: The number of times the server-to-server export operation was restarted.

Date and time of last restart
: The last date and time at which this server-to-server export operation was restarted.

Date and time of last suspend
: The last date and time at which this server-to-server export operation was suspended.

Policy domains exported
: The number of policy domain definitions successfully exported to the target server.

Policy sets exported
: The number of policy set definitions successfully exported to the target server.

Schedules exported
: The number of schedule definitions successfully exported to the target server.

Mgmt classes exported
: The number of management class definitions successfully exported to the target server.

Copy groups exported
: The number of copy group definitions successfully exported to the target server.

Administrators exported
: The number of administrator definitions successfully exported to the target server.

Option sets exported
: The number of option set definitions successfully exported to the target server.

Node definitions exported
: The number of node definitions successfully exported to the target server.

File space definitions exported

The number of file space definitions successfully exported to the target server.

Archive files exported
: The number of archive files successfully exported to the target server.

Backup files exported
: The number of backup files successfully exported to the target server.

Space managed files exported
: The number of space managed files successfully exported to the target server.

Archive files skipped
: The number of archive files that were eligible for export but were skipped.

Backup files skipped
: The number of backup files that were eligible for export but were skipped.

Space managed files skipped
: The number of space managed files that were eligible for export but were skipped.

Total bytes transferred (MB)
: The total number of bytes transmitted so far to the target server for this export operation.

Total files to be transferred
: The total number of files transmitted so far to the target server for this export operation.

Files remaining
: The total number of files remaining to be transmitted to the target server for this export operation.

Related commands

Table 1. Commands related to QUERY EXPORT

Command	Description
CANCEL PROCESS	Cancels a background server process.
CANCEL EXPORT	Deletes a suspended export operation.
EXPORT NODE	Copies client node information to external media or directly to another server.
EXPORT SERVER	Copies all or part of the server to external media or directly to another server.
IMPORT NODE	Restores client node information from external media.
IMPORT SERVER	Restores all or part of the server from external media.
QUERY PROCESS	Displays information about background processes.
RESTART EXPORT	Restarts a suspended export operation.
SUSPEND EXPORT	Suspends a running export operation.

AIX Linux Windows

QUERY EXTENTUPDATES (Query updated data extents)

Use this command to display information about updates to data extents in directory-container storage pools and to determine what data extents are deleted and what is eligible for deletion.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query EXTENTUPDates--pool_name-----------------------------><
```

Parameters

pool_name (Required)
: Specifies the storage pool to query. You cannot use wildcards to specify this name.

Example: Display information about updates to data extents

Display information about updates to data extents by issuing the following command:

```
query extentupdates

     Number of Extents Pending Update: 0
        Number of Extents Not Referenced: 0
 Number of Extents Eligible for Deletion: 0
               Extent Reuse Delay (Days): 1
```

See Field descriptions for field descriptions.

Field descriptions

Number of Extents Pending Update
: Specifies the number of data extent references that are pending an update in the directory-container storage pool. Data that is stored in the directory-container storage pool increases the number of references and data deletion decreases the number of references.

Number of Extents Not Referenced
: Specifies the number of data extents that are not referenced in the directory-container storage pool. You can delete the data extents if they are not referenced again within the reuse delay period that is specified on the DEFINE STGPOOL command.

Number of Extents Eligible for Deletion
: Specifies the number of data extents that can be deleted from the storage pool. The data extents exceed the reuse delay period that is specified on the DEFINE STGPOOL command.

Extent Reuse Delay (Days)
: Specifies the reuse delay time, in days, for data extents.

Related commands

Table 1. Commands related to QUERY EXTENTUPDATES

Command	Description
DEFINE STGPOOL (directory-container)	Define a directory-container storage pool.
DELETE STGPOOLDIRECTORY	Deletes a storage pool directory from a directory-container or cloud-container storage pool.

QUERY FILESPACE (Query one or more file spaces)

Use this command to display information about file spaces that belong to a client node. The output from this command includes the results of the last incremental backup or replication.

Tip: If a node has more than one file space, you can issue a DELETE FILESPACE command for one of the file spaces. However, if you issue a QUERY FILESPACE command for the node during the deletion process, the output shows no file spaces. To obtain accurate information about remaining file spaces, issue the QUERY FILESPACE command after the deletion process ends.

Privilege class

Any administrator can issue this command.

Syntax

```
                    .-*--*--------------------------.
>>-Query FIlespace--+------------------------------+---------->
                    |            .-*---------------. |
                    '-node_name--+-----------------+-'
                                 '-file_space_name-'

   .-Format--=--Standard-----.  .-NAMEType--=--SERVER------.
>--+-------------------------+--+-------------------------+---->
   '-Format--=--+-Standard-+-'  '-NAMEType--=--+-SERVER--+-'
```

```
                '-Detailed-'                    +-UNIcode-+
                                                '-FSID----'

   .-CODEType---=--BOTH-----------.
>--+-----------------------------+-----------------------------><
   '-CODEType---=--+-UNIcode----+-'
                   +-NONUNIcode-+
                   '-BOTH-------'
```

Parameters

node_name
: Specifies the client node to which the file space belongs. You can use wildcard characters to specify this name. This parameter is optional. The default is all client node names.

  You must specify a value for this parameter if you specify a file name.

file_space_name
: Specifies the name of the file space to be queried. You can use wildcard characters to specify this name. This parameter is optional. If a value is not specified, all file spaces are queried.

  If a server includes clients that use Unicode-enabled files spaces, the server might have to convert the name that you enter. For example, the server might have to convert the file space name that you enter from the server code page to Unicode. For more information, see the NAMETYPE parameter. If you do not specify a file space name, or if you specify only a single wildcard character for the name, you can use the CODETYPE parameter to limit the operation to Unicode file spaces or to non-Unicode file spaces.

  File space names are case-sensitive. You can use the QUERY FILESPACE command to determine the correct capitalization for the file space to be queried.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. You can specify one of the following values:

  Standard
  : Specifies that partial information is displayed for the specified file space.

  Detailed
  : Specifies that complete information is displayed for the specified file space.

NAMEType
: Specify how you want the server to interpret the file space names that you enter. This parameter is useful when the server has clients with support for Unicode. You can use this parameter for Unicode-enabled IBM Spectrum Protect™ clients that have Windows, Macintosh OS X, and NetWare operating systems.

  Use this parameter only when you enter a partly qualified or fully qualified file space name. The default value is SERVER. You can specify one of the following values:

  SERVER
  : The server uses the server code page to interpret the file space names.

  UNIcode
  : The server converts the file space name that is entered from the server code page to the UTF-8 code page. The success of the conversion depends on the actual characters in the name and the server code page. Conversion can fail if the string includes characters that are not available in the server code page, or if the server has problems accessing system conversion routines.

  FSID
  : The server interprets the file space names as their file space IDs (FSIDs).

CODEType
: Specify what type of file spaces are to be included in the operation. The default is BOTH, meaning that file spaces are included regardless of code page type. Use this parameter only when you enter a single wildcard character for the file space name. You can specify one of the following values:

  UNIcode
  : Include only file spaces that are in Unicode.

  NONUNIcode

Include only file spaces that are not in Unicode.

BOTH
Include file spaces regardless of code page type.

Example: List all file spaces

Query all file spaces that are associated with all client nodes.

```
query filespace

Node   Filespace   FSID  Platform  Filespace    Is      Capacity Pct
Name   Name                        Type      Filespace          Util
                                             Unicode?
------ ---------- ----  --------  --------  --------  -------- ----
JOE    \\joe\c$       1  WinNT     NTFS        Yes     2,502.3  75.2
JOE    \\joe\d$       2  WinNT     NTFS        Yes     6,173.4  59.6
```

See Field descriptions for field descriptions.

Example: Display detailed file space information for a virtual file space

Display detailed information for the file space /HomeDir, which is a virtual file space mapping and belongs to the NAS node NAS1.

```
query filespace nas1 /HomeDir

Node   Filespace   FSID  Platform  Filespace     Is     Capacity Pct
Name   Name                        Type      Filespace          Util
                                              Unicode?
----   ---------- ----  --------  --------  ---------  -------- ----
NAS1   /HomeDir     1    NetApp    WAFL (VFS)     No     2,502.3  75.2
```

See Field descriptions for field descriptions.
Important: You might not see the expected results after you request a detailed format because several fields must be completed by the API application. These fields include:

- File space type
- Platform
- Capacity
- Pct Util
- Last backup start Date/Time
- Last backup completion Date/Time

For more information about specific fields that are updated by the API, see the *IBM Spectrum Protect: Using the Application Programming Interface*.

Example: Display detailed file space information for a specific file space and node

Display detailed information about the \\joe\c$ file space that belongs to the client node JOE.

```
query filespace joe \\joe\c$ nametype=unicode format=detailed

                                 Node Name: JOE
                             Filespace Name: \\joe\c$
                    Hexadecimal Filespace Name: 5c5c6a6f655c6324
                                       FSID: 1
                        Collocation Group Name: FSGRP1
                                     Platform: WinNT
                             Filespace Type: NTFS
                          Is Filespace Unicode?: Yes
                                     Capacity: 2,502.3
                                     Pct Util: 75.2
                    Last Backup Start Date/Time:
                  Days Since Last Backup Started:
                Last Backup Completion Date/Time:
                Days Since Last Backup Completed:
                Last Replication Start Date/Time: 12/02/2012, 12:42:00
       Days Since Last Node Replication Started: 30
          Last Replication Completion Date/Time: 12/02/2012, 12:42:00
          Days Since Last Replication Completed: 30
```

Field descriptions

Important: You might not see the expected results after requesting a detailed format because several fields must be completed by the API application. These fields include:

- Filespace Type
- Platform
- Capacity
- Pct Util
- Last Backup Start Date/Time
- Last Backup Completion Date/Time

For more information about specific fields that are updated by the API, see the *IBM Spectrum Protect: Using the Application Programming Interface*.

Node Name
: Specifies the name of the client node.

Filespace Name
: The name of the file space that belongs to the node.

  File space names can be in a different code page or locale than the server. If they are, the names in the Operations Center and the administrative command-line interface might not be displayed correctly. Data is backed up and can be restored normally, but the file space name or file name might be displayed with a combination of invalid characters or blank spaces.

  If the file space name is Unicode-enabled, the name is converted to the server code page for display. The success of the conversion depends on the operating system, the characters in the name, and the server code page. Conversion can be incomplete if the string includes characters that are not available in the server code page or if the server cannot access system conversion routines. If the conversion is incomplete, the name might contain question marks, blanks, unprintable characters, or ellipses (...).

Hexadecimal Filespace Name
: Specifies the hexadecimal name of the file space for the client node in UTF-8 format.

FSID
: Specifies the file space ID of the file space.

Collocation Group Name
: The name of the collocation group, if any, to which the file space belongs.

Platform
: Specifies the platform for the client node.

Filespace Type
: Specifies the type of file space.

  A file space type that is appended with "(VFS)" denotes that this file space name is a virtual file space mapping for a directory path on a NAS device.

Is Filespace Unicode?
: Indicates whether the file space is Unicode.

Capacity
: Specifies the amount of space, in megabytes, assigned to this file space on the client node.

For a file space that is a virtual file space mapping for a directory path, this field represents the capacity of the file space on which the directory path is located.

Pct Util
: Specifies the percentage of the file space that is occupied.

  For a file space that is a virtual file space mapping for a directory path, the percentage used is calculated as the percentage of the capacity of the file space that was occupied by the directory at the time of the last full backup.

Last Backup Start Date/Time
: Specifies the start date and time of the last incremental backup of the file space.

Days Since Last Backup Started
: Specifies the number of days since the start of the last incremental backup of the file space.

Last Backup Completion Date/Time
: Specifies the completion date and time of the last incremental backup of the file space.

Days Since Last Backup Completed
: Specifies the number of days since the completion of the last incremental backup of the file space.

Last Replication Start Date/Time
: Specifies the date and time that the last replication of file space data started.

Days Since Last Replication Started
: Specifies the number of days since the last replication of file space data started.

Last Replication Completion Date/Time
: Specifies the date and time that the last replication of file space data ended.

Days Since Last Replication Completed
: Specifies the number of days since the last replication of file space data ended.

Last Backup Date/Time From Client (UTC)
: The date and time, in Universal Time Coordinates (UTC), of the last backup operation for this file space.

Last Archive Date/Time From Client (UTC)
: The date and time, in Universal Time Coordinates (UTC), of the last archive operation for this file space.

Backup Replication Rule Name
: Specifies the replication rule that applies to backup data in the file space. The following values are possible:

  ALL_DATA
  : Replicates active and inactive backup data. The data is replicated with a normal priority.

  ACTIVE_DATA
  : Replicates only active backup data. The data is replicated with a normal priority.
    Attention: If you specify ACTIVE_DATA and one or more of the following conditions are true, inactive backup data on the target replication server is deleted, and inactive backup data on the source replication server is not replicated.

    - When a server version earlier than Version 7.1.1 is installed on either the source or target replication servers.
    - When you are using the REPLICATE NODE command with the `FORCERECONCILE=YES` parameter.
    - When you are running the initial replication of a file space after you configure replication, restore the database, or upgrade both the source and target replication servers from a server version earlier than V7.1.1.

    If the previous conditions are not true, all new and changed files since the last replication are replicated, including inactive files, and files are deleted when they expire.

  ALL_DATA_HIGH_PRIORITY
  : Replicates active and inactive backup data. The data is replicated with a high priority.

  ACTIVE_DATA_HIGH_PRIORITY

    This rule is the same as the ACTIVE_DATA replication rule except data is replicated with a high priority.

  DEFAULT
  : Replicates backup data according to the client node rule for backup data. If the client node rule for backup data is DEFAULT, backup data is replicated according to the server rule for backup data.

  NONE
  : Backup data in the file space is not replicated.

Backup Replication Rule State
: Specifies whether replication of backup data in the file space is enabled or disabled. If the state is ENABLED, backup files are eligible for replication. If the state is DISABLED, backup files are not eligible for replication.

Archive Replication Rule Name
: Specifies the replication rule that applies to archive data in the file space. The following values are possible:

ALL_DATA
Replicates archive data. The data is replicated with a normal priority.
ALL_DATA_HIGH_PRIORITY
Replicates archive data. The data is replicated with a high priority.
DEFAULT
Replicates archive data according to the client rule for archive data. If the client rule for archive data is DEFAULT, archive data is replicated according to the server rule for archive data.
NONE
Archive data in the file space is not replicated.

Archive Replication Rule State
Specifies whether replication of archive data in the file space is enabled or disabled. If the state is ENABLED, archive files are eligible for replication. If the state is DISABLED, archive files are not eligible for replication.
Space Management Replication Rule Name
Specifies the replication rule that applies to space-managed data in the file space. The following values are possible:

ALL_DATA
Replicates space-managed data. The data is replicated with a normal priority.
ALL_DATA_HIGH_PRIORITY
Replicates space-managed data. The data is replicated with a high priority.
DEFAULT
Replicates space-managed data according to the client rule for space-managed data. If the client rule for space-managed data is DEFAULT, space-managed data is replicated according to the server rule for space-managed data.
NONE
Space-managed data in the file space is not replicated.

Space Management Replication Rule State
Specifies whether replication of space-managed data in the file space is enabled or disabled. If the state is ENABLED, space-managed files are eligible for replication. If the state is DISABLED, space-managed files are not eligible for replication.
At-risk type
Specifies the at-risk evaluation type. Values can be Default, Bypassed, or Custom. Default indicates that the node is evaluated with the same interval that was specified for the nodes classification by the SET STATUSATRISKINTERVAL command. Bypassed indicates that the node is not evaluated for at-risk status by the status monitor. Custom indicates that the node is evaluated with the interval that was specified by the SET VMATRISKINTERVAL command, rather than the interval that was specified by the SET STATUSATRISKINTERVAL command.
At-risk interval
Specifies the amount of time, in hours, between client backup activity before the status monitor considers the client at-risk. This field applies only when the at-risk type is Custom.
Decommissioned
Specifies whether the virtual machine that the file space represents is decommissioned.
Decommissioned Date
Specifies the date that the virtual machine that the file space represents was decommissioned.
MAC Address
Specifies the media access control (MAC) address of the file spaces backed up for VMWare virtual machines. In the case where the virtual machine has multiple MAC addresses this is the lowest valued address.

Related commands

Table 1. Commands related to QUERY FILESPACE

Command	Description
DEFINE VIRTUALFSMAPPING	Define a virtual file space mapping.
DELETE FILESPACE	Deletes data associated with client file spaces. If a file space is part of a collocation group and you remove the file space from a node, the file space is removed from the collocation group.
REGISTER NODE	Defines a client node to the server and sets options for that user.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.

Command	Description
RENAME FILESPACE	Renames a client filespace on the server.
UPDATE FILESPACE	Changes file-space node-replication rules.
UPDATE NODE	Changes the attributes that are associated with a client node.

QUERY LIBRARY (Query a library)

Use this command to display information about libraries.

Privilege class

Any administrator can issue this command.

Syntax

```
                  .-*------------.
>>-Query LIBRary--+--------------+----------------------------->
                  '-library_name-'

   .-Format--=--Standard-----.
>--+-------------------------+-------------------------------><
   '-Format--=--+-Standard-+-'
                '-Detailed-'
```

Parameters

library_name
: Specifies the name of the library to be queried. You can use wildcards to specify names. This parameter is optional.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed for the library.

  Detailed
  : Specifies that complete information is displayed for the library.

Example: Display summary information about a specific library

Display information about the library named AUTO. Issue the command:

```
query library auto
```

```
         Library Name: AUTO
         Library Type: SCSI
              ACS Id:
     Private Category:
     Scratch Category:
WORM Scratch Category:
     External Manager:
               Shared: No
             LanFree:
   ObeyMountRetention:
```

See Field descriptions for field descriptions.

Example: Display detailed library information about a specific library

Display information in full detail about the library named EZLIFE. Issue the command: AIX Linux

```
query library ezlife format=detailed
```

AIX Linux

```
                 Library Name: EZLIFE
                 Library Type: SCSI
                       ACS Id:
              Private Category:
              Scratch Category:
        WORM Scratch Category:
              External Manager:
                       Shared: Yes
                     LanFree:
           ObeyMountRetention:
      Primary Library Manager: EZSERVER
                         WWN:
                Serial Number:
                    AutoLabel: OVERWRITE
             Relabel Scratch: Yes
Last Update by (administrator): DOCTOR_MIKE
         Last Update Date/Time: 2002-12-05 15:24:53
```

Windows

```
                 Library Name: EZLIFE
                 Library Type: SCSI
                       ACS Id:
              Private Category:
              Scratch Category:
        WORM Scratch Category:
              External Manager:
                       Shared: YES
                     LanFree:
           ObeyMountRetention:
      Primary Library Manager: EZSERVER
                         WWN:
                Serial Number:
                    AutoLabel: OVERWRITE
                Reset Drives: No
             Relabel Scratch: Yes
Last Update by (administrator): DOCTOR_MIKE
         Last Update Date/Time: 2000-12-05 15:24:53
```

See Field descriptions for field descriptions.

Field descriptions

Library Name
: The name of the library.

Library Type
: The type of library.

ACS Id
: Specifies that the library is a StorageTek library that is controlled by StorageTek Automated Cartridge System Library Software (ACSLS).

Private Category
: The category number for private volumes that must be mounted by name.

  The information that is displayed in this field applies only to an IBM® 3494 or 3495 Tape Library Dataserver.

Scratch Category
: The category number to use for scratch volumes in the library.

  The information that is displayed in this field applies only to an IBM 3494 or 3495 Tape Library Dataserver.

WORM Scratch Category
: The category number that is used for WORM scratch volumes in the library.

  The information that is displayed in this field applies only to an IBM 3494 or 3495 Tape Library Dataserver.

External Manager
: The location of the external library manager where the server can send media access requests.

Shared
: Whether this library is shared with other IBM Spectrum Protect™ servers in a storage area network (SAN).

LanFree

Whether an external library is used for LAN-free operations.

ObeyMountRetention
: Whether the server uses the value that is set for mount retention in the device class that is associated with this external library.

Primary Library Manager
: The name of the server that is responsible for controlling access to library resources.

WWN
: The Fibre Channel worldwide name for the library.

Serial Number
: Specifies the serial number for the library that is being queried.

AutoLabel
: Specifies whether the server attempts to automatically label tape volumes.

AIX Windows Reset Drives
: AIX Windows Specifies whether the server completes a target reset when the server is restarted or when a library client or storage agent re-connection is established.

Relabel Scratch
: Specifies whether the server relabels volumes that were deleted and returned to scratch.

Last Update by (administrator)
: Who completed the last update to the library.

Last Update Date/Time
: The date and time when the last update occurred.

Related commands

Table 1. Commands related to QUERY LIBRARY

Command	Description
AUDIT LIBRARY	Ensures that an automated library is in a consistent state.
DEFINE LIBRARY	Defines an automated or manual library.
DEFINE PATH	Defines a path from a source to a destination.
DELETE LIBRARY	Deletes a library.
QUERY PATH	Displays information about the path from a source to a destination.
UPDATE LIBRARY	Changes the attributes of a library.

QUERY LIBVOLUME (Query a library volume)

Use this command to display information about one or more volumes that are checked into an automated library for use by the IBM Spectrum Protect™ server.

Privilege class

Any administrator can issue this command.

Syntax

```
                    .-*------------.  .-*-----------.
>>-Query LIBVolume--+--------------+--+-------------+----------->
                    '-library_name-'  '-volume_name-'

   .-Format--=--Standard-----.
>--+-------------------------+-------------------------------><
   '-Format--=--+-Standard-+-'
                '-Detailed-'
```

Parameters

library_name

Specifies the name of the library. You can use wildcard characters to specify this name. This parameter is optional. The default is all libraries.

volume_name
: Specifies the volume name. You can use wildcard characters to specify this name. This parameter is optional. The default is all volumes.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed.

Example: List checked in volumes for a specific library

Display information about all of the volumes that are checked into the library named TAPE. See Field descriptions for field descriptions.

```
query libvolume tape
```

```
Library Name  Volume Name  Status   Owner   Last Use   Home     Device
                                                      Element  Type
------------  -----------  -------- ------- --------   ------  ------
TAPE          000114       Scratch                     1,000    LTO
TAPE          NY1602       Scratch                     1,001    DLT
```

Example: Display detailed information for a specific library

Display detailed information about a volume named JJY008. See Field descriptions for field descriptions.

```
query libvolume jjy008 format=detailed
```

```
                        Library Name: HPW3494
                         Volume Name: JJY008
                              Status: Private
                               Owner: SUNSET
                           Last Use: Data
                        Home Element:
                         Device Type:
                      Cleanings Left:
                          Media Type:
```

Field descriptions

Library Name
: The name of the library where the storage volume is located.

Volume Name
: The name of the storage volume.

Status
: The status of the storage volume according to the library inventory. If the status is Private, the volume is being used by IBM Spectrum Protect. If the status is Scratch, the volume is available for use.

Owner
: The owner server of the volume, if the volume is private.

Last Use
: The type of data on the volume. This field applies only to volumes in Private status. For storage pool volumes, this field shows **Data**. For database backup volumes (full, incremental, or snapshot), this field shows **DbBackup**.

Home Element
: The element address of the library slot containing the volume.

Device Type
: The type of device that the volume is used on. This field will display a value only for volumes checked into a library that has mixed media capabilities.

Cleanings Left
: For cleaner cartridges, the number of cleanings left.

Media Type
: The type of media the volume represents (for example, 8mm tape).

Related commands

Table 1. Commands related to QUERY LIBVOLUME

Command	Description
AUDIT LIBRARY	Ensures that an automated library is in a consistent state.
CHECKIN LIBVOLUME	Checks a storage volume into an automated library.
CHECKOUT LIBVOLUME	Checks a storage volume out of an automated library.
DEFINE VOLUME	Assigns a volume to be used for storage within a specified storage pool.
LABEL LIBVOLUME	Labels volumes in manual or automated libraries.
QUERY LIBRARY	Displays information about one or more libraries.
UPDATE LIBVOLUME	Changes the status of a storage volume.

QUERY LICENSE (Display license information)

Use this command to display license audit, license terms, and compliance information.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query LICense-----------------------------------------------><
```

Parameters

None.

To display the license information, issue the following command:

```
query license
```

The following example output is displayed:

```
                            ANR2017I Administrator
                     SERVER_CONSOLE issued command: QUERY LICENSE
                               Last License Audit: 10/17/2016

Field descriptions

Last License Audit
: Specifies the date and time when the last license audit occurred.

Number of Data Protection for Oracle in use
: Specifies the number of Data Protection for Oracle that are in use. A product is in use if you purchased the product and registered the license.

Number of Data Protection for Oracle in try buy mode
: Specifies the number of Data Protection for Oracle that are in try buy mode.

Number of Data Protection for Microsoft SQL in use
: Specifies the number of Data Protection for Microsoft SQL that are in use. A product is in use if you purchased the product and registered the license.

Number of Data Protection for Microsoft SQL in try buy mode
: Specifies the number of Data Protection for Microsoft SQL that are in try buy mode.

Number of Data Protection for Microsoft Exchange in use
: Specifies the number of Data Protection for Microsoft Exchange that are in use. A product is in use if you purchased the product and registered the license.

Number of Data Protection for Microsoft Exchange in try buy mode
: Specifies the number of Data Protection for Microsoft Exchange that are in try buy mode.

Number of TDP for Lotus Notes® in use
: Specifies the number of TDP for Lotus Notes that are in use. A product is in use if you purchased the product and registered the license.

Number of TDP for Lotus Notes in try buy mode
: Specifies the number of TDP for Lotus Notes that are in try buy mode.

Number of Data Protection for Lotus® Domino® in use
: Specifies the number of Data Protection for Lotus Domino that are in use. A product is in use if you purchased the product and registered the license.

Number of Data Protection for Lotus Domino in try buy mode
: Specifies the number of Data Protection for Lotus Domino that are in try buy mode.

Number of TDP for Informix® in use
: Specifies the number of TDP for Informix that are in use. A product is in use if you purchased the product and registered the license.

Number of TDP for Informix in try buy mode
: Specifies the number of TDP for Informix that are in try buy mode.

Number of TDP for SAP R/3 in use
: Specifies the number of TDP for SAP R/3 that are in use. A product is in use if you purchased the product and registered the license.

Number of TDP for SAP R/3 in try buy mode
: Specifies the number of TDP for SAP R/3 that are in try buy mode.

Number of TDP for ESS in use
: Specifies the number of TDP for ESS that are in use. A product is in use if you purchased the product and registered the license.

Number of TDP for ESS in try buy mode

Specifies the number of TDP for ESS that are in try buy mode.

Number of TDP for ESS R/3 in use
: Specifies the number of TDP for ESS R/3 that are in use. A product is in use if you purchased the product and registered the license.

Number of TDP for ESS R/3 in try buy mode
: Specifies the number of TDP for ESS R/3 that are in try buy mode.

Number of TDP for EMC Symmetrix in use
: Specifies the number of TDP for EMC Symmetrix that are in use. A product is in use if you purchased the product and registered the license.

Number of TDP for EMC Symmetrix in try buy mode
: Specifies the number of TDP for EMC Symmetrix that are in try buy mode.

Number of TDP for EMC Symmetrix R/3 in use
: Specifies the number of TDP for EMC Symmetrix R/3 that are in use. A product is in use if you purchased the product and registered the license.

Number of TDP for EMC Symmetrix R/3 in try buy mode
: Specifies the number of TDP for EMC Symmetrix R/3 that are in try buy mode.

Number of TDP for WAS in use
: Specifies the number of TDP for WAS that are in use. A product is in use if you purchased the product and registered the license.

Number of TDP for WAS in try buy mode
: Specifies the number of TDP for WAS that are in try buy mode.

Is IBM Spectrum Protect™ for Data Retention in use ?
: Specifies whether the IBM Spectrum Protect for Data Retention is in use. A product is in use if you purchased the product and registered the license.

Is IBM Spectrum Protect for Data Retention licensed ?
: Specifies whether the IBM Spectrum Protect for Data Retention is licensed.

Is IBM Spectrum Protect Basic Edition in use
: Specifies whether the IBM Spectrum Protect Basic Edition is in use. A product is in use if you purchased the product and registered the license.

Is IBM Spectrum Protect Basic Edition licensed
: Specifies whether the IBM Spectrum Protect Basic Edition is licensed.

Is IBM Spectrum Protect Extended Edition in use
: Specifies whether the IBM Spectrum Protect Extended Edition is in use. A product is in use if you purchased the product and registered the license.

Is IBM Spectrum Protect Extended Edition licensed
: Specifies whether the IBM Spectrum Protect Extended Edition is licensed.

Server License Compliance
: Specifies whether the server license is valid.

Related commands

Table 1. Commands related to QUERY LICENSE

Command	Description
AUDIT LICENSES	Verifies compliance with defined licenses.
QUERY AUDITOCCUPANCY	Displays the server storage utilization for a client node.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY PVUESTIMATE	Displays processor value unit estimates. Remember: The QUERY PVUESTIMATE command reports licenses by providing PVU information on a per-node basis for server devices.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REGISTER LICENSE	Registers a license with the IBM Spectrum Protect server.
REGISTER NODE	Defines a client node to the server and sets options for that user.

Command	Description
SET CPUINFOREFRESH	Specifies the number of days between client scans for workstation information used for PVU estimates.
SET LICENSEAUDITPERIOD	Specifies the number of days between automatic license audits.
UPDATE NODE	Changes the attributes that are associated with a client node.

QUERY LOG (Display information about the recovery log)

Use this command to display information about the recovery log.

Privilege class

Any administrator can issue this command.

Syntax

```
              .-Format--=--Standard-----.
>>-Query LOG--+-------------------------+----------------------><
              '-Format--=--+-Standard-+-'
                           '-Detailed-'
```

Parameters

Format
: Specifies how the information is displayed. This parameter is optional. The default is STANDARD. The following values are possible:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed.

Example: Display summary information about the recovery log

Display summary information about the recovery log. See Field descriptions for field descriptions.

```
query log
```

```
Total Space (MB)    Used Space (MB)     Free Space (MB)
----------------    ---------------     ---------------
          38,912              543.3            38,368.7
```

AIX | Linux

Example: Display detailed information about the recovery log

Display detailed information about the recovery log. See Field descriptions for field descriptions.

```
query log format=detailed
```

```

Archive Failover Log Directory :
Total Size of File System (MB):
Used Space on File System (MB):
Free Space on File System (MB):
```

Field descriptions

Total Space
: Specifies the maximum size of the active log, in megabytes.

Used Space
: Specifies the amount of used active log space, in megabytes.

Free Space
: Specifies the amount of active log space that is not being used by uncommitted transactions, in megabytes.

Total Size of File System
: Specifies the total size of the file system, in megabytes.

Space Used on File System
: Specifies the amount of used space on the file system, in megabytes.

Free Space on File System
: Specifies the amount of space that is available on the file system, in megabytes.

Archive Log Compressed
: Specifies whether the archive logs are compressed.

Active Log Directory
: Specifies the location where active log files are stored. When you change the active log directory, the server moves all archived logs to the archive log directory and all active logs to a new active log directory.

Mirror Log Directory
: Specifies the location where the mirror for the active log is maintained.

Archive Failover Log Directory
: Specifies the location into which the server saves archive logs if the logs cannot be archived to the archive log directory.

Archive Log Directory
: Specifies the location into which the server can archive a log file after all the transactions that are represented in that log file are completed.

QUERY MACHINE (Query machine information)

Use this command to display information for one or more machines. You can use this information to recover IBM Spectrum Protect™ client machines in case of a disaster.

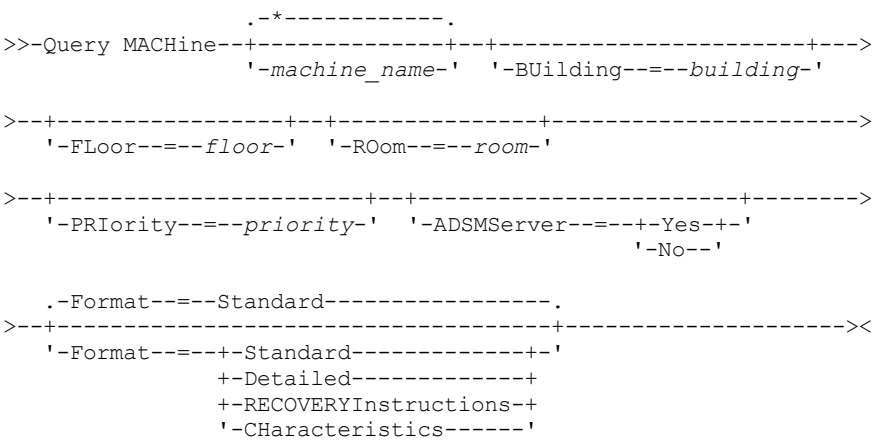
Attention: IBM Spectrum Protect does not use the information in any way. It is available only to help you plan for the disaster recovery of client machines.
IBM Spectrum Protect displays information for multiple machines in the following order:

- According to the priority specified.
- Within a priority, according to the specified location and machine name.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

machine_name
: Specifies the name of one or more machines to be queried. You can use wildcard characters to specify this name. This parameter is optional. The default is all machines that meet the specified criteria.

BUilding
: Specifies the name or number of the building that the machines are in. This parameter is optional. Enclose the text in quotation marks if it contains any blank characters.

FLoor
: Specifies the name or number of the floor that the machines are on. This parameter is optional. Enclose the text in quotation marks if it contains any blank characters.

ROom
: Specifies the name or number of the room that the machines are in. This parameter is optional. The text can be up to 16 characters. Enclose the text in quotation marks if it contains any blank characters.

PRIority

Specifies the priority number of the machines. This parameter is optional.

ADSMServer
: Specifies if the machine contains an IBM Spectrum Protect server. This parameter is optional. The default is to display any machines that meet the other criteria. Possible values are:

  Yes
  : The machine contains an IBM Spectrum Protect server.

  No
  : The machines do not contain an IBM Spectrum Protect server.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

  Standard
  : Displays partial information for the machines.

  Detailed
  : Displays all information for the machines.

  RECOVERYInstructions
  : Displays only machine recovery instructions. This option is valid only when querying a specific machine.

  CHaracteristics
  : Displays only machine characteristics. This option is valid only when querying a specific machine.

Example: Display information for a specific machine

Display information for a machine named MACH1. See Field descriptions for field descriptions.

```
query machine MACH1
```

```
Machine  Machine  Building Floor Room  Node Name  Recovery
Name     Priority                               Media Name
-------  -------- -------- ----- -----  ---------  ----------
MACH1       1       21       2   2929  VIRGINIA   RECMED1
```

Example: Display detailed information for priority 1 machines

Display detailed information for all priority 1 machines on the second floor of building 21. See Field descriptions for field descriptions.

```
query machine * building=21 floor=2 priority=1
format=detailed
```

```
                 Machine Name: MACH1
              Machine Priority: 1
                      Building: 21
                         Floor: 2
                          Room: 2929
                       Server?: Yes
                   Description: TSM server machine
                     Node Name: VIRGINIA
          Recovery Media Name: RECMED1
             Characteristics?: Yes
       Recovery Instructions?: Yes
```

Field descriptions

Machine Name
: The name of the machine.

Machine Priority
: The recovery priority of the machine.

Building
: The building in which the machine is located.

Floor
: The floor on which the machine is located.

Room
: The room in which the machine is located.

Server?

Whether the machine contains an IBM Spectrum Protect server.

Description
: A description of the machine.

Node Name
: The IBM Spectrum Protect client nodes associated with this machine.

Recovery Media Name
: The recovery media associated with this machine.

Characteristics?
: Whether the characteristics text of the machine is stored in the database.

Recovery Instructions?
: Specifies whether recovery instructions text for a machine is stored in the IBM Spectrum Protect database.

Related commands

Table 1. Commands related to QUERY MACHINE

Command	Description
DEFINE MACHINE	Defines a machine for DRM.
DEFINE MACHNODEASSOCIATION	Associates an IBM Spectrum Protect node with a machine.
DEFINE RECMEDMACHASSOCIATION	Associates recovery media with a machine.
DELETE MACHINE	Deletes a machine.
INSERT MACHINE	Inserts machine characteristics or recovery instructions into the IBM Spectrum Protect database.
UPDATE MACHINE	Changes the information for a machine.

QUERY MEDIA (Query sequential-access storage pool media)

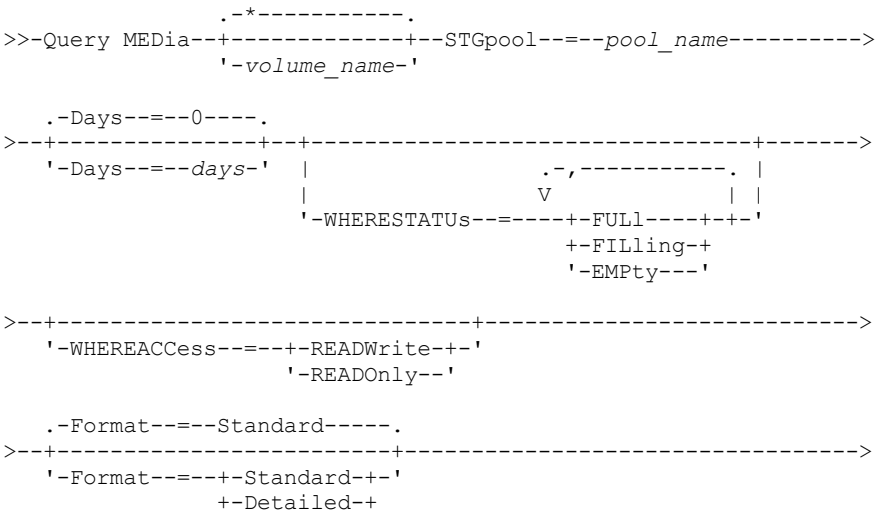
Use this command to display information about the sequential-access primary and copy storage pool volumes moved by the MOVE MEDIA command.

Privilege class

Any administrator with system or operator privilege can issue this command unless it includes the CMD parameter. If the CMD parameter is specified and the REQSYSAUTHOUTFILE server option is set to NO, the administrator must have operator, unrestricted storage, or system privilege. If the CMD parameter is specified and the REQSYSAUTHOUTFILE server option is set to YES (the default), the administrator must have system privilege.

The QUERY MEDIA command displays only volumes with an ACCESS MODE value of READONLY or READWRITE.

Syntax



```
                '-Cmd------'

>--+-------------------------------------+--------------------->
   '-WHERESTate--=--+-All---------------+-'
                    +-MOUNTABLEInlib----+
                    '-MOUNTABLENotinlib-'

>--+--------------------------------+--+--------------------+----->
   '-WHEREOVFLOcation--=--location-'  '-CMd--=--"command"-'

                                  .-APPend--=--No------.
>--+---------------------------+--+--------------------+------><
   '-CMDFilename--=--file_name-'  '-APPend--=--+-No--+-'
                                               '-Yes-'
```

Parameters

volume_name
: Specifies the name of the sequential-access primary or copy storage pool volume to display. This parameter is optional. You can use a wildcard character to specify the name. All matching volumes are considered for processing. If you do not specify this parameter, all volumes defined in the storage pool specified with the STGPOOL parameter display.

STGpool (Required)
: Specifies the name of the sequential-access primary or copy storage pool that is used to select the volumes for processing. You can use wildcard characters to specify the name. All matching storage pools are processed. If the storage pool specified is not managed by an automated library, no volumes display.

Days
: Specifies the number of days that must elapse, after the volume has been written to or read from, before the volume is eligible for processing. This parameter is optional. You can specify a number from 0 to 9999. The default value is 0. The most recent of the volume's last written date or last read date is used to calculate the number of days elapsed.

WHERESTATUs
: Specifies that the output of the query should be restricted by volume status. This parameter is optional. You can specify more than one status in a list by separating each status with a comma and no intervening spaces. If you do not specify a value for this parameter, all volumes in the specified storage pool, regardless of their status, are displayed.

  Possible values are:

  FULl
  : Specifies that volumes with a status of FULL display.

  FILling
  : Specifies that volumes with a status of FILLING display.

  EMPty
  : Specifies that volumes with a status of EMPTY display.

WHEREACCess
: Specifies that output should be restricted by volume access mode. This parameter is optional. If you do not specify a value for this parameter, output is not restricted by access mode.

  Possible values are:

  READWrite
  : Specifies that volumes with an access mode of READWRITE display.

  READOnly
  : Specifies that volumes with an access mode of READONLY display.

Format
: Specifies how information displays. This parameter is optional. The default value is STANDARD. Possible values are:

  Standard
  : Specifies that partial information displays for the specified sequential access storage pool volumes.

  Detailed
  : Specifies that complete information displays for the specified sequential access storage pool volumes.

  Cmd
  : Specifies that executable commands are built for the storage pool volumes processed by the QUERY MEDIA command. These commands will be in the file specified with the CMDFILENAME parameter on the QUERY MEDIA command. If you want the commands to display on the console only, specify a null string ("") for the CMDFILENAME.

If FORMAT=CMD is specified but no command string is specified with the CMD parameter, the QUERY MEDIA command will fail.

WHERESTate
Specifies the state of volumes to process. This parameter restricts processing to volumes that have the specified state. This parameter is optional. The default is ALL. Possible values are:

All
Specifies that volumes in all states are queried. The valid states are: MOUNTABLEINLIB and MOUNTABLENOTINLIB.
MOUNTABLEInlib
Specifies that volumes that are currently in the MOUNTABLEINLIB state are queried. Volumes in the MOUNTABLEINLIB state are in the library, and are onsite, contain valid data, and are available for onsite processing.
MOUNTABLENotinlib
Specifies that volumes that are currently in the MOUNTABLENOTINLIB state are queried. Volumes in the MOUNTABLENOTINLIB state are not in the library, do not contain valid data, and are not available for onsite processing.

WHEREOVFLOcation
Specifies the overflow location of the volumes to display. This parameter is optional. This parameter restricts processing to volumes that are in the specified location. The maximum length of the location is 255 characters. The location must be enclosed in quotation marks if it contains any blank characters.

CMd
Specifies the creation of executable commands. Enclose the command specification in quotation marks. The maximum length of the command specification is 255 characters. This parameter is optional.

For each volume successfully processed by the QUERY MEDIA command, the server writes the associated commands to a file. Specify the file name with the CMDFILENAME parameter.

AIX Linux If you do not specify a filename, the command will generate a default filename by appending the string exec.cmds.media to the server directory.

Windows If you do not specify a filename, the command will generate a default filename by appending the string exec.cmd.media to the server directory.

Remember:

1. If the command written to the file exceeds 255 characters, it is split into multiple lines, and a continuation character (+) is added to all but the last line. You may need to alter the continuation character according to the requirements of the product that runs the commands.
2. If an executable command is specified with any value for FORMAT other than CMD, the command string is ignored, and the QUERY MEDIA command will not write any command line.

Specify a command string and any substitution variables:

string
Specifies the string to build an executable command to process the volume name or volume location or both. You can specify any free form text for the string. Do not use embedded quotation marks. For example, the following is a valid executable command specification:

```
cmd="checkin libvolume &vol"
```

The following is an invalid executable command specification:

```
cmd="checkin libvolume "&vol""
```

substitution
Specifies a variable for which you want the QUERY MEDIA command to substitute a value. The possible substitution variables are:

&VOL
Substitute the volume name for &VOL. You can specify lowercase characters, &vol. No spaces or blanks are allowed between ampersand, &, and VOL. If there are spaces or blanks between ampersand and VOL, the QUERY MEDIA command will treat them as strings and no substitution will be set. If &VOL is not specified, no volume name is set in the executable command.
&LOC

Substitute the volume location for &LOC. You can specify lowercase characters, &loc. No spaces or blanks are allowed between ampersand, &, and LOC. If there are spaces or blanks between ampersand and LOC, the QUERY MEDIA command will treat them as strings and no substitution will be set. If &LOC is not specified, no location name is set in the executable command.

&VOLDSN

Substitute the volume file name for &VOLDSN. An example of a copy storage pool tape volume file name using the defined prefix IBM Spectrum Protect™310 is IBM Spectrum Protect310.BFS. If &VOLDSN is not specified, no volume file name is set in the executable command.

&NL

Substitute the new line character for &NL. When &NL is specified, the QUERY MEDIA command will split the command at the position where the &NL is and will not append any continuation character. The user is responsible for specifying the proper continuation character before the &NL if one is required. The user is also responsible for the length of the line written. If the &NL is not specified and the command exceeds 255 characters, the command is split into multiple lines, and a continuation character (+) is added to all but the last line.

CMDFilename

Specifies the full path name that will contain the commands specified with CMD parameter when FORMAT=CMD is specified. This parameter is optional. The maximum length of the file name is 1279 characters.

AIX Linux If you specify "" with the CMDFILENAME parameter, the QUERY MEDIA command will generate a file name by appending the "exec.cmds.media" to the server directory. The server directory is the current working directory of the server process.

Windows If you specify "" with the CMDFILENAME parameter, the QUERY MEDIA command will generate a file name by appending the "exec.cmd.media" to the server directory. The server directory is the current working directory of the server process.

If you specify a null string ("") for the CMDFILENAME, the commands built are displayed on the console only. You can redirect the commands displayed to a file by using the redirection characters for the operating system (> or >>).

AIX Linux If the filename is not specified, the command will generate a default filename by appending the string "exec.cmds.media" to the server directory.

Windows If the filename is not specified, the command will generate a default filename by appending the string "exec.cmd.media" to the server directory.

The QUERY MEDIA command automatically allocates the file name specified or generated. If the file name exists, the QUERY MEDIA command will attempt to use it and the existing data, if any, in the file to be overwritten. You can specify APPEND=YES to prevent the existing data from being overwritten. If the QUERY MEDIA command fails after the command file is allocated, the file is not deleted.

APPend

Specifies to write at the beginning or the ending of the command file data. This parameter is optional. The default is NO. Possible values are:

No

Specifies to write the data from the beginning of the command file. If the given command file exists, its contents are overwritten.

Yes

Specifies to append the command file by writing at the end of the command file data.

Example: Display information on a specific sequential access storage pool

Display all full and partial full volumes that are in the sequential access primary storage pool, ARCHIVE. See Field descriptions for field descriptions.

```
query media * stgpool=archive wherestatus=full, filling

Volume Name State                Location             Automated
                                                      LibName
---------- -------------------   --------------------  -----------
TAPE01      Mountable in Library                       LIB3494
TAPE03      Mountable not in Lib. Room1234/Bldg31
```

```
TAPE07      Mountable in Library                        LIB3494
TAPE09      Mountable not in Lib. Room1234/Bldg31
```

Example: Display information on sequential access storage pool with a specific prefix

Display in detail all full volumes in MOUNTABLENOTINLIB state for sequential access storage pools that have a prefix name of ONSITE. See Field descriptions for field descriptions.

```
query media wherestate=mountablenotinlib stgpool=onsite*
wherestatus=full format=detailed

      Volume Name: TAPE21
                   State: Mountable not in library
          Volume Status: Full
                 Access: ReadOnly
    Last Reference Date: 01/30/98
  Last Update Date/Time: 08/20/1996 13:29:02
               Location: Rm569/bldg31
      Storage Pool Name: ONSITE.ARCHIVE
      Automated Libname:

            Volume Name: TAPE22
                  State: Mountable not in library
          Volume Status: Full
                 Access: ReadOnly
    Last Reference Date: 01/30/98
  Last Update Date/Time: 08/20/1996 15:29:02
               Location: Rm569/bldg31
      Storage Pool Name: ONSITE.ARCHIVEPOOL
      Automated Libname:
```

Example: Generate checkin commands

Generate the CHECKIN LIBVOLUME commands for full and partially full volumes that are in the ONSITE.ARCHIVE primary storage pool and stored in the overflow location Room 2948/Bldg31.

```
query media * stgpool=onsite.archive format=cmd
wherestatus=full,filling wherestate=mountablenotinlib
whereovflocation=room2948/bldg31
cmd="checkin libvol lib3494 &vol status=private"
cmdfilename=/tsm/move/media/checkin.vols
```

The QUERY MEDIA command created the CHECKIN LIBVOLUME executable commands in /tsm/move/media/checkin.vols, which can be run by issuing the MACRO command with /tsm/move/media/checkin.vols as the macro name.

```
checkin libvol lib3494 TAPE04 status=private
checkin libvol lib3494 TAPE13 status=private
checkin libvol lib3494 TAPE14 status=private
```

Field descriptions

Volume Name
: Specifies the name of the primary sequential access storage pool volume.

State
: Specifies the state of the volume.

Volume Status
: Specifies the status of the volume.

Access
: Specifies the access mode of the volume.

Last Reference Date
: Specifies the volume's last written date or last read date, whichever is more recent.

Last Update Date/Time
: Specifies the date and time when the volume was most recently updated.

Location
: Specifies where the volume is stored. If the volume is ejected from the library and its location is not specified or defined, a question mark (?) is displayed for the location.

Storage Pool Name

Specifies the name of the sequential access storage pool where the volume is defined.

Automated LibName

Specifies the automated library name if the volume is in the library.

Related commands

Table 1. Commands related to QUERY MEDIA

Command	Description
AIX Linux Windows MOVE MEDIA	Moves storage pool volumes that are managed by an automated library.

QUERY MGMTCLASS (Query a management class)

Use this command to display information about management classes.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query MGmtclass-------------------------------------------->

   .-*--*--*-----------------------------------------.
>--+-------------------------------------------------+--------->
   |               .-*--*--------------------------. |
   '-domain_name--+----------------------------------+-'
                  |                  .-*----------. |
                  '-policy_set_name--+------------+-'
                                     '-class_name-'

   .-Format--=--Standard-----.
>--+-------------------------+-------------------------------><
   '-Format--=--+-Standard-+-'
                '-Detailed-'
```

Parameters

domain_name

Specifies the policy domain associated with the management class to query. This parameter is optional. You can use wildcard characters to specify this name. If you do not specify a value for this parameter, management classes in all policy domains are queried. You must specify this parameter when querying an explicitly named management class.

policy_set_name

Specifies the policy set associated with the management class to query. This parameter is optional. You can use wildcard characters to specify this name. If you do not specify a value for this parameter, management classes in all policy sets are queried. You must specify this parameter when querying an explicitly named management class.

class_name

Specifies the management class to query. This parameter is optional. You can use wildcard characters to specify this name. If you do not specify a value for this parameter, all management classes are queried.

Format

Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

Standard

Specifies that partial information is displayed.

Detailed

Specifies that complete information is displayed.

Example: Display information for all management classes

Query all management classes for all policy domains. Create the output in standard format. See Field descriptions for field descriptions.

```
query mgmtclass
```

```
Policy       Policy       Mgmt         Default     Description
Domain       Set Name     Class        Mgmt
Name                      Name         Class ?
---------    ---------    ---------    ---------   ------------------
EMPLOYEE-    ACTIVE       ACTIVEFI-    Yes         Modified default
 _RECORDS                  LES                      management class
EMPLOYEE-    HOLIDAY      ACTIVEFI-    Yes         Modified default
 _RECORDS                  LES                      management class
EMPLOYEE-    HOLIDAY      FILEHIST-    No          Test modified
 _RECORDS                  ORY                      management class
EMPLOYEE-    VACATION     ACTIVEFI-    Yes         Original default
 _RECORDS                  LES                      management class
EMPLOYEE-    VACATION     FILEHIST-    No          Test modified
 _RECORDS                  ORY                      management class
PROG1        SUMMER       MCLASS1      No          Technical Support
                                                     Mgmt Class
PROG2        SUMMER       MCLASS1      No          Technical Support
                                                     Mgmt Class
STANDARD     ACTIVE       STANDARD     Yes         Installed default
                                                     management class
STANDARD     STANDARD     STANDARD     Yes         Installed default
                                                     management class
```

To display information about management classes in a specific policy domain, for example the domain ENGPOLDOM, issue the following command:

```
query mgmtclass engpoldom * *
```

Example: Display detailed information for a specific management class

Query the ACTIVEFILES management class that is assigned to the VACATION policy set of the EMPLOYEE_RECORDS policy domain. Create the output in detailed format. See Field descriptions for field descriptions.

```
query mgmtclass employee_records vacation
activefiles format=detailed
```

```
             Policy Domain Name: EMPLOYEE_RECORDS
                Policy Set Name: VACATION
                Mgmt Class Name: ACTIVEFILES
           Default Mgmt Class ?: Yes
                    Description: Installed default management class
     Space Management Technique: None
        Auto-Migrate on Non-Use: 0
     Migration Requires Backup?: Yes
          Migration Destination: SPACEMGPOOL
 Last Update by (administrator): $$CONFIG_MANAGER$$
          Last Update Date/Time: 05/31/1998 13:15:45
               Managing Profile: EMPLOYEE
                Changes Pending: Yes
```

Field descriptions

Policy Domain Name
: The policy domain.

Policy Set Name
: The policy set.

Mgmt Class Name
: The management class.

Default Mgmt Class ?
: Whether the management class is the default management class for the policy set.

Description
: The description of the management class.

Space Management Technique
: The space management technique for the management class, for IBM Spectrum Protect™ for Space Management clients.

Auto-Migrate on Non-Use

The number of days that must elapse since a file was last accessed before it is eligible for automatic migration by IBM Spectrum Protect for Space Management clients.

Migration Requires Backup?

Whether a backup version of a file must exist before a file can be migrated by IBM Spectrum Protect for Space Management clients.

Migration Destination

The storage pool that is the destination for files migrated by IBM Spectrum Protect for Space Management clients.

Last Update by (administrator)

The administrator or server that most recently updated the management class. If this field contains $$CONFIG_MANAGER$$, the management class is associated with a domain that is managed by the configuration manager.

Last Update Date/Time

The date and time when the management class was most recently defined or updated.

Managing profile

The profile or profiles to which the managed server subscribed to get the definition of this management class.

Changes Pending

Whether or not changes are being made but not activated. Once the changes are activated, the field resets to No.

Related commands

Table 1. Commands related to QUERY MGMTCLASS

Command	Description
COPY MGMTCLASS	Creates a copy of a management class.
DEFINE MGMTCLASS	Defines a management class.
DEFINE PROFASSOCIATION	Associates objects with a profile.
DELETE MGMTCLASS	Deletes a management class and its copy groups from a policy domain and policy set.
QUERY DOMAIN	Displays information about policy domains.
UPDATE MGMTCLASS	Changes the attributes of a management class.

QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)

Use this command to display information about alert monitoring and server status settings.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query MONITORSEttings---------------------------------------><
```

Display monitoring settings

Display details about the monitoring settings. See Field descriptions for more details.

```
query monitorsettings
```

Example output:

```
                     Monitor Status: On
Status Refresh Interval (Minutes): 5
         Status Retention (Hours): 48
           Monitor Message Alerts: On
  Alert Update Interval (Minutes): 10
```

```
                          Alert to Email: On
          Send Alert Summary to Administrators: On
                    Alert from Email Address: DJADMIN@MYDOMAIN.COM
                             Alert SMTP Host: DJHOST.MYDOMAIN.COM
                             Alert SMTP Port: 25
               Alert Active Duration (Minutes): 480
             Alert Inactive Duration (Minutes): 480
               Alert Closed Duration (Minutes): 60
                           Monitoring Admin: ADMIN
                            Monitored Group: MONGROUP
                          Monitored Servers: SERVER2
            At-Risk Interval for Applications: 24
    Skipped files as At-Risk for Applications?: Yes
         At-Risk Interval for Virtual Machines: 24
Skipped files as At-Risk for Virtual Machines?: Yes
                  At-Risk Interval for Systems: 24
         Skipped files as At-Risk for Systems?: Yes
```

Field descriptions

Monitor status
: Specifies whether alert monitoring on the server is enabled or disabled.

Status Refresh Interval (Minutes)
: Specifies the number of minutes between intervals that the monitoring server gathers event data.

Status Retention (Hours)
: Specifies the number of hours that status monitoring indicators are retained.

Monitor Message Alerts
: Specifies whether alerts are sent to administrators by email.

Alert Update Interval (Minutes)
: Specifies the length of time, in minutes, that the alert monitor waits before the alert is updated and pruned on the server.

Alert to Email
: Specifies whether alerts are sent to administrators by email.

Send Alert Summary to Administrators
: Specifies the administrators that receive a summary of existing alerts on the server in an email.

Alert from Email Address
: Specifies the email address of the sender.

Alert SMTP Host
: Specifies the Simple Mail Transfer Protocol (SMTP) host mail server that is used to send alerts by email.

Alert SMTP Port
: Specifies the SMTP mail server port that is used to send alerts by email.

Alert Active Duration (Minutes)
: Specifies how long, in minutes, an alert remains active.

Alert Inactive Duration (Minutes)
: Specifies how long, in minutes, an alert remains inactive.

Alert Closed Duration (Minutes)
: Specifies how long, in minutes, an alert remains closed before it is deleted from the server.

Monitoring Admin
: Specifies the name of the monitoring administrator that is used to connect to the servers in the monitored group.

Monitored Group
: Specifies the name of the monitored server group.

Monitored Servers
: Specifies the names of the servers in the monitored server group. The monitor settings might be different on each monitored server. If so, issue the query command for each server to display the monitoring settings.

At-Risk Interval for Applications
: Specifies how long, in hours, an applications client can log no activity before it is considered at-risk.

Skipped files as At-Risk for Applications?
: Specifies that the server considers skipped files, by the client as a failure, and marks the client at-risk.

At-Risk Interval for Virtual Machines
: Specifies how long, in hours, a virtual client can log no activity before it is considered at-risk.

Skipped files as At-Risk for Virtual Machines?
: Specifies that the server considers skipped files, by the client as a failure and marks the client at-risk.

At-Risk Interval for Systems
: Specifies how long, in hours, a systems client can log no activity before it is considered at-risk.

Skipped files as At-Risk for Systems?

Specifies that the server considers skipped files, by the client as a failure, and marks the client at-risk.

Related commands

Table 1. Commands related to QUERY MONITORSETTINGS

Command	Description
DEFINE ALERTTRIGGER (Define an alert trigger)	Associates specified messages to an alert trigger.
DELETE ALERTTRIGGER (Remove a message from an alert trigger)	Removes a message number that can trigger an alert.
DELETE GRPMEMBER (Delete a server from a server group)	Deletes a server from a server group.
DELETE SERVER (Delete a server definition)	Deletes the definition of a server.
QUERY ALERTSTATUS (Query the status of an alert)	Displays information about alerts that have been issued on the server.
QUERY ALERTTRIGGER (Query the list of defined alert triggers)	Displays message numbers that trigger an alert.
SET ALERTMONITOR (Set the alert monitor to on or off)	Specifies whether alert monitoring is set to on or off.
SET STATUSATRISKINTERVAL (Specifies whether to enable client at-risk activity interval evaluation)	Specifies whether to enable client at-risk activity interval evaluation
SET STATUSMONITOR (Specifies whether to enable status monitoring)	Specifies whether to enable status monitoring.
SET STATUSSKIPASFAILURE (Specifies whether to use client at-risk skipped files as failure evaluation)	Specifies whether to use client at-risk skipped files as failure evaluation
UPDATE ALERTTRIGGER (Update a defined alert trigger)	Updates the attributes of one or more alert triggers.
UPDATE ALERTSTATUS (Update the status of an alert)	Updates the status of a reported alert.

QUERY MONITORSTATUS (Query the monitoring status)

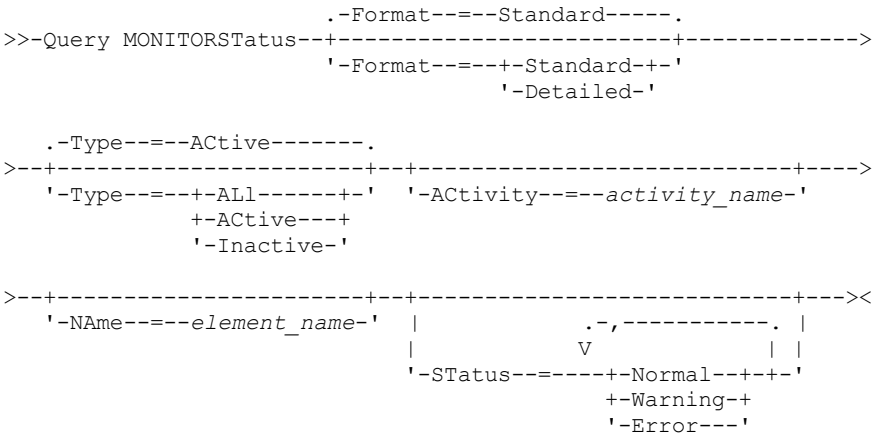
Use this command to display monitoring messages that are within the defined status retention period.

You can limit the output to a specified status, such as only messages with a status of active. If you do not specify any parameters, all messages are displayed.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

Format
: Specifies the amount of information that is displayed. The default value is STANDARD. Specify one of the following values:

  Standard
  : Specifies that only partial information is displayed for the specified messages.

  Detailed
  : Specifies that all information is displayed for the specified messages.

Type
: This parameter restricts the output to only messages with the specified type value. Specify one of the following values:

  ALl
  : Displays all information.

  ACtive
  : Displays all active messages. This is the default value.

  Inactive
  : Displays all inactive messages.

ACtivity
: Specifies the activity that you want to query. See the DEFINE STATUSTHRESHOLD command for details on available activities to query.

NAme
: Specifies the name that you want to query. The NAME value refers to the name of the element with the specified activity. For example, a status indicator that contains information about a storage pool that is called `backuppool` has the NAME set to BACKUPPOOL.

STatus
: Specifies the status of the messages that you want to query. You can specify multiple status values in a list by separating the values with commas and no intervening spaces. If you do not specify a value for this parameter, information for all status values is displayed. Specify one of the following values:

  Normal
  : Displays all messages with a normal status.

  Warning
  : Displays all messages with a warning status.

  Error
  : Displays all messages with an error status.

Display monitoring settings

Display details about the monitoring status.

```
Query MONITORStatus type=active
```

Example output:

```
          Server Name: SERVER1
        Activity Date: 03/05/2013 15:57:37
        Activity Name: CAPACITY OF PRIMARY DISK AND FILE STORAGE
         Element Name: CAPACITY OF PRIMARY DISK AND FILE STORAGE
Element Numeric Value: 0
 Element String Value:
        Element State: NORMAL

          Server Name: SERVER1
        Activity Date: 03/05/2013 15:57:37

Field descriptions

Server Name
: The name of the server.

Activity Date
: The last date and time activity was reported.

Activity Name
: The name of the activity.

Element Name
: The name of the element.

Element Numeric Value
: The numeric value of the element.

Element String Value
: The string value of the element.

Element State
: The state of the element.

Element Details
: The detailed information of the element.

Primary Repair Suggestion
: The primary repair suggestion.

First Alternate Repair Suggestion
: The repair suggestion to follow if the primary suggestion is not adequate.

Second Alternate Repair Suggestion
: The repair suggestion to follow if the primary and first alternate suggestions are not adequate.

Related commands

Table 1. Commands related to QUERY MONITORSTATUS

Command	Description
DEFINE STATUSTHRESHOLD (Define a status monitoring threshold)	Defines a status monitoring threshold.
DELETE STATUSTHRESHOLD (Delete a status monitoring threshold)	Deletes a status monitoring threshold.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
QUERY STATUSTHRESHOLD (Query status monitoring thresholds)	Displays information about a status monitoring thresholds.
SET STATUSATRISKINTERVAL (Specifies whether to enable client at-risk activity interval evaluation)	Specifies whether to enable client at-risk activity interval evaluation
SET STATUSMONITOR (Specifies whether to enable status monitoring)	Specifies whether to enable status monitoring.
SET STATUSREFRESHINTERVAL (Set refresh interval for status monitoring)	Specifies the refresh interval for status monitoring.
SET STATUSSKIPASFAILURE (Specifies whether to use client at-risk skipped files as failure evaluation)	Specifies whether to use client at-risk skipped files as failure evaluation
UPDATE STATUSTHRESHOLD (Update a status monitoring threshold)	Changes the attributes of an existing status monitoring threshold.

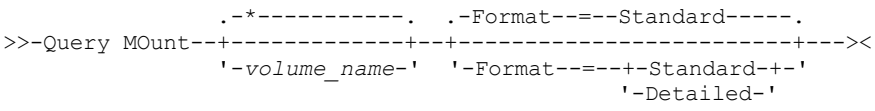
QUERY MOUNT (Display information on mounted sequential access volumes)

Use this command to display information about the status of one or more sequential access volumes that are mounted.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

volume_name
: Specifies the name of the mounted sequential access volume. You can use wildcard characters to specify this name. This parameter is optional. The default is all mounted volumes.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed.

Example: List all mounted sequential volumes

Display information on all mounted sequential media volumes.

```
query mount
```

AIX

```
ANR8330I 3590 volume D6W992 is mounted R/O
in drive RMT1(/dev/rmt1), status: IN USE.
ANR8334I  1 volumes found.
ANR8331I 8MMTAPE volume WPD000 is mounted R/W
in drive 8MM.1 (/dev/mt0), status: DISMOUNTING.
ANR8334I  1 volumes found.
```

Linux

```
ANR8330I 3590 volume D6W992 is mounted R/O
in drive RMT1/dev/IBMtape1, status: IN USE.
ANR8334I  1 volumes found.
ANR8331I 8MMTAPE volume WPD000 is mounted R/W
in drive 8MM.1 (/dev/tsmscsi/mt0), status: DISMOUNTING.
ANR8334I  1 volumes found.
```

Windows

```
ANR8330I 3590 volume D6W992 is mounted R/O
in drive RMT1(/dev/rmt1), status: IN USE.
ANR8334I  1 volumes found.
ANR8331I 8MMTAPE volume WPD000 is mounted R/W
in drive 8MM.1 (mt3.0.0.0), status: DISMOUNTING.
ANR8334I  1 volumes found.
```

Remember:

1. If the status of a volume is full or if its access mode is read-only (R/O), the mount mode of the volume is R/O. To determine the status and access mode of a volume, issue the QUERY VOLUME FORMAT=DETAILED command. If a volume can be written to (that is, the status is filling or empty), the mount mode of the volume is read/write (R/W), even if it is only being read.
2. In a storage pool that is associated with the FILE or CENTERA device type, the server can complete concurrent multiple read-access and one write-access to the same volume. As a result, a volume in a storage pool with a device type of FILE or CENTERA can appear to be mounted more than once.
3. In the message ANR8448I, the drive name is listed as `UNKNOWN` for volumes of the FILE device type with a non-shared device class. The reason is that no drive is associated with the volumes; drive names are shown in the file-based library.

4. If you issue the QUERY MOUNT command while the drive is being cleaned, the command output continues to show a `DISMOUNTING` status for the dismounted volume until the cleaning completes.

Example: Display detailed information about mounted sequential volumes

Display details about mounted volumes.

```
query mount format=detailed

ANR2017I Administrator SERVER_CONSOLE issued command: QUERY
MOUNT format=detailed
ANR8487I Mount point in device class FILE is waiting for the
volume mount to
complete -- owning server: SERVER1, status: WAITING FOR VOLUME
(session: 0, process: 1).
ANR8488I LTO volume 015005L4 is mounted R/W in drive IBMVTL1
(/dev/rmt37) -- owning
server: SERVER1, status: IN USE (session: 0, process: 2).
ANR8486I Mount point in device class FILE is reserved -- owning
server: SERVER1,
status: RESERVED (session: 5, process: 0).
ANR8334I         3 matches found.
```

Related commands

Table 1. Commands related to QUERY MOUNT

Command	Description
DISMOUNT VOLUME	Dismounts a sequential, removable volume by the volume name.
REPLY	Allows a request to continue processing.

QUERY NASBACKUP (Query NAS backup images)

Use this command to display information about the file system image objects that have been backed up for a specific NAS node and file space. You can only use this command to display objects that were backed up for a NAS node using NDMP.

The server displays all matching objects, the dates that these objects were backed up, and information about a table of contents (TOC) for the object.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query NASBAckup--node_name--filespace_name------------------>

   .-BEGINDate--=--TODAY - 7-.  .-BEGINTime--=--00:00:00-.
>--+-------------------------+--+-----------------------+------>
   '-BEGINDate--=--date------'  '-BEGINTime--=--time-----'

   .-ENDDate--=--TODAY-.  .-ENDTime--=--23:59:59-.
>--+-------------------+--+---------------------+-------------->
   '-ENDDate--=--date--'  '-ENDTime--=--time-----'

   .-TYPE--=--BACKUPImage-----.
>--+--------------------------+------------------------------><
   '-TYPE--=--+-BACKUPImage-+-'
              '-SNAPMirror--'
```

Parameters

node_name (Required)

Specifies the name of the NAS node for which backup objects are displayed. You cannot use wildcards to specify this name.

filespace_name (Required)

Specifies the name of the file space for which backup objects are displayed. You can use wildcards to specify this name.

BEGINDate

Specifies the beginning date to select the backup objects to display. All backup objects that were created on or after the specified date are displayed. The default is seven days prior to the current date. You can use this parameter with the BEGINTIME parameter to specify a range for the date and time. This parameter is optional.

You can specify the date using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/2002
TODAY	The current date	TODAY
TODAY-days *or* -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY –7 *or* –7. To display information about the image objects that have been created a week ago, you can specify BEGINDATE=TODAY-7 or BEGINDATE= -7.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

BEGINTime

Specifies the beginning time to select the backup objects to display. All backup objects created on or after the specified time display. This parameter is optional. The default is midnight (00:00:00) on the date specified for the BEGINDATE.

You can specify the time using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time on the specified begin date	10:30:08
NOW	The current time on the specified begin date	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes on the specified begin date	NOW+03:00 *or* +03:00. If you issue this command at 9:00 with BEGINTIME=NOW+3 or BEGINTIME=+3, the server displays image objects with a time of 12:00 or later on the begin date.
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes on the specified begin date	NOW-04:00 *or* -04:00. If you issue this command at 9:00 with BEGINTime=NOW-3:30 or BEGINTime= -3:30, the server displays image objects with a time of 5:30 or later on the begin date.

ENDDate

Specifies the ending date used to select the backup objects to be displayed. All backup objects created on or before the specified date are displayed. This parameter is optional. The default is the current date. You can use this parameter with the ENDTIME parameter to specify an ending date and time.

You can specify the date using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/2002

Value	Description	Example
TODAY	The current date	TODAY
TODAY-days *or* -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY–1 *or* –1. To display information created up to yesterday, you can specify ENDDATE=TODAY-1 or simply ENDDATE= -1.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

ENDTime

Specifies the ending time used to select the backup objects to be displayed. All backup objects created on or before the specified time are displayed. This parameter is optional. The default is 23:59:59. You can use this parameter with the ENDDATE parameter to specify a range for the date and time.
You can specify the time using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time on the specified end date	10:30:08
NOW	The current time on the specified end date	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes on the specified end date	NOW+03:00 *or* +03:00. If you issue this command at 9:00 with ENDTIME=NOW+3:00 or ENDTIME= +3:00, the server displays image objects with a time of 12:00 or later on the end date you specify.
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes on the specified end date	NOW-03:30 *or* -03:30. If you issue this command at 9:00 with ENDTIME=NOW-3:30 or ENDTIME= -3:30, the server displays image objects with a time of 5:30 or later on the end date you specify.

TYPE

Specifies the type of NDMP backup images for which you want to display information. The default value for this parameter is BACKUPIMAGE. Other image types represent backup methods that might be specific to a particular file server. Possible values are:

BACKUPImage
: Specifies that the output should show only the standard NAS base and differential images. This is the default value for this parameter.

SNAPMirror
: Specifies whether to display information about NetApp SnapMirror images. SnapMirror images are block-level full-backup images of a file system. A SnapMirror image can only be restored to a file system that has been prepared as a SnapMirror target volume. Refer to the documentation that came with your NetApp file server for more information. This parameter is valid for NetApp and IBM N-Series file servers only.

Example:

Issue the QUERY NASBACKUP command to display information about a node, nas1, and a filespace, /vol/vol1.

```
query nasbackup nas1 /vol/vol1

Node  Filespace Object      Object  Creation   Has       Mgmt      Image
Name  Name      Type        Size    Date       Table of  Class     Storage
                (MB)        (MB)    Contents   Contents  Name      Pool
                                               (TOC)               Name
----- --------  ---------   -----   ---------- --------  --------  --------
NAS1  vol/vol1  Full image  1050.5  10/22/2002  YES       DEFAULT   NASBACKUPS
                                     10:50:57
NAS1  vol/vol1  Differential  9.1   10/22/2002  YES       DEFAULT   NASBACKUPS
                image                 11:03:21
NAS1  vol/vol1  Full image  1050.5  10/22/2006  YES       STANDARD  FILEPOOL
                                     10:43:00
NAS1  vol/vol1  Differential  9.1   10/25/2006  YES       STANDARD  FILEPOOL
                image                 11:53:21
```

Example:

Issue the QUERY NASBACKUP command to display information about all NetApp SnapMirror to Tape images for a node, nas2, and a filespace, /vol/vol2.

```
query nasbackup nas2 /vol/vol2 type=snapmirror

Node  Filespace Object      Object  Creation    Mgmt Class  Image
Name  Name      Type        Size    Date        Name        Storage
                            (MB)                            Pool Name
----- --------  ----------  ------  ----------  ----------  ---------
NAS2  vol/vol2  SnapMirror  1050.5  04/02/2008  STANDARD    MYPOOL
                                     10:50:57
NAS2  vol/vol2  SnapMirror  1450.5  04/02/2008  STANDARD    MYPOOL
                                     11:03:21
```

Field descriptions

Node Name
: The name of the client node.

Filespace Name
: The name of the filespace.

Object Type
: The type of object backed up.

Object Size (MB)
: The size of the object in megabytes.

Creation Date
: The date the backup was created.

Mgmt Class Name
: The name of the management class.

Image Storage Pool Name
: The name of the storage where the backup resides.

Related commands

Table 1. Commands related to QUERY NASBACKUP

Command	Description
BACKUP NODE	Backs up a network-attached storage (NAS) node.
BACKUP NAS (IBM Spectrum Protect™ client command)	Creates a backup of NAS node data.
QUERY TOC	Displays details about the table of contents for a specified backup image.
RESTORE NODE	Restores a network-attached storage (NAS) node.

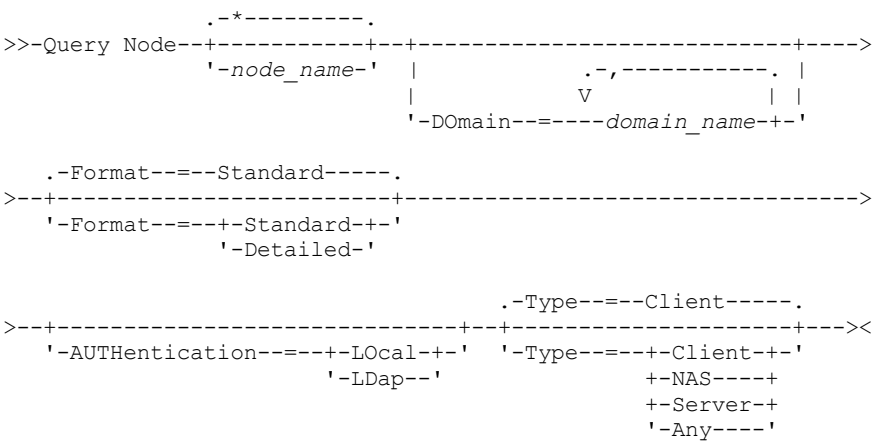
QUERY NODE (Query nodes)

Use this command to view information about one or more registered nodes.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

node_name
: Specifies the name of the client node to be queried. You can use wildcard characters to specify this name. All matching client nodes are queried. If you do not specify a value for this parameter, all client nodes are queried. The parameter is optional.

DOmain
: Specifies a list of policy domains that limit the client node query. Only nodes that are assigned to one of the specified policy domains are displayed. This parameter is optional. Separate the items in the list by commas, with no intervening spaces. You can use wildcard characters to specify a domain. All clients that are assigned to a matching domain are displayed. If you do not specify a value for this parameter, all policy domains are included in the query.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. You can specify one of the following values:

  Standard
  : Specifies that partial information is displayed for the specified client nodes.

  Detailed
  : Specifies that complete information is displayed for the specified client nodes.

Type
: Specifies the type of node to include in the query results. The parameter is optional. The default value is CLIENT. You can specify one of the following values:

  Any
  : Specifies any type of node.

  Client
  : Specifies client nodes that are backup-archive clients, IBM Spectrum Protect™ for Space Management clients, or application clients.

  NAS
  : Specifies NAS nodes.

  Server
  : Specifies client nodes that are other servers.

Authentication
: Specifies the password authentication method for the node.

  LOcal

Display those nodes that authenticate to the IBM Spectrum Protect server.

LDap
Display those nodes that authenticate to an LDAP directory server. The node password is case-sensitive.

Example: Display information about registered client nodes

Display information about all registered client nodes.

```
query node
```

```
Node Name   Platform  Policy Domain  Days Since  Days Since  Locked?
                      Name                Last    Password
                                       Access         Set
---------   --------  --------       ---------   ---------- -------

Field descriptions

Node Name
: The name of the client node.

Platform
: The operating system of the client node, as of the last time that the client node contacted the server. A question mark (?) is displayed until the client node first accesses the server and reports its operating system type.

Client OS Level
: The level of the operating system for the client as of the last time that the client node contacted the server.

Client Version
: The version of the client that is installed on the client node.

  This field does not apply to NAS nodes.

Application Version
: The version of the Data Protection for VMware client.

Policy Domain Name
: The assigned policy domain of the client node.

Last Access Date/Time
: The last date and time that the client node accessed the server.

Days Since Last Access
: The number of days that elapsed since the last time that the client node accessed the server.

Password Set Date/Time
: The date and time that the password was set for the client node.

Days Since Password Set
: The number of days that elapsed since the password was set for the client node.

Invalid Sign-on Count
: The number of invalid sign-on attempts that were made since the last successful sign-on. This count can be non-zero only when the invalid password limit (SET INVALIDPWLIMIT) is greater than zero. When the number of invalid attempts equals the limit that is set by the SET INVALIDPWLIMIT command, the node is locked out of the system.

Locked?
: Whether the client node is locked out of IBM Spectrum Protect.

Contact
: Any contact information for the client node.

Compression
: Whether compression is enabled on the client node.

  This field does not apply to NAS nodes.

Archive Delete Allowed?
: Whether the client node can delete its own archive files.

Backup Delete Allowed?
: Whether the client node can delete its own backup files.

Registration Date/Time
: The date and time that the client node was registered.

Registering Administrator
: The name of the administrator that registered the client node.

Last Communication Method Used
: The communication method that was last used by the client node to contact the server.

Bytes Received Last Session
: The number of bytes received by the server during the last client node session.

  This field does not apply to NAS nodes.

Bytes Sent Last Session
: The number of bytes sent to the client node.

  This field does not apply to NAS nodes.

Duration of Last Session
: How long the most recent client node session lasted, in seconds.

  This field does not apply to NAS nodes.

Pct. Idle Wait Last Session
: The percentage of the total session time that the client was not running any functions.

  This field does not apply to NAS nodes.

Pct. Comm. Wait Last Session
: The percentage of the total session time that the client waited for a communication response from the server.

  This field does not apply to NAS nodes.

Pct. Media Wait Last Session
: The percentage of the total session time that the client waited for a removable volume to be mounted.

  This field does not apply to NAS nodes.

Optionset
: The name of the client option set.

URL
: The URL of the IBM Spectrum Protect web client that is configured on the client system. You can use the URL in a web browser and in the Operations Center to remotely manage the client node.

Node Type
: The type of client node. One of the following values is possible:

  - Client: a backup-archive client, an IBM Spectrum Protect for Space Management client, or an application client
  - Server: an IBM Spectrum Protect server
  - NAS: a NAS file server

Password Expiration Period
: The password expiration period of the client node.

Keep Mount Point?
: Whether the client node retains a mount point during a session.

Maximum Mount Points Allowed
: The number of mount points that a client node can use on the server for IBM Spectrum Protect for Space Management migration and for backup and archive operations. This parameter does not apply to nodes with a type of NAS or SERVER. If a client node was registered to a server at Version 3.7 or later, the value is 0-999, depending on the value that is set with the MAXNUMMP parameter of the REGISTER NODE command. If the client node was registered under previous versions of

the server and the MAXNUMMP parameter was not explicitly set by using the UPDATE NODE command, the value is set to NOLIMIT. The MAXNUMMP value is not evaluated or enforced during client data read operations such as restore, retrieve, and IBM Spectrum Protect for Space Management recall. However, mount points in use for data read operations are evaluated against attempted concurrent data store operations for the same client node. This evaluation might prevent the data store operations from acquiring mount points.

Auto Filespace Rename
: Whether IBM Spectrum Protect prompts the client to rename file spaces when the client system upgrades to a client that supports Unicode. This field is valid only for client systems that use Windows, Macintosh OS X, or NetWare operating systems.

Validate Protocol (deprecated)
: Whether the client has data validation enabled. If the client has data validation enabled, this field specifies whether IBM Spectrum Protect validates only the file data or all data, which includes file metadata. You can enable data validation by using the REGISTER NODE or UPDATE NODE command. This field is deprecated.

TCP/IP Name
: The host name of the client node as of the last time that the client node contacted the server. The field is blank if the client software does not support reporting this information to the server.

TCP/IP Address
: The TCP/IP address of the client node as of the last time that the client node contacted the server. The field is blank if the client software does not support reporting this information to the server.

Globally Unique ID
: The globally unique identifier (GUID) as of the last time that the client node contacted the server. This GUID identifies the host computer on which the node is located.

Transaction Group Max
: Specifies the number of files per transaction committed that are transferred between a client and a server. Client performance might be improved by using a larger value for this option.

Data Write Path
: Specifies the transfer path that is used when the client sends data to the server, storage agent, or both, during storage operations. If a path is unavailable, the node cannot send any data.

  AIX Linux Data transfer path options are ANY, LAN, or LAN-free.

Data Read Path
: Specifies the transfer path that is used when the server, storage agent, or both, read data for a client, during operations such as restore or retrieve. If a path is unavailable, data cannot be read.

  AIX Linux Data transfer path options are ANY, LAN, or LAN-free.

Session Initiation
: Controls whether the server or client initiates sessions. The following two options are available:

  - ClientOrServer
  - Serveronly

High-level Address
: Specifies the client IP address that the server contacts to initiate scheduled events when SESSIONINITIATION is set to SERVERONLY.

Low-level Address
: Specifies the client port number on which the client listens for sessions from the server when SESSIONINITIATION is set to SERVERONLY.

Collocation Group Name
: Specifies the name of the collocation group to which a node belongs. If a node does not belong to a collocation group, this field is blank.
  Tip: If the node contains file spaces that are members of a file space collocation group, this field is left blank. You can find file space names by issuing the QUERY FILESPACE command.

Proxynode Target
: Specifies which nodes are proxy nodes (agents) for other nodes, in a space-separated list. If there are no nodes in that type of association, this field is blank.

Proxynode Agent
: Specifies the originating (target) node name for a proxy node session, in a space separated list. If there are no nodes in that type of association, this field is blank.

Node Groups
: Specifies the name of the node group to which a node belongs. If a node does not belong to a node group, this field is blank.

Email Address
: Specifies the email address of the client node.

Deduplication
: The location where data is deduplicated. The value ServerOnly specifies that data stored by this node can be deduplicated on the server only. The Clientorserver value specifies that data stored by this node can be deduplicated on either the client or the server.

AIX Linux Users allowed to back up
: AIX Linux Specifies whether a non-root user ID or only a root user ID can back up files to the server. ALL indicates all users, while ROOT indicates that just the root user ID can back up files to the server. This output is not available if the client node operating system is considered a single-user operating system.

Replication State
: Indicates whether the node is enabled for replication. The following values are possible:

  Enabled
  : The node is configured for replication and ready to replicate.

  Disabled
  : The node is configured for replication but is not ready to replicate.

  None
  : The node is not configured for replication.

Replication Mode
: Indicates whether the node is configured as the source of or target for replicated data. If this field is blank, the node is not configured for replication. The following values are possible:

  Send
  : The node is configured as the source of data for replication.

  Receive
  : The node is configured as the target of data for replication.

  SyncSend
  : The data that belongs to the node is to be synchronized with the node data that is on the target replication server. Synchronization applies only to nodes whose data was imported from a source replication server and imported to the target replication server. Synchronization occurs during replication.

  SyncReceive
  : The data that belongs to the node is to be synchronized with the node data that is on the source replication server. Synchronization applies only to nodes whose data was imported from a source replication server and imported to the target replication server. Synchronization occurs during replication.

  None
  : The node is not configured for replication.

Replication Primary Server
: Specifies the source replication server for the client node.

Backup Replication Rule
Archive Replication Rule
Space Management Replication Rule
: The replication rule that applies to back up, archive, and space-managed data that belongs to the node. The following values are possible:

  ALL_DATA
  : Replicates backup, archive, or space-managed data. The data is replicated with normal priority.

  ACTIVE_DATA
  : Replicates active backup data. The data is replicated with normal priority.
  Attention: If you specify ACTIVE_DATA and one or more of the following conditions are true, inactive backup data on the target replication server is deleted, and inactive backup data on the source replication server is not replicated.

    - When a server version earlier than Version 7.1.1 is installed on either the source or target replication servers.
    - When you are using the REPLICATE NODE command with the `FORCERECONCILE=YES` parameter.
    - When you are running the initial replication of a file space after you configure replication, restore the database, or upgrade both the source and target replication servers from a server version earlier than V7.1.1.

    If the previous conditions are not true, all new and changed files since the last replication are replicated, including inactive files, and files are deleted when they expire.

  ALL_DATA_HIGH_PRIORITY
  : Replicates backup, archive, or space-managed data. The data is replicated with high priority.

  ACTIVE_DATA_HIGH_PRIORITY

This rule is the same as the ACTIVE_DATA replication rule except data is replicated with a high priority.

DEFAULT
: Replicates backup, archive, or space-managed data according to the domain rule for the data type.

NONE
: No data is replicated. For example, if the replication rule for archive data is NONE, archive data that belongs to the node is not replicated.

Last Replicated to Server
: Specifies the name of the server that the node was last replicated to and the name of the server that the client fails over to during restore operations.

Client OS Name
: The operating system of the client. The client deployment wizard uses this information to deploy a package to the client. This field is reported only for IBM Spectrum Protect clients at V6.2.0.0 and later.

Client Processor Architecture
: The client architecture. The client deployment wizard uses this value to determine which package to deploy when the client is being updated. This field is reported only for IBM Spectrum Protect clients at V6.2.0.0 and later.

Client Products Installed
: The products that are on the node. The following products might be listed:

- BA (Backup-Archive Client)
- VE (Virtual Environments)
- FCM (FlashCopy® Manager)

Client Target Version
: The version of the client that is installed at a time that is scheduled through the DEFINE SCHEDULE or UPDATE SCHEDULE command. This field is reported only for IBM Spectrum Protect clients at V6.2.0.0 and later.

Authentication
: Specifies the password authentication method: LOCAL, LDAP, or LDAP (pending).

Authentication Target	**Authentication Method**
IBM Spectrum Protect server	LOCAL
LDAP directory server	LDAP
This node is configured to authenticate with an LDAP directory server, but the node did not yet authenticate.	LDAP (pending)

SSL Required (deprecated)
: Specifies whether the security setting for the node requires the Secure Sockets Layer (SSL) protocol. Values can be YES, NO, or Default. You must have system level authority to update the node SSLREQUIRED setting. This field is deprecated.

Session Security
: Specifies the level of session security that is enforced for the node. Values can be STRICT or TRANSITIONAL.

Transport Method
: Specifies the transport method that was last used for the specified node. Values can be TLS 1.2, TLS 1.1, or NONE. A question mark (?) is displayed until a successful authentication is completed.

Split Large Objects
: Specifies whether large objects that are stored by this node are automatically split into smaller pieces, by the server, to optimize server processing. Yes indicates that the server splits large objects (over 10 GB) into smaller pieces when stored by a client node. No indicates that this process is bypassed. The default value is Yes.

At-risk type
: Specifies the at-risk evaluation type. Values can be Default, Bypassed, or Custom. Default indicates that the node is evaluated with the same interval that was specified for the nodes classification by the SET STATUSATRISKINTERVAL command. Bypassed indicates that the node is not evaluated for at-risk status by the status monitor. Custom indicates that the node is evaluated with the interval that was specified by the SET NODEATRISKINTERVAL command, rather than the interval that was specified by the SET STATUSATRISKINTERVAL command.

At-risk interval
: Specifies the number of hours between two client backup activities, or two replication activities, after which the status monitor indicates that the activity is at risk. This field contains a value only when the `At-risk type` field contains the value of `Custom`.

Utility URL

Specifies the address of the IBM Spectrum Protect client management services that are configured on the client system. This URL is used by the Operations Center to access client log files so that you can remotely diagnose client issues from the Operations Center.

Replication Recovery of Damaged Files

Specifies whether damaged files can be recovered for this node from a target replication server.

Decommissioned

Specifies whether the client node is decommissioned. The following values are possible:

YES

Specifies that the node is decommissioned.

Null value

Specifies that the node is not decommissioned.

PENDING

Specifies that the node is being decommissioned, or the decommission process failed.

Tip: If you want to determine the status of a pending decommission process, follow the instructions in Decommissioning a client node.

Decommissioned Date

Specifies the date that the client node was decommissioned.

Example: Display information about node roles

The example output is only a portion of the full display.

```
query node alvin f=d

                  Proxynode Agent:
                      Node Groups:
                    Email Address:
                    Deduplication: ServerOnly
         Users allowed to back up: All
                             Role: Server
                    Role Override: UseReported
                 Processor Vendor: ORACLE
                  Processor Brand: UltraSPARC-T2
                   Processor Type: 4
                  Processor Model:
                  Processor Count: 1
                       Hypervisor:
                  API Application: NO
                       Scan Error: NO
                      MAC Address:
```

Field Descriptions

Role

The processor role as reported by the client.

Role Override

The override value for role, which is specified with the UPDATE NODE command.

Processor Vendor

The processor vendor as reported by the client.

Processor Brand

The processor brand as reported by the client.

Processor Type

The processor type as reported by the client. This value specifies the number of processor cores that are used for PVU calculation.

Processor Model

The processor model as reported by the client.

Processor Count

The processor count as reported by the client.

Hypervisor

The hypervisor as reported by the client.

API Application

The client indicator that the client is an API application.

Scan Error

The indicator of whether the latest scan for processor information might be failing and needs investigation.

MAC Address

MAC Address as reported by the client.

Example: View all nodes that authenticate to the IBM Spectrum Protect server

If you want to view all nodes that authenticate locally, specify the following command:

```
query node * authentication=local
```

```
Node    Platform  Policy       Days Since   Days Since   Locked?
Name              Domain Name  Last Access  Password Set
_____________________________________________________________
NODE1   WinNT     STANDARD          3            3          No
LOCAL   (?)       STANDARD          7            7          No
```

Related commands

Table 1. Commands related to QUERY NODE

Command	Description
LOCK NODE	Prevents a client from accessing the server.
QUERY ADMIN	Displays information about one or more IBM Spectrum Protect administrators.
QUERY REPLNODE	Displays information about the replication status of a client node.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REGISTER NODE	Defines a client node to the server and sets options for that user.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.
REMOVE REPLNODE	Removes a node from replication.
RENAME NODE	Changes the name for a client node.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
RESET PASSEXP	Resets the password expiration for nodes or administrators.
SET INVALIDPWLIMIT	Sets the number of invalid logon attempts before a node is locked.
SET MINPWLENGTH	Sets the minimum length for client passwords.
SET PASSEXP	Specifies the number of days after which a password is expired and must be changed.
UNLOCK NODE	Enables a locked user in a specific policy domain to access the server.
UPDATE NODE	Changes the attributes that are associated with a client node.

QUERY NODEDATA (Query client data in volumes)

Use this command to display information about the data for one or more nodes in a sequential access storage pool. QUERY NODEDATA displays the name of the volume on which a node's data is written and the amount of space that is occupied by the data on that volume. This information is useful when you determine how to group nodes into collocated storage pools.

Privilege class

Restriction: You cannot use this command to display information for container storage pools.

Any administrator can issue this command.

Syntax

```
                    .-,---------.
                    V           |
>>-Query NODEData--+---node_name-+----------------+------------>
                   '-COLLOCGroup--=--colloc_group-'

>--+----------------------+--+--------------------+---------><
   '-STGpool--=--pool_name-'  '-VOLume--=--vol_name-'
```

Parameters

node_name
: Specifies the name of the client node for which you want to locate data. You can specify one or more names. If you specify multiple names, separate the names with commas; do not use intervening spaces. You can also use wildcard characters to specify multiple names. You must specify either a node name or collocation group name, but not both.

COLLOCGroup
: Specifies the name of the collocation group for which you want to locate data. You must specify either a node name or collocation group name, but not both.
Important: If the amount of space that is needed to complete the query about a collocation group exceeds the SQL buffer limit, the QUERY NODEDATA command can fail. If the command fails for this reason, issue the QUERY COLLOCGROUP command to display a list of nodes in the group. Then, issue the QUERY NODEDATA command for each node in the group.

STGpool
: Specifies the name of the sequential storage pool to query. This parameter is optional. You can use wildcard characters to specify the names. If a wildcard matches the name of a disk storage pool, the name of the disk storage pool is ignored. If you do not specify a value for this parameter, all sequential storage pools are queried.

VOLume
: Specifies the volume that contains the data. This parameter is optional. You can use wildcard characters to specify multiple names. If you do not specify a value for this parameter, all volumes in the storage pool are queried.

Use wildcards to display node data for a sequential access storage pool

Display information about where node data is stored in a sequential storage pool. Use a wildcard character to indicate node names. See Field descriptions for field descriptions.

```
query nodedata e*
```

```
   Node Name   Volume Name                     Storage Pool  Physical
                                               Name          Space
                                                             Occupied
                                                             (MB)
   ---------   ----------------------------   ------------  --------
   EDU_J2      E:\tsm\server\00000117.BFS     EDU512        0.01
   EDU_J2      E:\tsm\server\00000122.BFS     EDU319        0.01
   EDU_J3      E:\tsm\server\00000116.BFS     EDU512        0.01
   EDU_J3      E:\tsm\server\00000120.BFS     EDU319        0.01
   EDU_J7      E:\tsm\server\00000118.BFS     EDU512        0.04
   EDU_J7      E:\tsm\server\00000123.BFS     EDU319        0.04
   EDU_JJ1     E:\tsm\server\00000116.BFS     EDU512        0.01
   EDU_JJ1     E:\tsm\server\00000121.BFS     EDU512        0.01
```

Display node data information for a specific collocation group

Display information about the location of node data in a sequential storage pool for a particular collocation group. In this example, nodes EDU_J3 and EDU_JJ1 are the only members that belong to collocation group, grp1, and have data in a sequential access storage pool.

```
query nodedata collocgroup=grp1
```

```
   Node Name   Volume Name                     Storage Pool  Physical
                                               Name          Space
                                                             Occupied
                                                             (MB)
```

```
---------   ----------------------------   ------------  --------
EDU_J3      E:\tsm\server\00000116.BFS      EDU512        0.01
EDU_J3      E:\tsm\server\00000120.BFS      EDU319        0.01
EDU_JJ1     E:\tsm\server\00000116.BFS      EDU512        0.01
EDU_JJ1     E:\tsm\server\00000121.BFS      EDU512        0.01
```

If you specify a file space collocation group, only the volumes of the file spaces that belong to the collocation group are displayed. If you specify a file space collocation group and a volume, the file space volumes within the collocation group that are also in the specified volume are displayed.

Field descriptions

Node Name
: Specifies the name of the node.

Volume Name
: Specifies the name of the volume that contains the node data.

Storage Pool Name
: Specifies the name of the storage pool in which the volume is located.

Physical Space Occupied (MB)
: Specifies the amount of physical space that is occupied by the node's data. Physical space includes empty space within aggregates, from which files might be deleted or expired.

Related commands

Table 1. Commands related to QUERY NODEDATA

Command	Description
DEFINE COLLOCGROUP	Defines a collocation group.
DEFINE COLLOCMEMBER	Adds a client node or file space to a collocation group.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DELETE COLLOCGROUP	Deletes a collocation group.
DELETE COLLOCMEMBER	Deletes a client node or file space from a collocation group.
MOVE NODEDATA	Moves data for one or more nodes, or a single node with selected file spaces.
QUERY COLLOCGROUP	Displays information about collocation groups.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY STGPOOL	Displays information about storage pools.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.
UPDATE COLLOCGROUP	Updates the description of a collocation group.
UPDATE STGPOOL	Changes the attributes of a storage pool.

QUERY NODEGROUP (Query a node group)

Use this command to display the node groups defined on the server.

Privilege class

Any administrator can issue this command.

Syntax

```
.-*----------.
```

```
>>-Query NODEGroup--+------------+------------------------------>
                   '-group_name-'

   .-Format--=--Standard-----.
>--+-------------------------+--------------------------------><
   '-Format--=--+-Standard-+-'
                '-Detailed-'
```

Parameters

group_name
: Specifies the name of the node group to display. To specify multiple names, use a wildcard character. This parameter is optional. The default is to display all node groups.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed. To display the members of the node group, you must specify FORMAT=DETAILED.

Example: List node groups on the server

Display the node groups defined on the server. See Field descriptions for field descriptions.

```
query nodegroup

Node Group Name              Node Group Description
-------------------------    ------------------------------
DEPT_ED                      Education department
GROUP1                       Low cap client nodes.
```

Example: Display detailed node group information

Display complete information about all node groups and determine which client nodes belong to which node groups. See Field descriptions for field descriptions.

```
query nodegroup format=detailed

               Node Group Name: DEPT_ED
        Node Group Description: Education department
Last Update by (administrator): SERVER_CONSOLE
         Last Update Date/Time: 04/21/2006 10:59:03
          Node Group Member(s): EDU_1 EDU_7

               Node Group Name: GROUP1
        Node Group Description: Low cap client nodes.
Last Update by (administrator): SERVER_CONSOLE
         Last Update Date/Time: 04/21/2006 10:59:16
          Node Group Member(s): CHESTER REX NOAH JARED
```

Field descriptions

Node Group Name
: The name of the node group.

Node Group Description
: The description for the node group.

Last Update by (administrator)
: The name of the administrator that defined or most recently updated the node group.

Last Update Date/Time
: The date and time that an administrator defined or most recently updated the node group.

Node Group Member(s)
: The members of the node group.

Related commands

Table 1. Commands related to QUERY NODEGROUP

Command	Description
DEFINE BACKUPSET	Defines a previously generated backup set to a server.
DEFINE NODEGROUP	Defines a group of nodes.
DEFINE NODEGROUPMEMBER	Adds a client node to a node group.
DELETE BACKUPSET	Deletes a backup set.
DELETE NODEGROUP	Deletes a node group.
DELETE NODEGROUPMEMBER	Deletes a client node from a node group.
GENERATE BACKUPSET	Generates a backup set of a client's data.
QUERY BACKUPSET	Displays backup sets.
UPDATE BACKUPSET	Updates a retention value associated with a backup set.
UPDATE NODEGROUP	Updates the description of a node group.

QUERY OCCUPANCY (Query client file spaces in storage pools)

Use this command to show where client file spaces are stored and how much space they occupy.

Privilege class

Any administrator can issue this command.

Syntax

Parameters

node_name
: Specifies the node that owns the file spaces that you want to locate. This parameter is optional. You can use wildcard characters to specify names. If you do not specify a value for this parameter, all nodes are queried.

file_space_name
: Specifies the file space that you want to locate. This parameter is optional. You can use wildcard characters to specify names. If you do not specify a value for this parameter, all file spaces are queried. You must specify a node name if you specify a file space name.

For a server that has clients with Unicode support, you might need to have the server convert the file space name that you enter. For example, you might need to have the server convert the name that you enter from the server's code page to Unicode. See the NAMETYPE parameter for details. If you do not specify a file space name or specify only a single wildcard character for the name, you can use the CODETYPE parameter to limit the operation to Unicode file spaces or non-Unicode file spaces.

STGpool
: Specifies the storage pool to query for files from the specified file space. This parameter is optional. You can use wildcard characters to specify names. If you do not specify a value for this parameter, all storage pools are queried.

DEVclass
: Specifies the device class that is associated with the devices where the file spaces are stored. This parameter is optional. You can use wildcard characters to specify names. If you do not specify a value for this parameter, storage pools that are associated with any device class are queried.

Type
: Specifies the types of files to query in the file spaces. This parameter is optional. The default value is ANY. Possible values are:

  ANY
  : Specifies that all types of files are queried: back up versions of files, archived copies of files, and files that are migrated from IBM Spectrum Protect™ for Space Management clients.

  Backup
  : Specifies that backup files are queried.

  Archive
  : Specifies that archive files are queried.

  SPacem
  : Specifies that space-managed files (files that were migrated by an IBM Spectrum Protect for Space Management client) are queried.

NAMEType
: Specifies how you want the server to interpret the file space names that you enter. This parameter is useful when the server has clients with Unicode support. A backup-archive client with Unicode support is available only for Windows, Macintosh OS 9, Macintosh OS X, and NetWare. Use this parameter only when you specify a partly or fully qualified file space name.

  The default value is SERVER. Possible values are:

  SERVER
  : The server uses the server's code page to interpret the file space names.

  UNIcode
  : The server converts the file space names from the server code page to the UTF-8 code page. The success of the conversion depends on the actual characters in the names and the server's code page. Conversion can fail if the string includes characters that are not available in the server code page, or if the server has a problem accessing system conversion routines.

  FSID
  : The server interprets the file space names as their file space IDs (FSIDs).

CODEType
: Specifies how you want the server to interpret the file space names that you enter. Use this parameter only when you enter a single wildcard character for the file space name or when you do not specify any file space name.

  The default value is BOTH, which means that the file spaces are included regardless of code page type. Possible values are:

  UNIcode
  : Include file spaces that are only Unicode enabled.

  NONUNIcode
  : Include file spaces that are not only Unicode enabled.

  BOTH
  : Include file spaces regardless of code page type.

Example: Display file spaces assigned to a specific node

Display information about where all file spaces assigned to the node named DAISY are stored. See Field descriptions for field descriptions.

```
query occupancy daisy
```

```
Node     Type  Filespace    FSID  Storage    Number   Physical   Logical
Name           Name               Pool       of       Space      Space
                                  Name       Files    Occupied   Occupied
                                                      (MB)       (MB)
-------- ----  ---------- -----  --------  -------- --------   --------
 DAISY   Bkup  DRIVED         1    COPYFILE     38     0.45       0.42
```

Example: Display file spaces assigned to a specific node with a backup file type

Display information about the file spaces that belong to the node WAYNE, and that have a backup file type. See Field descriptions for field descriptions.

```
query occupancy wayne type=backup
```

```
 Node    Type  Filespace FSID   Storage     Number  Physical   Logical
 Name          Name              Pool        of      Space      Space
                                 Name        Files   Occupied   Occupied
                                                     (MB)       (MB)
 ------ ----- --------- -----  ----------- ------- ---------  --------
 WAYNE  Bkup  DWG1        1    BACKUPPOOL1 2,330   53.19      50.01
 WAYNE  Bkup  OS2C        2    BACKUPPOOL1 1,554   32.00      31.30
```

Field descriptions

Node Name
: The node that owns the file space. If the node was previously deleted, the node name DELETED is displayed.

Type
: The type of data. Possible values are:

  Arch
  : Data that has been archived.

  Bkup
  : Data that has been backed up.

  SpMg
  : Data that has been migrated from an IBM Spectrum Protect for Space Management client.

Filespace Name
: The name of the file space that belongs to the node.

  If the file space was previously deleted, the file space name DELETED is displayed.

  File space names can be in a different code page or locale than the server. If they are, the names in the Operations Center and the administrative command-line interface might not be displayed correctly. Data is backed up and can be restored normally, but the file space name or file name might be displayed with a combination of invalid characters or blank spaces.

  If the file space name is Unicode-enabled, the name is converted to the server code page for display. The success of the conversion depends on the operating system, the characters in the name, and the server code page. Conversion can be incomplete if the string includes characters that are not available in the server code page or if the server cannot access system conversion routines. If the conversion is incomplete, the name might contain question marks, blanks, unprintable characters, or ellipses (...).

Storage Pool Name
: The storage pool where the file space is located.

Number of Files
: The number of logical files that belong to the file space and are stored in this storage pool. When storing a file larger than 10 GB, the server splits the file into 10 GB fragments. The number of fragments is also included in this value for occupancy calculations.

Physical Space Occupied (MB)
: The amount of physical space that is occupied by the file space. Physical space includes empty space within aggregates, from which files might have been deleted or expired. For this value, 1 MB = 1048576 bytes.
  Tip: This field does not display a value for storage pools that are set up for data deduplication. If you turn off data deduplication for a storage pool, a value for physical occupancy is not displayed until the storage pool is empty of deduplicated files.

Logical Space Occupied (MB)

The amount of space that is occupied by logical files in the file space. Logical space is the space that is actually used to store files, excluding empty space within aggregates. For this value, 1 MB = 1048576 bytes.

FSID

The file space ID (FSID) for the file space. The server assigns a unique FSID when a file space is first stored on the server.

Related commands

Table 1. Commands related to QUERY OCCUPANCY

Command	Description
DELETE FILESPACE	Deletes data associated with client file spaces. If a file space is part of a collocation group and you remove the file space from a node, the file space is removed from the collocation group.
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.
QUERY NODE	Displays partial or complete information about one or more clients.

QUERY OPTION (Query server options)

Use this command to display information about server options.

Change server options by editing the server options file or by issuing the SETOPT command. When you edit the server options file, you must restart the server before any changes take effect. Any changes you make by issuing the SETOPT command take effect immediately.

Privilege class

Any administrator can issue this command.

Syntax

```
                .-*----------.
>>-Query OPTion--+------------+--------------------------------><
                '-optionname-'
```

Parameters

optionname

Specifies the name of an option in the server options file. This parameter is optional. You can use wildcard characters to specify this name. All matching server options display. If you do not specify this parameter, information on all options displays.

Example: Display all server options

Display general information about all server options. The output lists all options with their specified values.

```
query option
```

Example: Display options settings using a wildcard character

View the option settings for all options that begin with L.

```
query option l*

Server Option         Option Setting
-----------------     --------------------
Language              AMENG
```

Example: Display LDAP directory servers

View the settings for all LDAP directory servers.

```
query option ldapurl

Server Option         Option Setting
----------------      --------------------
LDAP URL               ldap:\\tophoy.tucson.com\cn=tsmdata
LDAP URL               ldap:\\krypton.ibm.com\ou=tsmdata,dc=ibm,dc=com
```

Field descriptions

Server Option
: Specifies the name of the option in the server options file.

Option Setting
: Specifies the name of the option in the server options file.

Related commands

Table 1. Commands related to QUERY OPTION

Command	Description
SETOPT	Updates a server option without stopping and restarting the server.

QUERY PATH (Display a path definition)

Use this command to display the path between a source and a destination.

Privilege class

Any administrator can issue this command.

Syntax

Parameters

source_name
: Specifies the name of a source for which to display paths. This parameter is optional. You can specify wildcard characters. The default is to display paths for all sources.

  A source is a data mover, a server, or a storage agent.

destination_name
: Specifies the name of a destination for which to display paths. This parameter is optional. You can specify wildcard characters. The default is to display paths for all destinations.

SRCType
: Specifies the type of the source. This parameter is optional. The default is to display paths for all source types. Possible values are:

  ANY
  : Specifies to display paths with any source type.

  DATAMover
  : Specifies to only display paths with the DATAMOVER source type.

  SERVer
  : Specifies to only display paths with the SERVER source type. (A source that has a source type of SERVER is a storage agent.)

DESTType
: Specifies the type of the destination. This parameter is optional. The default is to display paths for all destination types. Possible values are:

  ANY
  : Specifies to display paths with any destination type.

  DRive
  : Specifies to display only paths with the DRIVE destination type. When the destination type is a drive, you must specify the library name. You can refine which paths are displayed by entering a name in the LIBRARY parameter.

  LIBRary
  : Specifies that only paths with destination type LIBRARY display.

LIBRary
: Specifies the name of the library to which the drive belongs. This parameter is required when the destination type is a drive (DESTTYPE=DRIVE).

Format
: Specifies how the information is displayed. This parameter is optional. The default is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed.

Example: Display summary path information

Display information about paths for the source `NETAPP1`. See Field descriptions for field descriptions.

```
query path netapp1
```

```
Source Name  Source Type  Destination Name  Destination Type  Online
-----------  -----------  ----------------  ----------------  ------
NETAPP1      DATAMOVER    DRIVE1            DRIVE             Yes
NETAPP1      DATAMOVER    NASLIB            LIBRARY           Yes
```

Example: Display detailed path information

Display detailed information about paths for the source `NETAPP1`. See Field descriptions for field descriptions.

```
query path netapp1 format=detailed
```

Linux

```

Field descriptions

Source Name
: The name of the source.

Destination Name
: The name of the destination.

Source Type
: The type of the source.

Destination Type
: The type of the destination.

Library

The name of the library that contains the drive that is the destination.

This field will be blank if the destination type is library. The library name is in destination name field when the destination is a library.

Node Name
The name of the device that is the destination.

Device
The name of the device that is the destination.

External Manager
The name of the external manager.

ZOS Media Server
The name of the z/OS media server.

Comm. Method
Specifies the type of communication method.

LUN
Specifies the logical unit name through which the disk can be accessed by the source.

Initiator
Specifies the initiator of the communication.

Directory
Specifies the directory location of a file on the source.

On-Line
Whether the path is online and available for use.

Last Update by (administrator)
The ID of the administrator who performed the last update.

Last Update Date/Time
The date and time when the last update occurred.

Related commands

Table 1. Commands related to QUERY PATH

Command	Description
DEFINE PATH	Defines a path from a source to a destination.
DELETE PATH	Deletes a path from a source to a destination.
UPDATE PATH	Changes the attributes associated with a path.

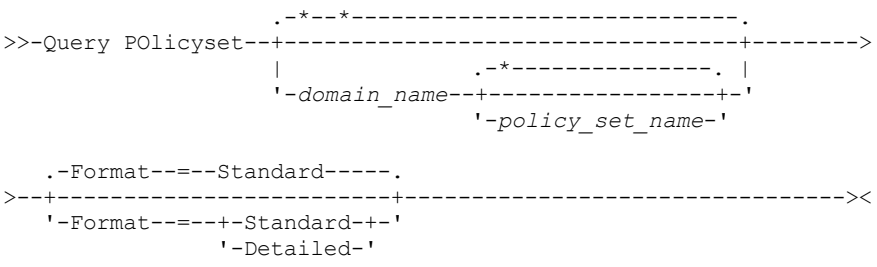
QUERY POLICYSET (Query a policy set)

Use this command to display information about one or more policy sets.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

domain_name

Specifies the policy domain associated with the policy set to query. This parameter is optional. You can use wildcard characters to specify names. If you do not specify a value for this parameter, all policy domains are queried. You must specify this parameter when querying an explicitly named policy set.

policy_set_name

Specifies the policy set to query. This parameter is optional. You can use wildcard characters to specify names. If you do not specify either ACTIVE or a policy set name, all policy sets are queried.

Format

Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

Standard

Specifies that partial information is displayed.

Detailed

Specifies that complete information is displayed.

Example: List policy sets for all policy domains

Query all policy sets for all policy domains. Create the output in standard format. See Field descriptions for field descriptions.

```
query policyset

Policy        Policy        Default       Description
Domain        Set Name      Mgmt
Name                        Class
                            Name
---------     ---------     ---------     ------------------------
EMPLOYEE-     ACTIVE        ACTIVEFI-     Personnel Department
 _RECORDS                    LES
EMPLOYEE-     HOLIDAY       ACTIVEFI-     Personnel Department

                                           Policies
PROG2         SUMMER                      Programming Group
                                           Policies
STANDARD      ACTIVE        STANDARD      Installed default policy
                                           set.
STANDARD      STANDARD      STANDARD      Installed default policy
                                           set.
```

Example: Displayed detailed information about a specific policy set

Query the VACATION policy set that is in the EMPLOYEE_RECORDS policy domain. Create the output in detailed format. See Field descriptions for field descriptions.

```
query policyset employee_records vacation
format=detailed

            Policy Domain Name: EMPLOYEE_RECORDS
               Policy Set Name: VACATION
       Default Mgmt Class Name: ACTIVEFILES
                   Description: Personnel Department
Last Update by (administrator): $$CONFIG_MANAGER$$
         Last Update Date/Time: 05/31/1998 13:15:50
              Managing profile: ADSM_INFO
                Changes Pending: Yes
```

Field descriptions

Policy Domain Name

The name of the policy domain.

Policy Set Name

The name of the policy set.

Default Mgmt Class Name

The management class assigned as the default for the policy set.

Description

The description of the policy set.

Last Update by (administrator)

The name of the administrator or server that most recently updated the policy set. If this field contains $$CONFIG_MANAGER$$, the policy set is associated with a domain that is managed by the configuration manager.

Last Update Date/Time
The date and time when the policy set was most recently defined or updated.

Managing Profile
The profile or profiles that manage the domain to which this policy set belongs.

Changes Pending
Whether or not changes are being made but not activated. Once the changes are activated, the field resets to No.

Related commands

Table 1. Commands related to QUERY POLICYSET

Command	Description
ACTIVATE POLICYSET	Validates and activates a policy set.
COPY POLICYSET	Creates a copy of a policy set.
DEFINE POLICYSET	Defines a policy set within the specified policy domain.
DELETE POLICYSET	Deletes a policy set, including its management classes and copy groups, from a policy domain.
QUERY DOMAIN	Displays information about policy domains.
UPDATE POLICYSET	Changes the description of a policy set.
VALIDATE POLICYSET	Verifies and reports on conditions the administrator must consider before activating the policy set.

QUERY PROCESS (Query one or more server processes)

Use this command to display information about active background processes.

To cancel background processes, issue the CANCEL PROCESS command. To display detailed information about node replication processes, issue the QUERY REPLICATION command.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query PRocess--+----------------+---------------------------->
                  '-process_number-'

>--+-----------------------+--+------------------+----------><
   '-DESCription--=--string-'  '-STATus--=--string-'
```

Parameters

process_number
Specifies the number of the background process to be queried. This parameter is optional. If not specified, information about all background processes is displayed.

DESCription
Specifies a text string that you want to search for in the list of active processes' descriptions. Enclose the string expression in quotation marks if it contains blanks. You can use text and a wildcard character to specify this string. This parameter is optional.

STATus
Specifies a text string that you want to search for in the list of active processes' statuses. Enclose the string expression in quotation marks if it contains blanks. You can use text and a wildcard character to specify this string. This parameter is optional.

Example: Query a single background process

Display information about background process 202. See Field descriptions for field descriptions.

```
query process 202
```

```
Process   Process              Process
Number    Description          Status
--------  -------------        ---------
     202  EXPORT SERVER        ANR0NNNI EXPORT
                               Identifier MYEXPORTSERVER

                           1 Minute(s).
```

Field descriptions

Process Number
: Specifies the number that is assigned to the active background process.

Process Description
: Specifies a description of the active background process.

Process Status
: Specifies the status of the active background process.

Tip: When a node replication process is finished on the target replication server, only end process information is stored in the activity summary table. The full summary for the replication process is stored in the activity summary table on the source replication server.

Related commands

Table 1. Command related to QUERY PROCESS

Command	Description
CANCEL EXPORT	Deletes a suspended export operation.
CANCEL PROCESS	Cancels a background server process.
IDENTIFY DUPLICATES	Identifies duplicate data in a storage pool.
QUERY EXPORT	Displays the export operations that are currently running or suspended.
QUERY REPLICATION	Displays information about node replication processes.
QUERY REPLNODE	Displays information about the replication status of a client node.
RESTART EXPORT	Restarts a suspended export operation.
SUSPEND EXPORT	Suspends a running export operation.

QUERY PROFILE (Query a profile)

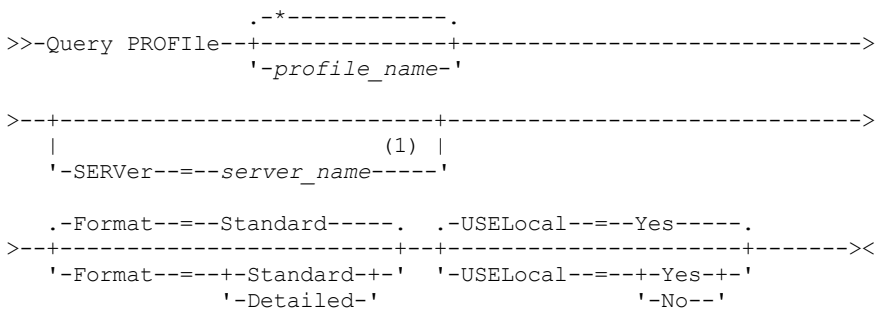
Use this command to display information about profiles and associated objects. Issue this command from a configuration manager or from a managed server. You can use this command to get profile information from any configuration manager defined to the server, even if the server does not subscribe to any profile.

If you query a locked profile from the configuration manager to which the profile belongs, complete profile information is displayed. If you query a locked profile from another server, the query displays only that the profile is locked.

Privilege class

Any administrator can issue this command.

Syntax



Notes:

1. The server name you specify depends on the server from which you issue the command. See the description of the SERVER parameter.

Parameters

profile_name
: Specifies the profile to display. To specify multiple names, use a wildcard character. This parameter is optional. The default is to display all profiles.

SERVer
: Specifies the configuration manager whose profile information is displayed. The requirements for the name depends on where the query is issued:

  - From a configuration manager: This parameter is optional. The default is the configuration manager's name.
  - From a managed server: This parameter is optional. The default is the name of the configuration manager for this managed server.
  - From a server that is neither a configuration manager nor a managed server: You must specify a name.

Format
: Specifies whether partial or detailed information is displayed. The default is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that detailed information is displayed.

USELocal
: When you perform the query from a managed server, this parameter specifies whether the profile information is obtained from the configuration manager or the managed server. If the profile information does not exist on the managed server, the information is obtained from the configuration manager, regardless of the value of this parameter.

  If you use this parameter on a server that is not managed by the configuration manager that owns the profile, the parameter is ignored. The default value is YES. Possible values are:

  Yes
  : Specifies that the profile information, if available, is obtained from the managed server. The configuration manager is contacted if information is not available from the managed server.

  No
  : Specifies that the profile information is obtained from the configuration manager even if the information is available from the managed server. This ensures that you receive current information about the profile.

Example: List profiles from a configuration manager

Display profile information from a configuration manager. See Field descriptions for field descriptions.

```
query profile

Configuration       Profile name          Locked?
manager
```

```
---------------     ---------------       ------
SERVER1             DEFAULT_PROFILE       No
SERVER1             ADMIN_INFO            No
SERVER1             EMPLOYEE              No
SERVER1             PERSONNEL             Yes
```

Example: Display detailed profile information for a managed server

From a managed server, display current detailed information for profile ADMIN_INFO. See Field descriptions for field descriptions. Note: When the profile is locked, most fields are not displayed.

```
query profile admin_info
format=detailed uselocal=no

           Configuration manager: SERVER1
                    Profile name: ADMIN_INFO
                          Locked: No
                     Description: Distributed administrative schedules
           Server administrators: DENNIS EMILY ANDREA
                   Policy domains: ADMIN RECORDS
Administrative command schedules: ** all objects **
          Server Command Scripts:
              Client Option Sets:
                         Servers:
                   Server Groups:
```

Field descriptions

Configuration manager
: The name of the configuration manager that owns the profile.

Profile name
: The name of the profile.

Locked?
: Whether the profile is locked.

Description
: The description of the profile.

Server administrators
: The administrators that are associated with the profile.

Policy domains
: The policy domains that are associated with the profile.

Administrative command schedules
: The administrative schedules that are associated with the profile.

Server Command Scripts
: The server command scripts that are associated with the profile.

Client Option Sets
: The client option sets that are associated with the profile.

Servers
: The servers that are associated with the profile.

Server Groups
: The names of server groups that are associated with the profile.

Related commands

Table 1. Commands related to QUERY PROFILE

Command	Description
COPY PROFILE	Creates a copy of a profile.
DEFINE PROFASSOCIATION	Associates objects with a profile.
DEFINE PROFILE	Defines a profile for distributing information to managed servers.
DEFINE SUBSCRIPTION	Subscribes a managed server to a profile.
DELETE PROFASSOCIATION	Deletes the association of an object with a profile.

Command	Description
DELETE PROFILE	Deletes a profile from a configuration manager.
LOCK PROFILE	Prevents distribution of a configuration profile.
SET CONFIGMANAGER	Specifies whether a server is a configuration manager.
UNLOCK PROFILE	Enables a locked profile to be distributed to managed servers.
UPDATE PROFILE	Changes the description of a profile.

QUERY PROTECTSTATUS (Query the status of storage pool protection)

Use this command to display information about the status of storage pool protection for directory-container storage pools.

Privilege class

Any administrator can issue this command.

Syntax

```
                          .-*---------.
>>-Query PROTECTStatus--+-----------+--------------------------->
                        '-pool_name-'

   .-Format--=--Standard-----.
>--+-------------------------+--------------------------------><
   '-Format--=--+-Standard-+-'
                '-Detailed-'
```

Parameters

pool_name
: Specifies the name of the directory-container storage pool to be queried. This parameter is optional. You can use wildcard characters to specify this name. If you do not specify a value, the status of all directory-container storage pools is displayed.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Specify one of the following values:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed.

Example: Display summary information about a specific storage pool

Display information about the storage pool that is named POOL1. Issue the following command:

```
query protectstatus pool1
```

```
Source         Source         Target         Target          Pct.        Last Complete
Server Name    Storage Pool   Server Name    Storage Pool    Protected   Protect
------------   ------------   ------------   ------------    ----------  --------------
NEXT           POOL1          NEXT           POOL1COPY       96.55       02/17/2017 11:15:07
NEXT           POOL1          NEXT1          POOL2           99.99       02/17/2017 11:14:53
NEXT           POOL1          UNKNOWN        UNKNOWN         UNKNOWN     02/17/2017 11:13:44
NEXT1          POOL2          NEXT           POOL1           100.00      02/17/2017 12:56:58
```

See Field descriptions for field descriptions.

Example: Display detailed information about a specific storage pool

Display information in full detail about the storage pool named, POOL1. Issue the following command:

```
query protectstatus pool1 format=detailed

       Source Server Name: NEXT
      Source Storage Pool: POOL1
       Target Server Name: NEXT
      Target Storage Pool: POOL1COPY
           Pct. Protected: 96.55
   Data Extents Protected: 1,747
       Data Extents Total: 1,852
           Protected (MB): 165.33
               Total (MB): 171.23
Last Completed Protection: 02/17/2017 11:15:07
   Last Refresh Date/Time: 02/19/2017 00:27:12
```

See Field descriptions for field descriptions.

Field descriptions

Source Server Name
: The name of the source server.

Source Storage Pool
: The name of the directory-container storage pool on the source server.

Target Server Name
: The name of the target server.

Target Storage Pool
: The name of the directory-container storage pool on the target server.

Pct. Protected
: The percentage of protected data in the directory-container storage pool.

Data Extents Protected
: The number of data extents that are protected in the directory-container storage pool.

Data Extents Total
: The total number of data extents in the directory-container storage pool.

Protected (MB)
: The total amount of protected data that is in the directory-container storage pool, in megabytes.

Total (MB)
: The total amount of data that is in the directory-container storage pool, in megabytes.

Last Completed Protection
: The date and time that the directory-container storage pool was last protected.

Last Refresh Date/Time
: The date and time that the directory-container storage pool was last refreshed.

Related commands

Table 1. Commands related to QUERY PROTECTSTATUS

Command	Description
PROTECT STGPOOL	Protects a directory-container storage pool.

QUERY PROXYNODE (Query proxy authority for a client node)

Use this command to display client nodes with authority to act as proxy to other client nodes in the IBM Spectrum Protect™ server.

Privilege class

Any administrator can issue this command.

Syntax

```
                                .-*----------------.
>>-Query PROXynode----TArget--=--+------------------+----------><
```

```
'-target_node_name-'
```

Parameters

TArget
: Specifies the name of the node targeted by the node with proxy authority. It is optional to specify a target node name. Wildcard names can be used to specify the target node name. A comma-separated list of node names is also allowed.

Example: List client nodes with proxy authority

To display all IBM Spectrum Protect client nodes with proxy authority to the target node named MYCLUSTER, issue the following command.

```
query proxynode target=mycluster
```

```
Target Node         Agent Node
---------------     ----------------
FRED                MOE MINIE MICKEY
ALPHA               BETA GAMMA DELTA
```

Field descriptions

Target Node
: Specifies the name of the node targeted by the node with proxy authority.

Agent Node
: Specifies the name of the agent node.

Related commands

Table 1. Commands related to QUERY PROXYNODE

Command	Description
GRANT PROXYNODE	Grant proxy authority to an agent node.
REVOKE PROXYNODE	Revoke proxy authority from an agent node.

QUERY PVUESTIMATE (Display processor value unit estimate)

Use this command to obtain an estimate of the client devices and server devices that are being managed by the IBM Spectrum Protect™ server. In addition, this command provides an estimate of the processor value unit (PVU) totals for the server devices.

This command generates a PVU estimate that is based on the number of logical nodes that are defined to the IBM Spectrum Protect server. By contrast, the calculation of license obligations is based on the number of physical computers. There might not be a one-to-one correlation between the number of logical nodes and the number of physical computers. The report that is generated by the QUERY PVUESTIMATE command is an estimate, which is not legally binding.

For purposes of the QUERY PVUESTIMATE command, nodes on Microsoft Windows 7, Microsoft Windows XP Professional, and Apple systems are assumed to be client devices. Nodes on all other platforms are considered to be server devices. The server on which IBM Spectrum Protect is running is also classified as a server device. However, you can reclassify server devices as client devices if required. If your system includes retired workstations, test workstations, or others that can be ignored for purposes of PVU calculation, you can specify them as type other. To change a node classification, use the UPDATE NODE command or the REGISTER NODE command.

Note: The PVU information reported by IBM Spectrum Protect is not considered an acceptable substitute for the IBM® License Metric Tool.

Privilege class

Any administrator can issue this command.

Syntax

```
                        .-Format--=--Standard-----.
>>-Query PVUESTIMate--+-------------------------+-------------><
                      '-Format--=--+-Standard-+-'
                                   '-Detailed-'
```

Parameters

Format
: Specifies the output format. This parameter is optional. The default is Standard. The following values can be used:

  Standard
  : Specifies standard output.

  Detailed
  : Specifies detailed output.

Example: Display the estimated number of devices and PVU

Display the estimated number of client devices and server devices, and the estimated PVU for the server devices, for an IBM Spectrum Protect server. Issue the following command:

```
query pvuestimate
```

Table 1. Sample output for several products managed by one IBM Spectrum Protect server

Product	Number of Client Devices	Number of Server Devices	PVU of Server Devices
IBM Spectrum Protect Extended Edition	1,000	905	90,500
IBM Spectrum Protect for Storage Area Networks	50	10	1,000
IBM Spectrum Protect for Space Management	0	0	0
IBM Spectrum Protect for Mail	0	25	5,000
IBM Spectrum Protect for Databases	0	1,025	20,500
IBM Spectrum Protect for Enterprise Resource Planning	0	25	5,000
IBM Spectrum Protect for System Backup and Recovery	0	0	0

Other Node Classifications	Number
Nodes earlier than Version 6.3 with no PVU information available at this time	10
Nodes at Version 6.3 or later with no PVU match	9
Nodes classified by the administrator as "other-device"	8
Nodes defined as a non-licensed API application	6

The following list provides details about the example fields:

Product
: The IBM Spectrum Protect product name.

Number of Client Devices
: The estimated number of client devices that are managed by the product. By default, only nodes on Microsoft Windows 7, Microsoft Windows XP Professional, and Apple systems are assumed to be client devices.

Number of Server Devices
: The estimated number of server devices that are managed by the product. By default, nodes on all platforms except for Microsoft Windows 7, Microsoft Windows XP Professional, and Apple systems are assumed to be server devices. This number also includes the server on which IBM Spectrum Protect is running.

PVU of Server Devices
: The estimated PVUs of all nodes that are connected as server devices.

Nodes earlier than Version 6.3 with no PVU information available at this time
: Devices that do not report processor information to the server.

Nodes at Version 6.3 or later with no PVU match

Devices that do not report all required values or some values were reported as "Unknown".

Nodes classified by the administrator as "other-device"

Nodes that are excluded from PVU counting by the administrator by using the update node roleoverride=other command.

Nodes defined as a non-licensed API application

Nodes such as DB2® backup or custom API applications.

Example: Display detailed node information

Display information for individual nodes by specifying the detailed (d) value for the Format parameter. Issue the following command:

```
tsm: PATMOS_630> query pvuestimate f=d
```

Table 2. Node classifications for specific products

Product	Number of Client Devices	Number of Server Devices	PVU of Server Devices
IBM Spectrum Protect Extended Edition	1,000	905	90,500
- banode1	1

Related commands

Table 3. Commands related to QUERY PVUESTIMATE

Command	Description
AUDIT LICENSES	Verifies compliance with defined licenses.
QUERY LICENSE	Displays information about licenses and audits.
QUERY NODE	Displays partial or complete information about one or more clients.
REGISTER LICENSE	Registers a license with the IBM Spectrum Protect server.
REGISTER NODE	Defines a client node to the server and sets options for that user.
SET CPUINFOREFRESH	Specifies the number of days between client scans for workstation information used for PVU estimates.
SET LICENSEAUDITPERIOD	Specifies the number of days between automatic license audits.
UPDATE NODE	Changes the attributes that are associated with a client node.

QUERY RECOVERYMEDIA (Query recovery media)

Use this command to display information about the media (for example, boot media) needed to recover a machine. Media are displayed in alphabetical order by name.

Remember: IBM Spectrum Protect™ does not use the information. It is available only to help you plan for the disaster recovery of client machines.

Privilege class

Any administrator can issue this command.

Syntax

```
                          .-*----------.
>>-Query RECOVERYMedia--+------------+-------------------------->
                          '-media_name-'

>--+--------------------+--+----------------------+------------>
   '-Type--=--+-BOot--+-'  '-LOcation--=--location-'
              '-OTher-'

   .-Format--=--Standard-----.
>--+-------------------------+--------------------------------><
   '-Format--=--+-Standard-+-'
                '-Detailed-'
```

Parameters

media_name
: Specifies the name of the recovery media. You can use wildcard characters to specify the name. This parameter is optional. The default is all recovery media.

Type
: Specifies the type of media to be queried. This parameter is optional. If this parameter is not specified, all recovery media are queried. Possible values are:

  BOot
  : Only boot media are queried.

  OTher
  : All media other than boot media are queried.

LOcation
: Specifies the location of the recovery media to be queried. This parameter is optional. You can specify up to 255 characters. Enclose the description in quotation marks if it contains any blank characters.

Format
: Specifies how the information is displayed. This parameter is optional. Possible values are:

  Standard
  : Displays partial information. This is the default.

  Detailed
  : Displays all information.

Example: Display summary information for a specific recovery media

Display information for the recovery media named RECMED1. See Field descriptions for field descriptions.

```
query recoverymedia RECMED1

Recovery Media Name   Volume Names      Location          Machine Name
--------------------  ----------------  ----------------  ------------
RECMED1               vol1 vol2 vol3    IRONMOUNTAIN      MACH1
                       vol4
```

Example: Display detailed information for a specific recovery media

Display detailed information for the recovery media named RECMED1. See Field descriptions for field descriptions.

```
query recoverymedia RECMED1 format=detailed

Recovery Media Name: RECMED1
               Type: Boot
       Volume Names: vol1 vol2 vol3 vol4
           Location: IRONMOUNTAIN
        Description:
            Product:
Product Information:
       Machine Name: MACH1
```

Field descriptions

Recovery Media Name
: The name of the recovery media.

Type
: Whether the recovery media are boot media or another type of media. Possible values are:

  Boot
  : The recovery media are boot media.

  Other
  : The recovery media are not boot media.

Volume Names
: The set of volumes that contain the data needed to recover machines associated with this media.

Location
: Where the recovery media is stored.

Description
: A description of the recovery media.

Product
: The product used to create the boot media.

Product Information
: Information about the product that created the boot media. This information may be needed for restoring the machine.

Machine Name
: The machines that are associated with this recovery media.

Related commands

Table 1. Commands related to QUERY RECOVERYMEDIA

Command	Description
DEFINE RECMEDMACHASSOCIATION	Associates recovery media with a machine.
DEFINE RECOVERYMEDIA	Defines the media required to recover a machine.
DELETE RECOVERYMEDIA	Deletes recovery media.
UPDATE RECOVERYMEDIA	Changes the attributes of recovery media.

QUERY REPLICATION (Query node replication processes)

Use this command to display information about running and ended node-replication processes.

Issue this command on the server that acts as a source for replicated data.

Important: You cannot display information about running replication processes for client nodes that are being converted from import and export operations to replication operations. The conversion process might run for a long time, but it occurs only once for a client node that is being converted.

By default, records about completed node-replication processes are retained for 30 calendar days. A *calendar day* consists of 24-hours, from midnight to midnight.

To display the retention period, issue the QUERY STATUS command. Check the value in the Replication Record Retention Period field. To change the retention period, issue the SET REPLRETENTION command.

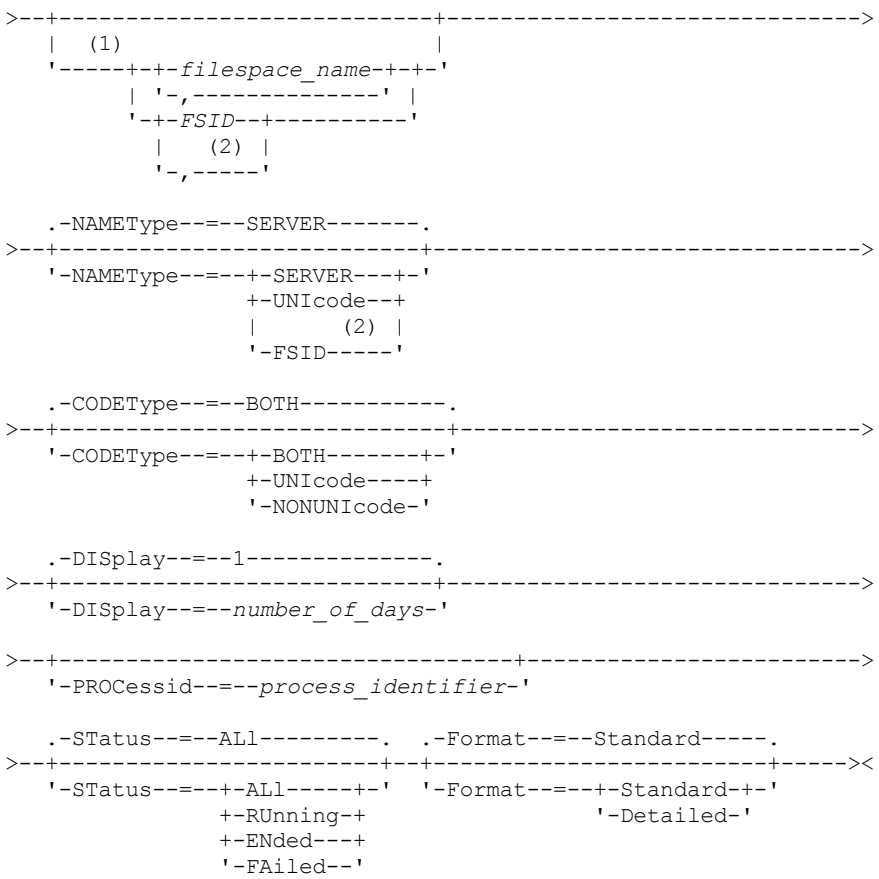
Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query REPLIcation--node_name---------------------------------->

   .-*-------------------------.
```



Notes:

1. Do not mix FSIDs (file space identifiers) and file space names in the same command.
2. Do not specify FSID if you use wildcard characters for the client node name.

Parameters

node_name (Required)

Specifies the name of the client node to be queried. You can use wildcard characters when you specify this name, with one exception. If the value of the NAMETYPE parameter is FSID, do not specify wildcard characters for the client node name. The FSID value indicates the file space identifier. File spaces with identical names can have different identifiers in different client nodes.

filespace_name or FSID

Specifies the name of the file space or the file space identifier (FSID) to be queried. A name or FSID is optional. If you do not specify a name or an FSID, all file spaces are queried.

filespace_name

Specifies the name of the file space that has data to be queried. File space names are case-sensitive. To determine the correct capitalization for the file space, issue the QUERY FILESPACE command. Separate multiple names with commas with no intervening spaces. When you specify a name, you can use wildcard characters.

A server that has clients with Unicode-enabled file spaces might have to convert the file space name. For example, the server might have to convert a name from the server code page to Unicode. For details, see the NAMETYPE parameter. If you do not specify a file space name, or if you specify only a single wildcard character for the name, you can use the CODETYPE parameter to limit the operation to Unicode file spaces or to non-Unicode file spaces.

FSID

Specifies the file space identifier for the file space to be queried. The server uses FSIDs to find the file spaces to replicate. To determine the FSID for a file space, issue the QUERY FILESPACE command. Separate multiple FSIDs with commas with no intervening spaces. If you specify an FSID, the value of the NAMETYPE parameter must be FSID.

NAMEType

Specifies how you want the server to interpret the file space names that you enter. You can use this parameter for IBM Spectrum Protect™ clients that are Unicode-enabled and that have Windows, Macintosh OS X, or NetWare operating systems.

Use this parameter only if you enter a partly qualified or fully qualified file space name. The default value is SERVER. You can specify one of the following values:

SERVER
: The server uses the server code page to interpret file space names.

UNIcode
: The server converts file space names from the server code page to the UTF-8 code page. The success of the conversion depends on the characters in the name and the server code page. Conversion can fail if the string includes characters that are not available in the server code page. Conversion can also fail if the server cannot access system conversion routines.

FSID
: The server interprets file space names by using their file space identifiers.

CODEType

Specifies the type of file spaces to be included in the query. The default value is BOTH, which means that file spaces are included regardless of code page type. Use this parameter only if you enter a single wildcard character for the file space name. You can specify one of the following values:

UNIcode
: Include file spaces that are in Unicode only.

NONUNIcode
: Include file spaces that are not in Unicode only.

BOTH
: Include all file spaces regardless of code page type.

DISplay

Specifies the number of days of node replication history to display. The default value is 1, which displays information about running node replication processes and about processes that completed during the current calendar day. The maximum value is 9999.

You can specify a number that is the same as or less than the number of days that are specified as the retention period for the replication history records. If you specify a value that is more than the value of the replication retention period or more than the number of days that replication records are collected, the server displays only the number of replication history records that are available. For example, suppose that the replication retention period is 30 days and that the replication process is running for only 10 days. If you specify `DISPLAY=20`, only 10 days of replication history are displayed.

PROCessid
: Specifies the node replication history that is associated with a particular process identified by the process identifier. This parameter is optional. If you do not specify this parameter, all processes are displayed for the number of days that are specified by the DISPLAY parameter.

Restarting the server can cause the server to reuse process IDs. Reuse of process IDs can result in duplicate process IDs for separate processes.

STatus
: Specifies the status of the file spaces to query. This parameter is optional. The default value is ALL. You can specify one of the following values:

ALl
: Specifies all file spaces that are replicating, file spaces that replicated successfully, and file spaces that did not finish replicating or replicated with errors.

RUnning
: Specifies all file spaces that are replicating to the target replication server.

ENded
: Specifies all file spaces that replicated successfully and file spaces that did not finish replicating or replicated with errors.

FAiled

Specifies all file spaces that did not finish replicating or replicated with errors.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. You can specify one of the following values:

  Standard
  : Specifies that partial information is displayed for node replication processes.

  Detailed
  : Specifies that all available information for the node replication processes is displayed.

Example: Display information about replication processes for a file space

Display information about replication processes for a file space in client node PAYROLL. The file space identifier is 10.

```
query replication ironman

NodeName    Filespace    FSID    Start Time    End Time    Status   Phase
            Name

Field descriptions

Node Name
: The name of the client node whose data is displayed.

Filespace Name
: The name of the client file space whose data is displayed.

FSID
: The file space identifier.

Start Time
: The date and time that the node replication process started.

End Time
: The date and time that the node replication process ended.

Status
: The status of the node replication process. The following values are possible:

  Running
  : The process is active and is either searching for eligible data or sending data to the target replication server.

  Ended

The process ended or failed.

Failed
The process failed.

Process Number
The identifier for the node replication process.

The same process number can have different start times. If a replication process starts and the server is restarted, the server begins assigning process numbers that begin with the number 1. Replication processes that start after a server restart can obtain process numbers that are already assigned to other replication processes in the replication history. To identify unique replication processes, use the start time.

Command
The command that was issued to start the node replication process.

Phase
The phase of a running node-replication process. The following phases are listed in the order in which they occur:

Identifying
The node replication process started to identify data to be replicated, but data is not yet being sent to the target replication server.

Identifying and replicating
The node replication process is identifying data to be replicated and transferring the data to the target replication server.

Replicating
The node replication process identified the data and is transferring files to the target replication server.

None
The node replication process is not running.

Process Running Time
The running time of the node replication process.

Completion State
The state of the node replication process. The following values are possible:

Complete
The node replication process completed.

Incomplete
The node replication process ended without running to completion. To determine the reason, check the value in the Reason for Incompletion field.

Reason for Incompletion
The reason why the node replication process ended without completing. Possible values include *canceled* and *other*. The value *other* can indicate that the server was halted during replication or that the server failed.

Backup Last Update Date/Time
The date and time that statistics for backup were last updated. The specified time is the time that the files in the file space were identified for replication or when each batch of files was sent to the target replication server.

Archive Last Update Date/Time
The date and time that statistics for archive were last updated. The specified time is the time that the files in the file space were identified for replication or when each batch of files was sent to the target replication server.

Space Managed Last Update Date/Time
The date and time that statistics for space-managed files were last updated. The specified time is the time that the files in the file space were identified for replication or when each batch of files was sent to the target replication server.

Backup Target Server
The name of the target replication server for backup files.

Archive Target Server
The name of the target replication server for archive files.

Space Management Target Server
The name of the target replication server for space-managed files.

Backup Files Needing No Action
The number of backup files in the file space that did not need to be replicated, updated, or deleted.

Archive Files Needing No Action
The number of archive files in the file space that did not need to be replicated, updated, or deleted.

Space Managed Files Needing No Action
The number of space-managed files in the file space that did not need to be replicated, updated, or deleted.

Backup Files To Replicate

The number of backup files to replicate to the target replication server.

Archive Files To Replicate
The number of archive files to replicate to the target replication server.

Space Managed Files To Replicate
The number of space-managed files to replicate to the target replication server.

Backup Files Replicated
The number of backup files that are replicated to the target replication server.

Archive Files Replicated
The number of archive files that are replicated to the target replication server.

Space Managed Files Replicated
The number of space-managed files that are replicated to the target replication server.

Backup Files Not Replicated Due To Errors
The number of backup files that were not replicated to the target replication server because of errors.

Archive Files Not Replicated Due To Errors
The number of archive files that were not replicated to the target replication server because of errors.

Space Managed Files Not Replicated Due To Errors
The number of space-managed files that were not replicated to the target replication server because of errors.

Backup Files Not Yet Replicated
The number of backup files that are not yet replicated to the target replication server.

Archive Files Not Yet Replicated
The number of archive files that are not yet replicated to the target replication server.

Space Managed Files Not Yet Replicated
The number of space-managed files that are not yet replicated to the target replication server.

Backup Files To Delete
The number of backup files to be deleted on the target replication server.

Archive Files To Delete
The number of archive files to be deleted on the target replication server.

Space Managed Files To Delete
The number of space-managed files to be deleted on the target replication server.

Backup Files Deleted
The number of backup files that are deleted on the target replication server.

Archive Files Deleted
The number of archive files that are deleted on the target replication server.

Space Managed Files Deleted
The number of space-managed files that are deleted on the target replication server.

Backup Files Not Deleted Due To Errors
The number of backup files that were not deleted from the target replication server because of errors.

Archive Files Not Deleted Due To Errors
The number of archive files that were not deleted from the target replication server because of errors.

Space Managed Files Not Deleted Due To Errors
The number of space-managed files that were not deleted from the target replication server because of errors.

Backup Files To Update
The number of backup files to update on the target replication server. If the metadata of a file is changed, the changed fields are sent to the target replication server.

Archive Files To Update
The number of archive files to update on the target replication server. If the metadata of a file is changed, the changed fields are sent to the target replication server.

Space Managed Files To Update
The number of space-managed files to update on the target replication server. If the metadata of a file is changed, the changed fields are sent to the target replication server.

Backup Files Updated
The number of backup files that are updated on the target replication server.

Archive Files Updated
The number of archive files that are updated on the target replication server.

Space Managed Files Updated
The number of space-managed files that are updated on the target replication server.

Backup Files Not Updated Due To Errors
The number of backup files that were not updated on the target replication server because of errors.

Archive Files Not Updated Due To Errors
The number of archive files that were not updated on the target replication server because of errors.

Space Managed Files Not Updated Due To Errors
The number of space-managed files that were not updated on the target replication server because of errors.

Backup Bytes To Replicate (MB)
The number of backup bytes to replicate to the target replication server.

Archive Bytes To Replicate (MB)
The number of archive bytes to replicate to the target replication server.

Space Managed Bytes To Replicate (MB)
The number of space-managed bytes to replicate to the target replication server.

Backup Bytes Replicated (MB)
The number of backup bytes that are replicated to the target replication server.

If a file was stored in a deduplicated storage pool, the number of bytes in the stored file might be less than the number of bytes in the original file. This field represents the number of physical bytes in the original file.

Archive Bytes Replicated (MB)
The number of archive bytes that are replicated to the target replication server.

If a file was stored in a deduplicated storage pool, the number of bytes in the stored file might be less than the number of bytes in the original file. This field represents the number of physical bytes in the original file.

Space Managed Bytes Replicated (MB)
The number of space-managed bytes that are replicated to the target replication server.

If a file was stored in a deduplicated storage pool, the number of bytes in the stored file might be less than the number of bytes in the original file. This field represents the number of physical bytes in the original file.

Backup Bytes Transferred (MB)
The number of backup bytes that were sent to the target replication server.

The value in this field represents the actual number of file bytes sent to the target replication server. This value is calculated by subtracting the number of bytes not sent because of deduplication from the number of bytes to replicate.

Archive Bytes Transferred (MB)
The number of archive bytes that were sent to the target replication server.

The value in this field represents the actual number of file bytes sent to the target replication server. This value is calculated by subtracting the number of bytes not sent because of deduplication from the number of bytes to replicate.

Space Managed Bytes Transferred (MB)
The number of space-managed bytes that were sent to the target replication server.

The value in this field represents the actual number of file bytes sent to the target replication server. This value is calculated by subtracting the number of bytes not sent because of deduplication from the number of bytes to replicate.

Backup Bytes Not Replicated Due to Errors (MB)
The number of backup bytes that were not replicated to the target replication server because of errors.

Archive Bytes Not Replicated Due to Errors (MB)
The number of archive bytes that were not replicated to the target replication server because of errors.

Space Managed Bytes Not Replicated Due to Errors (MB)
The number of space-managed bytes that were not replicated to the target replication server because of errors.

Backup Bytes Not Yet Replicated (MB)
The number of backup bytes not yet replicated to the target replication server.

Archive Bytes Not Yet Replicated (MB)
The number of archive bytes not yet replicated to the target replication server.

Space Managed Bytes Not Yet Replicated (MB)
The number of space-managed bytes not yet replicated to the target replication server.

Total Files Needing No Action
The total number of files in the file space that did not need to be replicated, updated, or deleted.

Total Files To Replicate
The total number of files to replicate to the target replication server.

Total Files Replicated
The total number of files that are replicated to the target replication server.

Total Files Not Replicated Due To Errors
The total number of files that were not replicated because of errors.

Total files Not Yet Replicated
The total number of files that are not yet replicated to the target replication server.

Total Files To Delete

The total number of files that were deleted on the target replication server.

Total Files Deleted
: The total number of files that are deleted on the target replication server.

Total Files Not Deleted Due to Errors
: The total number of backup, archive, and space-managed files that were not deleted on the target replication server because of errors.

Total Files To Update
: The total number of files to be updated on the target replication server. When the metadata of a file is changed, the changed fields are sent to the target replication server.

Total Files Updated
: The total number of files that are updated on the target replication server.

Total Files Not Updated Due to Errors
: The total number of backup, archive, and space-managed files that were not updated on the target replication server because of errors.

Total Bytes To Replicate (MB)
: The total number of bytes to replicate to the target replication server.

Total Bytes Replicated (MB)
: The total number of bytes that are replicated to the target server.

  If a file was stored in a deduplicated storage pool, the number of bytes in the stored file might be less than the number of bytes in the original file. This field represents the number of physical bytes in the original file.

Total Bytes Transferred (MB)
: The total number of bytes that were transferred to the target replication server.

  For files stored in a deduplicated storage pool, the value in this field includes the number of bytes in the original file before duplicate extents were removed. If duplicate extents were already on the target replication server, the number of bytes in the original file is more than the number of bytes transferred.

Total Bytes Not Replicated Due to Errors (MB)
: The total number of bytes that were skipped because the source replication server was unable to transfer them to the target replication server.

Total Bytes Not Yet Replicated (MB)
: The total number of bytes not yet transferred to the target replication server.

Estimated Percentage Complete
: The estimated completion percentage that is based on the number of bytes.

Estimated Time Remaining
: The estimated time that remains before the node replication process is complete.

Estimated Time Of Completion
: The estimated time when the node replication process ends.

Table 1. Commands related to QUERY REPLICATION

Command	**Description**
CANCEL REPLICATION	Cancels node replication processes.
QUERY ACTLOG	Displays messages from the server activity log.
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY PROCESS	Displays information about background processes.
QUERY REPLNODE	Displays information about the replication status of a client node.
QUERY REPLRULE	Displays information about node replication rules.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
SET REPLRETENTION	Specifies the retention period for replication history records.

QUERY REPLNODE (Display information about replication status for a client node)

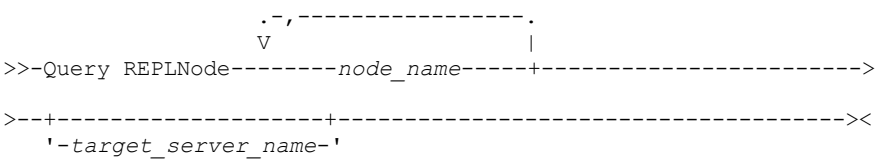
Use this command to display the number of files that are stored for each replicated file space. Information is displayed about file spaces for every client node that is configured for replication.

A client node is configured for replication if it is enabled or disabled.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

node_name (Required)

Specifies the client node that owns the files about which you want information. You can specify one or more names. If you specify multiple names, separate the names with commas. Do not use intervening spaces. You can use wildcard characters to specify multiple names.

Information about client nodes that match the file criteria, but that are not configured for replication, is not displayed.

target_server_name

Specifies the name of the replication server to query for replication information. This parameter is optional. If you do not specify a value for this parameter, the server that is the default target for replicated data is queried.

As the value for this parameter, you can also specify a server that was formerly a target for replicated data.

The client nodes that are defined to a replication server can be the source or the target of replicated data. To determine whether a particular client node is sending or receiving data, issue the QUERY NODE command. Look for the value *Send* or *Receive* in the Replication Mode field of the output.

To display the name of the active target replication server, issue the QUERY STATUS command, and look for the name in the Target Replication Server field.

Example: List client node files on a source and a target replication server

The name of the client node is NODE1.

```
query replnode *

Node   Type   Filespace  FSID   Files on   Replication   Files on
Name           Name             Server     Server (1)    Server (1)
-------------------------------------------------------------------
NODE1  SpMg    /hmsmfs    1      1
NODE1  Bkup    /lspace2   2      27
NODE1  Arch    /lspace2   2      22         TGTSRV     22
NODE1  Bkup    /lspace    3      18,096
NODE1  Arch    /lspace    3      61,150     TGTSRV     61,150
NODE2
```

The number of files that are displayed for the replication servers might be different for the following reasons:

- The output of the QUERY REPLNODE command displays the number of files obtained from the occupancy table. The occupancy table contains only files that have a length greater than zero. Files that have a length of 0 and have been

replicated are not reflected in this output.

- If only active data is replicated to the target server, the number of files that are displayed for the source server will be larger than the number of files that are displayed on the target server. The reason for the difference is that the source replication server has both active and inactive data, and the target server has only active data.
- A client node might have data that was exported from the source replication server and imported to the target replication server. If that data was synchronized and if the client node also stored data to the target replication server, then the number of files on the target replication server will be greater than the number of files stored as a result of export-and-import operations and replication.
- When you replicate node data from a source server prior to version 7.1, to a target server at version 7.1 or later, files that are larger than 10 GB are split in to smaller files if the SPLITLARGEOBJECTS parameter for the node definition is set to `Yes`. Each of these split files are counted on the target server.

Field descriptions

Node Name
: The name of the client node that owns the files.

Type
: The type of data. If this field is blank, the client node is configured for replication, but it does not have data on the replication server. In the example output, NODE2 is configured for replication, but it does not have backup, archive, or space-managed data.

  The following values are possible:

  Arch
  : Archive data

  Bkup
  : Backup data

  SpMg
  : Data that was migrated by IBM Spectrum Protect™ for Space Management clients

Filespace Name
: The name of the file space that belongs to the node.

  If this field is blank, the client node is configured for replication, but it does not have data on the replication server.

  File space names can be in a different code page or locale than the server. If they are, the names in the Operations Center and the administrative command-line interface might not be displayed correctly. Data is backed up and can be restored normally, but the file space name or file name might be displayed with a combination of invalid characters or blank spaces.

  If the file space name is Unicode-enabled, the name is converted to the server code page for display. The success of the conversion depends on the operating system, the characters in the name, and the server code page. Conversion can be incomplete if the string includes characters that are not available in the server code page or if the server cannot access system conversion routines. If the conversion is incomplete, the name might contain question marks, blanks, unprintable characters, or ellipses (...).

FSID
: The file space identifier for the file space. The server assigns a unique FSID when a file space is initially stored on the server. If this field is blank, the client node is configured for replication, but it does not have data on the replication server.

Files on Server
: The number of backup, archive, and space-managed files on the server on which this command is issued. If this field is blank, the client node is configured for replication, but it does not have data on the replication server.

Replication Server (1)
: The name of the replication server that is being queried for information. If this field is blank, one or more of the following conditions might exist:

  - The file space of the node on the replication server where the command was issued does not have any data.
  - The client node is not defined on replication server (1).
  - The client node is defined on replication server (1), but the node is not configured for replication.
  - The corresponding file space on replication server (1) does not have data or the file space is not defined.

Files on Server (1)
: The number of files for the data type that are stored on the target replication server. This field can be blank. If it is, one or more of the following conditions might exist:

- Replication server (1) does not have any data.
- The client node is not defined on replication server (1).
- The client node is defined on replication server (1), but the node is not configured for replication.
- The corresponding file space on replication server (1) does not have data or the file space is not defined.

Related commands

Table 1. Commands related to QUERY REPLNODE

Command	Description
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY REPLICATION	Displays information about node replication processes.
QUERY REPLRULE	Displays information about node replication rules.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
UPDATE REPLRULE	Enables or disables replication rules.

QUERY REPLRULE (Query replication rules)

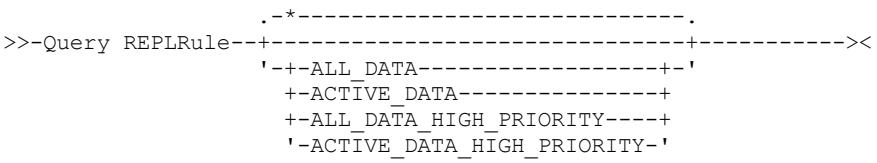
Use this command to display information about replication rules.

Issue this command on the server that acts as a source for replicated data.

Privilege class

Any administrator can issue this command.

Syntax



Privilege class

Any administrator can issue this command.

Parameters

rule_name
: Specifies the name of the replication rule that you want to display information about. This parameter is optional. You can use wildcard characters to specify one or more rules. If you do not specify this parameter, information about all rules is displayed in the query output. You can specify the following values:

  ALL_DATA
  : Displays information about the ALL_DATA replication rule. This rule replicates backup, archive, or space-managed data. The data is replicated with a normal priority.

  ACTIVE_DATA
  : Displays information about ACTIVE_DATA replication rule. This rule replicates only active backup data. The data is replicated with a normal priority. This rule is not valid for archive or space-managed data.
  Attention: If you specify ACTIVE_DATA and one or more of the following conditions are true, inactive backup data on the target replication server is deleted, and inactive backup data on the source replication server is not replicated.

- When a server version earlier than Version 7.1.1 is installed on either the source or target replication servers.
- When you are using the REPLICATE NODE command with the `FORCERECONCILE=YES` parameter.
- When you are running the initial replication of a file space after you configure replication, restore the database, or upgrade both the source and target replication servers from a server version earlier than V7.1.1.

If the previous conditions are not true, all new and changed files since the last replication are replicated, including inactive files, and files are deleted when they expire.

ALL_DATA_HIGH_PRIORITY
: Displays information about the ALL_DATA_HIGH_PRIORITY rule. This rule replicates backup, archive, or space-managed data. The data is replicated with a normal priority. In a replication process, high-priority data is replicated before normal-priority data.

ACTIVE_DATA_HIGH_PRIORITY
: Displays information about the ACTIVE_DATA_HIGH_PRIORITY rule.

  This rule is the same as the ACTIVE_DATA replication rule except data is replicated with a high priority.

Example: Display information about a server replication rule

The name of the rule is ALL_DATA_HIGH_PRIORITY

```
query replrule all_data_high_priority

Replication Rule Name: ALL_DATA_HIGH_PRIORITY
Target Replication Server:
Active Only: No
Enabled: Yes
```

Field descriptions

Replication Rule Name
: Specifies the name of the rule that was queried.

Target Replication Server
: Specifies the name of the target replication server.

Active Only
: Specifies whether the rule applies only to active backup data. The following values are possible:

  Yes
  : Specifies that only active backup data is replicated for file spaces to which this rule is assigned.

  No
  : Specifies that all backup data is replicated for file spaces to which this rule is assigned.

Enabled
: Specifies whether the rule is enabled or disabled. The following values are possible:

  Yes
  : Specifies that the rule is enabled for replication. Data in file spaces to which the rule is assigned is replicated.

  No
  : Specifies that the rule is not enabled for replication. Data in file spaces to which the rule is assigned is not replicated.

Related commands

Table 1. Commands related to QUERY REPLRULE

Command	Description
QUERY REPLICATION	Displays information about node replication processes.
QUERY REPLNODE	Displays information about the replication status of a client node.
UPDATE REPLRULE	Enables or disables replication rules.

QUERY REPLSERVER (Query a replication server)

Use this command to view information about all replication servers that are known server. The output from this command includes server information for the server from which the command was issued. The command indicates whether a replication server definition is deleted as a result of a REMOVE REPLSERVER command.

Privilege class

Any administrator can issue this command.

Syntax

```
                      .-*-----------.
>>-Query REPLServer--+-------------+--------------------------><
                      '-server_name-'
```

Example: Display summary statistics about all replicating servers

Display information about the replicating server. Issue the command from either the source or the target replication server:

```
query replserver *

Replication Globally Unique ID: 4d.83.fc.30.67.c1.11.e1.b8.
                                      40.f0.de.f1.5e.f1.89
                   Server Name: Server1
               Last Replication:
                      Heartbeat:
   Failover High Level Address: server1.example.com
      Failover TCP Port Number: 1500
      Failover SSL Port Number: 1542
          Deletion in Progress: No
           Dissimilar Policies:

Replication Globally Unique ID: 91.0f.ef.90.5c.cc.11.e1.ae.
                                34.08.00.27.00.58.dc
                   Server Name: DRServer1
               Last Replication: 06/30/2012 08:16:30 PM
                      Heartbeat: 07/09/2012 22:15:22 PM
  Fail over High Level Address: drserver1.example.com
      Failover TCP Port Number: 1500
      Failover SSL Port Number: 1542
          Deletion in Progress: No
           Dissimilar Policies: On

Replication Globally Unique ID: 90.4f.53.b0.8e.cb.11.e3.a8.
                                2f.00.14.5e.55.b3.67
                   Server Name: DRSERVER2
               Last Replication: 04/01/14   12:38:28
                      Heartbeat: 05/29/14   11:15:44
   Failover High Level Address: drserver2.example.com
      Failover TCP Port Number: 1500
      Failover SSL Port Number:
          Deletion in Progress: No
           Dissimilar Policies: Off
```

Example: Display summary statistics about a specific replicating server

Display information about the replicating server DRServer1. Issue the command from either the source or the target replication server:

```
query replserver drserver1

Replication Globally Unique ID: 91.0f.ef.90.5c.cc.11.e1.ae.
                                      34.08.00.27.00.58.dc
                   Server Name: DRServer1
               Last Replication: 06/30/2012 08:16:30 PM
                      Heartbeat: 07/09/2012 22:15:22 PM
  Fail over High Level Address: drserver1.example.com
      Failover TCP Port Number: 1500
      Failover SSL Port Number: 1542
```

```
Deletion in Progress: No
 Dissimilar Policies: On
```

Parameters

server_name
: Specifies the name of the replication server to be queried. You can use wildcard characters to specify this name. All matching servers are queried. If you do not specify a value for this parameter, all servers are queried. The parameter is optional.

Field descriptions

Replication Globally Unique ID
: The unique identifier for the IBM Spectrum Protect™ server. The values for the Replication Globally Unique ID are created when a server is first used in a replication process.
Tip: The ID listed in the Replication Globally Unique ID field is not the same value as the value for the ID listed in the Machine Globally Unique ID field that is shown in the QUERY STATUS command.

Server Name
: The name of the replication server.

Last Replication
: The date of the last replication process that used the server.

Heartbeat
: The last time that the server completed a successful test communication session.

Failover TCP Port Number
: The active Transmission Control Protocol (TCP) client port on the replication server that is used for client connections. If the client is configured for TCP, the port is used to connect to the failover server.

Failover SSL Port Number
: The active Secure Sockets Layer (SSL) port on the replication server that is used for client connections. If the client is configured for SSL, the port is used to connect to the failover server.

Failover High Level Address
: The high-level address that the client uses to connect to the replication server during failover.

Deletion in Progress
: Specifies whether a REMOVE REPLSERVER command was issued for this replication server and is still in progress. The following values are possible:

  Yes
  : The deletion of the replication server is in progress.

  No
  : The deletion of the replication server is not in progress.

Dissimilar Policies
: Specifies whether the policies that are defined on the target replication server are enabled. The following values are possible:

  On
  : The policies on the target replication server manage replicated client-node data.

  Off
  : The policies on the source replication server manage replicated client-node data.

Related commands

Table 1. Commands related to QUERY REPLSERVER

Command	Description
REMOVE REPLNODE (Remove a client node from replication)	Removes a node from replication.
REMOVE REPLSERVER (Remove a replication server)	Removes a server from replication.

QUERY REQUEST (Query one or more pending mount requests)

Use the QUERY REQUEST command to show information about one or more pending mount requests. The server makes requests for the administrator to complete an action, like inserting a tape volume in a library after a CHECKIN LIBVOL is issued.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query REQuest--+----------------+--------------------------><
                  '-request_number-'
```

Parameters

request_number
: Specifies the identification number of the pending mount request. This parameter is optional. The default is all pending mount requests.

Example: List all pending mount requests

Display information about all pending mount requests after a CHECKIN LIBVOL is issued.

```
query request
```

Output for a manual Library

AIX

```
ANR8352I Requests outstanding:
ANR8326I 001: Mount 8MM volume EXP001 R/W
in drive 8MM.1 (/dev/mt0) of library
MANUALLIB within 60 minute(s).
```

Linux

```
ANR8352I Requests outstanding:
ANR8326I 001: Mount 8MM volume EXP001 R/W
in drive 8MM.1 (/dev/mt0) of library
MANUALLIB within 60 minute(s).
```

Windows

```
ANR8352I Requests outstanding:
ANR8326I 001: Mount GENERICTAPE volume EXP001 R/W
in drive 8MM.1 (mt3.0.0.0) of library
MANUALLIB within 60 minute(s).
```

Output for an automated Library

AIX | Windows

```
ANR8352I Requests outstanding:
ANR8306I 001: Insert LTO volume 133540L5 R/W into the slot with
 element number 31 of library LTOLIB within 60 minutes; issue
 'REPLY' along with the request ID when ready.
```

Linux

```
ANR8352I Requests outstanding:
ANR8306I 001: Insert 3590 volume 133540 R/W into the slot with element
 number 31 of library 3590LIB within 60 minutes; issue 'REPLY'
 along with the request ID when ready.
```

Related commands

Table 1. Related commands for QUERY REQUEST

Command	Description
CANCEL REQUEST	Cancels pending volume mount requests.

Command	Description
REPLY	Allows a request to continue processing.

QUERY RESTORE (Query restartable restore sessions)

Use this command to display information about the restartable restore sessions.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query--RESTore--+-----------+--+-----------------+----------->
                   '-node_name-'  '-file_space_name-'

   .-Format--=--Standard-----.  .-NAMEType--=--SERVER------.
>--+-------------------------+--+-------------------------+---><
   '-Format--=--+-Standard-+-'  '-NAMEType--=--+-SERVER--+-'
                '-Detailed-'                   +-UNIcode-+
                                               '-FSID----'
```

Parameters

node_name
: Specifies the client node to be queried. This parameter is optional. If you do not specify a value, all client nodes with restartable restore sessions are displayed. You must specify a value for this parameter if you specify a file space name.

file_space_name
: Specifies the file space to be queried. This parameter is optional. If you do not specify a value, all file spaces are matched for the specified node.

  For a server that has clients with support for Unicode, you may need to have the server convert the file space name that you enter. For example, you may need to have the server convert the name you enter from the server's code page to Unicode. See the NAMETYPE parameter for details.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed.

NAMEType
: Specify how you want the server to interpret the file space names that you enter. This parameter is useful when the server has clients with support for Unicode. You can use this parameter for Unicode-enabled IBM Spectrum Protect™ clients using Windows, Macintosh OS 9, Macintosh OS X, and NetWare operating systems.

  Use this parameter only when you enter a partly or fully qualified file space name. The default value is SERVER. Possible values are:

  SERVER
  : The server uses the server's code page to interpret the file space names.

  UNIcode
  : The server converts the file space name entered from the server code page to the UTF-8 code page. The success of the conversion depends on the actual characters in the name and the server's code page. Conversion can fail if the string includes characters that are not available in the server code page, or if the server has a problem accessing system conversion routines.

  FSID
  : The server interprets the file space names as their file space IDs (FSIDs).

Example: Display a restartable restore session on a specific client node

Display detailed information about client node JAMES associated with file space DRIVE_F_R. See Field descriptions for field descriptions.

```
query restore james drive_f_r format=detailed

    Sess Number: -1
  Restore State: Restartable
Elapsed Minutes: 2
      Node Name: JAMES
           FSID: 1
 Filespace Name: DRIVE_F_R:
      File Spec: /RESTORE/TESTDIRF\\
```

Field descriptions

Sess Number
: Specifies the session number for the restartable restore session. The number for active restore sessions is the same number displayed on the QUERY SESSION command. For restore sessions in the restartable state, a negative number is displayed for the session number. Any session number displayed in the QUERY RESTORE output may be specified from the QUERY RESTORE output.

Restore State

- Active: Specifies the restore session is actively restoring files to the client.
- Restartable: Specifies the restore session failed and can be restarted from where it left off.

Elapsed Minutes
: Specifies the number of minutes since the restore session started. Any restartable restore session with an elapsed time greater than the RESTOREINTERVAL server option can be automatically deleted from the database when needed or during expiration processing. If the elapsed time is less than the RESTOREINTERVAL, you can delete this entry (and unlock the filespace) only by issuing the CANCEL RESTORE command lowering the RESTOREINTERVAL value.

Node Name
: Specifies the node associated with the restartable restore session.

FSID
: Specifies the file space ID of the file space.

Filespace Name
: Specifies the file space associated with the restartable restore session.

  File space names can be in a different code page or locale than the server. If they are, the names in the Operations Center and the administrative command-line interface might not be displayed correctly. Data is backed up and can be restored normally, but the file space name or file name might be displayed with a combination of invalid characters or blank spaces.

  If the file space name is Unicode-enabled, the name is converted to the server code page for display. The success of the conversion depends on the operating system, the characters in the name, and the server code page. Conversion can be incomplete if the string includes characters that are not available in the server code page or if the server cannot access system conversion routines. If the conversion is incomplete, the name might contain question marks, blanks, unprintable characters, or ellipses (...).

File Spec
: Specifies the file specification used on the restore operation. The same file specification must be specified if a failed restore operation is to be restarted from where it stopped.

Related commands

Table 1. Commands related to QUERY RESTORE

Command	Description
CANCEL RESTORE	Cancels a restartable restore session.

QUERY RPFCONTENT (Query recovery plan file contents stored on a target server)

Use this command to display the contents of a recovery plan file stored on a target server (that is, when the DEVCLASS parameter was specified on the PREPARE command). You can issue this command from either the server that created the file (the source server) or the server that stores the recovery plan file (the target server). You cannot issue this command from the server console.

The output may be delayed if the file is on tape.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Query RPFContent--plan_file_name----------------------------->

>--+-DEVclass--=--device_class_name-+------------------------><
   '-NODEName--=--node_name---------'
```

Parameters

plan_file_name (Required)
: Specifies the name of the recovery plan file to be queried. The format of the file name is servername.yyyymmdd.hhmmss. To see the names of existing files, issue the QUERY RPFILE command.

DEVclass
: Specifies the name of the device class used to create the recovery plan file. Wildcard characters are not allowed.
Specify this parameter when:

- You want to display the contents of the recovery plan file that was created for this server.
- You are issuing this command to the same server on which the PREPARE command was issued (the source server).
- The specified device class name was used on the PREPARE command that created the recovery plan file.

NODEName
: Specifies the node name, registered on the target server, of the source server that created the recovery plan file. Wildcard characters are not allowed.
Specify this parameter when:

- You want to display the contents of the recovery plan file that was stored on this server.
- You are issuing this command to the server that was the target of the PREPARE command that created the recovery plan file.
- The specified node name is registered to this server with a node type of SERVER.
- The IBM Spectrum Protect™ server that created the recovery plan file is not available.

Example: Display the source server recovery plan

On the source server, display the contents of a recovery plan file that was created for this server on March 19, 1998, at 6:10 A.M. The PREPARE command specifies the device class REMOTE. The output of this command is the entire contents of the recovery plan file.

```
query rpfcontent branch1.19980319.061000 devclass=remote
```

Example: Display the target server recovery plan

On the target server, display the contents of a recovery plan file that was stored in this server on March 19, 1998, at 6:10 A.M. The server that created the file is registered on the target server as a node named POLARIS with a node type of SERVER. The output of this command is the entire contents of the recovery plan file.

```
query rpfcontent branch1.19980319.061000 nodename=polaris
```

Related commands

Table 1. Commands related to QUERY RPFCONTENT

Command	Description

Command	Description
PREPARE	Creates a recovery plan file.
QUERY RPFILE	Displays information about recovery plan files.
QUERY VOLHISTORY	Displays sequential volume history information that has been collected by the server.

Related information:

Disaster recovery plan file

QUERY RPFILE (Query recovery plan file information stored on a target server)

Use this command to display information about recovery plan files stored on a target server. You can issue this command from either the server that created the file (the source server) or the server that stores the recovery plan file (the target server).

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query RPFile--+-DEVclass--=--device_class_name-+------------->
                 '-NODEName--=--node_name---------'

   .-Source--=--DBBackup-------.  .-Format--=--Standard-----.
>--+---------------------------+--+-------------------------+--><
   '-Source--=--+-DBBackup---+-'  '-Format--=--+-Standard-+-'
                '-DBSnapshot-'                 '-Detailed-'
```

Parameters

DEVclass
: Specifies the name of the device class that was used to create the recovery plan files. Use this parameter when logged on to the server that created the recovery plan file. You can use wildcard characters in the device class name. All recovery plan files that are created with the device class specified are included in the query.

NODEName
: Specifies the node name, registered on the target server, of the source server that created the recovery plan files. Use this parameter when logged on to the target server. You can use this parameter when the source server is not available. You can use wildcard characters to specify the node name. All file objects that are stored with the node name specified are included in this query.

Source
: Specifies the type of database backup that was specified when the recovery plan file was prepared. This parameter is optional. The default is DBBACKUP. Possible values are:

  DBBackup
  : The recovery plan file was prepared with full and incremental database backups specified.

  DBSnapshot
  : The recovery plan file was prepared with snapshot database backups specified.

Format
: Specifies how the information is displayed. This parameter is optional. The default is STANDARD. Possible values are:

  Standard
  : Displays partial information for the recovery plan file.

  Detailed
  : Displays all information for the recovery plan file.

Example: Display detailed information about the recovery plans

Display recovery plan files that were created for this server using the specified device class. See Field descriptions for field descriptions.

```
query rpfile devclass=* format=detailed

    Recovery Plan File Name: ALASKA.20000406.170423
                  Node Name: BRANCH1
        Device Class Name: REMOTE
    Recovery Plan File Type: RPFILE
          Mgmt Class Name: STANDARD
    Recovery Plan File Size: 16,255 Bytes
        Marked for Deletion: Yes
              Deletion Date: 06/12/2000 13:05:31

    Recovery Plan File Name: ALASKA.20000407.170845
                  Node Name: BRANCH1
        Device Class Name: REMOTE
    Recovery Plan File Type: RPFSNAPSHOT
          Mgmt Class Name: STANDARD
    Recovery Plan File Size: 16,425 Bytes
        Marked for Deletion: No
              Deletion Date:
```

Example: Display a list of recovery plans for a specific node name

Display a list of all recovery plan file objects that are stored with the specified node name (TYPE=SERVER). See Field descriptions for field descriptions.

```
query rpfile nodename=branch1

    Recovery Plan File Name       Node Name       Device Class Name
    ----------------------        ---------       -----------------
     ALASKA.19980406.170423         BRANCH1         REMOTE
     ALASKA.19980407.170845         BRANCH1         REMOTE
```

Field descriptions

Recovery Plan File Name
: The recovery plan file name.

Node Name
: The node name that is registered with the target server and used to store the recovery plan file objects.

Device Class Name
: The device class name that is defined in the source server and used to create the recovery plan files.

Recovery Plan File Type
: The type of recovery plan file:

  RPFILE
  : The plan assumes full plus incremental database backups.

  RPFSNAPSHOT
  : The plan assumes snapshot database backups.

Mgmt Class Name
: The management class name that the recovery plan file is associated with in the target server.

Recovery Plan File Size
: Estimated size of the recovery plan file object on the target server.

Marked For Deletion
: Whether the object that contains the recovery plan file has been deleted from the source server and marked for deletion on the target server if the grace period has not expired. Possible values are:

  Yes
  : The object is marked for deletion.

  No
  : The object is not marked for deletion.

Deletion Date
: Date that the object has been deleted from the source server and marked for deletion on the target server. This field is blank if the object has not been marked for deletion.

Related commands

Table 1. Commands related to QUERY RPFILE

Command	Description
PREPARE	Creates a recovery plan file.
QUERY VOLHISTORY	Displays sequential volume history information that has been collected by the server.
QUERY RPFCONTENT	Displays the contents of a recovery plan file.

QUERY SAN (Query the devices on the SAN)

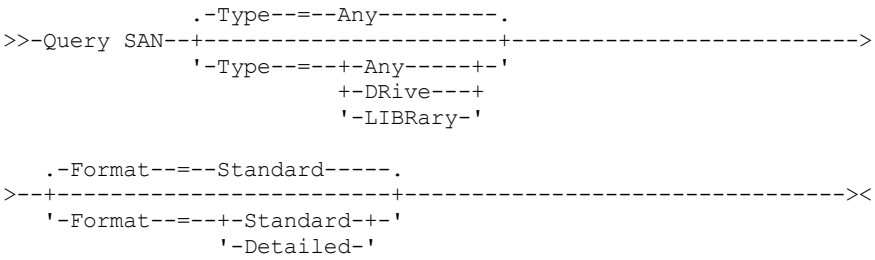
Use this command to obtain information about devices that can be detected on a storage area network (SAN) so that you can configure IBM Spectrum Protect™ for LAN-free data movement.

AIX The QUERY SAN command requires the libhbaapi.a that supports SNIA common Host Bus Adapter (HBA) API. With this library object, IBM Spectrum Protect can call the hbaapi functions that are specified in the SNIA common HBAAPI standard.
Windows The QUERY SAN command requires the hbaapi.dll that supports SNIA common Host Bus Adapter (HBA) API. With this library object, IBM Spectrum Protect can call the hbaapi functions that are specified in the SNIA common HBAAPI standard.
Linux The QUERY SAN command requires the libhaapi.so that supports SNIA common Host Bus Adapter (HBA) API. With this library object, IBM Spectrum Protect can call the hbaapi functions that are specified in the SNIA common HBAAPI standard.
The QUERY SAN command might not show all the devices if the SANDISCOVERY server option is not set to ON.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

Type
: Specifies the type of device that is displayed. This parameter is optional. The default value is Any. Possible values are:

  Any
  : Specifies that any device detected on the SAN is displayed.

  DRive
  : Specifies that only drive devices are displayed.

  LIBRary
  : Specifies that only library devices are displayed.

Format
: Specifies the type of information that is displayed. This parameter is optional. The default value is Standard. Possible values are:

  Standard
  : Specifies that the information displayed is summarized.

  Detailed
  : Specifies that complete information is displayed.

Tip: The output might not display the serial number of the device. If this happens, look on the back of the device or contact the manufacturer of the device.

Example: List drive devices

Display summary information for drive devices on a SAN. See Field descriptions for field descriptions.

```
query san type=drive
```

```
Device Type      Vendor         Product     Serial           Device
-------------    ----------     ---------   ---------        ----------
LIBRARY          STK            L180        MPC01000128      /dev/smc1
DRIVE            STK            9840D       331001017229     /dev/rmt3
DRIVE            Quantum        DLT4000     JF62806275       /dev/rmt4
DRIVE            Quantum        DLT4000     JP73213185       /dev/rmt5
DRIVE            STK            9840D       331000028779     /dev/rmt6
```

Example: Display drive device information

Display detailed information for all drive devices on a SAN. See Field descriptions for field descriptions.

```
query san type=drive format=detailed
```

```
                    Device Type:    DRIVE
                         Vendor:    IBM
                        Product:    03570B02
                  Serial Number:
                         Device:    mt10.2.0.3
                     DataMover:    No
                      Node WWN:    5005076206039E05
                      Port WWN:    5005076206439E05
                           LUN:    0
                     SCSI Port:    3
                      SCSI Bus:    0
                   SCSI Target:    10
```

Field descriptions

Device Type
: The type of device that is being displayed.

Vendor
: The name of the device's vendor.

Product
: The name of the product that is assigned by the vendor.

Serial Number
: The serial number of the device.

Device
: The device special file name.

Data Mover
: Whether the device is a data mover.

Node WWN
: The worldwide name for the device.

Port WWN
: The worldwide name for the device, which is specific to the port that the device is connected to.

LUN
: The Logical Unit Number of the device.

SCSI Port
: The port of the Fibre Channel (or SCSI) Host Bus Adapter.

SCSI Bus
: The bus of the Host Bus Adapter card.

SCSI Target
: The target number of the device.

Related commands

Table 1. Commands related to QUERY SAN

Command	Description
DEFINE DATAMOVER	Defines a data mover to the IBM Spectrum Protect server.
DEFINE DRIVE	Assigns a drive to a library.
DEFINE LIBRARY	Defines an automated or manual library.

QUERY SCHEDULE (Query schedules)

Use this command to display information about one or more schedules.

The QUERY SCHEDULE command takes two forms, depending on whether the schedule applies to client operations or administrative commands. The syntax and parameters for each operation are defined separately. Some options in the query display will be blank depending on whether the schedule style is classic or enhanced.

Table 1. Commands related to QUERY SCHEDULE

Command	Description
COPY SCHEDULE	Creates a copy of a schedule.
DEFINE SCHEDULE	Defines a schedule for a client operation or an administrative command.
UPDATE SCHEDULE	Changes the attributes of a schedule.

- QUERY SCHEDULE (Query client schedules)
  Use this command to display information about one or more client schedules.
- QUERY SCHEDULE (Query an administrative schedule)
  Use this command to display information about one or more administrative schedules.

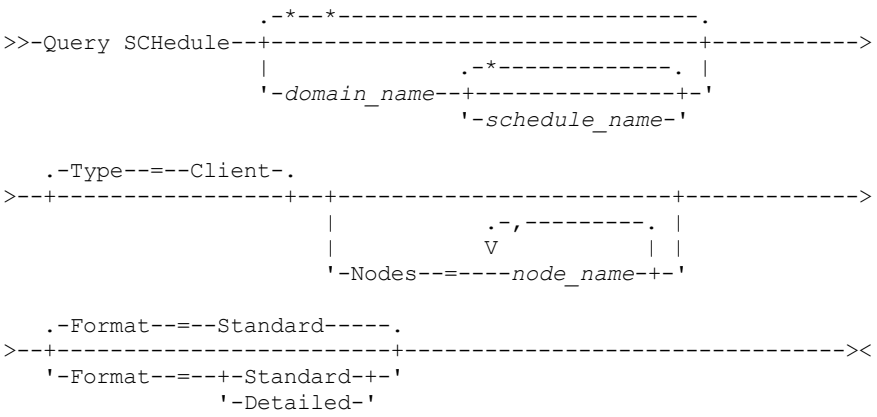
QUERY SCHEDULE (Query client schedules)

Use this command to display information about one or more client schedules.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

domain_name
: Specifies the name of the policy domain to which the schedule belongs. You can use a wildcard character to specify this name. If you specify a domain name, you do not have to specify a schedule name.

schedule_name
: Specifies the name of the schedule that belongs to the specified policy domain. You can use a wildcard character to specify this name. If you specify a schedule name, you must also specify a policy domain name.

Type=Client
: Specifies that the query displays client schedules. This parameter is optional. The default is CLIENT.

Nodes
: Specifies the name of one or more client nodes that are associated with the schedules to be displayed. This parameter is optional. You can use a wildcard character to specify client nodes. If you do not specify a client name, all schedules matching the DOMAINNAME and SCHEDULENAME parameters are displayed. You can specify multiple client nodes by separating the names with commas and no intervening spaces.

Format
: Specifies how information is displayed. This parameter is optional. The default is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed for the schedules.

  Detailed
  : Specifies that detailed information is displayed for the schedules.

  The standard format displays a blank in the period column and an asterisk in the day column for enhanced schedules. To display complete information about an enhanced schedule, issue FORMAT=DETAILED.

Example: List schedules for a specific policy domain

Display all schedules that belong to the EMPLOYEE_RECORDS policy domain. See Field descriptions: Schedules for a specific policy domain for field descriptions.

```
query schedule employee_records
```

The standard format displays a blank in the period column and an asterisk in the day column for enhanced schedules. To display complete information about an enhanced schedule, issue FORMAT=DETAILED.

```
Domain  * Schedule Name   Action Start       Duration Period Day
                                Date/Time
------- - --------------  ------ ----------  -------- ------ ---
EMPLOY    WEEKLY_BACKUP   Inc Bk 2004.06.04  1 H      1 D    Any
EE_RE-                          17.04.20
CORDS
EMPLOY-   EMPLOYEE_BACKUP Inc Bk 2004.06.04  1 H             (*)
EE_RE-                          17.04.20
CORDS
```

Field descriptions: Schedules for a specific policy domain

Domain
: Specifies the name of the policy domain to which the specified schedule belongs.

* (Asterisk)
: Specifies whether the corresponding schedule has expired. If there is an asterisk in this column, the corresponding schedule has expired.

Schedule Name
: Specifies the name of the schedule.

Action
: Specifies the action that occurs when this schedule is processed.

Start Date/Time
: Specifies the initial starting date and time for this schedule.

Duration
: Specifies the length of the startup window for this schedule.

Period
: Specifies the time between startup windows (assuming DAYOFWEEK=ANY). The column is blank for enhanced schedules.

Day
: Specifies the day of the week on which the startup windows for the schedule begin. The column contains an asterisk for enhanced schedules.

Example: Display detailed client schedules

From a managed server, display detailed information about client schedules. See Field descriptions: Detailed client schedules for field descriptions.

```
query schedule * type=client format=detailed

            Policy Domain Name: ADMIN_RECORDS
                 Schedule Name: ADMIN_BACKUP
                   Description:
                        Action: Backup
                     Subaction: vApp
                       Options:
                       Objects:

```

Field descriptions: Detailed client schedules

Policy Domain Name
: Specifies the name of the policy domain.

Schedule Name
: Specifies the name of the schedule.

Description
: Specifies the description of the schedule.

Action
: Specifies the type of action that occurs when this schedule is run. See the DEFINE SCHEDULE command for a listing of actions.

Subaction
: Specifies that the type of operation identified by the ACTION parameter is to be scheduled. See the DEFINE SCHEDULE command for a listing of subactions.

Options
: Specifies the options that are supplied to the DSMC command when the schedule is run.

Objects
: Specifies the objects for which the specified action is performed.

Priority
: Specifies the priority value for the schedule.

Start Date/Time
: Specifies the initial starting date and time for the schedule.

Duration
: Specifies the length of the startup window for the schedule.

Maximum Run Time (Minutes)
: Specifies the number of minutes during which all client sessions that are started by the scheduled operation should be completed. If sessions are still running after the maximum run time, the server issues a warning message, but the sessions continue to run.

Schedule Style
: Specifies whether classic or enhanced schedule rules are used.

Period
: Specifies the time between startup windows (assuming DAYOFWEEK=ANY). This is not displayed for enhanced syntax schedules.

Day of Week
: Specifies the day of the week on which the startup windows for the schedule begin. Using a standard format displays an asterisk in the day of week field for enhanced schedules.

Month
: Specifies the months during which the schedule will run. This is not displayed for classic syntax schedules.

Day of Month
: Specifies the days of the month during which the schedule will run. This is not displayed for classic syntax schedules.

Week of Month
: Specifies the weeks (first, second, third, fourth, or last) of the month during which the schedule will run. This is not displayed for classic syntax schedules.

Expiration
: Specifies the date and time on which this schedule expires. If this column is blank, the schedule does not expire.

Last Update by (administrator)
: Specifies the name of the administrator that most recently updated the schedule. If this field contains a $$CONFIG_MANAGER$$, the schedule is associated with a domain that is managed by the configuration manager.

Last Update Date/Time
: Specifies the last date and time the schedule was last updated.

Managing Profile
: Specifies the profile or profiles to which the managed server subscribed to get the definition of this schedule.

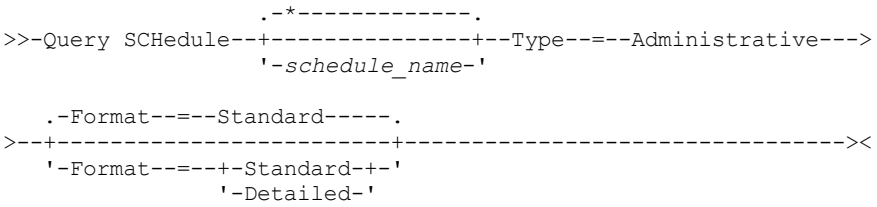
QUERY SCHEDULE (Query an administrative schedule)

Use this command to display information about one or more administrative schedules.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

schedule_name
: Specifies the name of the schedule to be queried. You can use a wildcard character to specify this name.

Type=Administrative (Required)
: Specifies that the query displays administrative command schedules.

Format
: Specifies how information is displayed. This parameter is optional. The default is STANDARD. Possible values are:

Standard
: Specifies that partial information is displayed for the schedules.

Detailed
: Specifies that detailed information is displayed for the schedules.

The standard format displays a blank period column and an asterisk in the day column for enhanced schedules. Issue FORMAT=DETAILED to display complete information about an enhanced schedule.

Example: Display detailed information on administrative command schedules

From a managed server, display detailed information about administrative command schedules. See Field descriptions for field descriptions.

```
query schedule * type=administrative
format=detailed

                 Schedule Name: BACKUP_ARCHIVEPOOL
                   Description:
                       Command: backup db
                      Priority: 5
                Start Date/Time: 2004.06.04 16.57.15
                      Duration: 1 Hour(s)
    Maximum Run Time (Minutes): 0
                Schedule Style: Classic
                        Period: 1 Day(s)
                   Day of Week: Any
                         Month:
                  Day of Month:
                 Week of Month:
                    Expiration:
                        Active: No
Last Update by (administrator): $$CONFIG MANAGER$$
         Last Update Date/Time: 2004.06.04 17.51.49
              Managing Profile: ADMIN_INFO

                 Schedule Name: MONTHLY_BACKUP
                   Description:
                       Command: q status
                      Priority: 5
                Start Date/Time: 2004.06.04 16.57.14
                      Duration: 1 Hour(s)
    Maximum Run Time (Minutes): 0
                Schedule Style: Enhanced
                        Period:
                   Day of Week: Tue,Thu,Fri
                         Month: Aug,Nov
                  Day of Month:
                 Week of Month: Second,Third
                    Expiration:
                        Active: No
Last Update by (administrator): $$CONFIG MANAGER
         Last Update Date/Time: 2004.06.04 17.51.49
              Managing Profile: ADMIN_INFO
```

Field descriptions

Schedule Name
: Specifies the name of the schedule.

Description
: Specifies the description of the schedule.

Command
: Specifies the command that is scheduled.

Priority
: Specifies the priority value for this schedule.

Start Date/Time
: Specifies the initial starting date and time for this schedule.

Duration
: Specifies the length of the startup window.

Maximum Run Time (Minutes)
: Specifies the number of minutes during which server processes that are started by the scheduled commands must be completed. If processes are still running after the maximum run time, the central scheduler cancels the processes.
Tips:

- This parameter does not apply to some processes, such as duplicate-identification processes, which can continue to run after the maximum run time.
- Another cancel time might be associated with some commands. For example, the MIGRATE STGPOOL command can include a parameter that specifies the length of time that the storage pool migration runs before the migration is automatically canceled. If you schedule a command for which a cancel time is defined, and you also define a maximum run time for the schedule, the processes are canceled at whichever cancel time is reached first.

Schedule Style
: Specifies whether classic or enhanced schedule rules are used.

Period
: Specifies the time between startup windows (assuming DAYOFWEEK=ANY). This is not displayed for enhanced syntax schedules.

Day of Week
: Specifies the day of the week on which the startup windows begin.

Month
: Specifies the months during which the schedule will run. This is not displayed for classic syntax schedules.

Day of Month
: Specifies the days of the month during which the schedule will run. This is not displayed for classic syntax schedules.

Week of Month
: Specifies the weeks (first, second, third, fourth, or last) of the month during which the schedule will run. This is not displayed for classic syntax schedules.

Expiration
: Specifies the date after which this schedule will no longer be used. If this column is blank, the schedule does not expire.

Active?
: Specifies whether the schedule has been processed according to the time and date set for this schedule.

Last Update by (administrator)
: Specifies the name of the administrator that most recently updated the schedule. If this field contains a $$CONFIG_MANAGER$$, the schedule is associated with a domain that is managed by the configuration manager.

Last Update Date/Time
: Specifies the last date and time the schedule was modified.

Managing Profile
: Specifies the profile or profiles to which the managed server subscribed to get the definition of this schedule.

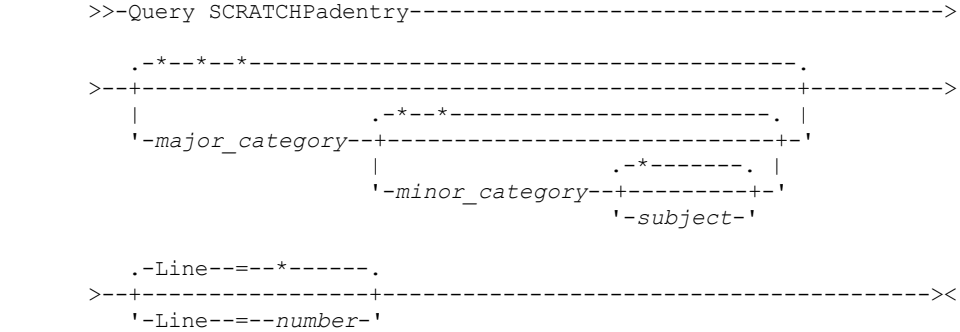
QUERY SCRATCHPADENTRY (Query a scratch pad entry)

Use this command to display data that is contained in the scratch pad.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

major_category
: Specifies the major category to be queried. This parameter is case sensitive. You can query all major categories by omitting this parameter.

minor_category
: Specifies the minor category to be queried. This parameter is case sensitive. You can query all minor categories in the major category by omitting this parameter.

subject
: Specifies the subject to be queried. This parameter is case sensitive. You can query all subjects in the minor category by omitting this parameter.

Line
: Specifies the number of the line to be queried. For *number*, enter an integer in the range 1 - 1000. You can query all lines of data in the subject by omitting this parameter.

Example: Query scratch pad entries

Query a database that stores information about the location of all administrators.

```
query scratchpadentry admin_info location

Scratchpad major category: admin_info
     Scratchpad minor category: location
            Scratchpad subject: codjo
        Scratchpad line number: 1
               Scratchpad data: Toronto 5A24
         Date/time of creation: 2013-09-10, 10:15:50
         Last Update Date/Time: 2013-09-10, 10:15:50
Last Update by (administrator): CODJO

     Scratchpad major category: admin_info
     Scratchpad minor category: location
            Scratchpad subject: jane
        Scratchpad line number: 1
               Scratchpad data: Raleigh GF85
         Date/time of creation: 2013-09-09, 14:29:40
         Last Update Date/Time: 2013-09-09, 14:29:40
Last Update by (administrator): JANE_W

     Scratchpad major category: admin_info
     Scratchpad minor category: location
            Scratchpad subject: jane
        Scratchpad line number: 2
               Scratchpad data: Out of the office from 1-15 Nov.
         Date/time of creation: 2013-09-09, 14:30:05
         Last Update Date/Time: 2013-10-31, 16:55:52
Last Update by (administrator): JANE_W

     Scratchpad major category: admin_info
     Scratchpad minor category: location
            Scratchpad subject: montse
        Scratchpad line number: 1
               Scratchpad data: Barcelona B19
         Date/time of creation: 2013-09-10, 04:34:37
         Last Update Date/Time: 2013-09-10, 04:34:37
Last Update by (administrator): MONTSERRAT
```

Field descriptions

Scratchpad data
: The data that is stored in the scratch pad entry.

Date/time of creation
: The date and time at which the scratch pad entry was created.

Last Update Date/Time
: The date and time at which the scratch pad entry was last updated.

Last Update by (administrator)
: The administrator who last updated the scratch pad entry.

Related commands

Table 1. Commands related to QUERY SCRATCHPADENTRY

Command	Description
DEFINE SCRATCHPADENTRY	Creates a line of data in the scratch pad.
DELETE SCRATCHPADENTRY	Deletes a line of data from the scratch pad.
SET SCRATCHPADRETENTION	Specifies the amount of time for which scratch pad entries are retained.
UPDATE SCRATCHPADENTRY	Updates data on a line in the scratch pad.

QUERY SCRIPT (Query IBM Spectrum Protect scripts)

Use this command to display information about scripts.

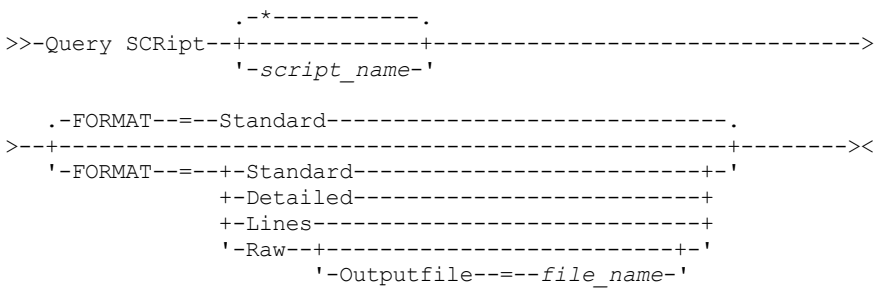
You can use this command with the DEFINE SCRIPT command to create a new script by using the contents from another script.

Privilege class

The privilege class that is required for this command depends on whether the Outputfile parameter is specified in the command.

- If the Outputfile parameter is not specified, any administrator can issue this command.
- If the Outputfile parameter is specified and the REQSYSAUTHOUTFILE server option is set to YES, the administrator must have system privilege.
- If the Outputfile parameter is specified and the REQSYSAUTHOUTFILE server option is set to NO, the administrator must have operator, policy, storage, or system privilege.

Syntax



Parameters

script_name
: Specifies the name of the script for which information is to be displayed. You can include a wildcard character to specify this name.
Important: If you do not specify a script, the query displays information about all scripts. The time that is used to process this command and the amount of information that is displayed can be extensive.

Format
: Specifies the output format for displaying script information. The default is STANDARD. Possible values are:

  Standard
  : Specifies that only the script name and description in a script are displayed.

  Detailed
  : Specifies that detailed information about the script is displayed. This information includes the commands in the script and their line numbers, the date of the last update and the administrator that completed the updates.

  Lines
  : Specifies that the script name, the line number of the commands, comment lines, and the commands in the script are displayed.

  Raw

Specifies that commands contained in the script are written to a file named with the Outputfile parameter. This format is a way of directing output from a script to a file so that it can be copied into another script by using the DEFINE SCRIPT command.

If no output file is specified, the IBM Spectrum Protect™ server outputs the "query script" with "format=raw" to the console.

Outputfile
Specifies the name of the file to which output is directed when you specify FORMAT=Raw. The file that you specify must be on the server that is running this command. If the file exists, the query output is appended to the end of the file.

Example: List the script descriptions

Display the standard information about scripts.

```
query script *
```

```
Name             Description
---------------  ----------------------------------------------------
QCOLS            Display columns for a specified SQL table
QSAMPLE          Sample SQL Query
EXAMPLE          Backup the store pools and database when no sessions
```

Example: Display the contents of a script with line numbers

Display the lines of information for a script named Q_AUTHORITY.

```
query script q_authority format=lines
```

```
Name         Line    Command
             Number
----------   ------  ------------------------------------------------
Q_AUTHORITY  1       /* ----------------------------------------*/
             5       /* Script Name:  Q_AUTHORITY               */
             10      /* Description: Display administrators that  */
             15      /*              have the authority to issue  */
             20      /*              commands requiring a         */
             25      /*              specific privilege.          */
             30      /* Parameter 1: privilege name - in the form */
             35      /*              x_priv - EX. policy_priv     */
             40      /* Example:  run q_authority storage_priv    */
             45      /* ----------------------------------------*/
             50      select admin_name from admins where -
             55        upper(system_priv) <> 'NO' or -
             60        upper($1) <> 'NO'
```

Example: Create a script from an existing script

Query the ENGDEV script and direct the output to a file named MY.SCRIPT.

```
query script engdev format=raw outputfile=my.script
```

Example: Display detailed script information

Display detailed information about scripts. See Field descriptions for field descriptions.

```
query script * format=detailed
```

```
                        Name: QCOLS
                 Line Number: DESCRIPTION
                     Command: Display columns for a specified SQL
                              table
Last Update by (administrator): SERVER_CONSOLE
         Last Update Date/Time: 12/02/1997 16:05:29

                        Name: QCOLS
                 Line Number: 1
                     Command: select colname from columns where
                              tabname='$1'
```

```
Last Update by (administrator): SERVER_CONSOLE
         Last Update Date/Time: 12/02/1997 16:05:29
```

Field descriptions

Name
: The name of the script.

Line Number
: The line number of the script or the string DESCRIPTION.

Command
: The command included on the line number that is displayed in the previous field.

Last Update by (administrator)
: The name of the administrator that defined or most recently updated the script.

Last Update Date/Time
: The date and time that the administrator defined or updated the script.

Related commands

Table 1. Commands related to QUERY SCRIPT

Command	Description
COPY SCRIPT	Creates a copy of a script.
DEFINE SCRIPT	Defines a script to the IBM Spectrum Protect server.
DELETE SCRIPT	Deletes the script or individual lines from the script.
RENAME SCRIPT	Renames a script to a new name.
RUN	Runs a script.
UPDATE SCRIPT	Changes or adds lines to a script.

Server scripts

QUERY SERVER (Query a server)

Use this command to display information about a server definition.

Privilege class

Any administrator can issue this command.

Syntax

```
                .-*-----------.  .-Format--=--Standard-----.
>>-Query SERver--+-------------+--+------------------------+--><
                 '-server_name-'  '-Format--=--+-Standard-+-'
                                               '-Detailed-'
```

Parameters

server_name
: Specifies the name of the server to be queried. You can use wildcard characters to specify this name. This parameter is optional. The default is all server names.

Format
: Specifies how the information is displayed. The parameter is optional. The default is STANDARD.

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed.

Example: List all servers

Display information in standard format about all servers. See Field descriptions for field descriptions.

```
query server *
```

```
Server  Comm.   High-level  Low-level Days  Server   Virtual  Allow

                        Transport Method: TLS 1.2
```

Field descriptions

Server Name
: The name of the server.

Comm. Method
: The communication method that is used to connect to the server.

Transfer Method
: The method that is used for server-to-server data transfer.

High-level Address

The IP address (in dotted decimal format) of the server.

Low-level Address
The port number of the server.

Description
The server description.

Allow Replacement
Specifies whether a server definition on a managed server can be replaced with a definition from a configuration manager.

Node Name
The name of the client node.

Last Access Date/Time
The last date and time that the client node accessed the server.

Days Since Last Access
The number of days since the client node accessed the server.

Compression
The type of compression that is completed by IBM Spectrum Protect™ on client files.

Archive Delete Allowed?
Specifies whether the client node can delete its own archive files. A value of (?) denotes that this field is not set and does not apply to this definition.

URL
The URL used to access this server from a web browser-based interface.

Registration Date/Time
The date and time that the client node was registered.

Registering Administrator
The name of the administrator that registered the client node.

Bytes Received Last Session
The number of bytes received by the server during the last client node session.

Bytes Sent Last Session
The number of bytes sent to the client node.

Duration of Last Session
The length of the last client node session, in seconds.

Pct. Idle Wait Last Session
The percentage of the total session time during which the client did not complete any functions.

Pct. Comm. Wait Last Session
The percentage of the total session time that the client waited for a response from the server.

Pct. Media Wait Last Session
The percentage of the total session time that the client waited for a removable volume to be mounted.

Grace Deletion Period
The number of days an object remains on the target server after it is marked for deletion.

Managing Profile
The profile from which the managed server got the definition of this server.

Server Password Set
Specifies whether the password for the server is set.

Server Password Set Date/Time
Specifies when the password for the server is set.

Days since Server Password Set
The number of days since the server password was set.

Invalid Sign-on count for Server
The maximum number of invalid sign-on attempts that the server can accept.

Virtual Volume Password Set
Specifies whether the password used to log on to the target server is set.

Virtual Volume Password Set Date/Time
Specifies when the password for virtual volume support is set.

Days Since Virtual Volume Password Set
The number of days since the password for virtual volume support was set.

Invalid Sign-on Count for Virtual Volume Node
The maximum number of invalid sign-on attempts that are accepted on the target server.

Validate Protocol (deprecated)

Specifies whether the storage agent has the data validation function enabled. This field is deprecated.

Version
The software version of the IBM Spectrum Protect server.

Release
: The software release of the IBM Spectrum Protect server.

Level
: The software level of the IBM Spectrum Protect server.

Role(s)
: The role of the server. For example, one of the roles that the server is used for is replication.

SSL
: Specifies whether Secure Sockets Layer (SSL) communication is used.

Session Security
: Specifies the level of session security that is enforced for the server. Values can be STRICT or TRANSITIONAL.

Transport Method
: Specifies the transport method that was last used for the specified server. Values can be TLS 1.2, TLS 1.1, or NONE. A question mark (?) is displayed until a successful authentication is completed.

Related commands

Table 1. Commands related to QUERY SERVER

Command	Description
DEFINE DEVCLASS	Defines a device class.
DEFINE SERVER	Defines a server for server-to-server communications.
DELETE DEVCLASS	Deletes a device class.
DELETE FILESPACE	Deletes data associated with client file spaces. If a file space is part of a collocation group and you remove the file space from a node, the file space is removed from the collocation group.
DELETE SERVER	Deletes the definition of a server.
AIX Linux Windows PROTECT STGPOOL	AIX Linux Windows Protects a directory-container storage pool.
QUERY NODE	Displays partial or complete information about one or more clients.
RECONCILE VOLUMES	Reconciles source server virtual volume definitions and target server archive objects.
REGISTER NODE	Defines a client node to the server and sets options for that user.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
SET REPLSERVER	Specifies a target replication server.
UPDATE DEVCLASS	Changes the attributes of a device class.
UPDATE NODE	Changes the attributes that are associated with a client node.
UPDATE SERVER	Updates information about a server.

QUERY SERVERGROUP (Query a server group)

Use this command to display information about server groups and group members.

Privilege class

Any administrator can issue this command.

Syntax

```
.-*----------.
```

```
>>-QUERY SERVERGroup--+------------+--------------------------><
                     '-group_name-'
```

Parameters

group_name
: Specifies the server group to query. This parameter is optional. You can use wildcard characters to specify this name.

Example: List server groups

From a managed server, query all server groups. Field descriptions for field descriptions.

```
query servergroup *

Server Group    Members         Description          Managing Profile
------------    ------------    -----------------    ----------------
ADMIN_GROUP     SERVER_A        Headquarters         ADMIN_INFO
                SERVER_B
                SERVER_C
                SERVER_D
```

Field descriptions

Server Group
: The name of the server group.

Members
: The group members.

Description
: The description of the server group.

Managing Profile
: The profile or profiles to which the managed server subscribed to get the definition of the server groups.

Related commands

Table 1. Commands related to QUERY SERVERGROUP

Command	Description
COPY SERVERGROUP	Creates a copy of a server group.
DEFINE SERVERGROUP	Defines a new server group.
DELETE SERVERGROUP	Deletes a server group.
QUERY SERVER	Displays information about servers.
RENAME SERVERGROUP	Renames a server group.
UPDATE SERVERGROUP	Updates a server group.

QUERY SESSION (Query client sessions)

Use this command to display information about administrative, node, and server sessions.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query SEssion--+---------+-----------------------------------><
                  '-sessnum-'

>--+-------------------------------+---------------------------->
   '-MINTIMethreshold--=--minutes-'
```

```
>--+---------------------------------------+------------------>
   '-MAXTHRoughput--=--kilobytes_per_second-'

   .-Format--=--Standard-----.  .-Type--=--*----------.
>--+-------------------------+--+---------------------+--------->
   '-Format--=--+-Standard-+-'  '-Type--=--+-Admin--+-'
                '-Detailed-'               +-Node---+
                                           '-Server-'

   .-CLIENTName--=--*--------------.
>--+-------------------------------+-------------------------><
   '-CLIENTName--=----client_name---'
```

Parameters

sessnum
: Specifies the number of the administrative or client node session to query. This parameter is optional. If you do not specify a value for this parameter, all sessions display.

MINTIMethreshold
: Specifies to display sessions that had at least this number of minutes elapse from the time the client sent data to the server for storage. This parameter is optional. The minimum number of minutes is 1. The maximum number of minutes is 99999999.

MAXTHRoughput
: Specifies to display sessions that are transferring data at a rate less than this number of kilobytes per second. This parameter is optional. The minimum number of kilobytes per second is 0. The maximum number of kilobytes per second is 99999999.

Format
: Specifies how the information displays. This parameter is optional. The default value is STANDARD. The following values are possible:

  Standard
  : Specifies that partial information displays for the session.

  Detailed
  : Specifies that complete information displays for the session.

Type
: Specifies the type of sessions to include in the query results. If you do not specify a value for this parameter, all types of sessions are queried. This parameter is optional. You can specify one of the following values:

  Admin
  : Specifies that administrative sessions are displayed.

  Node
  : Specifies that node sessions are displayed.

  Server
  : Specifies that server sessions are displayed.

CLIENTName
: Specifies the name of an administrator, client node, or server to be queried. You can specify one or more names. You can also specify node groups and proxy nodes. If you specify multiple names, separate the names with commas; use no intervening spaces. You can use wildcard characters with node names but not with node group names. The parameter is optional.

  During node replication, the client name on the target server is displayed as *node_name (server_name)*, where *node_name* is the node whose data is being replicated, and *server_name* is the name of the source server. You can specify either the node name or the server name in the CLIENTName parameter to display the replication sessions.

Example: List active client node sessions

Display information about all administrative and client node sessions that are communicating with the server. See Field descriptions for field descriptions.

```
query session
```

```
  Sess Comm.  Sess     Wait   Bytes   Bytes Sess  Platform Client
Number Method State    Time    Sent   Recvd Type           Name
------ ------ ------ ------ ------- ------- ----- -------- ------
     4  TCP/IP  Run    0 S    1.4 K    162   Admin  WinNT   ADMIN
```

Example: Display detailed information about active client node sessions

Display detailed information about all administrative and client node sessions that are communicating with the server. See Field descriptions for field descriptions.

```
query session format=detailed
```

```
              Sess Number: 4
             Comm. Method: Tcp/Ip
               Sess State: Run
                Wait Time: 0 S
               Bytes Sent: 1.4 K
              Bytes Recvd: 162
                Sess Type: Admin
                 Platform: WinNT
              Client Name: ADMIN
      Media Access Status:
                User Name:
Date/Time First Data Sent:
   Proxy By Storage Agent:
                  Actions:
            Failover Mode: No
```

Field descriptions

Sess Number
: Specifies a unique session identification number that is assigned by the server.

Comm. Method
: Specifies the method that is used by the client to communicate with the server.

Sess State
: Specifies the current communications state of the server. The following states are possible:

  End
  : The session is ending (session resources are released).

  IdleW
  : Waiting for client's next request (session is idle).

  MediaW
  : The session is waiting for access to a sequential access volume.

  RecvW
  : Waiting to receive an expected message from the client.

  Run
  : The server is running a client request (and not waiting to send data).

  SendW
  : The server is waiting to send data to the client (waiting for data to be delivered to the client node that was already sent).

  SSLiW
  : The session is waiting for Secure Sockets Layer (SSL) initialization to complete.

  Start
  : The session is starting (authentication is in progress).

Wait Time
: Specifies the amount of time (seconds, minutes, or hours) the server is in the current state shown.

Bytes Sent
: Specifies the number of bytes of data that is sent to the client node since the session was initiated.

Bytes Recvd
: Specifies the number of bytes of data that is received from the client node since the session was initiated.

Sess Type
: Specifies the type of session in process: ADMIN for an administrative session, NODE for a client node session, or SERVER. SERVER specifies the server starts a session and initiates server-to-server operations such as central configuration, library sharing, and storage agent sessions.

Platform

Specifies the type of operating system that is associated with the client.

Client Name

Specifies the name of the client node or the administrator.

For node replication sessions, the client name is updated to *node_name (server_name)* on the target server after data transfer starts.

Media Access Status

Specifies the type of media wait state. When a session is in a media wait state, this field displays a list of all mount points and sequential volumes for the session. The list of mount points specifies the device class and the associated storage pool. The list of volumes specifies the primary storage pool volumes in addition to any copy storage pool and active-data pool volumes along with their assigned storage pool.

The server allows multiple sessions to read and one session to write to a volume concurrently in a storage pool that is associated with the FILE or CENTERA device type. As a result, a volume in a storage pool with a device type of FILE or CENTERA can appear as the current volume for more than one session.

Proxy by Storage Agent

Specifies the storage agent that is the proxy for LAN-free data movement for the node.

User Name

Specifies the user ID of the node, on a multi-user system, that connects to the server when it is not the same system user who originally connected to the server.

Date/Time First Data Sent

Specifies the date and time that the client first sent data to the server for storage.

Actions

Displays a list of actions that are performed during the session. An action is listed only once, even if the action occurs multiple times during a session. The following actions are possible:

BkIns

One or more backup objects were stored on the server. The operation might have been an incremental backup or a selective backup.

BkUpd

One or more attributes were updated for a backup object that is stored on the server.

BkDel

One or more backup objects that are stored on the server are deleted.

BkRebind

One or more backup objects that are stored on the server are bound to a different management class.

NoQueryRestore

A no-query restore operation was initiated from the client to restore backed-up files from the server to the client system.

ArIns

One or more archive objects were stored on the server.

ObjRtrv

One or more files were retrieved from the server. This might have been to retrieve archive files, or to restore backup data (except for backup data from a no-query restore operation).

MigIns

One or more files are migrated and stored on the server by IBM Spectrum Protect™ for Space Management (HSM client).

MigDel

One or more space-managed files that were stored on the server are deleted.

MigRebind

One or more space-managed files that are stored on the server are bound to a different management class.

MigRecall

One or more space-managed files that are stored on the server are recalled.

MigUpd

The attributes for one or more space-managed files that are stored on the server are updated.

FSAdd

The client node added one or more new file spaces to server storage.

FSUpd

The client node updated attributes for one or more file spaces that are defined to the server.

DefAuth

A SET ACCESS command is processed by the client node, which caused an authorization rule for access to the client node's data to be added.

Failover Mode
: Specifies whether the client session was started in failover mode. The following values are possible:

  Force
  : The FORCEFAILOVER flag is specified on the client and the session is forced into failover mode.

  Yes
  : The client session was started in failover mode.

  No
  : The client session was not started in failover mode.

Related commands

Table 1. Command related to QUERY SESSION

Command	Description
CANCEL SESSION	Cancels active sessions with the server.

QUERY SHREDSTATUS (Query shredding status)

Use this command to display information about data waiting to be shredded.

Privilege class

To issue this command you must have administrator privilege.

Syntax

```
                        .-Format--=--Standard-----.
>>-QUERY SHREDstatus--+-------------------------+-------------><
                      '-Format--=--+-Standard-+-'
                                   '-Detailed-'
```

Parameters

Format
: Specifies how the information is displayed. This parameter is optional. The default is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed. This is the default.

  Detailed
  : Specifies that complete information is displayed.

Example: Display summary shredding information

Show partial information about data shredding on the server. See Field descriptions for field descriptions.

```
query shredstatus

Shredding      Objects
  Active      Awaiting
                 Shred
 -------      --------
      NO             4
```

Example: Display detailed shredding information

Display detailed information about data shredding on the server. See Field descriptions for field descriptions.

```
query shredstatus format=detailed

Shredding  Objects  Occupied   Data Left
  Active   Awaiting   Space    To Shred
```

```
                Shred      (MB)         (MB)
---------- ---------  ---------  -----------
    NO          4         182         364
```

Field descriptions

Shredding Active
: Indicates whether or not the server is actively shredding data at this time.

Objects Awaiting Shred
: The number of objects currently waiting to be shredded.

Occupied Space (MB)
: The amount of server storage space occupied by the objects currently waiting to be shredded, in megabytes. This is the amount of space that will become available when the objects are shredded.

Data Left to Shred (MB)
: The amount of data that still needs to be shredded.

Related commands

Table 1. Commands related to QUERY SHREDSTATUS

Command	Description
BACKUP STGPOOL	Backs up a primary storage pool to a copy storage pool.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
EXPORT NODE	Copies client node information to external media or directly to another server.
GENERATE BACKUPSET	Generates a backup set of a client's data.
GENERATE BACKUPSETTOC	Generates a table of contents for a backup set.
MOVE DATA	Moves data from a specified storage pool volume to another storage pool volume.
QUERY STGPOOL	Displays information about storage pools.
SETOPT	Updates a server option without stopping and restarting the server.
SHRED DATA	Manually starts the process of shredding deleted data.
UPDATE STGPOOL	Changes the attributes of a storage pool.

QUERY SPACETRIGGER (Query the space triggers)

Use this command to display the settings for storage pool space triggers.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query SPACETrigger--STG--+-------------------------+-------->
                            '-STGPOOL--=--storage_pool-'

   .-Format--=--Standard-----.
>--+-------------------------+--------------------------------><
   '-Format--=--+-Standard-+-'
                '-Detailed-'
```

Parameters

STG
: Specifies a storage pool space trigger.

STGPOOL
: Specifies one or more storage pools (using a wildcard) for which storage pool trigger information will be displayed. If STG is specified but STGPOOL is not, the default storage pool space trigger, if any, is displayed.

Format
: Specifies how the information is displayed. This parameter is optional. The default is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed.

Example: Display detailed settings for a storage pool space trigger

Issue this command:

```
query spacetrigger stg stgpool=archivepool format=detailed
```

AIX

```
         STGPOOL Full Percentage:   50
    STGPOOL Expansion Percentage:   20
        STGPOOL Expansion prefix:   /usr/tivoli/tsm/server/filevol/
                         STGPOOL:   ARCHIVEPOOL
  Last Update by (administrator):   SERVER_CONSOLE
           Last Update Date/Time:   05/10/2004 11:59:59
```

Linux

```
         STGPOOL Full Percentage:   50
    STGPOOL Expansion Percentage:   20
        STGPOOL Expansion prefix:   /opt/tivoli/tsm/server/filevol/
                         STGPOOL:   ARCHIVEPOOL

           Last Update Date/Time:   05/10/2004 11:59:59
```

Windows

```
         STGPOOL Full Percentage:   50
    STGPOOL Expansion Percentage:   20
        STGPOOL Expansion prefix:   c:\program files\tivoli\filevol\
                         STGPOOL:   ARCHIVEPOOL
  Last Update by (administrator):   SERVER_CONSOLE
           Last Update Date/Time:   05/10/2004 11:59:59
```

Field descriptions

STGPOOL Full Percentage
: The trigger utilization percentage at which IBM Spectrum Protect™ allocates more space for the storage pool.

STGPOOL Expansion Percentage
: The percentage of space by which the storage pool should be expanded.

STGPOOL Expansion prefix
: The prefix associated with the space trigger.

STGPOOL
: The storage pool name associated with the query.

Last Update by (administrator)
: The administrator who last updated the storage pool space trigger.

Last Update Date/Time
: The date and time when the administrator last updated the storage pool space trigger.

Related commands

Table 1. Commands related to QUERY SPACETRIGGER

Command	Description
DEFINE SPACETRIGGER	Defines a space trigger to expand the space for a storage pool.

Command	Description
DELETE SPACETRIGGER	Deletes the storage pool space trigger.
UPDATE SPACETRIGGER	Changes attributes of storage pool space trigger.

QUERY STATUS (Query system parameters)

Use the QUERY STATUS command to display information about system parameters.

Use this command for the following reasons:

- To display the service level of the server
- To display information about the general server parameters, such as those defined by the SET commands
- To request information about client sessions, such as the availability of the server, password authentication, accounting settings, or the retention period for the information that is retained in the activity log
- To display information about the central scheduler, such as the central scheduling mode of the server
- To display the maximum number of repeated attempts that are allowed after a failed attempt to run a scheduled command
- To display whether subfiles can be backed up to this server, as indicated by the SET SUBFILE command
- To display information about a target replication server
- To display licensing information

Tip: To display information about a target replication server, you must issue the command from the target replication server.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query STatus-------------------------------------------------><
```

Parameters

None.

Example: Query the status of a configuration manager

Display general information about server parameters. The command is run from a configuration manager. For descriptions of displayed fields, see Field descriptions.

```
query status
```

```

Field descriptions

Server Name
: Specifies the name of the server.

Server host name or IP address
: Specifies the server TCP/IP address.

Server TCP/IP port number
: Specifies the server port address.

Crossdefine
: Specifies whether another server that is running the DEFINE SERVER command automatically defines itself to this server. See the SET CROSSDEFINE command.

Server Password Set
: Specifies whether the password was set for the server.

Server Installation Date/Time
: Specifies the date and time when the server was installed.

Server Restart Date/Time
: Specifies the last date and time when the server was started.

Authentication
: Specifies whether password authentication is set on or off.

Password Expiration Period
: Specifies the period, in days, after which the administrator or client node password expires.

Invalid Sign-on Attempt Limit

Specifies the number of invalid sign-on attempts before a node is locked.

Minimum Password Length

Specifies the minimum number of characters for the password.

Registration

Specifies whether client node registration is open or closed.

Subfile Backup

Specifies whether subfiles can be backed up to this server, as indicated by the SET SUBFILE command.

Availability

Specifies whether the server is enabled or disabled.

Inbound Sessions Disabled

Specifies the names of servers from which server-to-server communications are not allowed. To enable inbound server sessions, use the ENABLE SESSIONS command.

Outbound Sessions Disabled

Specifies the names of servers to which server-to-server communications are not allowed. To enable outbound server sessions, use the ENABLE SESSIONS command.

Accounting

Specifies whether an accounting record is generated at the end of each client node session.

Activity Log Retention

Specifies the number of days information is retained in the activity log, or the size of the log.

Activity Log Number of Records

Specifies the number of records in the activity log.

Activity Log Size

Specifies the size of the activity log.

Activity Summary Retention Period

Specifies the number of days information is retained in the SQL activity summary table.

License Audit Period

Specifies the period, in days, after which the license manager automatically audits the IBM Spectrum Protect™ license. Additional licensing information is available by using the QUERY LICENSE command.

Last License Audit

Specifies the date and time when the last license audit occurred. Additional licensing information is available by using the QUERY LICENSE command.

Server License Compliance

Specifies whether the server is in compliance (Valid) or out of compliance (Failed) with the license terms. Use the QUERY LICENSE command to see what factors are causing the server to fail to comply with the license terms.

Central Scheduler

Specifies whether central scheduling is running (active or inactive).

Maximum Sessions

Specifies the maximum number of client/server sessions.

Maximum Scheduled Sessions

Specifies the maximum number of client/server sessions available for processing scheduled work.

Event Record Retention Period

Specifies the number of days central scheduler event records are retained.

Client Action Duration

Specifies the duration of the period during which the client processes the schedule that is defined with the DEFINE CLIENTACTION command.

Schedule Randomization Percentage

Specifies how much of the startup window is used for running scheduled events in client-polling mode.

Query Schedule Period

Specifies the frequency with which clients poll the server to obtain scheduled work, in client-polling mode. If the value in this field is Client, the polling frequency is determined by the client node.

Maximum Command Retries

Specifies the maximum number of times that a client scheduler tries to run a scheduled command after a failed attempt. If the value in this field is Client, the client node determines the maximum number.

Retry Period

Specifies the number of minutes between failed attempts by the client scheduler to contact the server or to run a scheduled command. If the value in this field is Client, the client node determines the number of minutes.

Client-side Deduplication Verification Level

Specifies a percentage of extents to be verified by the IBM Spectrum Protect server. The extents are created during client-side data deduplication.

Scheduling Modes

Specifies the central scheduling modes that are supported by the server.

Active Receivers

Specifies the receivers for which event logging began.

Configuration manager?
: Specifies whether the server is a configuration manager.

Refresh interval
: Specifies the interval that elapses before the managed server requests a refresh of any changes from a configuration manager.

Last refresh date/time
: If the server is a managed server, specifies the date and time of the last successful refresh of configuration information from the configuration manager.

Context Messaging
: Specifies whether context messaging is enabled or disabled.

Table of Contents (TOC) Load Retention
: Specifies the approximate number of minutes that unreferenced TOC data is retained in the database.

Machine Globally Unique ID
: The globally unique identifier (GUID) as of the last time that the server was started. This GUID identifies the host system to which the current server belongs.

Archive Retention Protection
: Specifies whether archive data retention protection is activated or deactivated.

Database Directories
: Specifies the locations of the database directories.

Total Space of File System (MB)
: Specifies the total size of the file system.

Used Space on File System (MB)
: Specifies the amount of space that is in use on the file system.

Free Space Available (MB)
: Specifies the amount of space that is available.

Encryption Strength
: Indicates data encryption strength: AES or DES.

Client CPU Information Refresh Interval
: Specifies the number of days that elapse between client scans for CPU information that is used for PVU estimation.

Outbound Replication
: Specifies whether replication processing is enabled or disabled. If outbound replication is disabled, new replication processes cannot start on the server.

Target Replication Server
: Specifies the name of the server that is the target for node replication operations. If a target replication server does not exist, this field is blank.

Default Replication Rule for Archive
: Specifies the server replication rule that applies to archive data. The following values are possible:

  ALL_DATA
  : Replicates archive data. The data is replicated with a normal priority.

  ALL_DATA_HIGH_PRIORITY
  : Replicates archive data. The data is replicated with a high priority.

  NONE
  : Archive data is not replicated.

Default Replication Rule for Backup
: Specifies the server replication rule that applies to backup data. The following values are possible:

  ALL_DATA
  : Replicates active and inactive backup data. The data is replicated with a normal priority.

  ACTIVE_DATA
  : Replicates only active backup data. The data is replicated with a normal priority.
  Attention: If you specify ACTIVE_DATA and one or more of the following conditions are true, inactive backup data on the target replication server is deleted, and inactive backup data on the source replication server is not replicated.

    - When a server version earlier than Version 7.1.1 is installed on either the source or target replication servers.
    - When you are using the REPLICATE NODE command with the `FORCERECONCILE=YES` parameter.
    - When you are running the initial replication of a file space after you configure replication, restore the database, or upgrade both the source and target replication servers from a server version earlier than V7.1.1.

    If the previous conditions are not true, all new and changed files since the last replication are replicated, including inactive files, and files are deleted when they expire.

ALL_DATA_HIGH_PRIORITY
Replicates active and inactive backup data. The data is replicated with a high priority.
ACTIVE_DATA_HIGH_PRIORITY

This rule is the same as the ACTIVE_DATA replication rule except data is replicated with a high priority.

NONE
Backup data is not replicated.

Default Replication Rule for Space Management
Specifies the server replication rule that applies to space-managed data. The following values are possible:

ALL_DATA
Replicates space-managed data. The data is replicated with a normal priority.
ALL_DATA_HIGH_PRIORITY
Replicates space-managed data. The data is replicated with a high priority.
NONE
Space-managed data is not replicated.

Replication Record Retention Period
Specifies the number of days that replication history records are retained in the database of the source replication server.
LDAP User
Specifies the user ID that is named in the SET LDAPUSER command. This user ID can issue administrative commands on the namespace that is reserved for IBM Spectrum Protect on the LDAP directory server.
LDAP Password Set
This output field shows if a password is defined for the user ID that is named in the SET LDAPUSER command. The values are YES and NO. If YES, the user ID that is named in the SET LDAPUSER command can issue administrative commands on the LDAP namespace that is reserved for IBM Spectrum Protect. If NO, issue the SET LDAPPASSWORD command to set the password for the user ID that is named in the SET LDAPUSER command.
Default Authentication
Specifies the default password authentication method: LOCAL or LDAP.

Authentication Target	**Authentication Method**
IBM Spectrum Protect server	LOCAL
LDAP directory server	LDAP

When you issue the SET DEFAULTAUTHENTICATION command, you define the resulting authentication method for all REGISTER ADMIN and REGISTER NODE commands. The default is LOCAL.
Failover High Level Address
Specifies the high-level address for the failover server that is used by the client. Client restore operations fail over to this high-level address when the interface that is used by the client is different from the interface that is used by replication.
Scratchpad retention
Specifies the number of days for which scratch pad entries are retained since they were last updated.
Replication Recovery of Damaged Files
Specifies whether node replication is enabled to recover damaged files from a target replication server. This is a system-side setting. If ON is specified, the node replication process can be configured to detect damaged files on a source replication server and replace them with undamaged files from a target replication server. If OFF is specified, damaged files are not recovered from a target replication server.
SUR Occupancy (TB)
If you have an IBM Spectrum Protect Suite (SUR) license, this field specifies the SUR occupancy on the server. The *SUR occupancy* is the amount of space that is used to store data that is managed by the IBM Spectrum Protect products that are included in the SUR bundle.
SUR Occupancy Date/Time
Specifies the date and time when SUR occupancy data was last collected.
Front-End Capacity (MB)
Specifies the amount of primary data that is reported as being backed up by clients. Clients include applications, virtual machines, and systems. This value is used for the front-end licensing model.
Front-End Client Count
Specifies the number of clients that reported capacity usage based on the front-end licensing model.
Front-End Capacity Date
Specifies the date and time when front-end capacity data was last collected.
Product Offering
Specifies a product offering.

Value specified by the SET PRODUCTOFFERING command	Value shown in the QUERY STATUS command output
ENTry	IBM Spectrum Protect Entry
DATARet	IBM Spectrum Protect for Data Retention
BASIC	IBM Spectrum Protect
EE	IBM Spectrum Protect Extended Edition
SUIte	IBM Spectrum Protect Suite
SUITEEntry	IBM Spectrum Protect Suite Entry
SUITEArchive	IBM Spectrum Protect Suite - Archive
SUITEProtectier	IBM Spectrum Protect Suite - ProtecTier
SUITEFrontend	IBM Spectrum Protect Suite - FrontEnd
SUITEENTRYFrontend	IBM Spectrum Protect Suite Entry - FrontEnd
CLEAR	NULL

Related commands

Table 1. Commands related to QUERY STATUS

Command	Description
BEGIN EVENTLOGGING	Starts event logging to a specified receiver.
DISABLE REPLICATION	Prevents outbound replication processing on a server.
DISABLE SESSIONS	Prevents new sessions from accessing IBM Spectrum Protect but permits existing sessions to continue.
ENABLE REPLICATION	Allows outbound replication processing on a server.
ENABLE SESSIONS	Resumes server activity following the DISABLE command or the ACCEPT DATE command.
END EVENTLOGGING	Ends event logging to a specified receiver.
QUERY LICENSE	Displays information about licenses and audits.
SET ACCOUNTING	Specifies whether accounting records are created at the end of each client session.
SET ACTLOGRETENTION	Specifies the number of days to retain log records in the activity log.
SET CONTEXTMESSAGING	Specifies to turn on context messaging to debug an ANR9999D message.
SET CPUINFOREFRESH	Specifies the number of days between client scans for workstation information used for PVU estimates.
SET CROSSDEFINE	Specifies whether to cross define servers.
SET DEDUPVERIFICATIONLEVEL	Specifies the percentage of extents verified by the server during client-side deduplication.
SET DEFAULTAUTHENTICATION	Specifies the default password authentication method for any REGISTER NODE or REGISTER ADMIN commands.
SET EVENTRETENTION	Specifies the number of days to retain records for scheduled operations.
SET LDAPPASSWORD	Sets the password for the LDAPUSER.
SET LDAPUSER	Sets the user who oversees the passwords and administrators on the LDAP directory server.
SET MAXCMDRETRIES	Specifies the maximum number of retries after a failed attempt to execute a scheduled command.

Command	Description
SET MAXSCHEDSESSIONS	Specifies the maximum number of client/server sessions available for processing scheduled work.
SET PASSEXP	Specifies the number of days after which a password is expired and must be changed.
SET PRODUCTOFFERING	Set the product offering licensed to your enterprise.
SET QUERYSCHEDPERIOD	Specifies the frequency for clients to obtain scheduled work, in client-polling mode.
SET RANDOMIZE	Specifies the randomization of start times within a window for schedules in client-polling mode.
SET REPLRECOVERDAMAGED	Specifies whether node replication is enabled to recover damaged files from a target replication server.
SET RETRYPERIOD	Specifies the time between retry attempts by the client scheduler.
SET SCHEDMODES	Specifies the central scheduling mode for the server.
SET SERVERHLADDRESS	Specifies the high-level address of a server.
SET SERVERLLADDRESS	Specifies the low-level address of a server.
SET SERVERNAME	Specifies the name by which the server is identified.
SET SERVERPASSWORD	Specifies the server password.
SET SUMMARYRETENTION	Specifies the number of days to retain information for the activity summary table.
SET TOCLOADRETENTION	Specifies the number of minutes to retain information for unreferenced TOC sets.

QUERY STATUSTHRESHOLD (Query status monitoring thresholds)

Use this command to display information about status monitoring thresholds.

Status monitoring thresholds compare the defined conditions to the status monitoring server queries and inserts the results in the status monitoring table.

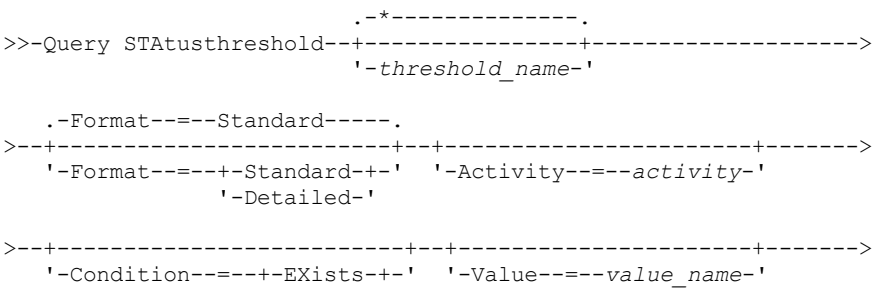
Multiple thresholds can be defined for an activity. For example, you can create a threshold that provides a warning status if storage pool capacity utilization is greater than 80%. You can then create another threshold that provides error status if storage pool capacity utilization is greater than 90%.

Note: If a threshold is already defined for an EXISTS condition, you cannot define another threshold with one of the other condition types.

Privilege class

Any administrator can issue this command.

Syntax



```
                    +-GT-----+
                    +-GE-----+
                    +-LT-----+
                    +-LE-----+
                    '-EQual--'

>--+------------------------+-----------------------------------><
   '-STatus--=--+-Normal--+-'
                +-Warning-+
                '-Error---'
```

Parameters

threshold_name
: Specifies the threshold name. The name cannot exceed 48 characters in length.

Format
: Specifies how the information is displayed. The default value is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed for the specified status thresholds.

  Detailed
  : Specifies that complete information is displayed for the specified status thresholds.

activity
: Specifies the activity for which you want to display status indicators. If you do not specify a value, information is displayed for all activities. For a list of activities, see the DEFINE STATUSTHRESHOLD command.

Condition
: Restricts the output to only those matching the specified value. Possible values are:

  EXists
  : Displays status thresholds where the condition equals EXISTS.

  GT
  : Displays status thresholds where the condition equals GT.

  GE
  : Displays status thresholds where the condition equals GE.

  LT
  : Displays status thresholds where the condition equals LT.

  LE
  : Displays status thresholds where the condition equals LE.

  EQual
  : Displays status thresholds where the condition equals EQUAL.

Value
: Displays thresholds that have the specified value. If you do not specify a value, information is displayed for all values. You can specify an integer from 0 to 9223372036854775807.

STatus
: Displays status thresholds that have the specified status value. If you do not specify a value, information is displayed for all values. Possible values are:

  Normal
  : Displays the status thresholds that have a normal status value.

  Warning
  : Displays the status thresholds that have a warning status value.

  Error
  : Displays the status thresholds that have an error status value.

QUERY status threshold

Query all status thresholds by issuing the following command:

```
query statusthreshold

Threshold Name    Activity Name     Condition   Value     Report
                                    Name                  Status
---------------   ---------------   ---------   -------   -------
```

```
ACTIVELOGCHECK    ACTIVE LOG        >           90        ERROR
                   UTILIZATION
                   (%)
AVGSTGPLW         AVERAGE STORAGE   >           85        WARNING
                   POOL
                   UTILIZATION
                   (%)
AVGSTGPLE         AVERAGE STORAGE   >           90        ERROR
                   POOL
                   UTILIZATION
                   (%)
```

Query status thresholds and display detailed format

Query status thresholds and display the output in detailed format, by issuing the following command:

```
query statusthreshold f=d

Threshold Name: ACTIVELOGCHECK
 Activity Name: ACTIVE LOG UTILIZATION (%)
Condition Name: >
         Value: 90
 Report Status: ERROR
   Server Name: TSMAWP24

Threshold Name: AVGSTGPLW
 Activity Name: AVERAGE STORAGE POOL UTILIZATION (%)
Condition Name: >
         Value: 85
 Report Status: WARNING
   Server Name: TSMAWP24

Threshold Name: AVGSTGPLE
 Activity Name: AVERAGE STORAGE POOL UTILIZATION (%)
Condition Name: >
         Value: 95
 Report Status: ERROR
   Server Name: TSMAWP24
```

Related commands

Table 1. Commands related to QUERY STATUSTHRESHOLD

Command	Description
DEFINE STATUSTHRESHOLD (Define a status monitoring threshold)	Defines a status monitoring threshold.
DELETE STATUSTHRESHOLD (Delete a status monitoring threshold)	Deletes a status monitoring threshold.
QUERY MONITORSTATUS (Query the monitoring status)	Displays information about monitoring alerts and server status settings.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
SET STATUSATRISKINTERVAL (Specifies whether to enable client at-risk activity interval evaluation)	Specifies whether to enable client at-risk activity interval evaluation
SET STATUSMONITOR (Specifies whether to enable status monitoring)	Specifies whether to enable status monitoring.
SET STATUSREFRESHINTERVAL (Set refresh interval for status monitoring)	Specifies the refresh interval for status monitoring.
SET STATUSSKIPASFAILURE (Specifies whether to use client at-risk skipped files as failure evaluation)	Specifies whether to use client at-risk skipped files as failure evaluation
UPDATE STATUSTHRESHOLD (Update a status monitoring threshold)	Changes the attributes of an existing status monitoring threshold.

QUERY STGPOOL (Query storage pools)

Use this command to display information about one or more storage pools. You can also use this command to monitor migration processes for storage pools.

Privilege class

Any administrator can issue this command.

Syntax

```
                  .-*---------.  .-Format--=--Standard-----.
>>-Query STGpool--+-----------+--+-------------------------+---->
                  '-pool_name-'  '-Format--=--+-Standard-+-'
                                              '-Detailed-'

   .-POoltype--=--ANY---------------.
>--+--------------------------------+-------------------------><
   '-POoltype--=--+-ANY-----------+-'
                  +-PRimary-------+
                  +-COpy----------+
                  +-COPYCONtainer-+
                  '-ACTIVEdata----'
```

Parameters

pool_name
: Specifies the storage pool to query. This parameter is optional. You can use wildcard characters to specify this name. If you do not specify a value for this parameter, all storage pools are displayed.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Specify one of the following values:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed.

POoltype
: Specifies the type of storage pool to query. This parameter is optional. The default value is ANY. Specify one of the following values:

  ANY
  : Query primary storage pools, copy storage pools, and active-data pools.

  PRimary
  : Query only primary storage pools.

  COpy
  : Query only copy storage pools.

  COPYCONtainer
  : Query only container-copy storage pools.

  ACTIVEdata
  : Query only active-data storage pools.

Example: Display detailed random-access disk storage pool information

Tip: In the examples of detailed output, some fields are blank because the item does not apply in the specified environment. Display details for a storage pool that is named DISKPOOL. See Field descriptions for field descriptions.

```
query stgpool diskpool format=detailed

                     Storage Pool Name: DISKPOOL
                     Storage Pool Type: Primary
                     Device Class Name: DISK
```

```
                         Storage Type: DEVCLASS

Field descriptions

Storage Pool Name
: The name of the storage pool.

Storage Pool Type
: The type of storage pool.

Device Class Name
: The name of the device class that is assigned to the storage pool.

Storage Type
: The type of storage that is defined for the storage pool. The following storage types can be shown:

  DEVCLASS
  : The storage pool specifies a device class, which determines the type of device where data is stored.

  DIRECTORY
  : The storage pool creates logical containers for data in file system directories.

  CLOUD
  : The storage pool creates logical containers for data in a cloud environment.

Cloud Type
: For cloud storage pools, the type of cloud platform.

Cloud URL
: For cloud storage pools, the URL for accessing the on-premises private cloud or off-premises public cloud.

Cloud Identity
: For cloud storage pools, the user ID for accessing the on-premises private cloud or off-premises public cloud.

Cloud Location
: For cloud storage pools, indicates whether the cloud is an on-premises private cloud or off-premises public cloud.

Estimated Capacity

The estimated capacity of the storage pool in megabytes (M) or gigabytes (G).

For DISK devices, estimated capacity is the capacity of all volumes in the storage pool, including any volumes that are varied offline.

For sequential-access storage pools, estimated capacity is the total estimated space of all the sequential-access volumes in the storage pool, regardless of their access mode. At least one volume must be used in a sequential-access storage pool (either a scratch volume or a private volume) to calculate estimated capacity.

For tape and FILE devices, the estimated capacity for the storage pool includes the following factors:

- The capacity of all the scratch volumes that the storage pool already acquired or can acquire. The number of scratch volumes is defined by the MAXSCRATCH parameter on the DEFINE STGPOOL or UPDATE STGPOOL command.
- The total number of available scratch volumes in the tape library.
- Estimated capacity is the smaller number between the MAXSCRATCH value and the total number of available scratch volumes in the tape library.

The calculations for estimated capacity depend on the available space of the storage for the device that is assigned to the storage pool. For FILE storage pools, the capacity for the storage pool is reduced if the available storage is less than the total estimated space of all the FILE volumes in the storage pool. The value that is displayed for capacity is reduced by the size of a FILE volume incrementally as the available space continues to decline.

For Centera, value represents the total capacity of the Centera storage device that is being queried.

Space Trigger Util
Utilization of the storage pool, as calculated by the storage pool space trigger, if any, for this storage pool. You can define space triggers for storage pools that are associated with DISK or FILE device types only.

For sequential access devices, space trigger utilization is expressed as follows as a percentage of the number of used bytes on each sequential access volume relative to the size of the volume and estimated capacity of all existing volumes in the storage pool. It does not include potential scratch volumes. Unlike the calculation for percent utilization, the calculation for space trigger utilization favors creation of new private file volumes by the space trigger over usage of more scratch volumes.

For disk devices, space trigger utilization is expressed as a percentage of the estimated capacity, including cached data. However, it excludes data that is on any volumes that are varied offline. The value for space trigger utilization can be higher than the value for percent migration if you issue QUERY STGPOOL while a file creation is in progress. The value for space trigger utilization is determined by the amount of space that is allocated while the transaction is in progress. The value for percent migration represents only the space that is occupied by committed files. At the end of the transaction, these values are synchronized.

The value for space trigger utilization includes cached data on disk volumes. Therefore, when cache is enabled and migration occurs, the value remains the same because the migrated data remains on the volume as cached data. The value decreases only when the cached data expires or when the space that cached files occupy must be used for noncached files.

Pct Util
An estimate of the utilization of the storage pool, as a percentage.

For sequential access devices, it is a percentage of the number of active bytes on each sequential access volume and the estimated capacity of all volumes in the storage pool. The percentage includes the number of potential scratch volumes that might be allocated.

For disk devices, it is a percentage of the estimated capacity, including cached data and data that is on any volumes that are varied offline. The value for Pct Util can be higher than the value for Pct Migr if you issue this command while a file creation transaction is in progress. The value for Pct Util is determined by the amount of space that is allocated, while the transaction is in progress. The value for Pct Migr represents only the space that is occupied by committed files. At the end of the transaction, these values become synchronized.

The Pct Util value includes cached data on disk volumes. Therefore, when cache is enabled and migration occurs, the Pct Util value remains the same because the migrated data remains on the volume as cached data. The Pct Util value decreases only when the cached data expires or when the space that cached files occupy must be used for noncached files.

For Centera, this represents an estimate of the utilization of the entire Centera storage device, not the storage pool that is being queried.

Pct Migr (primary storage pools only)

An estimate of the percentage of data in the storage pool that can be migrated. The server uses this value and the high and low migration thresholds to determine when to start and stop migration.

For random-access disk devices, this value is specified as a percentage of the value for the estimated capacity, excluding cached data, but including data on any volumes varied offline.

For sequential-access disk devices, this value is specified as a percentage of the value for the estimated capacity. The value includes the capacity of all the scratch volumes that are specified for the pool. For other types of sequential-access devices, this value is the percentage of the total number of volumes in the pool that contain at least one byte of active data. The total number of volumes includes the maximum number of scratch volumes.

The Pct Util value includes cached data on a volume; the Pct Migr value excludes cached data. Therefore, when cache is enabled and migration occurs, the Pct Migr value decreases but the Pct Util value remains the same because the migrated data remains on the volume as cached data. The Pct Util value decreases only when the cached data expires or when the space that cached files occupy must be used for noncached files.

Pct Logical
: The logical occupancy of the storage pool as a percentage of the total occupancy. Logical occupancy is space that is occupied by client files that might or might not be part of an aggregate. A Pct Logical value less than 100% indicates that there is vacant space within aggregates in the storage pool.

High Mig Pct (primary storage pools only)
: The high migration threshold, which specifies when the server can begin migration for the storage pool. The server starts migration processes when capacity utilization reaches this threshold.

Low Mig Pct (primary storage pools only)
: The low migration threshold, which specifies when the server can stop migration for the storage pool. The server stops migration processes when capacity utilization reaches this threshold.

Migration Delay (primary storage pools only)
: The minimum number of days that a file must remain in a storage pool before the server can migrate the file to the next storage pool. For a disk storage pool, the days are counted from the time that the file was stored in the storage pool or last retrieved by a client. For a sequential access storage pool, the days are counted from the time that the file was stored in the storage pool.

Migration Continue (primary storage pools only)
: Whether the server continues to migrate files to the next storage pool even if the files have not been in the pool for the number of days that are specified by the migration delay.

Migration Processes
: The number of parallel processes that are used for migrating files from a random or sequential access primary storage pool.

Reclamation Processes
: The number of parallel processes that are used for reclaiming the volumes in a sequential access primary or copy storage pool.

Next Storage Pool (primary storage pools only)
: The storage pool that is the destination for data that is migrated from this storage pool.

Reclaim Storage Pool (primary, sequential access storage pools only)
: If specified, the storage pool that is the destination for data that is moved from volumes during reclamation processing. If no pool is specified, by default reclamation processing moves data only among volumes within the same storage pool.

Maximum Size Threshold (primary storage pools only)
: The maximum size of files that might be stored in the storage pool.

Access
: The access mode for data in the storage pool. The following access modes are possible:

  Read/Write
  : The data can be accessed in read-write mode.

  Read only
  : The data can be accessed in read-only mode.

  Converting
  : The storage pool is being converted to a directory-container storage pool.

  Conversion Stopped
  : The process of converting the storage pool to a directory-container storage pool is stopped.

  Conversion Cleanup Needed
  : To convert the storage pool successfully, you must clean up the storage pool. Conversion could not complete because of damaged data. Issue the QUERY CLEANUP command to identify damaged files.

  Converted
  : The storage pool is converted to a directory-container storage pool.

Description
: The description of the storage pool.

Overflow Location (sequential access storage pools only)
: The location where volumes in the storage pool are stored when they are ejected from an automated library with the MOVE MEDIA command.

Cache Migrated Files? (random access storage pools only)
: Whether caching is enabled for files that are migrated to the next storage pool.

Collocate? (sequential access storage pools only)
: Whether collocation is disabled or enabled. If collocation is disabled, the value of this field is No. If collocation is enabled, the possible values are Group, Node, and File space.

Reclamation Threshold (sequential access storage pools only)
: The threshold that determines when volumes in a storage pool are reclaimed. The server compares the percentage of reclaimable space on a volume to this value to determine whether reclamation is necessary.

Offsite Reclamation Limit
: The number of offsite volumes that have space that is reclaimed during reclamation for this storage pool. This field applies only when POOLTYPE=COPY.

Maximum Scratch Volumes Allowed (sequential access storage pools only)
: The maximum number of scratch volumes that the server can request for the storage pool.

Number of Scratch Volumes Used (sequential access storage pools only)
: The number of scratch volumes that are used in the storage pool.

Delay Period for Container Reuse (container storage pools only)
: The number of days that must elapse after all files are deleted from a container before the server reuses the container.

Migration in Progress? (primary storage pools only)
: Whether at least one migration process is active for the storage pool.

Amount Migrated (MB) (primary storage pools only)
: The amount of data, in megabytes, that is migrated, if migration is in progress. If migration is not in progress, this value indicates the amount of data that was migrated during the last migration. When multiple, parallel migration processes are used for the storage pool, this value indicates the total amount of data that is migrated by all processes.

Elapsed Migration Time (seconds) (primary storage pools only)
: The amount of time that elapsed since migration began, if migration is active. If migration is not active, this value indicates the amount of time that is required to complete the last migration. When multiple, parallel migration processes are used for the storage pool, this value indicates the total time from the beginning of the first process until the completion of the last process.

Reclamation in Progress? (sequential access storage pools only)
: Whether a reclamation process is active for the storage pool.

Last Update by (administrator)
: The name of the administrator that is defined or most recently updated the storage pool.

Last Update Date/Time
: The date and time that an administrator defined or most recently updated the storage pool.

Storage Pool Data Format
: The type of data format that is used to write data to this storage pool (for example NATIVE, NETAPPDUMP, CELERRADUMP, or NDMPDUMP).

Copy Storage Pool(s)
: The copy storage pools that are listed have data that is simultaneously written to them when data is backed up or archived to the primary storage pool queried by this command.

Active Data Pool(s)
: The active-data pools that are listed here have data that is simultaneously written to them when data is backed up to the primary storage pool queried by this command.

Continue Copy on Error?
: Whether a server continues to write data to other copy storage pools in the list or ends the entire transaction when a write failure occurs to one of the copy pools in the list. This field applies only to primary random-access and primary sequential-access storage pools.

CRC Data
: Whether data is validated by a cyclic redundancy check (CRC) when data is transferred during data storage and retrieval on a device.

Reclamation Type
: Whether volumes in this storage pool are reclaimed by threshold or by SnapLock retention date.

Overwrite Data when Deleted
: The number of times data will be physically overwritten after it is deleted from the database.

Deduplicate Data?
: Whether data in the storage pool is deduplicated.

Processes for Identifying Duplicates

The number of duplicate-identification processes that are specified as the default for the storage pool. The number of duplicate-identification processes that are specified in this field might not equal the number of duplicate-identification processes that are running.

Compressed
: Whether the storage pool is compressed.

Additional space for protected data
: The amount of space, in MB, that is used to protect data from remote servers. This is the total amount of space used for data received from other servers as a result of running the PROTECT STGPOOL command.

Total Unused Pending Space
: The amount of space that is scheduled to become available in a directory-container storage pool. The space is occupied by deduplicated data extents that will be removed from the storage pool when the time period specified by the REUSEDELAY parameter on the DEFINE STGPOOL command expires.

Deduplication Savings
: The amount and percentage of data that is saved in the storage pool by using data deduplication.

Compression Savings
: The amount of data that is saved in the storage pool by compression.

Total Space Saved
: The total amount of data that was saved in the storage pool.

Auto-copy Mode
: Indicates whether data is written simultaneously to copy storage pools or active-data pools during client store sessions, server import processes, server data migration processes, or all three operations. The value CLIENT indicates either client store or server import operations. The value ALL indicates that simultaneous-write operations occur whenever this pool is a target for any of the eligible operations.

  If the storage pool is a copy storage pool or an active-data pool or if the simultaneous-write function is disabled, this field is blank.

Contains Data Deduplicated by Client?
: Indicates whether the storage pool contains data that was deduplicated by clients. Storage pools that contain data that is deduplicated by clients are not accessible for LAN-free data movement by storage agents V6.1 or earlier.
  Tip: This field is blank for container storage pools. You cannot use container storage pools for LAN-free data movement.

Maximum Simultaneous Writers
: The maximum number of I/O that can run concurrently on the storage pool.

Protect Processes
: The set of protect processes.

Protection Storage Pool
: The name of the container storage pool where the data is protected to on the target replication server.

Protect Local Storage Pool(s)
: Indicates whether local storage pools are protected.

Reclamation Volume Limit
: For container-copy storage pools, indicates the maximum number of volumes that the server reclaims during storage pool protection.

Date of Last Protection to Remote Pool
: The date that the storage pool was last protected to a storage pool on a remote server.

Date of Last Protection to Local Pool
: The date that the storage pool was last protected to a storage pool on the local server.

Deduplicate Requires Backup?
: Indicates whether the sequential storage pool must be backed up if the storage pool contains deduplicated data.

Encrypted
: For directory-container or cloud-container storage pools, indicates whether client data is encrypted before it is written to the storage pool.

Pct Encrypted
: The percentage of deduplicated client data that is encrypted in the directory-container or cloud-container storage pool.

Cloud Space Utilized (MB)
: For cloud storage pools, the space that is used by the cloud storage, in megabytes.

Bucket Name
: For cloud storage pools that use Simple Storage Service (S3), the name IBM Spectrum Protect™ assigns to the S3 bucket or IBM® Cloud Object Storage vault. This value can also be the name you assigned to the bucket by using the BUCKETNAME parameter in the DEFINE STGPOOL command or the UPDATE STGPOOL command.

Local Estimated Capacity
: For cloud storage pools that use local storage, the estimated capacity of the local storage in megabytes (M) or gigabytes (G).

Local Pct Util
: For cloud storage pools that use local storage, an estimate of the utilization of the local storage component of the cloud storage pool, as a percentage.

Local Pct Logical
: For cloud storage pools that use local storage, the logical occupancy of the cloud storage pool as a percentage of the total occupancy. Logical occupancy is space that is occupied by client files that might or might not be part of an aggregate. A Local Pct Logical value less than 100% indicates that there is vacant space within aggregates in the cloud storage pool.

Related commands

Table 1. Commands related to QUERY STGPOOL

Command	Description
CONVERT STGPOOL	Convert a storage pool to a directory-container storage pool.
COPY ACTIVEDATA	Copies active backup data.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DELETE STGPOOL	Deletes a storage pool from server storage.
QUERY STGPOOLDIRECTORY	Displays information about storage pool directories.
UPDATE STGPOOL	Changes the attributes of a storage pool.

AIX Linux Windows

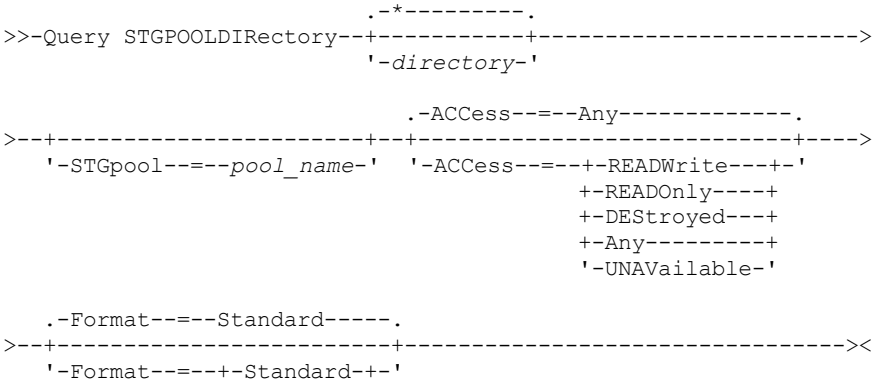
QUERY STGPOOLDIRECTORY (Query a storage pool directory)

Use this command to display information about one or more storage pool directories.

Privilege class

Any administrator can issue this command.

Syntax



```
'-Detailed-'
```

Parameters

directory
: Specifies the storage pool directory to query. This parameter is optional.

  *
  : Specifies that an asterisk (*) represents a wildcard character. Use wildcard characters such as an asterisk to match any characters. Alternatively, you can use a question mark (?) or a percent sign (%) to match exactly one character. This is the default.

  directory
  : Specifies the storage pool directory. If you do not specify a value for this parameter, all storage pool directories are displayed. The maximum length of the storage pool directory is 1024.

STGpool
: Specifies the name of the storage pool to query. If you do not specify a value for this parameter, all storage pool directories are displayed. The maximum length of the storage pool name is 30. This parameter is optional.

ACCess
: Specifies that output is restricted by directory access mode. This parameter is optional. Specify one of the following values:

  READWrite
  : Display all storage pool directories with an access mode of `READWRITE`.

  READOnly
  : Display all storage pool directories with an access mode of `READONLY`.

  DEStroyed
  : Display all storage pool directories with an access mode of `DESTROYED`. The directories are designated as permanently damaged in the storage pool directory.

  Any
  : Display all storage pool directories. This is the default.

  UNAVailable
  : Display directories with an access mode of `UNAVAILABLE`.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. You can specify one of the following values:

  Standard
  : Specifies that partial information is displayed.

  Detailed
  : Specifies that complete information is displayed.

Example: Display summary information for a specific storage pool directory

Display information for the storage pool directory that is named DPOOL. See Field descriptions for field descriptions.

```
query stgpooldirectory C:\data
```

```
Storage     Directory     Access
Pool Name
----------  ----------   ---------
DPOOL       C:\data       Read/Write
```

Example: Display detailed storage pool directory information

Display details for the storage pool directory named that is named DPOOL.

```
query stgpooldirectory stgpool=dpool format=detailed
```

AIX | Linux

```
               Storage Pool Name: DPOOL
                       Directory: /storage/sampleDir
                          Access: Read/Write
```

```
     Free Space(MB): 323,170
    Total Space(MB): 476,938
        File System: /storage
      Absolute Path: /storage/data
```

Windows

```
Storage Pool Name: DPOOL
        Directory: /storage2/sampleDir
           Access: Read/Write
     Free Space(MB): 323,170
    Total Space(MB): 476,938
        File System: /storage
      Absolute Path: /storage2/sampleDir
```

Field descriptions

Storage Pool Name
: The name of the storage pool.

Directory
: The name of the storage pool directory.

Access
: The access mode of the data in the storage pool directory.

Free Space (MB)
: The amount of space in the storage pool directory, in megabytes, that is not in use.

Total Space (MB)
: The total amount of space in the storage pool directory, in megabytes.

File System
: The name of the file system where the storage pool directory is located.

Absolute Path
: The absolute path name where the storage pool directory is located. The absolute path name contains the name of the root directory and all subdirectories in the path name. All symbolic links are resolved in the absolute path name.

Table 1. Commands related to QUERY STGPOOLDIRECTORY

Command	Description
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
AIX Linux Windows DEFINE STGPOOLDIRECTORY	Defines a storage pool directory to a directory-container or cloud-container storage pool.
AIX Linux Windows DELETE STGPOOLDIRECTORY	Deletes a storage pool directory from a directory-container or cloud-container storage pool.
AIX Linux Windows UPDATE STGPOOLDIRECTORY	Changes the attributes of a storage pool directory.

QUERY SUBSCRIBER (Display subscriber information)

Use this command on a configuration manager to display information about subscribers and their profile subscriptions.

Privilege class

Any administrator can issue this command.

Syntax

```
                    .-*-----------.
>>-Query SUBSCRIBer--+-------------+---------------------------><
                     '-server_name-'
```

```
   .-PROFIle--=--*------------.
>--+--------------------------+-------------------------------><
   '-PROFIle--=--profile_name-'
```

Parameters

server_name
: Specifies the name of a managed server for which subscription information is displayed. You can use wildcard characters to specify multiple server names. This parameter is optional. The default is all managed servers.

PROFIle
: Specifies a profile name for which information is displayed. You can use wildcard characters to specify multiple profile names. This parameter is optional. The default is all profiles.

Example: List a configuration manager's profile subscriptions

Display subscriber information for all profile subscriptions to this configuration manager. See Field descriptions for field descriptions.

```
query subscriber
```

```
Subscriber        Profile name       Is current?    Last update
                                                    date/time
---------------   ---------------    ------------   -----------------
SERVER2           DEFAULT_PROFILE    Yes            Thu, May 14, 1998
                                                    01:14:42 PM
SERVER2           SETUP              Yes            Thu, May 14, 1998
                                                    01:14:42 PM
```

Field descriptions

Subscriber
: The name of the subscriber (managed server).

Profile name
: The name of the profile.

Is current?
: Whether the subscription has been refreshed with the current information associated with the profile. Possible values are:

  Yes
  : The managed server is current.

  No
  : The managed server is not current. If this field is NO after the profile has been refreshed, check the server messages for error conditions that might cause the refresh to fail.

  Unknown
  : Either the managed server has a more recent version of the profile than the configuration manager, or the profile no longer exists on the configuration manager, but the subscription is still associated with the profile.

Last update date/time
: Specifies the date and time that configuration information for the subscription was successfully distributed to the subscriber.

Related commands

Table 1. Commands related to QUERY SUBSCRIBER

Command	Description
DEFINE SUBSCRIPTION	Subscribes a managed server to a profile.
DELETE SUBSCRIBER	Deletes obsolete managed server subscriptions.
DELETE SUBSCRIPTION	Deletes a specified profile subscription.
NOTIFY SUBSCRIBERS	Notifies servers to refresh their configuration information.
SET CONFIGMANAGER	Specifies whether a server is a configuration manager.

Command	Description
QUERY SUBSCRIPTION	Displays information about profile subscriptions.

QUERY SUBSCRIPTION (Display subscription information)

Use this command on a managed server to display profile subscription information.

Privilege class

Any administrator can issue this command.

Syntax

```
                        .-*------------.
>>-Query SUBSCRIPtion--+--------------+------------------------><
                        '-profile_name-'
```

Parameters

profile_name
: Specifies the name of the profile for which subscription information is displayed. You can use wildcard characters to specify multiple names. This parameter is optional. The default is all profiles.

Example: Display description information

Display subscription information for all profiles.

```
query subscription

Configuration       Profile name          Last update
manager                                   date/time
---------------     ---------------       ---------

SERVER1             EMPLOYEE              Thu, May 14, 1998
                                          01:35:13 PM
```

Field descriptions

Configuration manager
: The name of the configuration manager.

Profile name
: The name of the profile.

Last update date/time
: When the most recent configuration information was successfully distributed to the subscriber.

Related commands

Table 1. Commands related to QUERY SUBSCRIPTION

Command	Description
DEFINE SUBSCRIPTION	Subscribes a managed server to a profile.
DELETE SUBSCRIBER	Deletes obsolete managed server subscriptions.
DELETE SUBSCRIPTION	Deletes a specified profile subscription.
NOTIFY SUBSCRIBERS	Notifies servers to refresh their configuration information.

Command	Description
QUERY SUBSCRIBER	Displays information about subscribers and their subscriptions to profiles.

QUERY SYSTEM (Query the system configuration and capacity)

Use this command to obtain consolidated information about the server's configuration and capacity.

This command consolidates output from select statements, SHOW commands, and other IBM Spectrum Protect™ commands. Output is generated from several IBM Spectrum Protect commands, for example:

- QUERY ASSOCIATION
- QUERY COPYGROUP
- QUERY DATAMOVER
- QUERY DB
- QUERY DBSPACE
- QUERY DEVCLASS
- QUERY DIRSPACE
- QUERY DOMAIN
- QUERY LIBRARY
- QUERY LOG
- QUERY MGMTCLASS
- QUERY OPTION
- QUERY PROCESS
- QUERY REPLRULE
- QUERY SCHEDULE
- QUERY SERVER
- QUERY SESSION
- QUERY STATUS
- QUERY STGPOOL
- QUERY VOLHISTORY
- QUERY VOLUME

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query SYStem-------------------------------------------------><
```

Example: View consolidated system information

Issue the QUERY SYSTEM command to obtain consolidated system information. For sample outputs for these query commands, see the individual commands.

```
query system
```

Related commands

Table 1. Commands related to QUERY SYSTEM

Command	Description
QUERY ASSOCIATION	Displays the clients associated with one or more schedules.
QUERY COPYGROUP	Displays the attributes of a copy group.
QUERY DB	Displays allocation information about the database.

Command	Description
QUERY DBSPACE	Displays information about the storage space defined for the database.
QUERY DEVCLASS	Displays information about device classes.
QUERY DOMAIN	Displays information about policy domains.
QUERY LOG	Displays information about the recovery log.
QUERY MGMTCLASS	Displays information about management classes.
QUERY OPTION	Displays information about server options.
QUERY PROCESS	Displays information about background processes.
QUERY SCHEDULE	Displays information about schedules.
QUERY SESSION	Displays information about all active administrator and client sessions with IBM Spectrum Protect.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
QUERY STGPOOL	Displays information about storage pools.
QUERY VOLHISTORY	Displays sequential volume history information that has been collected by the server.
QUERY VOLUME	Displays information about storage pool volumes.

QUERY TAPEALERTMSG (Display status of SET TAPEALERTMSG command)

Use this command to display the status of the SET TAPEALERTMSG command. You can enable or disable tape alerts. When enabled, IBM Spectrum Protect™ can retrieve diagnostic information from a tape or library device and display it using ANR messages. When disabled, IBM Spectrum Protect will not query a device for this information.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-Query TAPEAlertmsg----------------------------------------><
```

Example: Display the status of the QUERY TAPEALERTMSG command

Use the QUERY TAPEALERTMSG command to determine if tape alerts are to be retrieved from devices and displayed in the form of ANR messages.

```
query tapealertmsg

ANR2017I Administrator SERVER_CONSOLE issued command:
         QUERY TAPEALERTMSG
ANR8960I QUERY TAPEALERTMSG: The display of Tape Alerts from SCSI
         devices is Enabled.
```

Related commands

Table 1. Commands related to QUERY TAPEALERTMSG

Command	Description

Command	Description
SET TAPEALERTMSG	Specifies whether tape and library devices report diagnostic information to the server.

QUERY TOC (Display table of contents for a backup image)

Use this command to display directory and file information contained in the table of contents (TOC) for a specified backup image. This command does not load table of contents information into the IBM Spectrum Protect™ database. The specified table of contents are read from a storage pool each time the QUERY TOC command is issued.

This command cannot be issued from the server console. If the table of contents is stored on removable media, a mount point is required and output is delayed while the storage pool volume is mounted.

Privilege class

To issue this command you must have either system privilege, policy privilege for the domain to which the node is assigned, or client owner authority over the node.

Syntax

```
>>-Query TOC--node_name--filespace_name------------------------>

>--+-----------------------------------------------+------------>
   '-CREATIONDate--=--date--CREATIONTime--=--time-'

   .-Format--=--Standard-----.
>--+-------------------------+-------------------------------><
   '-Format--=--+-Standard-+-'
                '-Detailed-'
```

Parameters

node_name (Required)
: Specifies the name of the NAS node to which the table of contents (TOC) belongs. You cannot use wildcards to specify this name.

filespace_name (Required)
: Specifies the name of the file space to which the table of contents belongs. The file space name you specify cannot contain wildcard characters.

CREATIONDate
: Specifies the creation date of the backup image for which the table of contents is to be displayed. This parameter is optional. If you specify CREATIONDATE, you must also specify CREATIONTIME. If you do not specify these parameters, the contents of the latest backup image for the specified node and file space will be displayed, provided that this image has a table of contents. You can only specify the creation date as the following:

Value	Description	Example
MM/DD/YYYY	A specific date	05/15/2002

This specifies that you want to display the contents of the backup image created on this date. You can obtain this date from the output of the QUERY NASBACKUP command.

CREATIONTime
: Specifies the creation time of the backup image for which the table of contents is to be displayed. This parameter is optional. If you specify CREATIONTIME, you must also specify CREATIONDATE. If you do not specify these parameters, the contents of the latest backup image for the specified node and file space will be displayed, provided that this image has a table of contents. You can only specify the creation time as the following:

Value	Description	Example
HH:MM:SS	A specific time on the specified creation date.	10:30:08

This specifies that you want to display the contents of the backup image created on this time for the specified date. You can obtain this time from the output of the QUERY NASBACKUP command.

Format

Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

Standard
: Specifies that partial information is displayed for the files.

Detailed
: Specifies that complete information is displayed for the files, including the hexadecimal representation of each file or directory name.

Example: Display detailed table of contents information for a specific node

Use the QUERY TOC command to display information in the table of contents belonging to NAS node NETAPP in the file space /vol/vol1 created on 12/06/2002 at 11:22:46. Specify a detailed format.

```
query toc netapp /vol/vol1 creationdate=12/06/2002 creationtime=11:22:46
    format=detailed

Objects in the image backed up on 12/06/2002 11:22:46
for filespace /vol/vol1 in node NETAPP:

                          Object Name: /.etc
                Hexadecimal Object Name: 2f657463
                          Object Type: Directory
                          Object Size: 4,096
          Last data Modification Date/Time: 07/31/2002 14:21:19

                          Object Name: /.etc/oldmaps/ndmp
                Hexadecimal Object Name: 2f6574632f6f6c646d6170
                                         732f6e646d70
                          Object Type: Directory
                          Object Size: 4,096
          Last data Modification Date/Time: 07/31/2002 14:21:19

                          Object Name: /.etc/oldmaps/ndmp/TSM
                                       /vol/vol1/3df0e8fd
                Hexadecimal Object Name: 2f6574632f6f6c646d6170
                                         732f6e646d702f54534d2
                                         02f766f6c2f766f6c312f3
                                         364663065386664
                          Object Type: File
                          Object Size: 36,864
          Last data Modification Date/Time: 12/06/2002 11:14:22
```

Field descriptions

Object Name
: The name of the object.

Hexadecimal Object Name
: The name of the object in hexadecimal format.

Object Type
: The type of the object.

Object Size
: The size of the object.

Last data Modification Date/Time
: The date and time the object was last modified.

Related commands

Table 1. Commands related to QUERY TOC

Command	Description
BACKUP NODE	Backs up a network-attached storage (NAS) node.
QUERY NASBACKUP	Displays information about NAS backup images.
RESTORE NODE	Restores a network-attached storage (NAS) node.

QUERY VIRTUALFSMAPPING (Query a virtual file space mapping)

Use this command to query a virtual file space mapping definition.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-Query VIRTUALFSmapping ------------------------------------>

   .-*--*-----------------------------------.
>--+-----------------------------------------+-------------------><
   |            .-*----------------------. |
   '-node_name--+------------------------+-'
                '-virtual_filespace_name-'
```

Parameters

node_name
: Specifies the client node to which the virtual file space belongs. You can use wildcard characters to specify this name. This parameter is optional. The default is all client node names. You must specify a value for this parameter if you specify a virtual file space name.

virtual_file_space_name
: Specifies the name of the virtual file space mappings to be queried. You can use wildcard characters to specify this name. This parameter is optional. If a value is not specified, all virtual file space mappings are queried. Virtual file space mapping names are case sensitive. Use the QUERY VIRTUALFSMAPPING command to determine the correct capitalization for the virtual file space mapping to be queried.

Example: Display virtual file spaces for a specific node

Display the currently defined virtual file spaces for node NAS1. See Field descriptions for field descriptions.

```
query virtualfsmapping nas1
```

```
Node     Virtual Filespace  Filespace   Path              Hexadecimal
Name     Mapping Name       Name                          Path?
------   -----------------  ----------  ----------------- -----------
NAS1     /mikesdir          /vol/vol2   /mikes            No
NAS1     /tmpdir            /vol/vol1   /tmp              No
NAS1     /nonASCIIDir       /vol/vol3   2f73657276657231  Yes
```

Field descriptions

Node Name
: Specifies the name of the client node.

Virtual Filespace Mapping Name
: Specifies the name of the virtual file space mapping.

Filespace Name

: The name of the file space that belongs to the node.

: File space names can be in a different code page or locale than the server. If they are, the names in the Operations Center and the administrative command-line interface might not be displayed correctly. Data is backed up and can be restored normally, but the file space name or file name might be displayed with a combination of invalid characters or blank spaces.

: If the file space name is Unicode-enabled, the name is converted to the server code page for display. The success of the conversion depends on the operating system, the characters in the name, and the server code page. Conversion can be incomplete if the string includes characters that are not available in the server code page or if the server cannot access system conversion routines. If the conversion is incomplete, the name might contain question marks, blanks, unprintable characters, or ellipses (...).

Path
: Specifies the path to the client node.

Hexadecimal Path
: Indicates whether the path is hexadecimal.

Related commands

Table 1. Commands related to QUERY VIRTUALFSMAPPING

Command	Description
DEFINE VIRTUALFSMAPPING	Define a virtual file space mapping.
DELETE VIRTUALFSMAPPING	Delete a virtual file space mapping.
UPDATE VIRTUALFSMAPPING	Update a virtual file space mapping.

QUERY VOLHISTORY (Display sequential volume history information)

Use this command to display sequential volume history information. To save sequential volume history information to one or more files, use the BACKUP VOLHISTORY command.

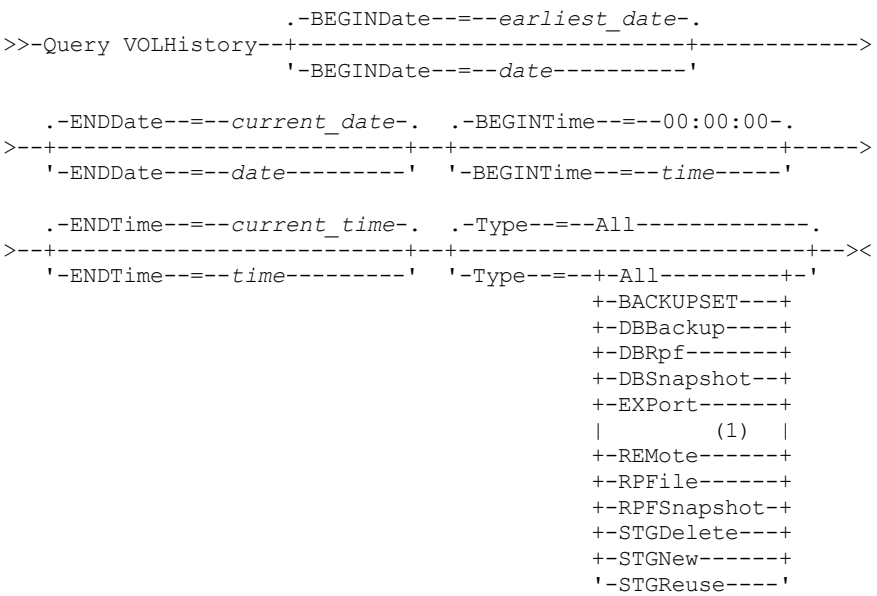
Use the VOLUMEHISTORY server option to specify one or more volume history files. After the server is restarted, IBM Spectrum Protect™ updates volume information in both the database and the files.

Use the QUERY BACKUPSET command to query specified backup set information.

Privilege class

Any administrator can issue this command.

Syntax



Notes:

1. This parameter is only available on AIX, HP-UX, Linux, Solaris and Windows operating systems.

Parameters

BEGINDate
: Specifies that you want to display information beginning with records created on the specified date. This parameter is optional. The default is the earliest date for which history information exists.

You can specify the date using one of the values below:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY-days **or** -days	The current date minus days specified	TODAY–7 **or** –7. To display information beginning with records created a week ago, specify BEGINDATE=TODAY-7 or BEGINDATE=-7.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

ENDDate

Specifies that you want to display information ending with records created on the specified date. This parameter is optional. The default is the current date.

You can specify the date using one of the values below:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days is 9999.	TODAY–1 **or** –1. To display records created up to yesterday, specify ENDDATE=TODAY-1 or ENDDATE=-1.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

BEGINTime

Specifies that you want to display information beginning with records created at the specified time. This parameter is optional. The default is midnight (00:00:00).

You can specify the time using one of the values below:

Value	Description	Example
HH:MM:SS	A specific time on the specified begin date	12:33:28
NOW	The current time on the specified begin date	NOW

Value	Description	Example
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes on the specified begin date	NOW+03:00 **or** +03:00. If you issue this command at 9:00 with BEGINTIME=NOW+03:00 or BEGINTIME=+03:00. IBM Spectrum Protect displays records with a time of 12:00 or later on the begin date.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes on the specified begin date	NOW-03:30 **or** -03:30. If you issue this command at 9:00 with BEGINTIME=NOW-03:30 or BEGINTIME=-03:30, IBM Spectrum Protect displays records with a time of 5:30 or later on the begin date.

ENDTime

Specifies that you want to display information ending with records created at the specified time on the end date. This parameter is optional. The default is the current time.
You can specify the time using one of the values below:

Value	Description	Example
HH:MM:SS	A specific time on the specified end date	10:30:08
NOW	The current time on the specified end date	NOW
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes on the specified end date	NOW+03:00 **or** +03:00. If you issue this command at 9:00 with ENDTIME=NOW+03:00 or ENDTIME=+03:00, IBM Spectrum Protect displays records with a time of 12:00 or later on the end date.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes on the specified end date	NOW-03:30 **or** -03:30 If you issue this command at 9:00 with ENDTIME=NOW-3:30 or ENDTIME=-3:30, IBM Spectrum Protect displays records with a time of 5:30 or earlier on the end date.

Type

Specifies the type of records to display from the volume history file. This parameter is optional. The default is ALL. Possible values are:

All
: Specifies all records.

BACKUPSET
: Specifies to display only information about backup set volumes.

DBBackup
: Specifies to display only records that contain information about full and incremental database backup volumes, that is with the volume types of BACKUPFULL and BACKUPINCR.

DBRpf
: Specifies to display only records that contain information about full and incremental database backup volumes and recovery plan file object volumes (volume types of BACKUPFULL, BACKUPINCR, and RPFILE).

DBSnapshot
: Specifies to display only records that contain information about volumes used for database snapshot backups.

EXPort
: Specifies only records that contain information about export volumes.

REMote
: Specifies to display only records that contain information about volumes used by library clients.

RPFile
: Specifies to display only records that contain information about file objects of a recovery plan that are saved on a target server and that were created assuming database full and incremental backups. The parameter displays only records about recovery plan files that are saved on another IBM Spectrum Protect server by using the server-to-server virtual volume function for IBM Spectrum Protect.

RPFSnapshot

Specifies to display only records that contain information about file objects of a recovery plan that are saved on a target server and that were created assuming database snapshot backups. RPFSnapshot only displays records about recovery plan files that are saved on another IBM Spectrum Protect server by using the server-to-server virtual volume function for IBM Spectrum Protect.

STGDelete
: Specifies only records that contain information about deleted sequential storage pool volumes.

STGNew
: Specifies only records that contain information about new sequential access storage volumes.

STGReuse
: Specifies only records that contain information about reused sequential storage pool volumes.

Example: Display volume history information for a storage pool volume

Display volume history information for a storage pool volume stored in the database. See Field descriptions for field descriptions. Issue the command:

```
query volhistory type=stgnew
```

```
                              Date/Time: 02/25/2011 18:28:06
                            Volume Type: STGNEW
                           Backup Series:
                        Backup Operation:
                              Volume Seq:
                            Device Class: FILE
                             Volume Name: /adsmfct/server/prvol1
                          Volume Location:
                                  Command:
                 Database Backup ID High:
                  Database Backup ID LOW:
          Database Backup Home Position:
                     Database Backup HLA:
                     Database Backup LLA:
   Database Backup Total Data Bytes (MB):
    Database Backup total Log Bytes (MB):
         Database Backup Block Num High:
          Database Backup Block Num Low:
              Database Backup Stream Id:
Database Backup Volume Sequence for Stream:
```

Note: The volume history file will contain additional fields that do not appear in the query output. These fields are specific to database backup and restore support. They are not intended for use or modification by IBM Spectrum Protect administrators. The fields will be bracketed with a message indicating these are for IBM Spectrum Protect internal use only and not meant to be modified.

Example: Display volume history information for a database backup volume

Display volume history information for a database backup volume stored in the database. See Field descriptions for field descriptions. Issue the command:

```
query volhistory type=dbb
```

```
                              Date/Time: 02/25/2011 18:28:06
                            Volume Type: BACKUPFULL
                           Backup Series: 176
                        Backup Operation: 0
                              Volume Seq: 0
                            Device Class: FILE
                             Volume Name: /adsmfct/server/prvol1
                          Volume Location:
                                  Command:
                 Database Backup ID High: 0
                  Database Backup ID LOW: 0
          Database Backup Home Position: 0
                     Database Backup HLA:
                     Database Backup LLA:
   Database Backup Total Data Bytes (MB): 0
    Database Backup total Log Bytes (MB): 0
         Database Backup Block Num High: 0
          Database Backup Block Num Low: 0
```

```
                Database Backup Stream Id: 1
Database Backup Volume Sequence for Stream: 10,001
```

Note: The volume history file will contain additional fields that do not appear in the query output. These fields are specific to database backup and restore support. They are not intended for use or modification by IBM Spectrum Protect administrators. The fields will be bracketed with a message indicating these are for IBM Spectrum Protect internal use only and not meant to be modified.

Field descriptions

Date/Time
: The date and time that the volume was created.

Volume Type
: The type of volume:

  BACKUPFULL
  : Full database backup volume.

  BACKUPINCR
  : Incremental database backup volume.

  BACKUPSET
  : Client backup set volume.

  DBSNAPSHOT
  : Snapshot database backup volume.

  EXPORT
  : Export volume.

  REMOTE
  : A volume used on the library client, which is the IBM Spectrum Protect server named in the Volume Location field. See the volume history on the server that is the library client to get details about how the volume is used.

  RPFILE
  : Recovery plan file object volume created assuming full and incremental database backups.

  RPFSnapshot
  : Recovery plan file object volume created assuming snapshot database backups.

  STGDELETE
  : Deleted sequential access storage pool volume.

  STGNEW
  : Added sequential access storage pool volume.

  STGREUSE
  : Reused sequential access storage pool volume.

Backup Series
: The value of this field depends on the volume type:

  - For BACKUPFULL or BACKUPINCR volume types: the backup series identifier.
  - For the DBSNAPSHOT volume type: the identifier of the backup series that is associated with the DBSNAPSHOT entry.
  - For the RPFILE volume type: the identifier of the backup series that is associated with the RPFILE entry.
  - For the RPFSNAPSHOT volume type: the identifier of the backup series that is associated with the RPFSNAPSHOT entry.
  - For BACKUPSET volume types: this field is blank.
  - For all other volume types: always 0.

  A backup series is a full backup and all incremental backups that apply to that full backup. Another series begins with the next full backup of the database.

Backup Operation
: For BACKUPFULL or BACKUPINCR volume types: the operation number of this backup volume within the backup series. The full backup within a backup series is operation 0. The first incremental backup for that full backup is operation 1, the second incremental backup is operation 2, and so on.

  For DBSNAPSHOT volume types: the operation number of this DBSNAPSHOT volume within the DBSNAPSHOT series.

  For all other volume types: always 0.

This field is blank when the volume type is BACKUPSET.

Volume Seq
The sequence or position of the volume within the backup series.

- For BACKUPFULL or BACKUPINCR volume types: the sequence, or position, of the volume within the backup series. Volume sequence 1 identifies the first volume used for the first operation (a full backup), and so on. For example, if the full backup occupies three volumes, these volumes are identified as volume sequence 1, 2, and 3, respectively. The first volume of the next operation (the first incremental backup) is then volume sequence 4.
- For BACKUPSET volume types: the sequence, or position, of the volume within the BACKUPSET series.
- For DBSNAPSHOT volume types: the sequence, or position, of the volume within the DBSNAPSHOT series. Volume sequence 1 identifies the first volume used for the first DBSNAPSHOT operation, and so on.
- For EXPORT volume types: the sequence number of the volume when it was used for exporting data.
- For RPFILE volume types: the value of this field is always one (1).
- For all other volume types: always 0.

Device Class
The name of the device class associated with this volume.
Volume Name
The name of the volume.
Volume Location
The location of the volume. This information is available only for the following volume types:

- BACKUPFULL
- BACKUPINCR
- EXPORT
- REMOTE
- RPFILE

For the volume type of REMOTE, this location field is the server name of the library client that owns this volume.

For the volume type of RPFILE, this location field is the server name defined in the device class definition used by the PREPARE command when the DEVCLASS parameter is specified.

Command
When the volume type is EXPORT or BACKUPSET and the volume sequence is 1 (for example, the first volume), this field shows the command that was used to generate the volume. If the EXPORT or BACKUPSET is on more than one volume, the command is displayed with the first volume but not with any of the other volumes.

For any volume type other than EXPORT or BACKUPSET, this field is blank.

Tip: The following fields are not used by IBM Spectrum Protect servers that are V6.3 or later. However, the fields are displayed for compatibility with earlier releases.

- Database Backup ID High
- Database Backup ID Low
- Database Backup Home Position
- Database Backup HLA
- Database Backup LLA
- Database Backup Total Data Bytes (MB)
- Database Backup Total Log Bytes (MB)
- Database Backup Block Num High
- Database Backup Block Num Low

Related commands

Table 1. Commands related to QUERY VOLHISTORY

Command	Description
BACKUP VOLHISTORY	Records volume history information in external files.
DELETE VOLHISTORY	Removes sequential volume history information from the volume history file.
PREPARE	Creates a recovery plan file.

Command	Description
QUERY RPFILE	Displays information about recovery plan files.
QUERY BACKUPSET	Displays backup sets.
UPDATE VOLHISTORY	Adds or changes location information for a volume in the volume history file.

QUERY VOLUME (Query storage pool volumes)

Use this command to display information about one or more storage pool volumes.

Privilege class

Any administrator can issue this command.

Syntax

Parameters

volume_name
: Specifies the volume to query. This parameter is optional. You can use wildcard characters to specify names. If you do not specify a name, all storage pool volumes are included in the query.

ACCess
: Specifies that output is restricted by volume access mode. This parameter is optional. You can specify multiple access modes by separating the modes with commas and no intervening spaces. If you do not specify a value for this parameter, output is not restricted by access mode. Possible values are:

  READWrite
  : Display volumes with an access mode of READWRITE. Client nodes and server processes can read from and write to files stored on the volumes.

  READOnly

Display volumes with an access mode of READONLY. Client nodes and server processes can read only files that are stored on the volumes.

UNAVailable
: Display volumes with an access mode of UNAVAILABLE. Client nodes and server processes cannot access files that are stored on the volumes.

OFFsite
: Display copy storage pool volumes with an access mode of OFFSITE. The volumes are at offsite locations from which they cannot be mounted.

DEStroyed
: Display primary storage pool volumes with an access mode of DESTROYED. The volumes are designated as permanently damaged.

STatus
: Specifies that output is restricted by volume status. This parameter is optional. You can specify multiple status values by separating values with commas and no intervening spaces. If you do not specify a value for this parameter, output is not restricted by volume status. Possible values are:

ONline
: Display random access volumes that are available to the server.

OFFline
: Display random access volumes that are not available to the server.

EMPty
: Display sequential access volumes that have no data.

PENding
: Display volumes with a status of PENDING. These volumes might be sequential-access volumes from which all files were deleted, but for which the time specified by the REUSEDELAY parameter on the DEFINE STGPOOL command has not elapsed. These volumes might also be random-access disk volumes that were deleted, but that still contain discarded data that is waiting to be shredded. After the data is shredded, the volume will be physically deleted.

FILling
: Display sequential access volumes that the server has written to but has not yet filled to capacity.

FULl
: Display sequential access volumes that the server filled.

STGPool
: Specifies the storage pool to include in the query. This parameter is optional. You can use wildcard characters to specify names. If you do not specify a storage pool name, all storage pools are included in the query.

DEVclass
: Specifies the device class to include in the query. This parameter is optional. You can use wildcard characters to specify names. If you do not specify a device class name, all devices are included in the query.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

Standard
: Specifies that partial information is displayed.

Detailed
: Specifies that complete information is displayed.

AIX | Linux

Example: List all file storage pool volumes

Display information on all storage pool volumes with the device class name of FILE. See Field descriptions for field descriptions.

```
query volume devclass=file
```

```
Volume Name              Storage     Device     Estimated  Pct   Volume
                         Pool Name   Class Name  Capacity  Util  Status
----------------------- ----------- ---------- --------- ----- -------
/FCT/SERVER/COVOl1       COPYSTG      FILE         0.0 M    0.0 Pending
/FCT/SERVER/COVOl2       COPYSTG      FILE         0.0 M    0.0 Empty
/FCT/SERVER/COVOl3       COPYSTG      FILE         0.0 M    0.0 Empty
/FCT/SERVER/PRVOl1       PRIMESTG     FILE         0.0 M    0.0 Empty
/FCT/SERVER/PRVOl2       PRIMESTG     FILE         0.0 M    0.0 Empty
```

Windows

Example: List all storage pool volumes with the same prefix

Display information on all storage pool volumes that are prefixed with the name ATF. See Field descriptions for field descriptions.

```
query volume atf*
```

```
Volume Name              Storage     Device      Estimated  Pct   Volume
                         Pool Name   Class Name  Capacity  Util  Status
----------------------- ----------- ---------- --------- ----- -------
ATF001                   8MMPOOL     8MMTAPE       4.8 G   18.2 Filling
ATF002                   8MMPOOL     8MMTAPE       4.8 G   18.2 Filling
```

AIX | Linux

Example: Display detailed information about a specific storage pool volume

Display details about the storage pool volume named /fct/server/covol1. See Field descriptions for field descriptions.

```
query volume covol1 format=detailed
```

```

Field descriptions

Volume Name
: The name of the storage pool volume.

Storage Pool Name
: The storage pool to which the volume is defined.

Device Class Name
: The device class that is assigned to the storage pool.

Estimated Capacity
: The estimated capacity of the volume, in megabytes (M), gigabytes (G), or terabytes (T).

  For DISK devices, this value is the capacity of the volume.

  For sequential access devices, this value is an estimate of the total space available on the volume, which is based on the device class.

Scaled Capacity Applied
: The percentage of capacity to which a volume is scaled. For example, a value of 20 for a volume whose maximum capacity is 300 GB indicates that the volume can store only 20 percent of 300 GB, or 60 GB. This attribute applies only to IBM® 3592 devices.

Pct Util
: An estimate of the utilization of the volume. The utilization includes all space that is occupied by both files and aggregates, including empty space within aggregates.

  For DISK volumes, the utilization also includes space that is occupied by cached data.

Volume Status
: The status of the volume.

Access
: Whether the volume is available to the server.

Pct. Reclaimable Space (sequential access volumes only)
: The amount of space on this volume that can be reclaimed because data has expired or been deleted. This value is compared to the reclamation threshold for the storage pool to determine whether reclamation is necessary. Reclaimable space includes empty space within aggregates.

  When determining which volumes in a storage pool to reclaim, the server first determines the reclamation threshold. The reclamation threshold is indicated by the value of the THRESHOLD parameter on the RECLAIM STGPOOL command or, if that value was not specified, the value of the RECLAIM parameter in a storage pool definition. The server then examines the percentage of reclaimable space for each volume in the storage pool. If the percentage of reclaimable space on a volume is greater that the reclamation threshold of the storage pool, the volume is a candidate for reclamation.

  For example, suppose that storage pool FILEPOOL has a reclamation threshold of 70 percent. This value indicates that the server can reclaim any volume in the storage pool that has a percentage of reclaimable space that is greater that 70 percent. The storage pool has three volumes:

  - FILEVOL1 with 65 percent reclaimable space
  - FILEVOL2 with 80 percent reclaimable space
  - FILEVOL3 with 95 percent reclaimable space

  When reclamation begins, the server compares the percent of reclaimable space for each volume with the reclamation threshold of 70 percent. In this example, FILEVOL2 and FILEVOL3 are candidates for reclamation because their percentages of reclaimable space are greater than 70.

  For volumes that belong to a SnapLock storage pool, the value is displayed but is not used.

Scratch Volume? (sequential access volumes only)
: Whether this volume is returned to scratch when the volume becomes empty.

In Error State?
: Whether the volume is in an error state. The server cannot write to volumes in an error state.

Number of Writable Sides
: This information is reserved for IBM Spectrum Protect™.

Number of Times Mounted
: The number of times that the server opened the volume for use. The number of times that the server opened the volume is not always the same as the number of times that the volume was physically mounted in a drive. After a volume is physically mounted, the server can open the same volume multiple times for different operations, for example for different client backup sessions.

Write Pass Number (sequential access volumes only)
: The number of times the volume was written to from the beginning to the end.

Approx. Date Last Written
: The approximate date on which the volume was last written.

Approx. Date Last Read
: The approximate date on which the volume was last read.

Date Became Pending
: The date that the status of the volume was changed to pending.

Number of Write Errors
: The number of writing errors that occurred on the volume.

Number of Read Errors
: The number of reading errors that occurred on the volume.

Volume Location
: The location of the volume.

Volume is MVS Lanfree Capable
: Whether the volume is LAN-free capable. A LAN-free capable volume is one that was defined and used (at least once) by the IBM Spectrum Protect z/OS® data manager server.

Last Update by (administrator)
: The administrator that defined or most recently updated the volume.

Last Update Date/Time
: When the volume was defined or most recently updated.

Begin Reclaim Period
: Represents the date after which the server begins reclaiming this volume, but not later than the date represented by the end reclaim period. If, when the reclaim period begins, there are files on the volume that have not expired, they are moved to a new WORM volume during reclamation processing. This field displays a date only if this volume is in a storage pool for which the value of the RECLAMATIONTYPE parameter is SNAPLOCK.

  If more than one archive is stored on the same volume, the start of the volume's reclamation period is based on the date of the most recent archive. For SnapLock volumes, the RETVer parameter of the DEFINE COPYGROUP command determines how long an archive is stored. If RETVer is set to 100 days, the volume's reclamation period will start 100 days after the first archive is stored on it. If a second archive is stored on the same volume, the reclamation start date will be adjusted to 100 days after the new archive is stored. If the RETVer value is changed after the first archive is stored, the latest reclamation date will apply for all of the archives on the volume. For example, assume RETVer is set to 100 for an initial archive, but is then changed to 50. If a second archive is stored on the volume three days after the first, the reclamation period will not start until 100 days after the first archive was stored.

End Reclaim Period
: Represents the date by which the IBM Spectrum Protect must complete reclamation processing on this volume to ensure continued protection of the data. It also represents the Last Access Date physical file attribute in the NetApp Filer, which prevents the file from being deleted until after that date. This field displays a date only if this volume is in a storage pool for which the value of the RECLAMATIONTYPE parameter is SNAPLOCK.

Drive Encryption Key Manager
: The drive encryption key manager. This field applies only to volumes in a storage pool that is associated with a device type of 3592, LTO, or ECARTRIDGE.

Logical Block Protected
: Specifies whether logical block protection is enabled for the volume. You can use logical block protection only with the following types of drives and media:

  - IBM LTO5 and later
  - IBM 3592 Generation 3 drives and later with 3592 Generation 2 media and later
  - Oracle StorageTek T10000C and T10000D drives

Related commands

Table 1. Commands related to QUERY VOLUME

Command	Description
DEFINE DEVCLASS	Defines a device class.
DEFINE VOLUME	Assigns a volume to be used for storage within a specified storage pool.
DELETE VOLUME	Deletes a volume from a storage pool.
UPDATE DEVCLASS	Changes the attributes of a device class.
UPDATE VOLUME	Updates the attributes of storage pool volumes.
VARY	Specifies whether a disk volume is available to the server for use.

QUIT (End the interactive mode of the administrative client)

Use this command to end an administrative client session in interactive mode.

You cannot use the QUIT command from the SERVER_CONSOLE administrative ID, or the console, batch, or mount modes of the administrative client.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-QUIT-----------------------------------------------------><
```

Parameters

None.

Example: End an interactive administrative client session

End an administrative client session in the interactive mode.

```
quit
```

Related commands

None.

RECLAIM STGPOOL (Reclaim volumes in a sequential-access storage pool)

Use this command to reclaim volumes in a sequential-access storage pool. Reclamation does not move inactive versions of backup data from volumes in active-data pools.

This command cannot be used for the following types of storage pools:

- Container-copy storage pools. Space in these storage pools is reclaimed as part of the processing that is done by PROTECT STGPOOL commands.
- Storage pools with one of the following data formats:
  - NETAPPDUMP
  - CELERRADUMP

    - NDMPDUMP
- Storage pools that use a CENTERA device class.
- Storage pools that use a Write Once Read Many (WORM) device class. Reclamation is not necessary because WORM volumes are not reusable, but you can run reclamation to consolidate data onto fewer volumes.

Use this command only if you are not going to use automatic reclamation for the storage pool. This command accepts the values of the RECLAIMPROCESS and RECLAIMSTGPOOL attributes of the storage pool definition. This command also accepts the values of the OFFSITERECLAIMLIMIT and RECLAIM parameters of the storage pool definition, if not overridden by the OFFSITERECLAIMLIMIT and THRESHOLD command parameters.

Tips:

- When you issue this command, duplicate data in a primary storage pool, copy storage pool, or active-data pool that is set up for data deduplication is removed.
- When you use this command to restore deduplicated objects to the same storage pool, any duplicate data blocks are replaced with references to deduplicated extents.

For storage pools defined with RECLAMATIONTYPE=SNAPLOCK, this command also deletes empty WORM FILE volumes that exceeded their reclaim period.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the storage pool that is being reclaimed and the reclaim storage pool, if applicable.

Syntax

```
>>-RECLaim STGpool--pool_name--+----------------------+--------->
                               '-THreshold--=--number-'

                             .-Wait--=--No------.
>--+-----------------------+--+------------------+--------------->
   '-DUration--=--minutes-'  '-Wait--=--+-No--+-'
                                        '-Yes-'

>--+-------------------------------------------+--------------><
   '-OFFSITERECLAIMLimit--=--number_of_volumes-'
```

Parameters

pool_name (Required)
: Specifies the storage pool in which volumes are to be reclaimed.

DUration
: Specifies the maximum number of minutes that the reclamation runs before it is automatically canceled. You can specify a number 1 - 9999. This parameter is optional.

  After the specified number of minutes elapses, the next time the server checks the reclamation process the server stops the reclamation process. The server checks the reclamation process when the server mounts another eligible volume from the storage pool that is being reclaimed. The server also checks the reclamation process when the server begins to reclaim a new batch of files from the currently mounted volume. As a result, the reclamation can run longer than the value you specified for this parameter.

  Until the server checks the reclamation process, there is no indication the duration period expired. When the server stops the reclamation process, the server issues message ANR4927W: `Reclamation terminated for volume xxx - duration exceeded.`

  If you do not specify this parameter, the process stops only when no more volumes meet the threshold.

  If you specify a duration value for reclamation of a copy storage pool with offsite volumes, you might cause the reclamation to end before any volumes are reclaimed. In most situations when you initiate reclamation for a copy storage pool with offsite volumes, consider limiting the number of offsite volumes to be reclaimed rather than limiting the duration. For details, see the OFFSITERECLAIMLIMIT parameter.

THreshold

Specifies the percentage of reclaimable space on a volume that makes it eligible for reclamation. Reclaimable space is the amount of space that is occupied by files that are expired or deleted from the server database. Reclaimable space also includes unused space.

You can specify a number 1 - 99. This parameter is optional. If not specified, the RECLAIM attribute of the storage pool definition is used.

To determine the percentage of reclaimable space for a volume, issue the QUERY VOLUME command and specify FORMAT=DETAILED. The value in the field Pct. Reclaimable Space is the percentage of reclaimable space for the volume.

Specify a value of 50 percent or greater for this parameter so that files stored on two volumes can be combined into a single target volume.

OFFSITERECLAIMLimit
Specifies the maximum number of offsite storage pool volumes that the server tries to reclaim. This parameter is valid only for copy storage pools. You can specify a number 0 - 99999. This parameter is optional. If not specified, the OFFSITERECLAIMLIMIT attribute of the storage pool definition is used.

Wait
Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default is NO. You can specify one of the following values:

No
Specifies that the server processes this command in the background.

You can continue with other tasks while the command is processed. Messages that are created from the background process are displayed either in the activity log or the server console, depending on where messages are logged.

If you cancel this process, some files might already be moved to new volumes before the cancellation.

Yes
Specifies that the server processes this command in the foreground. The operation must complete before you can continue with other tasks. Output messages are displayed to the administrative client when the operation completes. Messages are also displayed either in the activity log or the server console, or both, depending on where the messages are logged.
Restriction: You cannot specify WAIT=YES from the server console.

Example: Reclaim volumes in a sequential-access storage pool

Reclaim volumes in the storage pool named TAPEPOOL. Specify that reclamation ends as soon as possible after 60 minutes.

```
reclaim stgpool tapepool duration=60
```

Related commands

Table 1. Commands related to RECLAIM STGPOOL

Command	Description
CANCEL PROCESS	Cancels a background server process.
MIGRATE STGPOOL	Migrates files from a primary storage pool to the next storage pool in the hierarchy.
MOVE DRMEDIA	Moves DRM media onsite and offsite.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY PROCESS	Displays information about background processes.
QUERY STGPOOL	Displays information about storage pools.

RECONCILE VOLUMES (Reconcile differences in the virtual volume definitions)

Issue this command from the source server to reconcile differences between virtual volume definitions on the source server and archive files on the target server. IBM Spectrum Protect™ finds all volumes of the specified device class on the source server and

all corresponding archive files on the target server. The target server inventory is also compared to the local definition for virtual volumes to see if inconsistencies exist.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                      .-*-----------------.
>>-REConcile Volumes--+-------------------+--------------------->
                      '-device_class_name-'

   .-Fix--=--No------.
>--+-----------------+----------------------------------------><
   '-Fix--=--+-No--+-'
             '-Yes-'
```

Parameters

device_class_name
: Specifies the device class name of the virtual volumes. If you do not specify a name, IBM Spectrum Protect reconciles all virtual volumes. This parameter is optional.

FIX
: Specifies whether or not IBM Spectrum Protect attempts to correct any identified inconsistencies. This parameter is optional. The default is NO. Possible values are:

  No
  : Specifies that IBM Spectrum Protect does not fix any inconsistencies.

  Yes
  : Specifies that IBM Spectrum Protect makes the following corrections:

    - IBM Spectrum Protect marks as unavailable storage pool volumes on the source server that cannot be located on the target server. Volumes that are only found in the volume history, such as database backups and import and export volumes, are reported as being inconsistent.
    - Archive files on the target server that do not correspond to any virtual volumes on the source server are marked for deletion from the target server.

    The following table shows the details of the actions taken:

FIX=	At the Source Server	At the Target Server	Action
NO	Volumes exist	No files exist	Report error
		Files exist but are marked for deletion	
		Active files exist but attributes do not match	
	Volumes do not exist	Active files exist	Report error
		Files exist but are marked for deletion	None
YES	Volumes exist	No files exist	Report error **Storage pool volumes:** Marked as unavailable

FIX=	At the Source Server	At the Target Server	Action
		Files exist but marked for deletion	Report error **Storage pool volumes:** If attributes match, mark files on the target server as active again, mark volumes on the source server as unavailable, and recommend that an AUDIT VOLUME be done to verify the data. If attributes do not match, mark volumes as unavailable.
		Active files exist but attributes do not match	Report error **Storage pool volumes:** Mark as unavailable and recommend that an AUDIT VOLUME be done to verify the data.
	Volumes do not exist	Active files exist	Mark files for deletion on the target server.
		Files exist but marked for deletion	None

Example: Reconcile differences in the virtual volume definitions

Reconcile the differences between all virtual volumes definitions on the source server and archive files on the target server to correct any inconsistencies.

```
reconcile volumes remote1 fix=yes
```

Related commands

Table 1. Commands related to RECONCILE VOLUMES

Command	Description
DEFINE DEVCLASS	Defines a device class.
DEFINE SERVER	Defines a server for server-to-server communications.
DELETE SERVER	Deletes the definition of a server.
QUERY SERVER	Displays information about servers.
UPDATE SERVER	Updates information about a server.

REGISTER commands

Use the REGISTER commands to define or add objects to IBM Spectrum Protect™.

- REGISTER ADMIN (Register an administrator ID)
- REGISTER LICENSE (Register a new license)
- REGISTER NODE (Register a node)

REGISTER ADMIN (Register an administrator ID)

Use this command to add an administrator to the server. After registration, the administrator can issue a limited set of commands, including all query commands. To provide additional privileges, use the GRANT AUTHORITY command.

Privilege class

To issue this command, you must have system privilege.

When you register an administrator with the same name as an existing node, be aware of the administrator authentication method and the SSLREQUIRED setting. Any node that has the same name as the administrator that is being registered inherits those settings.

For users of Lightweight Directory Access Protocol (LDAP) servers:

- The information in this documentation applies to the LDAP authentication method that is preferred for IBM Spectrum Protect™ V7.1.7 or later servers. For instructions about using the previous LDAP authentication method, see Managing passwords and logon procedures.
- Do not specify an administrative user ID that matches a node name. If the administrative user ID matches the node name, you might see unexpected behavior because of automatic password changes that update the same password twice. As a result, the password might become unknown to the administrative user ID. Alternatively, the password update operation might fail.

Syntax

```
>>-REGister Admin--admin_name--+----------+---------------------->
                               '-password-'

>--+-----------------------+--+-----------------+------------>
   |  (1)                  |  '-CONtact--=--text-'
   '-------PASSExp--=--days-'

   .-FORCEPwreset--=--No------.
>--+--------------------------+------------------------------->
   '-FORCEPwreset--=--+-No--+-'
                      '-Yes-'

>--+-----------------------------+---------------------------->
   '-EMAILADdress--=--userID@node-'

      (2)
   .-------AUTHentication--=--LOcal-.
>--+--------------------------------+--------------------------->
   '-AUTHentication--=--+-LOcal-+---'
                        '-LDap--'

                                (3)
   .-SSLrequired--=--DEFault-------.
>--+-------------------------------+---------------------------->
   '-SSLrequired--=--+-Yes-----+---'
                     +-No------+
                     '-DEFault-'

   .-SESSIONSECurity--=--TRANSitional-----.
>--+--------------------------------------+--------------------->
   '-SESSIONSECurity--=--+-STRict-------+-'
                         '-TRANSitional-'

   .-ALert--=--No------.
>--+-------------------+-------------------------------------><
   '-ALert--=--+-Yes-+-'
               '-No--'
```

Notes:

1. The PASSEXP command does not apply to administrators who authenticate to an LDAP directory server.
2. The default value can change if you issued the SET DEFAULTAUTHENTICATION command and specified LDAP.
3. The SSLREQUIRED parameter is deprecated.

Parameters

admin_name (Required)
: Specifies the name of the administrator to be registered. The maximum length of the name is 64 characters.

  You cannot specify an administrator name of NONE.

  If you plan to authenticate the administrator ID with an LDAP server, ensure that the administrator ID does not match the name of any node that authenticates with an LDAP server.

password
: Specifies the password of the administrator to be registered. The maximum length of the password is 64 characters.

If you authenticate passwords locally with the IBM Spectrum Protect server, you must specify a password. The password is not case-sensitive.

If you authenticate passwords with a Lightweight Directory Access Protocol (LDAP) server, do not specify a password on the REGISTER ADMIN command.

PASSExp

Specifies the number of days the password remains valid. You can set the password expiration period in the range 0 - 9999 days. A value of 0 means that the password never expires. This parameter is optional. If you do not specify this parameter, the password is set with the global expiration period of 90 days. This parameter does not affect passwords that authenticate with an LDAP directory server.

CONtact

Specifies information identifying the administrator being registered. This parameter is optional. The maximum length of this string is 255 characters. The contact information must be enclosed in quotation marks if it contains any blanks.

FORCEPwreset

Specifies whether the administrator is required to change or reset the password. This parameter is optional. The default value is NO. Possible values are:

No

Specifies that the administrator does not need to change or reset the password while attempting to sign on to the server.

Yes

Specifies that the administrator's password expires at the next sign-on. The client or administrator must change or reset the password then. If a password is not specified, you receive an error message.

Restriction: For administrative user IDs that authenticate with an LDAP server, password expiration is set by using LDAP server utilities. For this reason, do not specify FORCEPWRESET=YES if you specify AUTHENTICATION=LDAP.

EMAILADdress

Specifies the email address for this administrator.

AUTHentication

This parameter specifies the authentication method for the administrator user ID. Specify one of the following values: LDAP or LOCAL. The parameter is optional and defaults to LOCAL. The default can change to LDAP if you use the SET DEFAULTAUTHENTICATION command and specify LDAP.

LOcal

Specifies that the local IBM Spectrum Protect server database is used.

LDap

Specifies that the administrator user ID authenticates passwords with an LDAP directory server. Passwords that authenticate with an LDAP directory server are case-sensitive.

Tip: A password is not required if you register an administrator and select `AUTHENTICATION=LDAP`. At logon, you are prompted for a password.

SSLrequired (deprecated)

Specifies whether the administrator user ID must use the Secure Sockets Layer (SSL) protocol to communicate between the IBM Spectrum Protect server and the backup-archive client. When you authenticate passwords with an LDAP directory server, you must protect the sessions by using SSL or another network security method.

Important: Beginning with IBM Spectrum Protect Version 8.1.2, this parameter is deprecated. Validation that was enabled by this parameter is replaced by the TLS 1.2 protocol, which is enforced by the SESSIONSECURITY parameter. The SSLREQUIRED parameter is ignored. Update your configuration to use the SESSIONSECURITY parameter.

SESSIONSECurity

Specifies whether the administrator must use the most secure settings to communicate with an IBM Spectrum Protect server. This parameter is optional.

You can specify one of the following values:

STRict

Specifies that the strictest security settings are enforced for the administrator. The STRICT value uses the most secure communication protocol available, which is currently TLS 1.2. The TLS 1.2 protocol is used for SSL sessions between the server and the administrator. To specify whether the server uses TLS 1.2 for the entire session or only for authentication, see the SSL client option.

To use the STRICT value, the following requirements must be met to ensure that the administrator can authenticate with the server:

- Both the administrator and server must be using IBM Spectrum Protect software that supports the SESSIONSECURITY parameter.
- The administrator must be configured to use the TLS 1.2 protocol for SSL sessions between the server and the administrator.

Administrators set to STRICT that do not meet these requirements are unable to authenticate with the server.

TRANSitional
: Specifies that the existing security settings are enforced for the administrator. This is the default value. This value is intended to be used temporarily while you update your security settings to meet the requirements for the STRICT value.

  If SESSIONSECURITY=TRANSITIONAL and the administrator has never met the requirements for the STRICT value, the administrator will continue to authenticate by using the TRANSITIONAL value. However, after an administrator meets the requirements for the STRICT value, the SESSIONSECURITY parameter value automatically updates from TRANSITIONAL to STRICT. Then, the administrator can no longer authenticate by using a version of the client or an SSL/TLS protocol that does not meet the requirements for STRICT. In addition, after an administrator successfully authenticates by using a more secure communication protocol, the administrator can no longer authenticate by using a less secure protocol. For example, if an administrator that is not using SSL is updated and successfully authenticates by using TLS 1.2, the administrator can no longer authenticate by using no SSL protocol or TLS 1.1. This restriction also applies when you use functions such as command routing or server-to-server export, when the administrator authenticates to the IBM Spectrum Protect server as an administrator from another server.

ALert
: Specifies whether alerts are sent to an administrators email address.

  Yes
  : Specifies that alerts are sent to the specified administrators email address.

  No
  : Specifies that alerts are not sent to the specified administrators email address. This is the default value.

  Tip: Alert monitoring must be enabled, and email settings must be correctly defined to successfully receive alerts by email. To view the current settings, issue the QUERY MONITORSETTINGS command.

Example: Register an administrator

Define an administrator, LARRY, with the password PASSONE. You can identify LARRY as second-shift personnel by specifying this information with the CONTACT parameter. Issue the command:

```
register admin larry passone contact='second shift'
```

Example: Register an administrator ID and set the authentication method

Define an administrator ID for Harry so that Harry can authenticate to an LDAP server. Issue the command:

```
register admin harry authentication=ldap
```

Example: Register an administrator and enforce strict session security

Register an administrator named Harry, and require Harry to use the strictest security settings to authenticate with the server. Issue the command:

```
register admin harry sessionsecurity=strict
```

Related commands

Table 1. Commands related to REGISTER ADMIN

Command	Description
GRANT AUTHORITY	Assigns privilege classes to an administrator.
LOCK ADMIN	Prevents an administrator from accessing IBM Spectrum Protect.
QUERY ADMIN	Displays information about one or more IBM Spectrum Protect administrators.

Command	Description
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
REGISTER NODE	Defines a client node to the server and sets options for that user.
REMOVE ADMIN	Removes an administrator from the list of registered administrators.
RENAME ADMIN	Changes an IBM Spectrum Protect administrator's name.
SET DEFAULTAUTHENTICATION	Specifies the default password authentication method for any REGISTER NODE or REGISTER ADMIN commands.
SET PASSEXP	Specifies the number of days after which a password is expired and must be changed.
UNLOCK ADMIN	Enables a locked administrator to access IBM Spectrum Protect.
UPDATE ADMIN	Changes the password or contact information associated with any administrator.
UPDATE NODE	Changes the attributes that are associated with a client node.

REGISTER LICENSE (Register a new license)

Use this command to register new licenses for server components, including IBM Spectrum Protect™ (base), IBM Spectrum Protect Extended Edition, and IBM Spectrum Protect for Data Retention.

Licenses are stored in enrollment certificate files. The enrollment certificate files contain licensing information for the server product. The NODELOCK file preserves the licensing information for your installation. Your license agreement determines what you are licensed to use, even if you cannot use the REGISTER LICENSE command to register all components. You are expected to comply with the license agreement and use only what you have purchased. Use of the REGISTER LICENSE command implies that you agree to and accept the license terms specified in your license agreement.

Important:

- Before upgrading from a previous version of IBM Spectrum Protect, you must delete or rename the NODELOCK file.
- To unregister licenses, you must erase the NODELOCK file in the server instance directory of your installation, and reregister any previously registered licenses.
- You cannot register licenses for IBM Spectrum Protect for Mail, IBM Spectrum Protect for Databases, IBM Spectrum Protect for ERP, and IBM Spectrum Protect for Space Management.

To generate a report that can help you understand the license requirements for your system, run the QUERY PVUESTIMATE command. The report contains estimates of the number of client devices and PVU totals for server devices. The estimates are not legally binding.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-REGister LICense--FILE--=--+-tsmbasic.lic-+-----------------><
                              +-tsmee.lic-----+
                              +-dataret.lic--+
                              '-*.lic--------'
```

Parameters

FILE

Specifies the name of the enrollment certificate file containing the license to be registered. The specification can contain a wildcard (*). Enter the complete file name or a wildcard in place of the file name. The file names are case-sensitive. The following values can be used:

tsmbasic.lic
: To license base IBM Spectrum Protect.

tsmee.lic
: To license IBM Spectrum Protect Extended Edition. This includes the disaster recovery manager, large libraries, and NDMP.

dataret.lic
: To license IBM Spectrum Protect for Data Retention. This is required to enable Data Retention Protection as well as Expiration and Deletion Suspension (Deletion Hold).

*.lic
: To license all IBM Spectrum Protect licenses for server components.

Example: Register a license

Register the base IBM Spectrum Protect license.

```
register license file=tsmbasic.lic
```

Related commands

Table 1. Commands related to REGISTER LICENSE

Command	Description
AUDIT LICENSES	Verifies compliance with defined licenses.
QUERY LICENSE	Displays information about licenses and audits.
QUERY PVUESTIMATE	Displays processor value unit estimates.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
SET LICENSEAUDITPERIOD	Specifies the number of days between automatic license audits.

REGISTER NODE (Register a node)

Use this command to register a node to the server.

This command can create an administrative user ID with client owner authority over the node. You can use this administrative user ID to access the web backup-archive client from remote locations through a web browser.
Tip:

- In earlier product releases, the REGISTER NODE command automatically created an administrative user ID whose name matched the node name. Beginning with IBM Spectrum Protect™ V8.1, the REGISTER NODE command does not automatically create an administrative user ID that matches the node name.
- If you plan to use the LAN-free option with this node, you must register an administrative ID that matches the node name. To register the administrative ID, use the USERID parameter or manually register the administrator and grant owner authority to the node.

If a client requires a different policy domain than STANDARD, you must register the client node with this command or update the registered node.

Requirement: When you set `sslrequired=serveronly` in a REGISTER NODE command, the admin SSLREQUIRED setting reverts to YES. To use a non-SSL session with a storage agent, rename the admin with the identical name by issuing the RENAME ADMIN command.
For users of Lightweight Directory Access Protocol (LDAP) servers: The information in this documentation applies to the LDAP authentication method that is preferred for IBM Spectrum Protect V7.1.7 or later servers. For instructions about using the

previous LDAP authentication method, see Managing passwords and logon procedures.
When you register or update a node, you can specify whether damaged files on the node can be recovered from a replication server. Files can be recovered only if all the following conditions are met:

- Version 7.1.1 or later, is installed on the source and target replication servers.
- The REPLRECOVERDAMAGED system parameter is set to ON. The system parameter can be set by using the SET REPLRECOVERDAMAGED command.
- The source server includes at least one file that is marked as damaged in the node that is being replicated.
- The node data was replicated before the damage occurred.

The following table describes how parameter settings affect the recovery of damaged, replicated files.

Table 1. Settings that affect the recovery of damaged files

Setting for the REPLRECOVERDAMAGED system parameter	Value of the RECOVERDAMAGED parameter on the REPLICATE NODE command	Value of the RECOVERDAMAGED parameter on the REGISTER NODE and UPDATE NODE commands	Result
OFF	YES, NO, or not specified	YES or NO	During node replication, standard replication occurs and damaged files are not recovered from the target replication server.
OFF	ONLY	YES or NO	An error message is displayed because files cannot be recovered when the REPLRECOVERDAMAGED system parameter is set to OFF.
ON	YES	YES or NO	During node replication, standard replication occurs and damaged files are recovered from the target replication server.
ON	NO	YES or NO	During node replication, standard replication occurs and damaged files are not recovered from the target replication server.
ON	ONLY	YES or NO	Damaged files are recovered from the target replication server, but standard node replication does not occur.
ON	Not specified	YES	During node replication, standard replication occurs and damaged files are recovered from the target replication server.
ON	Not specified	NO	During node replication, standard replication occurs and damaged files are not recovered from the target replication server.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the client node is assigned.

Syntax

```
>>-REGister Node--node_name--+----------+----------------------->

Notes:

1. The PASSEXP command does not apply to administrators who authenticate with a Lightweight Directory Access Protocol (LDAP) directory server.
2. This parameter is only available for AIX®, Linux, Solaris, and Windows operating systems.
3. The VALIDATEPROTOCOL parameter is deprecated.
4. The BACKUPINITIATION parameter is ignored if the client node operating system is not supported.
5. You can specify the BKREPLRULEDEFAULT, ARREPLRULEDEFAULT, or SPREPLRULEDEFAULT parameter only if you specify the REPLSTATE parameter.
6. The default value can change if you issued the SET DEFAULTAUTHENTICATION command and specified LDAP.
7. The SSLREQUIRED parameter is deprecated.

Parameters

node_name (Required)
: Specifies the name of the client node to be registered. The maximum length of the name is 64 characters.

  You cannot specify a node name of NONE.

password
: Specifies the client node password, which has a maximum length of 64 characters.

  If you authenticate passwords locally with the IBM Spectrum Protect server, you must specify a password. The password is not case-sensitive.

  If you authenticate passwords with an LDAP server, do not specify a password on the REGISTER NODE command.

PASSExp
: Specifies the number of days the password remains valid. You can set the password expiration period 0 - 9999 days. A value of 0 means that the password never expires. This parameter is optional. If you do not specify this parameter, the server common-password expiration period is used. The common password expiration period is 90 days unless changed by issuing the SET PASSEXP command.

  You can change the password expiration period by using the UPDATE NODE or SET PASSEXP commands. You can issue the SET PASSEXP command to set a common expiration period for all administrators and client nodes. You can also use the command to selectively set password expiration periods. If you selectively set a password expiration period by using the REGISTER NODE command, the UPDATE NODE command, or the SET PASSEXP command, the expiration period is excluded from common password expiration periods that were created by using the SET PASSEXP command.

  You can use the RESET PASSEXP command to reset the password expiration period to the common expiration period. The PASSEXP command does not apply to nodes that authenticate with an LDAP server.

USerid
: Specifies the administrative user ID with client owner authority. This parameter is optional. When PASSWORDACCESS=GENERATE is used by the client to change the password, the administrative user ID with the same name can be used to access the web backup-archive client from a remote location. You can specify one of the following values:

  NONE
  : Specifies that no administrative user ID is created. This is the default value.

  user_id
  : Specifies that an administrative user ID is created with the specified name. You can use this parameter to grant client owner authority to an existing administrative user ID.

  If you register a node that has the same name as an administrator, the administrator authentication method and SSLREQUIRED setting change to match the authentication method of the node. Passwords that are shared between same-named nodes and administrators are kept synchronized during an authentication change.

If you plan to use the LAN-free option with this node, use the USERID parameter to register an administrative ID that matches the node name.

For users of LDAP servers: If you plan to authenticate the node with an LDAP server, keep the default setting (USERID=NONE) or specify an administrative user ID that differs from the node name. If the administrative user ID matches the node name, you might see unexpected behavior because of automatic password changes that update the same password twice. As a result, the password might become unknown to the administrative user ID. Alternatively, the password update operation might fail.

CONtact
Specifies a text string of information that identifies the node. The parameter is optional. The maximum length of the text string is 255 characters. The contact information must be enclosed in quotation marks if it contains any blanks.

DOmain
Specifies the name of the policy domain to which the node is assigned. The parameter is optional. If you do not specify a policy domain name, the node is assigned to the default policy domain (STANDARD).

When a source server is registered as a node, it is assigned to a policy domain. Data from the source server is stored in the storage pool that is specified in the archive copy group of the default management class of that domain.

COMPression
Specifies whether the client node compresses its files before it sends these files to the server for backup and archive. The parameter is optional. The default value is CLIENT.
Restriction: This parameter does not apply to nodes with a type of NAS or SERVER.

You can specify one of the following values:

Client
Specifies that the client determines whether to compress files.

Yes
Specifies that the client node compresses its files before it sends these files to the server for backup and archive.

No
Specifies that the client node does not compress its files before it sends these files to the server for backup and archive.

ARCHDELete
Specifies whether the client node can delete its own archive files from the server. The parameter is optional. The default value is YES. You can specify one of the following values:

Yes
Specifies that the client node can delete its own archive files from the server.

No
Specifies that the client node cannot delete its own archive files from the server.

BACKDELete
Specifies whether the client node can delete its own backup files from the server. The parameter is optional. The default value is NO. You can specify one of the following values:

No
Specifies that the client node cannot delete its own backup files from the server.

Yes
Specifies that the client node can delete its own backup files from the server.

CLOptset
Specifies the name of the option set to be used by the client. The parameter is optional.

FORCEPwreset
Specifies whether to force a client to change or reset the password. The parameter is optional. The default value is NO. You can specify one of the following values:

No
Specifies that the password expiration period is set by the SET PASSEXP command. The client does not need to change or reset the password while the client is logging on to the server.

Yes
Specifies that the client node password expires at the next logon. The client must change or reset the password then. If a password is not specified, you receive an error message.
Restriction: For nodes that authenticate with an LDAP server, password expiration is set by using LDAP server utilities. For this reason, do not specify FORCEPWRESET=YES if you specify AUTHENTICATION=LDAP.

Type

Specifies the type of node that is being registered. The parameter is optional. The default value is CLIENT. You can specify one of the following values:

Client

Specifies that the client node is a Backup-Archive Client, IBM Spectrum Protect for Space Management client, or application client.

NAS

Specifies that the node is a network-attached storage (NAS) file server whose data is protected by using NDMP operations. The node name cannot be SERVER.

Note: The name of the NAS node must be the same as the data mover. Therefore, the name cannot be changed after a corresponding data mover is defined.

Server

Specifies that the client node is a source server that is being registered on the target server.

URL

Specifies the URL of the IBM Spectrum Protect web client that is configured on the client system. You can use the URL in a web browser and in the Operations Center to remotely manage the client node.

This parameter is optional. The URL must include the DNS name or IP address of the client system, and the port number that is defined on the client system for the IBM Spectrum Protect web client. For example, `http://client.mycorp.com:1581`

UTILITYUrl

Specifies the address of the IBM Spectrum Protect client management services that are configured on the client system. This URL is used by the Operations Center to access client log files so that you can remotely diagnose client issues from the Operations Center.

This parameter is optional. You can specify a URL of up to 200 characters in length. The URL must start with `https`. It includes the DNS name or IP address of the client system, and the port number that is defined on the client system for the IBM Spectrum Protect client management services. For example, `https://client.mycorp.com:9028`

If you omit the port number, the Operations Center uses the port number 9028, which is the default port number when you install the client management services on the client system.

MAXNUMMP

Specifies the maximum number of mount points a node is allowed to use on the server or storage agent only for operations such as backup, archive, and IBM Spectrum Protect for Space Management migration. The parameter is optional and does not apply to nodes with a type of NAS or SERVER. The default value is 1. You can specify an integer in the range 0 - 999. A value of 0 specifies that a node cannot acquire any mount point for a client data store operation. The MAXNUMMP value is not evaluated or enforced during client data read operations such as restore, retrieve, and IBM Spectrum Protect for Space Management recall. However, mount points in use for data read operations are evaluated against attempted concurrent data store operations for the same client node and might prevent the data store operations from being able to acquire mount points.

For volumes in a storage pool that is associated with the FILE or CENTERA device type, the server can have multiple sessions to read and one process to write to the same volume concurrently. To increase concurrency and provide efficient access for nodes with data in FILE or CENTERA storage pools, increase the value of the MAXNUMMP parameter.

For nodes that store data into primary storage pools with the simultaneous-write function that is enabled, you must adjust the value of the MAXNUMMP parameter to specify the correct number of mount points for each client session. A client session requires one mount point for the primary storage pool and one mount point for each copy storage pool and each active-data pool.

For server-to-server backup, if one server is at a different version than the other server, set the number of mount points on the target server to a value higher than one. Otherwise, you receive an error.

A storage agent independently tracks the number of points that are used during a client session. If a node has a storage agent that is installed, it might exceed the MAXNUMMP value. The MAXNUMMP value might also be exceeded under conditions where the node does not have to wait for a mount point.

Note: The server might preempt a client operation for a higher priority operation and the client might lose a mount point if no other mount points are available.

KEEPMP

Specifies whether the client node keeps the mount point for the entire session. The parameter is optional. The default value is NO. You can specify one of the following values:

Yes
: Specifies that the client node must retain the mount point during the entire session. If policy definitions cause data to be stored to a disk storage pool after the data is stored to a sequential access storage pool, any mount points that are held by the session will not be released.

No
: Specifies that the client node releases the mount point during the session. If policy definitions cause data to be stored to a disk storage pool after the data is stored to a sequential access storage pool, any mount points that are held by the session will be released.

AUTOFSRename
: Specify whether file spaces are automatically renamed when you upgrade the client system to support Unicode or specify whether file spaces are renamed by the client, if needed. The parameter is optional. The default is NO. Setting the parameter to YES enables automatic renaming, which occurs when the client runs one of the following operations: archive, selective backup, full incremental backup, or partial incremental backup. The automatic renaming changes the names of existing backed-up file spaces that are not in Unicode in server storage. Then, the file spaces are backed up in Unicode. You can use this parameter for Unicode-enabled IBM Spectrum Protect clients by using Windows, Macintosh OS X, and NetWare operating systems.

  After the client with support for Unicode is installed, any new file spaces that the client backs up are stored in server storage by using the UTF-8 code page. UTF-8 is a byte-oriented encoding form that is specified by the Unicode Standard.

  You can specify one of the following values:

  Yes
  : Existing file spaces are automatically renamed when you upgrade to a client that supports Unicode and the client runs one of the following operations: archive, selective backup, full incremental backup, or partial incremental backup. The renaming occurs whether the client uses the graphical user interface, the command line, or the client scheduler.
    For example, the server renames a drive as follows:

    ```
    Original name: D_DRIVE
    New name: D_DRIVE_OLD
    ```

    The new name indicates that the file space is stored on the server in a format that is not Unicode.

  No
  : Existing file spaces are not automatically renamed when the client system upgrades to a client that supports Unicode, and the client runs one of the following operations: archive, selective backup, full incremental backup, or partial incremental backup.

  Client
  : The option AUTOFSRENAME in the client's option file determines whether file spaces are renamed.

    By default, the client option is set to PROMPT. When the client system upgrades to a client that supports Unicode and the client runs an IBM Spectrum Protect operation with the graphical user interface or the command line, the program displays a one-time prompt to the user about whether to rename file spaces.

    When the client scheduler runs an operation, the program does not prompt for a choice about renaming, and does not rename file spaces. Backups of existing file spaces are sent as before (not in Unicode).

VALIdateprotocol (deprecated)
: Specifies whether IBM Spectrum Protect completes a cyclic redundancy check (CRC) to validate the data that is sent between the client and server. The parameter is optional. The default is NO.
  Important: Beginning in V8.1.2, this parameter is deprecated. The validation that was enabled by this parameter is replaced by the TLS 1.2 protocol, which is enforced by the SESSIONSECURITY parameter. The VALIDATEPROTOCOL parameter is ignored. Update your configuration to use the SESSIONSECURITY parameter.

TXNGroupmax
: Specifies the number of files per transaction commit that are transferred between a client and a server. The parameter is optional. Client performance might be improved by using a larger value for this option.

  The default value is 0. Specifying 0 indicates that the node uses the server global value that is set in the server options file. To use a value other than the server global value, specify a value of 4 through 65,000 for this parameter. The node value takes precedence over the server value.

Attention: Increasing the TXNGROUPMAX value increases the recovery log usage. Higher recovery log usage might increase the risk of running out of log space. Evaluate the performance of each node before you change the parameter.

DATAWritepath

Specifies the transfer path that is used when the client sends data to the server, storage agent, or both, during storage operations such as backup or archive. The parameter is optional. The default is ANY.
Note: If a path is unavailable, the node cannot send any data. For example, if you select the LAN-free option but a LAN-free path is not defined, the operation fails.

You can specify one of the following values:

ANY
: Specifies that data is sent to the server, storage agent, or both, by any available path. A LAN-free path is used if one is available. If a LAN-free path is unavailable, the data is moved by using the LAN.

LAN
: Specifies that data is sent by using the LAN.

LANFree
: Specifies that data is sent by using a LAN-free path.

DATAReadpath

Specifies the transfer path that is used when the server, storage agent, or both read data for a client, during operations such as restore or retrieve. The parameter is optional. The default is ANY.
Note: If a path is unavailable, data cannot be read. For example, if you select the LAN-free option but a LAN-free path is not defined, the operation fails. The value for the transfer path also applies to failover connections. If the value is set to LANFree, failover cannot occur for the node on the secondary server.

You can specify one of the following values:

ANY
: Specifies that the server, storage agent, or both use any available path to read data. A LAN-free path is used if one is available. If a LAN-free path is unavailable, the data is read by using the LAN.

LAN
: Specifies that data is read by using the LAN.

LANFree
: Specifies that data is read by using a LAN-free path.

TARGETLevel

Specifies the client deployment package that is targeted for this node. You can substitute an applicable release package for Version.Release.Modification.Fix (V.R.M.F) Level. For example: `TARGETLevel=6.2.0.0`.

You must specify each segment with a number that is applicable to a deployment package. You cannot use an asterisk in any field as a substitution for a valid number. The parameter is optional.
Restriction: The TARGETLEVEL parameter does not apply to nodes with a type of NAS or SERVER.

SESSIONINITiation

Controls whether the server or the client initiates sessions. The default is that the client initiates sessions. The parameter is optional.

Clientorserver
: Specifies that the client might initiate sessions with the server by communicating on the TCP/IP port that is defined with the server option TCPPORT. Server-prompted scheduling might also be used to prompt the client to connect to the server.

SERVEROnly
: Specifies that the server does not accept client requests for sessions. All sessions must be initiated by server-prompted scheduling on the port that is defined for the client with the REGISTER or UPDATE NODE commands. You cannot use the client acceptor, dsmcad, to start the scheduler when SESSIONINITIATION is set to SERVERONLY.

  HLAddress

  Specifies the client IP address that the server contacts to initiate scheduled events. This parameter must be used when SESSIONINITIATION is set to SERVERONLY, regardless of any addresses that are previously used by the client to contact the server.

  The address can be specified either in numeric or host name format. If a numeric address is used, it is saved without verification by a domain name server. If the address is not correct, it can cause failures when the

server attempts to contact the client. Host name format addresses are verified with a domain name server. Verified names are saved and resolved with Domain Name Services when the server contacts the client.

LLAddress

Specifies the client port number on which the client listens for sessions from the server. This parameter must be used when SESSIONINITIATION is set to SERVERONLY, regardless of any addresses that are previously used by the client to contact the server.

The value for this parameter must match the value of client option TCPCLIENTPORT. The default value is 1501.

EMAILADdress

This parameter is used for more contact information. The parameter is optional. The information that is specified by this parameter is not acted upon by IBM Spectrum Protect.

DEDUPlication

Specifies where data deduplication can occur for this node. The parameter is optional. You can specify one of the following values:

Clientorserver

Specifies that data that is stored by this node can be deduplicated on either the client or the server. This value is the default. For data deduplication to take place on the client, you must also specify a value of YES for the DEDUPLICATION client option. You can specify this option in the client option file or in the client option set on the IBM Spectrum Protect server.

SERVEROnly

Specifies that data that is stored by this node can be deduplicated on the server only.

BACKUPINITiation

Specifies whether the non-root user ID on the client node can back up files to the server. The parameter is optional. The default value is ALL, indicating that non-root user IDs can back up data to the server. You can select one of the following values:

All

Specifies that non-root user IDs can back up files to the server. ALL is the default if BACKUPINITIATION is not specified.

ROOT

Specifies that the root user ID can back up files to the server. If you are using the V6.4 or later backup-archive client, authorized users have the same privileges as the root user ID.
Restriction: The attribute is ignored by the server if the backup-archive client connects from an operating system other than AIX, Linux, Solaris, or Mac OS.
Remember: The application programming interface (API) is affected by the BACKUPINITIATION parameter on the server. By default, all API users are allowed to back up data. Setting the parameter to `ROOT` on an API node is not recommended.

REPLState

Specifies whether data that belongs to the client node is ready to be replicated. This parameter is optional. Specify this parameter only if you are issuing the REGISTER NODE command on a server that is configured to replicate data to a target replication server. If you register a client node on a source replication server and set up replication for the node, do not register the node on the target replication server. The client node is created automatically on the target server the first time that replication occurs.
You can select one of the following values:

ENabled

Specifies that the client node is configured for replication and is ready to replicate. When you specify this parameter, the replication mode in the client node definition on the source replication server is automatically set to SEND. This setting indicates that data that belongs to the client node is sent to a target server during replication.

When replication first occurs for the client node, the replication state of the node on the target replication server is automatically set to ENABLED. The replication mode on the target replication server is set to RECEIVE. This setting indicates that data that belongs to the client node is received from a source replication server. To determine the replication state and mode, issue the QUERY NODE command on a source or a target replication server.

DISabled

Specifies that the node is configured for replication but that replication does not occur until you enable it.

BKREPLRuledefault, ARREPLRuledefault, and SPREPLRuledefault

Specifies the replication rule that applies to a data type if the file space rules for the data type are set to DEFAULT. Restriction: You can specify the BKREPLRULEDEFAULT, ARREPLRULEDEFAULT, or SPREPLRULEDEFAULT parameter only if you specify the REPLSTATE parameter.

BKREPLRuledefault
: Specifies the replication rule for backup data.

ARREPLRuledefault
: Specifies the replication rule for archive data.

SPREPLRuledefault
: Specifies the replication rule for space-managed data.

If the file space rules for the data type are set to DEFAULT and you do not specify a rule for the BKREPLRULEDEFAULT, ARREPLRULEDEFAULT, or SPREPLRULEDEFAULT parameter, data is replicated according to the server rule for the data type.

You can specify normal-priority replication or high-priority replication rules. In a replication process that includes both normal and high-priority data, high-priority data is replicated first. Before you specify a rule, consider the order in which you want the data to be replicated.

You can specify the following rules:

ALL_DATA
: Replicates active and inactive backup data, archive data, or space-managed data. The data is replicated with a normal priority.

ACTIVE_DATA
: Replicates only active backup data. The data is replicated with a normal priority. This rule is valid only for BKREPLRULEDEFAULT.
Attention:

  If you specify ACTIVE_DATA and one or more of the following conditions are true, inactive backup data on the target replication server is deleted, and inactive backup data on the source replication server is not replicated.

  - When a release version earlier than Version 7.1.1 is installed on either the source or target replication servers.
  - When you are using the REPLICATE NODE command with the `FORCERECONCILE=YES` parameter.
  - When you are running the initial replication of a file space after you configure replication, restore the database, or upgrade both the source and target replication servers from a release version earlier than V7.1.1.

  If the previous conditions are not true, all new and changed files since the last replication are replicated, including inactive files, and files are deleted when they expire.

ALL_DATA_HIGH_PRIORITY
: Replicates active and inactive backup data, archive data, or space-managed data. Data is replicated with a high priority.

ACTIVE_DATA_HIGH_PRIORITY
: This rule is the same as the ACTIVE_DATA replication rule except data is replicated with a high priority. This rule is valid only for BKREPLRULEDEFAULT.

DEFAULT
: Replicates data according to the server replication rule for backup data.

  For example, suppose that you want to replicate the archive data in all the file spaces that belongs to a client node. Replication of the archive data is a high priority. One method to accomplish this task is to specify `ARREPLRULEDEFAULT=DEFAULT`. Ensure that the file space rules for archive data are also set to DEFAULT and that the server rule for archive data is set to ALL_DATA_HIGH_PRIORITY.

  Restriction: If a node is configured for replication, the file space rules are set to DEFAULT after the node stores data on the source replication server.

NONE
: Data of the specified type is not replicated.

  For example, if you do not want to replicate space-managed data that belongs to a client node, specify `SPREPLRULEDEFAULT=NONE`

RECOVERDamaged

Specifies whether damaged files can be recovered for this node from a target replication server. The parameter is optional. The default value is YES. You can specify one of the following values:

Yes
: Specifies that recovery of damaged files from a target replication server is enabled for this node.

No
: Specifies that recovery of damaged files from a target replication server is not enabled for this node.
Tip: The value of the RECOVERDAMAGED parameter is only one of several settings that determine whether damaged files are recovered. For information about how to specify the settings, see Settings that affect the recovery of damaged files.

ROLEOVERRIDE

Specifies whether to override the reported role of the client for processor value unit (PVU) estimation reporting. The default is USEREPORTED. The parameter is optional.

The role reported by the client is either client-device (for example, a workstation) or server-device (for example, file/print server, application server, database). By default, the client reports its role that is based on the client type and the operating system. All clients initially report their role as server-device, except for Backup-Archive Clients running Microsoft Windows workstation distributions (Windows Vista) and Macintosh OS X.

Specify one of the following values:

Client
: Specifies a client-device.

Server
: Specifies a server-device.

Other
: Specifies that this node is not to be used for PVU estimation reporting. This value can be useful when multiple nodes are deployed for a physical system (for example, virtual environments, test nodes, retired nodes, and nodes not in production or clustering).

Usereported
: Use the reported role that is provided by the client.

AUTHentication
: This parameter specifies the password authentication method for the node. Specify one of the following values: LDAP or LOCAL. The parameter is optional and defaults to LOCAL. The default can change to LDAP if you use the SET DEFAULTAUTHENTICATION command and specify LDAP.

LOcal
: Specifies that the local IBM Spectrum Protect server database is used.

LDap
: Specifies that the node uses an LDAP server for password authentication.

SSLrequired (deprecated)

Specifies whether the node must use the Secure Sockets Layer (SSL) protocol to communicate with the IBM Spectrum Protect server. The parameter is optional. When you authenticate passwords with an LDAP directory server, you must protect the sessions by using SSL or another network security method.

Important: Beginning with V8.1.2, this parameter is deprecated. The validation that was enabled by this parameter is replaced by the TLS 1.2 protocol, which is enforced by the SESSIONSECURITY parameter. The SSLREQUIRED parameter is ignored. Update your configuration to use the SESSIONSECURITY parameter.

SESSIONSECurity
: Specifies whether the node must use the most secure settings to communicate with an IBM Spectrum Protect server. This parameter is optional.

You can specify one of the following values:

STRict
: Specifies that the strictest security settings are enforced for the node. The STRICT value uses the most secure communication protocol available, which is currently TLS 1.2. The TLS 1.2 protocol is used for SSL sessions between the server and the node. To specify whether the server uses TLS 1.2 for the entire session or only for authentication, see the SSL client option.
To use the STRICT value, the following requirements must be met to ensure that the node can authenticate with the server:

- Both the node and server must be using IBM Spectrum Protect software that supports the SESSIONSECURITY parameter.
- The node must be configured to use the TLS 1.2 protocol for SSL sessions between the server and the node.

Nodes set to STRICT that do not meet these requirements are unable to authenticate with the server.

TRANSitional

Specifies that the existing security settings are enforced for the node. This is the default value. This value is intended to be used temporarily while you update your security settings to meet the requirements for the STRICT value.

If SESSIONSECURITY=TRANSITIONAL and the node has never met the requirements for the STRICT value, the node will continue to authenticate by using the TRANSITIONAL value. However, after a node meets the requirements for the STRICT value, the SESSIONSECURITY parameter value automatically updates from TRANSITIONAL to STRICT. Then, the node can no longer authenticate by using a version of the client or an SSL/TLS protocol that does not meet the requirements for STRICT. In addition, after a node successfully authenticates by using a more secure communication protocol, the node can no longer authenticate by using a less secure protocol. For example, if a node that is not using SSL is updated and successfully authenticates by using TLS 1.2, the node can no longer authenticate by using no SSL protocol or by using TLS 1.1. This restriction also applies when you use functions such as virtual volumes, when the node authenticates to the IBM Spectrum Protect server as a node from another server.

SPLITLARGEObjects

Specifies whether large objects that are stored by this node are automatically split into smaller pieces, by the server, to optimize server processing. The parameter is optional. Specifying Yes causes the server to split large objects (over 10 GB) into smaller pieces when stored by a client node. Specifying No bypasses this process. Specify No only if your primary concern is maximizing throughput of backups directly to tape. The default value is Yes.

Example: Register a client node that only the root user can back up

Register the client node `mete0rite` with password *KingK0ng* to back up files from only the root user to the server.

```
register node mete0rite KingK0ng
backupinit=root
```

Example: Register a client node and password and set compression on

Register the client node `JOEOS2` with the password *SECRETCODE* and assign this node to the `DOM1` policy domain. This node can delete its own backup and archive files from the server. All files are compressed by the client node before they are sent to the server. This command automatically creates a `JOEOS2` administrative user ID with password *SECRETCODE*. In addition, the administrator now has client owner authority to the `JOEOS2` node.

```
register node joeos2 secretcode domain=dom1
 archdelete=yes backdelete=yes
 compression=yes
```

Example: Grant client owner authority for an existing administrative user

Grant client owner authority to an existing administrative user ID, *HELPADMIN*, when you register the client node `JAN`. This step would not automatically create an administrator ID named `JAN`, but would grant client owner authority for this node to the *HELPADMIN* administrator.

```
register node jan pwdsafe userid=helpadmin
```

Example: Register a NAS file server node that uses NDMP operations

Register a node name of `NAS1` for a NAS file server that is using NDMP operations. Assign this node to a special NAS domain.

```
register node nas1 pw4pw domain=nasdom type=nas
```

Example: Register a node and specify the maximum number of files per transaction commit

Register a node name of `ED` and set the TXNGroupmax to 1,000.

```
register node ed pw45twx txngroupmax=1000
```

Example: Register a node and allow it to deduplicate data on the client system

Register a node name of JIM and allow it to deduplicate data on the client system.

```
register node jim jim deduplication=clientorserver
```

Example: Register a node name of ED and set the role as a server-device for PVU estimation reporting

Register a node name of ED and set the role as a server-device for PVU estimation reporting.

```
register node ed pw45twx roleoverride=server
```

Example: Register a node on a source replication server

Define NODE1 to a source replication server. Specify a replication rule for the backup data that belongs to NODE1 so that active backup data is replicated with a high priority. Enable replication for the node.

```
register node node1 bkreplruledefault=active_data_high_priority replstate=enabled
```

Example: Register a node that authenticates with an LDAP server

Register a node name of NODE17 that must authenticate with an LDAP server.

```
register node node17 authentication=ldap
```

Tip: When you register a node in this way, an administrative user ID is not created.

Example: Register a node to communicate with a server by using strict session security

Register a node name of NODE4 to use the strictest security settings to authenticate with the server.

```
register node node4 sessionsecurity=strict
```

Example: Register a node and enable recovery of damaged files

Register a node name of PAYROLL. For the PAYROLL node, enable the recovery of damaged files from a target replication server.

```
register node payroll recoverdamaged=yes
```

Related commands

Table 2. Commands related to REGISTER NODE

Command	Description
DEFINE ASSOCIATION	Associates clients with a schedule.
DEFINE DATAMOVER	Defines a data mover to the IBM Spectrum Protect server.
DEFINE MACHNODEASSOCIATION	Associates an IBM Spectrum Protect node with a machine.
DELETE FILESPACE	Deletes data associated with client file spaces. If a file space is part of a collocation group and you remove the file space from a node, the file space is removed from the collocation group.
LOCK NODE	Prevents a client from accessing the server.
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY PVUESTIMATE	Displays an estimate of the client-devices and server-devices being managed.
QUERY REPLNODE	Displays information about the replication status of a client node.

Command	Description
REGISTER ADMIN	Defines a new administrator without granting administrative authority.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.
REMOVE REPLNODE	Removes a node from replication.
RENAME NODE	Changes the name for a client node.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
RESET PASSEXP	Resets the password expiration for nodes or administrators.
SET DEFAULTAUTHENTICATION	Specifies the default password authentication method for any REGISTER NODE or REGISTER ADMIN commands.
SET PASSEXP	Specifies the number of days after which a password is expired and must be changed.
SET CPUINFOREFRESH	Specifies the number of days between client scans for workstation information used for PVU estimates.
SET DEDUPVERIFICATIONLEVEL	Specifies the percentage of extents verified by the server during client-side deduplication.
SET REPLRECOVERDAMAGED	Specifies whether node replication is enabled to recover damaged files from a target replication server.
UNLOCK NODE	Enables a locked user in a specific policy domain to access the server.
UPDATE ADMIN	Changes the password or contact information associated with any administrator.
UPDATE FILESPACE	Changes file-space node-replication rules.
UPDATE NODE	Changes the attributes that are associated with a client node.

Ssl client option

REMOVE commands

Use the REMOVE commands to remove an object from IBM Spectrum Protect™.

- REMOVE ADMIN (Delete an administrative user ID)
- AIX Linux Windows REMOVE DAMAGED (Remove damaged data from a source storage pool)
- REMOVE NODE (Delete a node or an associated machine node)
- REMOVE REPLNODE (Remove a client node from replication)
- REMOVE REPLSERVER (Remove a replication server)

REMOVE ADMIN (Delete an administrative user ID)

Use this command to remove an administrative user ID from the system.

You cannot remove the last system administrative user ID or the SERVER_CONSOLE administrative ID from the system.

For users of Lightweight Directory Access Protocol (LDAP) servers: The information in this documentation applies to the LDAP authentication method that is preferred for IBM Spectrum Protect™ V7.1.7 or later servers. For instructions about using the previous LDAP authentication method, see Managing passwords and logon procedures.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                              .-SYNCldapdelete--=--No------.
>>-REMove Admin--admin_name--+----------------------------+---><
                              '-SYNCldapdelete--=--+-No--+-'
                                                   '-Yes-'
```

Parameters

admin_name (Required)
: Specifies the administrative user ID to be removed.

SYNCldapdelete
: Specifies whether to delete the administrative user ID on the Lightweight Directory Access Protocol (LDAP) server.

  Yes
  : Deletes the administrative user ID on the LDAP server.
    Restriction: Do not specify a value of YES. (The value of YES is appropriate only for users of the previous LDAP authentication method, which is described in Managing passwords and logon procedures.)

  No
  : Does not delete the administrative user ID on the LDAP server. This is the default value.

Example: Remove an administrative user ID

Remove an administrative user ID larry that is not defined on an LDAP server. Issue the following command:

```
remove admin larry
```

Related commands

Table 1. Commands related to REMOVE ADMIN

Command	Description
LOCK ADMIN	Prevents an administrator from accessing IBM Spectrum Protect.
QUERY ADMIN	Displays information about one or more IBM Spectrum Protect administrators.
REGISTER ADMIN	Defines a new administrator without granting administrative authority.
RENAME ADMIN	Changes an IBM Spectrum Protect administrator's name.

AIX Linux Windows

REMOVE DAMAGED (Remove damaged data from a source storage pool)

After storage pool conversion, use this command to remove damaged data from a storage pool that uses a FILE device class, a tape device class, or a virtual tape library (VTL).

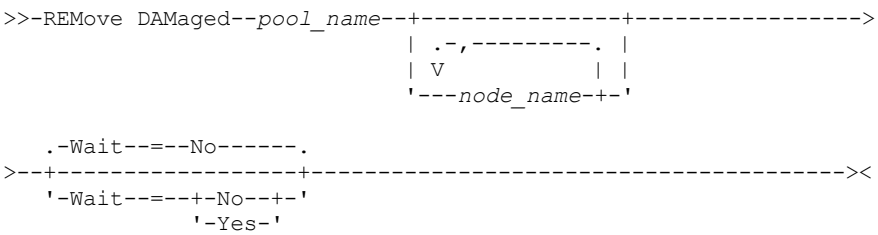
The REMOVE DAMAGED command permanently deletes damaged data from the storage pool.
Tip: Before you remove damaged data from the storage pool, try to recover an undamaged version of the data from a copy or active-data storage pool by issuing the RESTORE STGPOOL command. Recover an undamaged version of the data from a target replication server by issuing the REPLICATE NODE command and specifying the RECOVERDAMAGED=YES parameter.

Privilege class

To issue this command, you must have restricted storage privilege.

Syntax

```
                .-*-------------.
```



Parameters

pool_name (Required)
: Specify a primary storage pool that uses a FILE device class, a tape device class, or a virtual tape library (VTL). The storage pool contains the damaged data. This parameter is required.

node_name
: Specifies the name of the client node. Separate multiple names with commas and no intervening spaces. You can use a wildcard character instead of a node name if you want to remove damage from all of the nodes in the storage pool.

Wait
: Specifies whether to wait for the server to remove damaged data from the storage pool. This parameter is optional. The default value is NO. You can specify this parameter only from an administrative command line. You can specify one of the following values:

  No
  : Specifies that the command processes run in the background.

  Yes
  : Specifies that the command processes run in the foreground. Messages are not displayed until the command completes processing.

Example: Remove damaged data from a storage pool and wait for the server to complete processing

Remove damaged data from a storage pool that is named POOL1 and wait for the server to complete processing in the foreground.

```
remove damaged pool1 wait=yes
```

Table 1. Commands related to REMOVE DAMAGED

Command	Description
CONVERT STGPOOL	Convert a storage pool to a directory-container storage pool.
PROTECT STGPOOL	Protects a directory-container storage pool.
REPAIR STGPOOL	Repairs a directory-container storage pool.

REMOVE NODE (Delete a node or an associated machine node)

Use this command to remove a node from the server. If you are using disaster recovery manager and the node to be removed is associated with a machine, the association between the node and the machine is also deleted.

If a node is part of a collocation group and you remove the node from the server, the node is removed from the collocation group. If a node is removed and the node contained file spaces in a file space collocation group, those file spaces are removed from the group member list.

If you remove a node that stored data in a deduplicated storage pool, the node name DELETED is displayed in the QUERY OCCUPANCY command output until all data deduplication dependencies are removed.

When a node is removed, the corresponding administrative ID is removed only if the following issues are true:

- The administrator name is identical to the node name.
- The administrator has client owner or client access authority *only* to the node that is being removed.
- The administrator is not a managed object.

Before you can remove a node, you must delete all backup and archive file spaces that belong to that node.

Before you can remove a NAS node that has a corresponding data mover, you must complete the following tasks in order:

1. Delete any paths from the data mover
2. Delete the data mover
3. Delete all virtual file space definitions for the node
4. Remove the NAS node

For users of Lightweight Directory Access Protocol (LDAP) servers: The information in this documentation applies to the LDAP authentication method that is preferred for IBM Spectrum Protect™ V7.1.7 or later servers. For instructions about using the previous LDAP authentication method, see Managing passwords and logon procedures.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the client node is assigned.

Syntax

```
                            .-SYNCldapdelete--=--No------.
>>-REMove Node--node_name--+----------------------------+------><
                            '-SYNCldapdelete--=--+-No--+-'
                                                 '-Yes-'
```

Parameters

node_name (Required)
: Specifies the name of the node to be removed.

SYNCldapdelete
: Specifies whether to remove the node from the Lightweight Directory Access Protocol (LDAP) server.

  Yes
  : Specifies that the node is removed.
    Restriction: Do not specify a value of YES. (The value of YES is appropriate only for users of the previous LDAP authentication method, which is described in Managing passwords and logon procedures.)

  No
  : Specifies that the node is not removed. This is the default value.

Example: Remove a client node

Remove the client node LARRY.

```
remove node larry
```

Related commands

Table 1. Commands related to REMOVE NODE

Command	Description
AIX Windows DELETE MACHNODEASSOCIATION	AIX Windows Deletes association between a machine and node.
DELETE DATAMOVER	Deletes a data mover.
DELETE FILESPACE	Deletes data associated with client file spaces. If a file space is part of a collocation group and you remove the file space from a node, the file space is removed from the collocation group.
DELETE PATH	Deletes a path from a source to a destination.
DELETE VIRTUALFSMAPPING	Delete a virtual file space mapping.
LOCK NODE	Prevents a client from accessing the server.
QUERY COLLOCGROUP	Displays information about collocation groups.

Command	Description
AIX Windows QUERY MACHINE	AIX Windows Displays information about machines.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY SESSION	Displays information about all active administrator and client sessions with IBM Spectrum Protect.
REGISTER NODE	Defines a client node to the server and sets options for that user.
RENAME NODE	Changes the name for a client node.

REMOVE REPLNODE (Remove a client node from replication)

Use this command to remove a node from replication if you no longer want to replicate the data that belongs to the node.

You cannot delete client node data by issuing the REMOVE REPLNODE command. You can issue the command on a source or on a target replication server. You can only issue this command from an administrative command-line client. You cannot issue this command from the server console.

If you issue the REMOVE REPLNODE command for a client node whose replication mode is set to SEND or RECEIVE, the mode is set to NONE. The replication state is also set to NONE. After you remove a client node from replication, the target replication server can accept backup, archive, and space-managed data directly from the node.

If a client node is removed from replication, information in the database about replication for the node is deleted. If the client node is enabled for replication later, the replication process replicates all the data that is specified by replication rules and settings.

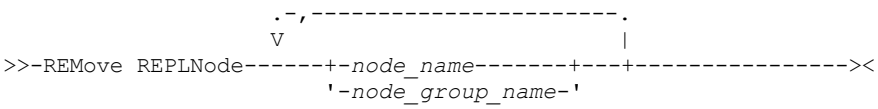
When you issue the REMOVE REPLNODE command, the data that belongs to a client node is not deleted. To delete file space data that belongs to the client node, issue the DELETE FILESPACE command for each of the file spaces that belong to the node. If you do not want to keep the client node definition, issue the REMOVE NODE command. To delete file space data and the client node definition, issue DELETE FILESPACE and REMOVE NODE on the target replication server.

Restriction: If a node replication process is running for a client node that is specified by this command, the command fails and the replication information for the node is not removed.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the client node is assigned.

Syntax



Parameters

node_name or node_group_name (Required)
: Specifies the name of the client node or defined group of client nodes that you want to remove from replication. To specify multiple client node names and client-node group names, separate the names with commas and no intervening spaces. You can use wildcard characters to specify client node names, but not to specify client-node group names. You cannot combine node or node group names with the domain name.

Example: Remove three client nodes and a client node group from replication

The names of the client nodes are NODE1, NODE2, and NODE3. The name of the client node group is PAYROLL. Issue the following command on the source and target replication servers:

```
remove replnode node*,payroll
```

Related commands

Table 1. Commands related to REMOVE REPLNODE

Command	Description
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY REPLICATION	Displays information about node replication processes.

REMOVE REPLSERVER (Remove a replication server)

Use this command to remove or to switch to a replication server from the list of replication servers. This command deletes all information about replication state for all nodes that were replicated to that server.

You can issue the command on a source or on a target replication server.
Restriction: You cannot delete client node data by using the REMOVE REPLSERVER command.

Use the command to switch replication servers and to remove replication information for an old server. The command does not affect the current replication mode or state of any node definitions. Issue the command on both the source and target servers to keep the replication state information about both servers consistent.

Restriction: If you specify the default replication server for the REMOVE REPLSERVER command and a node replication process is running, the command fails and no replication information is removed.

This command runs as a background operation and it cannot be canceled. IBM Spectrum Protect™ deletes replication information that is associated with the specified server as a series of batch database transactions. If a system failure occurs, a partial deletion can occur.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-REMove REPLServer--GUID-----------------------------------><
```

Parameters

replication_guid (Required)

The unique identifier for the replication server that is being removed. You can use wildcards to specify the Replication Global Unique Identifier (GUID), however, only one GUID can match the wildcard. If the wildcard sequence matches more than one GUID, the command fails. You must qualify the wildcard string until only the GUID that you want to delete is found.

Example: Use a wildcard to remove a replication server

Remove a replication server by using a wildcard character to indicate the GUID.

```
remove replserver e*
```

Related commands

Table 1. Commands related to REMOVE REPLSERVER

Command	Description
REMOVE REPLNODE (Remove a client node from replication)	Removes a node from replication.

Command	Description
QUERY REPLSERVER (Query a replication server)	Displays information about replicating servers.

RENAME commands

Use the RENAME commands to change the name of an existing object.

- RENAME ADMIN (Rename an administrator)
- RENAME FILESPACE (Rename a client file space on the server)
- RENAME NODE (Rename a node)
- RENAME SCRIPT (Rename an IBM Spectrum Protect script)
- RENAME SERVERGROUP (Rename a server group)
- RENAME STGPOOL (Change the name of a storage pool)

RENAME ADMIN (Rename an administrator)

Use this command to change an administrative user ID. Existing information for this administrator such as password, contact information, and privilege classes is not altered.

If you assign an existing administrative user ID to another person, use the UPDATE ADMIN command to change the password.

When an administrator and a node share a name and you change the administrator authentication method, the node authentication method also changes. If you rename an administrator to the same name as an existing node, the authentication method and the SSLREQUIRED setting for the node can change. If those settings are different, after the renaming, both administrator and node will have the same authentication method and SSLREQUIRED setting.

For users of Lightweight Directory Access Protocol (LDAP) servers:

- The information in this documentation applies to the LDAP authentication method that is preferred for IBM Spectrum Protect™ V7.1.7 or later servers. For instructions about using the previous LDAP authentication method, see Managing passwords and logon procedures.
- Do not rename an administrative user ID to match a node name. If the names match, you might see unexpected behavior because of automatic password changes that update the same password twice. As a result, the password might become unknown to the administrative user ID. Alternatively, the password update might fail.

You cannot rename the SERVER_CONSOLE administrative ID.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-REName Admin--current_admin_name--new_admin_name------------>

   .-SYNCldapdelete--=--No------.
>--+----------------------------+----------------------------><
   '-SYNCldapdelete--=--+-No--+-'
                        '-Yes-'
```

Parameters

current_admin_name (Required)
: Specifies the administrative user ID to be renamed.

new_admin_name (Required)
: Specifies the new administrative user ID. The maximum length of the name is 64 characters.

SYNCldapdelete
: Specifies whether to delete the administrative user ID on the Lightweight Directory Access Protocol (LDAP) server and replace the ID with a new one.

Yes
: Deletes the administrative user ID on the LDAP server and replaces it with a new ID.
Restriction: Do not specify a value of YES. (The value of YES is appropriate only for users of the previous LDAP authentication method, which is described in Managing passwords and logon procedures.)

No
: Does not delete and replace the administrative user ID on the LDAP server. This is the default value.

Example: Rename an administrator

Rename the IBM Spectrum Protect administrator CLAUDIA to BILL.

```
rename admin claudia bill
```

Related commands

Table 1. Commands related to RENAME ADMIN

Command	Description
QUERY ADMIN	Displays information about one or more IBM Spectrum Protect administrators.
UPDATE ADMIN	Changes the password or contact information associated with any administrator.

RENAME FILESPACE (Rename a client file space on the server)

Use this command to rename an existing client file space on the server to a new file space name or to rename imported file spaces.

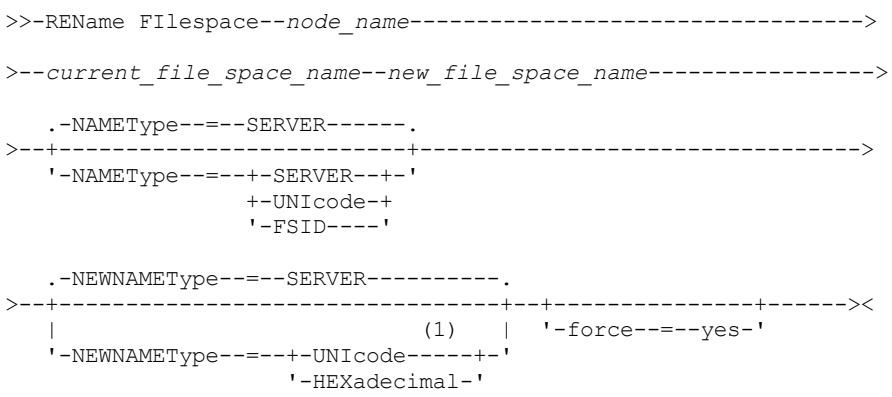
You might want to rename a file space that was imported or to cause the creation of new Unicode-enabled file spaces for Unicode-enabled clients.

Restriction: Do not rename NAS or VMware file spaces. If you rename a NAS or VMware file space, it is no longer visible and cannot be restored. To restore a renamed NAS or VMware file space, you must rename it back to its original name and set the force parameter as follows:force=yes

Privilege class

Any administrator with unrestricted policy authority or with restricted policy authority over the client's policy domain can issue this command.

Syntax



Notes:

1. This parameter is the default when you specify NAMEType=UNIcode.

Parameters

node_name (Required)
: Specifies the name of the client node to which the file space to be renamed belongs.

current_file_space_name (Required)
: Specifies the name of the file space to be renamed. A file space name is case-sensitive and must be specified exactly as defined to the server. Virtual file space mapping names are allowed.

new_file_space_name (Required)
: Specifies the new name for the file space. A client file space name is case-sensitive and must be specified exactly as it is to be defined to the server. This parameter cannot be an existing virtual file space mapping name. If the current_file_space_name is a virtual file space, the new_file_space_name must follow all the rules for defining a virtual file space name. See the DEFINE VIRTUALFSMAPPING command for more information.
Important: If the new name type is hexadecimal, specify valid UTF-8 hexadecimal values so the server's code page displays the file space name as intended. For example, do not specify a value that can be interpreted as a backspace.
When you rename a file space that is part of a file space collocation group, the collocation group is updated with the new name.

NAMEType
: Specify how you want the server to interpret the current file space name that you enter. This parameter is useful when the server has clients with support for Unicode. You can use this parameter for Unicode-enabled IBM Spectrum Protect™ clients with Windows, Macintosh OS X, and NetWare operating systems.

  The default value is SERVER. If a virtual file space mapping name is specified, you must use SERVER. Possible values are:

  SERVER
  : The server uses the server's code page to interpret the file space name.

  UNIcode
  : The server converts the file space name that is entered from the server code page to the UTF-8 code page. The success of the conversion depends on the actual characters in the name and the server's code page. Conversion can fail if the string includes characters that are not available in the server code page, or if the server cannot access system conversion routines.

  FSID
  : The server interprets the file space name as the file space ID (FSID).

NEWNAMEType
: Specify how you want the server to interpret the new file space name that you enter. The default is SERVER if you specified the NAMETYPE as SERVER, or if the file space to be renamed is not Unicode. The default is UNICODE if you specified the NAMETYPE as UNICODE, or if the file space to be renamed is Unicode. If a virtual file space mapping name is specified, you must use SERVER. Possible values are:

  SERVER
  : The server uses the server's code page to interpret the file space name.

  UNIcode
  : The server converts the file space name that is entered from the server code page, to the UTF-8 code page. The success of the conversion depends on the actual characters in the name and the server's code page. If the conversion is not successful, you might want to specify the HEXADECIMAL parameter.

  HEXadecimal
  : The server interprets the file space name that you enter as the hexadecimal representation of a name in Unicode. Using hexadecimal ensures that the server is able to correctly rename the file space, regardless of the server's code page.
  To view the hexadecimal representation of a file space name, you can use the QUERY FILESPACE command with FORMAT=DETAILED.
  Restriction: You cannot specify a new name of a type that is different from the original name. You can rename a file space that is Unicode to another name in Unicode. You can rename a file space that is not Unicode, and use a new name in the server's code page. You cannot mix the two types.

force
: To rename a NAS or VMware file space you must set this parameter as follows: force=yes

Rename an imported file space to prevent overwriting

An AIX® client node named LARRY backed up file space /r033 to the IBM Spectrum Protect server. The file space was exported to tape and later reimported to the server. When this file space was imported, a system-generated name, /r031, was created for it because /r033 existed for client node LARRY.

Client node LARRY, however, already had a file space named /r031 that was not backed up, therefore, was unknown to the server. Unless the imported file space is renamed, it overlays file space /r031 because the file space name generated by the IMPORT function is the same as a file space on client node LARRY that is unknown to the server.

Use the following command to rename imported file space /r031. The new name, /imported-r033, identifies that the new file space is an imported image of file space /r033.

```
rename filespace larry /r031 /imported-r033
```

Rename file space to create a Unicode-enabled file space

Client JOE is using an English Unicode-enabled IBM Spectrum Protect client. JOE backed up several large file spaces that are not Unicode that is enabled in server storage. File space \\joe\c$ contains some files with Japanese file names that cannot be backed up to a file space that is not Unicode that is enabled. Because the file spaces are large, the administrator does not want to convert all of JOE's file spaces to Unicode-enabled file spaces now. The administrator wants to rename only the non-Unicode file space, \\joe\c$, so that the next backup of the file space causes the creation of a new Unicode-enabled file space. The new Unicode-enabled file space allows the Japanese files to be successfully backed up.

Use the following command to rename \\joe\c$:

```
rename filespace joe \\joe\c$ \\joe\c$_old
```

Related commands

Table 1. Commands related to RENAME FILESPACE

Command	Description
DEFINE VIRTUALFSMAPPING	Define a virtual file space mapping.
DELETE FILESPACE	Deletes data associated with client file spaces. If a file space is part of a collocation group and you remove the file space from a node, the file space is removed from the collocation group.
EXPORT NODE	Copies client node information to external media or directly to another server.
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.
QUERY OCCUPANCY	Displays file space information by storage pool.

RENAME NODE (Rename a node)

Use this command to rename a node.

If you are assigning an existing node ID to another person, use the UPDATE NODE command to change the password.

For users of Lightweight Directory Access Protocol (LDAP) servers:

- The information in this documentation applies to the LDAP authentication method that is preferred for IBM Spectrum Protect™ V7.1.7 or later servers. For instructions about using the previous LDAP authentication method, see Managing passwords and logon procedures.
- Do not rename a node to match an existing administrative user ID. If you rename a node, and the node name matches an administrative user ID, you might see unexpected behavior because of automatic password changes that update the same password twice. As a result, the password might become unknown to the administrative user ID. Alternatively, the password update might fail.

Restrictions:

- You cannot rename a NAS node name that has a corresponding data mover defined. If the data mover has defined paths, the paths must first be deleted.
- If a node is configured for replication, it cannot be renamed.

If you rename a node to the same name as an existing administrator, the administrator authentication method and SSLREQUIRED setting are updated to match the node. When a node and an administrator share a name and you change the node authentication

method or the node SSLREQUIRED setting, the administrator settings also change. You must have system level authority to update the node authentication method or the node SSLREQUIRED setting and also update a same-named administrator.

Privilege class

You must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the client node is assigned.

Syntax

```
>>-REName Node--current_node_name--new_node_name---------------->

   .-SYNCldapdelete--=--No------.
>--+----------------------------+------------------------------><
   '-SYNCldapdelete--=--+-No--+-'
                        '-Yes-'
```

Parameters

current_node_name (Required)
: Specifies the name of the node to be renamed.

new_node_name (Required)
: Specifies the new name of the node. The maximum length is 64 characters.

SYNCldapdelete
: Specifies whether the node name is deleted and replaced on the Lightweight Directory Access Protocol (LDAP) server.

  Yes
  : Specifies that the node name is deleted and replaced.
    Restriction: Do not specify a value of YES. (The value of YES is appropriate only for users of the previous LDAP authentication method, which is described in Managing passwords and logon procedures.)

  No
  : Specifies that the node name is not deleted and replaced. This is the default value.

Example: Rename a node

Rename the node JOE to JOYCE.

```
rename node joe joyce
```

Example: Rename a node that shares a namespace with other servers

Rename the node JOYCE to JOE and do not delete the previous name from corresponding LDAP servers.

```
rename node joyce joe
```

Related commands

Table 1. Commands related to RENAME NODE

Command	Description
QUERY NODE	Displays partial or complete information about one or more clients.
UPDATE NODE	Changes the attributes that are associated with a client node.

Related tasks:
Managing NAS file server nodes

RENAME SCRIPT (Rename an IBM Spectrum Protect script)

Use this command to rename an IBM Spectrum Protect™ script.

Privilege class

To issue this command, you must have operator, policy, system, storage, or system privilege.

Syntax

```
>>-REName SCRipt--current_script_name--new_script_name --------><
```

Parameters

current_script_name (Required)
: Specifies the name of the script to rename.

new_script_name (Required)
: Specifies the new name for the script. The name can contain as many as 30 characters.

Example: Rename a script

Rename SCRIPT1 to a new script named SCRIPT2.

```
rename script script1 script2
```

Related commands

Table 1. Commands related to RENAME SCRIPT

Command	Description
COPY SCRIPT	Creates a copy of a script.
DEFINE SCRIPT	Defines a script to the IBM Spectrum Protect server.
DELETE SCRIPT	Deletes the script or individual lines from the script.
QUERY SCRIPT	Displays information about scripts.
RUN	Runs a script.
UPDATE SCRIPT	Changes or adds lines to a script.

RENAME SERVERGROUP (Rename a server group)

Use this command to rename a server group.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-REName SERVERGroup--current_group_name--new_group_name------><
```

Parameters

current_group_name (Required)
: Specifies the server group to rename.

new_group_name (Required)
: Specifies the new name of the server group. The maximum length of the name is 64 characters.

Example: Rename a server group

Rename server group WEST_COMPLEX to BIG_WEST.

```
rename servergroup west_complex big_west
```

Related commands

Table 1. Commands related to RENAME SERVERGROUP

Command	Description
COPY SERVERGROUP	Creates a copy of a server group.
DEFINE SERVERGROUP	Defines a new server group.
DELETE SERVERGROUP	Deletes a server group.
QUERY SERVERGROUP	Displays information about server groups.
UPDATE SERVERGROUP	Updates a server group.

RENAME STGPOOL (Change the name of a storage pool)

Use this command to change the name of a storage pool. You can change storage pool names to use the same names on a configuration manager and its managed servers.

When you rename a storage pool, any administrators with restricted storage privilege for the old storage pool automatically retain restricted storage privilege for the renamed storage pool. If the renamed storage pool is in a storage pool hierarchy, the hierarchy is preserved. You must update the management class or copy group to specify the new storage pool name as the destination for files.

If processes are active when a storage pool is renamed, the old name might still be displayed in messages or queries for those processes.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-REName STGpool--current_pool_name--new_pool_name------------><
```

Parameters

current_pool_name (Required)
: Specifies the storage pool to rename.

new_pool_name (Required)
: Specifies the new name of the storage pool. The maximum length of the name is 30 characters.

Example: Change the name of a storage pool

Rename storage pool STGPOOLA to STGPOOLB:

```
rename stgpool stgpoola stgpoolb
```

Related commands

Table 1. Commands related to RENAME STGPOOL

Command	Description
BACKUP STGPOOL	Backs up a primary storage pool to a copy storage pool.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DELETE STGPOOL	Deletes a storage pool from server storage.

Command	Description
QUERY STGPOOL	Displays information about storage pools.
RESTORE STGPOOL	Restores files to a primary storage pool from copy storage pools.
UPDATE STGPOOL	Changes the attributes of a storage pool.

AIX Linux Windows

REPAIR STGPOOL (Repair a directory-container storage pool)

Use this command to repair deduplicated extents in a directory-container storage pool. Damaged deduplicated extents are repaired with extents that are backed up to the target replication server or to container-copy storage pools on the same server.

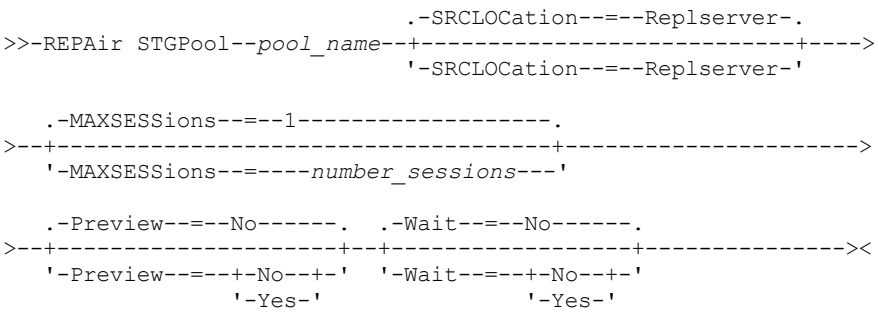
Restrictions:

- You can issue the REPAIR STGPOOL command only if you already issued the PROTECT STGPOOL command to back up data to another storage pool on a replication target server or on the same server.
- When you repair a directory-container storage pool from the replication server, the REPAIR STGPOOL command fails when any of the following conditions occur:
  - The target server is unavailable.
  - The target storage pool is damaged.
  - A network outage occurs.
- When you repair a directory-container storage pool from container-copy pools, the REPAIR STGPOOL command fails when any of the following conditions occur:
  - The container-copy storage pool is unavailable.
  - The container-copy storage pool is damaged.

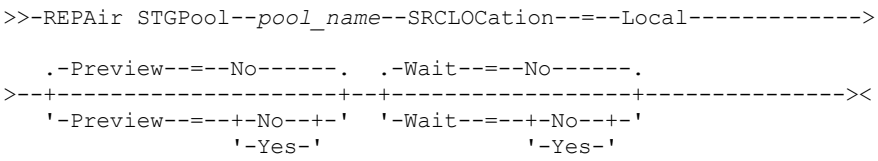
Privilege class

To issue this command, you must have system privilege.

Syntax when the source is the replication server



Syntax when the source is a storage pool on the same server



Parameters

pool_name (Required)
Specifies the name of the directory-container storage pool that contains the data that must be repaired.
SRCLOCation

Specifies the source location that is used to repair the data. The default value is REPLSERVER. This parameter is only required when the source location is on the same server. You can specify one of the following values:

Local
: Specifies that the data is repaired from container-copy storage pools on the same server.

Replserver
: Specifies that the data is repaired from a directory-container storage pool on the target replication server.

MAXSESSions
: Specifies the maximum number of data sessions that can send data to a target server. This parameter is optional when you repair data from a replication server.
The value that you specify can be in the range 1 - 20. The default value is 1. If you increase the number of sessions, you can repair the storage pool faster.

When you set a value for the MAXSESSIONS parameter, ensure that the available bandwidth and the processor capacity of the source and target servers are sufficient.

Tips:

- If you issue a QUERY SESSION command, the total number of sessions might exceed the number of data sessions.
- The number of sessions that are used to repair storage pools depends on the amount of data that is repaired. If you repair only a small amount of data, there is no benefit to increasing the number of sessions.

Preview
: Specifies whether to preview data or to repair the data. This parameter is optional. The default value is NO. You can specify one of the following values:

No
: Specifies that the data is repaired to the storage pool but the data is not previewed.

Yes
: Specifies that the data is previewed but not repaired.

Wait
: Specifies whether to wait for the server to complete the repair processing of the storage pool. This parameter is optional. The default value is NO. You can specify this parameter only from an administrative command line. You can specify one of the following values:

No
: Specifies that the command processes run in the background. To monitor the background processing of the REPAIR STGPOOL command, issue the QUERY PROCESS command.

Yes
: Specifies that the command processes run in the foreground. Messages are not displayed until the command completes processing.

Example: Repair a storage pool and preview the data

Repair a storage pool that is named POOL1 and preview the data.

```
repair stgpool pool1 preview=yes
```

Example: Repair a storage pool and specify a maximum number of sessions

Repair a storage pool that is named POOL1 and specify 10 maximum sessions.

```
repair stgpool pool1 maxsessions=10
```

Example: Repair a storage pool from tape

Repair a storage pool that is named POOL1 and specify local for the source location.

```
repair stgpool pool1 SRCLOCation=local
```

Table 1. Commands related to REPAIR STGPOOL

Command	Description

Command	Description
DEFINE STGPOOL (directory-container)	Define a directory-container storage pool.
DEFINE STGPOOL (container-copy)	Define a container-copy storage pool that stores copies of data from a directory-container storage pool.
DEFINE STGPOOLDIRECTORY	Defines a storage pool directory to a directory-container or cloud-container storage pool.
PROTECT STGPOOL	Protects a directory-container storage pool.

REPLICATE NODE (Replicate data in file spaces that belong to a client node)

Use this command to replicate data in file spaces that belong to one or more client nodes or defined groups of client nodes.

When you issue this command, a process is started in which data that belongs to the specified client nodes is replicated according to replication rules. Files that are no longer stored on the source replication server, but that exist on the target replication server, are deleted during this process.

If a node replication process is already running for a client node that is specified by this command, the node is skipped, and replication begins for other nodes that are enabled for replication.

After the node replication process is completed, a recovery process can be started on the target replication server. Files are recovered only if all the following conditions are met:

- Version 7.1.1 or later, is installed on the source and target replication servers.
- The REPLRECOVERDAMAGED system parameter is set to ON. The system parameter can be set by using the SET REPLRECOVERDAMAGED command.
- The source server includes at least one file that is marked as damaged in the node that is being replicated.
- The node data was replicated before the damage occurred.

The following table describes how settings affect the recovery of damaged, replicated files.
Restriction: You cannot use the REPLRECOVERDAMAGED parameter for directory-container or cloud storage pools.

Table 1. Settings that affect the recovery of damaged files

Setting for the REPLRECOVERDAMAGED system parameter	Value of the RECOVERDAMAGED parameter on the REPLICATE NODE command	Value of the RECOVERDAMAGED parameter on the REGISTER NODE and UPDATE NODE commands	Result
OFF	YES, NO, or not specified	YES or NO	During node replication, standard replication occurs and damaged files are not recovered from the target replication server.
OFF	ONLY	YES or NO	An error message is displayed because files cannot be recovered when the REPLRECOVERDAMAGED system parameter is set to OFF.
ON	YES	YES or NO	During node replication, standard replication occurs and damaged files are recovered from the target replication server.
ON	NO	YES or NO	During node replication, standard replication occurs and damaged files are not recovered from the target replication server.
ON	ONLY	YES or NO	Damaged files are recovered from the target replication server, but standard node replication does not occur.

Setting for the REPLRECOVERDAMAGED system parameter	Value of the RECOVERDAMAGED parameter on the REPLICATE NODE command	Value of the RECOVERDAMAGED parameter on the REGISTER NODE and UPDATE NODE commands	Result
ON	Not specified	YES	During node replication, standard replication occurs and damaged files are recovered from the target replication server.
ON	Not specified	NO	During node replication, standard replication occurs and damaged files are not recovered from the target replication server.

Tip: When the QUERY PROCESS command is issued during node replication, the output can show unexpected results for the number of completed replications. The reason is that, for node replication purposes, each file space is considered to contain three logical file spaces:

- One for backup objects
- One for archive objects
- One for space-managed objects

By default, the QUERY PROCESS command generates results for each logical file space. Other factors also affect the output of the QUERY PROCESS command:

- If a file space has a replication rule that is set to NONE, the file space is not included in the count of file spaces that are being processed.
- If you specify data types in the REPLICATE NODE command, only those data types are included in the count of file spaces that are being processed, minus any file spaces that are excluded.

Issue this command on the server that acts as a source for replicated data.

Privilege class

To issue this command, you must have system privilege.

Syntax

Notes:

1. Do not mix file space identifiers (FSIDs) and file space names in the same command.
2. Do not specify FSID if you use wildcard characters for the client node name.
3. Linux The TRANSFERMETHOD parameter is available only on Linux x86_64 operating systems.

Parameters

node_name or node_group_name (Required)

Specifies the name of the client node or defined group of client nodes whose data is to be replicated. You can also specify a combination of client node names and client-node group names. To specify multiple client node names or client-node group names, separate the names with commas with no intervening spaces. You can use wildcard characters with client node names but not with client-node group names. The replication rules for all file spaces in the specified client nodes are checked.

filespace_name or FSID

Specifies the name of the file space or the file space identifier (FSID) to be replicated. A name or FSID is optional. If you do not specify a name or an FSID, all the data in all the file spaces for the specified client nodes is eligible for replication.

filespace_name

Specifies the name of the file space that has data to be replicated. File space names are case-sensitive. To determine the correct capitalization for the file space, issue the QUERY FILESPACE command. Separate multiple names with commas with no intervening spaces. When you specify a name, you can use wildcard characters.

A server that has clients with file spaces that are enabled for Unicode might have to convert the file space name. For example, the server might have to convert a name from the server code page to Unicode. For details, see the NAMETYPE parameter. If you do not specify a file space name, or if you specify a single wildcard character for the name, you can use the CODETYPE parameter to limit the operation to Unicode file spaces or to non-Unicode file spaces.

FSID
: Specifies the file space identifier for the file space to be replicated. The server uses FSIDs to find the file spaces to replicate. To determine the FSID for a file space, issue the QUERY FILESPACE command. Separate multiple FSIDs with commas with no intervening spaces. If you specify an FSID, the value of the NAMETYPE parameter must be FSID.

NAMEType
: Specifies how you want the server to interpret the file space names that you enter. You can use this parameter for IBM Spectrum Protect™ clients that are enabled for Unicode and that have Windows, Macintosh OS X, or NetWare operating systems.
Use this parameter only when you enter a partly qualified or fully qualified file space name. The default value is SERVER. You can specify one of the following values:

SERVER
: The server uses the server code page to interpret file space names.

UNIcode
: The server converts file space names from the server code page to the UTF-8 code page. The success of the conversion depends on the characters in the name and the server code page. Conversion can fail if the string includes characters that are not available in the server code page or if the server cannot access system conversion routines.

FSID
: The server interprets file space names by using their file space identifiers.

CODEType
: Specifies the type of file spaces to be included in node replication processing. Use this parameter only when you enter a single wildcard character for the file space name. The default value is BOTH, which specifies that file spaces are included regardless of code page type. You can specify one of the following values:

UNIcode
: Specifies file spaces that are only in Unicode.

NONUNIcode
: Specifies file spaces that are not in Unicode.

BOTH
: Specifies all file spaces regardless of code page type.

DATAtype
: Specifies the type of data to be replicated. Data is replicated according to the replication rule that applies to the data type. This parameter is optional. You can specify one or more data types. If you do not specify a data type, all backup, archive, and space-managed data is replicated. Separate multiple data types with commas with no intervening spaces. You cannot use wildcard characters. You can specify one of the following values:

ALl
: Replicates all backup, archive, and space-managed data in a file space according to the rule that is assigned to the data type. For example, suppose that NODE1 has a single file space. The following replication rules apply:

- The file space rules for backup and archive data in the file space are set to ALL_DATA.
- The file space rule for space-managed data is set to DEFAULT.
- The client node rule for space-managed data is set to NONE.

If you issue `REPLICATE NODE NODE1 DATATYPE=ALL`, only backup data and archive data are replicated.

BACKUP
: Replicates active and inactive backup data in a file space if the controlling replication rule is ALL_DATA, ACTIVE_DATA, ALL_DATA_HIGH_PRIORITY, or ACTIVE_DATA_HIGH_PRIORITY.

BACKUPActive
: Replicates only active backup data in a file space if the controlling replication rule is ACTIVE_DATA or ACTIVE_DATA_HIGH_PRIORITY.

ARCHive

Replicates archive data only in a file space if the controlling replication rule is ALL_DATA or ALL_DATA_HIGH_PRIORITY.

SPACEManaged
Replicates only space-managed data in a file space if the controlling replication rule is ALL_DATA or ALL_DATA_HIGH_PRIORITY.

PRIority
Specifies the data to replicate based on the priority of the replication rule. You can specify one of the following values:

All
Replicates all data in a file space if the controlling replication rule is ALL_DATA, ACTIVE_DATA, ALL_DATA_HIGH_PRIORITY, or ACTIVE_DATA_HIGH_PRIORITY.

High
Replicates only data in a file space that has a controlling replication rule of ALL_DATA_HIGH_PRIORITY or ACTIVE_DATA_HIGH_PRIORITY.

Normal
Replicates only data in a file space that has a controlling replication rule of ALL_DATA or ACTIVE_DATA.

MAXSESSions
Specifies the maximum allowable number of data sessions to use for sending data to a target replication server. This parameter is optional. The value can be 1 - 99. The default value is 10.

Increasing the number of sessions can improve node replication throughput.

When you set this value, consider the number of logical and physical drives that can be dedicated to the replication process. To access a sequential-access volume, IBM Spectrum Protect uses a mount point and, if the device type is not FILE, a physical drive. The number of available mount points and drives depends on the following factors:

- Other IBM Spectrum Protect and system activity
- The mount limits of the device classes for the sequential access storage pools that are involved

Ensure that sufficient mount points and drives are available to allow node replication processes to complete. Each replication session might need a mount point on the source and target replication servers for storage pool volumes. If the device type is not FILE, each session might also need a drive on both the source and target replication servers.

When you set a value for MAXSESSIONS, also consider the available bandwidth and the processor capacity of the source and target replication servers.

Tip:

- The value that is specified by the MAXSESSIONS parameter applies only to data sessions. Data sessions are sessions during which data is sent to a target replication server. However, if you issue a QUERY SESSION command, the total number of sessions might exceed the number of data sessions. The difference is because of short control sessions that are used for querying and setting up replication operations.
- The value of the MAXSESSIONS parameter represents the maximum allowable number of sessions. The number of sessions that are used for replication depends on the amount of data to be replicated. If you are replicating only a small amount of data, you do not achieve any benefit by increasing the number of sessions. The total number of sessions might be less than the value that is specified by the MAXSESSIONS parameter.

Preview
Specifies whether to preview data. This parameter is optional. The default value is NO. You can specify one of the following values:

No
Specifies that the data is replicated to the target server but that the data is not previewed.

Yes
Specifies that data is previewed but not replicated. If you specify PREVIEW=YES, only volumes that must be physically mounted, such as tape volumes, are displayed. Volumes that are assigned to storage pools that have a device class of FILE are not displayed.

The following information is displayed in the output:

- The names of client nodes whose data would be replicated.
- The number of files that would be replicated or deleted.
- The estimated amount of time it would take to complete the node replication process.

- A list of volumes that would be mounted.
- A summary of information about replicated, damaged data. The summary lists the number of nodes, file spaces, files, and bytes that can be recovered during a replication recovery process. The summary is displayed only if RECOVERDAMAGED=YES or RECOVERDAMAGED=ONLY is specified.

If the client node data that is specified by the REPLICATE NODE command was never replicated and you specify `PREVIEW=YES`, the node and its file spaces are automatically defined on the target replication server.

LISTfiles

Specifies whether to list the names of files that would be replicated. This parameter is optional. The default is NO. Specifying this parameter signifies that the WAIT parameter is set to YES and that you cannot issue the WAIT parameter from the server console.

You can specify one of the following values:

No
: Specifies that the names of files that would be replicated are not displayed.

Yes
: Specifies that the names of files that would be replicated are displayed.

Wait

Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default value is NO. You can specify one of the following values:

No
: Specifies that the command processes in the background. To monitor the background processing of the REPLICATE NODE command, issue the QUERY PROCESS command.

Yes
: Specifies that the command processes in the foreground. Messages are not displayed until the command completes processing. You cannot specify `WAIT=YES` from the server console.

RECOVERDamaged

Specifies whether a recovery process is started on a target replication server after the node replication process is completed. This parameter is optional, and it overrides any value that you specified for the RECOVERDamaged parameter when you defined or updated a node. You can specify one of the following values:

Yes
: Specifies that a replication process is started to recover damaged files, but only if the setting for the REPLRECOVERDAMAGED system parameter is ON. If the setting is OFF, damaged files are not recovered.

No
: Specifies that damaged files are not recovered.

Only
: Specifies that a replication process is started for the sole purpose of recovering damaged files, but only if the setting for the REPLRECOVERDAMAGED system parameter is ON. If the setting is OFF, damaged files are not recovered, and you receive a notification that recovery was not started.
Restriction: If you specify an invalid combination of values and settings for file recovery, replication is stopped, and an error message is displayed.

FORCEREConcile

Specifies whether to compare all files on the source replication server with files on the target replication server and to synchronize the differences between them. Before V7.1.1, this behavior was the default for replication processing. When IBM® Tivoli® Storage Manager V7.1.1 or later is installed on the source and target replication servers, a reconcile is automatically completed during initial replication. After initial replication, you might use this parameter for the following reasons:

- To synchronize files on the source and target replication servers if they are different.
- To replicate inactive files that were skipped after you change your replication rules from ACTIVE_DATA to ALL_DATA.
- To delete inactive files from the target replication server when you change your replication rules from ALL_DATA to ACTIVE_DATA.
- To ensure that you replicate only active data when you are using the ACTIVE_DATA replication rule so that the target replication server has active files only.
- To resynchronize the files so that the target replication server has the same files as the source replication server if you have previously or are currently using the policies on the target replication server to manage replicated files.

- To resynchronize the files on the source and target replication servers if the database is regressed to an earlier point-in-time by using a method other than the DSMSERV RESTORE DB command.
- To rebind files to the new management class on the target replication server if this management class did not exist when the files were replicated. You must be using the policies that are defined on the target replication server to manage replicated files.

Remember: When the ACTIVE_DATA rule is assigned, a reconcile is completed only for active files on the source replication server.

This parameter is optional. You can specify one of the following values:

No
: Specifies that replication processing does not force a reconcile to compare all files on the source replication server with files on the target replication server. Instead, replication processing tracks file changes on the source replication server since the last replication and synchronizes these changes on the target replication server. NO is the default value.

Yes
: Specifies that replication processing forces a reconcile to compare all files on the source replication server with files on the target replication server and synchronizes the files on the target replication server with the source replication server.

Linux TRANSFERMethod
: Linux Specifies the method that is used for server-to-server data transfer. This parameter is optional. You can specify one of the following values:

Tcpip
: Specifies that TCP/IP is used to transfer data. This value is the default.

Fasp
: Specifies that Aspera® Fast Adaptive Secure Protocol (FASP) technology is used to transfer data. Aspera FASP technology can help you optimize data transfer in a wide area network (WAN). If you specify TRANSFERMETHOD=FASP, you override any TRANSFERMETHOD parameters that you specified on the DEFINE SERVER or UPDATE SERVER commands.
  Restrictions:

  - Only data that is stored in a directory-container storage pool can be transferred by using Aspera FASP technology. Data that is not stored in a directory-container storage pool is transferred by using TCP/IP.
  - Before you enable Aspera FASP technology, determine whether the technology is appropriate for your system environment and install the appropriate licenses. For instructions, see Determining whether Aspera FASP technology can optimize data transfer in your system environment. If the licenses are missing or expired, node replication fails.
  - If WAN performance meets your business needs, do not enable Aspera FASP technology.

Example: Replicate data by data type and priority

Replicate high-priority active backup data and high-priority archive data that belongs to all the client nodes in group PAYROLL.

```
replicate node payroll datatype=backupactive,archive priority=high
```

Example: Replicate all the data that belongs to a node according to the assigned replication rules

NODE1 has a single file space. The following replication rules apply:

- File space rules:
  - Backup data: ACTIVE_DATA
  - Archive data: DEFAULT
  - Space-managed data: DEFAULT
- Client node rules:
  - Backup data: DEFAULT
  - Archive data: ALL_DATA_HIGH_PRIORITY
  - Space-managed data: DEFAULT
- Server rules:
  - Backup data: ALL_DATA

- Archive data: ALL_DATA
- Space-managed data: NONE

```
replicate node node1 priority=all
```

Active backup data in the file space is replicated with normal priority. Archive data is replicated with high priority. Space-managed data is not replicated.

Example: Recover damaged files without starting the full replication process

Without starting the full replication process, recover any damaged files in the client nodes of the PAYROLL group. Ensure that the setting for the REPLRECOVERDAMAGED system parameter is ON. Then, issue the following command:

```
replicate node payroll recoverdamaged=only
```

Related commands

Table 2. Commands related to REPLICATE NODE

Command	Description
CANCEL PROCESS	Cancels a background server process.
CANCEL REPLICATION	Cancels node replication processes.
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY REPLICATION	Displays information about node replication processes.
QUERY REPLNODE	Displays information about the replication status of a client node.
QUERY REPLRULE	Displays information about node replication rules.
QUERY SERVER	Displays information about servers.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REGISTER NODE	Defines a client node to the server and sets options for that user.
REMOVE REPLNODE	Removes a node from replication.
AIX Linux Windows PROTECT STGPOOL	Protects a directory-container storage pool.
SET REPLRECOVERDAMAGED	Specifies whether node replication is enabled to recover damaged files from a target replication server.
UPDATE FILESPACE	Changes file-space node-replication rules.
UPDATE NODE	Changes the attributes that are associated with a client node.
UPDATE REPLRULE	Enables or disables replication rules.
VALIDATE REPLICATION	Verifies replication for file spaces and data types.

REPLY (Allow a request to continue processing)

Use this command and an identification number to inform the server that you have completed a requested operation. Not all server requests require a reply. This command is required only if the request message specifically indicates that a reply is needed.

Privilege class

To issue this command, you must have system privilege or operator privilege.

Syntax

```
>>-REPly--request_number--+-----------------------+----------><
                          '-LABEL--=--volume_label-'
```

Parameters

request_number **(Required)**
: Specifies the identification number of the request.

LABEL
: Specifies the label to be written on a volume when you reply to a message from a LABEL LIBVOLUME command process. This parameter is optional.

Example: Reply to a request

Respond to a reply request using 3 as the request number.

```
reply 3
```

Related commands

Table 1. Commands related to REPLY

Command	Description
CANCEL REQUEST	Cancels pending volume mount requests.
QUERY REQUEST	Displays information about all pending mount requests.

RESET PASSEXP (Reset password expiration)

Use the RESET PASSEXP command to reset the password expiration period to the common expiration period for administrator and client node passwords. The RESET PASSEXP command does not apply to passwords that are stored on an LDAP directory server.

Restriction: You cannot reset the password expiration period to the common expiration period with the SET PASSEXP command.

Use the QUERY STATUS command to display the common password expiration period.

Restriction: If you do not specify either the NODE or ADMIN parameters, the password expiration period for all client nodes and administrators will be reset.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-RESet PASSExp--+-------------------------+-------------------->
                  |           .-,---------. |
                  |           V           | |
                  '-Node--=----node_name-+-'

>--+-------------------------+-------------------------------><
   |           .-,----------. |
   |           V            | |
   '-Admin--=----admin_name-+-'
```

Parameters

Node

Specifies the name of the node whose password expiration period you would like to reset. To specify a list of nodes, separate the names with commas and no intervening spaces. This parameter is optional.

Admin

Specifies the name of the administrator whose password expiration period you would like to reset. To specify a list of administrators, separate the names with commas and no intervening spaces. This parameter is optional.

Example: Reset the password expiration for specific client nodes

Reset the password expiration period for client nodes bj and katie.

```
reset passexp node=bj,katie
```

Example: Reset the password expiration for all users

Reset the password expiration period for all users to the common expiration period.

```
reset passexp
```

Related commands

Table 1. Commands related to RESET PASSEXP

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
SET PASSEXP	Specifies the number of days after which a password is expired and must be changed.
UPDATE ADMIN	Changes the password or contact information associated with any administrator.
UPDATE NODE	Changes the attributes that are associated with a client node.

RESTART EXPORT (Restart a suspended export operation)

Use this command to restart a suspended export operation.

An export operation is suspended when any of the following conditions is detected:

- A SUSPEND EXPORT command is issued for the running export operation
- Segment preemption - the file being read for export is deleted by some other process
- Communication errors on a server-to-server export
- No available mount points
- Necessary volumes are unavailable
- I/O errors encountered

Important: Nodes or file spaces (on the exporting server) in the original export operation that are subsequently renamed are not included in the resumed operation. Any remaining data for nodes or file spaces on the target server that are deleted prior to resumption are discarded.

Privilege class

You must have system privilege to issue this command.

Syntax

```
                  .-*--------------------.
>>-RESTART EXPORT -+----------------------+------------------><
                  '---export_identifier---'
```

Parameters

export_identifier
: This optional parameter is the unique identifier for the suspended server-to-server export operation. You can use the wildcard character to specify this name. The export identifier name can be found by issuing the QUERY EXPORT command to list all the currently suspended server-to-server export operations.

Example: Restart a suspended export

Restart the suspended export operation identified by the export identifier EXPORTALLACCTNODES.

```
restart export exportallacctnodes
```

Related commands

Table 1. Commands related to RESTART EXPORT

Command	Description
CANCEL EXPORT	Deletes a suspended export operation.
EXPORT NODE	Copies client node information to external media or directly to another server.
EXPORT SERVER	Copies all or part of the server to external media or directly to another server.
QUERY EXPORT	Displays the export operations that are currently running or suspended.
SUSPEND EXPORT	Suspends a running export operation.

RESTORE commands

Use the RESTORE commands to restore IBM Spectrum Protect™ storage pools or volumes.

- RESTORE NODE (Restore a NAS node)
- RESTORE STGPOOL (Restore storage pool data from a copy pool or an active-data pool)
- RESTORE VOLUME (Restore primary volume data from a copy pool or an active-data pool)

RESTORE NODE (Restore a NAS node)

Use this command to initiate a restore operation for a network-attached storage (NAS) node.

You can use the RESTORE NODE command to restore backups that were created by using either the client's BACKUP NAS command or the server's BACKUP NODE command. NAS data may be restored from primary or copy native IBM Spectrum Protect™ pools; primary or copy NAS pools; or any combination needed to achieve the restore.

Privilege class

To issue this command, you must have system privilege, policy privilege for the domain to which the node is assigned, or client owner authority over the node.

Syntax

```
>>-RESTORE Node--node_name--source_file_system------------------>

   .-source_file_system------.
>--+-------------------------+--------------------------------->
   '-destination_file_system-'

>--+-----------------------------------+------------------------>
   |                .-,---------.      |
   |                V           |      |
   '-FILELIST--=---+---file_name-+----+-'
                   '-FILE:--file_list-'
```

```
   .-NAMEType--=--SERVER----------.
>--+-----------------------------+-----------------------------><
   '-NAMEType--=--+-SERVER------+-'
                  +-HEXadecimal-+
                  '-UNIcode-----'

   .-PITDate--=--TODAY-------------.
>--+-------------------------------+---------------------------><
   '-PITDate--=--+-mm/dd/yyyy----+-'
                 +-TODAY---------+
                 +-TODAY-numdays-+
                 '- -numdays-----'

   .-PITTime--=--NOW-----------.  .-Wait--=--No------.
>--+---------------------------+--+------------------+----------><
   '-PITTime--=--+-hh:mm:ss--+-'  '-Wait--=--+-No--+-'
                 +-NOW-------+               '-Yes-'
                 +-NOW-hh:mm-+
                 '- -hh:mm---'

   .-TYPE--=--BACKUPImage-----.
>--+--------------------------+-------------------------------><
   '-TYPE--=--+-BACKUPImage-+-'
              '-SNAPMirror--'
```

Parameters

node_name (Required)
: Specifies the name of the node to restore. You cannot use wildcard characters or specify a list of names.

source_file_system (Required)
: Specifies the name of the file system to restore. You cannot use wildcard characters for this name. You cannot specify more than one file system to restore. Virtual file space names are allowed.

destination_file_system
: Specifies that the file server restores the data to an existing, mounted file system on the file server. This parameter is optional. The default is the original location of the file system on the file server. Virtual file space names are allowed.

FILELIST
: Specifies the list of file or directory names to be restored. This parameter is optional. The default is to restore the entire file system. If this value is specified, the server attempts to restore the objects from the appropriate image. If the PITDATE and PITTIME parameters are specified, then the file is restored from the last backup image prior to the specified time. If no PITDATE and PITTIME parameters are specified, the file is restored from the latest backup image of the file system.

  If the image is a differential backup, objects are first restored from the corresponding full backup and then from the differential backup. The restore is done by scanning the appropriate images for the specified objects and restoring any that are found. The TOCs for these images is not accessed, so the server does not check whether the objects are actually contained within the images.

  The folder path and file name must be entered using forward slash (/) symbols. No ending forward slash (/) is needed at the end of the file name. All arguments that contain a space must have double quotation marks ("argument with spaces") surrounding the entire argument.

  ```
  FILELIST="/path/to/filename1 with blanks",/path/to/filename2_no_blanks
  ```

  Any file names that contain commas must have double quotation marks surrounding the entire argument, surrounded by single quotation marks ('"argument with commas"').

  ```
  FILELIST='"/path/to/filename1,with,commas"',/path/to/filename2_no_commas
  ```

  To restore a complete directory, specify a directory name instead of a file name. All files in the directory and its subdirectories are restored. An ending forward slash (/) is not needed at the end of the directory name:

  ```
  FILELIST=/path/to/mydir
  ```

  file_name
  : Specifies one or more file or directory names to be restored. The names you specify cannot contain wildcards. Multiple names must be separated with commas and no intervening blanks. File names are case-sensitive.

  FILE:file_list

Specifies the name of a file that contains a list of the file or directory names to be restored. In the specified file, each file or directory name must be on a separate line. Blank lines and comment lines that begin with an asterisk are ignored. For example:
To restore files FILE01, FILE02, and FILE03, create a file named RESTORELIST that contains a line for each file:

```
FILE01
FILE02
FILE03
```

You can specify the files to be restored with the command as follows:

```
FILELIST=FILE:RESTORELIST
```

NAMEType
Specifies how you want the server to interpret the names specified as FILELIST=file_name or the names listed in the file specified with FILELIST=file_list. This parameter is useful when the names may contain Unicode characters. It has no effect if the FILELIST parameter is not specified. The default value is SERVER. Possible values are:

SERVER
The server uses the server's code page to interpret the names.
HEXadecimal
The server interprets the names that you enter as the hexadecimal representation of a name in Unicode. To view the hexadecimal representation of a file or directory name, you can use the QUERY TOC command with FORMAT=DETAILED.
UNIcode
The server interprets the names as being UTF-8 encoded. This option only applies when you have specified a list with FILELIST=FILE:file_list.

Restriction: Network Data Management Protocol (NDMP) has limitations that prevent IBM Spectrum Protect from reporting whether or not individual files and directories are successfully restored.

PITDate
Specifies the point-in-time date. When used with the PITTIME parameter, PITDATE establishes the point in time from which you want to select the data to restore. The latest data that was backed up on or before the date and time that you specify will be restored. This parameter is optional. The default is TODAY.
You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	06/25/2001
TODAY	The current date	TODAY
TODAY-days *or* -days	The current date minus days specified	TODAY–7 *or* –7. To restore data that was backed up a week ago, specify PITDATE=TODAY-7 or PITDATE=-7.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

PITTime
Specifies the point-in-time time. When used with the PITDATE parameter, PITTIME establishes the point in time from which you want to select the data to restore. The latest data that was backed up on or before the date and time that you specify will be restored. This parameter is optional. The default is the current time.
You can specify the time by using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time on the specified date	12:33:28

Value	Description	Example
NOW	The current time on the specified date	NOW
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes on the specified begin date	NOW-03:30 *or* -03:30. If you issue this command at 9:00 with PITTIME=NOW-03:30 or PITTIME=-03:30, the server restores backup records with a time of 5:30 or later on the point-in-time date.

Wait

Specifies whether to wait for the server to complete processing this command in the foreground. The default is NO. Possible values are:

No

Specifies that the server processes this command in the background. Use the QUERY PROCESS command to monitor the background processing of this command.

Yes

Specifies that the server processes this command in the foreground. You wait for the command to complete before continuing with other tasks. The server then displays the output messages to the administrative client when the command completes.
Restriction: You cannot specify WAIT=YES from the server console.

TYPE

Specifies the type of image to restore. The default value for this parameter is BACKUPIMAGE and it is used to restore data from standard NDMP base or differential backups. Other image types represent backup methods that might be specific to a particular file server. Possible values are:

BACKUPImage

Specifies that the file system should be restored from the appropriate standard NDMP backup images. This is the default method for performing an NDMP restore operation. Using the BACKUPIMAGE type, you can restore data from base and differential backups, and data at the file level.

SNAPMirror

Specifies that the file system should be retrieved from a NetApp SnapMirror image. SnapMirror images are block-level full-backup images of a NetApp file system. A SnapMirror image can only be restored to a file system that has been prepared as a SnapMirror target volume. Refer to the documentation that came with your NetApp file server for details.

After a SnapMirror image is retrieved and copied to a target file system, IBM Spectrum Protect breaks the SnapMirror relationship that was created by the file server during the operation. After the restore is complete, the target file system returns to the same state as that of the original file system at the point-in-time of the backup.

When setting the TYPE parameter to SNAPMIRROR, note the following restrictions:

Restrictions:

- You cannot specify the FILELIST parameter.
- Neither the *source_file_system_name* nor the *destination_file_system_name* can be a virtual filespace name.
- This parameter is valid for NetApp and IBM® N-Series file servers only.

Example: Restore a complete directory

Restore all of the files and subdirectories in the directory `/mydir`.

```
restore node nasnode /myfs /dest filelist=/path/to/mydir
```

Example: Restore data from a file system

Restore the data from the `/vol/vol10` file system on NAS node `NAS1`.

```
restore node nas1 /vol/vol10
```

Example: Restore a directory-level backup to the same location

Restore the directory-level backup to the original location. The source is the virtual file space name `/MIKESDIR` and no destination is specified.

```
restore node nas1 /mikesdir
```

For this example and the next example, assume the following virtual file space definitions exist on the server for the node `NAS1`.

```
VFS Name             Filesystem      Path
/mikesdir            /vol/vol2       /mikes
/TargetDirVol2       /vol/vol2       /tmp
/TargetDirVol1       /vol/vol1       /tmp
```

Example: Restore a directory-level backup to a different file system

Restore the directory-level backup to a different file system but preserve the path.

```
restore node nas1 /mikesdir /vol/vol0
```

Related commands

Table 1. Commands related to RESTORE NODE

Command	Description
BACKUP NODE	Backs up a network-attached storage (NAS) node.
CANCEL PROCESS	Cancels a background server process.
DEFINE VIRTUALFSMAPPING	Define a virtual file space mapping.
QUERY NASBACKUP	Displays information about NAS backup images.
QUERY TOC	Displays details about the table of contents for a specified backup image.

RESTORE STGPOOL (Restore storage pool data from a copy pool or an active-data pool)

Use this command to restore files from one or more copy storage pools or active-data pools to a primary storage pool.

IBM Spectrum Protect™ restores all the primary storage pool files that:

- Have been identified as having errors
- Reside on a volume with an access mode of DESTROYED

Restriction: You cannot use this command for container storage pools. Use the REPLICATE STGPOOL command to protect data for container storage pools.

You can also use this command to identify volumes that contain damaged, primary files. During restore processing, a message is issued for every volume in the restored storage pool that contains damaged, non-cached files. Use the QUERY CONTENT command to identify damaged, primary files on a specific volume.

You cannot restore a storage pool defined with a CENTERA device class.

In addition to restoring data to primary storage pools that have NATIVE or NONBLOCK data formats, this command also lets you restore data to primary storage pools that have NDMP data formats (NETAPPDUMP, CELERRADUMP, or NDMPDUMP). The primary storage pool must have the same data format as the copy storage pool from which data is to be restored. IBM Spectrum Protect supports backend data movement for NDMP images.

Tip: To restore NAS client-node data to NAS storage pools, you must manually change the access mode of the volumes to DESTROYED using the UPDATE VOLUME command. However, if you are using disaster recovery manager, the plan file will contain the information the server needs to automatically mark the volumes as DESTROYED.
Restoration of files might be incomplete if backup file copies in copy storage pools or active-data pools were moved or deleted by other IBM Spectrum Protect processes during restore processing. To prevent this problem, do not issue the following commands for copy storage pool or active-data pool volumes while restore processing is in progress:

- MOVE DATA

- DELETE VOLUME (DISCARDDATA=YES)
- AUDIT VOLUME (FIX=YES)

Also, you can prevent reclamation processing for your copy storage pools by setting the RECLAIM percentage to 100 with the UPDATE STGPOOL command.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the primary storage pool for which files are to be restored. If you are a restricted storage administrator and you want to restore files to a new primary storage pool, you must also have authority for the new storage pool.

Syntax

```
>>-RESTORE STGpool--primary_pool_name--------------------------->

>--+--------------------------------+-------------------------->
   '-COPYstgpool--=--copy_pool_name-'

   .-ACTIVEDATAOnly--=--No-------------.
>--+-----------------------------------+------------------------>
   '-ACTIVEDATAOnly--=--+-No---------+-'
                        '-Yes--| A |-'

>--+-------------------------------------+--------------------->
   '-NEWstgpool--=--new_primary_pool_name-'

   .-MAXPRocess--=--1------.  .-Preview--=--No------.
>--+----------------------+--+---------------------+----------->
   '-MAXPRocess--=--number-'  '-Preview--=--+-No--+-'
                                            '-Yes-'

   .-Wait--=--No------.
>--+------------------+---------------------------------------><
   '-Wait--=--+-No--+-'
              '-Yes-'

A (Yes)

|--ACTIVEDATAPool--=--active-data_pool_name--------------------|
```

Parameters

primary_pool_name (Required)
: Specifies the name of the primary storage pool that is being restored.

COPYstgpool
: Specifies the name of the copy storage pool from which the files are to be restored. This parameter is optional. If this parameter is not specified, files are restored from any copy pool in which copies can be located. Do not use this parameter with the ACTIVEDATAONLY or ACTIVEDATAPOOL parameters.

ACTIVEDATAOnly
: Specifies that active versions of backup files are to be restored from active-data pools only. This parameter is optional. The default is NO. If this parameter is not specified, files are restored from copy-storage pools. Do not use this parameter with the COPYSTGPOOL parameter. Possible values are:

  No
  : Specifies that the storage pool will not be restored from active-data pools.

  Yes
  : Specifies that the storage pool will be restored from active-pool or pools that you specify using the ACTIVEDATAPOOL parameter. If you specify YES as a value for ACTIVEDATAONLY, but do not specify a value for ACTIVEDATAPOOL, files are restored from any active-data pool in which active versions of backup files can be located.

  Attention: Restoring a primary storage pool from an active-data pool might cause some or all inactive files to be deleted from the database if the server determines that an inactive file needs to be replaced but cannot find it in the active-data pool.

ACTIVEDATAPool
: Specifies the name of the active-data pool from which the active versions of backup files are to be restored. This parameter is optional. If this parameter is not specified, files are restored from any active-data pool in which active versions of backup files can be located.

NEWstgpool
: Specifies the name of the new storage pool to which to restore the files. This parameter is optional. If this parameter is not specified, files are restored to the original primary storage pool (the pool being restored).

MAXPRocess
: Specifies the maximum number of parallel processes that are used for restoring files. Using multiple, parallel processes may improve throughput for the restore. This parameter is optional. You can specify a value from 1 to 999. The default is 1.

  When determining this value, consider the number of mount points (logical drives) and physical drives that can be dedicated to this operation. To access a sequential access volume, IBM Spectrum Protect uses a mount point, and, if the device type is not FILE, a physical drive. The number of available mount points and drives depends on other IBM Spectrum Protect and system activity and on the mount limits of the device classes for the sequential access storage pools that are involved in the restore.

  Each process needs a mount point for copy storage pool volumes, and, if the device type is not FILE, each process also needs a drive. If you are restoring files in a sequential storage pool, each process needs an additional mount point for primary storage pool volumes and, if the device class is not FILE, an additional drive. For example, suppose you specify a maximum of 3 processes to restore a primary sequential storage pool from a copy storage pool of the same device class. Each process requires two mount points and two drives. To run all three processes, the device class must have a mount limit of at least 6, and at least 6 mount points and 6 drives must be available.

  To preview a restore, only one process is used and no mount points or drives are needed.

Preview
: Specifies if you want to preview but not perform the restore. The preview lets you identify volumes required to restore the storage pool. The preview displays:

  - A list of primary storage pool volumes that contain damaged files.
  - The number of files and the number of bytes to be restored, assuming that the access mode of the required copy storage pool volumes is READWRITE or READONLY when the restore operation is performed.
  - A list of copy storage pool volumes containing files to be restored. These volumes must be mounted if you perform the restore.
  - A list of any volumes containing files that cannot be restored.

  Note: For only a list of offsite copy storage pool volumes to be mounted during a restore, change the access mode of the copy pool volumes to UNAVAILABLE. This prevents reclamation and move data processing of the volumes until they are moved onsite for the restore.
  This parameter is optional. The default is NO. Possible values are:

  No
  : Specifies that the restore is done.

  Yes
  : Specifies that you want to preview the restore but not do the restore.

Wait
: Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default is NO. Possible values are:

  No
  : Specifies that the server processes this command in the background.

    You can continue with other tasks while the command is being processed.

    Messages created from the background process are displayed either in the activity log or the server console, depending on where messages are logged. To cancel a background process, use the CANCEL PROCESS command. If you cancel this process, some files may have already been restored prior to the cancellation.

  Yes
  : Specifies that the server performs this operation in the foreground. The operation must complete before you can continue with other tasks. The server then displays the output messages to the administrative client when the operation completes.
    Note: You cannot specify WAIT=YES from the server console.

Example: Restore files from a copy storage pool to the primary storage pool

Restore files from any copy storage pool to the primary storage pool, PRIMARY_POOL.

```
restore stgpool primary_pool
```

Example: Restore files from a specific active-data pool to the primary storage pool

Restore files from active-data pool ADP1 to the primary storage pool PRIMARY_POOL.

```
restore stgpool primary_pool activedataonly=yes activedatapool=adp1
```

Related commands

Table 1. Commands related to RESTORE STGPOOL

Command	Description
BACKUP STGPOOL	Backs up a primary storage pool to a copy storage pool.
CANCEL PROCESS	Cancels a background server process.
COPY ACTIVEDATA	Copies active backup data.
QUERY CONTENT	Displays information about files in a storage pool volume.
QUERY PROCESS	Displays information about background processes.
RESTORE VOLUME	Restores files stored on specified volumes in a primary storage pool from copy storage pools.
UPDATE STGPOOL	Changes the attributes of a storage pool.
UPDATE VOLUME	Updates the attributes of storage pool volumes.

RESTORE VOLUME (Restore primary volume data from a copy pool or an active-data pool)

Use this command to restore all files on damaged volumes in a primary storage pool that was backed up to a copy storage pool or copied to an active-data pool. IBM Spectrum Protect™ does not restore cached copies of files and removes those cached files from the database during restore processing.

In addition to restoring data to volumes in storage pools that have NATIVE or NONBLOCK data formats, this command also lets you restore data to volumes in storage pools that have NDMP data formats (NETAPPDUMP, CELERRADUMP, or NDMPDUMP). The volumes to be restored must have the same data format as the volumes in the copy storage pool. IBM Spectrum Protect supports backend data movement for NDMP images.

This command changes the access mode of the specified volumes to DESTROYED. When all files on a volume are restored to other locations, the destroyed volume is empty and is deleted from the database.

The restoration may be incomplete for one or more of the following reasons:

- Files were either never backed up or the backup copies are marked as damaged. Use the QUERY CONTENT command to get more information on the remaining files on the volume.
- A copy storage pool was specified on the RESTORE command, but files were backed up to a different copy storage pool. Use the PREVIEW parameter when you issue the RESTORE command again to determine if this is the problem.
- Volumes in the copy storage pool needed to perform the restore operation are offsite or unavailable. Check the activity log for messages that occurred during restore processing.
- Backup file copies in copy storage pools were moved or deleted by other processes during a restore. See note 3.
- An active-data pool was specified for the restore, and inactive files were not available to be copied.

Important:

1. You cannot restore volumes in storage pools defined with a CENTERA device class.
2. Before you restore a random-access volume, issue the VARY command to vary the volume offline.

3. To prevent copy storage pools files from being moved or deleted by other processes, do not issue the following commands for copy storage pool volumes during a restore:
   - MOVE DATA
   - DELETE VOLUME (DISCARDDATA=YES)
   - AUDIT VOLUME (FIX=YES)

   To prevent reclamation processing of copy storage pools, issue the UPDATE STGPOOL command with the RECLAIM parameter set to 100.

Privilege class

To issue this command you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the primary storage pool. If you have restricted privilege and want to restore files to a new primary storage pool, you must also have authority for the new storage pool.

Syntax

Parameters

volume_name (Required)
: Specifies the name of the primary storage pool volume to be restored. To specify a list of volumes that belong to the same primary storage pool, separate the names with commas and no intervening spaces.

COPYstgpool
: Specifies the name of the copy storage pool from which the files are to be restored. This parameter is optional. If you do not specify this parameter, files are restored from any copy pool in which copies can be located. Do not use this parameter with the ACTIVEDATAONLY or ACTIVEDATAPOOL parameters.

ACTIVEDATAOnly
: Specifies that active versions of backup files are to be restored from active-data pools only. This parameter is optional. The default is NO. If this parameter is not specified, files are restored from copy-storage pools. Do not use this parameter with the COPYSTGPOOL parameter. Possible values are:

  No
  : Specifies that the storage pool will not be restored from active-data pools.

  Yes
  : Specifies that the storage pool will be restored from active-pool or pools that you specify using the ACTIVEDATAPOOL parameter. If you specify YES as a value for ACTIVEDATAONLY, but do not specify a value for

ACTIVEDATAPOOL, files are restored from any active-data pool in which active versions of backup files can be located.

Attention: Restoring a volume from an active-data pool might cause some or all inactive files to be deleted from the database if the server determines that an inactive file needs to be replaced but cannot find it in the active-data pool.

ACTIVEDATAPool
Specifies the name of the active-data pool from which the active versions of backup files are to be restored. This parameter is optional. If this parameter is not specified, files are restored from any active-data pool in which active versions of backup files can be located.

NEWstgpool
Specifies the name of the new storage pool to which to restore the files. This parameter is optional. If you do not specify this parameter, files are restored to the original primary storage pool.

MAXPRocess
Specifies the maximum number of parallel processes to use for restoring files. Using parallel processes may improve throughput. This parameter is optional. You can specify a value from 1 to 999. The default is 1.

When determining this value, consider the number of mount points (logical drives) and physical drives that can be dedicated to this operation. To access a sequential access volume, IBM Spectrum Protect uses a mount point, and, if the device type is not FILE, a physical drive. The number of available mount points and drives depends on other IBM Spectrum Protect and system activity and on the mount limits of the device classes for the sequential access storage pools that are involved in the restore.

Each process needs a mount point for copy storage pool volumes. If the device type is not FILE, each process also needs a drive. If you are restoring a sequential storage pool, each process needs an additional mount point for primary storage pool volumes and, if the device type is not FILE, an additional drive. For example, suppose you specify a maximum of three processes to back up a primary sequential storage pool to a copy storage pool of the same device class. Each process requires two mount points and two drives. To run all three processes, the device class must have a mount limit of at least 6, and at least 6 mount points and 6 drives must be available.

To preview a backup, only one process is used and no mount points or drives are needed.

Preview
Specifies if you want to preview but not perform the restore. You can use this option to identify the offsite volumes required to restore a storage pool. This parameter is optional. The default is NO. Possible values are:

No
Specifies that you want to perform the restore operation.

Yes
Specifies that you want to preview the restore operation but restore the data.
Tip: If you preview a restore to see a list of offsite copy pool volumes to be mounted, you should you change the access mode of the identified volumes to UNAVAILABLE. This prevents reclamation and MOVE DATA processing for these volumes until they are transported to the onsite location for use in restore processing.
The preview displays the following:

- The number of files and bytes to be restored, if the access mode of the copy storage pool volumes is READWRITE or READONLY when the restoration is performed.
- A list of copy storage pool volumes containing files to be restored. These volumes must be mounted if you perform the restore.
- A list of volumes containing files that cannot be restored.

Wait
Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. This default is NO. Possible values are:

No
Specifies that the server processes this command in the background.

You can continue with other tasks while the command is being processed. Messages created from the background process are displayed either in the activity log or the server console, depending on where messages are logged.

To cancel a background process, use the CANCEL PROCESS command. If you cancel this process, some files may have already been backed up prior to the cancellation.

Yes

Specifies that the server processes this command in the foreground. The operation must complete before you can continue with other tasks. The server then displays the output messages to the administrative client when the command completes.
Remember: You cannot specify WAIT=YES from the server console.

Example: Restore primary volume data files

Restore files stored on volume PVOL2 in primary storage pool PRIMARY_POOL.

```
restore volume pvol2
```

Example: Restore primary volume data files from an active-data pool

Restore files stored on volume VOL001 in primary pool PRIMARY_POOL from active-data pool ADP1.

```
restore volume vol001 activedataonly=yes activedatapool=adp1
```

Related commands

Table 1. Commands related to RESTORE VOLUME

Command	Description
BACKUP STGPOOL	Backs up a primary storage pool to a copy storage pool.
COPY ACTIVEDATA	Copies active backup data.
CANCEL PROCESS	Cancels a background server process.
QUERY PROCESS	Displays information about background processes.
RESTORE STGPOOL	Restores files to a primary storage pool from copy storage pools.

REVOKE commands

Use the REVOKE commands to revoke privileges or access.

- REVOKE AUTHORITY (Remove administrator authority)
- REVOKE PROXYNODE (Revoke proxy authority for a client node)

REVOKE AUTHORITY (Remove administrator authority)

Use this command to revoke one or more privilege classes from an administrator.

You can also use this command to reduce the number of policy domains to which a restricted policy administrator has authority and the number of storage pools to which a restricted storage administrator has authority.

If you use the REVOKE AUTHORITY command without the CLASSES, DOMAINS, and STGPOOLS parameters, you will revoke all privileges for the specified administrator.

At least one administrator must have system privilege; therefore, if the administrator is the only one with system privilege, you cannot revoke the authority.

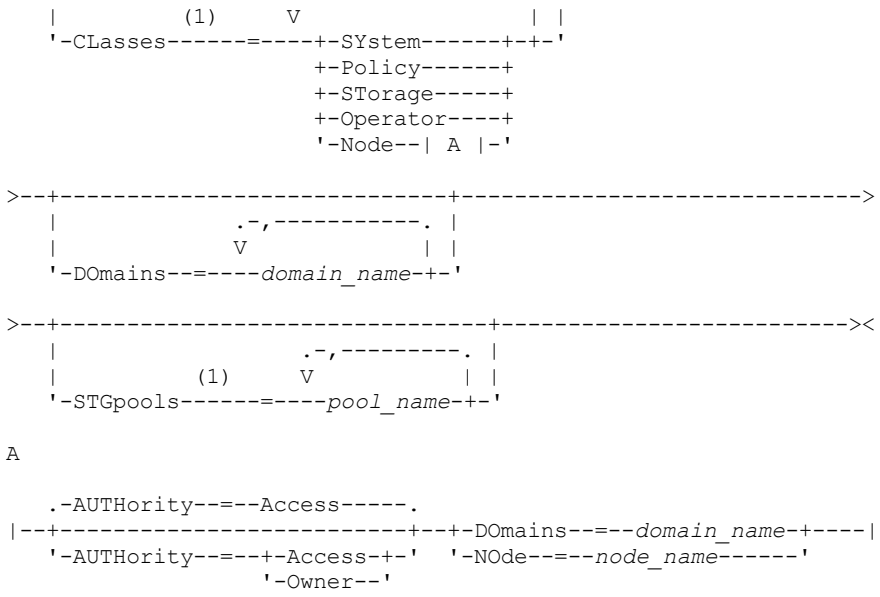
Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-REVoke AUTHority--admin_name--------------------------------->

>--+-------------------------------------+---------------------->
   |                 .-,---------------. |
```



Notes:

1. If all these parameters are omitted, all administrator privileges will be revoked for this administrator.

Parameters

admin_name (Required)
: Specifies the name of the administrator whose administrative privilege is to be revoked or reduced.

CLasses
: Specifies one or more administrative privilege classes to be revoked. You can specify more than one class by separating each with a comma.

  SYstem
  : Indicates that system authority is to be revoked for this administrator. If CLASSES=SYSTEM is specified, no other classes can be specified, and the DOMAINS and STGPOOLS parameters cannot be specified.

  Policy
  : Indicates that policy privilege is to be revoked for this administrator. To revoke all policy privilege, specify CLASSES=POLICY and do not specify the DOMAINS parameter.

  STorage
  : Indicates that storage privilege is to be revoked for this administrator. To revoke all storage privilege, specify CLASSES=STORAGE and do not specify the STGPOOLS parameter.

  Operator
  : Indicates that operator privilege is to be revoked for this administrator.

  Node
  : Indicates that node privilege is to be revoked for this user.

    AUTHority
    : Indicates the authority level to revoke for a user with node privilege. This parameter is optional.

      If an administrator already has system or policy privilege to the policy domain to which the node belongs, this command will not change the administrator's privilege.

      Possible authority levels are:

      Access
      : Indicates that client access authority is revoked. This is the default when CLASSES=NODE is specified. Note: A client node can set the REVOKEREMOTEACCESS option to prevent access by a user with node privilege and client access authority. If a user with node privilege has client owner authority, or has system or policy privileges to the policy domain to which the node belongs, that administrator can still access the web backup-archive client.

      Owner
      : Indicates that client owner authority is revoked.

DOmains
: Indicates that you want to revoke an administrator's client access or client owner authority to all clients in the specified policy domain. This parameter cannot be used together with the NODE parameter.

NOde
: Indicates that you want to revoke an administrator's client access or client owner authority to the node. This parameter cannot be used together with the DOMAIN parameter.

DOmains
: When used with CLASSES=POLICY, specifies a list of policy domains that can no longer be managed by a restricted policy administrator. (The administrator was authorized to manage these domains until the REVOKE command was issued.) This parameter is optional. The items in the list are separated by commas, with no intervening spaces. You can use wildcard characters to specify a name. Authority for all matching domains is revoked. If DOMAINS is specified, the parameter CLASSES=POLICY is optional.

STGpools
: Specifies a list of storage pools that can no longer be managed by a restricted policy administrator. (The administrator had been authorized to manage these storage pools until the REVOKE command was issued.) This parameter is optional. The items in the list are separated by commas, with no intervening spaces. You can use wildcard characters to specify a name. Authority for all matching storage pools will be revoked. If STGPOOLS is specified then the parameter CLASSES=STORAGE is optional.

Usage notes

1. To change an unrestricted storage administrator to a restricted storage administrator, you must first use this command to revoke the unrestricted privilege. Then, use the GRANT AUTHORITY command to grant the administrator restricted storage privilege and to identify the storage pools to which the administrator has authority.

   To revoke unrestricted storage privilege from an administrator, specify the CLASSES=STORAGE parameter. You cannot use the STGPOOLS parameter to revoke authority for selected storage pools from an unrestricted storage administrator.

2. To change an unrestricted policy administrator to a restricted policy administrator, you must first use this command to revoke the unrestricted privilege. Then, use the GRANT AUTHORITY command to grant the administrator restricted policy privilege and to identify the policy domains to which the administrator has authority.

   To revoke unrestricted policy privilege from an administrator, specify the CLASSES=POLICY parameter. You cannot use the DOMAINS parameter to revoke authority for selected domains from an unrestricted administrator.

Example: Revoke certain administrative privileges

Revoke part of administrator CLAUDIA's privileges. CLAUDIA has restricted policy privilege for the policy domains EMPLOYEE_RECORDS and PROG1. Restrict CLAUDIA's policy privilege to the EMPLOYEE_RECORDS policy domain.

```
revoke authority claudia classes=policy
domains=employee_records
```

Example: Revoke all administrative privileges

Administrator LARRY currently has operator and restricted policy privilege. Revoke all administrative privileges for administrator LARRY. To revoke all administrative privileges for an administrator, identify the administrator, but do not specify CLASSES, DOMAINS, or STGPOOLS. LARRY remains an administrator but he can only use those commands that can be issued by any administrator.

```
revoke authority larry
```

Example: Revoke node privilege

Help desk personnel user CONNIE currently has node privilege with client owner authority for client node WARD3. Revoke her node privilege with client owner authority.

```
revoke authority connie classes=node
authority=owner node=ward3
```

Related commands

Table 1. Commands related to REVOKE AUTHORITY

Command	Description
GRANT AUTHORITY	Assigns privilege classes to an administrator.
QUERY ADMIN	Displays information about one or more IBM Spectrum ProtectIBM Spectrum Protect™ administrators.

REVOKE PROXYNODE (Revoke proxy authority for a client node)

Use this command to revoke authority for an agent client node to perform backup and restore operations for a target node on the IBM Spectrum Protect™ server.

Privilege class

To issue this command, you must have one of the following privilege classes:

- System privilege
- Unrestricted policy privilege

Syntax

```
>>-REVoke PROXynode TArget--=--target_node_name----------------->

>--AGent--=--agent_node_name---------------------------------><
```

Parameters

TArget (Required)
: Specifies the target node to which an agent node has been granted proxy authority. Wildcard characters and comma-separated lists of node names are allowed.

AGent (Required)
: Specifies which node has authority to act as proxy to the target node. Wildcard characters and comma-separated lists of node names are allowed.

Example: Revoke a node's proxy authority

To revoke authority from target node NASCLUSTER to act as proxy for all agent nodes which start with the letter M, issue the following command.

```
revoke proxynode target=nascluster agent=m*
```

Related commands

Table 1. Commands related to REVOKE PROXYNODE

Command	Description
GRANT PROXYNODE	Grant proxy authority to an agent node.
QUERY PROXYNODE	Display nodes with authority to act as proxy nodes.

ROLLBACK (Rollback uncommitted changes in a macro)

Use this command within a macro to undo any processing changes made by commands run by the server but not yet committed to the database. A committed change is permanent and cannot be rolled back. The ROLLBACK command is useful for testing macros.

Ensure that your administrative client session is not running with the ITEMCOMMIT option when using this command.

Important: SETOPT commands inside a macro cannot be rolled back.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-ROLLBACK---------------------------------------------------><
```

Parameters

None

Example: Rollback changes in a macro

Run the REGN macro with the ROLLBACK command to verify that the macro works without committing any changes. The macro contents are:

```
/* Macro to register policy
administrators and grant authority */
REGister Admin sara hobby
GRant AUTHority sara CLasses=Policy
REGister Admin ken plane
GRant AUTHority ken CLasses=Policy
ROLLBACK  /* prevents any changes from being committed */
```

Administrative client macros

RUN (Run an IBM Spectrum Protect script)

Use this command to run an IBM Spectrum Protect™ script. To issue this command on another server, the script being run must be defined on that server.

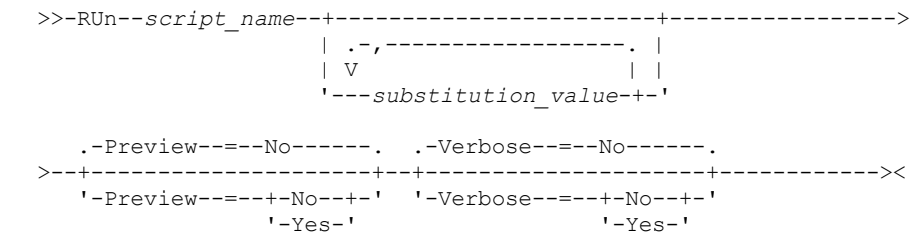
You can include RUN commands in scripts as long as they do not create loops. For example, you should avoid including RUN commands where SCRIPT_A runs SCRIPT_B and SCRIPT_B runs SCRIPT_A.

Important: IBM Spectrum Protect does not have a command that can cancel a script after it starts. To stop a script, you must halt the server.

Privilege class

To issue this command, you must have operator, policy, system, storage, or system privilege.

Syntax



Parameters

script_name (Required)
: Specifies the name of the script you want processed. The name you specify cannot be a substitution variable, such as $1.

substitution_value
: Specifies one or more values to substitute for variables when the script is run. In a script, a substitution variable consists of a '$' character, followed by a number. When you run the script, IBM Spectrum Protect replaces the substitution variables defined in a script with the values you supply with this command. You must specify values for each substitution variable defined in the script or the script will fail. This parameter is optional.

Preview
: Specifies whether to preview the command lines of a script without actually processing the script. The default is NO.
Possible values are:

  Yes
  : Specifies that the command lines included in a script are displayed, but the script is not processed.

  No
  : Specifies that the command lines included in a script are displayed and the script is processed.

Verbose
: Specifies whether command lines, variable substitution, and conditional logic testing used in a script are displayed as the script is being processed. This parameter is ignored if PREVIEW=YES is specified. The default is NO.
Possible values are:

  Yes
  : Specifies that the command lines, variable substitution, and conditional logic testing are displayed as the script is being processed.

  No
  : Specifies that the command lines, variable substitution, and conditional logic testing do not display as the script is being processed.

Example: View the commands generated by a script with a table name substitution variable

To run the following example script, called QSAMPLE, you issue a RUN command that specifies the table name ACTLOG as the value for the substitution variable, $1. Use the output to preview the commands generated by the script before running the commands.

```
001  /* This is a sample SQL Query in wide format */
005  SET SQLDISPLAYMODE WIDE
010  SELECT colname FROM -
015  COLUMNS WHERE TABNAME='$1'

run qsample actlog preview=yes

ANR1461I RUN: Executing command script QSAMPLE.
ANR1466I RUN: Command script QSAMPLE, Line 5 :
              set sqldisplaymode wide.
ANR1466I RUN: Command script QSAMPLE, Line 15 :
              select colname from columns where tabname='ACTLOG'.
ANR1470I RUN: Command script QSAMPLE completed successfully
              (PREVIEW mode)
```

Example: Run a script to display and run the commands generated by the script

Run the same script as show in the prior example to display both the generated commands and the results of the commands.

```
run qsample actlog verbose=yes

ANR1461I RUN: Executing command script QSAMPLE.
ANR1466I RUN: Command script QSAMPLE, Line 5 :
              set sqldisplaymode wide.
ANR1466I RUN: Command script QSAMPLE, Line 5 : RC=RC_OK
ANR1466I RUN: Command script QSAMPLE, Line 15 :
              select colname from columns where tabname='ACTLOG'.

COLNAME
------------------
DATE_TIME
```

```
MSGNO
SEVERITY
MESSAGE
ORIGINATOR
NODENAME
OWNERNAME
SCHEDNAME
DOMAINNAME
SESSID

ANR1462I RUN: Command script QSAMPLE, Line 15 : RC=RC_OK
ANR1462I RUN: Command script QSAMPLE completed successfully.
```

Example: Run a script to display just the results of the commands in the script

Run the previous example script, without displaying just the results of the generated commands in the script.

```
run qsample actlog verbose=no

COLNAME
------------------
DATE_TIME
MSGNO
SEVERITY
MESSAGE
ORIGINATOR
NODENAME
OWNERNAME
SCHEDNAME
DOMAINNAME
SESSID

ANR1462I RUN: Command script QSAMPLE completed successfully.
```

Related commands

Table 1. Commands related to RUN

Command	Description
COPY SCRIPT	Creates a copy of a script.
DEFINE SCRIPT	Defines a script to the IBM Spectrum Protect server.
DELETE SCRIPT	Deletes the script or individual lines from the script.
QUERY SCRIPT	Displays information about scripts.
RENAME SCRIPT	Renames a script to a new name.
UPDATE SCRIPT	Changes or adds lines to a script.

Related tasks:
Running a server script

SELECT (Perform an SQL query of the IBM Spectrum Protect database)

Use the SELECT command to create and format a customized query of the IBM Spectrum Protect™ database.

IBM Spectrum Protect provides an SQL interface to a DB2® program. Restrictions and guidelines for handling SQL queries are handled directly by DB2.

To help you find what information is available, IBM Spectrum Protect provides three system catalog tables:

SYSCAT.TABLES
: Contains information about all tables that can be queried with the SELECT command.

SYSCAT.COLUMNS
: Describes the columns in each table.

You can issue the SELECT command to query these tables to determine the location of the information that you want.

Usage notes

You cannot issue the SELECT command from a server console.

Because the select command does not lock and unlock records, contention for a record can cause the server to erroneously issue message ANR2034E: `SELECT: No match found using this criteria.` Check your selection criteria, and if you believe that it is correct, try the command again.

To stop the processing of a SELECT command after it starts, cancel the administrative session from which the command was issued. Cancel the session from either the server console or another administrative session.

Temporary table spaces are used to process SQL queries within DB2. Inadequate temporary space can cause SQL queries to fail.

To export output to a comma-separated file for import into a spreadsheet, use -comma and > command-line options on the dsmadmc command.

Privilege class

Any administrator can issue this command.

Syntax

For SELECT statement syntax and guidelines, search the DB2 product information.

Important: The appropriate syntax for the timestamp Select statement is:

```
SELECT * FROM SUMMARY WHERE ACTIVTY='EXPIRATION' AND START_TIME >'2009-05-10 00:00:00' AND
START_TIME <'2009-05-11 23:23:23'
```

List of examples

The SELECT command is used to customize a wide variety of queries. To give you an idea of what you can do with the command, this section includes many examples. There are, however, many more possibilities. Query output is shown only for the more complex commands to illustrate formatting.

The following list summarizes the example SELECT commands:

- List administrator user ID passwords that are authenticated with an external LDAP directory server
- List available tables
- List client nodes and administrative clients that are currently locked from server access
- List client nodes and administrative clients that have not specified the correct password lately
- List nodes in the standard policy domain that are not associated with the daily backup schedule DAILYBACKUP
- List the administrators that have policy authority
- List type E (ERROR) or W (WARNING) messages that have been issued in the time period for which activity log records have been maintained
- List the administrative schedules that have been defined or altered by administrator JAKE
- List the relative administrative schedule priorities
- List the management classes that have an archive copy group with a retention period greater than 365 days
- List the client nodes that are in each policy domain
- Count how many files have been archived from each node
- List the clients that are using space management
- Determine how many volumes would be reclaimed if the reclamation threshold is changed to 50 percent for storage pool TAPE
- Determine how many backup files would be affected for each node if the DAILY management class in the STANDARD policy domain is changed or deleted
- For all active client sessions, determine how long have they been connected and their effective throughput in bytes per second
- Determine how long the current background processes have been running and determine their effective throughput in time and files per second
- Count the number of client nodes are there for each platform type
- Count the number of file spaces each client node has and list the client nodes ascending order
- Obtain statistical information for calculating the number of off-site volumes that have their space reclaimed during reclamation of a storage pool
- Obtain PVU estimate detail records

- Obtain information about the node roles
- Obtain information about status

Example: List administrator user IDs that authenticate to the IBM Spectrum Protect server

List all the administrator user IDs whose passwords authenticate with the IBM Spectrum Protect server:

```
select admin_name from admins where
authentication=local
```

Example: List available tables

List all the tables available for querying the IBM Spectrum Protect database.

```
select * from syscat.tables
```

```
      ABSCHEMA: SERVER1
       TABNAME: ACTLOG
   CREATE_TIME: 1999-05-01 07:39:06
      COLCOUNT: 10
INDEX_COLCOUNT: 1
  UNIQUE_INDEX: FALSE
       REMARKS: Server activity log

     TABSCHEMA: SERVER1
       TABNAME: ADMIN_SCHEDULES
   CREATE_TIME: 1995-05-01 07:39:06
      COLCOUNT: 14
INDEX_COLCOUNT: 1
  UNIQUE_INDEX: TRUE
       REMARKS: Administrative command schedules

     TABSCHEMA: SERVER1
       TABNAME: ADMINS
   CREATE_TIME: 1995-05-01 07:39:06
      COLCOUNT: 15

       REMARKS: Server administrators

     TABSCHEMA: SERVER1
       TABNAME: ARCHIVES
   CREATE_TIME: 1995-05-01 07:39:06
      COLCOUNT: 10
INDEX_COLCOUNT: 5
  UNIQUE_INDEX: FALSE
       REMARKS: Client archive files
```

Example: List client nodes and administrative clients that are currently locked from server access

```
select node_name from nodes where locked='YES'

select admin_name from admins where locked='YES'
```

Example: List client nodes, administrative clients, and servers that are using transitional session security

```
select node_name from nodes where session_security='Transitional'

select admin_name from admins where session_security='Transitional'

select server_name from servers where session_security='Transitional'
```

Example: List client nodes and administrative clients that have not specified the correct password lately

```
select node_name from nodes where invalid_pw_count <>0

select admin_name from admins where invalid_pw_count <>0
```

Example: List nodes in the standard policy domain that are not associated with the daily backup schedule DAILYBACKUP

```
select node_name from nodes where domain_name='STANDARD' and
node_name not in (select node_name from associations
where domain_name='STANDARD' and
schedule_name='DAILYBACKUP')
```

Example: List the administrators who have policy authority

```
select admin_name from admins where
upper(system_priv) <>'NO'
or upper(policy_priv) <>'NO'
```

Example: List type E (ERROR) or W (WARNING) messages that have been issued in the time period for which activity log records have been maintained

```
select date_time,msgno,message from actlog
where severity='E' or severity='W'
```

Example: List the administrative schedules that have been defined or altered by administrator JAKE

```
select schedule_name from admin_schedules
where chg_admin='JAKE'
```

Example: List the relative administrative schedule priorities

```
select schedule_name,priority from admin_schedules order
by priority
```

Example: List the management classes that have an archive copy group with a retention period greater than 365 days

```
select domain_name,set_name,class_name from ar_copygroups
where retver='NOLIMIT' or cast(retver as integer) >365
```

Example: List the management classes that specify more than five backup versions

```
select domain_name,set_name,class_name from bu_copygroups
where verexists ='NOLIMIT' or
cast(verexists as integer)>5
```

Example: List the client nodes that are using the client option set named SECURE

```
select node_name from nodes where option_set='SECURE'
```

Example: List the client nodes that are in each policy domain

```
select domain_name,num_nodes from domains
```

Example: Count how many files have been archived from each node

Attention: This command might take a long time to complete.

```
select node_name,count(*) from archives
group by node_name
```

Example: List the clients that are using space management

```
select node_name from auditocc where spacemg_mb <>0
```

Example: Determine how many volumes would be reclaimed if the reclamation threshold is changed to 50 percent for storage pool TAPE

```
select count(*) from volumes where stgpool_name='TAPE'
and upper(status)='FULL' and pct_utilized < 50
```

Example: Determine how many backup files would be affected for each node if the DAILY management class in the STANDARD policy domain is changed or deleted

Note: This command takes significant time and resources to complete.

```
select node_name, count(*) as "Files" from backups
where class_name='DAILY' and node_name in
(select node_name from nodes where domain_name='STANDARD')
group by node_name
```

Example: For all active client sessions, determine how long have they been connected and their effective throughput in bytes per second

```
select session_id as "Session",
client_name as "Client",
state as "State",
current_timestamp-start_time as "Elapsed Time",
(cast(bytes_sent as decimal(18,0)) /
cast(second(current_timestamp-start_time) as decimal(18,0)))
as "Bytes sent/second",
(cast(bytes_received as decimal(18,0)) /
cast(second(current_timestamp-start_time) as decimal(18,0)))
as "Bytes received/second"
from sessions
```

```
                Session: 24
                 Client: ALBERT
                  State: Run
           Elapsed Time: 0 01:14:05.000000
      Bytes sent/second: 564321.9302768451
  Bytes received/second: 0.0026748857944

                Session: 26
                 Client: MILTON
                  State: Run
           Elapsed Time: 0 00:06:13.000000
      Bytes sent/second: 1638.5284210992221
  Bytes received/second: 675821.6888561849
```

Example: Determine how long the current background processes have been running and determine their effective throughput in time and files per second

Note: Expiration does not report the number of bytes processed.

```
select process_num as "Number",
process,
current_timestamp-start_time as "Elapsed Time",
(cast(files_processed as decimal(18,0)) /
cast(second(current_timestamp-start_time) as decimal(18,0)))
as "Files/second",
(cast(bytes_processed as decimal(18,0)) /
cast(second(current_timestamp-start_time) as decimal(18,0)))
as "Bytes/second"
from processes
```

```
         Number: 1
        PROCESS: Expiration
   Elapsed Time: 0 00:24:36.000000
   Files/second: 6.3216755870092
   Bytes/second: 0.0000000000000
```

Example: Count the number of client nodes for each platform type

```
select platform_name,count(*) as "Number of Nodes"
from nodes group by platform_name

PLATFORM_NAME     Number of Nodes
-------------     ---------------

  AIX                   6
  SunOS                27
  Win32                14
  Linux                20
```

Example: Count the number of file spaces each client node has and list the client nodes ascending order

```
select node_name, count(*) as "number of filespaces"
from filespaces group by node_name order by 2

NODE_NAME              number of filespaces
------------------     --------------------
    ALBERT                    2
    MILTON                    2
    BARNEY                    3
    SEBASTIAN                 3
    MAILHOST                  4
    FALCON                    4
    WILBER                    4
    NEWTON                    4
    JEREMY                    4
    WATSON                    5
    RUSSELL                   5
```

Example: Obtain statistical information for calculating the number of off-site volumes that have their space reclaimed during reclamation of a storage pool.

```
select * from summary where activity='OFFSITE RECLAMATION'

           START_TIME: 2004-06-16 13:47:31.000000
             END_TIME: 2004-06-16 13:47:34.000000
             ACTIVITY: OFFSITE RECLAMATION
               NUMBER: 4
               ENTITY: COPYPOOL
             COMMMETH:
              ADDRESS:
        SCHEDULE_NAME:
             EXAMINED: 170
             AFFECTED: 170
               FAILED: 0
                BYTES: 17821251
                 IDLE: 0
               MEDIAW: 0
           PROCESSES: 2
          SUCCESSFUL: YES
         VOLUME_NAME:
          DRIVE_NAME:
        LIBRARY_NAME:
            LAST_USE:
           COMM_WAIT:
    NUM_OFFSITE_VOLS: 2
```

Example: Identify which storage pools contain data that was deduplicated by clients

```
select stgpool_name,has_client_dedup_data from stgpools

STGPOOL_NAME               HAS_CLIENT_DEDUP_DATA
--------------------       --------------------
ADPOOL                     NO
ARCHIVEPOOL                NO
```

```
BACKUPPOOL                  NO
COPYDEDUP                   NO
COPYNODEDUP                 NO
FILEPOOL                    YES
FILEPOOL2                   NO
LANFREEFILEPOOL             YES
SPACEMGPOOL                 NO
```

Example: Obtain information about the database

```
select * from db
```

```
       DATABASE_NAME: TSMDB1
  TOT_FILE_SYSTEM_MB: 2048000
    USED_DB_SPACE_MB: 12576
       FREE_SPACE_MB: 1576871
         TOTAL_PAGES: 983044
        USABLE_PAGES: 982908
          USED_PAGES: 977736
          FREE_PAGES: 5172
      BUFF_HIT_RATIO: 96.2
      TOTAL_BUFF_REQ: 53967
       SORT_OVERFLOW: 0
     LOCK_ESCALATION: 0
       PKG_HIT_RATIO: 70.0
          LAST_REORG: 2010-07-15 17:32:55.000000
      FULL_DEV_CLASS: OUTFILE
     NUM_BACKUP_INCR: 0
    LAST_BACKUP_DATE: 2010-01-21 10:37:59.000000
    PHYSICAL_VOLUMES: 0
           PAGE_SIZE:
  NUM_BACKUP_STREAMS: 4
```

Example: Obtain PVU estimate detail records

Generate the PVU estimate for a node named ACCTSRECSRV, which is used by the IBM Spectrum Protect Extended Edition product.

```
select * from pvuestimate_details where node_name='ACCTSRECSRV'
```

```
            PRODUCT: PRODEE
       LICENSE_NAME: MGSYSLAN
          NODE_NAME: ACCTSRECSRV
          LAST_USED: 2008-01-20 16:12:24.000000
             TRYBUY: FALSE
        PROC_VENDOR: IBM
         PROC_BRAND: POWER5+ QCM
          PROC_TYPE: 4
         PROC_MODEL:
         PROC_COUNT: 2
               ROLE: SERVER
     ROLE_OVERRIDE: USEREPORTED
    ROLE_EFFECTIVE: SERVER
       VALUE_UNITS: 50
  VALUE_FROM_TABLE: YES
               PVU: 100

          MODEL_D: All Existing
        PRODUCT_D: IBM Spectrum Protect Extended Edition
```

Field descriptions

PRODUCT
: Rollup of license types into products at the level presented in the QUERY PVUESTIMATE command. Possible values are PRODEE, PROTBASIC, PRODDATARET, PRODMAIL, PRODDB, PRODSYSB, PRODSPACE, PRODSAN, PRODERP, or blank.

LICENSE_NAME
: The license assigned to this node.

NODE_NAME
: The node name.

LAST_USED
: Date and time the identified node last connected to the system under this license.

TRYBUY
: Indicates if running under try and buy mode. Possible values are TRUE or FALSE.

PROC_VENDOR
: Processor vendor name as reported by the client.

PROC_BRAND
: Processor brand name as reported by the client.

PROC_TYPE
: Processor type as reported by the client. This value also reflects the number of cores. Example values are 1=SINGLE CORE, 2=DUO CORE, and 4=QUAD CORE.

PROC_MODEL
: Processor model as reported by the client.

PROC_COUNT
: Processor quantity.

ROLE
: Node role. Possible values are CLIENT, SERVER, or OTHER.

ROLE_OVERRIDE
: Override value specified in the UPDATE NODE command.

ROLE_EFFECTIVE
: Actual role based on the values in the ROLE and ROLE_OVERRIDE fields.

VALUE_UNITS
: Assigned processor value unit (PVU) for the processor.

PVU
: Calculated PVU value.

```
PVU per node = number of processors per node * processor type * pvu value
```

where the `processor type` represents the number of cores, and the `pvu value` is the value defined for the processor type in the IBM® PVU table.

VALUE_FROM_TABLE
: Flag that indicates whether the PVU was calculated based on the IBM PVU table. Possible values are YES or NO. If NO, a value of 100 is applied for each node defined as a server. If no role is defined for a node, the role of server is assumed for purposes of PVU calculation.

SCAN_ERROR
: Flag that indicates whether license information was reported by client. Possible values are YES or NO.

API_CLIENT
: Flag that indicates an API application. Possible values are YES or NO.

PVU_AGNOSTIC
: Flag indicating that the client version release level is earlier than IBM Spectrum Protect V6.3. If the version is earlier than 6.3, valid PVU metrics are not expected. Possible values are YES or NO.

HYPERVISOR
: Name of the virtual machine software as reported by the client.

GUID
: Globally Unique Identifier (GUID) of the computer where the node is located. The GUID is obtained from the node table.

VERSION
: Version of client.

RELEASE
: Release of client.

LEVEL
: Level of client.

VENDOR_D
: Processor vendor display value from the PVU table.

BRAND_D
: Processor brand display value from the PVU table.

TYPE_D
: Processor type display value from the PVU table.

MODEL_D
: Processor model display value from the PVU table.

PRODUCT_D
: Product display value from the PVU table. The following values are possible:

  - IBM Spectrum Protect
  - IBM Spectrum Protect Extended Edition
  - IBM Spectrum Protect for Data Retention
  - IBM Spectrum Protect for SAN
  - IBM Spectrum Protect for Space Management
  - IBM Spectrum Protect for Mail
  - IBM Spectrum Protect for Databases
  - IBM Spectrum Protect for Enterprise Resource Planning
  - IBM Spectrum Protect for System Backup and Recovery
  - Blank

Example: Obtain role and PVU-related information

The following example shows partial results for a selected node, including PVU-related information and role information. Possible roles are CLIENT, SERVER, or OTHER. PVU is calculated only for nodes defined as servers.

```
select * from nodes

  ROLE: CLIENT
      ROLE_O: USEREPORTED
     PVENDOR: INTEL
      PBRAND: INTEL
       PTYPE: 4
      PMODEL:
      PCOUNT: 1
  HYPERVISOR:
        PAPI: NO
   SCANERROR: NO
```

SET commands

Use the SET commands to specify values that affect many different IBM Spectrum Protect™ operations.

- SET ACCOUNTING (Set accounting records on or off)
- SET ACTLOGRETENTION (Set the retention period or the size of the activity log)
- SET ALERTACTIVEDURATION (Set the duration of an active alert)
- SET ALERTCLOSEDDURATION (Set the duration of a closed alert)
- SET ALERTEMAIL (Set the alert monitor to email alerts to administrators)
- SET ALERTEMAILFROMADDR (Set the email address of the sender)
- SET ALERTEMAILSMTPHOST (Set the SMTP mail server host name)
- SET ALERTEMAILSMTPPORT (Set the SMTP mail server host port)
- SET ALERTINACTIVEDURATION (Set the duration of an inactive alert)
- SET ALERTMONITOR (Set the alert monitor to on or off)
- SET ALERTSUMMARYTOADMINS (Set the list of administrators to receive alert summaries by email)
- SET ALERTUPDATEINTERVAL (Set how often the alert monitor updates and prunes alerts)
- SET ARCHIVERETENTIONPROTECTION (Activate data retention protection)
- SET ARREPLRULEDEFAULT (Set the server replication rule for archive data)
- SET BKREPLRULEDEFAULT (Set the server replication rule for backup data)
- SET CLIENTACTDURATION (Set the duration period for the client action)
- SET CONFIGMANAGER (Specify a configuration manager)
- SET CONFIGREFRESH (Set managed server configuration refresh)
- SET CONTEXTMESSAGING (Set message context reporting on or off)
- SET CPUINFOREFRESH (Refresh interval for the client workstation information scan)
- SET CROSSDEFINE (Specifies whether to cross-define servers)
- SET DBRECOVERY (Set the device class for automatic backups)

- SET DEDUPVERIFICATIONLEVEL (Set the percentage of extents to verify)
- SET DEFAULTAUTHENTICATION (Set the default authentication method for REGISTER NODE and REGISTER ADMIN commands)
- SET DISSIMILARPOLICIES (Enable the policies on the target replication server to manage replicated data)
- SET DRMACTIVEDATASTGPOOL (Specify the active-data pools to be managed by DRM)
- SET DRMCHECKLABEL (Specify label checking)
- SET DRMCMDFILENAME (Specify the name of a file to contain commands)
- AIX Linux Windows SET DRMCOPYCONTAINERSTGPOOL (Specify the container-copy storage pools to be processed by DRM commands)
- SET DRMCOPYSTGPOOL (Specify the copy storage pools to be managed by DRM)
- SET DRMCOURIERNAME (Specify the courier name)
- SET DRMDBBACKUPEXPIREDAYS (Specify DB backup series expiration)
- SET DRMFILEPROCESS (Specify file processing)
- SET DRMINSTRPREFIX (Specify the prefix for recovery instructions file names)
- SET DRMNOTMOUNTABLENAME (Specify the not mountable location name)
- SET DRMPLANPREFIX (Specify a prefix for recovery plan file names)
- SET DRMPLANVPOSTFIX (Specify replacement volume names)
- SET DRMPRIMSTGPOOL (Specify the primary storage pools to be managed by DRM)
- SET DRMRPFEXPIREDAYS (Set criteria for recovery plan file expiration)
- SET DRMVAULTNAME (Specify the vault name)
- SET EVENTRETENTION (Set the retention period for event records)
- SET FAILOVERHLADDRESS (Set a failover high level address)
- SET INVALIDPWLIMIT (Set the number of invalid logon attempts)
- SET LDAPPASSWORD (Set the LDAP password for the server)
- SET LDAPUSER (Specify an ID for an LDAP directory server)
- SET LICENSEAUDITPERIOD (Set license audit period)
- SET MAXCMDRETRIES (Set the maximum number of command retries)
- SET MAXSCHEDSESSIONS (Set maximum scheduled sessions)
- SET MINPWLENGTH (Set minimum password length)
- SET MONITORINGADMIN (Set the name of the monitoring administrator)
- SET MONITOREDSERVERGROUP (Set the group of monitored servers)
- SET NODEATRISKINTERVAL (Specifies at-risk mode for an individual node)
- SET PASSEXP (Set password expiration date)
- SET PRODUCTOFFERING (Set the product offering that is licensed to your enterprise)
- SET QUERYSCHEDPERIOD (Set query period for polling client nodes)
- SET RANDOMIZE (Set randomization of scheduled start times)
- SET REPLRECOVERDAMAGED (Specify whether damaged files are recovered from a replication server)
- SET REPLRETENTION (Set the retention period for replication records)
- SET REPLSERVER (Set the target replication server)
- SET RETRYPERIOD (Set time between retry attempts)
- SET SCHEDMODES (Select a central scheduling mode)
- SET SERVERHLADDRESS (Set the high-level address of a server)
- SET SERVERLLADDRESS (Set the low-level address of a server)
- SET SERVERNAME (Specify the server name)
- SET SERVERPASSWORD (Set password for server)
- SET SPREPLRULEDEFAULT (Set the server replication rule for space-managed data)
- SET STATUSATRISKINTERVAL (Specifies whether to enable client at-risk activity interval evaluation)
- SET STATUSMONITOR (Specifies whether to enable status monitoring)
- SET STATUSREFRESHINTERVAL (Set refresh interval for status monitoring)
- SET STATUSSKIPASFAILURE (Specifies whether to use client at-risk skipped files as failure evaluation)
- SET SUBFILE (Set subfile backup for client nodes)
- SET SUMMARYRETENTION (Set number of days to keep data in activity summary table)
- SET TAPEALERTMSG (Set tape alert messages on or off)
- SET TOCLOADRETENTION (Set load retention period for table of contents)
- SET VMATRISKINTERVAL (Specifies the at-risk mode for an individual VM filespace)

SET ACCOUNTING (Set accounting records on or off)

Use this command to determine whether an accounting record is created every time a client node session ends. An accounting record tracks the amount of storage used by a client node session.

Use the QUERY STATUS command to determine whether accounting records are generated. At installation, this value is set to OFF.

The accounting records are stored in an accounting file named dsmaccnt.log.

AIX Linux The environment variable, DSMSERV_ACCOUNTING_DIR, specifies the directory where the accounting file is located.

Windows A registry entry controls the location of the accounting log.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set ACCounting--+-ON--+-------------------------------------><
                   '-OFf-'
```

Parameters

ON
: Specifies that the server creates an accounting record every time a client node session ends.

OFf
: Specifies that the server does not create accounting records.

Example: Create accounting records

To create an accounting record at the end of each client node session issue the command:

```
set accounting on
```

Related commands

Table 1. Commands related to SET ACCOUNTING

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

SET ACTLOGRETENTION (Set the retention period or the size of the activity log)

Use this command to manage the activity log records by date or size. The activity log contains normal activity messages generated by the server. These messages include information about server and client operations, such as the start time of sessions or device I/O errors.

Activity log information includes messages, such as the following:

- Client session starts and ends
- Migration starts and ends
- Diagnostic error messages
- Scheduled administrative command output

At server installation, activity log management is retention-based, and the retention period is set to 30 days.

You can choose to adjust the length of time that the activity log retains messages to avoid insufficient or outdated data. The server automatically removes the messages from the activity log after the retention period passes.

Alternatively, you can choose to limit the total size of the activity log to control the amount of space occupied by the activity log. The server will periodically remove the oldest activity log records until the activity log size no longer exceeds the configured maximum size allowed.

You can issue the QUERY STATUS command to display the current number of records in the activity log and the size (in megabytes) that the activity log currently occupies.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                                .-Mgmtstyle--=--Date-----.
>>-Set ACTlogretention--number--+------------------------+-----><
                                '-Mgmtstyle--=--+-Date-+-'
                                                '-Size-'
```

Parameters

number (Required)
: Specifies the number of days to retain messages in the activity log when the log is managed by date, or specifies the maximum size of the activity log when it is managed by size. With retention-based management, a value of 1 specifies to retain the activity log records only for the current day. With size-based management, a value of 1 specifies a maximum size of 1 MB for the activity log. You can specify a number from 0 to 9999. A value of 0 disables activity log retention.

Mgmtstyle
: Specifies whether activity log management is retention-based or size-based. This parameter is optional. The default is DATE. Possible values are:

  Date
  : Specifies that activity log management is retention-based.

  Size
  : Specifies that activity log management is size-based.

Example: Set the activity log retention period

Set the server to retain activity log records for 60 days. Issue the command:

```
set actlogretention 60
```

Example: Set the activity log size

Set the server to limit the size of the activity log to 300 MB. Issue the command:

```
set actlogretention 300 mgmtstyle=size
```

Related commands

Table 1. Command related to SET ACTLOGRETENTION

Command	Description
QUERY ACTLOG	Displays messages from the server activity log.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

SET ALERTACTIVEDURATION (Set the duration of an active alert)

Use this command to specify how long an alert remains active before it is becomes inactive. If an active alert is triggered again, the duration is restarted.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set ALERTACtiveduration -number_mins------------------------><
```

Parameters

number_mins (Required)
: Specifies the number of minutes that an alert remains active before it is becomes inactive. Specify a value from 1 to 20160. The initial server default value is 480 minutes.

Set the duration of an active alert to one day

Issue the following command to specify that alerts remain active for 1440 minutes before they change to inactive status:

```
set alertactiveduration 1440
```

Related commands

Table 1. Commands related to SET ALERTACTIVEDURATION

Command	Description
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
SET ALERTINACTIVEDURATION (Set the duration of an inactive alert)	Specifies how long an alert remains inactive before it is closed.
SET ALERTCLOSEDDURATION (Set the duration of a closed alert)	Specifies how long an alert remains closed before it is deleted.
SET ALERTMONITOR (Set the alert monitor to on or off)	Specifies whether alert monitoring is set to on or off.
SET ALERTUPDATEINTERVAL (Set how often the alert monitor updates and prunes alerts)	Specifies how often the alert monitor updates and prunes alerts from the database.

SET ALERTCLOSEDDURATION (Set the duration of a closed alert)

Use this command to specify how long an alert remains closed before it is deleted.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set ALERTCLosedduration -number_mins------------------------><
```

Parameters

number_mins (Required)
: Specifies the number of minutes that an alert remains closed before it is deleted. Setting the value to 0 causes alerts to be deleted immediately after they are closed. Specify a value from 0 to 99999. The default value is set to 60 minutes when the IBM Spectrum Protect™ server database is initially formatted.

Delete alerts two hours after they are closed

Specify that alerts remain closed for 120 minutes before they are deleted:

```
set alertclosedduration 120
```

Related commands

Table 1. Commands related to SET ALERTCLOSEDDURATION

Command	Description
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
SET ALERTACTIVEDURATION (Set the duration of an active alert)	Specifies how long an alert remains active before it is moved to inactive status.
SET ALERTINACTIVEDURATION (Set the duration of an inactive alert)	Specifies how long an alert remains inactive before it is closed.
SET ALERTMONITOR (Set the alert monitor to on or off)	Specifies whether alert monitoring is set to on or off.
SET ALERTUPDATEINTERVAL (Set how often the alert monitor updates and prunes alerts)	Specifies how often the alert monitor updates and prunes alerts from the database.

SET ALERTEMAIL (Set the alert monitor to email alerts to administrators)

Use this command to enable alerts to be sent to specified administrators by email.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set ALERTEMail--+-ON--+-------------------------------------><
                   '-OFf-'
```

Parameters

ON
: Specifies that alerts can be sent to specified administrators by email.

OFf
: Specifies that alerts cannot be sent to specified administrators by email. When the server database is initially formatted, the ALERTEMAIL setting is set to OFF.

Enable alerts to be sent to the administrator when they occur

Enable alerts to be sent by email by issuing the following command:

```
SET ALERTEMAIL ON
```

Related commands

Table 1. Commands related to SET ALERTEMAIL

Command	Description
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
SET ALERTEMAILFROMADDR (Set the email address of the sender)	Specifies the email address of the alert sender.
SET ALERTEMAILSMTPHOST (Set the SMTP mail server host name)	Specifies the SMTP mail server host name that is used to send alerts by email.
SET ALERTEMAILSMTPPORT (Set the SMTP mail server host port)	Specifies the SMTP mail server port that is used to send alerts by email.

Command	Description
SET ALERTSUMMARYTOADMINS (Set the list of administrators to receive alert summaries by email)	Specifies the administrators that want to receive alert summaries by email.

SET ALERTEMAILFROMADDR (Set the email address of the sender)

Use this command to specify the email address of the alert sender.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set ALERTEMAILFRomaddr -email_address----------------------><
```

Parameters

email_address (Required)
: Specifies the email address of the sender. Email addresses are in the form of *name@domain*. Email names, including the address, cannot exceed 64 characters in length, and the domain name cannot exceed 255 characters in length.

Specify the email address of the alert sender

Specify the email address of the sender by issuing the following command:

```
set alertemailfromaddr djadmin@mydomain.com
```

Related commands

Table 1. Commands related to SET ALERTEMAILFROMADDR

Command	Description
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
SET ALERTEMAIL (Set the alert monitor to email alerts to administrators)	Enables alerts to be sent by email to specified administrators.
SET ALERTEMAILSMTPHOST (Set the SMTP mail server host name)	Specifies the SMTP mail server host name that is used to send alerts by email.
SET ALERTEMAILSMTPPORT (Set the SMTP mail server host port)	Specifies the SMTP mail server port that is used to send alerts by email.
SET ALERTSUMMARYTOADMINS (Set the list of administrators to receive alert summaries by email)	Specifies the administrators that want to receive alert summaries by email.

SET ALERTEMAILSMTPHOST (Set the SMTP mail server host name)

Use this command to specify the Simple Mail Transfer Protocol (SMTP) mail server host name that is used to send the alert email.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set ALERTEMAILSMTPHost--host_name---------------------------><
```

Parameters

host_name (Required)
Specifies the SMTP mail server host name.

Specify the host name for the SMTP mail server as mail.domain.com

Specify `mail.domain.com` as the SMTP mail server, by issuing the following command:

```
set alertemailsmtphost mail.domain.com
```

Related commands

Table 1. Commands related to SET ALERTEMAILSMTPHOST

Command	Description
SET ALERTEMAIL (Set the alert monitor to email alerts to administrators)	Enables alerts to be sent by email to specified administrators.
SET ALERTEMAILFROMADDR (Set the email address of the sender)	Specifies the email address of the alert sender.
SET ALERTEMAILSMTPPORT (Set the SMTP mail server host port)	Specifies the SMTP mail server port that is used to send alerts by email.
SET ALERTSUMMARYTOADMINS (Set the list of administrators to receive alert summaries by email)	Specifies the administrators that want to receive alert summaries by email.

SET ALERTEMAILSMTPPORT (Set the SMTP mail server host port)

Use this command to specify the port number for the SMTP mail server. This mail server is used to send the alerts by email.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set ALERTEMAILSMTPPort--tcp_port---------------------------><
```

Parameters

tcp_port (Required)
Specifies the port number of the SMTP mail server. Specify a value of 1 through 32767. The default port number is 25.

Specify the port number of the SMTP mail server

Specify port number 450 as your SMTP mail server by issuing the following command:

```
set alertemailsmtpport 450
```

Related commands

Table 1. Commands related to SET ALERTEMAILSMTPPORT

Command	Description

Command	Description
SET ALERTEMAIL (Set the alert monitor to email alerts to administrators)	Enables alerts to be sent by email to specified administrators.
SET ALERTEMAILFROMADDR (Set the email address of the sender)	Specifies the email address of the alert sender.
SET ALERTEMAILSMTPHOST (Set the SMTP mail server host name)	Specifies the SMTP mail server host name that is used to send alerts by email.
SET ALERTSUMMARYTOADMINS (Set the list of administrators to receive alert summaries by email)	Specifies the administrators that want to receive alert summaries by email.

SET ALERTSUMMARYTOADMINS (Set the list of administrators to receive alert summaries by email)

Use this command to specify the administrators that want to receive alert summaries by email, every hour.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set ALERTSUMMARYToadmins--+-admin_name-+--------------------><
                             '-,----------'
```

Parameters

admin_name (Required)
: Specifies the administrator name that wants to receive alert summaries by email. You can specify up to three administrator names by separating them with commas and no intervening spaces.

Specify two administrators to receive alert summaries

Specify that administrators HARRY and COLIN want to receive alert summaries, by issuing the following command:

```
set alertsummarytoadmins HARRY,COLIN
```

Related commands

Table 1. Commands related to SET ALERTSUMMARYTOADMINS

SET ALERTEMAILSMTPHOST (Set the SMTP mail server host name)	Specifies the SMTP mail server host name that is used to send alerts by email.
SET ALERTEMAILSMTPPORT (Set the SMTP mail server host port)	Specifies the SMTP mail server port that is used to send alerts by email.

SET ALERTINACTIVEDURATION (Set the duration of an inactive alert)

Use this command to specify how long an alert remains inactive. After the inactive duration is past, the alert is closed.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set ALERTINactiveduration -number_mins---------------------><
```

Parameters

number_mins (Required)
: Specifies the number of minutes that an alert remains inactive before it is closed. You can specify a value in the range 1 - 20160. The initial server default value is 480 minutes.

Change alert status from inactive to closed after 60 minutes

Issue the following command to specify that an alert remains in inactive status for 60 minutes before it changes to closed status:

```
set alertinactiveduration 60
```

Related commands

Table 1. Commands related to SET ALERTINACTIVEDURATION

Command	Description
SET ALERTACTIVEDURATION (Set the duration of an active alert)	Specifies how long an alert remains active before it is moved to inactive status.
SET ALERTCLOSEDDURATION (Set the duration of a closed alert)	Specifies how long an alert remains closed before it is deleted.
SET ALERTMONITOR (Set the alert monitor to on or off)	Specifies whether alert monitoring is set to on or off.
SET ALERTUPDATEINTERVAL (Set how often the alert monitor updates and prunes alerts)	Specifies how often the alert monitor updates and prunes alerts from the database.

SET ALERTMONITOR (Set the alert monitor to on or off)

Use this command to turn the alert monitor on or off.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                    .-OFf-.
>>-Set ALERTMONITOR -+-ON--+-----------------------------------><
```

Parameters

ON
: Specifies that the IBM Spectrum Protect™ server monitors alerts.

OFf
: Specifies that the IBM Spectrum Protect server does not monitor alerts. When the IBM Spectrum Protect server database is initially formatted, the alert monitoring setting is set to OFF.

Turn on alert monitoring

Turn on alert monitoring by issuing the following command:

```
set alertmonitor on
```

Related commands

Table 1. Commands related to SET ALERTMONITOR

Command	Description
SET ALERTACTIVEDURATION (Set the duration of an active alert)	Specifies how long an alert remains inactive before it is closed.
SET ALERTINACTIVEDURATION (Set the duration of an inactive alert)	Specifies how long an alert remains inactive before it is closed.
SET ALERTCLOSEDDURATION (Set the duration of a closed alert)	Specifies how long an alert remains closed before it is deleted.
SET ALERTUPDATEINTERVAL (Set how often the alert monitor updates and prunes alerts)	Specifies how often the alert monitor updates and prunes alerts from the database.

SET ALERTUPDATEINTERVAL (Set how often the alert monitor updates and prunes alerts)

Use this command to specify how often the alert monitor updates and prunes alerts that are stored in the IBM Spectrum Protect™ server database.

During this check interval, the alert monitor examines each alert on the server and completes the following actions:

- The alert monitor determines whether the active or inactive durations elapsed. If the specified duration elapses, the alert status is updated to the next state. For example:
  - Active to Inactive
  - Inactive to Closed
- If an alert is closed for the duration that is specified by the SET ALERTCLOSEDDURATION command, the alert is deleted.

You can use the QUERY MONITORSETTINGS command to determine whether alert monitoring is on. Use the SET ALERTMONITOR command to turn on alert monitoring.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set ALERTUPDateinterval -number_mins------------------------><
```

Parameters

number_mins (Required)
: Specifies the length of time, in minutes, that the monitor waits before alerts are updated and pruned on the server. Specify a value from 1 to 9999. The server has an initial default value of 10 minutes.

Set alert update interval to 60 minutes

Specify that alerts are updated every hour by issuing the following command:

```
set alertupdateinterval  60
```

Related commands

Table 1. Commands related to SET ALERTUPDATEINTERVAL

Command	Description
SET ALERTACTIVEDURATION (Set the duration of an active alert)	Specifies how long an alert remains active before it is moved to inactive status.
SET ALERTINACTIVEDURATION (Set the duration of an inactive alert)	Specifies how long an alert remains inactive before it is closed.
SET ALERTCLOSEDDURATION (Set the duration of a closed alert)	Specifies how long an alert remains closed before it is deleted.
SET ALERTMONITOR (Set the alert monitor to on or off)	Specifies whether alert monitoring is set to on or off.

SET ARCHIVERETENTIONPROTECTION (Activate data retention protection)

Use this command to activate and deactivate archive data retention protection. The server cannot contain any data in order for this command to work. At installation, the value is set to OFF.

When archive data retention protection is active:

- Only archive copies can be stored on the server.
- No archive copy can be deleted until the RETVER parameter in the DEFINE COPYGROUP (archive) command is satisfied.

Defining storage pools of type RECLAMATIONTYPE=SNAPLOCK is only supported on servers with data retention protection enabled.

Use the QUERY STATUS command to display the status of archive data retention protection.

Privilege class

To issue this command you must have system privilege or unrestricted storage privilege.

Syntax

Parameters

OFf
: Specifies that archive data retention protection is not active.

ON
: Specifies the archive data retention protection is active.

Example: Activate data retention protection

Activate archive data retention protection by issuing the following command:

```
set archiveretentionprotection on
```

Related commands

Table 1. Commands related to SET ARCHIVERETENTIONPROTECTION

Command	Description
ACTIVATE POLICYSET	Validates and activates a policy set.
AUDIT VOLUME	Compares database and storage pool information, and optionally, resolves any inconsistencies.

Command	Description
DEFINE COPYGROUP	Defines a copy group for backup or archive processing within a specified management class.
DEFINE VOLUME	Assigns a volume to be used for storage within a specified storage pool.
DELETE FILESPACE	Deletes data associated with client file spaces. If a file space is part of a collocation group and you remove the file space from a node, the file space is removed from the collocation group.
QUERY COPYGROUP	Displays the attributes of a copy group.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
UPDATE COPYGROUP	Changes one or more attributes of a copy group.

SET ARREPLRULEDEFAULT (Set the server replication rule for archive data)

Use this command to set the server replication rule for archive data.

Restriction: The replication rule that you set with this command is applied only if file space rules and client node rules for archive data are set to DEFAULT.

Issue this command on the server that acts as a source for replicated data.

You can specify a normal-priority replication rule or a high-priority replication rule. In a replication process that includes both normal-priority and high-priority data, high-priority data is replicated first. Before you specify a rule, consider the order in which you want the data to be replicated.

For example, suppose that your client nodes contain archive data and backup data. Replication of the archive data is a higher priority than the backup data. To prioritize the archive data, issue the SET ARREPLRULEDEFAULT command and specify the ALL_DATA_HIGH_PRIORITY replication rule. To prioritize the backup data, issue the SET BKREPLRULEDEFAULT command and specify the ALL_DATA replication rule for backup data. The ALL_DATA rule for backup data replicates backup data with a normal priority.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set ARREPLRuledefault--+-ALL_DATA----------------+----------><
                          +-ALL_DATA_HIGH_PRIORITY-+
                          '-NONE--------------------'
```

Parameters

ALL_DATA
: Replicates archive data with a normal priority.

ALL_DATA_HIGH_PRIORITY
: Replicates archive data with a high priority.

NONE
: Archive data is not replicated.

Example: Set the server replication rule for archive data

Set up the default rule for archive data to replicate with a high priority.

```
set arreplruledefault all_data_high_priority
```

Related commands

Table 1. Commands related to SET ARREPLRULEDEFAULT

Command	Description
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY REPLICATION	Displays information about node replication processes.
QUERY REPLRULE	Displays information about node replication rules.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
SET BKREPLRULEDEFAULT	Specifies the server node-replication rule for backup data.
SET SPREPLRULEDEFAULT	Specifies the server node-replication rule for space-managed data.
UPDATE FILESPACE	Changes file-space node-replication rules.
UPDATE REPLRULE	Enables or disables replication rules.
VALIDATE REPLICATION	Verifies replication for file spaces and data types.

SET BKREPLRULEDEFAULT (Set the server replication rule for backup data)

Use this command to set the server replication rule for backup data.

Restriction: The replication rule that you set with this command is applied only if file space rules and client node rules for backup data are set to DEFAULT.

Issue this command on the server that acts as a source for replicated data.

You can specify normal-priority replication rules or high-priority replication rules. In a replication process that includes both normal and high-priority data, high-priority data is replicated first. Before you specify a rule, consider the order in which you want the data to be replicated.

For example, suppose that your client nodes contain archive data and active backup data. Replication of the active backup data is a higher priority than the archive data. To prioritize the backup data, issue the SET BKREPLRULEDEFAULT command and specify the ACTIVE_DATA_HIGH_PRIORITY replication rule. To prioritize the archive data, issue the SET ARREPLRULEDEFAULT command and specify the ALL_DATA replication rule for archive data. The ALL_DATA rule for archive data replicates archive data with a normal priority.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set BKREPLRuledefault--+-ALL_DATA------------------+--------><
                          +-ACTIVE_DATA----------------+
                          +-ALL_DATA_HIGH_PRIORITY----+
                          +-ACTIVE_DATA_HIGH_PRIORITY-+
                          '-NONE----------------------'
```

Parameters

ALL_DATA
: Replicates active and inactive backup data. The data is replicated with normal priority.

ACTIVE_DATA
: Replicates active backup data. The data is replicated with normal priority.
Attention: If you specify ACTIVE_DATA and one or more of the following conditions are true, inactive backup data on the target replication server is deleted, and inactive backup data on the source replication server is not replicated.

- When a server version earlier than Version 7.1.1 is installed on either the source or target replication servers.
- When you are using the REPLICATE NODE command with the `FORCERECONCILE=YES` parameter.
- When you are running the initial replication of a file space after you configure replication, restore the database, or upgrade both the source and target replication servers from a server version earlier than V7.1.1.

If the previous conditions are not true, all new and changed files since the last replication are replicated, including inactive files, and files are deleted when they expire.

ALL_DATA_HIGH_PRIORITY
: Replicates active and inactive backup data. Data is replicated with a high priority.

ACTIVE_DATA_HIGH_PRIORITY

This rule is the same as the ACTIVE_DATA replication rule except data is replicated with a high priority.

NONE
: Backup data is not replicated.

Example: Set the server replication rule for backup data

Set up the default rule for backup data to replicate only active data and to replicate the data with a high priority.

```
set bkreplruledefault active_data_high_priority
```

Related commands

Table 1. Commands related to SET BKREPLRULEDEFAULT

Command	Description
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY REPLICATION	Displays information about node replication processes.
QUERY REPLRULE	Displays information about node replication rules.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
SET ARREPLRULEDEFAULT	Specifies the server node-replication rule for archive data.
SET REPLRETENTION	Specifies the retention period for replication history records.
SET SPREPLRULEDEFAULT	Specifies the server node-replication rule for space-managed data.
UPDATE FILESPACE	Changes file-space node-replication rules.
UPDATE REPLRULE	Enables or disables replication rules.
VALIDATE REPLICATION	Verifies replication for file spaces and data types.

SET CLIENTACTDURATION (Set the duration period for the client action)

Use this command to specify the duration for the schedule that was defined with the DEFINE CLIENTACTION command. A client action defines a schedule that runs one time on a client.

The program deletes these event records whether or not the client has processed the schedule. However, the schedules are not deleted until after the first event records are deleted. The retention period for events defaults to 10 days at installation.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-SET CLIENTACTDuration--days---------------------------------><
```

Parameters

days (Required)
Specifies the number of days during which the schedule for the client action is active. You can specify an integer from 0 to 999. The default is 5 days.

The number of days you specify determines how long the database retains the schedule before deletion. A value of 0 indicates that the schedule duration is indefinite, and the schedule and associations are not deleted from the database.

Example: Set a 15–day duration period for the client action

To specify that the schedule for the client action be active for 15 days issue the following command.

```
set clientactduration 15
```

Related commands

Table 1. Commands related to SET CLIENTACTDURATION

Command	Description
DEFINE CLIENTACTION	Defines a command to be performed at a client node.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

SET CONFIGMANAGER (Specify a configuration manager)

Use this command to specify whether a server is a configuration manager. On a configuration manager, you can define configuration profiles to which other servers can subscribe.

You cannot designate a server as a configuration manager if the server subscribes to one or more profiles on another configuration manager.

If a server is a configuration manager, you cannot change this designation until you delete all profiles, including the default profile.

Issue the QUERY STATUS command to determine if a server is a configuration manager. When a server is installed, it is not designated as a configuration manager.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                      .-OFf-.
>>-Set CONFIGManager--+-----+---------------------------------><
                      '-ON--'
```

Parameters

ON
: Specifies that the server is a configuration manager.

  When you designate a server as a configuration manager, IBM Spectrum Protect™ creates a default profile named DEFAULT_PROFILE and associates with the profile all servers and server groups defined on the configuration manager. You can modify or delete the default profile.

OFf
: Specifies that the server is not a configuration manager.

Example: Specify a configuration manager

Designate a server as a configuration manager.

```
set configmanager on
```

Related commands

Table 1. Commands related to SET CONFIGMANAGER

Command	Description
DEFINE PROFILE	Defines a profile for distributing information to managed servers.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
SET CONFIGREFRESH	Specifies a time interval for managed servers to contact configuration managers.

SET CONFIGREFRESH (Set managed server configuration refresh)

Use this command on a managed server to specify how often that server contacts its configuration manager for updated configuration information.

To display the current setting, issue the QUERY STATUS command. At installation, the interval is set to 60 minutes.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set CONFIGRefresh--minutes---------------------------------><
```

Parameters

minutes (Required)
: Specifies the interval, in minutes, before a managed server contacts its configuration manager for configuration updates. Specify an integer from 0 to 10000.

  - If the value is greater than 0, the managed server immediately contacts the configuration manager. The next contact occurs when the specified interval is reached.
  - If the value is 0, the managed server does not contact the configuration manager.

  This value is ignored if the server does not subscribe to at least one profile on a configuration manager.

Example: Set a 45–minute refresh interval

Specify that a managed server contacts its configuration manager every 45 minutes.

```
set configrefresh 45
```

Related commands

Table 1. Commands related to SET CONFIGREFRESH

Command	Description
DEFINE PROFASSOCIATION	Associates objects with a profile.
DEFINE PROFILE	Defines a profile for distributing information to managed servers.
DELETE PROFASSOCIATION	Deletes the association of an object with a profile.
NOTIFY SUBSCRIBERS	Notifies servers to refresh their configuration information.
SET CONFIGMANAGER	Specifies whether a server is a configuration manager.
UPDATE PROFILE	Changes the description of a profile.

SET CONTEXTMESSAGING (Set message context reporting on or off)

Use this command to get additional information when ANR9999D messages occur. IBM Spectrum Protect™ polls the server components for information that includes process name, thread name, session ID, transaction data, locks that are held, and database tables that are in use.

Note: When consecutive messages are issued from the same code area by the same thread, only the first of these messages will report the context information.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set CONTEXTmessaging--+-ON--+------------------------------><
                         '-OFf-'
```

Parameters

ON
: Specifies to enable message context reporting.

OFf
: Specifies to disable message context reporting.

Example: Set message context reporting on or off

Turn on context messaging to receive additional information that could help determine the cause of ANR9999D messages.

```
set contextmessaging on
```

Related commands

Table 1. Commands related to SET CONTEXTMESSAGING

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

SET CPUINFOREFRESH (Refresh interval for the client workstation information scan)

Use this command to specify the number of days between client scans of workstation information that is used to estimate the processor value unit (PVU).

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set CPUINFOREFRESH--days-----------------------------------><
```

Parameters

days (Required)
: Specifies the number of days between scans for client devices. To retrieve the current setting, issue the QUERY STATUS command. The possible values are 1 - 9999. The default is 180.

Example: Set the amount of time before the next refresh to 90 days

```
SET CPUINFOREFRESH 90
```

Related commands

Table 1. Commands related to SET CPUINFOREFRESH

Command	Description
QUERY PVUESTIMATE	Displays an estimate of the client-devices and server-devices being managed.

SET CROSSDEFINE (Specifies whether to cross-define servers)

Use this command to specify whether a server is automatically defined to another server.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set CROSSDefine--+-ON--+-----------------------------------><
                    '-OFf-'
```

Parameters

ON
: Specifies that a server may be cross-defined to another server. To automatically define one server to another, you must also permit cross defining in the server definition.

OFf
: Specifies that a server may not be cross-defined to another server.

Example: Specifies whether to cross-define servers

Set cross define on to allow a server to be cross-defined to another server.

```
set crossdefine on
```

Related commands

Table 1. Command related to SET CROSSDEFINE

Command	Description
DEFINE SERVER	Defines a server for server-to-server communications.
SET SERVERHLADDRESS	Specifies the high-level address of a server.
SET SERVERLLADDRESS	Specifies the low-level address of a server.
SET SERVERPASSWORD	Specifies the server password.

SET DBRECOVERY (Set the device class for automatic backups)

Use this command to specify the device class and number of data streams to be used for automatic database backups. You can also use this command to configure the BACKUP DB command to automatically back up the master encryption key for the server.

The master encryption key is used to encrypt data in directory-container and cloud-container storage pools, and to encrypt sensitive information in the server database. If you do not back up the master encryption key, you might not be able to access any of these encrypted items if a disaster occurs.

If you run the BACKUP DB command, and the device class is not the one that is specified in the SET DBRECOVERY command, a warning message is returned. However, the backup operation continues and is not affected.

Privilege class

To issue this command, you must have system or unrestricted storage privilege.

Syntax

```
>>-SET DBRECOVery--device_class_name---------------------------->

   .-NUMStreams--=--1------.  .-COMPress--=--No------.
>--+----------------------+--+---------------------+---------->
   '-NUMStreams--=--number-'  '-COMPress--=--+-No--+-'
                                             '-Yes-'

   .-PROTECTKeys--=--Yes-----.
>--+-------------------------+--------------------------------->
   '-PROTECTKeys--=--+-No--+-'
                     '-Yes-'

>--+---------------------------+------------------------------><
   '-PASSword--=--password_name-'
```

Parameters

device_class_name **(Required)**
: Specifies the device class to use for database backups.

NUMStreams
: Specifies the number of parallel data movement streams to use when you back up the database. The default value is 1, and the maximum number is 32. Increasing this value causes a corresponding increase in the number of database backup sessions to be used and in the number of drives to be used for the device class. A NUMSTREAMS value that is specified in the BACKUP DB command overrides any value set in the SET DBRECOVERY command. The NUMSTREAMS value is used for all types of database backups.
  If a value is specified that is greater than the number of drives available for the device class, the number of available drives are used. The available drives are defined to the device class by the MOUNTLIMIT parameter or by the number of online drives for the specified device class. The session is displayed in the QUERY SESSION output.
  If you increase the number of streams, more volumes are used from the corresponding device class for this operation. Using more volumes might improve the speed of the database backups, but at the cost of more volumes that are not fully

used.

COMPress
: Specifies whether volumes are compressed during database backup processing. This parameter is optional. The default value is No. You can specify one of the following values:

  No
  : Specifies that the volumes that are created by the BACKUP DB command are not compressed.

  Yes
  : Specifies that the volumes that are created by the BACKUP DB command are compressed.

  If you specify the COMPRESS parameter on the BACKUP DB command, it overrides any value that is set in the SET DBRECOVERY command. Otherwise, the value that is set in the SET DBRECOVERY command is used.
  Restrictions:

  - Use caution when you specify the COMPRESS parameter. Using compression during database backups can reduce the size of the backup files. However, compression can increase the time to complete database backup processing.
  - Do not back up compressed data to tape. If your system environment stores database backups on tape, set the COMPRESS parameter to No in the SET DBRECOVERY and BACKUP DB commands.

PROTECTKeys
: Specifies that database backups include a copy of the master encryption key for the server that is used to encrypt storage pool data. This parameter is optional. The default value is Yes. You can specify one of the following values:

  No
  : Specifies that database backups do not include a copy of the master encryption key for the server.
  Attention: If you specify PROTECTKEYS=NO, you must manually back up the master encryption key for the server and make the key available when you implement disaster recovery.

  Yes
  : Specifies that database backups include a copy of the master encryption key for the server.
  Attention: If you specify PROTECTKEYS=YES, you must also specify the PASSWORD parameter.

PASSword
: Specifies the password that is used to protect the database backups. The default is to protect database backups.
  Important: Ensure that you remember this password. If you specify a password for database backup, you must specify the same password on the RESTORE DB command to restore the database.

Example: Specify a device class for database backups

Specify the DBBACK device class for database backups. Run the following command:

```
set dbrecovery dbback
```

Example: Specify a device class and number of streams for database backups

Specify the DBBACK device class for database backups, and specify that the backup is to use two data movement streams. Run the following command:

```
set dbrecovery dbback numstreams=2
```

AIX | Linux | Windows

Example: Protect storage pool encryption keys in database backups

Encrypt storage pool data by specifying that database backups include a copy of the master encryption key for the server. Run the following command:

```
set dbrecovery dbback protectkeys=yes password=password_name
```

Related commands

Table 1. Commands related to SET DBRECOVERY

Command	Description

Command	Description
BACKUP DB	Backs up the IBM Spectrum Protect database to sequential access volumes.
QUERY DB	Displays allocation information about the database.
QUERY DBSPACE	Displays information about the storage space defined for the database.

SET DEDUPVERIFICATIONLEVEL (Set the percentage of extents to verify)

Use this command to verify extents sent to the server during client-side data deduplication.

A rogue application that resides on a client system and that imitates the client, API, or GUI application can initiate an attack on the server. To reduce server vulnerability to such attacks, you can specify a percentage of client extents for the server to verify.

If the server detects that a security attack is in progress, the current session is canceled. In addition, the setting of the DEDUPLICATION parameter on the REGISTER NODE command is changed. The setting is changed from CLIENTORSERVER to SERVERONLY. The SERVERONLY setting disables client-side data deduplication for that node.

The server also issues a message that a potential security attack was detected and that client-side data deduplication was disabled for the node. If client-side data deduplication is disabled, all other client operations (for example, backup operations) continue. Only client-side data deduplication is disabled. If client-side data deduplication is disabled for a node because a potential attack was detected, the server deduplicates the data that is eligible for client-side data deduplication.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                                .-0-------------.
>>-Set DEDUPVERificationlevel--+---------------+---------------><
                                '-percent_value-'
```

Parameters

percent_value (Required)
: Specify an integer value 0 - 100 to indicate the percentage of client extents to be verified. A value of 0 indicates that no client extents are verified. The default for this command is 0.
Tips:

- Verifying extents consumes processing power and adversely affects server performance. For optimal performance, do not specify values greater than 10 for this command.
- To display the current value for SET DEDUPVERIFICATIONLEVEL, issue the QUERY STATUS command.

Example: Specify a minimum level of data deduplication verification

To specify that 1% of extents created during client-side data deduplication are verified, issue the following command:

```
set dedupverificationlevel 1
```

Example: Turn off data deduplication verification

To specify that none of the extents created during client-side data deduplication are verified, issue the following command:

```
set dedupverificationlevel 0
```

Related commands

Table 1. Commands related to SET DEDUPVERIFICATIONLEVEL

Command	Description
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
QUERY CONTENT	Displays information about files in a storage pool volume.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REGISTER NODE	Defines a client node to the server and sets options for that user.
UPDATE NODE	Changes the attributes that are associated with a client node.
UPDATE STGPOOL	Changes the attributes of a storage pool.

SET DEFAULTAUTHENTICATION (Set the default authentication method for REGISTER NODE and REGISTER ADMIN commands)

Use this command to set the default password authentication method for nodes and administrators that are the result of REGISTER NODE or REGISTER ADMIN commands.

If you specify LDAP, you establish the default value for authenticating to an external directory for any new REGISTER NODE or REGISTER ADMIN commands. This command makes it easier to register nodes or administrators when you use an LDAP directory server.
Tip: The default authentication setting can be overwritten when the authentication method is specified in a REGISTER NODE or REGISTER ADMIN command.

Privilege class

To issue this command you must have system privilege.

Syntax

```
>>-SET DEFAULTAUTHentication--+-LOcal-+------------------------><
                              '-LDap--'
```

Parameters

LOcal
: Specifies that any future REGISTER NODE or REGISTER ADMIN commands that you issue use LOCAL as the default authentication parameter value. Locally-authenticated passwords are those stored on the IBM Spectrum Protect™ server. The passwords authenticated locally are not case sensitive.

LDap
: Specifies that any future REGISTER NODE or REGISTER ADMIN commands that you issue use LDAP as the default authentication parameter value. LDAP-authenticated passwords are those stored on an LDAP directory server and are case sensitive.

Example: Set the default password authentication value to LDAP

Specify that any REGISTER NODE or REGISTER ADMIN commands that you issue authenticate passwords with an LDAP directory server.

```
set defaultauthentication ldap
```

Related commands

Table 1. Commands related to SET DEFAULTAUTHENTICATION

Command	Description

Command	Description
SET LDAPPASSWORD	Sets the password for the LDAPUSER.
SET LDAPUSER	Sets the user who oversees the passwords and administrators on the LDAP directory server.
SET LDAPUSER	Sets the user who oversees the passwords and administrators on the LDAP directory server.
REGISTER ADMIN	Defines a new administrator without granting administrative authority.
REGISTER NODE	Defines a client node to the server and sets options for that user.

SET DISSIMILARPOLICIES (Enable the policies on the target replication server to manage replicated data)

Use the SET DISSIMILARPOLICIES command to enable the policies that are defined on the target replication server to manage replicated client-node data. If you do not use the policies on the target replication server, replicated client-node data is managed by policies on the source replication server.

Ensure that IBM Spectrum Protect™, Version 7.1.1 or later, is installed on the source and target replication servers before you issue this command. Issue this command on the source replication server.

Before you use the policies that are defined on a target replication server, you must issue the VALIDATE REPLPOLICY command for that target replication server. This command displays the differences between the policies for the client nodes on the source replication server and policies on the target replication server. You can modify the policies on the target replication server before you enable these policies to manage replicated client-node data.

To obtain the name of the target replication server for which you want to manage data and to check whether the policies on the target replication server are set to ON, use the QUERY REPLSERVER command. At installation, the value is set to OFF.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                                                .-OFf-.
>>-Set DISSIMILARPolicies--target_server_name--+-----+---------><
                                                +-OFf-+
                                                '-ON--'
```

Parameters

target_server_name (Required)
: Specifies the name of the target replication server for which you want to enable the policies.

ON
: Specifies that replicated client-node data is managed by the policies that are defined on the target replication server.

OFf
: Specifies that replicated client-node data is managed by the policies that are defined on the source replication server. Off is the default value.

Example: Use the policies on a target replication server

To managed replicated client-node data from the target replication server, CVTCVS_LXS_SRV2, issue the following command on the source replication server:

```
set dissimilarpolicies CVTCVS_LXS_SRV2 on
```

Related commands

Table 1. Commands related to SET DISSIMILARPOLICIES

Command	Description
QUERY REPLSERVER	Displays information about replicating servers.
VALIDATE REPLPOLICY	Verifies the policies on the target replication server.

SET DRMACTIVEDATASTGPOOL (Specify the active-data pools to be managed by DRM)

Use this command to specify names of the active-data pools to be recovered after a disaster. IBM Spectrum Protect™ uses these names if the PREPARE , MOVE DRMEDIA, or QUERY DRMEDIA command does not include the ACTIVEDATASTGPOOL parameter.

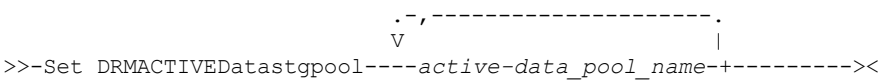
By default, volumes in active-data pools are not eligible for processing by disaster recovery manager. To process active-data pool volumes, you must issue the SET DRMACTIVEDATASTGPOOL command, or you must use the ACTIVEDATASTGPOOL command-line parameter on the MOVE DRMEDIA, QUERY DRMEDIA, or PREPARE command.

Use the QUERY DRMSTATUS command to display the current settings.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

active-data_pool_name (Required)
: Specifies the active-data pool names. Separate multiple names with commas with no intervening spaces. You can use wildcard characters. The specified names will overwrite any previous settings. If you enter a null string (""), all current names are removed, and no active-data pool volumes in MOUNTABLE state are processed if they were not explicitly entered as MOVE DRMEDIA , QUERY DRMEDIA, or PREPARE command parameters.

Example: Set an eligible active-data pool

Set ACTIVEDATAPOOL1 as the eligible active-data pool.

```
set drmactivedatapool activedatastgpool1
```

Related commands

Table 1. Commands related to SET DRMACTIVEDATASTGPOOL

Command	Description
MOVE DRMEDIA	Moves DRM media onsite and offsite.
PREPARE	Creates a recovery plan file.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY DRMSTATUS	Displays DRM system parameters.
SET DRMCOPYSTGPOOL	Specifies that copy storage pools are managed by DRM.
SET DRMPRIMSTGPOOL	Specifies that primary storage pools are managed by DRM.

SET DRMCHECKLABEL (Specify label checking)

Use this command to specify whether IBM Spectrum Protect™ reads the labels of sequential media checked out by the MOVE DRMEDIA command. At installation, the value of the DRMCHECKLABEL is set to YES.

Use the QUERY DRMSTATUS command to check the current setting.

AIX | Linux This command does not apply to 349X device types.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                        .-Yes-.
>>-Set DRMCHECKLabel--+-----+-----------------------------------><
                      +-Yes-+
                      '-No--'
```

Parameters

Yes
: Specifies that IBM Spectrum Protect reads the labels of sequential media checked out by the MOVE DRMEDIA command.

No
: Specifies that IBM Spectrum Protect does not read the labels of sequential media checked out by the MOVE DRMEDIA command.

Example: Specify no label checking

Specify that no label checking is completed.

```
set drmchecklabel no
```

Related commands

Table 1. Commands related to SET DRMCHECKLABEL

Command	Description
MOVE DRMEDIA	Moves DRM media onsite and offsite.
QUERY DRMSTATUS	Displays DRM system parameters.

SET DRMCMDFILENAME (Specify the name of a file to contain commands)

Use this command to name a file that can contain the commands created when the MOVE DRMEDIA or QUERY DRMEDIA commands are issued. If the SET DRMCMDFILENAME is not issued, the MOVE DRMEDIA or QUERY DRMEDIA command generates a file name.

Use the QUERY DRMSTATUS command to display the current command file name.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set DRMCMDFilename--file_name------------------------------><
```

Parameters

file_name (Required)

AIX Linux Specifies a full path name for a file to contain the commands created by the MOVE DRMEDIA or QUERY DRMEDIA command.

Windows Specifies a full path name for a file to contain the commands created by the MOVE DRMEDIA or QUERY DRMEDIA command. The file name can be up to 259 characters.

Attention: If a file of the same name already exists, MOVE DRMEDIA or QUERY DRMEDIA command tries to use it, and the existing data is overwritten.

Example: Specify a file name to contain DRMEDIA commands

AIX Linux Specify a file name of /adsm/drm/orm/exec.cmds.

```
set drmcmdfilename /adsm/drm/orm/exec.cmds
```

Windows Specify a file name of c:\drm\orm\exec.cmd.

```
set drmcmdfilename c:\drm\orm\exec.cmd
```

Related commands

Table 1. Commands related to SET DRMCMDFILENAME

Command	Description
MOVE DRMEDIA	Moves DRM media onsite and offsite.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY DRMSTATUS	Displays DRM system parameters.

AIX Linux Windows

SET DRMCOPYCONTAINERSTGPOOL (Specify the container-copy storage pools to be processed by DRM commands)

Use this command to specify the container-copy storage pools to be processed by the MOVE DRMEDIA or QUERY DRMEDIA command when that command does not include the COPYCONTAINERSTGPOOL parameter.

By default, volumes in container-copy storage pools are not processed by the MOVE DRMEDIA and QUERY DRMEDIA commands. To process the volumes, you must issue the SET DRMCOPYCONTAINERSTGPOOL command, or you must use the COPYCONTAINERSTGPOOL parameter on the MOVE DRMEDIA or QUERY DRMEDIA command.

Tip: To display the current settings, use the QUERY DRMSTATUS command.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                              .-,---------.
                              V           |
>>-Set DRMCOPYCONtainerstgpool----pool_name-+------------------><
```

Parameters

pool_name (Required)
Specifies the names of the container-copy storage pools. Separate multiple names with commas and no intervening spaces. You can use wildcard characters. The specified names replace any previous setting. If you enter a null string (""), all current names are removed.

Example: Specify storage pools to be processed by the MOVE DRMEDIA and QUERY DRMEDIA commands

Set CONTCOPY1 and CONTCOPY2 as the container-copy storage pools to be processed.

```
set drmcopycontainerstgpool contcopy1,contcopy2
```

Related commands

Table 1. Commands related to SET DRMCOPYCONTAINERSTGPOOL

Command	Description
MOVE DRMEDIA	Moves DRM media onsite and offsite.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY DRMSTATUS	Displays DRM system parameters.

SET DRMCOPYSTGPOOL (Specify the copy storage pools to be managed by DRM)

Use this command to specify names of the copy storage pools to be recovered after a disaster. IBM Spectrum Protect™ uses these names if the PREPARE command does not include the COPYSTGPOOL parameter.

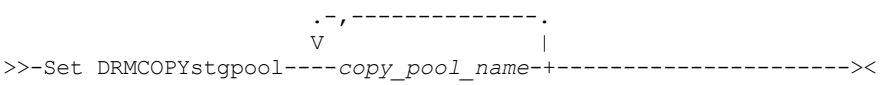
If the MOVE DRMEDIA or QUERY DRMEDIA command does not include the COPYSTGPOOL parameter, the command processes the volumes in the MOUNTABLE state that are in the copy storage pool named by the SET DRMCOPYSTGPOOL command. At installation, all copy storage pools are eligible for DRM processing.

Use the QUERY DRMSTATUS command to display the current settings.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

copy_pool_name (Required)
Specifies the copy storage pool names. Separate multiple names with commas and no intervening spaces. You can use wildcard characters. The specified names replace any previous setting. If you enter a null string (""), all current names are removed, and all copy storage pools are eligible for processing.

Example: Set an eligible copy storage pool

Set COPYSTGPOOL1 as the eligible copy storage pool.

```
set drmcopystgpool copystgpool1
```

Related commands

Table 1. Commands related to SET DRMCOPYSTGPOOL

Command	Description
MOVE DRMEDIA	Moves DRM media onsite and offsite.
PREPARE	Creates a recovery plan file.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY DRMSTATUS	Displays DRM system parameters.
SET DRMPRIMSTGPOOL	Specifies that primary storage pools are managed by DRM.

SET DRMCOURIERNAME (Specify the courier name)

Use this command to specify the courier name. At installation, this name is set to COURIER. The MOVE DRMEDIA command uses the courier name to set the location of volumes that are moving to the COURIER state.

You can use the QUERY DRMSTATUS to see the name of the courier.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set DRMCOUriername--courier_name---------------------------><
```

Parameters

courier_name (Required)
: Specifies the name of the courier. The name can be up to 255 characters. Enclose the name in quotation marks if it contains any blank characters.

Example: Set the courier name

Set the name of the courier to Joe's Courier Service.

```
set drmcouriername "Joe's Courier Service"
```

Related commands

Table 1. Commands related to SET DRMCOURIERNAME

Command	Description
MOVE DRMEDIA	Moves DRM media onsite and offsite.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY DRMSTATUS	Displays DRM system parameters.

SET DRMDBBACKUPEXPIREDAYS (Specify DB backup series expiration)

Use this command to specify when a database backup series is eligible to be expired.

The value set by this command applies to both a snapshot and a full plus incremental database backup series. Any type of database backup series is eligible for expiration if all of the following are true:

- The age of the last volume of the series exceeds the expiration value set with the SET DRMDBBACKUPEXPIREDAYS command and the value that is specified for the DELgraceperiod parameter in the DEFINE SERVER command. The DELgraceperiod parameter applies only to remote database backups. The default value for the DELgraceperiod parameter

is 5 days. For example, if you set the value for the SET DRMDBBACKUPEXPIREDAYS command to 7 days and set the value for the DELgraceperiod parameter to 6 days, the remote database backup series does not expire until 13 days elapse.
- For volumes that are not virtual volumes, all volumes in the series are in the VAULT state.
- The volume is not part of the most recent database backup series.

Remember: The most recent backup series of either type is not deleted.
See the MOVE DRMEDIA command for more information on the expiration of database backup volumes that are not virtual volumes. See the EXPIRE INVENTORY command for more information on expiration of database backup volumes that are virtual volumes.

Use the QUERY DRMSTATUS to see the number of days specified.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set DRMDBBackupexpiredays--days-----------------------------><
```

Parameters

days (Required)
Specifies the number of days that must elapse since a database series was created before it is eligible to be expired. The number of days must match the volume reuse delay period for copy storage pools that are managed by disaster recovery manager. Specify an integer value 0 - 9999.

Example: Set the database backup series expiration

Set the database backup series expiration value to 60.

```
set drmdbbackupexpiredays 60
```

Related commands

Table 1. Commands related to SET DRMDBBACKUPEXPIREDAYS

Command	Description
DSMSERV RESTORE DB	Restores an IBM Spectrum ProtectIBM Spectrum Protect™ database.
MOVE DRMEDIA	Moves DRM media onsite and offsite.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY DRMSTATUS	Displays DRM system parameters.
QUERY VOLHISTORY	Displays sequential volume history information that has been collected by the server.
DEFINE SERVER	Defines a server for server-to-server communications.

SET DRMFILEPROCESS (Specify file processing)

Use this command to specify if the MOVE DRMEDIA or QUERY DRMEDIA command should process database backup volumes and copy storage pool volumes that are associated with a FILE device class. At installation, the value is set to NO. Use the QUERY DRMSTATUS to determine the current setting.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                        .-No--.
>>-Set DRMFILEProcess--+-----+--------------------------------><
                       +-No--+
                       '-Yes-'
```

Parameters

No
: Specifies that the MOVE DRMEDIA and QUERY DRMEDIA commands does not process database backup and copy storage pool volumes that are associated with a FILE device class. This is the default.

Yes
: Specifies that the MOVE DRMEDIA and QUERY DRMEDIA commands process database backup and copy storage pool volumes that are associated with a FILE device class.

Example: Specify that the DRMEDIA commands do not include FILE type device classes

Set the file processing value to no.

```
set drmfileprocess no
```

Related commands

Table 1. Commands related to SET DRMFILEPROCESS

Command	Description
MOVE DRMEDIA	Moves DRM media onsite and offsite.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY DRMSTATUS	Displays DRM system parameters.

SET DRMINSTRPREFIX (Specify the prefix for recovery instructions file names)

Use this command to specify a prefix to the recovery instructions file name. If you issue this command, IBM Spectrum Protect™ uses the specified prefix if the PREPARE command is issued without the INSTRPREFIX parameter.

Use the QUERY DRMSTATUS command to display the current value for the prefix.

AIX Linux the prefix is the current IBM Spectrum Protect server working directory.

Windows If no prefix is set, the prefix is set to the directory representing this instance of the server, which is typically the directory that the server was originally installed from.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set DRMINSTRPrefix--prefix---------------------------------><
```

Parameters

AIX Linux prefix (Required)
AIX Linux

Specifies a path name prefix for the files that contain the recovery instructions. When processing the PREPARE command, IBM Spectrum Protect appends the name of the appropriate recovery plan file stanza to find the file. The maximum length is 250 characters.

The prefix can be one of the following:

- **Directory path:** End the prefix with a foward slash (/). For example:

  ```
  /adsmsrv/recinstr/
  ```

  For the RECOVERY.INSTRUCTIONS.GENERAL file, the resulting file name would be:

  ```
  /adsmsrv/recinstr/RECOVERY.INSTRUCTIONS.GENERAL
  ```

- **Directory path followed by a string:** IBM Spectrum Protect treats the string as part of the file name. For example:

  ```
  /adsmsrv/recinstr/accounts
  ```

  For the RECOVERY.INSTRUCTIONS.GENERAL file, the resulting file name would be:

  ```
  /adsmsrv/recinstr/accounts.RECOVERY.INSTRUCTIONS.GENERAL
  ```

- **String only:** IBM Spectrum Protect specifies the directory path and appends the appropriate recovery plan file stanza name.
  - IBM Spectrum Protect uses the name of the current working directory. For example, the current working directory is/opt/tivoli/tsm/server/bin. You specify the following:

    ```
    shipping
    ```

    For the RECOVERY.INSTRUCTIONS.GENERAL file, the resulting file name would look like this:

    ```
    /opt/tivoli/tsm/server/bin/shipping.RECOVERY.INSTRUCTIONS.GENERAL
    ```

Windows prefix (Required)

Windows

Specifies a path name prefix for the files that contain the recovery instructions. When processing the PREPARE command, IBM Spectrum Protect appends the name of the appropriate recovery plan file stanza to find the file. The maximum length is 200 characters.

The prefix can be one of the following:

- **Directory path:** End the prefix with a back slash (\). For example:

  ```
  c:\adsmsrv\recinstr\
  ```

  For the RECOVERY.INSTRUCTIONS.GENERAL file, the resulting file name would be:

  ```
  c:\adsmsrv\recinstr\RECOVERY.INSTRUCTIONS.GENERAL
  ```

- **Directory path followed by a string:** IBM Spectrum Protect treats the string as part of the file name. For example:

  ```
  c:\adsmsrv\recinstr\accounts
  ```

  For the RECOVERY.INSTRUCTIONS.GENERAL file, the resulting file name would be:

  ```
  c:\adsmsrv\recinstr\accounts.RECOVERY.INSTRUCTIONS.GENERAL
  ```

- **String only:** IBM Spectrum Protect specifies the directory path and appends the appropriate recovery plan file stanza name. The directory path is the directory representing this instance of the IBM Spectrum Protect server (typically the original IBM Spectrum Protect server installation directory). For example, the directory representing this instance of the server is c:\Program Files\Tivoli\TSM;\server2, and you specify the following prefix:

  ```
  shipping
  ```

  The resulting recovery plan file name is:

  ```
  c:\Program Files\Tivoli\TSM;\server2\shipping.19971115.051421
  ```

Example: Specify the recovery plan prefix

AIX Linux Specify reading the recovery plan instructions from directory /drmplan/primesrv.

```
set drminstrprefix /drmplan/primesrv/
```

Windows Specify reading the recovery plan instructions from directory c:\win32app\ibm\adsm\server2\.

```
set drminstrprefix c:\win32app\ibm\adsm\server2\
```

Related commands

Table 1. Commands related to SET DRMINSTRPREFIX

Command	Description
PREPARE	Creates a recovery plan file.
QUERY DRMSTATUS	Displays DRM system parameters.

SET DRMNOTMOUNTABLENAME (Specify the not mountable location name)

Use this command to specify the name of the onsite location for storing the media. At installation, the name is set to NOTMOUNTABLE. Use the QUERY DRMSTATUS command to see the location name.

The location name is used by the MOVE DRMEDIA command to set the location of volumes that are moving to the NOTMOUNTABLE state.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set DRMNOTMOuntablename--location---------------------------><
```

Parameters

location (Required)
: Specifies the name of the onsite location for storing the media. The name can be up to 255 characters. Enclose the name in quotation marks if it contains any blank characters.

Example: Specify the name of the onsite location

Set the name of the location to room 123/31.

```
set drmnotmountablename "room 123/31"
```

Related commands

Table 1. Commands related to SET DRMNOTMOUNTABLENAME

Command	Description
MOVE DRMEDIA	Moves DRM media onsite and offsite.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY DRMSTATUS	Displays DRM system parameters.

SET DRMPLANPREFIX (Specify a prefix for recovery plan file names)

Use this command to specify a prefix for a recovery plan file name.

If you issue this command, IBM Spectrum Protect™ uses the specified prefix if the PREPARE command does not include the PLANPREFIX parameter.

Use the QUERY DRMSTATUS command to display the current value for the recovery plan prefix.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set DRMPLANPrefix--prefix-----------------------------------><
```

Parameters

AIX Linux prefix (Required)

AIX Linux Specifies the prefix for a recovery plan file name. The maximum length of the prefix is 250 characters. If you enter a null string (""), the current prefix is removed, and the server uses the algorithm described in the PLANPREFIX parameter in the PREPARE command.
For the prefix, you can specify:

- **A directory path followed by a forward slash (/):** IBM Spectrum Protect appends to the prefix the date and time in the `yyyymmdd.hhmmss` format. For example, the SET DRMPLANPREFIX is set to the following:

  ```
  /adsmsrv/recplans/
  ```

  The resulting recovery plan file name is:

  ```
  /adsmsrv/recplans/19971115.051421
  ```

- **A directory path followed by a string:** IBM Spectrum Protect uses the string as part of the file name. IBM Spectrum Protect appends to the prefix the date and time in the `.yyyymmdd.hhmmss` format (note the initial period). For example, the SET DRMPLANPREFIX is set to the following:

  ```
  /adsmsrv/recplans/accounting
  ```

  The resulting recovery plan filename is:

  ```
  /adsmsrv/recplans/accounting.19971115.051421
  ```

- **A string that is not preceded by a directory path:** IBM Spectrum Protect appends to the prefix the date and time information in the `.yyyymmdd.hhmmss` format (note the initial period). IBM Spectrum Protect determines the directory path as follows:
  - IBM Spectrum Protect uses the directory path name of the current working directory of the IBM Spectrum Protect server. For example, the current IBM Spectrum Protect working directory is /opt/tivoli/tsm/server/binThe SET DRMPLANPREFIX command is set to the following:

    ```
    shipping
    ```

    The resulting recovery plan file name is:

    ```
    /opt/tivoli/tsm/server/bin/shipping.19971115.051421
    ```

Windows prefix (Required)

Windows Specifies a prefix for the path name used to generate the recovery plan file name. The prefix can be up to 200 characters. IBM Spectrum Protect uses the prefix if the PREPARE command is issued without the PLANPREFIX parameter. IBM Spectrum Protect builds a unique recovery plan file name by appending to the prefix the date and time format: `yyyymmdd.hhmmss` (for example, 19951115.051421). If you enter a null string (""), the current prefix is removed, and the server uses the algorithm described in the PLANPREFIX parameter in the PREPARE command.
For the prefix, you can specify:

1. A directory path
2. A directory path followed by a string
3. A string

The following describes the rules for possible prefix specifications:

1. To specify a directory path for the prefix, end the prefix with a back slash (\). IBM Spectrum Protect appends to the prefix the date and time information using the `yyyymmdd.hhmmss` format. For example the SET DRMPLANPREFIX is set to the following:

   ```
   c:\adsmsrv\recplans\
   ```

   The resulting recovery plan file name is:

   ```
   c:\adsmsrv\recplans\19951115.051421
   ```

   Important: If you issue the SET DRMPLANPREFIX command from a command line client and the last character in the command line is a back slash, IBM Spectrum Protect interprets it as a continuation character. To avoid this, enclose the prefix in quotation marks. For example: `"c:\adsmsrv\recplans\"`
2. If the prefix is a directory path followed by a string, IBM Spectrum Protect uses the string as part of the file name. IBM Spectrum Protect appends to the prefix the date and time in the `.yyyymmdd.hhmmss` format (note the initial period). For example, the SET DRMPLANPREFIX is set to the following

   ```
   c:\adsmsrv\recplans\accounting
   ```

   The resulting recovery plan filename is the following:

   ```
   c:\adsmsrv\recplans\accounting.19951115.051421
   ```

3. If the prefix is a string that is not preceded by a directory path, IBM Spectrum Protect appends to the prefix the date and time information in the `.yyyymmdd.hhmmss` format (note the initial period). The directory path that IBM Spectrum Protect uses is the directory path representing this instance of the IBM Spectrum Protect server (typically the directory that the IBM Spectrum Protect server was originally installed from). For example, the directory representing this instance of the server is c:\Program Files\Tivoli\TSM;\server2, and you set the prefix to:

   ```
   shipping
   ```

   The resulting recovery plan filename is:

   ```
   c:\Program Files\Tivoli\TSM;\server2\shipping.19951115.051421
   ```

Example: Specify a prefix for recovery plan file names

Specify a prefix so that the generated recovery plan files are stored in the following directory:

- AIX | Linux /drmplan/primsrv
- Windows c:\drmtest\prepare\

Issue the command: AIX | Linux

```
set drmplanprefix /drmplan/primsrv/
```

Windows

```
set drmplanprefix c:\drmtest\prepare\
```

Related commands

Table 1. Commands related to SET DRMPLANPREFIX

Command	Description
PREPARE	Creates a recovery plan file.
QUERY DRMSTATUS	Displays DRM system parameters.

SET DRMPLANVPOSTFIX (Specify replacement volume names)

Use this command to specify the character to be appended to replacement volume names in the recovery plan file. The character can help you find or generate replacement volume names when you use the recovery plan file.

At installation, the character is set to @. IBM Spectrum Protect™ generates replacement names for primary storage pool volumes that were added by the DEFINE VOLUME command. Use the appended character to:

- Find replacement volume names in the recovery plan stanzas so that you can change the names at recovery time. For example, you may not know the names of the available tape volumes at the recovery site.
- Generate replacement volume names. You need a naming convention that works for any device type in your primary storage pools. Consider the following:
  - The generated length of replacement volume name
  - Legal characters in the replacement volume name
  - Conflicts with existing volume names
  - A replacement volume name must be different from any destroyed, existing, or new volume name.

Use the QUERY DRMSTATUS command to see the character added to the end of the replacement volume names.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set DRMPLANVpostfix--character-----------------------------><
```

Parameters

character (Required)
Specifies the character appended to the replacement volume names in the recovery plan file. Specify an alphanumeric or special character.
AIX Attention: A special character can cause unpredictable results in the AIX® shell or command line environment.
Windows Attention: A special character can cause unpredictable results in the Windows batch/command line environment.

Example: Specify the appended character for replacement volume names

Set the character appended to the replace volume names to R.

```
set drmplanvpostfix R
```

Related commands

Table 1. Commands related to SET DRMPLANVPOSTFIX

Command	Description
PREPARE	Creates a recovery plan file.
QUERY DRMSTATUS	Displays DRM system parameters.

SET DRMPRIMSTGPOOL (Specify the primary storage pools to be managed by DRM)

Use this command to specify the names of primary storage pools that you want to recover. If the PREPARE command does not include the PRIMSTGPOOL parameter, DRM processes the names specified in this command.

Use the QUERY DRMSTATUS command to display the current settings. At installation, all primary storage pools defined to the server are eligible for DRM processing.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                        .-,-----------------.
                        V                   |
>>-Set DRMPRIMstgpool----primary_pool_name-+------------------><
```

Parameters

primary_pool_name (Required)
: Specifies the names of the primary storage pool names you want to recover. Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify names. The names that you specify replace any previous setting. If you enter a null string (""), all current names are removed, and all primary storage pools are eligible for DRM processing.

Example: Set a primary storage pool to be managed by DRM

Set the primary storage pool to be managed by DRM to PRIMSTGPOOL1.

```
set drmprimstgpool primstgpool1
```

Related commands

Table 1. Commands related to SET DRMPRIMSTGPOOL

Command	Description
PREPARE	Creates a recovery plan file.
QUERY DRMSTATUS	Displays DRM system parameters.
SET DRMCOPYSTGPOOL	Specifies that copy storage pools are managed by DRM.

SET DRMRPFEXPIREDAYS (Set criteria for recovery plan file expiration)

Use this command to specify when recovery plan files are eligible for expiration. This command and expiration processing apply only to recovery plan files that were created with the DEVCLASS parameter specified on the PREPARE command (that is, virtual volumes of type RPFILE and RPSNAPSHOT). Expiration processing on the source server expires plan files that are stored on the target server. Locally created recovery plan files are not expired.

An RPFILE file is associated with a full plus incremental database backup series. An RPFSNAPSHOT file is associated with a database snapshot backup series.

Attention: The latest RPFILE and RPFSNAPSHOT files are never deleted.
A recovery plan file is eligible for expiration if both of the following are true:

- The last recovery plan file of the series exceeds the expiration value that is specified with the SET DRMRPFEXPIREDAYS command and the value that is specified for the DELgraceperiod parameter in the DEFINE SERVER command. The default value for the DELgraceperiod parameter is 5 days. For example, if you set the value for the SET DRMRPFEXPIREDAYS command to 80 days and set the value for the DELgraceperiod parameter to 6 days, the recovery plan file does not expire until 86 days elapse.
- The latest recovery plan file is not associated with the most recent database backup series.

For more information about expiration processing, see the EXPIRE INVENTORY command.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set DRMRPFEXpiredays--days---------------------------------><
```

Parameters

days (Required)
Specifies the number of days that must elapse before a recovery plan file expires. You can specify a number 0 - 9999. At installation, this value is set to 60.

Example: Set the recovery plan expiration

Set the recovery plan file expiration value to 30.

```
set drmrpfexpiredays 30
```

Related commands

Table 1. Commands related to SET DRMRPFEXPIREDAYS

Command	Description
PREPARE	Creates a recovery plan file.
QUERY DRMSTATUS	Displays DRM system parameters.
QUERY RPFCONTENT	Displays the contents of a recovery plan file.
QUERY RPFILE	Displays information about recovery plan files.
QUERY VOLHISTORY	Displays sequential volume history information that has been collected by the server.
SET DRMDBBACKUPEXPIREDAYS	Specifies criteria for database backup series expiration.
DEFINE SERVER	Defines a server for server-to-server communications.

SET DRMVAULTNAME (Specify the vault name)

Use this command to specify the vault name. At installation the name is set to VAULT. Use the QUERY DRMSTATUS command to see the name of the vault.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-SET DRMVAultname--vault_name-------------------------------><
```

Parameters

vault_name (Required)
Specifies the name of the vault. The name can be up to 255 characters. Enclose the name in quotation marks if it contains any blank characters.

Example: Specify a vault name

Specify `ironmountain` as the vault name.

```
set drmvaultname ironmountain
```

Related commands

Table 1. Commands related to SET DRMVAULTNAME

Command	Description
MOVE DRMEDIA	Moves DRM media onsite and offsite.
QUERY DRMEDIA	Displays information about disaster recovery volumes.

Command	Description
QUERY DRMSTATUS	Displays DRM system parameters.

SET EVENTRETENTION (Set the retention period for event records)

Use this command to set the retention period for event records in the server database that will allow you to monitor completed schedules. An event record is created whenever processing of a scheduled command is started or missed.

You can adjust the length of time that the server maintains event information to avoid insufficient or outdated data. The server automatically removes the event records from the database after the retention period passes and the startup window for the event has elapsed.

You can issue the QUERY EVENT command to display information about scheduled and completed events.

You can issue the DELETE EVENT command to delete event records regardless of whether their retention period has passed.

You can issue the QUERY STATUS command to display the value for the event retention period. At installation, this value is set to 10 days.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set EVentretention--days-----------------------------------><
```

Parameters

days (Required)
: The number of days that the database retains event records. You can specify an integer from 0 to 9999. A value of 0 indicates that only event records for the current day are retained.

Example: Set the retention period for event records

Set the retention period to 15 days.

```
set eventretention 15
```

Related commands

Table 1. Commands related to SET EVENTRETENTION

Command	Description
DELETE EVENT	Deletes event records before a specified date and time.
QUERY EVENT	Displays information about scheduled and completed events for selected clients.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

SET FAILOVERHLADDRESS (Set a failover high level address)

Use this command to specify the IP address that a client uses to connect to this server as the secondary replication server during failover, if the address is different from the IP address that is specified for the replication process.

You must specify the address of the server that is used if the high-level address (HLA) is different. This command is required only if you use separate dedicated networks for server-to-server communication and client access.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-SET FAILOVERHladdress--high_level_address------------------><
```

Parameters

high_level_address (Required)

Specifies a server HLA as a numeric dotted decimal name or a host name to use during failover. If you specify a host name, a server that can resolve the name to the dotted decimal format must be available.

To remove the failover IP address, issue the command without specifying a value.

Example: Set a failover high-level address

The name of the HLA that you want to set for failover operations on this server.

```
set failoverhladdress server1
```

Example: Remove a high-level address

To remove a high-level address for a failover server, issue the following command:

```
set failoverhladdress
```

Related commands

Table 1. Commands related to QUERY REPLSERVER

Command	Description
QUERY REPLSERVER (Query a replication server)	Displays information about replicating servers.
REMOVE REPLSERVER (Remove a replication server)	Removes a server from replication.

SET INVALIDPWLIMIT (Set the number of invalid logon attempts)

Use this command to set the number of invalid logon attempts that are allowed before a node is locked.

The SET INVALIDPWLIMIT command also applies to LDAP directory servers that store complex node passwords. LDAP directory servers can limit the number of invalid password attempts independent of the IBM Spectrum Protect™ server. You might not want to set up the LDAP directory server for invalid attempts for the IBM Spectrum Protect namespace if you use the SET INVALIDPWLIMIT command.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set--INVALIDPwlimit--number--------------------------------><
```

Parameters

number (Required)
Specifies the number of invalid logon attempts allowed before a node is locked.

You can specify an integer from 0 to 9999. A value of 0 means that invalid logon attempts are not checked. A value of 1 means that if a user issues an invalid password one time, the node is locked by the server. The default is 0.

Important: If your password is authenticated with an LDAP directory server, it can be managed by the LDAP server and the IBM Spectrum Protect server. Not all IBM Spectrum Protect server commands affect passwords that authenticate with an LDAP server. For example, the SET PASSEXP and RESET PASSEXP commands do not affect passwords that authenticate with an LDAP directory server. You can manage your password features through the IBM Spectrum Protect server. If you issued the SET INVALIDPWLIMIT command, all IBM Spectrum Protect passwords are controlled by the limit that you set. If you configure the LDAP directory server to limit the number of invalid password attempts, a conflict might occur.

Example: Define the number of allowed invalid login attempts

Set the number of invalid logon attempts allowed.

```
set invalidpwlimit 6
```

Related commands

Table 1. Commands related to SET INVALIDPWLIMIT

Command	Description
QUERY ADMIN	Displays information about one or more IBM Spectrum Protect administrators.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
SET MINPWLENGTH	Sets the minimum length for client passwords.

SET LDAPPASSWORD (Set the LDAP password for the server)

Use this command to define a password for the user or account ID that you specified by using the SET LDAPUSER command.

Requirement: You must define the LDAPURL option and issue the SET LDAPUSER command before you issue the SET LDAPPASSWORD command. If the LDAPURL option is not defined when you set the user password for the Lightweight Directory Access Protocol (LDAP) server, you must restart the IBM Spectrum Protect™ server after you define the LDAPURL option.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set LDAPPassword--ldap_user_password------------------------><
```

Parameters

ldap_user_password
: Specifies the password that the IBM Spectrum Protect server uses when it authenticates to the LDAP server. The maximum length of the password is 64 characters. If you have equal signs within your password, you must contain the whole password within quotation marks. You can use the following characters:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9 . ! @ # $ % ^ & * _ - + = ` ( )
| { } [ ] : ; < > , ? / ~
```

Example: Set an LDAP password

```
set ldappassword LdAp20&12PaSsWoRd
```

Example: Set an LDAP password that includes an equal sign

```
set ldappassword "LdAp=LastWoRd"
```

Related commands

Table 1. Commands related to SET LDAPPASSWORD

Command	Description
AUDIT LDAPDIRECTORY	Audit an IBM Spectrum Protect-controlled namespace on an LDAP directory server.
SET DEFAULTAUTHENTICATION	Specifies the default password authentication method for any REGISTER NODE or REGISTER ADMIN commands.
SET LDAPUSER	Sets the user who oversees the passwords and administrators on the LDAP directory server.

SET LDAPUSER (Specify an ID for an LDAP directory server)

Use this command to specify the ID of a user or account that can access a Lightweight Directory Access Protocol (LDAP) server.

The specified ID must have read access to the accounts on the LDAP server that are used for authentication. To modify LDAP IDs or reset passwords for LDAP IDs, the specified ID must have write authority for accounts on the LDAP server.

Tip: The information in this documentation applies to the LDAP authentication method that is preferred for IBM Spectrum Protect™ V7.1.7 or later servers. For instructions about using the previous LDAP authentication method, see Managing passwords and logon procedures.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set LDAPUser--ldap_user_dn---------------------------------><
```

Parameters

ldap_user_dn
: Specifies the ID of a user or account that can access an LDAP server.

Example: Specify an administrative user ID for conducting operations on an LDAP server

To specify an administrator with a user ID of JACKSPRATT, who represents a US company that is named EXAMPLE, issue the following command:

```
set ldapuser JackSpratt@us.example.com
```

Related commands

Table 1. Commands related to SET LDAPUSER

Command	Description
AUDIT LDAPDIRECTORY	Audit an IBM Spectrum Protect-controlled namespace on an LDAP directory server.
SET DEFAULTAUTHENTICATION	Specifies the default password authentication method for any REGISTER NODE or REGISTER ADMIN commands.

Command	Description
SET LDAPPASSWORD	Sets the password for the LDAPUSER.

SET LICENSEAUDITPERIOD (Set license audit period)

Use this command to specify the period, in days, between automatic license audits performed by IBM Spectrum Protect™.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                              .-30---.
>>-Set--LICenseauditperiod--+------+---------------------------><
                              '-days-'
```

Parameters

days
: Specifies the number of days between automatic server license audits. This parameter is optional. The default value is 30. You can specify an integer from 1 to 30, inclusive.

Example: Specify a 14 day server license audit

Specify that the server audits licenses every 14 days.

```
set licenseauditperiod 14
```

Related commands

Table 1. Commands related to SET LICENSEAUDITPERIOD

Command	Description
AUDIT LICENSES	Verifies compliance with defined licenses.
QUERY AUDITOCCUPANCY	Displays the server storage utilization for a client node.
QUERY LICENSE	Displays information about licenses and audits.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REGISTER LICENSE	Registers a license with the IBM Spectrum Protect server.

SET MAXCMDRETRIES (Set the maximum number of command retries)

Use this command to set the maximum number of times that a scheduler on a client node can retry a failed, scheduled command.

You can use the command to override the maximum number of retries that are specified by the client node. A client's value is overridden only if the client is able to connect with the server.

This command is used with the SET RETRYPERIOD command to regulate the time and the number of retry attempts to rerun failed command.

You can issue the QUERY STATUS command to display the current retry value. At installation, IBM Spectrum Protect™ is configured so that each client determines its own retry value.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set MAXCMDRetries--+--------+-------------------------------><
                      '-number-'
```

Parameters

number
: Specifies the maximum number of times the scheduler on a client node can retry a failed scheduled command. This parameter is optional.

  The default is that each client determines its own value for this parameter. You can specify an integer from 0 to 9999. See the appropriate client documentation for more information on setting the maximum command retries from the client.

Example: Set the maximum number of command retries to 2

Retry, only twice, a failed attempt to process a scheduled command.

```
set maxcmdretries 2
```

Related commands

Table 1. Command related to SET MAXCMDRETRIES

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
SET RETRYPERIOD	Specifies the time between retry attempts by the client scheduler.

SET MAXSCHEDSESSIONS (Set maximum scheduled sessions)

Use this command to set the number of sessions that the server can use to process scheduled operations. This command specifies the maximum number of scheduled sessions as a percentage of the total number of available server sessions.

Limiting the number of sessions ensures that some are available for unscheduled operations, such as backup or archive. You can increase either the total number of sessions (with the MAXSESSIONS parameter) or the maximum percentage of scheduled sessions. Increasing the total number of sessions available, however, can affect server performance. Increasing the maximum percentage of scheduled sessions can reduce the sessions available for unscheduled operations.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set MAXSCHedsessions--percent-------------------------------><
```

Parameters

percent (Required)
: Specifies the percentage of total server sessions that can be used for scheduled operations. You can specify an integer from 0 to 100. The MAXSESSIONS parameter in the server options file determines the maximum number of total available server sessions.

If you set the maximum percentage of scheduled sessions to 0, no scheduled events can begin. If you set the maximum percentage of scheduled sessions to 100, the maximum number of scheduled sessions is the value of the MAXSESSIONS option.

Tip: If the maximum number of scheduled sessions do not coincide with the percentage that you set in the SET MAXSCHEDSESSIONS command, run the SET MAXSCHEDSESSIONS command again. Look in the MAXSESSIONS option and determine the number that is specified there. If the MAXSESSIONS option number changed and you did not issue the SET MAXSCHEDSESSIONS command since the change, the maximum number of scheduled sessions can change.

Set a maximum of 20 sessions for scheduled activities

The MAXSESSIONS option has a value of 80. If you want no more than 20 sessions to be available for scheduled activity, set the percentage to 25.

```
set maxschedsessions 25
```

Related commands

Table 1. Commands related to SET MAXSCHEDSESSIONS

Command	Description
QUERY OPTION	Displays information about server options.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

SET MINPWLENGTH (Set minimum password length)

Use this command to set the minimum length of a password.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set--MINPwlength--length-----------------------------------><
```

Parameters

length (Required)
Specifies the minimum length of a password. You can specify an integer from 0 to 64. A value of 0 means that the password length is not checked. The default value for minimum password length is set to 0.

Example: Set the minimum password length

Set the minimum password length to 5 characters.

```
set minpwlength 5
```

Related commands

Table 1. Commands related to SET MINPWLENGTH

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
SET INVALIDPWLIMIT	Sets the number of invalid logon attempts before a node is locked.

SET MONITOREDSERVERGROUP (Set the group of monitored servers)

Use this command to set the group of servers that are being monitored for alerts and status. You can also use this command to change or remove the group of monitored servers.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set MONITOREDSERVERGroup--+------------+-------------------><
                             '-group_name-'
```

Parameters

group_name
: Specifies the IBM Spectrum Protect™ server group name that contains all monitored servers. You can remove a monitored server group name by issuing the command without specifying a value, or by specifying an empty value (""). Any existing monitoring for alerts and status from remote servers is ended.

Set the name of a monitored server group

Set the name of a monitored server group SUBS, by issuing the following command:

```
set monitoredservergroup subs
```

Remove the name of a monitored server group

Remove the monitored server group, by issuing the following command:

```
set monitoredservergroup
```

Related commands

Table 1. Commands related to SET MONITOREDSERVERGROUP

Command	Description
DEFINE SERVERGROUP (Define a server group)	Defines a new server group.
DEFINE GRPMEMBER (Add a server to a server group)	Defines a server as a member of a server group.
DELETE GRPMEMBER (Delete a server from a server group)	Deletes a server from a server group.
QUERY SERVERGROUP (Query a server group)	Displays information about server groups.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
SET MONITORINGADMIN (Set the name of the monitoring administrator)	Set the name of the monitoring administrator.

SET MONITORINGADMIN (Set the name of the monitoring administrator)

Use this command to set the name of the monitoring administrator that is used to connect to the servers in the monitored server group.

To display the name of the monitored server group, issue the QUERY MONITORSETTINGS command.

The administrator name that you specify must match the name of an existing administrator, otherwise the command fails.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set MONITORINGADMIN--+------------+-------------------------><
                        '-admin_name-'
```

Parameters

admin_name
: Specifies administrator names. You can remove names by issuing the command without specifying a value, or by specifying an empty value ("").

Set the monitoring administrator name

Set the name of the monitoring administrator to MONADMIN, by issuing the following command:

```
set monitoringadmin monadmin
```

Remove the monitoring administrator name

Remove the monitoring administrator, by issuing the following command:

```
set monitoringadmin ""
```

Related commands

Table 1. Commands related to SET MONITORINGADMIN

Command	Description
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
SET MONITOREDSERVERGROUP (Set the group of monitored servers)	Set the group of monitored servers.

SET NODEATRISKINTERVAL (Specifies at-risk mode for an individual node)

Use this command to adjust the at-risk evaluation mode for an individual node.

Privilege class

To issue this command, you must have system privilege, policy privilege for the domain to which the node is assigned, or client owner authority over the node.

Syntax

```
>>---Set NODEATRISKINTERVAL--node_name-------------------------->

>--TYPE--=--+-DEFAULT--------------------+---------------------><
            +-BYPASSED-------------------+
            '-CUSTOM--Interval--=--value-'
```

Parameters

node_name (Required)
: Specifies the name of the client node that you want to update.

TYPE (Required)
Specifies the at-risk evaluation type. Specify one of the following values:

DEFAULT
Specifies that the node is evaluated with the same interval that was specified for the nodes classification by the SET STATUSATRISKINTERVAL command. The value is either system or applications, or VM, and is determined by the status monitor.

For example, you can specify `TYPE = DEFAULT`, which allows the status monitor to go ahead and classify the node automatically. Then the interval that is used, is the interval that was defined for that classification by the SET STATUSATRISKINTERVAL command.

BYPASSED
Specifies that the node is not evaluated for at-risk status by the status monitor. The at risk status is also reported as bypassed to the Operations Center.

CUSTOM
Specifies that the node is evaluated with the specified interval, rather than the interval that was specified by the SET STATUSATRISKINTERVAL command.

Interval
Specifies the amount of time, in hours, between client backup activity before the status monitor considers the client to be at risk. You can specify an integer in the range 6 - 8808. You must specify this parameter when `TYPE = CUSTOM`. You do not specify this parameter when `TYPE = BYPASSED` or `TYPE = DEFAULT`. The interval value for all client types is set to 24 at server installation.

Set node name to use a custom 90 day at-risk interval

Set the at-risk interval for a node named *fred* to 90 days.

```
set nodeatriskinterval fred type=custom interval=2160
```

Bypass the at-risk interval evaluation

Bypass the at-risk interval checking for a node named *bob*.

```
set nodeatriskinterval bob type=bypassed
```

Related commands

Table 1. Commands related to set nodeatriskinterval

Command	Description
SET STATUSATRISKINTERVAL (Specifies whether to enable client at-risk activity interval evaluation)	Specifies whether to enable client at-risk activity interval evaluation
SET VMATRISKINTERVAL (Specifies the at-risk mode for an individual VM filespace)	Sets the at-risk mode for a VM filespace
QUERY MONITORSTATUS (Query the monitoring status)	Displays information about monitoring alerts and server status settings.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
SET STATUSMONITOR (Specifies whether to enable status monitoring)	Specifies whether to enable status monitoring.
SET STATUSREFRESHINTERVAL (Set refresh interval for status monitoring)	Specifies the refresh interval for status monitoring.
SET STATUSSKIPASFAILURE (Specifies whether to use client at-risk skipped files as failure evaluation)	Specifies whether to use client at-risk skipped files as failure evaluation
QUERY NODE (Query nodes)	Displays partial or complete information about one or more clients.

Command	Description
QUERY FILESPACE (Query one or more file spaces)	Displays information about data in file spaces that belong to a client.

SET PASSEXP (Set password expiration date)

Use this command to set the expiration period for administrator and client node passwords. You can either set a common password expiration period for all administrators and client node passwords or selectively set password expiration periods.

Restriction: The SET PASSEXP command does not apply to passwords that authenticate with an LDAP directory server.

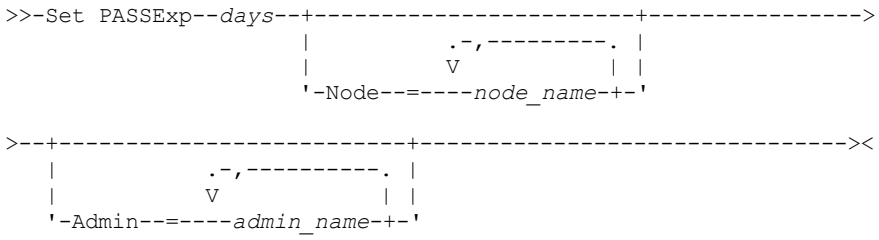
You can override the SET PASSEXP setting for one or more nodes by using the REGISTER NODE or UPDATE NODE command with the PASSEXP parameter.

The NODE or ADMIN parameters must be specified to change the password expiration period for client nodes or administrators with selectively set password expiration periods. If you do not specify the NODE or ADMIN parameters, *all* client node and administrator passwords will use the new password expiration period. If you selectively set a password expiration period for a client node or administrator that does not already have a set password expiration period, it is not modified if you later set a password expiration for all users.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

days (Required)
: Specifies the number of days that a password remains valid.

  You can specify from 1 to 9999 if you do not specify the NODE or the ADMIN parameter. If you specify the NODE or the ADMIN parameter, you can specify from 0 to 9999. A value of 0 means that the password never expires. If a password expires, the server prompts for a new password when the administrator or client node contacts the server.

Node
: Specifies the name of the node for which you are setting the password expiration period. To specify a list of nodes, separate the names with commas and no intervening spaces. This parameter is optional.

Admin
: Specifies the name of the administrator whose password expiration period you would like to set. To specify a list of administrators, separate the names with commas and no intervening spaces. This parameter is optional.

Example: Set the administrator and client node password expiration

Set the administrator and client node password expiration period to 45 days.

```
set passexp 45
```

Example: Set an administrator's password expiration

Set the administrator LARRY's password expiration period to 120 days.

```
set passexp 120 admin=larry
```

Related commands

Table 1. Commands related to SET PASSEXP

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REGISTER NODE	Defines a client node to the server and sets options for that user.
RESET PASSEXP	Resets the password expiration for nodes or administrators.
UPDATE ADMIN	Changes the password or contact information associated with any administrator.
UPDATE NODE	Changes the attributes that are associated with a client node.

SET PRODUCTOFFERING (Set the product offering that is licensed to your enterprise)

Use the SET PRODUCTOFFERING command to define the IBM Spectrum Protect™ product offering that is licensed to your enterprise.

The definition is used to determine whether automatic storage capacity measurement calculations are required and made available for use by the IBM® License Metric Tool (ILMT). Run this command only if you are using ILMT to determine license consumption.

For product offerings where automatic storage capacity measurement calculations are made available for use by ILMT, the parameter also defines which capacity measurement approach is used for those calculations.

The capacity measurement approach is defined by the licensing terms of your specific product offering. To determine the currently calculated storage capacity for your product offering, see Verifying license compliance.

The same storage capacity information is made available to ILMT on a weekly interval. After an applicable product offering is defined by using this command, IBM Spectrum Protect makes the current capacity calculation for that offering available to the ILMT. After the initial capacity calculation is made available to ILMT, IBM Spectrum Protect updates the value weekly.

Privilege class

To run this command, you must have system privilege.

Syntax

```
>>-SET PRODUCTOFFERING--product_offering-----------------------><
```

Parameters

product_offering (Required)
Specifies a product offering. The maximum length of the text string is 255 characters. The following options are available:

ENTry
Specifies that the product offering licensed in your enterprise is IBM Spectrum Protect Entry. This product offering uses a Per Managed Server licensing metric. Capacity measurements for this product offering are not applicable.

DATARet
Specifies that the product offering licensed in your enterprise is IBM Spectrum Protect for Data Retention. Capacity measurements for this product offering are not calculated automatically or made available for use by ILMT.

BASIC

Specifies that the product offering licensed in your enterprise is IBM Spectrum Protect. This product offering uses a processor value unit (PVU) licensing metric. Capacity measurements for this product offering are not applicable.

EE
Specifies that the product offering licensed in your enterprise is IBM Spectrum Protect Extended Edition. This product offering uses a PVU licensing metric. Capacity measurements for this product offering are not applicable.

SUIte
Specifies that the product offering licensed in your enterprise is IBM Spectrum Protect Suite. Capacity measurements for this product offering are calculated automatically and made available for use by ILMT.

SUITEEntry
Specifies that the product offering licensed in your enterprise is IBM Spectrum Protect Suite Entry. Capacity measurements for this product offering are calculated automatically and made available for use by ILMT.

SUITEArchive
Specifies that the product offering licensed in your enterprise is IBM Spectrum Protect Suite - Archive. Capacity measurements for this product offering are calculated automatically and made available for use by ILMT.

SUITEProtectier
Specifies that the product offering licensed in your enterprise is IBM Spectrum Protect Suite - ProtecTier. Capacity measurements for this product offering are calculated automatically and made available for use by ILMT.

SUITEFrontend
Specifies that the product offering licensed in your enterprise is IBM Spectrum Protect Suite - FrontEnd. Capacity measurements for this product offering are calculated automatically and made available for use by ILMT.

SUITEENTRYFrontend
Specifies that the product offering licensed in your enterprise is IBM Spectrum Protect Suite Entry - FrontEnd. Capacity measurements for this product offering are calculated automatically and made available for use by ILMT.

CLEAR
No product offering is specified.

Example: Set the product offering to IBM Spectrum Protect (BASIC)

```
set productoffering BASIC
```

Related commands

Table 1. Commands related to SET PRODUCTOFFERING

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

SET QUERYSCHEDPERIOD (Set query period for polling client nodes)

Use this command to regulate how often client nodes contact the server to obtain scheduled work when it is running in the client-polling scheduling mode.

Each client can set its own retry period at the time its scheduler is started. You can use this command to override the value specified by all clients that can connect with the server.

If client nodes poll more frequently for schedules, the nodes receive changes to schedules more quickly. However, increased polling by the client nodes also increases network traffic.

You can issue the QUERY STATUS command to display the value for the period between schedule queries. At installation, IBM Spectrum Protect™ is configured so that each client node determines its own value for this setting.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set QUERYSCHedperiod--+-------+----------------------------><
                         '-hours-'
```

Parameters

hours
: Specifies the maximum number of hours the scheduler on a client node waits between attempts to contact the server to obtain a schedule. This parameter is optional. You can specify an integer from 1 to 9999. If you do not specify a value for this parameter, each client determines its own value for this parameter.

Example: Set the polling period for all client nodes

Have all clients using the polling scheduling mode contact the server every 24 hours.

```
set queryschedperiod 24
```

Related commands

Table 1. Commands related to SET QUERYSCHEDPERIOD

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
SET SCHEDMODES	Specifies the central scheduling mode for the server.

SET RANDOMIZE (Set randomization of scheduled start times)

Use this command to set randomized start times within the startup window of each schedule for clients by using the client-polling scheduling mode. A startup window is the start time and duration during which a schedule must be initiated. A client-polling scheduling mode is a client/server communication technique where the client queries the server for work.

Each schedule has a window during which it can be run. To balance network and server load, the start times for clients can be scattered across that window. Use this command to specify the fraction of the window over which start times for clients are distributed.

The randomization occurs at the beginning of the window to allow time for retries, if necessary. When the scheduling mode is not set to polling, randomization does not occur if the client's first contact with the server is after the start time for the event.

You can issue the QUERY STATUS command to display the value for the schedule randomization percentage. At installation, the value is 25 percent.

Set the randomization percentage to a value greater than 0 to prevent communication errors. Communication errors can result from a large group of clients contacting the server simultaneously. If you do experience communication errors, you can increase the randomization percentage so that client contact is spread out. This decreases the chance for communication overload and failure.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set RANDomize--percent-------------------------------------><
```

Parameters

percent (Required)

Specifies the percentage of the startup window over which the start times for individual clients are distributed. You can specify an integer from 0 to 50.

A value of 0 indicates that no randomization occurs and that all clients run schedules at the beginning of the startup windows.

A value of 50 indicates that clients are assigned start times that are randomly scattered across the first half of each startup window.

At installation, this value is 25, indicating that the first 25 percent of the window is used for randomization.

If you have specified DURUNITS=INDEFINITE in the DEFINE SCHEDULE command, the percentage is applied to a 24 hour period. For example, a value of 25 percent would result in a 6 hour window.

Example: Set randomization of scheduled start times

Set randomization to 50 percent.

```
set randomize 50
```

Related commands

Table 1. Commands related to SET RANDOMIZE

Command	Description
DEFINE SCHEDULE	Defines a schedule for a client operation or an administrative command.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
SET SCHEDMODES	Specifies the central scheduling mode for the server.

SET REPLRECOVERDAMAGED (Specify whether damaged files are recovered from a replication server)

Use this command to enable the system-wide recovery of damaged files from a target replication server. If this setting is turned on, the node replication process can be configured to detect damaged files on the source replication server and replace them with undamaged files from the target replication server.

The REPLRECOVERDAMAGED system parameter affects all file recovery processes across all replication processes for all nodes and file spaces. File recovery is possible only if the server software, Version 7.1.1 or later, is installed on the source and target replication servers, and if the node data was replicated before the file damage occurred.

To display the current setting, use the QUERY STATUS command.

When you install the server, the default setting is ON.

If you upgrade the server and no damaged files are detected, the default setting is ON.

If you upgrade the server and damaged files are detected, the parameter is set to OFF, and a message is issued to indicate that the recovery of damaged files is disabled. The OFF setting prevents the server from scanning database tables for damaged objects that can be recovered. Prevention of the scan is necessary in case many damaged files are detected. In that case, a scan can take a considerable amount of time, and should be scheduled when use of server resources is at a minimum. When you are ready to start the scan and recover damaged files, you must issue the SET REPLRECOVERDAMAGED command and specify the ON setting. After the server successfully completes the scan, the REPLRECOVERDAMAGED system parameter is set to ON.

The following table describes how the REPLRECOVERDAMAGED system parameter and other parameters affect the recovery of damaged, replicated files.

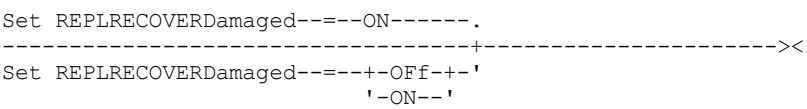
Table 1. Settings that affect the recovery of damaged files

Setting for the REPLRECOVERDAMAGED system parameter	Value of the RECOVERDAMAGED parameter on the REPLICATE NODE command	Value of the RECOVERDAMAGED parameter on the REGISTER NODE and UPDATE NODE commands	Result
OFF	YES, NO, or not specified	YES or NO	During node replication, standard replication occurs and damaged files are not recovered from the target replication server.
OFF	ONLY	YES or NO	An error message is displayed because files cannot be recovered when the REPLRECOVERDAMAGED system parameter is set to OFF.
ON	YES	YES or NO	During node replication, standard replication occurs and damaged files are recovered from the target replication server.
ON	NO	YES or NO	During node replication, standard replication occurs and damaged files are not recovered from the target replication server.
ON	ONLY	YES or NO	Damaged files are recovered from the target replication server, but standard node replication does not occur.
ON	Not specified	YES	During node replication, standard replication occurs and damaged files are recovered from the target replication server.
ON	Not specified	NO	During node replication, standard replication occurs and damaged files are not recovered from the target replication server.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

ON
: Specifies that node replication is enabled to recover damaged files from a target replication server.

OFf
: Specifies that node replication is not enabled to recover damaged files from a target replication server.

Example: Enable recovery of damaged files

To specify a system-wide setting that enables the server to recover damaged files from a target replication server, issue the following command:

```
set replrecoverdamaged on
```

Related commands

Table 2. Commands related to SET REPLRECOVERDAMAGED

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REGISTER NODE	Defines a client node to the server and sets options for that user.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
UPDATE NODE	Changes the attributes that are associated with a client node.

SET REPLRETENTION (Set the retention period for replication records)

To maintain adequate information about replication processes, you can use this command to adjust the length of time that the source replication server retains replication records in its database. The SET REPLRETENTION command specifies the retention period for client-node replication records in the source replication-server database. You can use client node replication records to monitor running and completed processes.

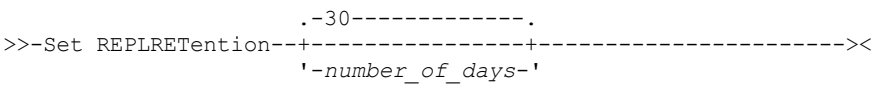
A replication record is created when REPLICATE NODE command processing is started. By default, IBM Spectrum Protect™ retains client-node replication records for 30 calendar days. A calendar day consists of 24 hours, from midnight to midnight. For example, suppose that the retention period is two calendar days. If a replication process completes at 11:00 p.m. on day *n*, a record of that process is retained for 25 hours until midnight on day *n+1*. To display the retention period for replication records, issue the QUERY STATUS command on the source replication server.

Issue the SET REPLRETENTION command on the server that acts as a source for replicated data.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

number_of_days (Required)

The number of days that the source replication server retains replication records. You can specify an integer 0 - 9999. The default value is 30.

Example: Set a retention period for client-node replication records

You want to retain client-node replication records for 10 days.

```
set replretention 10
```

Related commands

Table 1. Commands related to SET REPLRETENTION

Command	Description
QUERY REPLICATION	Displays information about node replication processes.
QUERY REPLNODE	Displays information about the replication status of a client node.

Command	Description
QUERY REPLRULE	Displays information about node replication rules.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

SET REPLSERVER (Set the target replication server)

Use this command to set the name of a target replication server. You can also use this command to change or remove a target replication server.

Issue this command on the server that acts as a source for replicated data.

To display the name of a target replication server, issue the QUERY STATUS command on a source replication server.

Important:

- The server name that you specify with this command must match the name of an existing server definition. It must also be the name of the server to be used as the target replication server. If the server name specified by this command does not match the server name of an existing server definition, the command fails.
- Use care when you are changing or removing a target replication server. If you change a target replication server, replicated client-node data is sent to a different target replication server. If you remove a target replication server, client node data is not replicated.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set REPLSERVer--+--------------------+---------------------><
                   '-target_server_name-'
```

Parameters

target_server_name

Specifies the name of the target replication server. The name that you specify must match the name of an existing server. The maximum length of a name is 64 characters.

To remove a target replication server, issue the command without specifying a value.
Note: If you do not want to continue replicating data, you can remove the node replication configuration after you remove the target replication server.

Example: Set a target replication server

The name of the server that you want to set as the target replication server is SERVER1.

```
set replserver server1
```

Related commands

Table 1. Commands related to SET REPLSERVER

Command	Description
DEFINE SERVER	Defines a server for server-to-server communications.
QUERY SERVER	Displays information about servers.

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
UPDATE SERVER	Updates information about a server.
REMOVE REPLNODE	Removes a node from replication.
REMOVE REPLSERVER	Removes a server from replication.

SET RETRYPERIOD (Set time between retry attempts)

Use this command to set the number of minutes the scheduler on a client node waits between retry attempts after a failed attempt to contact the server or after a scheduled command fails to process.

Each client can set its own retry period at the time its scheduler program is started. You can use this command to override the values specified by all clients that can connect with the server.

This command is used in conjunction with the SET MAXCMDRETRIES command to regulate the period of time and the number of retry attempts to run a failed command.

You can issue the QUERY STATUS command to display the value for the period between retries. At installation, IBM Spectrum Protect™ allows each client to determine its own retry period.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set RETRYPeriod--+---------+--------------------------------><
                    '-minutes-'
```

Parameters

minutes
: Specifies the number of minutes the scheduler on a client node waits between retry attempts after a failed attempt to contact the server or after a scheduled command fails to process. When setting the retry period, set a time period that permits more than one retry attempt within a typical startup window. You can specify an integer from 1 to 9999.

Example: Set a fifteen minute time period between retry attempts

Have the client scheduler retry failed attempts to contact the server or to process scheduled commands every fifteen minutes.

```
set retryperiod 15
```

Related commands

Table 1. Commands related to SET RETRYPERIOD

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
SET MAXCMDRETRIES	Specifies the maximum number of retries after a failed attempt to execute a scheduled command.

SET SCHEDMODES (Select a central scheduling mode)

Use this command to determine how the clients communicate with the server to begin scheduled work. You must configure each client to select the scheduling mode in which it operates.

Use this command with the SET RETRYPERIOD command to regulate the time and the number of retry attempts to process a failed command.

You can issue the QUERY STATUS command to display the value for the scheduling mode supported. At installation, this value is ANY.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set SCHEDMODes--+-ANY------+--------------------------------><
                   +-POlling--+
                   '-PRompted-'
```

Parameters

ANY
: Specifies that clients can run in either the client-polling or the server-prompted scheduling mode.

POlling
: Specifies that only the client-polling mode can be used. Client nodes poll the server at prescribed time intervals to obtain scheduled work.

PRompted
: Specifies that only the server-prompted mode can be used. This mode is only available for clients that communicate with TCP/IP. Client nodes wait to be contacted by the server when scheduled work needs to be performed and a session is available.

Example: Restrict scheduled operations to clients using client-polling

Clients can run under both server-prompted and client-polling central scheduling. You want to temporarily restrict the scheduled operations to clients that use the client-polling mode. If you set the schedule mode to POLLING, the server discontinues prompting clients to run scheduled commands. This means that any client scheduler using the server-prompted mode waits until you set the schedule mode to ANY or PROMPTED.

```
set schedmodes polling
```

Related commands

Table 1. Command related to SET SCHEDMODES

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
SET RETRYPERIOD	Specifies the time between retry attempts by the client scheduler.

SET SCRATCHPADRETENTION (Set scratch pad retention time)

Use this command to set the amount of time for which scratch pad entries are retained.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-SET SCRATCHPADRETENTION--days------------------------------><
```

Parameters

days (Required)
: Specifies the number of days that a scratchpad entry is retained after the last update to the scratchpad entry. You can enter an integer in the range 1 - 9999.

Example: Retain scratch pad entries for 367 days after they are updated

```
set scratchpadretention 367
```

Related commands

Command	Description
DEFINE SCRATCHPADENTRY	Creates a line of data in the scratch pad.
DELETE SCRATCHPADENTRY	Deletes a line of data from the scratch pad.
QUERY SCRATCHPADENTRY	Displays information that is contained in the scratch pad.
UPDATE SCRATCHPADENTRY	Updates data on a line in the scratch pad.

SET SERVERHLADDRESS (Set the high-level address of a server)

Use this command to set the high-level address (IP) of a server. IBM Spectrum Protect™ uses the address when you issue a DEFINE SERVER command with CROSSDEFINE=YES. You must use the SET SERVERHLADDRESS command for all automatic client deployments.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set SERVERHladdress--ip_address----------------------------><
```

Parameters

ip_address (Required)
: Specifies a server high-level address as a numeric dotted decimal name or a host name. If a host name is specified, a server that can resolve the name to the dotted decimal form must be available.

Example: Set the high-level address of a server

Set the high-level address of HQ_SERVER to 9.230.99.66.

```
set serverhladdress 9.230.99.66
```

Related commands

Table 1. Command related to SET SERVERHLADDRESS

Command	Description
SET CROSSDEFINE	Specifies whether to cross define servers.
SET SERVERLLADDRESS	Specifies the low-level address of a server.

Command	Description
SET SERVERPASSWORD	Specifies the server password.

SET SERVERLLADDRESS (Set the low-level address of a server)

Use this command to set the low-level address of a server. IBM Spectrum Protect™ uses the address when you issue a DEFINE SERVER command with CROSSDEFINE=YES.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set SERVERLladdress--tcp_port------------------------------><
```

Parameters

tcp_port (Required)
: Specifies the low-level address of the server. Generally, this address is identical to the TCPPORT option in the server option file of the server.

Example: Set the low-level address of a server

Set the low-level address of HQ_SERVER to 1500.

```
set serverlladdress 1500
```

Related commands

Table 1. Command related to SET SERVERLLADDRESS

Command	Description
SET CROSSDEFINE	Specifies whether to cross define servers.
SET SERVERHLADDRESS	Specifies the high-level address of a server.
SET SERVERPASSWORD	Specifies the server password.

SET SERVERNAME (Specify the server name)

Use this command to change the server name. When you install the IBM Spectrum Protect™ server, the name is set at installation to SERVER1.

Use the QUERY STATUS command to display the server name.

If you migrate from ADSM to IBM Spectrum Protect, the name is set to ADSM or the name last specified to ADSM with a SET SERVERNAME command.

Important:

- If this is a source server for a virtual volume operation, changing its name can impact its ability to access and manage the data it has stored on the corresponding target server.
- To prevent problems related to volume ownership, do not change the name of a server if it is a library client.

When changing the name of a server, be aware of the following additional restrictions:

- Windows clients use the server name to identify which passwords belong to which servers. Changing the server name after the clients are connected forces the clients to reenter the passwords.

- You must set unique names on servers that communicate with each other. On a network where clients connect to multiple servers, it is recommended that all of the servers have unique names.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set SERVername--server_name---------------------------------><
```

Parameters

server_name (Required)
Specifies the new server name. The name must be unique across a server network for enterprise event logging, enterprise configuration, command routing, or virtual volumes. The maximum length of the name is 64 characters.

Example: Name the server

Name the server WELLS_DESIGN_DEPT.

```
set servername wells_design_dept
```

Related commands

Table 1. Command related to SET SERVERNAME

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

SET SERVERPASSWORD (Set password for server)

Use this command to set the password for communication between servers to support enterprise administration and enterprise event logging and monitoring.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set SERVERPAssword--password-------------------------------><
```

Parameters

password (Required)
Specifies a password for the server. Other servers must have the same password in their definitions of this server.

Example: Set a server password

Set the password for HQ_SERVER to agave.

```
set serverpassword agave
```

Related commands

Table 1. Command related to SET SERVERPASSWORD

Command	Description
SET CROSSDEFINE	Specifies whether to cross define servers.
SET SERVERHLADDRESS	Specifies the high-level address of a server.
SET SERVERLLADDRESS	Specifies the low-level address of a server.

SET SPREPLRULEDEFAULT (Set the server replication rule for space-managed data)

Use this command to set the server replication rule for space-managed data.

Restriction: The replication rule that you set with this command is applied only if file space rules and client node rules for space-managed data are set to DEFAULT.

Issue this command on the server that acts as a source for replicated data.

You can specify a normal-priority replication rule or a high-priority replication rule. In a replication process that includes both normal and high-priority data, high-priority data is replicated first. Before you specify a rule, consider the order in which you want the data to be replicated.

For example, suppose that your client nodes contain space-managed data and backup data. Replication of the space-managed data is a higher priority than the backup data. To prioritize the space-managed data, issue the SET SPREPLRULEDEFAULT command and specify the ALL_DATA_HIGH_PRIORITY replication rule. To prioritize the backup data, issue the SET BKREPLRULEDEFAULT command and specify the ALL_DATA replication rule for backup data. The ALL_DATA rule for backup data replicates backup data with a normal priority.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set SPREPLRuledefault--+-ALL_DATA----------------+-----------><
                          +-ALL_DATA_HIGH_PRIORITY-+
                          '-NONE--------------------'
```

Parameters

ALL_DATA
: Replicates space-managed data with a normal priority.

ALL_DATA_HIGH_PRIORITY
: Replicates space-managed data with a high priority.

NONE
: Space-managed data is not replicated.

Example: Set the server replication rule for space-managed data

Set up the default rule for space-managed data to replicate with a high priority.

```
set spreplruledefault all_data_high_priority
```

Related commands

Table 1. Commands related to SET BKREPLRULEDEFAULT

Command	Description
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.

Command	Description
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY REPLICATION	Displays information about node replication processes.
QUERY REPLRULE	Displays information about node replication rules.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
SET ARREPLRULEDEFAULT	Specifies the server node-replication rule for archive data.
SET BKREPLRULEDEFAULT	Specifies the server node-replication rule for backup data.
UPDATE FILESPACE	Changes file-space node-replication rules.
UPDATE REPLRULE	Enables or disables replication rules.
VALIDATE REPLICATION	Verifies replication for file spaces and data types.

SET STATUSATRISKINTERVAL (Specifies whether to enable client at-risk activity interval evaluation)

Use this command to adjust the backup activity interval that is used when the status monitor assesses whether clients are at risk.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>---Set STATUSATRISKINTERVAL--TYPE--=-----+-ALl----------+------>
                                           +-APplications-+
                                           +-VM-----------+
                                           '-SYstems------'

>----Interval--=--value-----------------------------------------><
```

Parameters

TYPE (Required)
: Specifies the type of client that should be evaluated. Specify one of the following values:

  ALl
  : Specify this setting for all client types.

  APplications
  : Specify this setting for only application client types.

  VM
  : Specify this setting for virtual system clients types.

  SYstems
  : Specify this setting for systems client types.

Interval (Required)
: Specifies the amount of time, in hours, between client activity before the status monitor considers the client to be at risk. You can specify an integer in the range 6 - 8808. The interval value for all client types is set to 24 at server installation.

Set systems to use a two-week at-risk interval

Set the at-risk interval check for systems client types to 2 weeks.

```
set statusriskinterval type=systems interval=336
```

Related commands

Table 1. Commands related to

Command	Description
DEFINE STATUSTHRESHOLD (Define a status monitoring threshold)	Defines a status monitoring threshold.
DELETE STATUSTHRESHOLD (Delete a status monitoring threshold)	Deletes a status monitoring threshold.
QUERY MONITORSTATUS (Query the monitoring status)	Displays information about monitoring alerts and server status settings.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
QUERY STATUSTHRESHOLD (Query status monitoring thresholds)	Displays information about a status monitoring thresholds.
SET STATUSMONITOR (Specifies whether to enable status monitoring)	Specifies whether to enable status monitoring.
SET STATUSREFRESHINTERVAL (Set refresh interval for status monitoring)	Specifies the refresh interval for status monitoring.
SET STATUSSKIPASFAILURE (Specifies whether to use client at-risk skipped files as failure evaluation)	Specifies whether to use client at-risk skipped files as failure evaluation
UPDATE STATUSTHRESHOLD (Update a status monitoring threshold)	Changes the attributes of an existing status monitoring threshold.

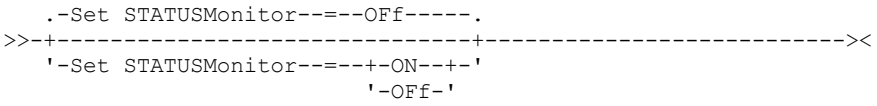
SET STATUSMONITOR (Specifies whether to enable status monitoring)

Use this command to enable and disable status monitoring. Turning status monitoring on for the first time also sets the default threshold values, and increases the event record retention to at least 14 days.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

ON

Specifies that the status monitoring is turned on. The first time that you set status monitoring to ON, it sets all the default threshold values that are specified in the DEFINE STATUSTHRESHOLD and UPDATE STATUSTHRESHOLD commands. It also sets the retention value for event records to at least 14 days. For example, when you turn status monitoring on, the default values for primary storage pool utilization is automatically set to display a warning when the threshold value reaches 80%, and an error when the threshold reaches 90% utilization.

OFF

Specifies that the status monitoring is turned off. Off is the default value.

Enable status monitoring

Set status monitoring to on to enable status monitoring.

```
set statusmonitor on
```

Related commands

Command	Description
DEFINE STATUSTHRESHOLD (Define a status monitoring threshold)	Defines a status monitoring threshold.
DELETE STATUSTHRESHOLD (Delete a status monitoring threshold)	Deletes a status monitoring threshold.
QUERY MONITORSTATUS (Query the monitoring status)	Displays information about monitoring alerts and server status settings.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
QUERY STATUSTHRESHOLD (Query status monitoring thresholds)	Displays information about a status monitoring thresholds.
SET STATUSATRISKINTERVAL (Specifies whether to enable client at-risk activity interval evaluation)	Specifies whether to enable client at-risk activity interval evaluation
SET STATUSREFRESHINTERVAL (Set refresh interval for status monitoring)	Specifies the refresh interval for status monitoring.
SET STATUSSKIPASFAILURE (Specifies whether to use client at-risk skipped files as failure evaluation)	Specifies whether to use client at-risk skipped files as failure evaluation
UPDATE STATUSTHRESHOLD (Update a status monitoring threshold)	Changes the attributes of an existing status monitoring threshold.

SET STATUSREFRESHINTERVAL (Set refresh interval for status monitoring)

Use this command to specify the number of minutes between status monitoring server queries.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set STATUSREFreshinterval--minutes--------------------------><
```

Parameters

minutes (Required)

Specifies the approximate number of minutes between status monitoring server queries. You can specify an integer in the range 1 - 2440. The default value is 5.

Restrictions:

- In a storage environment that is monitored by the Operations Center, set the same refresh interval on the hub and spoke servers. If you use different intervals, the Operations Center can show inaccurate information for spoke servers.
- Short status refresh intervals use more space in the server database and might require more processor and disk resources. For example, decreasing the interval by half doubles the required database and archive log space. Long intervals reduce the currency of Operations Center data but better suit a high-latency network configuration.
- A status refresh interval of less than 5 minutes can cause the following issues:

- Operations Center data that is supposed to be refreshed after the defined interval takes a longer time to be refreshed.
- Operations Center data that is supposed to be refreshed almost immediately when a related change occurs in the storage environment also takes a longer time to be refreshed.

Set the refresh interval for status monitoring

Specify that the server status is queried every 6 minutes, by issuing the following command:

```
set statusrefreshinterval 6
```

Related commands

Table 1. Commands related to SET STATUSREFRESHINTERVAL

Command	Description
DEFINE STATUSTHRESHOLD (Define a status monitoring threshold)	Defines a status monitoring threshold.
DELETE STATUSTHRESHOLD (Delete a status monitoring threshold)	Deletes a status monitoring threshold.
QUERY MONITORSTATUS (Query the monitoring status)	Displays information about monitoring alerts and server status settings.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
QUERY STATUSTHRESHOLD (Query status monitoring thresholds)	Displays information about a status monitoring thresholds.
SET STATUSATRISKINTERVAL (Specifies whether to enable client at-risk activity interval evaluation)	Specifies whether to enable client at-risk activity interval evaluation
SET STATUSMONITOR (Specifies whether to enable status monitoring)	Specifies whether to enable status monitoring.
SET STATUSSKIPASFAILURE (Specifies whether to use client at-risk skipped files as failure evaluation)	Specifies whether to use client at-risk skipped files as failure evaluation
UPDATE STATUSTHRESHOLD (Update a status monitoring threshold)	Changes the attributes of an existing status monitoring threshold.

SET STATUSSKIPASFAILURE (Specifies whether to use client at-risk skipped files as failure evaluation)

Use this command to enable the status monitor to consider clients as at risk when evaluating the status for each client.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set STATUSSKIPASFAILURE--+-Yes-+----------------------------->
                            '-No--'

>--TYPE--=--+-ALl----------+----------------------------------><
            +-APplications-+
            +-VM-----------+
            '-SYstems------'
```

Parameters

State (Required)
Specifies whether to enable the check for skipped files during the last backup. This check signifies that the client is at-risk if any files were skipped. Client data that is skipped or not backed up properly is considered at risk.

Yes
Specifies that the server evaluates whether a client is at risk.
No
Specifies that the server does not evaluate whether a client is at risk.

TYPE (Required)
Specifies the type of client that should be evaluated. Specify one of the following values:

ALl
Specify this setting for all client types.
APplications
Specify this setting for only application client types.
VM
Specify this setting for virtual system clients types.
SYstems
Specify this setting for systems client types.

Disable at-risk evaluation for virtual system client types

Disable the at-risk evaluation for virtual systems client types by issuing the following command:

```
set statusskipasfailure off type=vm
```

Related commands

Table 1. Commands related to SET STATUSSKIPASFAILURE

Command	Description
DEFINE STATUSTHRESHOLD (Define a status monitoring threshold)	Defines a status monitoring threshold.
DELETE STATUSTHRESHOLD (Delete a status monitoring threshold)	Deletes a status monitoring threshold.
QUERY MONITORSTATUS (Query the monitoring status)	Displays information about monitoring alerts and server status settings.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
QUERY STATUSTHRESHOLD (Query status monitoring thresholds)	Displays information about a status monitoring thresholds.
SET STATUSATRISKINTERVAL (Specifies whether to enable client at-risk activity interval evaluation)	Specifies whether to enable client at-risk activity interval evaluation
SET STATUSMONITOR (Specifies whether to enable status monitoring)	Specifies whether to enable status monitoring.
SET STATUSREFRESHINTERVAL (Set refresh interval for status monitoring)	Specifies the refresh interval for status monitoring.
UPDATE STATUSTHRESHOLD (Update a status monitoring threshold)	Changes the attributes of an existing status monitoring threshold.

SET SUBFILE (Set subfile backup for client nodes)

Use this command to set up the server to allow clients to back up subfiles. On the client's workstation, the SUBFILECACHEPATH and SUBFILECACHESIZE options must be specified in the client's options file (dsm.opt). If you are using a Windows client, you must also specify the SUBFILEBACKUP option.

With subfile backups, when a client's file has been previously backed up, any subsequent backups are typically made to the portion (a subfile) of the client's file that has changed, rather than the entire file.

Use the QUERY STATUS command to determine whether subfiles can be backed up to the server running this command.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set SUBFILE--+-Client-+-------------------------------------><
                '-No-----'
```

Parameters

Client
: Specifies that the client node can determine whether to use subfile backup.

No
: Specifies that the subfile backups are not to be used. At installation, this value is set to No.

Example: Set subfile backup for client nodes

Allow the client node to backup subfiles on the server.

```
set subfile client
```

Related commands

Table 1. Command related to SET SUBFILE

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

SET SUMMARYRETENTION (Set number of days to keep data in activity summary table)

Use this command to specify the number of days to keep information in the SQL activity summary table.

The SQL activity summary table contains statistics about each client session and server processes. For a description of the information in the SQL activity summary table, issue the following command:

```
select colname, remarks from columns where tabname='SUMMARY'
```

Issue the QUERY STATUS command to display the number of days the information is kept. At installation, IBM Spectrum Protect™ allows each server to determine its own number of days for keeping information in the SQL activity summary table.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-Set SUMmaryretention--+------+-----------------------------><
                         '-days-'
```

Parameters

days

Specifies the number of days to keep information in the activity summary table. You can specify a number from 0 to 9999. A value of 0 means that information in the activity summary table is not kept. A value of 1 specifies to keep the activity summary table for the current day.

Example: Specify the number of days to keep information in the SQL activity summary table

Set the server to retain the activity summary table information for 15 days.

```
set summaryretention 15
```

Related commands

Table 1. Commands related to SET SUMMARYRETENTION

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
SET ACTLOGRETENTION	Specifies the number of days to retain log records in the activity log.
QUERY ACTLOG	Displays messages from the server activity log.
SELECT	Allows customized queries of the IBM Spectrum Protect database.

SET TAPEALERTMSG (Set tape alert messages on or off)

Use this command to allow the IBM Spectrum Protect™ server to log notification of diagnostic information from library and drive devices. At installation, this value is set to OFF. When enabled, the server can retrieve diagnostic information from a tape or library device and display it using ANR messages. When disabled, the server will not query a device for this information.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-Set TAPEAlertmsg--+-ON--+-----------------------------------><
                     '-OFf-'
```

Parameters

ON

Specifies that diagnostic information will be reported to the server.

OFf

Specifies that diagnostic information will not be reported to the server.

Example: Set tape alert messages on

Allow the server to receive diagnostic information messages.

```
set tapealertmsg on
```

Related commands

Table 1. Command related to SET TAPEALERTMSG

Command	Description

Command	Description
QUERY TAPEALERTMSG	Displays whether the server logs hardware diagnostic information.

SET TOCLOADRETENTION (Set load retention period for table of contents)

Use this command to specify the approximate number of minutes that unreferenced table of contents data will remain loaded in the server database.

During NDMP-controlled backup operations of NAS file systems, the server can optionally collect information about files and directories in the image and store this information in a table of contents within a storage pool. The web client can be used to examine files and directories in one or more file-system images by displaying entries from the table of contents data. The server loads the necessary table of contents data into a temporary database table.

Once the data have been loaded, the user can then select those files and directories to be restored. Because this database table is temporary, the data will only remain loaded for a specified time since the last reference to that data. At installation, the retention time is set to 120 minutes. Use the QUERY STATUS command to see the table of contents load retention time.

Privilege class

To issue this command you must have system privilege.

Syntax

```
>>-Set TOCLOADRetention--minutes------------------------------><
```

Parameters

minutes (Required)
: Specifies the approximate number of minutes that an unreferenced table of contents data is retained in the database. You can specify an integer from 30 to 1000.

Example: Define the load retention period for the table of contents

Use the command, SET TOCLOADRETENTION, to specify that unreferenced table of contents data is to be retained in the database for 45 minutes.

```
set tocloadretention 45
```

Related commands

Table 1. Commands related to SET TOCLOADRETENTION

Command	Description
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

SET VMATRISKINTERVAL (Specifies the at-risk mode for an individual VM filespace)

Use this command to adjust the at-risk evaluation mode for an individual VM filespace.

Privilege class

To issue this command, you must have system privilege, policy privilege for the domain to which the node is assigned, or client owner authority over the node.

Syntax

```
>>---Set VMATRISKINTERVAL--node_name--fsid---------------------->

>--TYPE--=--+-DEFAULT--+--+--------------------+--------------><
            +-BYPASSED-+  '-Interval--=--value-'
            '-CUSTOM---'
```

Parameters

node_name (Required)
: Specifies the name of the client node, that owns the VM filespace, that you want to update.

fsid (Required)
: Specifies the filespace ID of the client node that you want to update.

TYPE (Required)
: Specifies which at-risk evaluation mode the status monitor should use when evaluating the at-risk classification for the specified nodes VM filespace. Specify one of the following values:

  DEFAULT
  : Specifies that the VM filespace is evaluated with the same interval that was specified for the SET STATUSATRISKINTERVAL command.

  BYPASSED
  : Specifies that the VM filespace is not evaluated for at-risk status by the status monitor. The at-risk status is also reported as bypassed to the Operations Center.

  CUSTOM
  : Specifies that the VM filespace is evaluated with the specified interval, rather than the interval that was specified for the SET STATUSATRISKINTERVAL command.

Interval
: Specifies the amount of time, in hours, between client backup activity before the status monitor considers the client to be at risk. You can specify an integer in the range 6 - 8808. You must specify this parameter when `TYPE = CUSTOM`. You do not specify this parameter when `TYPE = BYPASSED` or `TYPE = DEFAULT`. The interval value for all client types is set to 24 at server installation.

Set node name to use a custom 90 day at-risk interval

Set the at-risk interval for a node named *charlievm* (filespace ID 50) on datacenter node named *alice* to use a 90 day at-risk interval. You can issue the QUERY FILESPACE command to determine the filespace ID for the VM.

```
set vmatriskinterval alice 50 type=custom interval=2160
```

Bypass the at-risk interval evaluation

Exclude the VM called *davevm* (filespace ID 213) on datacenter node named *erin* from at-risk interval checking. You can issue the QUERY FILESPACE command to determine the filespace ID for the VM called *davevm*. Then set the at-risk interval check for the VM as bypassed.

```
set vmatriskinterval erin 213 type=bypassed
```

Related commands

Table 1. Commands related to set vmatriskinterval

Command	Description
SET STATUSATRISKINTERVAL (Specifies whether to enable client at-risk activity interval evaluation)	Specifies whether to enable client at-risk activity interval evaluation
SET NODEATRISKINTERVAL (Specifies at-risk mode for an individual node)	Sets the at-risk mode and interval for a node

Command	Description
QUERY MONITORSTATUS (Query the monitoring status)	Displays information about monitoring alerts and server status settings.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
SET STATUSMONITOR (Specifies whether to enable status monitoring)	Specifies whether to enable status monitoring.
SET STATUSREFRESHINTERVAL (Set refresh interval for status monitoring)	Specifies the refresh interval for status monitoring.
SET STATUSSKIPASFAILURE (Specifies whether to use client at-risk skipped files as failure evaluation)	Specifies whether to use client at-risk skipped files as failure evaluation
QUERY NODE (Query nodes)	Displays partial or complete information about one or more clients.
QUERY FILESPACE (Query one or more file spaces)	Displays information about data in file spaces that belong to a client.

SETOPT (Set a server option for dynamic update)

You can use the SETOPT command to update most server options dynamically without stopping and restarting the server. For the DBDIAGLOGSIZE option, you must stop and start the server. A SETOPT command contained in a macro or a script cannot be rolled back.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-SETOPT--option_name--option_value--------------------------><
```

Parameters

option_name (Required)

Specifies a text string of information identifying the server option to be updated. The maximum length of the text string is 255 characters. The following options are available:

- ADMINCOMMTimeout
- ADMINIDLETIMEOUT
- ALLOWREORGINDEX
- ALLOWREORGTABLE
- ARCHLOGCOMPress
- BACKUPINITIATIONROOT
- CHECKTAPEPOS
- CLIENTDEDUPTXNlimit
- COMMTimeout
- Windows DATEFORMAT
- DBDIAGLOGSize
- DBDIAGPATHFSTHreshold
- DEDUPTIER2FILESIZE
- DEDUPTIER3FILESIZE
- DEDUPREQUIRESBACKUP
- DNSLOOKUP
- EXPINterval
- EXPQUiet
- FSUSEDTHreshold

- IDLETimeout
- LDAPCACHEDURATION
- MAXSessions
- MOVEBatchsize
- MOVESizethresh
- NDMPPREFDATAINTERFACE
- Windows NUMBERFORMAT
- NUMOPENVOLSallowed
- RECLAIMDELAY
- RECLAIMPERIOD
- REORGBEGINTime
- REORGDURation
- RESOURCETimeout
- RESTOREINTERVAL
- RETENTIONEXTENSION
- AIX Linux Windows SANDISCOVERY
- AIX Linux Windows SANREFRESHTIME
- SERVERDEDUPTXNlimit
- SHREDding
- Windows TCPPORT
- THROUGHPUTDatathreshold
- THROUGHPUTTimethreshold
- Windows TIMEFORMAT
- TXNGroupmax

option_value (Required)
Specifies the value for the server option.

Example: Set the maximum number of client sessions

Update the server option for the maximum number of client sessions to a value of 40.

```
setopt maxsessions 40
```

Related commands

Table 1. Commands related to SETOPT

Command	Description
QUERY OPTION	Displays information about server options.
QUERY SYSTEM	Displays details about the IBM Spectrum ProtectIBM Spectrum Protect™ server system.

SHRED DATA (Shred data)

Use this command to manually start the process of shredding deleted sensitive data. Manual shredding is possible only if automatic shredding is disabled.

You can control automatic shred processing with the SHREDDING server option.

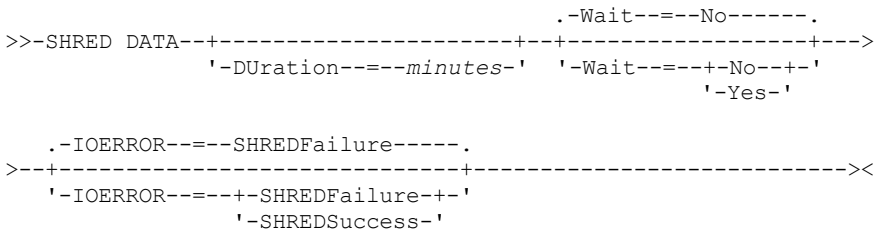
This command creates a background process that can be canceled with the CANCEL PROCESS command. To display information on background processes, use the QUERY PROCESS command.

If data from a storage pool that enforces shredding is deleted while a manual shredding process is running, it will be added to the running process.

Privilege class

To issue this command you must have system privilege.

Syntax



Parameters

DURATION

Specifies the maximum number of minutes the shredding process runs before being automatically canceled. When the specified number of minutes elapses, the server cancels the shredding process. As soon as the process recognizes the cancellation, it ends. Because of this, the process may run longer than the value you specified for this parameter. You can specify a number from 1 to 9999. This parameter is optional. If not specified, the server will stop only after all deleted sensitive data has been shredded.

Wait

Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default is No. Possible values are:

No

Specifies that the server processes this command in the background. You can continue with other tasks while the command is being processed. Messages created from the background process are displayed either in the activity log or the server console, or both, depending on where messages are logged. To cancel a background process, use the CANCEL PROCESS command. If you cancel this process, some files might already have been shredded before the cancellation. This is the default.

Yes

Specifies that the server processes this command in the foreground. You must wait for the operation to complete before continuing with other tasks. The server displays the output messages to the administrative client when the operation completes. Messages are also displayed either in the activity log or the server console, or both, depending on where messages are logged.

AIX Linux Note: You cannot specify WAIT=YES from the server console.

IOERROR

Specifies whether an I/O error encountered while shredding the data is to be considered a successful shred. This parameter is optional. The default is SHREDFAILURE. Possible values are:

SHREDFailure

Specifies that if the server encounters an I/O error while shredding, the data will not be considered successfully shredded and the owning file will be marked as damaged. The server will attempt to shred the data again the next time the shredding process runs, giving you a chance to correct the error and ensure the data can be properly shredded.

SHREDSuccess

Specifies that if the server encounters an I/O error while shredding and the owning file had been previously marked as damaged, the data will be considered successfully shredded. You should use this option only after the server has reported I/O errors while shredding and you are unable to correct the error.

Example: Shred data

Manually start the shredding of all deleted sensitive data. Continue the process for up to six hours before automatically canceling it.

```
shred data duration=360
```

Related commands

Table 1. Commands related to SHRED DATA

Command	Description
CANCEL PROCESS	Cancels a background server process.

Command	Description
QUERY PROCESS	Displays information about background processes.
QUERY SHREDSTATUS	Displays information about data waiting to be shredded.

SUSPEND EXPORT (Suspend a currently running export operation)

Use this command to suspend a currently running server-to-server export operation which has a FILEDATA value that is not NONE. The export operation that you want to suspend must be past the initialization phase to be eligible for suspension. The state of the export operation is saved. The operation can be restarted by issuing the RESTART EXPORT command.

Privilege class

You must have system privilege to issue this command.

Syntax

```
                    .-*---------------------.
>>-SUSPend EXPOrt -+-----------------------+-------------------><
                    '---export_identifier---'
```

Parameters

EXPORTIDentifier
: This optional parameter specifies the name of the export operation. You can find a name by issuing the QUERY EXPORT command to list all the currently running server-to-server export operations that can be suspended. You can also use the wildcard character to specify the name.

Example: Suspend a specific export operation

Suspend the running export operation EXPORTALLACCTNODES. No output is generated when you issue the SUSPEND EXPORT command. You must issue the QUERY EXPORT command to verify that the EXPORTALLACCTNODES operation is suspended.

```
suspend export exportallacctnodes
```

Example: Suspend all running export operations

Suspend all the export operations with a state of RUNNING.

```
suspend export *
```

Related commands

Table 1. Commands related to SUSPEND EXPORT

Command	Description
CANCEL EXPORT	Deletes a suspended export operation.
EXPORT NODE	Copies client node information to external media or directly to another server.
EXPORT SERVER	Copies all or part of the server to external media or directly to another server.
QUERY EXPORT	Displays the export operations that are currently running or suspended.
RESTART EXPORT	Restarts a suspended export operation.

UNLOCK commands

Use the UNLOCK commands to reestablish access after an object was locked.

- UNLOCK ADMIN (Unlock an administrator)
- UNLOCK NODE (Unlock a client node)
- UNLOCK PROFILE (Unlock a profile)

UNLOCK ADMIN (Unlock an administrator)

Use the UNLOCK ADMIN command to allow a locked administrator to access the server again. You can also unlock multiple administrators that authenticate with the same method.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-UNLOCK Admin--+-*----------+--+------------------------------+-><
                 '-admin_name-'  '-AUTHentication--=--+-LOcal-+-'
                                                      '-LDap--'
```

Parameters

admin_name (Required)
: Specifies the name of the administrator to unlock. You can use wildcard characters to specify the administrator name. You do not have to enter an administrator name if you want to unlock all of the administrators according to their method of authentication. Use the wildcard with an authentication method to unlock multiple administrators. The parameter is required (no default wildcard).

AUTHentication
: Specifies the method of password authentication that is needed for an administrator to log on.

  LOcal
  : Specifies that you want to unlock administrator user IDs that authenticate passwords with the IBM Spectrum Protect™ server.

  LDap
  : Specifies that you want to unlock administrator user IDs that authenticate passwords with an LDAP directory server.

Example: Unlock an administrator user ID

The administrator user ID JOE is locked out of IBM Spectrum Protect. Allow JOE to access the server. Issue the following command:

```
unlock admin joe
```

Example: Unlock all administrator user IDs that authenticate passwords with an LDAP directory server

The administrator user ID that use passwords that authenticate with an LDAP directory server must be unlocked so the IDs can communicate with the IBM Spectrum Protect server.

```
unlock admin * authentication=ldap
```

Command	Description
QUERY ADMIN	Displays information about one or more IBM Spectrum Protect administrators.

UNLOCK NODE (Unlock a client node)

Use this command to allow a locked client node to access the server again. You can also unlock multiple nodes that use the same method of authentication.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the client node is assigned.

Syntax

```
>>-UNLOCK Node--+-*---------+--+------------------------------+->< 
               '-node_name-'  '-AUTHentication--=--+-LOcal-+-'
                                                   '-LDap--'
```

Parameters

node_name (Required)
: Specifies the name of the client node to unlock. You can use wildcard characters to specify the node name. You do not have to enter a node name if you want to unlock all of the nodes according to their method of authentication. Use the wildcard with an authentication method to unlock groups of nodes. The parameter is required. There is no default wildcard character available.

AUTHentication
: Specifies the node password authentication method. This parameter is optional.

  LOcal
  : Specifies that you want to unlock nodes that authenticate passwords with the IBM Spectrum Protect™ server.

  LDap
  : Specifies that you want to unlock nodes that authenticate passwords with an LDAP directory server.

Example: Unlock a node

The client node SMITH is locked out of IBM Spectrum Protect. Allow SMITH to access the server.

```
unlock node smith
```

Example: Unlock all nodes that authenticate with the IBM Spectrum Protect server

The nodes that are not authenticating passwords with LDAP directory servers must be unlocked.

```
unlock node * authentication=local
```

Related commands

Table 1. Commands related to UNLOCK NODE

Command	Description
LOCK NODE	Prevents a client from accessing the server.
QUERY NODE	Displays partial or complete information about one or more clients.

UNLOCK PROFILE (Unlock a profile)

Use this command on a configuration manager to unlock a configuration profile so it can be distributed to subscribing managed servers.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-UNLOCK PROFIle--profile_name---------------------------------><
```

Parameters

profile_name (Required)
Specifies the profile to unlock. You can use wildcard characters to indicate multiple names.

Example: Unlock a profile

Unlock a profile named TOM.

```
unlock profile tom
```

Related commands

Table 1. Commands related to UNLOCK PROFILE

Command	Description
COPY PROFILE	Creates a copy of a profile.
DEFINE PROFASSOCIATION	Associates objects with a profile.
DEFINE PROFILE	Defines a profile for distributing information to managed servers.
DELETE PROFASSOCIATION	Deletes the association of an object with a profile.
DELETE PROFILE	Deletes a profile from a configuration manager.
LOCK PROFILE	Prevents distribution of a configuration profile.
QUERY PROFILE	Displays information about configuration profiles.
SET CONFIGMANAGER	Specifies whether a server is a configuration manager.
UPDATE PROFILE	Changes the description of a profile.

UPDATE commands

Use the UPDATE command to modify one or more attributes of an existing IBM Spectrum Protect™ object.

- UPDATE ADMIN (Update an administrator)
- UPDATE ALERTTRIGGER (Update a defined alert trigger)
- UPDATE ALERTSTATUS (Update the status of an alert)
- UPDATE BACKUPSET (Update a retention value assigned to a backup set)
- UPDATE CLIENTOPT (Update a client option sequence number)
- UPDATE CLOPTSET (Update a client option set description)
- UPDATE COLLOCGROUP (Update a collocation group)
- UPDATE COPYGROUP (Update a copy group)
- UPDATE DATAMOVER (Update a data mover)
- UPDATE DEVCLASS (Update the attributes of a device class)
- UPDATE DOMAIN (Update a policy domain)
- UPDATE DRIVE (Update a drive)
- UPDATE FILESPACE (Update file-space node-replication rules)

- UPDATE LIBRARY (Update a library)
- UPDATE LIBVOLUME (Change the status of a storage volume)
- UPDATE MACHINE (Update machine information)
- UPDATE MGMTCLASS (Update a management class)
- UPDATE NODE (Update node attributes)
- UPDATE NODEGROUP (Update a node group)
- UPDATE PATH (Change a path)
- UPDATE POLICYSET (Update a policy set description)
- UPDATE PROFILE (Update a profile description)
- UPDATE RECOVERYMEDIA (Update recovery media)
- UPDATE REPLRULE (Update replication rules)
- UPDATE SCHEDULE (Update a schedule)
- UPDATE SCRIPT (Update an IBM Spectrum Protect script)
- UPDATE SERVER (Update a server defined for server-to-server communications)
- UPDATE SERVERGROUP (Update a server group description)
- UPDATE SPACETRIGGER (Update the space triggers)
- UPDATE STATUSTHRESHOLD (Update a status monitoring threshold)
- UPDATE STGPOOL (Update a storage pool)
- AIX | Linux | Windows UPDATE STGPOOLDIRECTORY (Update a storage pool directory)
- UPDATE VIRTUALFSMAPPING (Update a virtual file space mapping)
- UPDATE VOLHISTORY (Update sequential volume history information)
- UPDATE VOLUME (Change a storage pool volume)

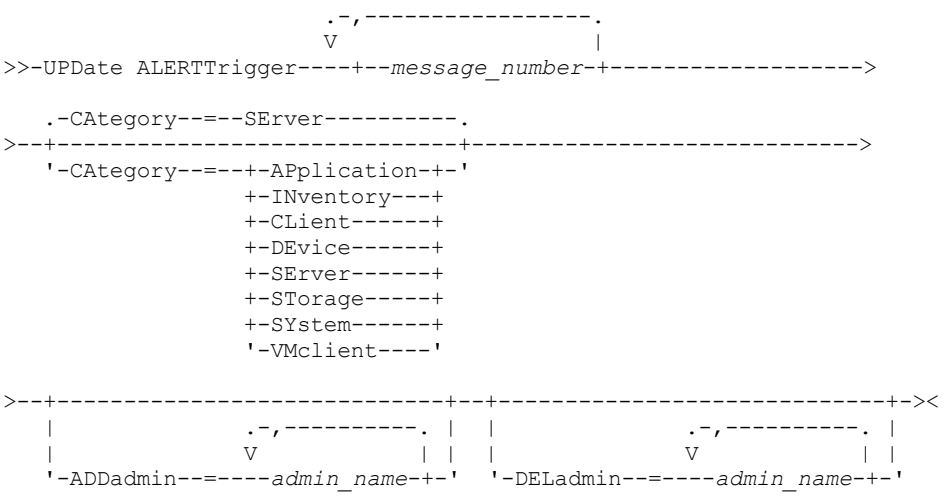
UPDATE ALERTTRIGGER (Update a defined alert trigger)

Use this command to update the attributes of one or more alert triggers.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

message_number (Required)
: Specifies the message number that you want to associate with the alert trigger. Specify multiple message numbers, which are separated by commas, and no intervening spaces. Message numbers are a maximum of eight characters in length.

CATegory
: Specifies the category type for the alert, which is determined by the message types. The default value is SERVER.
Note: Changing the category of an alert trigger does not change the category of existing alerts on the server. New alerts are categorized with the new category.

Specify one of the following values:

APplication
: Alert is classified as application category. For example, you can specify this category for messages that are associated with application (TDP) clients.

INventory
: Alert is classified as inventory category. For example, you can specify this category for messages that are associated with the database, active log file, or archive log file.

CLient
: Alert is classified as client category. For example, you can specify this category for messages that are associated with general client activities.

DEvice
: Alert is classified as device category. For example, you can specify this category for messages that are associated with device classes, libraries, drives, or paths.

SErver
: Alert is classified as general server category. For example, you can specify this category for messages that are associated with general server activities or events.

STorage
: Alert is classified as storage category. For example, you can specify this category for messages that are associated with storage pools.

SYstems
: Alert is classified under system clients category. For example, you can specify this category for messages that are associated with system backup and archive or hierarchical storage management (HSM) backup-archive clients.

VMclient
: Alert is classified under VMclient category. For example, you can specify this category for messages that are associated with virtual machine clients.

ADmin
: This optional parameter specifies the name of the administrator who receives email notification of this alert. The alert trigger is defined successfully even if no administrator names are specified.

ADDadmin
: Specifies the administrator name that you want to add to the list of administrators that receive email alerts. Specify multiple administrator names, which are separated by commas, and no intervening spaces.

DELadmin
: Specifies the administrator name that you want to delete from the list of administrators that receive email alerts. Specify multiple administrator names, which are separated by commas, and no intervening spaces.

Update alert trigger

Add the names of the administrators that want to be notified when ANR1073E, ANR1074E alerts occur, and also delete the name of an administrator that no longer wants to be notified, by issuing the following command:

```
update alerttrigger ANR1073E,ANR1074E ADDadmin=djee,cdawson,mhaye deladmin=harryh
```

Related commands

Table 1. Commands related to UPDATE ALERTTRIGGER

Command	Description
DEFINE ALERTTRIGGER (Define an alert trigger)	Associates specified messages to an alert trigger.
DELETE ALERTTRIGGER (Remove a message from an alert trigger)	Removes a message number that can trigger an alert.
QUERY ALERTSTATUS (Query the status of an alert)	Displays information about alerts that have been issued on the server.
QUERY ALERTTRIGGER (Query the list of defined alert triggers)	Displays message numbers that trigger an alert.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
UPDATE ALERTSTATUS (Update the status of an alert)	Updates the status of a reported alert.

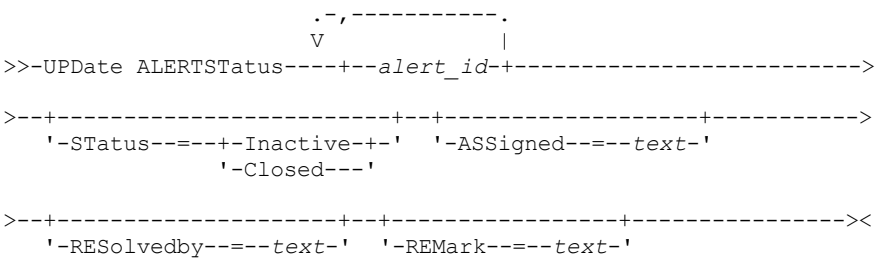
UPDATE ALERTSTATUS (Update the status of an alert)

Use this command to update the status of a reported alert.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

alert_id (Required)
: Species the alert that you want to update. You can specify multiple message numbers by separating them with commas and no intervening spaces.

STatus
: Specifies the status type that you want to update. Alerts can be changed from active to inactive or closed, or from inactive to closed. Possible values are:

  Inactive
  : Active alerts can be changed to inactive status.

  Closed
  : Active and inactive alerts can be changed to closed status.

ASSigned
: Specifies the administrator name that is assigned the alert that you want to query.

RESolvedby
: Specifies the administrator name that resolved the alert that you want to query.

REMark
: This parameter specifies comment text. The comment text cannot exceed 255 characters. If the description contains any blank spaces, enclose the entire text in quotation marks (""). Remove previously defined text by specifying a null string ("") for this value.

Update the comment text in an alert

Issue the following command to update the comment text for alert ID number 25 and indicate that *DJADMIN* is working on the alert:

```
update alertstatus 25 assigned=DJADMIN
```

Update alert status

Issue the following command to change alert ID number 72 to the closed status, and add a remark about how the alert was resolved:

```
update alertstatus 72 status=closed remark="Increased the file system size for
 the active log"
```

Related commands

Table 1. Commands related to UPDATE ALERTSTATUS

Command	Description
DEFINE ALERTTRIGGER (Define an alert trigger)	Associates specified messages to an alert trigger.
DELETE ALERTTRIGGER (Remove a message from an alert trigger)	Removes a message number that can trigger an alert.
QUERY ALERTSTATUS (Query the status of an alert)	Displays information about alerts that have been issued on the server.
QUERY ALERTTRIGGER (Query the list of defined alert triggers)	Displays message numbers that trigger an alert.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
UPDATE ALERTTRIGGER (Update a defined alert trigger)	Updates the attributes of one or more alert triggers.

UPDATE ADMIN (Update an administrator)

Use this command to change the password or contact information for an administrator. However, you cannot update the SERVER_CONSOLE administrator name.

AIX | Linux Passwords for administrators must be changed after a length of time that is determined by the SET PASSEXP command. The SET PASSEXP command does not affect passwords that authenticate with a Lightweight Directory Access Protocol (LDAP) server.

Restriction: You cannot update the authentication method for your own user ID. If necessary, another administrator must make that change. Also, when you update a password with the UPDATE ADMIN command, you cannot use a wildcard with the `admin_name` parameter.

Administrators with the same name as a node can be created during a REGISTER NODE command. To keep the node and administrator with the same name synchronized, the authentication method and the SSLREQUIRED setting for the node are updated to match the administrator. If the administrator authentication method is changed from LOCAL to LDAP and a password is not provided, the node is put in "LDAP pending" status. A password is then requested at the next logon. Passwords between same-named nodes and administrators are kept in sync through any authentication change.

You must use the RENAME ADMIN command to change the name of a registered administrator.

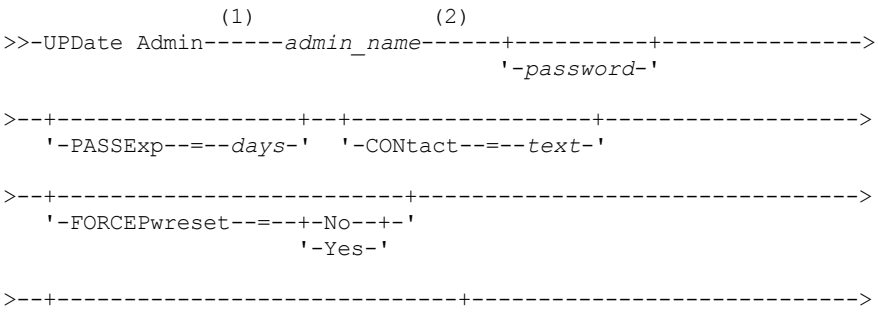
For users of Lightweight Directory Access Protocol (LDAP) servers:

- The information in this documentation applies to the LDAP authentication method that is preferred for IBM Spectrum Protect™ V7.1.7 or later servers. For instructions about using the previous LDAP authentication method, see Managing passwords and logon procedures.
- If an administrative user ID matches a node name, do not update the authentication method to LDAP. If you do, you might see unexpected behavior because of automatic password changes that update the same password twice. As a result, the password might become unknown to the administrative user ID. Alternatively, the password update operation might fail.

Privilege class

To issue this command to change another administrator password or contact information, you must have system privilege. Any administrator can issue this command to update his or her own password or contact information.

Syntax



```
   '-EMAILADdress--=--userID@node-'

>--+-------------------------------------------------------------+-->
   |                                                 (3)         |
   |                                .-SYNCldapdelete------=--No--. |
   '-AUTHentication--=--+-LOcal-+--+-----------------------------+-'
                        '-LDap--'  '-SYNCldapdelete--=--+-Yes-+-'
                                                        '-No--'

>--+---------------------------------+-------------------------->
   |                 (4)             |
   '-SSLrequired--=------+-Yes-----+-'
                         +-No------+
                         '-DEFault-'

   .-SESSIONSECurity--=--TRANSitional-----.
>--+--------------------------------------+-------------------->
   '-SESSIONSECurity--=--+-STRict-------+-'
                         '-TRANSitional-'

>--+------------------+----------------------------------------><
   '-ALert--=--+-Yes-+-'
               '-No--'
```

Notes:

1. You must specify at least one optional parameter on this command.
2. Passwords are optional for this command, except when changing the authentication method from LDAP to LOCAL.
3. The SYNCldapdelete parameter applies only if an administrator authenticating to an LDAP directory server reverts to local authentication.
4. The SSLREQUIRED parameter is deprecated.

Parameters

admin_name (Required)
: Specifies the name of the administrator to be updated.

password
: Specifies the administrator's password. This parameter is optional in most cases. If the administrator authentication method is changed from LDAP to LOCAL, a password is required. If an LDAP server is used to authenticate administrators, do not specify a password by using the UPDATE ADMIN command.

PASSExp
: Specifies the number of days the password remains valid. You can set the password expiration period in the range 0 - 9999. A value of 0 means that the password never expires. This parameter is optional. If you do not specify this parameter, the password expiration period is unchanged. This parameter does not apply to passwords that are stored on an LDAP directory server.

CONtact
: Specifies a text string that identifies the administrator. This parameter is optional. Enclose the text string in quotation marks if it contains any blanks. To remove previously defined contact information, specify a null string ("").

FORCEPwreset
: Specifies whether the administrator is required to change or reset the password. This parameter is optional. Possible values are:

  No
  : Specifies that the administrator does not need to change or reset the password while attempting to sign on to the server. The password expiration period is set by the SET PASSEXP command.

  Yes
  : Specifies that the administrator's password will expire at the next sign-on. The administrator must change or reset the password then. If a password is not specified, you receive a syntax error.
  Restrictions:

  - For administrative user IDs that authenticate with an LDAP server, password expiration is set by using LDAP server utilities. For this reason, do not specify FORCEPWRESET=YES if you plan to specify AUTHENTICATION=LDAP.
  - If you plan to update an administrative user ID to authenticate with an LDAP server, and you specified FORCEPWRESET=YES, you must change the password before you can specify FORCEPWRESET=NO and AUTHENTICATION=LDAP.

EMAILADdress
This parameter is used for additional contact information. The information that is specified by this parameter is not acted upon by IBM Spectrum Protect.

AUTHentication
This parameter determines the password authentication method that the administrator ID uses; either LDAP or LOCAL.

LOcal
Specifies that the administrator uses the local IBM Spectrum Protect server database to store passwords for authentication.

LDap
Specifies that the administrator uses an LDAP directory server for password authentication.

SYNCldapdelete
This parameter applies only if an administrator who authenticates to an LDAP server wants to revert to local authentication.

Yes
Specifies that the administrator is deleted from the LDAP server.
Restriction: Do not specify a value of YES. (The value of YES is appropriate only for users of the previous LDAP authentication method, which is described in Managing passwords and logon procedures.)

No
Specifies that the administrator is not deleted from the LDAP server. This is the default.

SSLrequired (deprecated)

Specifies whether the administrator user ID must use the Secure Sockets Layer (SSL) protocol to communicate between the IBM Spectrum Protect server and the backup-archive client. When you authenticate passwords with an LDAP directory server, you must protect the sessions by using SSL or another network security method.

Important: Beginning with IBM Spectrum Protect Version 8.1.2, this parameter is deprecated. Validation that was enabled by this parameter is replaced by the TLS 1.2 protocol, which is enforced by the SESSIONSECURITY parameter. The SSLREQUIRED parameter is ignored. Update your configuration to use the SESSIONSECURITY parameter.

SESSIONSECurity
Specifies whether the administrator must use the most secure settings to communicate with an IBM Spectrum Protect server. This parameter is optional.

You can specify one of the following values:

STRict
Specifies that the strictest security settings are enforced for the administrator. The STRICT value uses the most secure communication protocol available, which is currently TLS 1.2. The TLS 1.2 protocol is used for SSL sessions between the server and the administrator. To specify whether the server uses TLS 1.2 for the entire session or only for authentication, see the SSL client option.
To use the STRICT value, the following requirements must be met to ensure that the administrator can authenticate with the server:

- Both the administrator and server must be using IBM Spectrum Protect software that supports the SESSIONSECURITY parameter.
- The administrator must be configured to use the TLS 1.2 protocol for SSL sessions between the server and the administrator.

Administrators set to STRICT that do not meet these requirements are unable to authenticate with the server.

TRANSitional
Specifies that the existing security settings are enforced for the administrator. This is the default value. This value is intended to be used temporarily while you update your security settings to meet the requirements for the STRICT value.

If SESSIONSECURITY=TRANSITIONAL and the administrator has never met the requirements for the STRICT value, the administrator will continue to authenticate by using the TRANSITIONAL value. However, after an administrator meets the requirements for the STRICT value, the SESSIONSECURITY parameter value automatically updates from TRANSITIONAL to STRICT. Then, the administrator can no longer authenticate by using a version of the client or an SSL/TLS protocol that does not meet the requirements for STRICT. In addition, after an administrator successfully authenticates by using a more secure communication protocol, the administrator can no longer authenticate by using a less secure protocol. For example, if an administrator that is not using SSL is updated and successfully authenticates by using TLS 1.2, the administrator can no longer authenticate by using no SSL protocol or TLS 1.1.

This restriction also applies when you use functions such as command routing or server-to-server export, when the administrator authenticates to the IBM Spectrum Protect server as an administrator from another server.

ALert
Specifies whether alerts are sent to an administrators email address.

Yes
Specifies that alerts are sent to the specified administrators email address.

No
Specifies that alerts are not sent to the specified administrators email address. This is the default value.

Tip: Alert monitoring must be enabled, and email settings must be correctly defined to successfully receive alerts by email. To view the current settings, issue the QUERY MONITORSETTINGS command.

Example: Update a password and password expiration period

Update the administrator LARRY to have the password SECRETWORD and a password expiration period of 120 days. The administrator in this example is authenticated to the IBM Spectrum Protect server.

```
update admin larry secretword passexp=120
```

Example: Update all administrators to communicate with a server by using strict session security

Update all administrators to use the strictest security settings to authenticate with the server.

```
update admin * sessionsecurity=strict
```

Related commands

Table 1. Commands related to UPDATE ADMIN

Command	Description
QUERY ADMIN	Displays information about one or more IBM Spectrum Protect administrators.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
REGISTER ADMIN	Defines a new administrator without granting administrative authority.
REGISTER NODE	Defines a client node to the server and sets options for that user.
RENAME ADMIN	Changes an IBM Spectrum Protect administrator’s name.
SET PASSEXP	Specifies the number of days after which a password is expired and must be changed.
UPDATE NODE	Changes the attributes that are associated with a client node.

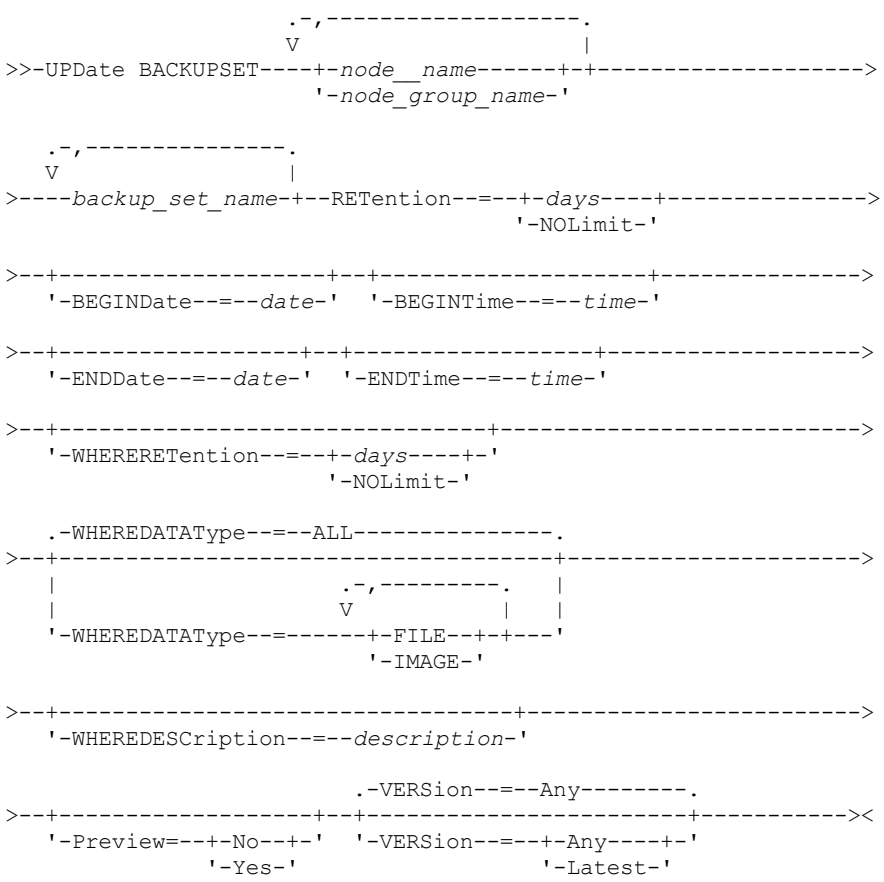
UPDATE BACKUPSET (Update a retention value assigned to a backup set)

Use this command to update the retention value associated with a client's backup set.

Privilege class

To issue this command, you must have system privilege or policy privilege for the domain to which the client node is assigned.

Syntax



Parameters

node_name or node_group_name (Required)
: Specifies the names of the client nodes or node groups whose data is contained in the specified backup set to be updated. To specify multiple node and node group names, separate the names with commas and no intervening spaces. The node names that you specify can contain wildcard characters, but node group names cannot contain wildcard characters.

backup_set_name (Required)
: Specifies the name of the backup set to update. The backup set name you specify can contain wildcard characters. You can specify more than one backup set name by separating the names with commas and no intervening spaces.

RETention (Required)
: Specifies the updated number of days to retain the backup set on the server. You can specify an integer from 0 to 30000. The values are:

  days
  : Specifies the updated number of days to retain the backup set.

  NOLimit
  : Specifies that the backup set is retained on the server indefinitely. If you specify NOLIMIT, the server retains the volumes containing the backup set forever, unless a user or administrator deletes the volumes from server storage. Attention: Updating the retention period of a backup set may cause it to expire at a different time from other backup sets that might be stored on the same output media. In either case, the media will not be made available for other uses until all of its backup sets have expired.

BEGINDate
: Specifies the beginning date in which the backup set to update was created. This parameter is optional. The default is the current date. You can use this parameter with the BEGINTIME parameter to specify a range for the date and time. If you specify a begin date without a begin time, the time will be at 12:00 a.m. (midnight) on the date you specify.
  You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1999
TODAY	The current date	TODAY
TODAY+days *or* +days	The current date plus days specified.	TODAY +3 *or* +3.
TODAY-days **or** -days	The current date minus days specified.	TODAY-3 *or* -3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

BEGINTime

Specifies the beginning time in which the backup set to update was created. This parameter is optional. The default is the current time. You can use this parameter with the BEGINDATE parameter to specify a range for the date and time. If you specify a begin time without a begin date, the date will be the current date at the time you specify.
You can specify the time by using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes on the specified end date	NOW+02:00 *or* +02:00.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes on the specified end date	NOW-02:00 *or* –02:00.

ENDDate

Specifies the ending date in which the backup set to update was created. This parameter is optional. You can use this parameter with the ENDTIME parameter to specify a range for the date and time. If you specify an end date without an ending time, the time will be at 11:59:59 p.m. on the specified end date.
You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1999
TODAY	The current date	TODAY
TODAY+days *or* +days	The current date plus days specified.	TODAY +3 *or* +3.
TODAY-days *or* — days	The current date minus days specified.	TODAY -3 *or* -3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM

Value	Description	Example
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

ENDTime

Specifies the ending time in which the backup set to update was created. This parameter is optional. You can use this parameter with the ENDDATE parameter to specify a range for the date and time. If you specify an end time without an end date, the date will be the current date at the time you specify.

You can specify the time by using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes specified	NOW+02:00 *or* +02:00.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes specified	NOW-02:00 *or* –02:00.

WHERERETention

Specifies the retention value, specified in days, that is associated with the backup set to update. The values are:

days
: Specifies that the backup set that is retained this number of days is updated.

NOLimit
: Specifies that the backup set retained indefinitely is updated.

WHEREDESCription

Specifies the description that is associated with the backup set to update. This parameter is optional. You can specify wildcard characters for the description. Enclose the description in quotation marks if it contains any blank characters.

WHEREDATAType

Specifies the backup sets containing the specified types of data are to be updated. This parameter is optional. The default is that backup sets for all types of data (file level, image, and application) are to be updated. To specify multiple data types, separate each data type with a comma and no intervening spaces. Possible values are:

ALL
: Specifies that backup sets for all types of data (file level, image, and application) are to be updated. This is the default.

FILE
: Specifies that a file level backup set is to be updated. File level backup sets contain files and directories backup up by the backup-archive client.

IMAGE
: Specifies that an image backup set is to be updated. Image backup sets contain images created by the backup-archive client BACKUP IMAGE command.

Preview

Specifies whether to preview the list of backup sets to update, without actually updating the backup sets. This parameter is optional. The default is No. The values are:

No
: Specifies that the backup sets are updated.

Yes
: Specifies that the server displays the backup sets to update, without actually updating the backup sets.

VERSion

Specifies the version of the backup set to update. Backup sets with the same prefix name are considered to be different versions of the same backup set. This parameter is optional. The default is to update any version that matches the criteria specified on the command. The values are:

Any
: Specifies that any version that matches the criteria specified on the command should be updated.

Latest
: Specifies that only the most recent version of the backup set should be updated. If other criteria specified on the command (for example, ENDDATE or WHERERETENTION) exclude the most recent version of the backup set, then no backup set will be updated.

Example: Update a retention period

Update the retention period where the description is Healthy Computers. The retention period is assigned to backup set PERS_DATA.3099 that contains data from client node JANE. Change the retention period to 70 days.

```
update backupset jane pers_data.3099
retention=70 wheredescription="healthy computers"
```

Related commands

Table 1. Commands related to UPDATE BACKUPSET

Command	Description
DEFINE BACKUPSET	Defines a previously generated backup set to a server.
DEFINE NODEGROUP	Defines a group of nodes.
DEFINE NODEGROUPMEMBER	Adds a client node to a node group.
DELETE BACKUPSET	Updates a retention value associated with a backup set.
DELETE NODEGROUP	Deletes a node group.
DELETE NODEGROUPMEMBER	Deletes a client node from a node group.
GENERATE BACKUPSET	Generates a backup set of a client's data.
GENERATE BACKUPSETTOC	Generates a table of contents for a backup set.
QUERY BACKUPSET	Displays backup sets.
QUERY BACKUPSETCONTENTS	Displays contents contained in backup sets.
QUERY NODEGROUP	Displays information about node groups.
UPDATE NODEGROUP	Updates the description of a node group.

UPDATE CLIENTOPT (Update a client option sequence number)

Use this command to update the sequence number of a client option in a client option set.

Privilege class

To issue this command, you must have system privilege or unrestricted policy privilege.

Syntax

```
>>-UPDate CLIENTOpt--option_set_name--option_name--------------->

>--current_sequence_number--new_sequence_number----------------><
```

Parameters

option_set_name (Required)
: Specifies the name of the option set.

option_name (Required)
: Specifies a valid client option.

current_sequence_number (Required)
: Specifies the current sequence number of the option.

new_sequence_number (Required)
Specifies the new sequence number of the option.

Example: Update a client option sequence number

To update the current client option sequence number issue the following command:

```
update clientopt eng dateformat 0 9
```

Related commands

Table 1. Commands related to UPDATE CLIENTOPT

Command	Description
COPY CLOPTSET	Copies a client option set.
DEFINE CLIENTOPT	Adds a client option to a client option set.
DELETE CLIENTOPT	Deletes a client option from a client option set.
DELETE CLOPTSET	Deletes a client option set.
QUERY CLOPTSET	Displays information about a client option set.

UPDATE CLOPTSET (Update a client option set description)

Use this command to update the description for a client option set.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the client node is assigned.

Syntax

```
>>-UPDate CLOptset--option_set_name------------------------------>

>--DESCription--=--description---------------------------------><
```

Parameters

option_set_name (Required)
Specifies the name of the option set.
DESCription (Required)
Specifies a description of the client option set. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains blank characters.

Example: Update a client option set description

Update the description for a client option set named ENG.

```
update cloptset eng description="unix"
```

Related commands

Table 1. Commands related to UPDATE CLOPTSET

Command	Description
COPY CLOPTSET	Copies a client option set.
DEFINE CLIENTOPT	Adds a client option to a client option set.
DEFINE CLOPTSET	Defines a client option set.

Command	Description
DELETE CLIENTOPT	Deletes a client option from a client option set.
DELETE CLOPTSET	Deletes a client option set.
QUERY CLOPTSET	Displays information about a client option set.
UPDATE CLIENTOPT	Updates the sequence number of a client option in a client option set.

UPDATE COLLOCGROUP (Update a collocation group)

Use this command to modify the description of a collocation group.

Privilege class

To issue this command, you must have system or unrestricted storage privilege.

Syntax

```
>>-UPDate COLLOCGroup--group_name------------------------------>

>--DESCription--=--description---------------------------------><
```

Parameters

group_name
: Specifies the name of the collocation group whose description you want to update.

DESCription (Required)
: Specifies a description of the collocation group. This parameter is required. The maximum length of the description is 255 characters. If the description contains any blanks, enclose the entire description in quotation marks.

Example: Update a collocation group

Update the collocation group, GROUP1, with a new description.

```
update collocgroup group1 "Human Resources"
```

Related commands

Table 1. Commands related to UPDATE COLLOCGROUP

Command	Description
DEFINE COLLOCGROUP	Defines a collocation group.
DEFINE COLLOCMEMBER	Adds a client node or file space to a collocation group.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DELETE COLLOCGROUP	Deletes a collocation group.
DELETE COLLOCMEMBER	Deletes a client node or file space from a collocation group.
MOVE NODEDATA	Moves data for one or more nodes, or a single node with selected file spaces.
QUERY COLLOCGROUP	Displays information about collocation groups.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY NODEDATA	Displays information about the location and size of data for a client node.

Command	Description
QUERY STGPOOL	Displays information about storage pools.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.
UPDATE STGPOOL	Changes the attributes of a storage pool.

UPDATE COPYGROUP (Update a copy group)

Use this command to update a backup or archive copy group. To allow clients to use the updated copy group, you must activate the policy set that contains the copy group.

Tip: The UPDATE COPYGROUP command fails if you specify a copy storage pool as a destination.

The UPDATE COPYGROUP command takes two forms, depending upon whether the update is for a backup copy group or for an archive copy group. The syntax and parameters for each form are defined separately.

Table 1. Commands related to UPDATE COPYGROUP

Command	Description
ACTIVATE POLICYSET	Validates and activates a policy set.
ASSIGN DEFMGMTCLASS	Assigns a management class as the default for a specified policy set.
COPY MGMTCLASS	Creates a copy of a management class.
DEFINE COPYGROUP	Defines a copy group for backup or archive processing within a specified management class.
DEFINE MGMTCLASS	Defines a management class.
DELETE COPYGROUP	Deletes a backup or archive copy group from a policy domain and policy set.
DELETE MGMTCLASS	Deletes a management class and its copy groups from a policy domain and policy set.
EXPIRE INVENTORY	Manually starts inventory expiration processing.
QUERY COPYGROUP	Displays the attributes of a copy group.
QUERY MGMTCLASS	Displays information about management classes.

- UPDATE COPYGROUP (Update a backup copy group)
  Use this command to update a defined backup copy group.
- UPDATE COPYGROUP (Update a defined archive copy group)
  Use this command to update a defined archive copy group.

UPDATE COPYGROUP (Update a backup copy group)

Use this command to update a defined backup copy group.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the copy group belongs.

Syntax

```
>>-UPDate COpygroup--domain_name--policy_set_name--class_name--->

>--+----------+--+-----------------+--------------------------->
   '-STANDARD-'  '-Type--=--Backup-'
```

```
>--+--------------------------+--+--------------------+-------->

                       '-DYnamic----'

>--+---------------------------------+------------------------><
   '-TOCDestination--=----pool_name---'
```

Parameters

domain_name (Required)
: Specifies the policy domain to which the copy group belongs.

policy_set_name (Required)
: Specifies the policy set to which the copy group belongs. You cannot update a copy group in the ACTIVE policy set.

class_name (Required)
: Specifies the management class to which the copy group belongs.

STANDARD
: Specifies the copy group, which must be STANDARD. This parameter is optional.

Type=Backup
: Specifies that you want to update a backup copy group. This parameter is optional.

DESTination
: Specifies the primary storage pool where the server initially stores backup data. This parameter is optional. You cannot specify a copy storage pool as the destination.

FREQuency
: Specifies how frequently the server can back up a file. This parameter is optional. The server backs up a file only when the specified number of days has elapsed since the last backup. The FREQUENCY value is used only during a full incremental backup operation. This value is ignored during selective backup or partial incremental backup. You can specify an integer from 0 to 9999. The value 0 means that the server can back up a file regardless of when the file was last backed up.

VERExists
: Specifies the maximum number of backup versions to retain for files that are currently on the client file system. This parameter is optional.
  If an incremental backup causes the limit to be exceeded, the server expires the oldest backup version that exists in server storage. Possible values are:

  number
  : Specifies the number of backup versions to retain for files that are currently on the client file system. You can specify an integer from 1 to 9999.

  NOLimit
  : Specifies that you want the server to retain all backup versions.

  The number of backup versions to retain is controlled by this parameter until versions exceed the retention time specified by the RETEXTRA parameter.

VERDeleted

Specifies the maximum number of backup versions to retain for files that have been deleted from the client file system after being backed up using the server. This parameter is optional.
If a user deletes a file from the client file system, the next incremental backup causes the server to change the active backup version of the file to inactive and expire the oldest versions in excess of this number. The expiration date for the remaining versions is determined by the retention time specified by the RETEXTRA or RETONLY parameter. Possible values are:

number
: Specifies the number of backup versions to retain for files that are deleted from the client file system after being backed up. You can specify a value from 0 to 9999.

NOLimit
: Specifies that you want the server to retain all backup versions for files that are deleted from the client file system after being backed up.

RETExtra
: Specifies the number of days that the server retains a backup version after that version becomes inactive. A version of a file becomes inactive when the client stores a more recent backup version, or when the client deletes the file from the workstation and then runs a full incremental backup. The server deletes inactive versions based on retention time even if the number of inactive versions does not exceed the number allowed by the VEREXISTS or VERDELETED parameters. This parameter is optional. Possible values are:

days
: Specifies the number of days to retain inactive backup versions. You can specify an integer from 0 to 9999.

NOLimit
: Specifies that you want to retain inactive backup versions indefinitely.

  If you specify NOLIMIT, the server deletes extra backup versions based on the VEREXISTS parameter (when the file still exists on the client file system) or the VERDELETED parameter (when the file no longer exists on the client file system).

RETOnly
: Specifies the number of days to retain the last backup version of a file that has been deleted from the client file system. This parameter is optional. Possible values are:

days
: Specifies the number of days to retain the last remaining inactive copy of a file. You can specify an integer from 0 to 9999.

NOLimit
: Specifies that you want to keep the last remaining inactive version of a file indefinitely.

  If you specify NOLIMIT, the server retains the last remaining backup version forever, unless a user or administrator deletes the file from server storage.

MODE
: Specifies whether the server backs up a file only if the file has changed since the last backup, or whenever a client requests a backup. This parameter is optional. Possible values are:

MODified
: Specifies that the file is backed up only if it has changed since the last backup. A file is considered changed if any of the following is true:

  - The date last modified is different
  - The file size is different
  - The file owner is different
  - The file permissions are different

ABSolute
: Specifies that the file is backed up regardless of whether it has been changed.

The MODE value is used only for full incremental backup. This value is ignored during partial incremental backup or selective backup.

SERialization
: Specifies how the server processes files or directories when they are modified during backup processing. This parameter is optional. Possible values are:

SHRSTatic
: Specifies that the server backs up a file or directory only if it is not being modified during backup. The server attempts to perform a backup as many as four times, depending on the value specified for the CHANGINGRETRIES client option. If the file or directory is modified during each backup attempt, the server does not back it up.

STatic
: Specifies that the server backs up a file or directory only if it is not being modified during backup. The server attempts to perform the backup only once.

  Platforms that do not support the STATIC option default to SHRSTATIC.

SHRDYnamic
: Specifies that if the file or directory is being modified during a backup attempt, the server backs up the file or directory during the last attempt even though the file or directory is being modified. the server attempts to perform a backup as many as four times, depending on the value specified for the CHANGINGRETRIES client option.

DYnamic
: Specifies that the server backs up a file or directory on the first attempt, regardless of whether the file or directory is being modified during backup processing.

Important: Be careful about using the SHRDYNAMIC and DYNAMIC values. IBM Spectrum Protect™ uses these values to determine if it backs up a file or directory while modifications are occurring. As a result, the backup version might be a fuzzy backup. A fuzzy backup does not accurately reflect what is currently in the file or directory because it contains some, but not all, modifications. If a file that contains a fuzzy backup is restored, the file may or may not be usable, depending on the application that uses the file. If a fuzzy backup is not acceptable, set SERIALIZATION to SHRSTATIC or STATIC so that IBM Spectrum Protect creates a backup version only if the file or directory is not being modified.

TOCDestination

Specifies the primary storage pool in which a table of contents (TOC) will initially be stored for any NDMP backup or backup set operation for which a TOC is generated. This parameter is optional. You cannot specify a copy storage pool as the destination. The storage pool specified for the destination must have NATIVE or NONBLOCK data format. To avoid mount delays, it is recommended that the storage pool have a device class of DISK or DEVTYPE=FILE. TOC generation is an option for NDMP backup operations, but is not supported for other image-backup operations.

To remove an existing TOC destination from the copy group, specify a null string ("") for this value.

If TOC creation is requested for a backup operation that uses NDMP and the image is bound to a management class whose backup copy group does not specify a TOC destination, the outcome will depend on the TOC parameter for the backup operation.

- If TOC=PREFERRED (the default), the backup proceeds without creation of a TOC.
- If TOC=YES, the entire backup fails because no TOC can be created.

Example: Update a backup copy group

Update the backup copy group (STANDARD) in the EMPLOYEE_RECORDS policy domain, VACATION policy set, ACTIVEFILES management class. Change the destination to DISKPOOL, with a minimum interval of seven days between backups, regardless of whether the files have been modified. Retain up to three backup versions while a file still exists on a client file system.

```
update copygroup employee_records vacation
activefiles type=backup destination=diskpool
frequency=7 verexists=3 mode=absolute
```

UPDATE COPYGROUP (Update a defined archive copy group)

Use this command to update a defined archive copy group.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the copy group belongs.

Syntax

```
>>-UPDate COpygroup--domain_name--policy_set_name--class_name--->
```

```
>--+----------+--Type--=--Archive------------------------------>
   '-STANDARD-'

>--+--------------------------+--+------------------+--------->
   '-DESTination--=--pool_name-'  '-FREQuency--=--Cmd-'

>--+------------------------+--+------------------+------------>
   '-RETVer--=--+-days----+-'  '-MODE--=--ABSolute-'
                '-NOLimit-'

>--+--------------------+-------------------------------------->
   '-RETMin--=----days---'

>--+---------------------------------+------------------------><
   '-SERialization--=--+-SHRSTatic--+-'
                       +-STatic-----+
                       +-SHRDYnamic-+
                       '-DYnamic----'
```

Parameters

domain_name (Required)
: Specifies the policy domain to which the copy group belongs.

policy_set_name (Required)
: Specifies the policy set to which the copy group belongs. You cannot update a copy group in the ACTIVE policy set.

class_name (Required)
: Specifies the management class to which the copy group belongs.

STANDARD
: Specifies the copy group, which must be STANDARD. This parameter is optional.

Type=Archive (Required)
: Specifies that you want to update an archive copy group. This parameter is required.

DESTination
: Specifies the primary storage pool where the server initially stores the archive copy. This parameter is optional. You cannot specify a copy storage pool as the destination.

FREQuency=Cmd
: Specifies the copy frequency, which must be CMD. This parameter is optional.

RETVer
: Specifies the number of days to keep an archive copy. This parameter is optional. Possible values are:

  days
  : Specifies the number of days to keep an archive copy. You can specify an integer from 0 to 30000.

  NOLimit
  : Specifies that you want to keep an archive copy indefinitely.

    If you specify NOLIMIT, the server retains archive copies forever, unless a user or administrator deletes the file from server storage.

  The value of the RETVER parameter can affect the management class to which the server binds an archived directory. If the client does not use the ARCHMC option, the server binds directories that are archived to the default management class. If the default management class has no archive copy group, the server binds directories that are archived to the management class with the shortest retention period.

MODE=ABSolute
: Specifies that a file is always archived when the client requests it. The MODE must be ABSOLUTE. This parameter is optional.

RETMin
: Specifies the minimum number of days to keep an archive copy after it has been archived. This parameter is optional. The default value is 365.

SERialization
: Specifies how the server processes files that are modified during archive. This parameter is optional. Possible values are:

  SHRSTatic
  : Specifies that the server does not archive a file that is being modified. The server attempts to perform an archive as many as four times, depending on the value specified for the CHANGINGRETRIES client option. If the file is modified

during the archive attempt, the server does not archive the file.

STatic
: Specifies that the server does not archive a file that is being modified. If a file is modified during the archive attempt, the server does not archive the file.

  Platforms that do not support the STATIC option default to SHRSTATIC.

SHRDYnamic
: Specifies that if the file is being modified during an archive attempt, the server archives the file during its last attempt even though the file is being modified. The server attempts to archive the file as many as four times, depending on the value specified for the CHANGINGRETRIES client option.

DYnamic
: Specifies that the server archives a file on the first attempt, regardless of whether the file is being modified during archive processing.

Important: Be careful about using the SHRDYNAMIC and DYNAMIC values. IBM Spectrum Protect™ uses them to determine if it archives a file while modifications are occurring. As a result, the archive copy might be a fuzzy backup. A fuzzy backup does not accurately reflect what is currently in the file because it contains some, but not all, modifications. If a file that contains a fuzzy backup is retrieved, the file may or may not be usable, depending on the application that uses the file. If a fuzzy backup is not acceptable, set SERIALIZATION to SHRSTATIC or STATIC so that IBM Spectrum Protect creates an archive copy only if the file is not being modified.
Tip: Be cautious when selecting retention values for primary storage pools that are of type RECLAMATIONTYPE=SNAPLOCK. Volumes in these types of storage pools cannot be deleted until after their retention dates have passed.

Example: Update multiple elements of a copy group

Update the archive copy group (STANDARD) in the EMPLOYEE_RECORDS policy domain, VACATION policy set, ACTIVEFILES management class. Change the destination to TAPEPOOL. Keep archive copies for 190 days.

```
update copygroup employee_records vacation
activefiles standard type=archive
destination=tapepool retver=190
```

UPDATE DATAMOVER (Update a data mover)

Use this command to update the definition for a data mover or set a data mover off-line when the hardware is being maintained.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate DATAMover--data_mover_name---------------------------->

>--+----------------------+--+-----------------------+-------->
   '-HLAddress--=--address-'  '-LLAddress--=--tcp_port-'

>--+--------------------+--+-----------------------+------------>
   '-USERid--=--userid-'  '-PASsword--=--password-'

>--+--------------------+-------------------------------------><
   '-ONLine--=--+-Yes-+-'
                '-No--'
```

Parameters

data_mover_name (Required)
: Specifies the name of the data mover.

HLAddress

Specifies either the new numerical IP address or the new domain name, which is used to access the NAS file server. This parameter is optional.

LLAddress
Specifies the new TCP port number to access the NAS file server for Network Data Management Protocol (NDMP) sessions. This parameter is optional.

USERid
Specifies the user ID for a user that is authorized to initiate an NDMP session with the NAS file server. For example, enter the administrative ID for a NetApp file server. This parameter is optional.

PASsword
Specifies the new password for the user ID to log onto the NAS file server. This parameter is optional.

ONLine
Specifies whether the data mover is available for use. This parameter is optional.

Yes
Specifies that the data mover is available for use.

No
Specifies that the data mover is not available for use.
Attention: If a library is controlled using a path from a data mover to the library, and the data mover is offline, the server will not be able to access the library. If the server is halted and restarted while the data mover is offline, the library will not be initialized.

Example: Update a data mover IP address

Update the data mover for the node named NAS1. Change the numerical IP address from 9.67.97.103 to 9.67.97.109.

```
update datamover nas1 hladdress=9.67.97.109
```

Example: Update a data mover domain name

Update the data mover for the node named NAS1. Change the numerical IP address from 9.67.97.109 to the domain name of NETAPP2.TUCSON.IBM.COM.

```
update datamover nas1 hladdress=netapp2.tucson.ibm.com
```

Related commands

Table 1. Commands related to UPDATE DATAMOVER

Command	Description
DEFINE DATAMOVER	Defines a data mover to the IBM Spectrum Protect server.
DEFINE PATH	Defines a path from a source to a destination.
DELETE DATAMOVER	Deletes a data mover.
QUERY DATAMOVER	Displays data mover definitions.
REGISTER NODE	Defines a client node to the server and sets options for that user.
UPDATE NODE	Changes the attributes that are associated with a client node.

UPDATE DEVCLASS (Update the attributes of a device class)

Use this command to update a defined device class.

Note: The DISK device class is predefined by IBM Spectrum Protect™ and cannot be modified with the UPDATE DEVCLASS command.

AIX Linux If you are updating a device class for devices that are to be accessed through a z/OS® media server, see UPDATE DEVCLASS - z/OS media server (Update device class for z/OS media server).

The syntax and parameter descriptions are provided according to the device type. The syntax and parameter information is presented in the following order.

- UPDATE DEVCLASS (Update a 3590 device class)
- UPDATE DEVCLASS (Update a 3592 device class)
- UPDATE DEVCLASS (Update a 4MM device class)
- UPDATE DEVCLASS (Update an 8MM device class)
- UPDATE DEVCLASS (Update a CENTERA device class)
- UPDATE DEVCLASS (Update a DLT device class)
- UPDATE DEVCLASS (Update an ECARTRIDGE device class)
- UPDATE DEVCLASS (Update a FILE device class)
- AIX Windows UPDATE DEVCLASS (Update a GENERICTAPE device class)
- UPDATE DEVCLASS (Update an LTO device class)
- UPDATE DEVCLASS (Update a NAS device class)
- UPDATE DEVCLASS (Update a REMOVABLEFILE device class)
- UPDATE DEVCLASS (Update a SERVER device class)
- UPDATE DEVCLASS (Update a VOLSAFE device class)

Table 1. Commands related to UPDATE DEVCLASS

Command	Description
BACKUP DEVCONFIG	Backs up IBM Spectrum Protect device information to a file.
DEFINE DEVCLASS	Defines a device class.
DEFINE LIBRARY	Defines an automated or manual library.
DELETE DEVCLASS	Deletes a device class.
QUERY DEVCLASS	Displays information about device classes.
QUERY DIRSPACE	Displays information about FILE directories.
UPDATE LIBRARY	Changes the attributes of a library.

UPDATE DEVCLASS (Update a 3590 device class)

Use the 3590 device class when you are using 3590 tape devices.

AIX Linux If you are defining a device class for devices that are to be accessed through a z/OS® media server, see UPDATE DEVCLASS (Update a 3590 device class for z/OS media server).

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate DEVclass--device_class_name--------------------------->

>--+-------------------------+--+----------------------+----->
   '-LIBRary--=--library_name-'  '-FORMAT--=--+-DRIVE---+-'
                                              +-3590B---+
                                              +-3590C---+
                                              +-3590E-B-+
                                              +-3590E-C-+
                                              +-3590H-B-+
                                              '-3590H-C-'

                 +-number-+
                 '-0------'
```

Parameters

device_class_name (Required)
Specifies the name of the device class to be defined.

LIBRary

Specifies the name of the defined library object that contains the tape drives that can be used by this device class.

This parameter is optional.

For information about defining a library object, see the DEFINE LIBRARY command.

FORMAT

Specifies the recording format to be used when data is written to sequential access media. This parameter is optional.

If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use.

The following tables list the recording formats, estimated capacities, and recording format options for 3590 devices:

Table 1. Recording formats and default estimated capacities for 3590

Format	Estimated Capacity	Description
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
3590B	10.0 GB	Uncompressed (basic) format
3590C	See note 20.0 GB	Compressed format
3590E-B	10.0 GB	Uncompressed (basic) format, similar to the 3590B format
3590E-C	See note 20.0 GB	Compressed format, similar to the 3590C format
3590H-B	30.0 GB (J cartridge-standard length) 60.0 GB (K cartridge-extended length)	Uncompressed (basic) format, similar to the 3590B format
3590H-C	See note 60.0 GB (J cartridge-standard length) 120.0 GB (K cartridge-extended length)	Compressed format, similar to the 3590C format
Note: If this format uses the tape drive hardware compression feature, depending on the effectiveness of compression, the actual capacity might be greater than the listed value.		

Table 2. 3590 device recording format selections

Device	Format					
	3590B	3590C	3590E-B	3590E-C	3590H-B	3590H-C

Device	Format					
	3590B	3590C	3590E-B	3590E-C	3590H-B	3590H-C
3590	Read/Write	Read/Write	–	–	–	–
Ultra-SCSI	Read/Write	Read/Write	–	–	–	–
3590E	Read	Read	Read/Write	Read/Write	–	–
3590H	Read	Read	Read	Read	Read/Write	Read/Write

ESTCAPacity

Specifies the estimated capacity for the sequential access volumes that are categorized by this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

To force the IBM Spectrum Protect™ server to determine the estimated capacity for the volumes that are assigned to this device class, specify ESTCAPACITY="".

PREFIX

Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention

Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types, setting this parameter to a low value (for example, two minutes) enhances device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait

Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. You can specify a number 0 - 9999.

Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit

Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES

Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.

Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number

Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)

Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

UPDATE DEVCLASS (Update a 3592 device class)

AIX | Linux If you are defining a device class for devices that are to be accessed through a z/OS® media server, see UPDATE DEVCLASS (Update a 3592 device class for z/OS media server).

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate DEVclass--device_class_name--------------------------->

>--+-------------------------+--------------------------------->
   '-LIBRary--=--library_name-'

>--+-----------------------------+----------------------------->
   '-LBProtect--=--+-READWrite-+-'
                   +-WRITEOnly-+
                   '-No--------'

>--+--------------------------+--+----------------------+---->
   '-SCALECAPacity--=--+-100-+-'  '-FORMAT--=--+-DRIVE---+-'
                       +-90--+                 +-3592----+
                       '-20--'                 +-3592C---+
                                               +-3592-2--+
                                               +-3592-2C-+
                                               +-3592-3--+
                                               +-3592-3C-+
                                               +-3592-4--+
                                               '-3592-4C-'

>--+---------------------+-------------------------------------->
   '-ESTCAPacity--=--size-'

>--+---------------------------------+----------------------->
   '-PREFIX--=--+-ADSM---------------+-'
                '-tape_volume_prefix-'

>--+-----------------------------+--+----------------------+---->
   '-MOUNTRetention--=--minutes-'  '-MOUNTWait--=--minutes-'
```

```
>--+--------------------------+--------------------------------->
   '-MOUNTLimit--=--+-DRIVES-+-'
                    +-number-+
                    '-0------'

>--+-------------------------------------------+------------><
   |  (1)   (2)                                |
   '-------------DRIVEEncryption--=--+-ON-------+-'
                                     +-ALLOW----+
                                     +-EXTERNAL-+
                                     '-OFF------'
```

Notes:

1. You cannot specify both WORM=Yes and DRIVEENCRYPTION=ON.
2. Drive encryption is supported only for 3592 Generation 2 or later drives.

Parameters

device_class_name (Required)
: Specifies the name of the device class to be updated. The maximum length of the device class name is 30 characters.

LIBRary
: Specifies the name of the defined library object that contains the tape drives that can be used by this device class.

  This parameter is optional.

  For information about defining a library object, see the DEFINE LIBRARY command.

LBProtect
: Specifies whether logical block protection is used to ensure the integrity of data stored on tape. When LBPROTECT is set to READWRITE or to WRITEONLY, the server uses this feature of the tape drive for logical block protection and generates cyclic redundancy check (CRC) protection information for each data block written on tape. The server also validates the CRC protection information when data is read from the tape.

  The following values are possible:

  READWrite
  : Specifies that logical block protection is enabled in the server and the tape drive for both read and write operations. Data is stored with CRC information in each block. This mode affects performance because additional processor usage is required for IBM Spectrum Protect™ and the tape drive to calculate and compare CRC values. The READWRITE value does not affect backup sets and data that is generated by the BACKUP DB command.

    When the LBPROTECT parameter is set to READWRITE, you do not have to specify the CRCDATA parameter in a storage pool definition because logical block protection provides better protection against data corruption.

  WRITEOnly
  : Specifies that logical block protection is enabled in the server and the tape drive for write operations only. Data is stored containing CRC information in each block. For read operations, the server and the tape drive do not validate the CRC. This mode affects performance because additional processor usage is required for IBM Spectrum Protect to generate the CRC and for the tape drive to calculate and compare CRC values for write operations. The WRITEONLY value does not affect backup sets and data that are generated by the BACKUP DB command.

  No
  : Specifies that logical block protection is not enabled in the server and the tape drive for read and write operations. However, the server enables logical block protection on write operations for a filling volume that already has data with logical block protection.

  Restriction: Logical block protection is supported only on IBM® 3592 Generation 3 drives and later with 3592 Generation 2 media and later.

  See Technote 1634851, Additional information on the Tivoli Storage Manager LBProtect option, for an explanation about when to use the LBProtect parameter.

SCALECAPacity

Specifies the percentage of the media capacity that can be used to store data. This parameter is optional. Possible values are 20, 90, or 100.

Setting the scale capacity percentage to 100 provides maximum storage capacity. Setting it to 20 provides fastest access time.

Note: The scale capacity value takes effect when data is first written to a volume. Any updates to the device class for scale capacity do not affect volumes that already have data that is written to them until the volume is returned to scratch status.

FORMAT

Specifies the recording format to be used when data is written to sequential access media. This parameter is optional.

If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use.

The following table lists the recording formats, estimated capacities, and recording format options for 3592 devices:

Table 1. Recording formats and default estimated capacities for 3592

Format	Estimated Capacity	Description
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
3592	300 GB	Uncompressed (basic) format
3592C	See note 900 GB	Compressed format
3592-2	500 GB 700 GB	Uncompressed (basic) format JA tapes Uncompressed (basic) format JB tapes
3592-2C	1.5 TB 2.1 TB	Compressed format JA tapes Compressed format JB tapes
3592–3	640 GB 1 TB	Uncompressed (basic) format JA tapes Uncompressed (basic) format JB tapes
3592–3C	1.9 TB 3 TB	Compressed format JA tapes Compressed format JB tapes
3592-4	400 GB 1.5 TB 3.1 TB	Uncompressed (basic) format JK tapes Uncompressed (basic) format JB tapes Uncompressed (basic) format JC tape
3592-4C	1.2 TB 4.4 TB 9.4 TB	Compressed format JK tapes Compressed format JB tapes Compressed format JC tapes
Note: If this format uses the tape-drive hardware-compression feature, depending on the effectiveness of compression, the actual capacity might be different from the listed value.		

Important: For optimal performance, avoid mixing different generations of drives in a single SCSI library.

Special configurations are also required for mixing different generations of 3592 drives in 349x and ACSLS libraries.

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

To force the IBM Spectrum Protect server to determine the estimated capacity for the volumes that are assigned to this device class, specify ESTCAPACITY="".

PREFIX
Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention
Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types, setting this parameter to a low value (for example, two minutes) enhances device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait
Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. You can specify a number 0 - 9999.
Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES
Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number
Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)
Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

DRIVEEncryption
Specifies whether drive encryption is allowed. This parameter is optional.

Updating this parameter affects empty volumes only. If a filling volume was previously encrypted or is unencrypted, and you update the DRIVEENCRYPTION parameter, the volume maintains its original encrypted or unencrypted status. The filling volume also maintains its original key-management status.

ON
Specifies that IBM Spectrum Protect is the key manager for drive encryption and allows drive encryption for empty storage pool volumes only if the application method is enabled. (Other types of volumes-for example, back up sets, export volumes, and database backup volumes-will not be encrypted.) If you specify ON and you enable either the library or system method of encryption, drive encryption is not allowed and backup operations fail.

ALLOW
Specifies that IBM Spectrum Protect does not manage the keys for drive encryption. However, drive encryption for empty volumes is allowed if either the library or system method of encryption is enabled.

EXTERNAL
Specifies that IBM Spectrum Protect does not manage the keys for drive encryption. Use this setting with an encryption methodology that is provided by another vendor and that is used with Application Method Encryption (AME) enabled on the drive.
When you specify EXTERNAL and IBM Spectrum Protect detects that AME encryption is enabled, IBM Spectrum Protect does not turn off encryption.
By contrast, when you specify ALLOW and IBM Spectrum Protect detects that AME encryption is enabled, IBM Spectrum Protect turns off encryption.

OFF
Specifies that drive encryption is not allowed. If you enable either the library or system method of encryption, backups fail. If you enable the application method, IBM Spectrum Protect disables encryption and backups are attempted.

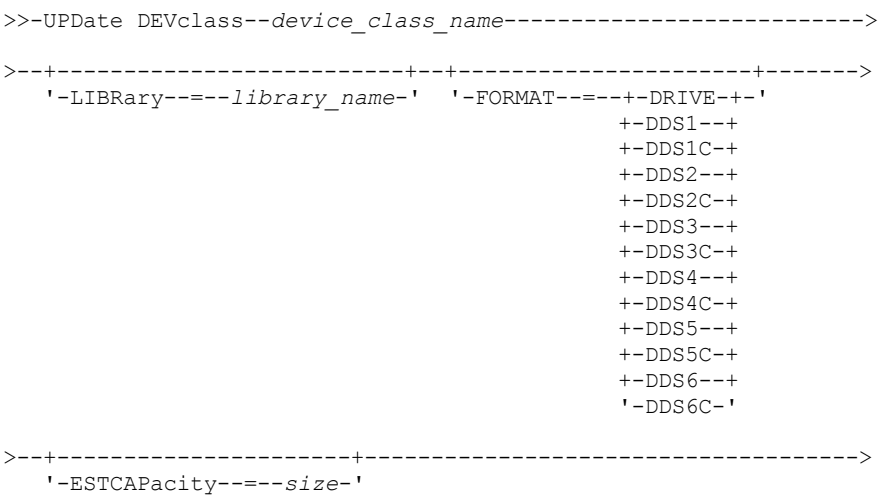
UPDATE DEVCLASS (Update a 4MM device class)

Use the 4MM device class when you are using 4 mm tape devices.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax



```
>--+-----------------------------------+------------------------>
   '-PREFIX--=--+-ADSM---------------+-'
                '-tape_volume_prefix-'

>--+-----------------------+--+---------------------------+---->
   '-MOUNTWait--=--minutes-'  '-MOUNTRetention--=--minutes-'

>--+---------------------------+-------------------------------><
   '-MOUNTLimit--=--+-DRIVES-+-'
                    +-number-+
                    '-0------'
```

Parameters

device_class_name (Required)
: Specifies the name of the device class to be defined.

LIBRary
: Specifies the name of the defined library object that contains the 4 mm tape drives used by this device class. This parameter is optional. For information about defining a library object, see the DEFINE LIBRARY command.

FORMAT
: Specifies the recording format to be used when data is written to sequential access media. This parameter is optional.

  If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use.

  The following table lists the recording formats and estimated capacities for 4 mm devices:

Table 1. Recording formats and default estimated capacities for 4 mm tapes

Format	Estimated Capacity	Description
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
DDS1	1.3 GB (60 meter) 2.0 GB (90 meter)	Uncompressed format, applies only to 60-meter and 90-meter tapes
DDS1C	See note 1.3 GB (60 meter) 2.0 GB (90 meter)	Compressed format, applies only to 60-meter and 90-meter tapes
DDS2	4.0 GB	Uncompressed format, applies only to 120-meter tapes
DDS2C	See note 8.0 GB	Compressed format, applies only to 120-meter tapes
DDS3	12.0 GB	Uncompressed format, applies only to 125-meter tapes
DDS3C	See note 24.0 GB	Compressed format, applies only to 125-meter tapes
DDS4	20.0 GB	Uncompressed format, applies only to 150-meter tapes
DDS4C	See note 40.0 GB	Compressed format, applies only to 150-meter tapes
DDS5	36 GB	Uncompressed format, when using DAT 72 media
DDS5C	See note 72 GB	Compressed format, when using DAT 72 media

Format	Estimated Capacity	Description
DDS6	80 GB	Uncompressed format, when using DAT 160 media
DDS6C	See note 160 GB	Compressed format, when using DAT 160 media
Note: If this format uses the tape drive hardware compression feature, depending on the effectiveness of compression, the actual capacity might be greater than the listed value.		

ESTCAPacity

Specifies the estimated capacity for the sequential access volumes that are categorized by this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

To force the IBM Spectrum Protect™ server to determine the estimated capacity for the volumes that are assigned to this device class, specify ESTCAPACITY="".

For more information about the default estimated capacity for 4 mm tapes, see Table 1.

PREFIX

Specifies the high-level qualifier of the file name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention

Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types (that is, a library that is managed by an external media management system), set this parameter to a low value (for example, two minutes) to enhance device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait

Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is

optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. You can specify a number 0 - 9999.
Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES
Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number
Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)
Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

UPDATE DEVCLASS (Update an 8MM device class)

Use the 8MM device class when you are using 8 mm tape devices.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate DEVclass--device_class_name--------------------------->

                    +-number-+
                    '-0------'
```

Parameters

device_class_name (Required)
: Specifies the name of the device class to be updated.

LIBRary
: Specifies the name of the defined library object that contains the 8 mm tape drives that can be used by this device class. For more information about defining a library object, see the DEFINE LIBRARY command.

FORMAT
: Specifies the recording format to be used when data is written to sequential access media. This parameter is optional.

  If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use.

  The following table lists the recording formats and estimated capacities for 8 mm devices:

Table 1. Recording format and default estimated capacity for 8 mm tape

Format **Medium Type**	**Estimated Capacity**	**Description**
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.

SDX1–25C	50 GB	AIT, AIT2 and AIT3 drives
SDX1–35C	91 GB	AIT, AIT2 and AIT3 drives
SDX2–36C	72 GB	AIT2 and AIT3 drives
SDX2–50C	130 GB	AIT2 and AIT3 drives
SDX3–100C	260 GB	AIT3, AIT4, and AIT5 drives
SDX3X-150C	390 GB	AIT3-Ex, AIT4, and AIT5 drives
SDX4–200C	520 GB	AIT4 and AIT5 drives
SDX5-400C	1040 GB	AIT5 drive
M2	See note	Drive (Read Write)
75m	20.0 GB	Mammoth II (RW)
150m	40.0 GB	Mammoth II (RW)
225m	60.0 GB	Mammoth II (RW)
M2C	See note	Drive (Read Write)
75m	50.0 GB	Mammoth II (RW)
150m	100.0 GB	Mammoth II (RW)
225m	150.0 GB	Mammoth II (RW)
SAIT	See note	Drive (Read Write)
	500 GB	Sony SAIT1–500(RW)
SAITC	See note	Drive (Read Write)
	1300 GB (1.3 TB)	Sony SAIT1–500(RW)

Format Medium Type	Estimated Capacity	Description
VXA2 V6 (62m) V10 (124m) V17 (170m)	See note 20 GB 40 GB 60 GB	Drive (Read Write) VXA–2
VXA2C V6 (62m) V10 (124m) V17 (170m)	See note 40 GB 80 GB 120 GB	Drive (Read Write) VXA–2
VXA3 X6 (62m) X10 (124m) X23 (230m)	See note 40 GB 86 GB 160 GB	Drive (Read Write) VXA–3
VXA3C X6 (62m) X10 (124m) X23 (230m)	See note 80 GB 172 GB 320 GB	Drive (Read Write) VXA–3
Note: The actual capacities might vary depending on which cartridges and drives are used. • For the AITC and SAITC formats, the normal compression ratio is 2.6:1. • For the M2C format, the normal compression ratio is 2.5:1.		

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

To force the IBM Spectrum Protect™ server to determine the estimated capacity for the volumes that are assigned to this device class, specify ESTCAPACITY="".

For more information about the default estimated capacity for 8 mm tapes, see Table 1.

PREFIX

Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention
: Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. You can specify a number 0 - 9999.

  This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

  However, for EXTERNAL library types (that is, a library that is managed by an external media management system), set this parameter to a low value (for example, two minutes) to enhance device sharing between applications.

  Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait
: Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. You can specify a number 0 - 9999.
  Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
: Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. You can specify a number 0 - 4096.

  If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

  The following are possible values:

  DRIVES
  : Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
    Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

  number
  : Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

  0 (zero)
  : Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

Example: Update the mount limit and capacity of an 8 mm device class

Update a device class named 8MMTAPE. Change the mount limit to 3 and the estimated capacity to 10 GB.

```
update devclass 8mmtape mountlimit=3 estcapacity=10G
```

Example: Update the mount retention period of an 8 mm device class

Update an 8 mm device class that is named 8MMTAPE to a 15-minute mount retention.

```
update devclass 8mmtape mountretention=15
```

UPDATE DEVCLASS (Update a CENTERA device class)

Use the CENTERA device class when you are using EMC Centera storage devices. The CENTERA device type uses files as volumes to store data sequentially. It is similar to the FILE device class.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate DEVclass--device_class_name---------------------------->

                                    (1)
>--HLAddress--=--ip_address?PEA_file---------------------------->

>--+--------------------------+--------------------------------->
   '-MINCAPacity--=----size---'

>--+---------------------------+------------------------------><
   '-MOUNTLimit--=----number---'
```

Notes:

1. For each Centera device class, you must specify an IP address. However, a Pool Entry Authorization (PEA) file name and path are optional, and the PEA file specification must follow the IP address. Use the "?" character to separate the PEA file name and path from the IP address.

Parameters

device_class_name (Required)
Specifies the name of the device class to be updated. The maximum length of the device class name is 30 characters.

HLAddress
Specifies an IP address for the Centera storage device and, optionally, the name and path of one Pool Entry Authorization (PEA) file. Specify the IP address with the dotted decimal format (for example, 9.10.111.222). A Centera device might have multiple IP addresses. However, you must specify one of them as a value for this parameter.

AIX The PEA file name and path name are case-sensitive.

If you append the name and path of a PEA file, ensure that the file is stored in a directory on the system that runs the IBM Spectrum Protect™ server. Separate the PEA file name and path from the IP address or addresses with the "?" character, for example: Windows

```
HLADDRESS=9.10.111.222?c:\controlFiles\TSM.PEA
```

AIX

```
HLADDRESS=9.10.111.222?/user/ControlFiles/TSM.PEA
```

Specify only one PEA file name and path for each device class definition. If you specify two different Centera device classes that point to the same Centera storage device and if the device class definitions contain different PEA file names and paths, the server uses the PEA file that is specified in the device class HLADDRESS parameter that was first used to open the Centera storage device.
Note:

1. The server does not include a PEA file during installation. If you do not create a PEA file, the server uses the Centera default profile, which can allow applications to read, write, delete, purge, and query data on a Centera storage device. To provide tighter control, create a PEA file with the command-line interface that is provided by EMC Centera. For details about Centera authentication and authorization, refer to the EMC Centera *Programmer's Guide*.
2. You can also specify the PEA file name and path in an environment variable by using the syntax CENTERA_PEA_LOCATION=*filePath_ fileName*. The PEA file name and path that is specified with this environment variable apply to all Centera clusters. If you use this variable, you do not need to specify the PEA file name and path using the HLADDRESS parameter.
3. Updating the device class with a new or changed PEA file name and location might require a server restart if the Centera storage device identified by the IP address has already been accessed in the current instance of the server.

MINCAPacity
Specifies the new minimum size for Centera volumes that are assigned to a storage pool in this device class. This value represents the minimum amount of data that is stored on a Centera volume before the server marks it full. Centera volumes

continue to accept data until the minimum amount of data is stored. This parameter is optional.

size
Specify this value as an integer followed by K (kilobytes), M (megabytes), G (gigabytes), or T (terabytes). The minimum value that is allowed is 1 MB (MINCAPACITY=1M). The maximum value that is allowed is 128 GB (MINCAPacity=128G).

MOUNTLimit
Specifies the new maximum number of sessions that access the Centera device. This parameter is optional. You can specify any number from 0 or greater; however, the sum of all mount limit values for all device classes that are assigned to the same Centera device must not exceed the maximum number of sessions that are allowed by Centera.

UPDATE DEVCLASS (Update a DLT device class)

Use the DLT device class when you are using DLT tape devices.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

Parameters

device_class_name (Required)
Specifies the name of the device class to be updated.

LIBRary
Specifies the name of the defined library object that contains the DLT tape drives that can be used by this device class. For information about defining a library object, see the DEFINE LIBRARY command.

FORMAT
Specifies the recording format to be used when data is written to sequential access media. This parameter is optional.

If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use.

The following table lists the recording formats and estimated capacities for DLT devices:

Table 1. Recording format and default estimated capacity for DLT

Format	Estimated Capacity	Description
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
DLT1	40.0 GB	Uncompressed format, using only CompacTape III or CompacTape IV cartridges
DLT1C	See note 1. 80.0 GB	Compressed format, using only CompacTape III and CompacTape IV cartridges
DLT10	10.0 GB	Uncompressed format, using only CompacTape III or CompacTape IV cartridges
DLT10C	See note 1. 20.0 GB	Compressed format, using only CompacTape III and CompacTape IV cartridges
DLT15	15.0 GB	Uncompressed format, using only CompacTape IIIxt or CompacTape IV cartridges (not CompacTape III) Note: Valid with DLT2000XT, DLT4000, and DLT7000 drives
DLT15C	See note 1. 30.0 GB	Compressed format, using only CompacTape IIIxt or CompacTape IV cartridges (not CompacTape III) Valid with DLT2000XT, DLT4000, and DLT7000 drives
DLT20	20.0 GB	Uncompressed format, using only CompacTape IV cartridges Valid with DLT4000, DLT7000, and DLT8000 drives
DLT20C	See note 1. 40.0 GB	Compressed format, using only CompacTape IV cartridges Valid with DLT4000, DLT7000, and DLT8000 drives
DLT35	35.0 GB	Uncompressed format, using only CompacTape IV cartridges Valid with DLT7000 and DLT8000 drives
DLT35C	See note 1. 70.0 GB	Compressed format, using only CompacTape IV cartridges Valid with DLT7000 and DLT8000 drives
DLT40	40.0 GB	Uncompressed format, using CompacTape IV cartridges Valid with a DLT8000 drive
DLT40C	See note 1. 80.0 GB	Compressed format, using CompacTape IV cartridges Valid with a DLT8000 drive
DLT2	80.0 GB	Uncompressed format, using Quantum DLT tape VS1 media

Format	Estimated Capacity	Description
DLT2C	See note 1. 160.0 GB	Compressed format, using Quantum DLT tape VS1 media
DLT4	160.0 GB	Uncompressed format, using Quantum DLTtape VS1 cartridges. Valid with Quantum DLT-V4 drive
DLT4C	See note 1. 320.0 GB	Compressed format, using Quantum DLTtape VS1 cartridges. Valid with Quantum DLT-V4 drive
SDLT See note 2.	100.0 GB	Uncompressed format, using Super DLT Tape 1 cartridges Valid with a Super DLT drive
SDLTC See note 2.	See note 1. 200.0 GB	Compressed format, using Super DLT Tape 1 cartridges Valid with a Super DLT drive
SDLT320 See note 2.	160.0 GB	Uncompressed format, using Quantum SDLT I media Valid with a Super DLT drive
SDLT320C See note 2.	See note 1. 320.0 GB	Compressed format, using Quantum SDLT I media Valid with a Super DLT drive
SDLT600	300.0 GB	Uncompressed format, using SuperDLTtape-II media Valid with a Super DLT drive
SDLT600C	See note 1. 600.0 GB	Compressed format, using SuperDLTtape-II media Valid with a Super DLT drive
DLTS4	800 GB	Uncompressed format, using Quantum DLT S4 media. Valid with a DLT-S4 drive
DLTS4C	See note 1. 1.6 TB	Compressed format, using Quantum DLT S4 media. Valid with a DLT-S4 drive

Note:

1. Depending on the effectiveness of compression, the actual capacity might be greater than the listed value.
2. IBM Spectrum Protect™ does not support a library that contains both Backward Read Compatible (BRC) SDLT and Non-Backward Read Compatible (NBRC) SDLT drives.

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

To force the IBM Spectrum Protect server to determine the estimated capacity for the volumes that are assigned to this device class, specify ESTCAPACITY="".

For more information about estimated capacities, see Table 1.

PREFIX

Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This

parameter is optional. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention
: Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. You can specify a number 0 - 9999.

  This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

  However, for EXTERNAL library types (that is, a library that is managed by an external media management system), set this parameter to a low value (for example, two minutes) to enhance device sharing between applications.

  Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait
: Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. You can specify a number 0 - 9999.
  Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
: Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. You can specify a number 0 - 4096.

  If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

  The following are possible values:

  DRIVES
  : Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
    Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

  number
  : Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

  0 (zero)
  : Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

UPDATE DEVCLASS (Update an ECARTRIDGE device class)

Use the ECARTRIDGE device class when you are using StorageTek drives such as the StorageTek T9840 or T10000.

AIX Linux If you are defining a device class for devices that are to be accessed through a z/OS® media server, see UPDATE DEVCLASS (Update an ECARTRIDGE device class for z/OS media server).

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate DEVclass--device_class_name--------------------------->

>--+-------------------------+--------------------------------->
   '-LIBRary--=--library_name-'

>--+-----------------------------+----------------------------->
   '-LBProtect--=--+-READWrite-+-'
                   +-WRITEOnly-+
                   '-No--------'

   '-MOUNTLimit--=--+-DRIVES-+-'
                    +-number-+
                    '-0------'

>--+---------------------------------------------+------------><
   |  (1)   (2)                                  |
   '-------------DRIVEEncryption--=--+-ON-------+-'
                                     +-ALLOW----+
                                     +-EXTERNAL-+
                                     '-OFF------'
```

Notes:

1. You can use drive encryption only for Oracle StorageTek T10000B drives with a format value of DRIVE, T10000B, or T10000B-C, for Oracle StorageTek T10000C drives with a format value of DRIVE, T10000C or T10000C-C, and for Oracle StorageTek T10000D drives with a format value of DRIVE, T10000D and T10000D-C.
2. You cannot specify both WORM=YES and DRIVEENCRYPTION=ON.

Parameters

device_class_name (Required)
: Specifies the name of the device class to be updated.

LIBRary
: Specifies the name of the defined library object with the ECARTRIDGE tape drives that can be used by this device class. For information about defining a library object, see the DEFINE LIBRARY command.

LBProtect

Specifies whether logical block protection is used to ensure the integrity of data stored on tape. When LBPROTECT is set to READWRITE or to WRITEONLY, the server uses this feature of the tape drive for logical block protection and generates cyclic redundancy check (CRC) protection information for each data block written on tape. The server also validates the CRC protection information when data is read from the tape.

The following values are possible:

READWrite
: Specifies that logical block protection is enabled in the server and the tape drive for both read and write operations. Data is stored with CRC information in each block. This mode affects performance because additional processor usage is required for IBM Spectrum Protect™ and the tape drive to calculate and compare CRC values. The READWRITE value does not affect backup sets and data that is generated by the BACKUP DB command.

  When the LBPROTECT parameter is set to READWRITE, you do not have to specify the CRCDATA parameter in a storage pool definition because logical block protection provides better protection against data corruption.

WRITEOnly
: Specifies that logical block protection is enabled in the server and the tape drive for write operations only. Data is stored containing CRC information in each block. For read operations, the server and the tape drive do not validate the CRC. This mode affects performance because additional processor usage is required for IBM Spectrum Protect to generate the CRC and for the tape drive to calculate and compare CRC values for write operations. The WRITEONLY value does not affect backup sets and data that are generated by the BACKUP DB command.

No
: Specifies that logical block protection is not enabled in the server and the tape drive for read and write operations. However, the server enables logical block protection on write operations for a filling volume that already has data with logical block protection.

Restriction: Logical block protection is supported only on Oracle StorageTek T10000C and Oracle StorageTek T10000D drives.

FORMAT

Specifies the recording format to be used when data is written to sequential access media. This parameter is optional.

If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use.

Important: If you specify DRIVE for a device class that has non-compatible sequential access devices, then you must mount volumes on devices that are capable of reading or writing the format that is established when the volume was first mounted. This can cause delays if the only sequential access device that can access the volume is already in use.
The following table lists the recording formats and estimated capacities for ECARTRIDGE devices:

Table 1. Recording formats and default estimated capacities for ECARTRIDGE tapes

Format	Estimated Capacity	Description
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
T9840C	40 GB	Uncompressed T9840C format, using a StorageTek 9840 cartridge
T9840C-C	80 GB	Compressed T9840C format, using a StorageTek 9840 cartridge
T9840D	75 GB	Uncompressed T9840D format, using a StorageTek 9840 cartridge
T9840D-C	150 GB	Compressed T9840D format, using a StorageTek 9840 cartridge
T10000A	500 GB	Uncompressed T10000A format, using a StorageTek T10000 cartridge
T10000A-C	1 TB	Compressed T10000A format, using a StorageTek T10000 cartridge
T10000B	1 TB	Uncompressed T10000B format, using an Oracle StorageTek T10000 cartridge
T10000B-C	2 TB	Compressed T10000B format, using an Oracle StorageTek T10000 cartridge

Format	Estimated Capacity	Description
T10000C	5 TB	Uncompressed T10000C format, using an Oracle StorageTek T10000 T2 cartridge
T10000C-C	10 TB	Compressed T10000C format, using an Oracle StorageTek T10000 T2 cartridge
T10000D	8 TB	Uncompressed T10000D format, using an Oracle StorageTek T10000 T2 cartridge
T10000D-C	15 TB	Compressed T10000D format, using an Oracle StorageTek T10000 T2 cartridge

Notes:

- Some formats use a tape drive hardware compression feature. Depending on the effectiveness of compression, the actual capacity might be double or more than the listed value.
- T10000A drives can read and write the T10000A format only. T10000B drives can read, but cannot write, the T10000A format. T10000C drives can read, but cannot write, the T10000A and T10000B formats. T10000D drives can read, but cannot write, the T10000A, T10000B, and T10000C formats.

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

To force the IBM Spectrum Protect server to determine the estimated capacity for the volumes that are assigned to this device class, specify ESTCAPACITY="".

For more information about the default estimated capacity for cartridge tapes, see Table 1.

PREFIX

Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention

Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types (that is, a library that is managed by an external media management system), set this parameter to a low value (for example, two minutes) to enhance device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait

Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. You can specify a number 0 - 9999.

Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit

Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES

Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.

Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number

Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)

Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

DRIVEEncryption

Specifies whether drive encryption is allowed. This parameter is optional.

Restriction:

1. You can use drive encryption only for the following drives:
   - Oracle StorageTek T10000B drives that have a format value of DRIVE, T10000B, or T10000B-C
   - Oracle StorageTek T10000C drives that have a format value of DRIVE, T10000C, or T10000C-C
   - Oracle StorageTek T10000D drives that have a format value of DRIVE, T10000D, or T10000D-C
2. You cannot specify IBM Spectrum Protect as the key manager for drive encryption of WORM (write once, read many) media. (Specifying both WORM=YES and DRIVEENCRYPTION=ON is not supported.)
3. If encryption is enabled for a device class, and the device class is associated with a storage pool, the storage pool should not share a scratch pool with other device classes that cannot be encrypted. If a tape is encrypted, and you plan to use it on a drive that cannot be encrypted, you must manually relabel the tape before it can be used on that drive.

ON

Specifies that IBM Spectrum Protect is the key manager for drive encryption and allows drive encryption for empty storage pool volumes only if the application method is enabled. (Other types of volumes are not encrypted. For example, back up sets, export volumes, and database backup volumes are not encrypted.) If you specify ON and you enable another method of encryption, drive encryption is not allowed and backup operations fail.

ALLOW

Specifies that IBM Spectrum Protect does not manage the keys for drive encryption. However, drive encryption for empty volumes is allowed if another method of encryption is enabled.

EXTERNAL

Specifies that IBM Spectrum Protect does not manage the keys for drive encryption. Use this setting with an encryption methodology that is provided by another vendor and that is used with Application Method Encryption (AME) enabled on the drive. When you specify EXTERNAL and IBM Spectrum Protect detects that AME encryption is enabled, IBM Spectrum Protect does not turn off encryption. By contrast, when you specify ALLOW and IBM Spectrum Protect detects that AME encryption is enabled, IBM Spectrum Protect turns off encryption.

OFF
Specifies that drive encryption is not allowed. If you enable another method of encryption, backups fail. If you enable the application method, IBM Spectrum Protect disables encryption and backups are attempted.

UPDATE DEVCLASS (Update a FILE device class)

Use the FILE device class when you are using files on magnetic disk storage as volumes that store data sequentially (as on tape).

AIX Linux The FILE device class does not support EXTERNAL libraries.

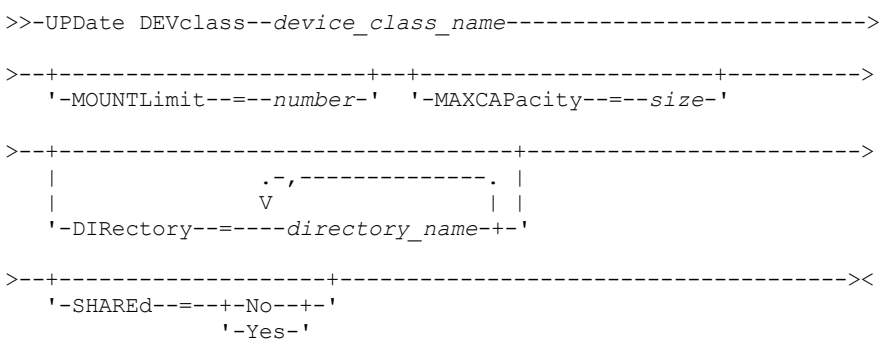
Windows The FILE device class does not support EXTERNAL libraries.

AIX Linux If you are defining a device class for devices that are to be accessed through a z/OS® media server, see UPDATE DEVCLASS (Update a FILE device class for z/OS media server).

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax



Parameters

device_class_name (Required)
Specifies the name of the device class to be updated.

MOUNTLimit
Specifies the maximum number of files that can be simultaneously open for input and output. This parameter is optional. You can specify a number from 0 to 4096.

Windows If the device class is shared with a storage agent (by specifying the SHARED=YES parameter), drives are defined or deleted to match the MOUNTLIMIT value.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

MAXCAPacity
Specifies the maximum size of any data storage files that are categorized by this device class. This parameter is optional.

Specify this value as an integer followed by K (kilobytes), M (megabytes), G (gigabytes), or T (terabytes). The minimum size is 1 MB (MAXCAPACITY=1M). If you are defining a FILE device class for database-backup volumes, specify a value for MAXCAPACITY that is appropriate for the size of the database and that minimizes the number of database volumes.

For example, MAXCAPACITY=5G specifies that the maximum capacity for a volume in this device class is 5 gigabytes. The value that is specified must be less than or equal to the maximum supported size of a file on the target file system.

AIX Linux Do not define a MAXCAPACITY value greater than 640M when this file is for REMOVABLEFILE CD support. A value less than a CD's usable space (650 MB) allows for a one-to-one match between files from the FILE device class and copies that are on CD.

DIRectory
: Specifies the directory location or locations of the files that are used in this device class. Enclose the entire list of directories within quotation marks, by using commas to separate individual directory names. Special characters (for example, blank spaces) are allowed within directory names. For example, the directory list "abc def,xyz" contains two directories: abc def and xyz. This parameter is optional.

  By specifying a directory name or names, you identify the locations where the server places the files that represent storage volumes for this device class.

  AIX Linux While the command is processed, the server expands the specified directory name or names into their fully qualified forms, starting from the root directory.

  Important: If you are using storage agents for shared access to FILE volumes, you must use the DEFINE PATH command to define a path for each storage agent. The path definition includes the directory names that are used by the storage agent to access each directory.

  Later, if the server must allocate a scratch volume, it creates a new file in one of these directories. (The server can choose any of the directories in which to create new scratch volumes.) For scratch volumes used to store client data, the file that is created by the server has a file name extension of .bfs. For scratch volumes used to store export data, a file name extension of .exp is used.

  AIX Linux For example, if you define a device class with a directory of tsmstor and the server needs a scratch volume in this device class to store export data, the file that the server creates might be named /tsmstor/00566497.exp.

  Windows For example, if you define a device class with a directory of c:\server and the server needs a scratch volume in this device class to store export data, the file that the server creates might be named c:\server\00566497.exp.

  Tip: If you specify multiple directories for a device class, ensure that the directories are associated with separate file systems. Space trigger functions and storage pool space calculations take into account the space that remains in each directory. If you specify multiple directories for a device class and the directories are in the same file system, the server calculates space by adding values that represent the space that remains in each directory. These space calculations are inaccurate. Rather than choosing a storage pool with sufficient space for an operation, the server might choose the wrong storage pool and run out of space prematurely. For space triggers, an inaccurate calculation might result in a failure to expand the space available in a storage pool. Failure to expand space in a storage pool is one of the conditions that can cause a trigger to become disabled. If a trigger is disabled because the space in a storage pool was not expanded, you can re-enable the trigger by issuing the following command: `update spacetrigger stg`. No further changes are required to the space trigger.
  Restriction: To modify a list of directories, you must replace the entire list.

SHAREd
: Specifies that this FILE device class is shared between the server and one or more storage agents. To prepare for sharing, a library is automatically defined along with a number of drives corresponding to the MOUNTLIMIT associated with the device class. If the library and drives exist and the MOUNTLIMIT is changed, drives can either be created to reach a new higher MOUNTLIMIT value or deleted to reach a new lower value.

Storage agents using FILE volumes

You must ensure that storage agents can access newly created FILE volumes. To access FILE volumes, storage agents replace names from the directory list in the device-class definition with the names in the directory list for the associated path definition. The following illustrates the importance of matching device classes and paths to ensure that storage agents can access newly created FILE volumes.

Suppose you want to use these three directories for a FILE library:

Windows

- c:\server
- d:\server
- e:\server

AIX

- /usr/tivoli1
- /usr/tivoli2
- /usr/tivoli3

Linux

- /opt/tivoli1
- /opt/tivoli2
- /opt/tivoli3

1. You use the following command to set up a FILE library named CLASSA with one drive named CLASSA1 on SERVER1:

   Windows

   ```
   define devclass classa devtype=file
   directory="c:\server,d:\server,e:\server"
   shared=yes mountlimit=1
   ```

   AIX

   ```
   define devclass classa devtype=file
   directory="/usr/tivoli1,/usr/tivoli2,/usr/tivoli3"
   shared=yes mountlimit=1
   ```

   Linux

   ```
   define devclass classa devtype=file
   directory="/opt/tivoli1,/opt/tivoli2,/opt/tivoli3"
   shared=yes mountlimit=1
   ```

2. You want the storage agent STA1 to be able to use the FILE library, so you define the following path for storage agent STA1:

   - Windows

     ```
     define path server1 sta1 srctype=server desttype=drive device=file
     directory="\\192.168.1.10\c\server,\\192.168.1.10\d\server,
     \\192.168.1.10\e\server" library=classa
     ```

     In this scenario, the storage agent, STA1, replaces the directory name c:\server with the directory name \\192.168.1.10\c\server to access FILE volumes that are in the c:\server directory on the server.

   - AIX

     ```
     define path server1 sta1 srctype=server desttype=drive device=file
     directory="/usr/ibm1,/usr/ibm2,/usr/ibm3" library=classa
     ```

     In this scenario, the storage agent, STA1, replaces the directory name /usr/tivoli1 with the directory name /usr/ibm1 to access FILE volumes that are in the /usr/tivoli1 directory on the server.

   - Linux

     ```
     define path server1 sta1 srctype=server desttype=drive device=file
     directory="/opt/ibm1,/opt/ibm2,/opt/ibm3" library=classa
     ```

     In this scenario, the storage agent, STA1, replaces the directory name /opt/tivoli1 with the directory name /opt/ibm1/ to access FILE volumes that are in the /opt/tivoli1 directory on the server.

The following results occur:

- Windows File volume c:\server\file1.dsm is created by SERVER1. If you later change the first directory for the device class with the following command:

  ```
  update devclass classa directory="c:\otherdir,d:\server,e:\server"
  ```

  SERVER1 is still able to access file volume c:\server\file1.dsm, but the storage agent STA1 is not able to access it because a matching directory name in the PATH directory list no longer exists. If a directory name is not available in the directory list that is associated with the device class, the storage agent can lose access to a FILE volume in that directory. Although the volume is still accessible from the server for reading, failure of the storage agent to access the FILE volume can cause operations to be retried on a LAN-only path or to fail.
- AIX If file volume /usr/tivoli1/file1.dsm is created on SERVER1, and if the following command is issued,

  ```
  update devclass classa directory="/usr/otherdir,/usr/tivoli2,
  /usr/tivoli3"
  ```

  SERVER1 is still able to access file volume /usr/tivoli1/file1.dsm, but the storage agent STA1 is not able to access it because a matching directory name in the PATH directory list no longer exists. If a directory name is not available in the directory list that is associated with the device class, the storage agent can lose access to a FILE volume in that directory.

Although the volume is still accessible from the server for reading, failure of the storage agent to access the FILE volume can cause operations to be retried on a LAN-only path or to fail.

- Linux If file volume /opt/tivoli1/file1.dsm is created on SERVER1, and if the following command is issued,

  ```
  update devclass classa directory="/opt/otherdir,/opt/tivoli2,
  /opt/tivoli3"
  ```

  SERVER1 is still able to access file volume /opt/tivoli1/file1.dsm, but the storage agent STA1 is not able to access it because a matching directory name in the PATH directory list no longer exists. If a directory name is not available in the directory list that is associated with the device class, the storage agent can lose access to a FILE volume in that directory. Although the volume is still accessible from the server for reading, failure of the storage agent to access the FILE volume can cause operations to be retried on a LAN-only path or to fail.

Example: Update a FILE device class for sharing

Prepare a FILE device class (named PLAINFILES) for sharing with an IBM Spectrum Protect™ storage agent.

```
update devclass plainfiles shared=yes
```

Example: Update the capacity of a FILE device class

Update a file device class named STORFILES to a maximum capacity of 25 MB.

```
update devclass storfiles maxcap=25m
```

AIX

Example: Add a directory to a FILE device class

Update the FILE device class, CLASSA, by adding a directory, /usr/otherdir, to the directory list. The directories /opt/tivoli2 and /opt/tivoli3 were specified when the device class was first defined.

```
update devclass classa
 directory="/opt/tivoli2,/opt/tivoli3,/usr/otherdir"
```

Linux

Example: Add a directory to a FILE device class

Update the FILE device class, CLASSA, by adding a directory, /usr/otherdir, to the directory list. The directories /usr/tivoli2 and /usr/tivoli3 were specified when the device class was first defined.

```
update devclass classa
directory="/usr/tivoli2,/usr/tivoli3,/usr/otherdir"
```

Windows

Example: Add a directory to a FILE device class

Update the FILE device class, CLASSA, by adding a directory, c:\otherdir, to the directory list. The directories d:\server and e:\server were specified when the device class was first defined.

```
update devclass classa
 directory="d:\server,e:\server,c:\otherdir"
```

AIX Windows

UPDATE DEVCLASS (Update a GENERICTAPE device class)

Use the GENERICTAPE device class for tape drives that are supported by operating system device drivers.

When this device type is used, the server does not recognize either the type of device or the cartridge recording format. Because the server does not recognize the type of device, if an I/O error occurs, error information is less detailed compared to error information for a specific device type (for example, 8MM). When you define devices to the server, do not mix various types of devices within the same device type.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate DEVclass--device_class_name--------------------------->

>--+-------------------------+--+---------------------+------->
   '-LIBRary--=--library_name-'  '-ESTCAPacity--=--size-'

>--+---------------------------+--+-----------------------+---->
   '-MOUNTRetention--=--minutes-'  '-MOUNTWait--=--minutes-'

>--+---------------------------+------------------------------><
   '-MOUNTLimit--=--+-DRIVES-+-'
                    +-number-+
                    '-0------'
```

Parameters

device_class_name (Required)
Specifies the name of the device class to be updated.

LIBRary

Specifies the name of the defined library object that contains the tape drives that can be used by this device class.

This parameter is optional.

For information about defining a library object, see the DEFINE LIBRARY command.

ESTCAPacity
Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

Specify a capacity appropriate to the particular tape drive that is being used.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

To force the IBM Spectrum Protect™ server to determine the estimated capacity for the volumes that are assigned to this device class, specify ESTCAPACITY="".

MOUNTRetention
Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types, setting this parameter to a low value (for example, two minutes) enhances device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait
Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is

optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. You can specify a number 0 - 9999.
Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES
Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number
Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)
Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

UPDATE DEVCLASS (Update an LTO device class)

Use the LTO device class when you are using LTO tape devices.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate DEVclass--device_class_name--------------------------->

>--+-------------------------+-------------------------------->
   '-LIBRary--=--library_name-'

>--+-----------------------------+----------------------------->
   '-LBProtect--=--+-READWrite-+-'
                   +-WRITEOnly-+
                   '-No--------'

>--+-------------------------+--+---------------------+------->
   '-FORMAT--=--+-DRIVE-----+-'  '-ESTCAPacity--=--size-'
                +-ULTRIUM---+
                +-ULTRIUMC--+
                +-ULTRIUM2--+
                +-ULTRIUM2C-+
                +-ULTRIUM3--+
                +-ULTRIUM3C-+
                +-ULTRIUM4--+
                +-ULTRIUM4C-+
                +-ULTRIUM5--+
                +-ULTRIUM5C-+
                +-ULTRIUM6--+
                '-ULTRIUM6C-'

>--+---------------------------------+----------------------->
   '-PREFIX--=--+-ADSM---------------+-'
                '-tape_volume_prefix-'

>--+---------------------------+--+----------------------+---->
```

```
   '-MOUNTRetention--=--minutes-'  '-MOUNTWait--=--minutes-'

>--+--------------------------+-------------------------------->
   '-MOUNTLimit--=--+-DRIVES-+-'
                    +-number-+
                    '-0------'

>--+-----------------------------------------------+------------><
   |  (1)   (2)                                    |
   '-------------DRIVEEncryption--=--+-ON-------+-'
                                     +-ALLOW----+
                                     +-EXTERNAL-+
                                     '-OFF------'
```

Notes:

1. You cannot specify DRIVEENCRYPTION=ON if your drives are using WORM (write once, read many) media.
2. Drive encryption is supported only for Ultrium 4, Ultrium 5, and Ultrium 6 drives and media.

Parameters

device_class_name (Required)
: Specifies the name of the device class to be updated. The maximum length of the device class name is 30 characters.

LIBRary
: Specifies the name of the defined library object that contains the LTO tape drives used by this device class. For information about defining a library object, see the DEFINE LIBRARY command.

LBProtect

: Specifies whether logical block protection is used to ensure the integrity of data stored on tape. When LBPROTECT is set to READWRITE or to WRITEONLY, the server uses this feature of the tape drive for logical block protection and generates cyclic redundancy check (CRC) protection information for each data block written on tape. The server also validates the CRC protection information when data is read from the tape.

  The following values are possible:

  READWrite
  : Specifies that logical block protection is enabled in the server and the tape drive for both read and write operations. Data is stored with CRC information in each block. This mode affects performance because additional processor usage is required for IBM Spectrum Protect™ and the tape drive to calculate and compare CRC values. The READWRITE value does not affect backup sets and data that is generated by the BACKUP DB command.

    When the LBPROTECT parameter is set to READWRITE, you do not have to specify the CRCDATA parameter in a storage pool definition because logical block protection provides better protection against data corruption.

  WRITEOnly
  : Specifies that logical block protection is enabled in the server and the tape drive for write operations only. Data is stored containing CRC information in each block. For read operations, the server and the tape drive do not validate the CRC. This mode affects performance because additional processor usage is required for IBM Spectrum Protect to generate the CRC and for the tape drive to calculate and compare CRC values for write operations. The WRITEONLY value does not affect backup sets and data that are generated by the BACKUP DB command.

  No
  : Specifies that logical block protection is not enabled in the server and the tape drive for read and write operations. However, the server enables logical block protection on write operations for a filling volume that already has data with logical block protection.

  Restriction: Logical block protection is supported only on IBM® LTO5 and supported LTO6 drives.

FORMAT
: Specifies the recording format to be used when data is written to sequential access media. This parameter is optional.

  If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use.

  When migrating all drives from Ultrium to Ultrium 2 devices:

  - Delete all existing Ultrium drive definitions and the paths that are associated with them.
  - Define the new Ultrium 2 drives and paths.

If you are considering mixing different generations of LTO media and drives, be aware of the following restrictions.

Table 1. Read - write capabilities for different generations of LTO drives

Drives	Generation 1 media	Generation 2 media	Generation 3 media	Generation 4 media	Generation 5 media	Generation 6 media
Generation 1	Read and write	n/a	n/a	n/a	n/a	n/a
Generation 2	Read and write	Read and write	n/a	n/a	n/a	n/a
Generation 3 [1]	Read only	Read and write	Read and write	n/a	n/a	n/a
Generation 4 [2]	n/a	Read only	Read and write	Read and write	n/a	n/a
Generation 5 [3]	n/a	n/a	Read only	Read and write	Read and write	n/a
Generation 6 [4]	n/a	n/a	n/a	Read only	Read and write	Read and write

[1] In a library with a Generation 3 drive, all Generation 1 scratch volumes must be checked out, and all Generation 1 storage pool volumes must be updated to read-only.

[2] In a library with a Generation 4 drive, all Generation 2 scratch volumes must be checked out, and all Generation 2 storage pool volumes must be updated to read-only.

[3] In a library with a Generation 5 drive, all Generation 3 scratch volumes must be checked out, and all Generation 3 storage pool volumes must be updated to read-only.

[4] In a library with a Generation 6 drive, all Generation 4 scratch volumes must be checked out, and all Generation 4 storage pool volumes must be updated to read-only.

The following table lists the recording formats and estimated capacities for LTO devices:

Table 2. Recording format and default estimated capacity for LTO

Format	Estimated capacity	Description
DRIVE	-	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
ULTRIUM	100 GB	Uncompressed format, using Ultrium cartridges
ULTRIUMC	See note 200 GB	Compressed format, using Ultrium cartridges
ULTRIUM2	200 GB	Uncompressed (standard) format, using Ultrium 2 cartridges
ULTRIUM2C	See note 400 GB	Compressed format, using Ultrium 2 cartridges
ULTRIUM3	400 GB	Uncompressed (standard) format, using Ultrium 3 cartridges
ULTRIUM3C	See note 800 GB	Compressed format, using Ultrium 3 cartridges
ULTRIUM4	800 GB	Uncompressed (standard) format, using Ultrium 4 cartridges
ULTRIUM4C	See note 1.6 TB	Compressed format, using Ultrium 4 cartridges
ULTRIUM5	1.5 TB	Uncompressed (standard) format, using Ultrium 5 cartridges
ULTRIUM5C	See note 3.0 TB	Compressed format, using Ultrium 5 cartridges
ULTRIUM6	2.5 TB	Uncompressed (standard) format, using Ultrium 6 cartridges

Format	Estimated capacity	Description
ULTRIUM6C	See note 6.25 TB	Compressed format, using Ultrium 6 cartridges
Note: If this format uses the tape drive hardware compression feature, depending on the effectiveness of compression, the actual capacity might be greater than the listed value.		

ESTCAPacity

Specifies the estimated capacity for the sequential access volumes that are categorized by this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

To force the IBM Spectrum Protect server to determine the estimated capacity for the volumes that are assigned to this device class, specify ESTCAPACITY="".

For more information about estimated capacities, see Table 2.

PREFIX

Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention

Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types, setting this parameter to a low value (for example, two minutes) enhances device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait

Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. You can specify a number 0 - 9999.

Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit

Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES

Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number

Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)

Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

DRIVEEncryption

Specifies whether drive encryption is allowed. This parameter is optional. Drive encryption is supported only for Ultrium 4, Ultrium 5, and Ultrium 6 drives and media.
Restriction: If encryption is enabled for a device class, and the device class is associated with a storage pool, the storage pool should not share a scratch pool with other device classes that cannot be encrypted. If a tape is encrypted, and you plan to use it on a drive that cannot be encrypted, you must manually relabel the tape before it can be used on that drive.

ON

Specifies that IBM Spectrum Protect is the key manager for drive encryption and allows drive encryption for empty storage pool volumes only if the application method is enabled. (Other types of volumes are not encrypted. For example, back up sets, export volumes, and database backup volumes are not encrypted.) If you specify ON and you enable another method of encryption, drive encryption is not allowed and backup operations fail.
Note: You cannot specify IBM Spectrum Protect as the key manager for drive encryption of WORM (write once, read many) media. (If you are using WORM media, you cannot specify DRIVEENCRYPTION=ON.)

ALLOW

Specifies that IBM Spectrum Protect does not manage the keys for drive encryption. However, drive encryption for empty volumes is allowed if another method of encryption is enabled.

EXTERNAL

Specifies that IBM Spectrum Protect does not manage the keys for drive encryption. Use this setting with an encryption methodology that is provided by another vendor and that is used with Application Method Encryption (AME) enabled on the drive. When you specify EXTERNAL and IBM Spectrum Protect detects that AME encryption is enabled, IBM Spectrum Protect does not turn off encryption. By contrast, when you specify ALLOW and IBM Spectrum Protect detects that AME encryption is enabled, IBM Spectrum Protect turns off encryption.

OFF

Specifies that drive encryption is not allowed. If you enable another method of encryption, backups fail. If you enable the application method, IBM Spectrum Protect disables encryption and backups are attempted.

Example: Update the mount limit for an LTO device class

Update a device class named LTOTAPE. Change the mount limit to 2.

```
update devclass ltotape mountlimit=2
```

UPDATE DEVCLASS (Update a NAS device class)

Use the NAS device class when you are using NDMP (Network Data Management Protocol) operations to back up network-attached storage (NAS) file servers. The device class is for drives that are supported by the NAS file server for backups.

AIX Linux The NAS device class does not support EXTERNAL libraries.

Windows The NAS device class does not support EXTERNAL libraries.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate DEVclass--device_class_name--------------------------->

>--+-------------------------+--+---------------------+------->
   '-LIBRary--=--library_name-'  '-MOUNTRetention--=--0-'

>--+-----------------------+--+--------------------------+----->
   '-MOUNTWait--=--minutes-'  '-MOUNTLimit--=--+-DRIVES-+-'
                                               +-number-+
                                               '-0------'

>--+---------------------+-------------------------------------->
   '-ESTCAPacity--=--size-'

>--+-------------------------------+--------------------------><
   '-PREFIX--=--tape_volume_prefix-'
```

Parameters

device_class_name (Required)
: Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

LIBRary
: Specifies the name of the defined library object that contains the SCSI tape drives used by this device class. For information about defining a library object, see the DEFINE LIBRARY command.

MOUNTRetention=0
: Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. Zero (0) is the only supported value for device classes with DEVType=NAS.

MOUNTWait
: Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. You can specify a number 0 - 9999.
  Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
: Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. You can specify a number 0 - 4096.

  If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

  The following are possible values:

  DRIVES
  : Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
    Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

  number
  : Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

  0 (zero)
  : Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

To force the IBM Spectrum Protect™ server to determine the estimated capacity for the volumes that are assigned to this device class, specify ESTCAPACITY="".

PREFIX

Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

Example: Update the estimated capacity for a NAS device class

Update a device class named NASTAPE. Change the estimated capacity to 200 GB.

```
update devclass nastape library=naslib estcapacity=200G
```

UPDATE DEVCLASS (Update a REMOVABLEFILE device class)

Use the REMOVABLEFILE device class for removable media devices that are attached as local, removable file systems.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate DEVclass--device_class_name---------------------------->

>--+-------------------------+--+----------------------+------->
   '-LIBRary--=--library_name-'  '-MAXCAPacity--=--size-'

>--+---------------------------+--+-----------------------+---->
   '-MOUNTRetention--=--minutes-'  '-MOUNTWait--=--minutes-'

>--+-------------------------+-----------------------------><
   '-MOUNTLimit--=--+-DRIVES-+-'
                    +-number-+
                    '-0------'
```

Parameters

device_class_name (Required)
Specifies the name of the device class to be updated.

LIBRary
Specifies the name of the defined library object that contains the removable media drives used by this device class. This parameter is optional. For information about defining a library object, see the DEFINE LIBRARY command.

MAXCAPacity
Specifies the maximum size of any volumes that are defined to a storage pool categorized by this device class. This parameter is optional.

AIX Windows Because the server opens only one file per physical removable medium, specify a capacity that enables one file to make full use of your media capacity.

You must specify this value as an integer followed by K (kilobytes), M (megabytes), G (gigabytes), or T (terabytes).

For example, MAXCAPACITY=5M specifies that the maximum capacity for a volume in this device class is 5 MB. The smallest value that is allowed is 1 MB (that is, MAXCAPACITY=1M).

MOUNTRetention
Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait
Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. You can specify a number 0 - 9999.
Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES
Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number
Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)
Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

UPDATE DEVCLASS (Update a SERVER device class)

Use the SERVER device class to use storage volumes or files that are archived in another IBM Spectrum Protect™ server.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDdate DEVclass--device_class_name-------------------------->

>--+-----------------------------+--+----------------------+----->
   '-SERVERName--=--server_name-'  '-MAXCAPacity--=--size-'

>--+-----------------------------------+------------------------>
   '-PREFIX--=--+-ADSM---------------+-'
                '-tape_volume_prefix-'

>--+-----------------------------+----------------------------->
   '-RETRYPeriod--=----minutes---'

>--+-------------------------------+--------------------------->
   '-RETRYInterval--=----seconds---'

>--+-----------------------------+----------------------------->
   '-MOUNTRetention--=--minutes-'

>--+---------------------------+------------------------------><
   '-MOUNTLimit--=--+-number-+-'
                    '-1------'
```

Parameters

device_class_name (Required)
: Specifies the name of the device class to be updated.

SERVERName
: Specifies the name of the server. The SERVERNAME parameter must match a defined server.
Note: If you change the SERVERNAME of an existing server to a new name, data on the volumes under the old SERVERNAME is no longer accessible with this device class.

MAXCAPacity
: Specifies the maximum size that objects can be when created on the target server. This parameter is optional.

  Specify this value as an integer followed by `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The minimum value that is allowed is 1 MB (MAXCAPACITY=1M).

PREFIX
: Specifies the beginning portion of the high-level archive file name on the target server. This parameter is optional. The maximum length of this prefix is 8 characters.

  If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

  Values that are specified for this parameter must meet the following conditions:

  - The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

    ```
    AB.CD2.E
    ```

  - The qualifiers must be separated by a single period.
  - The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

  An example of a high-level archive file name that uses the default prefix is ADSM.volume1.

RETRYPeriod
: Specifies the retry period in minutes. The retry period is the interval during which the server attempts to contact a target server if there is a suspected communications failure. This parameter is optional. You can specify a number 0 - 9999.

RETRYInterval
: Specifies the retry interval in seconds. The retry interval is how often retries are done within a specific time period. This parameter is optional. You can specify a number 1 - 9999.

MOUNTRetention
: Specifies the number of minutes to retain an idle connection with the target server before the connection is closed. This parameter is optional. You can specify a number 0 - 9999.
  Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTLimit
: Specifies the maximum number of simultaneous sessions between the source server and the target server. Any attempts to access more sessions than indicated by the mount limit cause the requester to wait. This parameter is optional. You can specify a number 1 - 4096.
  The following are possible values:

  number
  : Specifies the maximum number of simultaneous sessions between the source server and the target server.

  1
  : Specifies the number of simultaneous sessions between the source server and the target server.

UPDATE DEVCLASS (Update a VOLSAFE device class)

Use the VOLSAFE device type to work with StorageTek VolSafe brand media and drives. This technology uses media that cannot be overwritten. Therefore, do not use these media for short-term backups of client files, the server database, or export tapes.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

Parameters

device_class_name (Required)

Specifies the name of the device class to be updated. The maximum length of the device class name is 30 characters.

LIBRary

Specifies the name of the defined library object that contains the VolSafe drives that can be used by this device class. If any drives in a library are VolSafe-enabled, all drives in the library must be VolSafe-enabled. For more information about the VolSafe device type, see DEFINE DEVCLASS (Define a VOLSAFE device class).

FORMAT

Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. The default value is DRIVE.

Attention: If you specify DRIVE for a device class that has non-compatible sequential access devices, then you must mount volumes on devices that are capable of reading or writing the format that is established when the volume was first mounted. This can cause delays if the only sequential access device that can access the volume is already in use.

The following table lists the recording formats and estimated capacities for VolSafe devices:

Table 1. Recording formats and default estimated capacities for volsafe tapes

Format	Estimated Capacity	Description
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
9840	20 GB	Uncompressed (standard) format, using a 20 GB cartridge with 270 meters (885 feet) of tape
9840-C	80 GB	LZ-1 Enhanced (4:1) compressed format, using an 80 GB cartridge with 270 meters (885 feet) of tape
T9840C	40 GB	Uncompressed T9840C format, using a StorageTek 9840 cartridge
T9840C-C	80 GB	Compressed T9840C format, using a StorageTek 9840 cartridge
T9840D	75 GB	Uncompressed T9840D format, using a StorageTek 9840 cartridge
T9840D-C	150 GB	Compressed T9840D format, using a StorageTek 9840 cartridge
T10000A	500 GB	Uncompressed T10000A format, using a StorageTek T10000 cartridge
T10000A-C	1 TB	Compressed T10000A format, using a StorageTek T10000 cartridge
T10000B	1 TB	Uncompressed T10000B format, using an Oracle StorageTek T10000 cartridge
T10000B-C	2 TB	Compressed T10000B format, using an Oracle StorageTek T10000 cartridge
T10000C	5 TB	Uncompressed T10000C format, using an Oracle StorageTek T10000 T2 cartridge
T10000C-C	10 TB	Compressed T10000C format, using an Oracle StorageTek T10000 T2 cartridge
T10000D	8 TB	Uncompressed T10000D format, using an Oracle StorageTek T10000 T2 cartridge
T10000D-C	15 TB	Compressed T10000D format, using an Oracle StorageTek T10000 T2 cartridge

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

To force the IBM Spectrum Protect™ server to determine the estimated capacity for the volumes that are assigned to this device class, specify ESTCAPACITY="".

For more information about the default estimated capacity for cartridge tapes, see Table 1.

PREFIX

Specifies the beginning portion of the high-level archive file name on the target server. This parameter is optional. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a high-level archive file name that uses the default prefix is ADSM.volume1.

MOUNTRetention

Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types (that is, a library that is managed by an external media management system), set this parameter to a low value (for example, two minutes) to enhance device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait

Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. You can specify a number 0 - 9999.

Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit

Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES

Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.

Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number

Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)

Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

AIX Linux

UPDATE DEVCLASS - z/OS media server (Update device class for z/OS media server)

Use this command to update a device class. A limited set of device class types is available for devices that are accessed through a z/OS® media server.

- UPDATE DEVCLASS (Update a 3590 device class for z/OS media server)
- UPDATE DEVCLASS (Update a 3592 device class for z/OS media server)
- UPDATE DEVCLASS (Update an ECARTRIDGE device class for z/OS media server)
- UPDATE DEVCLASS (Update a FILE device class for z/OS media server)

Table 1. Commands related to UPDATE DEVCLASS

Command	Description
BACKUP DEVCONFIG	Backs up IBM Spectrum Protect device information to a file.
DEFINE DEVCLASS (z/OS media server)	Defines a device class to use storage managed by a z/OS media server.
DEFINE LIBRARY	Defines an automated or manual library.
DELETE DEVCLASS	Deletes a device class.
QUERY DEVCLASS	Displays information about device classes.
UPDATE LIBRARY	Changes the attributes of a library.

AIX Linux

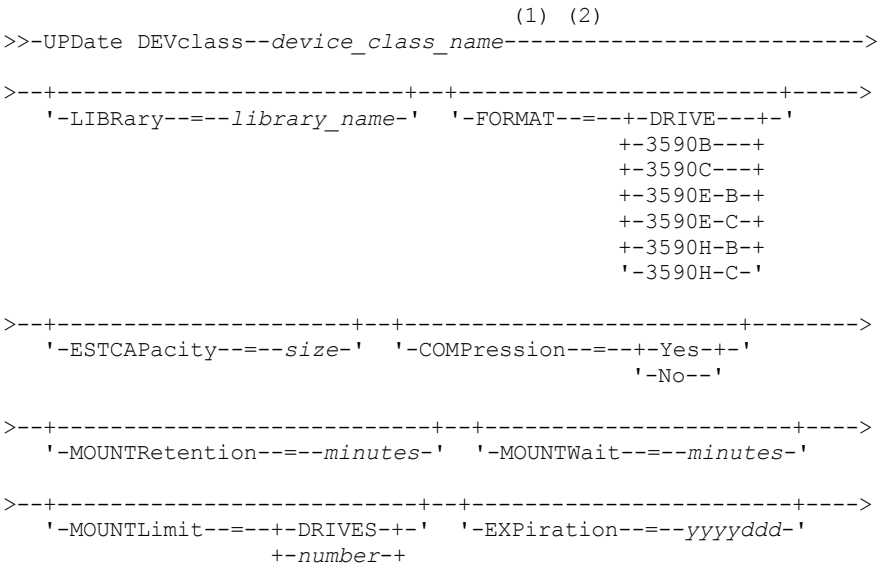
UPDATE DEVCLASS (Update a 3590 device class for z/OS media server)

Use this command to update a device class that you defined to use a z/OS® media server to access 3590 devices. The device class that targets storage for the z/OS media server requires a library definition of type ZOSMEDIA.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax



```
                    '-0------'

>--+--------------------+--+-----------------------------+----->
   '-RETention---=--days-'  '-PROtection---=--+-No--------+-'
                                              +-Yes-------+
                                              '-Automatic-'

>--+--------------------+-------------------------------------><
   '-UNIT---=--unit_name-'
```

Notes:

1. You must specify at least one optional parameter on this command.
2. You cannot update the PREFIX parameter with this command. You must create a device class with the value that you require for the PREFIX parameter.

Parameters

device_class_name (Required)
Specifies the name of the device class to be updated.

LIBRary

Specifies the name of a library that was defined with the LIBTYPE=ZOSMEDIA parameter. The library and the tape drives that can be used by this device class are controlled by the z/OS media server.

This parameter is optional.

For information about defining a library, see the DEFINE LIBRARY command.

FORMAT
Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. The following table lists the recording format options for 3590 devices:

Table 1. Recording formats for 3590

Format	Description
3590B	Uncompressed (basic) format
3590C	Compressed format
3590E-B	Uncompressed (basic) format, similar to the 3590B format
3590E-C	Compressed format, similar to the 3590C format
3590H-B	Uncompressed (basic) format, similar to the 3590B format
3590H-C	Compressed format, similar to the 3590C format
Note: If the format uses the tape drive hardware compression feature the actual capacity can increase, depending on the effectiveness of compression.	

ESTCAPacity
Specifies the estimated capacity for the sequential access volumes that are categorized by this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate because of compression of data. The value does not determine the amount of data stored on the volume. The server uses the value to estimate the usage before a volume is filled. After a volume is full, the actual amount of data stored on the tape is used for the usage calculation.

Specify the value as an integer with one of the following unit indicators: `K` (KB), `M` (MB), `G` (GB), or `T` (TB). For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G. The smallest value that is accepted is 100 KB (ESTCAPACITY=100K).

COMPression
Specifies whether file compression is used for this device class. This parameter is optional.
You can specify one of the following values:

Yes
Specifies that the data for each tape volume is compressed.

No
Specifies that the data for each tape volume is not compressed.

MOUNTRetention
Specifies the number of minutes that an idle tape volume is retained before it is dismounted. The time span for mount retention begins after the idle timeout period has expired. This parameter is optional. Specify a number, 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

MOUNTWait
Specifies the maximum number of minutes that the z/OS media server waits for a volume mount. If the mount request is not satisfied within the specified time, the mount request fails. If a device is successfully allocated and the device-open request does not complete within the specified time, the device-open request ends and the mount request fails.

This parameter is optional. Specify a number, 1 - 9999.

Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

You can specify one of the following values:

DRIVES
Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.

number
Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class. You can specify a number, 0 - 4096.

0 (zero)
Specifies that no new transactions can gain access to the storage pool.

EXPiration
Specifies the expiration date that is placed on the tape labels for this device class. This parameter is optional.

Specify the date when the server no longer requires the tape. The server does not use this information, but this information is passed to the z/OS media server for use by z/OS or tape management systems.

Specify the expiration date using the format, *yyyyddd* (four digits for the year and three digits for the day). For example, January 7, 2014 is specified as `2014007` (the seventh day of year 2014).

If you specify the EXPIRATION parameter, you cannot specify the RETENTION parameter.

RETention
Specifies the number of days to retain the tape. This parameter is optional.

Specify the number of days (1 - 9999) that the server is expected to use the tape. The server does not use this information, but this information is passed to the z/OS media server for use by z/OS or tape management systems.

If you specify the RETENTION parameter, you cannot specify the EXPIRATION parameter.

Tip: You can specify a value of zero for this parameter. However, do so only if you also want to specify a value for the EXPIRATION parameter. You cannot specify a value for the EXPIRATION parameter if you specify a non-zero value for the RETENTION parameter.

PROtection
Specifies whether the RACF® program, if installed, protects volumes that are assigned to this device class. If protection is provided, RACF profiles are created when volumes are first used. This parameter is optional. You can specify one of the following values:

No
: Specifies that the RACF program does not protect volumes that are assigned to this device class.

Yes
: Specifies that the RACF program protects volumes that are assigned to this device class. RACF profiles are created for volumes when the server first uses the volumes, but the profiles are not deleted when volumes are deleted from the server. Profiles must be manually deleted.
Tip: If sensitive data is stored on volumes that are assigned to this device class, use PROTECTION=YES and manually delete RACF profiles only after tape volumes have been erased.

  The profiles that are created for volumes depend on the system RACF settings. The protection that is provided is the same as using PROTECT=YES in JCL. If the RACF program is active and both TAPEVOL and TAPEDSN are inactive, allocation of tapes fails.

Automatic
: Specifies that the RACF program protects volumes that are assigned to this device class. RACF profiles are created for volumes when the server first uses the volumes. RACF profiles are deleted when volumes are deleted from the server.

  The profiles that are created for volumes depend on the system RACF settings. The protection that is provided is the same as using PROTECT=YES in JCL. If the RACF program is active and both TAPEVOL and TAPEDSN are inactive, allocation of tapes fails.

  Important: If you specify PROTECTION=AUTOMATIC, when a volume is deleted, its RACF profile is deleted. The volume therefore is no longer protected by the RACF program. The data on these volumes can be accessed by other users.

  If you specify PROTECTION=AUTOMATIC, the z/OS media server issues RACROUTE commands to delete profiles when a volume is deleted from the server. The deletion commands that are issued depend on the current system settings for TAPEVOL and TAPEDSN. If the system settings are changed, the z/OS media server might not delete existing profiles.

  Do not change the setting to PROTECTION=AUTOMATIC for a device class that was set to PROTECTION=NO. Volumes without profiles might exist and error messages are generated when such volumes are deleted. If a different value for PROTECTION is required, define a new device class.

Profile creation and deletion occur based on the protection setting when the volume is first used and when it is deleted. The server does not attempt to create profiles for volumes that it has already used. If protection is set to AUTOMATIC, the server attempts to delete profiles when volumes are deleted.

See the documentation for the RACF program for details about the TAPEVOL and TAPEDSN settings and the profiles that are created when these settings are active.

UNIT
: Specifies an esoteric unit name to specify a group of tape devices that support 3590 tape. This parameter is optional. The unit name can be up to 8 characters.

AIX Linux

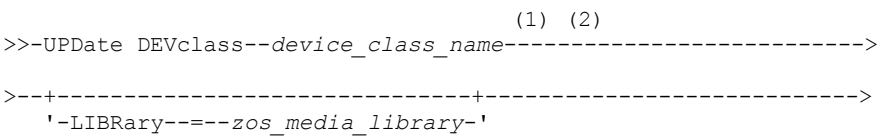
UPDATE DEVCLASS (Update a 3592 device class for z/OS media server)

Use this command to update a device class that you defined to use a z/OS® media server to access 3592 devices. The device class that targets storage for the z/OS media server requires a library definition of type ZOSMEDIA.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax



```
>--+------------------------+--+----------------------+--------->
   '-FORMAT--=--+-DRIVE---+-'  '-ESTCAPacity--=--size-'
                +-3592----+
                +-3592C---+
                +-3592-2--+
                +-3592-2C-+
                +-3592-3--+
                +-3592-3C-+
                +-3592-4--+
                '-3592-4C-'

>--+-------------------------+---------------------------------->
   '-COMPression--=--+-Yes-+-'
                     '-No--'

>--+---------------------------+--+-----------------------+---->
   '-MOUNTRetention--=--minutes-'  '-MOUNTWait--=--minutes-'

>--+---------------------------+--+-----------------------+---->
   '-MOUNTLimit--=--+-DRIVES-+-'  '-EXPiration--=--yyyyddd-'
                    +-number-+
                    '-0------'

>--+--------------------+--+-----------------------------+----->
   '-RETention--=--days-'  '-PROtection--=--+-No--------+-'
                                            +-Yes-------+
                                            '-Automatic-'

>--+--------------------+------------------------------------><
   '-UNIT--=--unit_name-'
```

Notes:

1. You must specify at least one optional parameter on this command.
2. You cannot update the PREFIX parameter with this command. You must create a device class with the value that you require for the PREFIX parameter.

Parameters

device_class_name (Required)
Specifies the name of the device class to be updated. The maximum length of the device class name is 30 characters.

LIBRary

Specifies the name of a library that was defined with the LIBTYPE=ZOSMEDIA parameter. The library and the tape drives that can be used by this device class are controlled by the z/OS media server.

This parameter is optional.

For information about defining a library, see the DEFINE LIBRARY command.

FORMAT

Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. The default value is DRIVE.
See the following table for the recording formats.

Table 1. Recording formats for 3592

Format	Description
3592	Uncompressed (basic) format
3592C	Compressed format
3592-2	Uncompressed (basic) format, similar to the 3592 format
3592-C	Compressed format, similar to the 3592C format
3592-3	Uncompressed (basic) format, similar to the 3592 format
3592-3C	Compressed format, similar to the 3592C format

Format	Description
3592-4	Uncompressed (basic) format, similar to the 3592 format
3592-4C	Compressed format, similar to the 3592C format
DRIVE	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library containing some drives that support recording formats superior to other drives.
Note: If this format uses the tape drive hardware compression feature, depending on the effectiveness of compression, the actual capacity might be different from the listed value.	

If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use. For optimal results, do not mix generations of drives in the same library. If a library contains mixed generations, media problems can result. For example, generation 1 and generation 2 drives cannot read generation 3 media. If possible, upgrade all drives to 3592 generation 3. If you cannot upgrade all drives to 3592 generation 3, you must use a special configuration.

ESTCAPacity
Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate because of compression of data. The value does not determine the amount of data stored on the volume. The server uses the value to estimate the usage before a volume is filled. After a volume is full, the actual amount of data stored on the tape is used for the usage calculation.

Specify the value as an integer with one of the following unit indicators: `K` (KB), `M` (MB), `G` (GB), or `T` (TB). For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G. The smallest value that is accepted is 100 KB (ESTCAPACITY=100K).

COMPression
Specifies whether file compression is used for this device class. This parameter is optional. The default value is YES. You can specify one of the following values:

Yes
Specifies that the data for each tape volume is compressed.
No
Specifies that the data for each tape volume is not compressed.

MOUNTRetention
Specifies the number of minutes that an idle tape volume is retained before it is dismounted. The time span for mount retention begins after the idle timeout period has expired. This parameter is optional. Specify a number, 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

MOUNTWait
Specifies the maximum number of minutes that the z/OS media server waits for a volume mount. If the mount request is not satisfied within the specified time, the mount request fails. If a device is successfully allocated and the device-open request does not complete within the specified time, the device-open request ends and the mount request fails.

This parameter is optional. Specify a number, 1 - 9999.

Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

You can specify one of the following values:

DRIVES
: Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.

number
: Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class. You can specify a number, 0 - 4096.

0 (zero)
: Specifies that no new transactions can gain access to the storage pool.

EXPiration
: Specifies the expiration date that is placed on the tape labels for this device class. This parameter is optional.

Specify the date when the server no longer requires the tape. The server does not use this information, but this information is passed to the z/OS media server for use by z/OS or tape management systems.

Specify the expiration date using the format, *yyyyddd* (four digits for the year and three digits for the day). For example, January 7, 2014 is specified as `2014007` (the seventh day of year 2014).

If you specify the EXPIRATION parameter, you cannot specify the RETENTION parameter.

RETention
: Specifies the number of days to retain the tape. This parameter is optional.

Specify the number of days (1 - 9999) that the server is expected to use the tape. The server does not use this information, but this information is passed to the z/OS media server for use by z/OS or tape management systems.

If you specify the RETENTION parameter, you cannot specify the EXPIRATION parameter.

Tip: You can specify a value of zero for this parameter. However, do so only if you also want to specify a value for the EXPIRATION parameter. You cannot specify a value for the EXPIRATION parameter if you specify a non-zero value for the RETENTION parameter.

PROtection
: Specifies whether the RACF® program, if installed, protects volumes that are assigned to this device class. If protection is provided, RACF profiles are created when volumes are first used. This parameter is optional. You can specify one of the following values:

No
: Specifies that the RACF program does not protect volumes that are assigned to this device class.

Yes
: Specifies that the RACF program protects volumes that are assigned to this device class. RACF profiles are created for volumes when the server first uses the volumes, but the profiles are not deleted when volumes are deleted from the server. Profiles must be manually deleted.
Tip: If sensitive data is stored on volumes that are assigned to this device class, use PROTECTION=YES and manually delete RACF profiles only after tape volumes have been erased.

The profiles that are created for volumes depend on the system RACF settings. The protection that is provided is the same as using PROTECT=YES in JCL. If the RACF program is active and both TAPEVOL and TAPEDSN are inactive, allocation of tapes fails.

Automatic
: Specifies that the RACF program protects volumes that are assigned to this device class. RACF profiles are created for volumes when the server first uses the volumes. RACF profiles are deleted when volumes are deleted from the server.

The profiles that are created for volumes depend on the system RACF settings. The protection that is provided is the same as using PROTECT=YES in JCL. If the RACF program is active and both TAPEVOL and TAPEDSN are inactive, allocation of tapes fails.

Important: If you specify PROTECTION=AUTOMATIC, when a volume is deleted, its RACF profile is deleted. The volume therefore is no longer protected by the RACF program. The data on these volumes can be accessed by other users.

If you specify PROTECTION=AUTOMATIC, the z/OS media server issues RACROUTE commands to delete profiles when a volume is deleted from the server. The deletion commands that are issued depend on the current system settings for TAPEVOL and TAPEDSN. If the system settings are changed, the z/OS media server might not delete existing profiles.

Do not change the setting to PROTECTION=AUTOMATIC for a device class that was set to PROTECTION=NO. Volumes without profiles might exist and error messages are generated when such volumes are deleted. If a different value for PROTECTION is required, define a new device class.

Profile creation and deletion occur based on the protection setting when the volume is first used and when it is deleted. The server does not attempt to create profiles for volumes that it has already used. If protection is set to AUTOMATIC, the server attempts to delete profiles when volumes are deleted.

See the documentation for the RACF program for details about the TAPEVOL and TAPEDSN settings and the profiles that are created when these settings are active.

UNIT

Specifies an esoteric unit name to specify a group of tape devices that support 3592 tape. This parameter is optional. This name can be as many as 8 characters.

AIX | Linux

UPDATE DEVCLASS (Update an ECARTRIDGE device class for z/OS media server)

Use this command to update a device class that you defined to use a z/OS® media server to access StorageTek drives such as the StorageTek T9840 or T10000. The device class that targets storage for the z/OS media server requires a library definition of type ZOSMEDIA.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
                                      (1)  (2)
>>-UPDate DEVclass--device_class_name-------------------------->

>--+-------------------------------+---------------------------->
   '-LIBRary--=--zos_media_library-'

>--+--------------------------+--+----------------------+------->

                +-T9840C----+
                +-T9840C-C--+
                +-T9840D----+
                +-T9840D-C--+
                +-T10000A---+
                +-T10000A-C-+
                +-T10000B---+
                +-T10000B-C-+
                +-T10000C---+
                +-T10000C-C-+
                +-T10000D---+
                '-T10000D-C-'

>--+----------------------------+--+-----------------------+---->
   '-MOUNTRetention--=--minutes-'  '-MOUNTWait--=--minutes-'

>--+--------------------------+--+-------------------------+--->
   '-MOUNTLimit--=--+-DRIVES-+-'  '-COMPression--=--+-Yes-+-'
                    +-number-+                     '-No--'
                    '-0------'

>--+------------------------+--+--------------------+----------->
   '-EXPiration--=--yyyyddd-'  '-RETention--=--days-'
```

```
>--+-------------------------------+--+--------------------+----><
   '-PROtection--=--+-No--------+-'  '-UNIT--=--unit_name-'
                    +-Yes-------+
                    '-Automatic-'
```

Notes:

1. You must specify at least one optional parameter on this command.
2. You cannot update the PREFIX parameter with this command. You must create a device class with the value that you require for the PREFIX parameter.

Parameters

device_class_name (Required)
Specifies the name of the device class to be updated.

LIBRary

Specifies the name of a library that was defined with the LIBTYPE=ZOSMEDIA parameter. The library and the tape drives that can be used by this device class are controlled by the z/OS media server.

This parameter is optional.

For information about defining a library, see the DEFINE LIBRARY command.

FORMAT
Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. See the following table for the recording formats.

Table 1. Recording formats for ECARTRIDGE tapes

Format	Estimated Capacity	Description
DRIVE	-	The server selects the highest format that is supported by the drive on which a volume is mounted. DRIVE is the default value. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library containing some drives that support recording formats superior to other drives.
T9840C	40 GB	Uncompressed T9840C format, using a StorageTek 9840 cartridge
T9840C-C	80 GB	Compressed T9840C format, using a StorageTek 9840 cartridge
T9840D	75 GB	Uncompressed T9840D format, using a StorageTek 9840 cartridge
T9840D-C	150 GB	Compressed T9840D format, using a StorageTek 9840 cartridge
T10000A	500 GB	Uncompressed T10000A format, using a StorageTek T10000 cartridge
T10000A-C	1 TB	Compressed T10000A format, using a StorageTek T10000 cartridge
T10000B	1 TB	Uncompressed T10000B format, using an Oracle StorageTek T10000 cartridge
T10000B-C	2 TB	Compressed T10000B format, using an Oracle StorageTek T10000 cartridge
T10000C	5 TB	Uncompressed T10000C format, using an Oracle StorageTek T10000 T2 cartridge
T10000C-C	10 TB	Compressed T10000C format, using an Oracle StorageTek T10000 T2 cartridge
T10000D	8 TB	Uncompressed T10000D format, using an Oracle StorageTek T10000 T2 cartridge
T10000D-C	15 TB	Compressed T10000D format, using an Oracle StorageTek T10000 T2 cartridge

Format	Estimated Capacity	Description
Note: • Some formats use a compression feature of the tape drive hardware. Depending on the effectiveness of compression, the actual capacity might be double or more than the listed value. • T10000A drives can read and write the T10000A format only. T10000B drives can read, but cannot write, the T10000A format. T10000C drives can read, but cannot write, the T10000A and T10000B formats. T10000D drives can read, but cannot write, the T10000A, T10000B, and T10000C formats.		

ESTCAPacity
Specifies the estimated capacity for the sequential access volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate because of compression of data. The value does not determine the amount of data stored on the volume. The server uses the value to estimate the usage before a volume is filled. After a volume is full, the actual amount of data stored on the tape is used for the usage calculation.

Specify the value as an integer with one of the following unit indicators: `K` (KB), `M` (MB), `G` (GB), or `T` (TB). For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G. The smallest value that is accepted is 100 KB (ESTCAPACITY=100K).

MOUNTRetention
Specifies the number of minutes that an idle tape volume is retained before it is dismounted. The time span for mount retention begins after the idle timeout period has expired. This parameter is optional. Specify a number, 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

MOUNTWait
Specifies the maximum number of minutes that the z/OS media server waits for a volume mount. If the mount request is not satisfied within the specified time, the mount request fails. If a device is successfully allocated and the device-open request does not complete within the specified time, the device-open request ends and the mount request fails.

This parameter is optional. Specify a number, 1 - 9999.

Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

You can specify one of the following values:

DRIVES
Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.

number
Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class. You can specify a number, 0 - 4096.

0 (zero)
Specifies that no new transactions can gain access to the storage pool.

COMPression
Specifies whether file compression is used for this device class. This parameter is optional.
You can specify one of the following values:

Yes
Specifies that the data for each tape volume is compressed.

No
Specifies that the data for each tape volume is not compressed.

EXPiration
Specifies the expiration date that is placed on the tape labels for this device class. This parameter is optional.

Specify the date when the server no longer requires the tape. The server does not use this information, but this information is passed to the z/OS media server for use by z/OS or tape management systems.

Specify the expiration date using the format, *yyyyddd* (four digits for the year and three digits for the day). For example, January 7, 2014 is specified as `2014007` (the seventh day of year 2014).

If you specify the EXPIRATION parameter, you cannot specify the RETENTION parameter.

RETention
Specifies the number of days to retain the tape. This parameter is optional.

Specify the number of days (1 - 9999) that the server is expected to use the tape. The server does not use this information, but this information is passed to the z/OS media server for use by z/OS or tape management systems.

If you specify the RETENTION parameter, you cannot specify the EXPIRATION parameter.

Tip: You can specify a value of zero for this parameter. However, do so only if you also want to specify a value for the EXPIRATION parameter. You cannot specify a value for the EXPIRATION parameter if you specify a non-zero value for the RETENTION parameter.

PROtection
Specifies whether the RACF® program, if installed, protects volumes that are assigned to this device class. If protection is provided, RACF profiles are created when volumes are first used. This parameter is optional. You can specify one of the following values:

No
Specifies that the RACF program does not protect volumes that are assigned to this device class.

Yes
Specifies that the RACF program protects volumes that are assigned to this device class. RACF profiles are created for volumes when the server first uses the volumes, but the profiles are not deleted when volumes are deleted from the server. Profiles must be manually deleted.
Tip: If sensitive data is stored on volumes that are assigned to this device class, use PROTECTION=YES and manually delete RACF profiles only after tape volumes have been erased.

The profiles that are created for volumes depend on the system RACF settings. The protection that is provided is the same as using PROTECT=YES in JCL. If the RACF program is active and both TAPEVOL and TAPEDSN are inactive, allocation of tapes fails.

Automatic
Specifies that the RACF program protects volumes that are assigned to this device class. RACF profiles are created for volumes when the server first uses the volumes. RACF profiles are deleted when volumes are deleted from the server.

The profiles that are created for volumes depend on the system RACF settings. The protection that is provided is the same as using PROTECT=YES in JCL. If the RACF program is active and both TAPEVOL and TAPEDSN are inactive, allocation of tapes fails.

Important: If you specify PROTECTION=AUTOMATIC, when a volume is deleted, its RACF profile is deleted. The volume therefore is no longer protected by the RACF program. The data on these volumes can be accessed by other users.

If you specify PROTECTION=AUTOMATIC, the z/OS media server issues RACROUTE commands to delete profiles when a volume is deleted from the server. The deletion commands that are issued depend on the current system settings for TAPEVOL and TAPEDSN. If the system settings are changed, the z/OS media server might not delete existing profiles.

Do not change the setting to PROTECTION=AUTOMATIC for a device class that was set to PROTECTION=NO. Volumes without profiles might exist and error messages are generated when such volumes are deleted. If a different value for PROTECTION is required, define a new device class.

Profile creation and deletion occur based on the protection setting when the volume is first used and when it is deleted. The server does not attempt to create profiles for volumes that it has already used. If protection is set to AUTOMATIC, the server attempts to delete profiles when volumes are deleted.

See the documentation for the RACF program for details about the TAPEVOL and TAPEDSN settings and the profiles that are created when these settings are active.

UNIT
Specifies an esoteric unit name to specify a group of tape devices that support ECARTRIDGE tapes. Use the unit name that represents the subset of drives in the library that are attached to the z/OS system. This parameter is optional. The unit name can be up to 8 characters.

AIX | Linux

UPDATE DEVCLASS (Update a FILE device class for z/OS media server)

Use this command to update a device class that you defined to use a z/OS® media server to access files on magnetic disk storage as sequential-access volumes (like tape). The device class that targets storage for the z/OS media server requires a library definition of type ZOSMEDIA.

A volume in this device class is a Virtual Storage Access Method (VSAM) linear data set that is accessed by the z/OS media server. SCRATCH volumes can be used with a device class and the z/OS media server dynamically allocates the VSAM LDS. It is not necessary to define volumes for the server to use the device class. If you define volumes, set the high-level qualifier (HLQ) so that SMS recognizes the allocation request by the z/OS media server. If you are using defined volumes, the format volume function is not supported for the server when you use this device class. The z/OS media server z/OS media server uses a FormatWrite feature of DFSMS Media Manager when filling FILE volumes.

You can define volumes for the FILE device class by using the DEFINE VOLUME command. However, the z/OS media server does not allocate space for a defined volume until the volume is opened for its first use.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate DEVclass--device_class_name---------------------------->

>--+---------------------+--+----------------------+---------->
   '-MAXCAPacity--=--size-'  '-PRIMARYalloc--=--size-'

>--+-------------------------+-------------------------------->
   '-SECONDARYalloc--=--size-'

>--+-----------------------------+---------------------------->
   '-PREFIX--=--file_volume_prefix-'

>--+----------------------+-----------------------------------><
   '-MOUNTLimit--=--number-'
```

Parameters

device_class_name (Required)
Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

MAXCAPacity
Specifies the maximum size of file volumes that are defined to a storage pool in this device class. This parameter is optional.

Specify this value as an integer followed by K (KB), M (MB), G (GB), or T (TB). The minimum size is 1 MB (MAXCAPACITY=1M). The maximum size is 16384 GB (MAXCAPACITY=16384G).

PRIMARYalloc

Specifies the initial amount of space that is dynamically allocated when a new volume is opened. Enough space must be available to satisfy the primary allocation amount. Storage Management Subsystem (SMS) policy determines whether multiple physical volumes can be used to satisfy the primary allocation request.

This parameter is optional. Specify this value as an integer followed by `K` (KB), `M` (MB), `G` (GB), or `T` (TB). The minimum size is 100 KB (PRIMARYALLOC=100K). The maximum size is 16384 GB (MAXCAPACITY=16384G). All values are rounded to the next higher multiple of 256 KB.

To avoid wasted space, the dynamic allocation operation uses the smaller of the values that are specified in the two parameters, PRIMARYALLOC and MAXCAPACITY.

SMS automatic class selection (ACS) routines can affect whether the PRIMARYALLOC and SECONDARYALLOC parameter values are used.

SECONDARYalloc
Specifies the amount of space by which a file volume is extended when space that is already allocated to the file volume is used up. The data set for a file volume is extended up to the size set by the MAXCAPACITY parameter, then the volume is marked full.

Because secondary allocation of a linear data set cannot span a physical volume, consider the size of the physical volume when selecting a secondary allocation size. For example, physical volumes for a 3390 Model 3 are approximately 2.8 GB. To ensure that each extend request occupies nearly an entire physical volume but not more, use a secondary allocation size that is just less than 2.8 GB. A secondary allocation amount of 2600 MB allots enough space for the VSAM volume data set (VVDS), the volume label, and the volume table of contents (VTOC).

This parameter is optional. Specify this value as an integer followed by `K` (KB), `M` (MB), `G` (GB), or `T` (TB). The minimum value is 0 KB (SECONDARYALLOC=0K). The maximum value is 16384 GB. Except for 0, all values are rounded to the next higher multiple of 256 KB.

If you specify 0 (SECONDARYALLOC=0), the file volume cannot be extended beyond the primary allocation amount.

SMS automatic class selection (ACS) routines can affect whether the PRIMARYALLOC and SECONDARYALLOC parameter values are used.

If you specify a value for the SECONDARYALLOCATION parameter that is not 0, or if you allow the value to default to 2600M, the SMS DATACLAS associated with the PREFIX identifier (for example, High Level Qualifier) must have the Extended Addressability (EA) attribute specified. Without the EA attribute, the SMS DATACLAS limits the allocation of the VSAM LDS FILE volume to the primary extent. (See the description of the PRIMARYALLOCATION parameter). With the data set limited to primary allocation size, the data set cannot be extended by the z/OS media server, and the volume is marked FULL before the maximum capacity is reached.

Restriction: Ensure that the values that you specify for the PRIMARYALLOC and SECONDARYALLOC parameters are within practical limits for the storage device. The server cannot check whether the values exceed practical device limits, and does not check whether the two values together exceed the current MAXCAPACITY setting.
Tip: To fill volumes when you specify a large value for the MAXCAPACITY parameter, specify large values for the PRIMARYALLOC and SECONDARYALLOC parameters. Use larger MVS™ volume sizes to reduce the chance of extend failure.

PREFIX
Specifies the high-level qualifier of the data set name that is used to allocate scratch volume data sets. For all scratch file volumes created in this device class, the server uses this prefix to create the data set name. This parameter is optional. The maximum length of the prefix, including periods, is 32 characters.
Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a file volume data set name using the default prefix is `ADSM.B0000021.BFS`.

If you have a data set naming convention, use a prefix that conforms to your naming conventions. For example, the following value is acceptable: `TSM.SERVER2.VSAMFILE`.

If you are running multiple server instances for either IBM Spectrum Protect™ or Tivoli® Storage Manager for z/OS Media you must use a unique value for the PREFIX parameter for each device class that you update.

MOUNTLimit
: Specifies the maximum number of FILE volumes that can be open concurrently for this device class. This parameter is optional. For 3995 devices emulating 3390 devices, the value must not be set higher than the numbers of concurrent input and output streams possible on the media storing the volumes.

  The value that you specify in this parameter is important if there is a significant penalty switching from one volume to another. For example, switching can take place when using IBM® 3995 devices to emulate 3390 devices. The value that you specify must be no higher than the number of physical drives available on the device.

  If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

UPDATE DOMAIN (Update a policy domain)

Use this command to change a policy domain.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the specified policy domain.

Syntax

```
>>-UPDate DOmain--domain_name----------------------------------->

>--+-----------------------------+----------------------------->
   '-DESCription--=--description-'

>--+-------------------------+--+-------------------------+------->
   '-BACKRETention--=--days-'  '-ARCHRETention--=--days-'

>--+-------------------------------------------------------+-----><
   |                        .-,--------------------------. |
   |                        V                            | |
   '-ACTIVEDESTination--=------active-data_pool_name---+-'
```

Parameters

domain_name (Required)
: Specifies the name of the policy domain.

DESCription
: Describes the policy domain by using a text string. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters. To remove a previously defined description, specify a null string ("").

BACKRETention
: Specifies the number of days (from the date the backup versions became inactive) to retain backup versions that are no longer on the client file system. This parameter is optional. You can specify an integer in the range 0 - 9999. The server uses the backup retention value to manage inactive versions of files when any of the following conditions occur:

  - A file is rebound to a new management class, but the new management class and the default management class do not contain a backup copy group.
  - The management class to which a file is bound no longer exists. The default management class does not contain a backup copy group.
  - The backup copy group is deleted from the management class to which a file is bound. The default management class does not contain a backup copy group.

ARCHRETention

Specifies the number of days (from the date of archive) to retain archive copies. This parameter is optional. You can specify an integer in the range 0 - 30000. The server uses the archive retention value to manage archive copies of files when either of the following conditions occur:

- The management class to which a file is bound, no longer exists. The default management class does not contain an archive copy group.
- The archive copy group is deleted from the management class to which a file is bound. The default management class does not contain an archive copy group.

ACTIVEDESTination

Specifies the names of active-data pools that store active versions of backup data for nodes that are assigned to the domain. This parameter is optional. Spaces between the names of the active-data pools are not permitted. You cannot specify more than 10 active-data pools for a domain.

Before the IBM Spectrum Protect™ server writes data to an active-data pool, it verifies that the node that owns the data is assigned to a domain that has the active-data pool that is listed in the ACTIVEDESTINATION list. If the server verifies that the node meets this criteria, the data is stored in the active-data pool. If the node does not meet the criteria, then the data is not stored in the active-data pool. If the simultaneous-write function is used to write data to an active-data pool, the server completes the verification during backup operations by IBM Spectrum Protect backup-archive clients or by application clients by using the IBM Spectrum Protect API. The verification is also done when active-data is being copied by using the COPY ACTIVEDATA command.

Example: Update the backup retention period for a policy domain

Update the policy domain ENGPOLDOM so that the backup retention grace period is extended to 90 days and the archive retention grace period is extended to two years. Specify an active-data pool as the destination for active versions of backup data belonging to nodes that are assigned to the domain. Use *engactivedata* as the name of the active-data pool. Issue the following command:

```
update domain engpoldom description='Engineering Policy Domain'
backretention=90 archretention=730 activedestination=engactivedata
```

Related commands

Table 1. Commands related to UPDATE DOMAIN

Command	Description
COPY DOMAIN	Creates a copy of a policy domain.
DEFINE DOMAIN	Defines a policy domain that clients can be assigned to.
DEFINE POLICYSET	Defines a policy set within the specified policy domain.
DELETE DOMAIN	Deletes a policy domain along with any policy objects in the policy domain.
QUERY DOMAIN	Displays information about policy domains.

UPDATE DRIVE (Update a drive)

Use this command to update a drive.

Privilege class

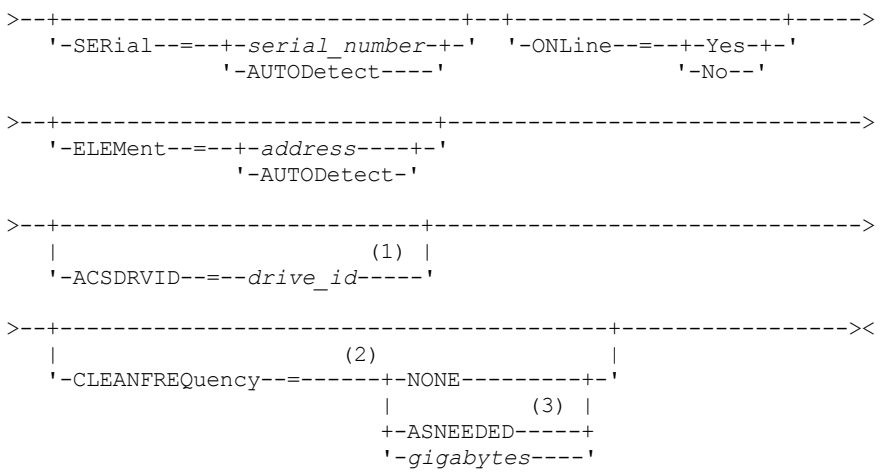
For detailed and current drive support information, see the Supported Devices website for your operating system:

- AIX Windows Supported devices for AIX and Windows
- Linux Supported devices for Linux

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate DRive--library_name--drive_name----------------------->
```



Notes:

1. The ACSDRVID parameter is valid only for drives in ACSLS libraries.
2. The CLEANFREQUENCY parameter is valid only for drives in SCSI libraries.
3. The CLEANFREQUENCY=ASNEEDED parameter value does not work for all tape drives. For more information, see the parameter description.

Parameters

library_name (Required)
Specifies the name of the library to which the drive is assigned.

drive_name (Required)
Specifies the name that is assigned to the drive.

SERial
Specifies the serial number for the drives that are being updated. This parameter is valid only for drives in a SCSI or virtual tape library (VTL). This parameter is optional. The possible values are:

serial_number
Specifies the serial number for the drive that is being updated.
Note: If a path to this drive is already defined, then the number you enter here is compared to the number detected by IBM Spectrum Protect™. If the numbers do not match, the command fails.

AUTODETECT
Specifies that the serial number is automatically detected and used by IBM Spectrum Protect if a path is already defined to this drive.

If a path to this drive is not defined, then the serial number is not detected.

ONLine
Specifies whether the drive is available for use. This parameter specifies whether drives can be taken offline and used for another activity, such as maintenance. This parameter is optional.

You can issue this command when the drive is involved in an active process or session, but it is not advised. If you issue a command to take the drive offline while it is in use, an error message is issued. The mounted volume completes its current process. If this volume was part of a series of volumes for a specific transaction, the drive is not available to complete mounting the series. If no other drives are available, the process fails.

Attention: When a drive is in use, do not specify the ELEMENT parameter with the ONLINE parameter. The drive is not updated, and the command fails.

The drive state is not changed even if the server is halted and restarted. If a drive is offline when the server is restarted, a warning message is issued stating that the drive must be manually brought online. If all of the drives in a library are updated to be offline, processes that need a library mount point fail, rather than queue up for a mount point.

YES
Specifies that the drive is available for use (online).

No
Specifies that the drive is not available for use (offline).

ELEMent
Specifies the element address of the drive within a SCSI or VTL library. The server uses the element address to connect the physical location of the drive to the SCSI address of the drive. This parameter is valid only for a drive in a SCSI or VTL library when the command is issued from an IBM Spectrum Protect library manager server. The possible values are:

address
Specifies the element address for the drive that is being updated.

To find the element address for your library configuration, consult the information from the manufacturer.

Remember: If a path to this drive is already defined, then the number you enter here is compared to the number previously detected by IBM Spectrum Protect. If the numbers do not match, then this command fails.

AUTODETECT
Specifies that the element number is automatically detected and used by IBM Spectrum Protect if a path is already defined to this drive.

If a path to this drive is not defined, then the element number is not detected.

Restriction: If the library in which the drive is located does not support the Read Element Status SCSI command, and ELEMENT=AUTODETECT, the command fails with an IBM Spectrum Protect error message.

ACSDRVID
Specifies the ID of the drive that is being accessed in an ACSLS library. The drive ID is a set of numbers that indicates the physical location of a drive within an ACSLS library. This drive ID must be specified as *a,l,p,d,* where *a* is the ACSID, *l* is the LSM (library storage module), *p* is the panel number, and *d* is the drive ID. The server needs the drive ID to connect the physical location of the drive to the drive's SCSI address. See your StorageTek documentation for details.

CLEANFREQuency
Specifies how often the server activates drive cleaning. This parameter is optional. For the most complete automation of cleaning for an automated library, you must have a cleaner cartridge checked into the volume inventory for the library. If you are using library based cleaning, NONE is advised when your library type supports this function. This parameter is valid only for drives in SCSI libraries, and not valid for externally managed libraries, such as 3494 libraries or StorageTek libraries that are managed under ACSLS.
Important: There are special considerations if you plan to use server-activated drive cleaning with a SCSI library that provides automatic drive cleaning support in its device hardware.

NONE
Specifies that the server does not track cleaning for this drive. Use this parameter for libraries that have their own automatic cleaning.

ASNEEDED
Specifies that the server loads the drive with a checked-in cleaner cartridge only when a drive reports to the device driver that it needs cleaning.

The CLEANFREQUENCY=ASNEEDED parameter value does not work for all tape drives. Visit the Supported Devices website for your operating system to view detailed drive information. If ASNEEDED is not supported, you can use the gigabytes value for automatic cleaning.

For IBM 3592 and LTO drives, library based cleaning is advised. If library based cleaning is not supported, then ASNEEDED must be used. Gigabytes is not recommended.

Restriction: IBM Spectrum Protect does not control the drives that are connected to the NAS file server. If a drive is attached only to a NAS file server (no connection to a storage agent or server), do not specify ASNEEDED for the cleaning frequency.

gigabytes
Specifies, in gigabytes, how much data is processed on the drive before the server loads the drive with a cleaner cartridge. The server resets the gigabytes-processed counter each time it loads a cleaner cartridge in the drive.
Important: When CLEANFREQUENCY=gigabyte, drive cleaning can occur before the gigabyte setting is reached, if the drive notifies the device driver that a cleaning is necessary.

Consult the information from the drive manufacturer for cleaning recommendations. If the information gives recommendations for cleaning frequency in terms of hours of use, convert to a gigabytes value by doing the following:

1. Use the bytes-per-second rating for the drive to determine a gigabytes-per-hour value.
2. Multiply the gigabytes-per-hour value by the recommended hours of use between cleanings.
3. Use the result as the cleaning frequency value.

Tip: For IBM 3590, specify a value for the cleaning frequency to ensure that the drives receive adequate cleaning. Consult the information from the drive manufacturer for cleaning recommendations. Using the cleaning frequency that is recommended by IBM does not over clean the drives.

Example: Update the element address for a drive

Update DRIVE3, in the library named AUTO, by changing the element address to 119.

```
update drive auto drive3 element=119
```

Example: Take a drive offline

Update DRIVE3, in the library named MANLIB, to take it offline.

```
update drive manlib drive3 online=no
```

Related commands

Table 1. Commands related to UPDATE DRIVE

Command	Description
CLEAN DRIVE	Marks a drive for cleaning.
DEFINE DRIVE	Assigns a drive to a library.
DEFINE PATH	Defines a path from a source to a destination.
DELETE DRIVE	Deletes a drive from a library.
QUERY DRIVE	Displays information about drives.
QUERY LIBRARY	Displays information about one or more libraries.
UPDATE PATH	Changes the attributes associated with a path.

UPDATE FILESPACE (Update file-space node-replication rules)

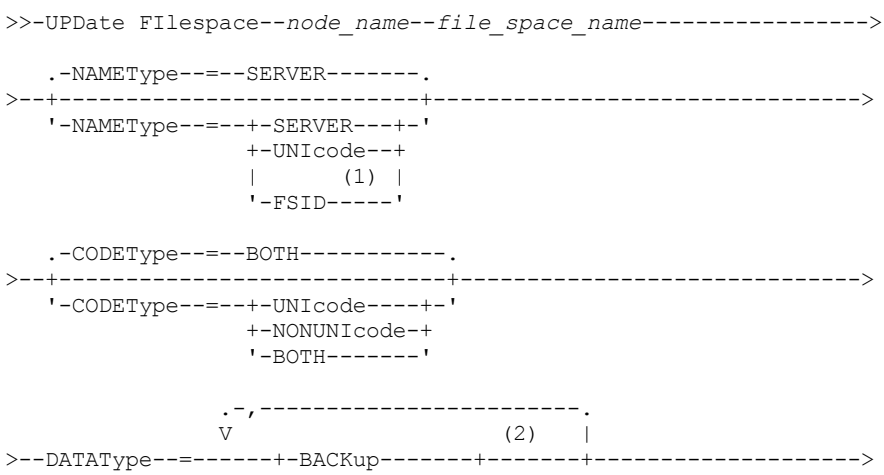
Use this command to update file-space replication rules. You can also enable or disable replication of data to which a file space rule applies.

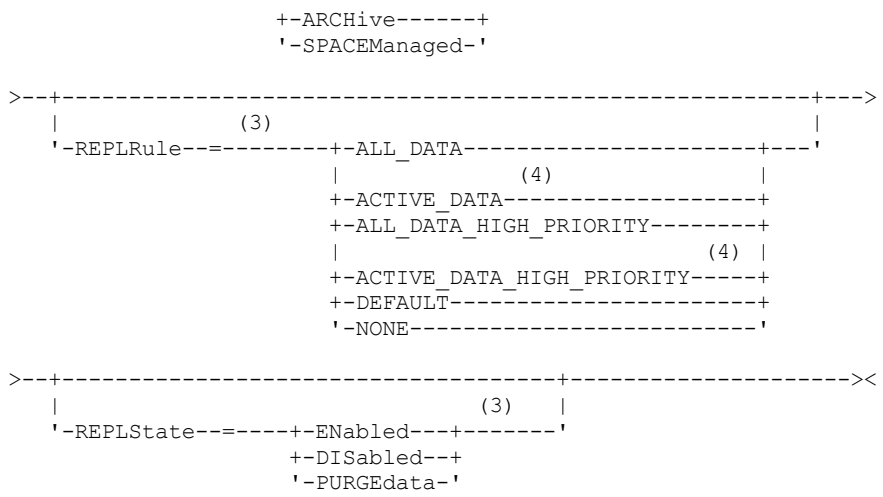
Issue this command on the server that acts as a source for replicated data.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the client node with the file space to be updated belongs.

Syntax





Notes:

1. You cannot specify a file space identifier (FSID) if you use wildcard characters for the client node name.
2. You can specify each rule only once.
3. You must specify either the REPLRULE or the REPLSTATE parameter on this command.
4. The ACTIVE_DATA and ACTIVE_DATA_HIGH_PRIORITY rules are valid only if you specify `DATATYPE=BACKUP`.

Parameters

node_name (Required)
: Specifies the client node to which the file space belongs. You can use wildcard characters to specify this name. However, file space identifiers can be different among client nodes for the same file space. Therefore, you cannot specify wildcard characters for the client node name and FSID as the value for the NAMETYPE parameter.

file_space_name (Required)

: Specifies the name of the file space to be updated. You can use wildcard characters or a comma-delineated list to specify names.

: For a server that has clients with Unicode-enabled file spaces, you might have to make the server convert the file space name that you enter. For example, you might have to make the server convert a name from the server code page to Unicode. For details, see the NAMETYPE parameter. If you specify only a single wildcard character for the name, you can use the CODETYPE parameter to limit the operation to Unicode file spaces or to non-Unicode file spaces.

: File space names are case-sensitive. To determine the correct capitalization for the file space to be updated, use the QUERY FILESPACE command.

NAMEType
: Specifies how you want the server to interpret the file space names that you enter. You can use this parameter for IBM Spectrum Protect™ clients that Unicode-enabled and that have Windows, Macintosh OS X, or NetWare operating systems. Use this parameter only when you enter a partly-qualified or fully-qualified file space name. The default value is SERVER. You can specify one of the following values:

: SERVER
: The server uses the server code page to interpret file space names.

: UNIcode
: The server converts file space names from the server code page to the UTF-8 code page. The success of the conversion depends on the operating system, on the characters in the name, and the server code page. Conversion can fail if the string includes characters that are not available in the server code page or if the server cannot access system conversion routines. If the conversion fails, the name can contain question marks, blanks, or ellipses (...).

: FSID
: The server interprets file space names as file space identifiers.

CODEType
: Specifies the type of file spaces to be included in node replication processing. The default value is BOTH, meaning that file spaces are included regardless of code page type. Use this parameter only when you enter a single wildcard character for the file space name. You can specify one of the following values:

UNIcode
: Specifies only file spaces that are in Unicode.

NONUNIcode
: Specifies only file spaces that are not in Unicode.

BOTH
: Specifies all file spaces regardless of code page type.

DATAType (Required)
: Specifies the data type to which a replication rule applies. To specify multiple data types, separate the names with commas and no intervening spaces. You can specify the following values:

  BACKup
  : Specifies the backup data type.

  ARCHive
  : Specifies the archive data type.

  SPACEManaged
  : Specifies the space-managed data type.

REPLRule
: Specifies the replication rule that applies to a data type. You cannot use wildcards. If you specify multiple data types, the replication rule applies to each data type. For example, if you specify `DATATYPE=BACKUP,ARCHIVE`, the replication rule applies to backup data and to archive data.
  Restriction: The REPLRULE parameter is optional. However, if you do not specify it, you must specify the REPLSTATE parameter.

  You can specify normal-priority replication or high-priority replication rules. In a replication process that includes both normal and high-priority data, high-priority data is replicated first. Before you specify a rule, consider the order in which you want the data to be replicated.

  For example, suppose that a file space contains active backup data and archive data. Replication of the active backup data is a higher priority than the archive data. To prioritize the active backup data, specify `DATATYPE=BACKUP REPLRULE=ACTIVE_DATA_HIGH_PRIORITY`. To assign a normal priority to archive data, issue the UPDATE FILESPACE command again, and specify `DATATYPE=ARCHIVE REPLRULE=ALL_DATA`.

  You can specify the following rules:

  ALL_DATA
  : Replicates backup, archive, or space-managed data. The data is replicated with a normal priority.

  ACTIVE_DATA
  : Replicates only the active backup data in a file space. The data is replicated with a normal priority.
    Attention: If you specify ACTIVE_DATA and one or more of the following conditions are true, inactive backup data on the target replication server is deleted, and inactive backup data on the source replication server is not replicated.

    - When a server version earlier than Version 7.1.1 is installed on either the source or target replication servers.
    - When you are using the REPLICATE NODE command with the `FORCERECONCILE=YES` parameter.
    - When you are running the initial replication of a file space after you configure replication, restore the database, or upgrade both the source and target replication servers from a server version earlier than V7.1.1.

    If the previous conditions are not true, all new and changed files since the last replication are replicated, including inactive files, and files are deleted when they expire.

  ALL_DATA_HIGH_PRIORITY
  : Replicates backup, archive, or space-managed data. The data is replicated with a high priority.

  ACTIVE_DATA_HIGH_PRIORITY

    This rule is the same as the ACTIVE_DATA replication rule except data is replicated with a high priority.

  DEFAULT
  : Data is replicated according to the client node rule for the data type.

    For example, suppose that you want to replicate the archive data in all the file spaces that belong to a client node. Replication of the archive data is a high priority. One method to accomplish this task is to specify `DATATYPE=ARCHIVE REPLRULE=DEFAULT` for each file space. Ensure that the client replication rule for archive data is set to ALL_DATA_HIGH_PRIORITY or to DEFAULT. If the client replication rule is DEFAULT, the server replication rule for archive data must be set to ALL_DATA_HIGH_PRIORITY.

NONE
Data is not replicated. For example, if you do not want to replicate the space-managed data in a file space, specify `DATATYPE=SPACEMANAGED REPLRULE=NONE`.

REPLState
Specifies the replication state for a data type. If you specified multiple data types, the state applies to all the data types. For example, if you specified `DATATYPE=BACKUP,ARCHIVE`, the state applies to backup data and archive data.

The REPLSTATE parameter is optional. However, if you do not specify it, you must specify the REPLRULE parameter. You can specify one of the following values for the REPLSTATE parameter:

ENabled
Specifies that the data type is ready for replication.
DISabled
Specifies that replication does not occur until you enable it.
PURGEdata
Specifies that data is deleted from the target replication server. The type of data deleted is the type of data specified by the DATATYPE parameter. For example, if you specify `DATATYPE=BACKUP,ARCHIVE` and `REPLSTATE=PURGEDATA`, backup data and archive data are deleted from the file space on the target replication server.

After the data is deleted, the REPLSTATE parameter is set to DISABLED, preventing future replication of the data type or types. The replication rule for the data type is set to DEFAULT.

Remember: PURGEDATA processing does not delete file spaces. Only data is deleted. The file space shows as empty in the output of the QUERY OCCUPANCY command.

Example: Update replication rules for two data types

NODE1 has three file spaces: /a, /b, and /c. The replication rules for all file spaces are set to ALL_DATA. However, you want to replicate the backup and archive data in file space /a before the data in other file spaces is replicated.

```
update filespace node1 /a datatype=backup,archive replrule=
       all_data_high_priority
```

Example: Update replication rules for two data types

NODE2 has two file spaces: /a and /b. You want to temporarily suspend replication of all data in file space /b.

```
update filespace node2 /b datatype=backup,archive,spacemanaged
 replstate=disabled
```

Related commands

Table 1. Commands related to UPDATE FILESPACE

Command	Description
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY REPLICATION	Displays information about node replication processes.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
SET REPLRETENTION	Specifies the retention period for replication history records.
UPDATE NODE	Changes the attributes that are associated with a client node.
UPDATE REPLRULE	Enables or disables replication rules.
VALIDATE REPLICATION	Verifies replication for file spaces and data types.

UPDATE LIBRARY (Update a library)

Use this command to update a library definition.

AIX Windows To update the device name, the ACS number, or the external manager path name of a library, you must use the UPDATE PATH command.

Linux To update the device name or the external manager path name of a library, you must use the UPDATE PATH command.

Syntax and parameter descriptions are available for the following library types.

- UPDATE LIBRARY (Update a 349X library)
- UPDATE LIBRARY (Update an ACSLS library)
- UPDATE LIBRARY (Update an EXTERNAL library)
- UPDATE LIBRARY (Update a FILE library)
- UPDATE LIBRARY (Update a manual library)
- UPDATE LIBRARY (Update a SCSI library)
- UPDATE LIBRARY (Update a shared library)
- UPDATE LIBRARY (Update a VTL library)

For detailed and current library support information, see the Supported Devices website for your operating system:

- AIX Windows Supported devices for AIX and Windows
- Linux Supported devices for Linux

Windows

To automatically label tape volumes in SCSI-type libraries, use the AUTOLABEL parameter on the DEFINE LIBRARY and UPDATE LIBRARY commands. Using this parameter eliminates the need to pre-label a set of tapes. It is also more efficient than using the LABEL LIBVOLUME command, which requires you to mount volumes separately. If you use the AUTOLABEL parameter, you must check in tapes by specifying CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

A label cannot include embedded blanks or periods and must be valid when used as a file name on the media.

You must label CD-ROM, Zip, or Jaz volumes with the device utilities from the manufacturer or the Windows utilities because IBM Spectrum Protect™ does not provide utilities to format or label these media types. The operating system utilities include the Disk Administrator program (a graphical user interface) and the label command.

Related commands

Table 1. Commands related to UPDATE LIBRARY

Command	Description
AUDIT LIBRARY	Ensures that an automated library is in a consistent state.
CHECKIN LIBVOLUME	Checks a storage volume into an automated library.
CHECKOUT LIBVOLUME	Checks a storage volume out of an automated library.
DEFINE DRIVE	Assigns a drive to a library.
DEFINE LIBRARY	Defines an automated or manual library.
DEFINE PATH	Defines a path from a source to a destination.
DELETE DRIVE	Deletes a drive from a library.
DELETE LIBRARY	Deletes a library.
DELETE PATH	Deletes a path from a source to a destination.
LABEL LIBVOLUME	Labels volumes in manual or automated libraries.
QUERY DRIVE	Displays information about drives.
QUERY LIBRARY	Displays information about one or more libraries.
QUERY PATH	Displays information about the path from a source to a destination.

Command	Description
UPDATE DRIVE	Changes the attributes of a drive.
UPDATE LIBVOLUME	Changes the status of a storage volume.
UPDATE PATH	Changes the attributes associated with a path.

UPDATE LIBRARY (Update a 349X library)

Use this syntax to update a 349X library.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate LIBRary--library_name--+-------------------+--------->
                                 '-SHAREd--=----Yes---'

>--+-------------------------+---------------------------------->
   '-RESETDrives--=--+-Yes-+-'
                     '-No--'

>--+-----------------------------+----------------------------->
   '-AUTOLabel--=--+-No--------+-'
                   +-Yes-------+
                   '-OVERWRITE-'

>--+-------------------------------+------------------------><
   '-WORMSCRatchcategory--=--number-'
```

Parameters

library_name (Required)
: Specifies the name of the library to be updated.

SHAREd
: Specifies that this library is shared with other servers in a storage area network (SAN). You must issue this command from the server defined as the primary library manager for the shared library. This parameter is required for libraries defined to a library manager and for libraries used for NDMP operations. Specify SHARED=YES to update a library that is not currently shared.

  Important: If a library has a path from a data mover (such as a NAS file server) but no connection to the server, the library cannot be shared with another server.

AUTOLabel
: Specifies whether the server attempts to automatically label tape volumes. This parameter is optional.

  To use this option, you must check in the tapes with CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

  No
  : Specifies that the server does not attempt to label any volumes.

  Yes
  : Specifies that the server only labels unlabeled volumes.

  OVERWRITE
  : Specifies that the server attempts to overwrite an existing label. The server overwrites existing labels *only* if both the existing label and the bar code label are not already defined in any server storage pool or volume history list.

WORMSCRatchcategory
: Specifies the category number to be used for WORM scratch volumes in the library. This parameter is required if you use WORM volumes. You can specify a number from 1 to 65279. This number must be unique. It cannot be shared with other applications or defined libraries, and it must be different from the other category numbers in this library. This parameter is only valid when 3592 WORM volumes are used.

Restriction: This parameter can only be updated if the device class WORM parameter is set to YES and the WORMSCRATCHCATEGORY currently has no defined value.

RESETDrives

Specifies whether the server preempts a drive reservation with persistent reserve when the server is restarted or when a library client or storage agent reconnection is established.

AIX Windows If persistent reserve is not supported, the server completes a reset of the path to the target device.

Linux If persistent reserve is not supported, the server is not able to reset the path to the target device.

Support for persistent reservation has the following limitations:

- If you are using the IBM Spectrum Protect™ device driver, persistent reserve is only supported on some tape drives. See Technote 1470319 for details.
- If you are using the IBM® device driver, persistent reserve must be enabled at the device driver level. See the *IBM Tape Device Drivers Installation and User's Guide* for information about driver configuration.
- If you are using a virtual tape library that is emulating a supported drive, it might not support persistent reserve.

The following table describes the three possible configurations for drives that are attached to NAS devices.

Table 1. Configurations for drives that are attached to NAS devices.

Library device configuration	The behavior for persistent reserve
The library device is attached to the IBM Spectrum Protect server, and the tape drives are shared by the server and the NAS device.	Drive reservation preemption is supported when the NAS device supports persistent reserve and it is enabled. For more information about setting persistent reserve, see the documentation for your NAS device.
The library device is attached to the IBM Spectrum Protect server and the tape drives are accessed only from the NAS device.	Drive reservation preemption is not supported. If you enable persistent reserve on the NAS device for these drives and a reservation is set by the NAS device but never cleared, you must use another method to clear the reservation.

AIX Windows

Yes

Specifies that drive preemption through persistent reserve or target reset are used.

No

Specifies that drive preemption through persistent reserve or target reset are not used. The RESETDRIVES parameter must be set to YES in a clustered environment when SHARED=NO.

Linux

Yes

Specifies that drive preemption through persistent reserve is used.

No

Specifies that drive preemption through persistent preserve is not used.

Note: A library manager will not be able to break a drive reservation if the system that has the drive reservation is not configured to use persistent reservation.

Example: Add new devices to a shared library

Update a 3494 shared library named 3494LIB2 with new device names. AIX Linux

```
update library 3494lib2 device=/dev/lmcp1,/dev/lmcp2,/dev/lmcp3
```

Windows

```
update library 3494lib device=lb3.0.0.0,lb4.0.0.0,lb5.0.0.0
```

UPDATE LIBRARY (Update an ACSLS library)

Use this syntax to update an ACSLS library.

Privilege class

Windows In order to use ACSLS functions, the installation of StorageTek Library Attach software is required.

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate LIBRary--library_name--+--------------------+--------->
                                 '-SHAREd--=----Yes---'

>--+------------------------+---------------------------------->
   '-RESETDrives--=--+-Yes-+-'
                     '-No--'

>--+-----------------------------+--+------------------+------><
   '-AUTOLabel--=--+-No--------+-'  '-ACSID--=--number-'
                   +-Yes-------+
                   '-OVERWRITE-'
```

Parameters

library_name (Required)
: Specifies the name of the library to be updated.

SHAREd
: Specifies that this library is shared with other servers in a storage area network (SAN). You must issue this command from the server defined as the primary library manager for the shared library. This parameter is required for libraries defined to a library manager and for libraries used for NDMP operations. Specify SHARED=YES to update a library that is not currently shared.

  Important: If a library has a path from a data mover (such as a NAS file server) but no connection to the server, the library cannot be shared with another server.

RESETDrives
: Specifies whether the server preempts a drive reservation with persistent reserve when the server is restarted or when a library client or storage agent reconnection is established.

  AIX Windows If persistent reserve is not supported, the server completes a reset of the path to the target device.

  Linux If persistent reserve is not supported, the server is not able to reset the path to the target device.

  Support for persistent reservation has the following limitations:

  - If you are using the IBM Spectrum Protect™ device driver, persistent reserve is only supported on some tape drives. See Technote 1470319 for details.
  - If you are using the IBM® device driver, persistent reserve must be enabled at the device driver level. See the *IBM Tape Device Drivers Installation and User's Guide* for information about driver configuration.
  - If you are using a virtual tape library that is emulating a supported drive, it might not support persistent reserve.

  The following table describes the three possible configurations for drives that are attached to NAS devices.

  Table 1. Configurations for drives that are attached to NAS devices.

Library device configuration	The behavior for persistent reserve
The library device is attached to the IBM Spectrum Protect server, and the tape drives are shared by the server and the NAS device.	Drive reservation preemption is supported when the NAS device supports persistent reserve and it is enabled. For more information about setting persistent reserve, see the documentation for your NAS device.
The library device is attached to the IBM Spectrum Protect server and the tape drives are accessed only from the NAS device.	Drive reservation preemption is not supported. If you enable persistent reserve on the NAS device for these drives and a reservation is set by the NAS device but never cleared, you must use another method to clear the reservation.

  AIX Windows

  Yes
  : Specifies that drive preemption through persistent reserve or target reset are used.

  No

Specifies that drive preemption through persistent reserve or target reset are not used. The RESETDRIVES parameter must be set to YES in a clustered environment when SHARED=NO.

Linux

Yes
Specifies that drive preemption through persistent reserve is used.
No
Specifies that drive preemption through persistent preserve is not used.

Note: A library manager will not be able to break a drive reservation if the system that has the drive reservation is not configured to use persistent reservation.

AUTOLabel
Specifies whether the server attempts to automatically label tape volumes. This parameter is optional.

To use this option, you must check in the tapes with CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

No
Specifies that the server does not attempt to label any volumes.
Yes
Specifies that the server only labels unlabeled volumes.
OVERWRITE
Specifies that the server attempts to overwrite an existing label. The server overwrites existing labels *only* if both the existing label and the bar code label are not already defined in any server storage pool or volume history list.

ACSID (Required)
Specifies the number of this StorageTek library assigned by the ACSSA (Automatic Cartridge System System Administrator). This can be a number from 0 to 126. Issue QUERY ACS on your system to get the number for your library ID. This parameter is required.

See your StorageTek documentation for more information.

Example: Update an ID number for an ACSLS library

Update an ACSLS library named ACSLSLIB with a new ID number.

```
update library acslslib acsid=1
```

UPDATE LIBRARY (Update an EXTERNAL library)

Use this syntax to update an external library.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate LIBRary--library_name---------------------------------->

>--+-----------------------------+----------------------------><
   '-AUTOLabel--=--+-No---------+-'
                   +-Yes--------+
                   '-OVERWRITE-'
```

Parameters

library_name (Required)
Specifies the name of the library to be updated.
AUTOLabel
Specifies whether the server attempts to automatically label tape volumes. This parameter is optional.

To use this option, you must check in the tapes with CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

No
: Specifies that the server does not attempt to label any volumes.

Yes
: Specifies that the server only labels unlabeled volumes.

OVERWRITE
: Specifies that the server attempts to overwrite an existing label. The server overwrites existing labels *only* if both the existing label and the bar code label are not already defined in any server storage pool or volume history list.

Example: Update the path name for an external library

Update an external library named EXTLIB with a new path name for the media manager. AIX | Linux

```
update library extlib externalmanager=/v/server/mediamanager
```

Windows

```
update library extlib externalmanager=c:\server\mediamanager
```

UPDATE LIBRARY (Update a FILE library)

Use this syntax to update a FILE library

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate LIBRary--library_name--+--------------------+-------><
                                 '-SHAREd--=----Yes---'
```

Parameters

library_name (Required)
: Specifies the name of the library to be updated.

SHAREd
: Specifies that this library is shared with other servers in a storage area network (SAN). You must issue this command from the server defined as the primary library manager for the shared library. This parameter is required for libraries defined to a library manager and for libraries used for NDMP operations. Specify SHARED=YES to update a library that is not currently shared.
  Important: If a library has a path from a data mover (such as a NAS file server) but no connection to the server, the library cannot be shared with another server.

Example: Update a FILE library to be shared

Update a file library named FILE2, so that it is shared:

```
update library file2 shared=yes
```

UPDATE LIBRARY (Update a manual library)

Use this syntax to update a manual library.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate LIBRary--library_name--+-------------------------+---->
                                '-RESETDrives--=--+-Yes-+-'
                                                  '-No--'

>--+-----------------------------+----------------------------><
   '-AUTOLabel--=--+-No--------+-'
                   +-Yes-------+
                   '-OVERWRITE-'
```

Parameters

library_name (Required)
: Specifies the name of the library to be updated.

RESETDrives
: Specifies whether the server preempts a drive reservation with persistent reserve when the server is restarted or when a library client or storage agent reconnection is established.

  AIX Windows If persistent reserve is not supported, the server completes a reset of the path to the target device.

  Linux If persistent reserve is not supported, the server is not able to reset the path to the target device.

  Support for persistent reservation has the following limitations:

  - If you are using the IBM Spectrum Protect™ device driver, persistent reserve is only supported on some tape drives. See Technote 1470319 for details.
  - If you are using the IBM® device driver, persistent reserve must be enabled at the device driver level. See the *IBM Tape Device Drivers Installation and User's Guide* for information about driver configuration.
  - If you are using a virtual tape library that is emulating a supported drive, it might not support persistent reserve.

  AIX Windows

  Yes
  : Specifies that drive preemption through persistent reserve or target reset are used.

  No
  : Specifies that drive preemption through persistent reserve or target reset are not used. The RESETDRIVES parameter must be set to YES in a clustered environment when SHARED=NO.

  Linux

  Yes
  : Specifies that drive preemption through persistent reserve is used.

  No
  : Specifies that drive preemption through persistent preserve is not used.

  Note: A library manager will not be able to break a drive reservation if the system that has the drive reservation is not configured to use persistent reservation.

AUTOLabel
: Specifies whether the server attempts to automatically label tape volumes. This parameter is optional.

  To use this option, you must check in the tapes with CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

  No
  : Specifies that the server does not attempt to label any volumes.

  Yes
  : Specifies that the server labels only unlabeled volumes.

  OVERWRITE
  : Specifies that the server attempts to overwrite an existing label. The server overwrites existing labels *only* if both the existing label and the bar code label are not already defined in any server storage pool or volume history list.

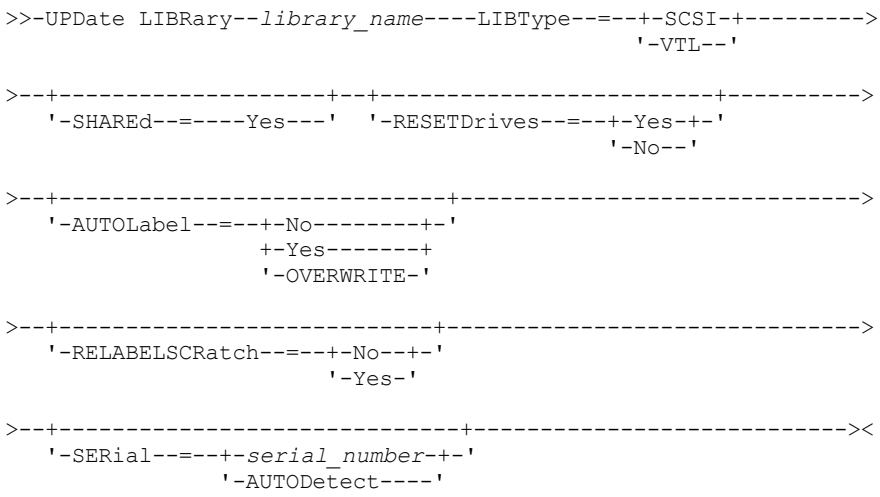
UPDATE LIBRARY (Update a SCSI library)

Use this syntax to update a SCSI library.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax



Parameters

library_name (Required)
Specifies the name of the library to be updated.

LIBType (Required)
Specifies the library type that you want to update to. Possible values are:

VTL
Specifies that the library has a SCSI-controlled media changer device that is represented by a Virtual Tape Library. To mount volumes on drives in this type of library, IBM Spectrum Protect™ uses the media changer device. This value is effective when specified for libraries with a current library type of SCSI.
Note: Selecting the VTL library type assumes that the following conditions are true:

- Your environment does not include mixed-media
- Paths are defined between all drives in the library and all defined servers, including storage agents, that use the library

If both conditions are not met, performance can degrade to the same levels as the SCSI library type especially during times of high stress when most drives are in use concurrently.

SCSI
Specifies that the library has a SCSI-controlled media changer device. To mount volumes on drives in this type of library, IBM Spectrum Protect uses the media changer device. This value is effective when specified for libraries with a current library type of VTL.

SHAREd
Specifies that this library is shared with other servers in a storage area network (SAN). You must issue this command from the server defined as the primary library manager for the shared library. This parameter is required for libraries defined to a library manager and for libraries used for NDMP operations. Specify SHARED=YES to update a library that is not currently shared.
Important: If a library has a path from a data mover (such as a NAS file server) but no connection to the server, the library cannot be shared with another server.

RESETDrives
Specifies whether the server preempts a drive reservation with persistent reserve when the server is restarted or when a library client or storage agent reconnection is established.

AIX Windows If persistent reserve is not supported, the server completes a reset of the path to the target device.

Linux If persistent reserve is not supported, the server is not able to reset the path to the target device.

Support for persistent reservation has the following limitations:

- If you are using the IBM Spectrum Protect device driver, persistent reserve is only supported on some tape drives. See Technote 1470319 for details.
- If you are using the IBM® device driver, persistent reserve must be enabled at the device driver level. See the *IBM Tape Device Drivers Installation and User's Guide* for information about driver configuration.
- If you are using a virtual tape library that is emulating a supported drive, it might not support persistent reserve.

The following table describes the three possible configurations for drives that are attached to NAS devices.

Table 1. Configurations for drives that are attached to NAS devices.

Library device configuration	The behavior for persistent reserve
The library device is attached to the IBM Spectrum Protect server, and the tape drives are shared by the server and the NAS device.	Drive reservation preemption is supported when the NAS device supports persistent reserve and it is enabled. For more information about setting persistent reserve, see the documentation for your NAS device.
The library device is attached to the IBM Spectrum Protect server and the tape drives are accessed only from the NAS device.	Drive reservation preemption is not supported. If you enable persistent reserve on the NAS device for these drives and a reservation is set by the NAS device but never cleared, you must use another method to clear the reservation.
The library device is attached to the NAS device and accessed indirectly by NDMP (network data management protocol), and the tape drives are accessed only from the NAS device.	Drive reservation preemption is not supported. If you enable persistent reserve on the NAS device for these drives and a reservation is set by the NAS device but never cleared, you must use another method to clear the reservation.

AIX Windows

Yes
: Specifies that drive preemption through persistent reserve or target reset are used.

No
: Specifies that drive preemption through persistent reserve or target reset are not used. The RESETDRIVES parameter must be set to YES in a clustered environment when SHARED=NO.

Linux

Yes
: Specifies that drive preemption through persistent reserve is used.

No
: Specifies that drive preemption through persistent preserve is not used.

Note: A library manager will not be able to break a drive reservation if the system that has the drive reservation is not configured to use persistent reservation.

AUTOLabel
: Specifies whether the server attempts to automatically label tape volumes.

To use this option, you must check in the tapes with CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

No
: Specifies that the server does not attempt to label any volumes.

Yes
: Specifies that the server only labels unlabeled volumes.

OVERWRITE
: Specifies that the server attempts to overwrite an existing label. The server overwrites existing labels *only* if both the existing label and the bar code label are not already defined in any server storage pool or volume history list.

SERial
: Specifies the serial number for the library being updated. This parameter is optional. The possible values are:

serial_number
: Specifies the serial number for the library being updated.

If a path to this library has already been defined, then the number you enter here is compared to the number detected by IBM Spectrum Protect. If the numbers do not match, the command fails. If a path has not been defined, this serial number is verified when a path is defined.

AUTODetect

Specifies that the serial number is automatically detected and used by IBM Spectrum Protect if a path has already been defined to this library.

If a path to this library has not been defined, then the serial number is not detected.

RELABELSCRatch
: Specifies whether the server relabels volumes that have been deleted and returned to scratch. When this parameter is set to YES, a LABEL LIBVOLUME operation is started and the existing volume label is overwritten. This parameter is optional and intended for use with a Virtual Tape Library (VTL).
Note: If you have both virtual and real volumes in your VTL, both types are relabeled when this parameter is enabled. If the VTL includes real volumes, specifying this option might affect performance.

  No
  : Specifies that the server does not relabel volumes that are deleted and returned to scratch.

  Yes
  : Specifies that the server relabels volumes that are deleted and returned to scratch.

UPDATE LIBRARY (Update a shared library)

Use this syntax to update a shared library.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate LIBRary--library_name---------------------------------->

>--PRIMarylibmanager--=--server_name--------------------------><
```

Parameters

library_name (Required)
: Specifies the name of the library to be defined. The maximum length of this name is 30 characters.

PRIMarylibmanager
: Specifies the name of the server that is responsible for controlling access to library resources. You must define this server with the DEFINE SERVER command before you can use it as a library manager.

Example: Change the library manager server for a library

For a library client server, change the name of the library manager server to CASTOR.

```
update library ltolib primarylibmanager=castor
```

UPDATE LIBRARY (Update a VTL library)

Use this syntax to update a library that is defined as VTL.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate LIBRary--library_name----LIBType--=--+-VTL--+--------->
                                               '-SCSI-'

>--+--------------------+--+------------------------+---------->
   '-SHAREd--=----Yes---'  '-RESETDrives--=--+-Yes-+-'
```

```
                                                '-No--'

>--+-----------------------------+-------------------------------->
   '-AUTOLabel--=--+-No--------+-'
                   +-Yes-------+
                   '-OVERWRITE-'

>--+-----------------------------+-------------------------------->
   '-RELABELSCRatch--=--+-No--+-'
                        '-Yes-'

>--+-----------------------------+----------------------------><
   '-SERial--=--+-serial_number-+-'
                '-AUTODetect----'
```

Parameters

library_name (Required)
: Specifies the name of the library to be defined. The maximum length of this name is 30 characters.

LIBType (Required)
: Specifies the type of library that is being defined. Possible values are:

  SCSI
  : Specifies that the library has a SCSI-controlled media changer device. To mount volumes on drives in this type of library, IBM Spectrum Protect™ uses the media changer device. This value is effective when specified for libraries with a current library type of VTL.

  VTL
  : Specifies that the library has a SCSI-controlled media changer device that is represented by a Virtual Tape Library. To mount volumes on drives in this type of library, IBM Spectrum Protect uses the media changer device. This value is effective when specified for libraries with a current library type of SCSI.
    Note: Select the VTL library type only if the following conditions are true:

    - Your environment does not include mixed-media
    - Paths are defined between all drives in the library and all defined servers, including storage agents, that use the library

    If both conditions are not met, performance can degrade to the same levels as the SCSI library type especially during times of high stress when most drives are in use concurrently.

SHAREd
: Specifies that this library is shared with other servers in a storage area network (SAN). You must issue this command from the server defined as the primary library manager for the shared library. This parameter is required for libraries defined to a library manager and for libraries used for NDMP operations. Specify SHARED=YES to update a library that is not currently shared.
  Important: If a library has a path from a data mover (such as a NAS file server) but no connection to the server, the library cannot be shared with another server.

RESETDrives
: Specifies whether the server preempts a drive reservation with persistent reserve when the server is restarted or when a library client or storage agent reconnection is established.

  AIX Windows If persistent reserve is not supported, the server completes a reset of the path to the target device.

  Linux If persistent reserve is not supported, the server is not able to reset the path to the target device.

  Support for persistent reservation has the following limitations:

  - If you are using the IBM Spectrum Protect device driver, persistent reserve is only supported on some tape drives. See Technote 1470319 for details.
  - If you are using the IBM® device driver, persistent reserve must be enabled at the device driver level. See the *IBM Tape Device Drivers Installation and User's Guide* for information about driver configuration.
  - If you are using a virtual tape library that is emulating a supported drive, it might not support persistent reserve.

  AIX Windows

  Yes
  : Specifies that drive preemption through persistent reserve or target reset are used.

No
Specifies that drive preemption through persistent reserve or target reset are not used. The RESETDRIVES parameter must be set to YES in a clustered environment when SHARED=NO.

Linux

Yes
Specifies that drive preemption through persistent reserve is used.
No
Specifies that drive preemption through persistent preserve is not used.

Note: A library manager will not be able to break a drive reservation if the system that has the drive reservation is not configured to use persistent reservation.

AUTOLabel
Specifies whether the server attempts to automatically label tape volumes. This parameter is optional.

To use this option, you must check in the tapes with CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

No
Specifies that the server does not attempt to label any volumes.
Yes
Specifies that the server only labels unlabeled volumes.
OVERWRITE
Specifies that the server attempts to overwrite an existing label. The server overwrites existing labels *only* if both the existing label and the bar code label are not already defined in any server storage pool or volume history list.

RELABELSCRatch
Specifies whether the server relabels volumes that have been deleted and returned to scratch. When this parameter is set to YES, a LABEL LIBVOLUME operation is started and the existing volume label is overwritten.
Note: If you have both virtual and real volumes in your VTL, both types are relabeled when this parameter is enabled. If the VTL includes real volumes, specifying this option might affect performance.

Yes
Specifies that the server relabels volumes that are deleted and returned to scratch.
No
Specifies that the server does not relabel volumes that are deleted and returned to scratch.

SERial
Specifies the serial number for the library being updated. This parameter is optional. The possible values are:

serial_number
Specifies the serial number for the library being updated.

If a path to this library has already been defined, then the number you enter here is compared to the number detected by IBM Spectrum Protect. If the numbers do not match, then the command fails. If a path has not been defined, this serial number is verified when a path is defined.

AUTODetect
Specifies that the serial number is automatically detected and used by IBM Spectrum Protect if a path has already been defined to this library.

If a path to this library has not been defined, then the serial number is not detected.

UPDATE LIBVOLUME (Change the status of a storage volume)

Use this command to change the status of a sequential access storage volume in a library.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate LIBVolume--library_name--volume_name--STATus--=--+-PRIvate-+-->
                                                           '-SCRatch-'

>--+----------------------+-----------------------------------><
   '-OWNer--=--server_name-'
```

Parameters

library_name (Required)
: Specifies the name of the library.

volume_name (Required)
: Specifies the volume name of the storage volume.

STATus (Required)
: Specifies a change to the status of a storage volume. Possible values are as follows:

  PRIvate
  : Specifies that the server updates the storage volume to a private volume.

  SCRatch
  : Specifies that the server updates the storage volume to a scratch volume.

  Restriction: You cannot change the status of a volume from private to scratch if the volume belongs to a storage pool or is defined in the volume history file. You can change the status if you make a mistake when you check in volumes to the library and assign the volumes the wrong status.

AIX Linux Windows OWNer
: AIX Linux Windows Specifies which server owns a private volume in a shared library that is shared across a SAN. You can change the owner of a private volume in a shared library (SAN) when you issue the command from the library manager server. If you do not specify this parameter, the library manager server owns the private volume.
  Important: Do not use OWNER as a value for scratch volumes. However, you can use OWNER when you change a scratch volume to private.

Example: Update a volume's status

Update the volume that is named WPDV00 in the library that is named AUTO to reflect a status of PRIVATE.

```
update libvolume auto wpdv00 status=private
```

Related commands

Table 1. Commands related to UPDATE LIBVOLUME

Command	Description
AUDIT LIBRARY	Ensures that an automated library is in a consistent state.
CHECKIN LIBVOLUME	Checks a storage volume into an automated library.
CHECKOUT LIBVOLUME	Checks a storage volume out of an automated library.
DEFINE VOLUME	Assigns a volume to be used for storage within a specified storage pool.
AIX Linux Windows LABEL LIBVOLUME	AIX Linux Windows Labels volumes in manual or automated libraries.
QUERY LIBRARY	Displays information about one or more libraries.
QUERY LIBVOLUME	Displays information about a library volume.

UPDATE MACHINE (Update machine information)

Use this command to update machine information. This information will be included in the plan file to help you to recover the client machines.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-UPDate MACHine--machine_name---------------------------------->

>--+-----------------------------+--+-----------------------+--->
   '-DESCription--=--description-'  '-BUilding--=--building-'

>--+-----------------+--+---------------+----------------------->
   '-FLoor--=--floor-'  '-ROom--=--room-'

>--+---------------------+--+-----------------------+--------><
   '-PRIority--=--number-'  '-ADSMServer--=--+-Yes-+-'
                                             '-No--'
```

Parameters

machine_name (Required)
: Specifies the name of the machine to be updated.

DESCription
: Specifies a description of the machine. This parameter is optional. The text can be up to 255 characters. Enclose the text in quotation marks if it contains any blank characters. To remove existing text, specify a null string ("").

BUilding
: Specifies the name or number of the building that this machine is in. This parameter is optional. The text can be up to 16 characters. Enclose the text in quotation marks if it contains any blank characters. To remove existing text, specify a null string ("").

FLoor
: Specifies the name or number of the floor that this machine is on. This parameter is optional. The text can be up to16 characters. Enclose the text in quotation marks if it contains any blank characters. To remove existing text, specify a null string ("").

ROom
: Specifies the name or number of the room that this machine is in. This parameter is optional. The text can be up to 16 characters. Enclose the text in quotation marks if it contains any blank characters. To remove existing text, specify a null string ("").

PRIority
: Specifies the restore priority for the machine as an integer from 1 to 99. The highest priority is 1. This parameter is optional. Use this value to prioritize client machine recovery.

ADSMServer
: Specifies whether the machine contains an IBM Spectrum Protect™ server. This parameter is optional. Possible values are:

  No
  : This machine does not contain an IBM Spectrum Protect server.

  Yes
  : This machine contains an IBM Spectrum Protect server. Only one machine can be defined as containing an IBM Spectrum Protect server.

Example: Update information for a specific machine

Update the DISTRICT5 machine information to reflect that it contains the server.

```
update machine district5 adsmserver=yes
```

Related commands

Table 1. Commands related to UPDATE MACHINE

Command	Description
DEFINE MACHINE	Defines a machine for DRM.
DELETE MACHINE	Deletes a machine.

Command	Description
INSERT MACHINE	Inserts machine characteristics or recovery instructions into the IBM Spectrum Protect database.
QUERY MACHINE	Displays information about machines.

UPDATE MGMTCLASS (Update a management class)

Use this command to change a management class. To allow clients to use the updated management class, you must activate the policy set that contains the management class.

Important: The UPDATE MGMTCLASS command fails if a copy storage pool is specified as the destination for files that were migrated by an IBM Spectrum Protect™ for Space Management client.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the policy set belongs.

Syntax

```
>>-UPDate MGmtclass--domain_name--policy_set_name--class_name--->

>--+-------------------------------------+---------------------->
   '-SPACEMGTECHnique--=--+-AUTOmatic-+-'
                          +-SELective-+
                          '-NONE------'

>--+-------------------------+---------------------------------->
   '-AUTOMIGNonuse--=--days-'

>--+-----------------------------+------------------------------>
   '-MIGREQUIRESBkup--=--+-Yes-+-'
                         '-No--'

>--+-------------------------------+---------------------------->
   '-MIGDESTination--=--pool_name-'

>--+-----------------------------+---------------------------><
   '-DESCription--=--description-'
```

Parameters

domain_name (Required)
: Specifies the policy domain to which the management class belongs.

policy_set_name (Required)
: Specifies the policy set to which the management class belongs. You cannot update a management class that belongs to the ACTIVE policy set.

class_name (Required)
: Specifies the management class to update.

SPACEMGTECHnique
: Specifies whether a file using this management class is eligible for migration. This parameter is optional. This parameter is effective only for IBM Spectrum Protect for Space Management clients, not for backup-archive clients or application clients. Possible values are:

  AUTOmatic
  : Specifies that the file is eligible for both automatic migration and selective migration.

  SELective
  : Specifies that the file is eligible for selective migration only.

  NONE
  : Specifies that the file is not eligible for migration.

AUTOMIGNonuse
: Specifies the number of days that must elapse since a file was last used before it is eligible for automatic migration. This parameter is optional. If SPACEMGTECHNIQUE is not AUTOMATIC, the server ignores this attribute. You can specify an integer from 0 to 9999.

  This parameter is effective only for IBM Spectrum Protect for Space Management clients, not for backup-archive clients or application clients.

MIGREQUIRESBkup
: Specifies whether a backup version of a file must exist before a file can be migrated. This parameter is optional. This parameter is effective only for IBM Spectrum Protect for Space Management clients, not for backup-archive clients or application clients. Possible values are:

  Yes
  : Specifies that a backup version must exist.

  No
  : Specifies that a backup version is optional.

MIGDESTination
: Specifies the primary storage pool where the server initially stores files migrated by IBM Spectrum Protect for Space Management clients. This parameter is effective only for IBM Spectrum Protect for Space Management clients, not for backup-archive clients or application clients.

  The command fails if you specify a copy storage pool as the destination.

DESCription
: Specifies a description of the management class. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters. To remove a previously defined description, specify a null string ("").

Example: Update the policy domain and storage pool of a specific management class

For the management class ACTIVEFILES, in policy set VACATION in the EMPLOYEE_RECORDS policy domain, change the storage pool where migrated files are stored.

```
update mgmtclass employee_records vacation
activefiles migdestination=diskpool2
```

Related commands

Table 1. Commands related to UPDATE MGMTCLASS

Command	Description
ASSIGN DEFMGMTCLASS	Assigns a management class as the default for a specified policy set.
COPY MGMTCLASS	Creates a copy of a management class.
DEFINE COPYGROUP	Defines a copy group for backup or archive processing within a specified management class.
DEFINE MGMTCLASS	Defines a management class.
DEFINE POLICYSET	Defines a policy set within the specified policy domain.
DELETE MGMTCLASS	Deletes a management class and its copy groups from a policy domain and policy set.
QUERY COPYGROUP	Displays the attributes of a copy group.
QUERY MGMTCLASS	Displays information about management classes.
QUERY POLICYSET	Displays information about policy sets.
UPDATE COPYGROUP	Changes one or more attributes of a copy group.

UPDATE NODE (Update node attributes)

Use this command to modify the attributes of a registered node.

You must use the RENAME NODE command to change the name of a registered node.

If you update the node authentication method or the node SSLREQUIRED setting and there is a same-named administrator, those administrator ID settings change.

You must have system level authority to update the node authentication method or the node SSLREQUIRED setting and also update a same-named administrator ID. If the same-named administrator ID has client owner authority over the node that is being updated, then system level authority is not required. You must have either unrestricted policy privilege or restricted policy privilege for the policy domain to which the client node belongs.

For users of Lightweight Directory Access Protocol (LDAP) servers:

- The information in this documentation applies to the LDAP authentication method that is preferred for IBM Spectrum Protect™ V7.1.7 or later servers. For instructions about using the previous LDAP authentication method, see Managing passwords and logon procedures.
- If you change the authentication mode to LDAP, and the node name matches an administrative user ID, you might see unexpected behavior when an automatic password change occurs because the password might be updated twice. As a result, the password might become unknown to the administrative user ID. Alternatively, the password update operation might fail.

When you register or update a node, you can specify whether damaged files on the node can be recovered from a target replication server. Files can be recovered only if all the following conditions are met:

- Version 7.1.1 or later, is installed on the source and target replication servers.
- The REPLRECOVERDAMAGED system parameter is set to ON. The system parameter can be set by using the SET REPLRECOVERDAMAGED command.
- The source server includes at least one file that is marked as damaged in the node that is being replicated.
- The node data was replicated before the damage occurred.

The following table describes how parameter settings affect the recovery of damaged, replicated files.

Table 1. Settings that affect the recovery of damaged files

Setting for the REPLRECOVERDAMAGED system parameter	**Value of the RECOVERDAMAGED parameter on the REPLICATE NODE command**	**Value of the RECOVERDAMAGED parameter on the REGISTER NODE and UPDATE NODE commands**	**Result**
OFF	YES, NO, or not specified	YES or NO	During node replication, standard replication occurs and damaged files are not recovered from the target replication server.
OFF	ONLY	YES or NO	An error message is displayed because files cannot be recovered when the REPLRECOVERDAMAGED system parameter is set to OFF.
ON	YES	YES or NO	During node replication, standard replication occurs and damaged files are recovered from the target replication server.
ON	NO	YES or NO	During node replication, standard replication occurs and damaged files are not recovered from the target replication server.
ON	ONLY	YES or NO	Damaged files are recovered from the target replication server, but standard node replication does not occur.

Setting for the REPLRECOVERDAMAGED system parameter	Value of the RECOVERDAMAGED parameter on the REPLICATE NODE command	Value of the RECOVERDAMAGED parameter on the REGISTER NODE and UPDATE NODE commands	Result
ON	Not specified	YES	During node replication, standard replication occurs and damaged files are recovered from the target replication server.
ON	Not specified	NO	During node replication, standard replication occurs and damaged files are not recovered from the target replication server.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the client node belongs.

Notes:

1. You must specify at least one optional parameter on this command.
2. Passwords are optional for this command, except when you change the authentication method from LDAP to LOCAL.
3. The VALIDATEPROTOCOL parameter is deprecated.
4. HLADDRESS and LLADDRESS must be previously set or specified in the UPDATE NODE or REGISTER NODE commands to use SESSIONINITIATION=SERVERONLY.
5. The BACKUPINITIATION parameter is ignored if the client node operating system is not supported.
6. If you specify the REPLSTATE parameter and you do not specify the REPLMODE parameter, the replication mode of the node is set to SEND.
7. If you specify the REPLMODE parameter, you must also specify the REPLSTATE parameter.
8. The SYNCLDAPDELETE parameter applies only if a node that authenticates to a Lightweight Directory Access Protocol (LDAP) server reverts to local authentication.
9. The SSLREQUIRED parameter is deprecated.

Parameters

node_name (Required)
Specifies the name of the client node to be updated. You can use wildcard characters to specify this name.
Restriction: When you update a password with the UPDATE NODE command, you cannot use a wildcard character with the `node_name` parameter.

password
Specifies the new password for the client node. This parameter is optional in most cases. If the node authentication method is changed from LDAP to LOCAL, a password is required. If the node authentication method is LDAP, do not specify a password by using the UPDATE NODE command. The maximum length of the password is 64 characters. Passwords remain current for a period that is determined by the password expiration period.

FORCEPwreset
Specifies whether to force a client to change or reset the password. This parameter is optional. You can specify one of the following values:

No

Specifies that the password expiration period is set by the SET PASSEXP command. Do not force a client to change or reset the password while it attempts to log on to the server.

Yes
Specifies that the client node or administrator password will expire at the next logon. The client must change or reset the password at the next logon.
Restrictions:

- For nodes that authenticate with an LDAP server, password expiration is set by using LDAP server utilities. For this reason, do not specify FORCEPWRESET=YES if you plan to specify AUTHENTICATION=LDAP.
- If you plan to update a node to authenticate with an LDAP server, and you specified FORCEPWRESET=YES, you must change the password before you can specify FORCEPWRESET=NO and AUTHENTICATION=LDAP.

PASSExp
Specifies the number of days the password remains valid. You can set the password expiration period in the range 0 - 9999 days. A value of 0 means that the password never expires. This parameter is optional. If you do not specify this parameter, the password expiration period is unchanged.

You can change the password expiration period by using the UPDATE NODE or SET PASSEXP commands. To set a common expiration period for all administrators and client nodes, issue the SET PASSEXP command. You can also use the SET PASSEXP command to selectively set password expiration periods. If you selectively set a password expiration period by using the REGISTER NODE command, the UPDATE NODE command, or the SET PASSEXP command, the expiration period is excluded from common password expiration periods that were created by using the SET PASSEXP command.

You can use the RESET PASSEXP command to reset the password expiration period to the common expiration period. This parameter does not apply to passwords that authenticate with an LDAP directory server.

CLOptset
Specifies the name of the option set to be used by the client. This parameter is optional. To remove a client option set, specify the CLOPTSET parameter with a null string ("").

CONtact
Specifies a text string of information that identifies the client node. This parameter is optional. The maximum length of the text string is 255 characters. Enclose the contact information in quotation marks if it contains any blanks. To remove previously defined contact information, specify a null string ("").

DOmain
Specifies the name of the policy domain to which you want to register the client node. This parameter is optional.
Restriction: For servers with data retention protection enabled, an archived registered node cannot be reassigned to a different policy domain.

COMPression
Specifies whether the client node compresses its files before it sends them to the server for backup and archive. This parameter is optional.
Restriction: This parameter cannot be specified for a NAS node.

You can specify one of the following values:

Client
Specifies that the client determines whether files are to be compressed.

Yes
Specifies that the client node compresses its files before it sends them to the server for backup and archive.

No
Specifies that the client node does not compress its files before it sends them to the server for backup and archive.

ARCHDELete
Specifies whether the client node can delete its own archived files from the server. This parameter is optional. You can specify one of the following values:

Yes
Specifies that the client node can delete its own archive files from the server.

No
Specifies that the client node cannot delete its own archive files from the server.

BACKDELete

Specifies whether the client node can delete its own backup files from the server. This parameter is optional. You can specify one of the following values:

No
: Specifies that the client node cannot delete its own backup files from the server.

Yes
: Specifies that the client node can delete its own backup files from the server.

WHEREDOmain
: Specifies the name of the policy domain to be used as a filter in combination with the node name to select nodes to update. This parameter is optional.

WHEREPLatform
: Specifies the name of the client platform to be used as a filter in combination with the node name to select nodes to update. This parameter is optional.

MAXNUMMP
: Specifies the maximum number of mount points a node can use on the server or storage agent only for operations such as backup, archive, and IBM Spectrum Protect for Space Management migration. The parameter is optional and does not apply to nodes with a type of NAS or SERVER. The default value is 1. You can specify an integer in the range 0 - 999. A value of 0 specifies that a node cannot acquire any mount point for a client data store operation. The MAXNUMMP value is not evaluated or enforced during client data read operations such as restore, retrieve, and IBM Spectrum Protect for Space Management recall. However, mount points in use for data read operations are evaluated against attempted concurrent data store operations for the same client node and might prevent the data store operations from being able to acquire mount points.

  For volumes in a storage pool that is associated with the FILE or CENTERA device type, the server can have multiple sessions to read and one process to write to the same volume concurrently. To increase concurrency and provide efficient access for nodes with data in FILE or CENTERA storage pools, increase the value of the MAXNUMMP parameter.

  For nodes that store data into primary storage pools with the simultaneous-write function that is enabled, you must adjust the value of the MAXNUMMP parameter to specify the correct number of mount points for each client session. A client session requires one mount point for the primary storage pool and one mount point for each copy storage pool and each active-data pool.

URL
: Specifies the URL of the IBM Spectrum Protect web client that is configured on the client system. You can use the URL in a web browser and in the Operations Center to remotely manage the client node.

  This parameter is optional. The URL must include the DNS name or IP address of the client system, and the port number that is defined on the client system for the IBM Spectrum Protect web client. For example, `http://client.mycorp.com:1581`

  If you want to remove the value from this parameter, specify empty single quotation marks or empty double quotation marks with no spaces ('' for single quotation marks, or "" for double quotation marks).

UTILITYUrl
: Specifies the address of the IBM Spectrum Protect client management services that are configured on the client system. This URL is used by the Operations Center to access client log files so that you can remotely diagnose client issues from the Operations Center.

  This parameter is optional. You can specify a URL of up to 200 characters in length. The URL must start with `https`. It includes the DNS name or IP address of the client system, and the port number that is defined on the client system for the IBM Spectrum Protect client management services. For example, `https://client.mycorp.com:9028`

  If you omit the port number, the Operations Center uses the port number 9028, which is the default port number when you install the client management services on the client system.

KEEPMP
: Specifies whether the client node keeps the mount point for the entire session. The parameter is optional. You can specify one of the following values:

  No
  : Specifies that the client node releases the mount point during the session. If policy definitions cause data to be stored to a disk storage pool after data is stored to a sequential access storage pool, any mount points that are held by the session will be released.

  Yes

Specifies that the client node must retain the mount point during the entire session. If policy definitions cause data to be stored to a disk storage pool after data is stored to a sequential access storage pool, any mount points that are held by the session will not be released.

AUTOFSRename

Specifies whether the client is prompted for renaming file spaces when the client system upgrades to a client that supports Unicode. The prompting and renaming, if allowed, occur only when the client runs one of the following operations: archive, selective backup, full incremental backup, or partial incremental backup. The renaming changes the names of existing backed-up file spaces that are not in Unicode in server storage. Then, the file spaces are backed up in Unicode. You can use this parameter for Unicode-enabled IBM Spectrum Protect clients by using Windows, Macintosh OS X, and NetWare operating systems.
Important: After the client with support for Unicode is installed, any new file spaces that the client backs up are stored in server storage by using the UTF-8 code page. UTF-8 is a byte-oriented encoding form that is specified by the Unicode Standard.

You can specify one of the following values:

Yes

The server automatically renames existing file spaces when the client system upgrades to a client that supports Unicode, and the client runs one of the following operations: archive, selective backup, full incremental backup, or partial incremental backup. The renaming occurs whether the client uses the graphical user interface, the command line, or the client scheduler.
For example, the server renames a drive as follows:

- Original name: D_DRIVE
- New name: D_DRIVE_OLD

The new name indicates that the file space is stored on the server in format that is not Unicode.

No

The server does not rename file spaces automatically when the client system upgrades to a client that supports Unicode, and the client runs one of the following operations: archive, selective backup, full incremental backup, or partial incremental backup.

Client

The option AUTOFSRENAME in the client option file determines whether file spaces are renamed.

By default, the client option is set to PROMPT. When the client system upgrades to a client that supports Unicode and the client runs an IBM Spectrum Protect operation with the graphical user interface or the command line, the program displays a one-time prompt to the user about whether to rename file spaces.

When the client scheduler runs an operation, the program does not prompt for a choice about renaming, and does not rename file spaces. Backups of existing file spaces are sent as before (not in Unicode).

VALIdateprotocol (deprecated)

Specifies whether IBM Spectrum Protect performs a cyclic redundancy check to validate the data that is sent between the client and the server. The parameter is optional.
Important: Beginning with IBM Spectrum Protect Version 8.1.2, this parameter is deprecated. The validation that was enabled by this parameter is replaced by the TLS 1.2 protocol, which is enforced by the SESSIONSECURITY parameter. The VALIDATEPROTOCOL parameter is ignored. Update your configuration to use the SESSIONSECURITY parameter.

TXNGroupmax

Specifies the number of files that are transferred as a group between a client and a server between transaction commit points. Client performance might be improved by using a larger value for this option.

Specifying 0 indicates that the node uses the server global value that is set in the server options file. To use a value other than the server global value, specify a value of 4 through 65,000 for this parameter. The node value takes precedence over the server value.

Tip: Increasing the TXNGROUPMAX value increases recovery log utilization. Higher recovery log utilization might increase the risk of running out of log space. Evaluate the performance of each node before you change the parameter.

DATAWritepath

Specifies the transfer path that is used when the client sends data to the server, storage agent, or both, during storage operations such as backup or archive. The parameter is optional.

Remember: If a path is unavailable, the node cannot send any data. For example, if you select the LAN-free option but a LAN-free path is not defined, the operation fails.

You can specify one of the following values:

ANY
: Specifies that data is sent to the server, storage agent, or both, using any available path. A LAN-free path is used if one is available. If a LAN-free path is unavailable, the data is moved over the LAN.

LAN
: Specifies that data is sent over the LAN.

LANFree
: Specifies that data is sent over a LAN-free path.

DATAReadpath
: Specifies the transfer path that is used when the server, storage agent, or both read data for a client, during operations such as restore or retrieve. The parameter is optional.
Remember: If a path is unavailable, data cannot be read. For example, if you select the LAN-free option but a LAN-free path is not defined, the operation fails. The value for the transfer path also applies to failover connections. If the value is set to LANFree, failover cannot occur for the node on the secondary server.

You can specify one of the following values:

ANY
: Specifies that the server, storage agent, or both use any available path to read data. A LAN-free path is used if one is available. If a LAN-free path is unavailable, the data is read over the LAN.

LAN
: Specifies that data is read over the LAN.

LANFree
: Specifies that data is read by using a LAN-free path.

SESSIONINITiation
: Controls whether the server or the client initiates sessions. The parameter is optional.

Clientorserver
: Specifies that the client might initiate sessions with the server by communicating on the TCP/IP port that is defined with the server option TCPPORT. Server-prompted scheduling might also be used to prompt the client to connect to the server.

SERVEROnly
: Specifies that the server does not accept client requests for sessions. All sessions must be initiated by server-prompted scheduling on the port that is defined for the client with the REGISTER or UPDATE NODE commands. You cannot use the client acceptor, dsmcad, to start the scheduler when SESSIONINITIATION is set to SERVERONLY.

HLAddress
: Specifies the client IP address that the server contacts to initiate scheduled events. This parameter must be used when SESSIONINITIATION is set to SERVERONLY, regardless of any addresses that are previously used by the client to contact the server.

  The address can be specified either in numeric or host name format. If a numeric address is used, it is saved without verification by a domain name server. If the address is not correct, it can cause failures when the server attempts to contact the client. Host name format addresses are verified with a domain name server. Verified names are saved and resolved with Domain Name Services when the server contacts the client.

LLAddress
: Specifies the client port number on which the client listens for sessions from the server. This parameter must be used when SESSIONINITIATION is set to SERVERONLY, regardless of any addresses that are previously used by the client to contact the server.

  The value for this parameter must match the value of client option TCPCLIENTPORT. The default value is 1501.

HLAddress

Specifies the client IP address that the server contacts to initiate scheduled events. This optional parameter is used only when SESSIONINITIATION is set to SERVERONLY, regardless of any addresses that were previously used by the client to contact the server. If SESSIONINITIATION SERVERONLY is not in use, this option has no effect.

The address can be specified either in numeric or host name format. If a numeric address is used, it is saved without verification by a domain name server. If the address is not correct, it can cause failures when the server attempts to contact the client. Host name format addresses are verified with a domain name server. Verified names are saved and resolved with Domain Name Services when the server contacts the client.

LLAddress

Specifies the client port number on which the client listens for sessions from the server. This optional parameter is used only when SESSIONINITIATION is set to SERVERONLY, regardless of any addresses that were previously used by the client to contact the server. If SESSIONINITIATION SERVERONLY is not in use, this option has no effect.

The value for this parameter must match the value of client option TCPCLIENTPORT. The default value is 1501.

EMAILADdress
: This parameter is used for more contact information. The information that is specified by this parameter is not acted upon by IBM Spectrum Protect.

DEDUPlication
: Specifies where data deduplication can occur for this node. You can specify one of the following values:

  SERVEROnly
  : Specifies that data that is stored by this node can be deduplicated on the server only.

  Clientorserver
  : Specifies that data that is stored by this node can be deduplicated on either the client or the server. For data deduplication to take place on the client, you must also specify a value of YES for the DEDUPLICATION client option. You can specify this option in the client option file or in the client option set on the IBM Spectrum Protect server.

TARGETLevel

Specifies the client deployment package that is targeted for this node. You can substitute an applicable release package for V.R.M.F (Version.Release.Modification.Fix) Level. For example: `TARGETLevel=6.2.0.0`.

You must specify each segment with a number that is applicable to a deployment package. You cannot use an asterisk in any field as a substitution for a valid number. To remove an existing value, specify a null string (" "). The parameter is optional.
Restriction: The TARGETLEVEL parameter does not apply to nodes with a type of NAS or SERVER.

BACKUPINITiation
: Specifies whether the non-root user ID on the client node can back up files to the server. The parameter is optional. The default value is ALL, indicating that non-root user IDs can back up data to the server. You can select one of the following values:

  All
  : Specifies that non-root user IDs can back up files to the server. ALL is the default if BACKUPINITIATION is not specified.

  ROOT
  : Specifies that only the root user ID can back up files to the server.
  Restriction: The attribute is ignored by the server if the backup-archive client connects from an operating system other than AIX®, Linux, Solaris, or Mac OS.

BKREPLRuledefault, ARREPLRuledefault, and SPREPLRuledefault
: Specifies the replication rule that applies to a data type if the file space rules for the data type are set to DEFAULT:

  BKREPLRuledefault
  : Specifies the replication rule for backup data.

  ARREPLRuledefault
  : Specifies the replication rule for archive data.

  SPREPLRuledefault
  : Specifies the replication rule for space-managed data.

You can specify normal-priority replication or high-priority replication rules. In a replication process that includes both normal and high-priority data, high-priority data is replicated first. Before you specify a rule, consider the order in which you want the data to be replicated.

For example, suppose that a client node contains active backup data and archive data. Replication of the active backup data is a higher priority than the archive data. To prioritize both types of data, specify `BKREPLRULEDEFAULT=ACTIVE_DATA_HIGH_PRIORITY ARREPLRULEDEFAULT=ALL_DATA`.

You can specify the following rules:

ALL_DATA
: Replicates active and inactive backup data, archive data, or space-managed data. The data is replicated with a normal priority.

ACTIVE_DATA
: Replicates only active backup data. The data is replicated with a normal priority. This rule is valid only for BKREPLRULEDEFAULT.
Attention:

  If you specify ACTIVE_DATA and one or more of the following conditions are true, inactive backup data on the target replication server is deleted, and inactive backup data on the source replication server is not replicated.

  - When a release version earlier than Version 7.1.1 is installed on either the source or target replication servers.
  - When you are using the REPLICATE NODE command with the `FORCERECONCILE=YES` parameter.
  - When you are running the initial replication of a file space after you configure replication, restore the database, or upgrade both the source and target replication servers from a release version earlier than V7.1.1.

  If the previous conditions are not true, all new and changed files since the last replication are replicated, including inactive files, and files are deleted when they expire.

ALL_DATA_HIGH_PRIORITY
: Replicates active and inactive backup data, archive data, or space-managed data. Data is replicated with a high priority.

ACTIVE_DATA_HIGH_PRIORITY
: This rule is the same as the ACTIVE_DATA replication rule except data is replicated with a high priority. This rule is valid only for BKREPLRULEDEFAULT.

DEFAULT
: Replicates data according to the server replication rule for backup data.

  For example, suppose that you want to replicate the archive data in all the file spaces that belongs to a client node. Replication of the archive data is a high priority. One method to accomplish this task is to specify `ARREPLRULEDEFAULT=DEFAULT`. Ensure that the file space rules for archive data are also set to DEFAULT and that the server rule for archive data is set to ALL_DATA_HIGH_PRIORITY.

  Restriction: If a node is configured for replication, the file space rules are set to DEFAULT after the node stores data on the source replication server.

NONE
: Data of the specified type is not replicated.

  For example, if you do not want to replicate space-managed data that belongs to a client node, specify `SPREPLRULEDEFAULT=NONE`

REPLState
: Specifies whether data that belongs to the client node is ready to be replicated. This parameter is optional. You can specify one of the following values:

  ENabled
  : Specifies that the client node is ready for replication.

  DISabled
  : Specifies that replication does not occur until you enable it.

  The system response to these settings depends on the following factors:

  Whether the client node definition exists only on the source replication server and you are configuring the client node for replication for the first time
  : If you set the replication state to ENABLED or DISABLED, the replication mode of the node on the source replication server is automatically set to SEND after the UPDATE NODE command is issued. When replication first occurs, a

client node definition on the target server is automatically created. The replication state of the client node on the target server is automatically set to ENABLED. The replication mode is set to RECEIVE.

Whether the client node definition exists on the source and the target replication servers, and the node data was previously replicated

For replication to occur, the replication state of the client node on both the source and the target servers must be set to ENABLED. For example, if the replication state of a client node on the source server is ENABLED and the replication state on the target server is DISABLED, replication does not occur.

Whether the client node definition exists on the source and the target replication servers, and the node data was previously exported from the source replication server and imported to the target replication server

In this case, you are configuring the client nodes to synchronize the data between the two servers. When replication first occurs, the replication state of the client node on the target server is automatically set to ENABLED. Data on the source and target servers is synchronized.

Restriction: To synchronize data, you must specify the REPLMODE parameter in addition to the REPLSTATE parameter.

You can specify the REPLMODE parameter only if the client node has never been replicated:

- If the client node definition exists only on the source replication server, the replication mode of the node on the source replication server is automatically set to SEND when the UPDATE NODE command is issued. The replication mode of the node on the target replication server is automatically set to RECEIVE.
- If data that belongs to the node was previously replicated, the replication mode of the node on the source replication server is SEND. The replication mode of the node on the target replication server is RECEIVE.

REPLMode

Specifies whether to synchronize the data that belongs to this client node. Specify this parameter only if data that belongs to the client node was exported from the source replication server and imported to the target replication server. Synchronization occurs during replication.

To synchronize data, you must issue the UPDATE NODE command on both the source and target replication servers and specify the REPLMODE and REPLSTATE parameters. The value that you specify for the REPLMODE parameter depends on whether the server is a source of or a target for replicated data.

You can specify one of the following values:

SYNCSEnd

Specifies that data that belongs to this client node is synchronized with data on a target server during replication. Specify this value only on the server that exported the data. When the synchronization is complete, the replication mode for the client node on the source server is automatically set to SEND. The replication mode remains SEND unless you remove the node by issuing the REMOVE REPLNODE command.

SYNCRECeive

Specifies that data that belongs to this client node is synchronized with data on a source server during replication. Specify this value only on the server that imported the data. When the synchronization is complete, the replication mode for the client node on the target server is automatically set to RECEIVE. The replication mode remains RECEIVE unless you remove the node by issuing the REMOVE REPLNODE command.

Restrictions:

- You can set the REPLMODE parameter only if the initial replication state is NONE. To synchronize data, you change the replication state to ENABLED or DISABLED and specify a value for the REPLMODE parameter.
- Data can be synchronized only if you specified `DATES=ABSOLUTE` on the IMPORT NODE command. If you specified `DATES=RELATIVE` to import data, you must rename the node or delete its data before replication. If you do not take one of these steps, you can lose data.
- If the REPLMODE parameter was set incorrectly, you must issue the REMOVE REPLNODE command before you update the client node definition. For example, suppose that you updated the definition of a client node whose data you wanted to replicate. The data that belongs to the node was previously exported to the target replication server. You specified ENABLED as the setting of the REPLSTATE parameter. However, you did not specify SYNCSEND on the source replication server. As a result, the REPLMODE parameter was automatically set to SEND, and data that belongs to the node could not be synchronized or replicated.

  Issuing REMOVE REPLNODE sets the replication state and the replication mode to NONE. After the REMOVE REPLNODE command is completed, reissue the UPDATE NODE command with the correct parameters and values.

RECOVERDamaged

Specifies whether damaged files can be recovered for this node from a target replication server. The parameter is optional. The default value is YES. You can specify one of the following values:

Yes
: Specifies that recovery of damaged files from a target replication server is enabled for this node.

No
: Specifies that recovery of damaged files from a target replication server is not enabled for this node.
Tip: The value of the RECOVERDAMAGED parameter is only one of several settings that determine whether damaged files are recovered. For information about how to specify the settings, see Settings that affect the recovery of damaged files.

ROLEOVERRIDE

Specifies whether to override the reported role of the client for processor value unit (PVU) estimation reporting. The default is USEREPORTED.

The role reported by the client is either client-device (for example, a workstation) or server-device (for example, file/print server, application server, database). By default, the client reports its role that is based on the client type and the operating system. All clients initially report their role as server-device, except for IBM Spectrum Protect backup-archive clients that are running Microsoft Windows workstation distributions (Windows Vista) and Macintosh OS X.

Specify one of the following values:

Client
: Specifies a client-device.

Server
: Specifies a server-device.

Other
: Specifies that this node is not to be used for PVU estimation reporting. The Other value is useful when multiple nodes are deployed for a physical system (for example, virtual environments, test nodes, retired nodes, and nodes not in production or clustering).

Usereported
: Use the reported role that is provided by the client.

AUTHentication
: This parameter determines the password authentication method that you use; either LDAP or LOCAL.

LOcal
: Specifies that the node uses the local IBM Spectrum Protect server database to store passwords.

LDap
: Specifies that the node uses an LDAP directory server to authenticate passwords. Passwords are not stored in the IBM Spectrum Protect database.

SYNCldapdelete
: This parameter applies only if you want a node that authenticates with a Lightweight Directory Access Protocol (LDAP) server to change to authenticate with the IBM Spectrum Protect server. The parameter specifies whether to remove the node from the LDAP server.

Yes
: Specifies that the node is removed.
Restriction: Do not specify a value of YES. (The value of YES is appropriate only for users of the previous LDAP authentication method, which is described in Managing passwords and logon procedures.)

No
: Specifies that the node is not removed. This is the default value.

SSLrequired (deprecated)

Specifies whether the node must use the Secure Sockets Layer (SSL) protocol to communicate with the IBM Spectrum Protect server. The parameter is optional. When you authenticate passwords with an LDAP directory server, you must protect the sessions by using SSL or another network security method.

Important: Beginning with V8.1.2, this parameter is deprecated. The validation that was enabled by this parameter is replaced by the TLS 1.2 protocol, which is enforced by the SESSIONSECURITY parameter. The SSLREQUIRED parameter is ignored. Update your configuration to use the SESSIONSECURITY parameter.

SESSIONSECurity

Specifies whether the node must use the most secure settings to communicate with an IBM Spectrum Protect server. This parameter is optional.

You can specify one of the following values:

STRict
: Specifies that the strictest security settings are enforced for the node. The STRICT value uses the most secure communication protocol available, which is currently TLS 1.2. The TLS 1.2 protocol is used for SSL sessions between the server and the node. To specify whether the server uses TLS 1.2 for the entire session or only for authentication, see the SSL client option.
To use the STRICT value, the following requirements must be met to ensure that the node can authenticate with the server:

- Both the node and server must be using IBM Spectrum Protect software that supports the SESSIONSECURITY parameter.
- The node must be configured to use the TLS 1.2 protocol for SSL sessions between the server and the node.

Nodes set to STRICT that do not meet these requirements are unable to authenticate with the server.

TRANSitional
: Specifies that the existing security settings are enforced for the node. This is the default value. This value is intended to be used temporarily while you update your security settings to meet the requirements for the STRICT value.

If SESSIONSECURITY=TRANSITIONAL and the node has never met the requirements for the STRICT value, the node will continue to authenticate by using the TRANSITIONAL value. However, after a node meets the requirements for the STRICT value, the SESSIONSECURITY parameter value automatically updates from TRANSITIONAL to STRICT. Then, the node can no longer authenticate by using a version of the client or an SSL/TLS protocol that does not meet the requirements for STRICT. In addition, after a node successfully authenticates by using a more secure communication protocol, the node can no longer authenticate by using a less secure protocol. For example, if a node that is not using SSL is updated and successfully authenticates by using TLS 1.2, the node can no longer authenticate by using no SSL protocol or by using TLS 1.1. This restriction also applies when you use functions such as virtual volumes, when the node authenticates to the IBM Spectrum Protect server as a node from another server.

SPLITLARGEObjects
: Specifies whether large objects that are stored by this node are automatically split into smaller pieces, by the server, to optimize server processing. Specifying Yes causes the server to split large objects (over 10 GB) into smaller pieces when stored by a client node. Specifying No bypasses this process. Specify No only if your primary concern is maximizing throughput of backups directly to tape. The default value is Yes.

Example: Update node SIMON to authenticate with an LDAP directory server and connect using SSL

```
update node simon authentication=ldap sslrequired=yes
```

When you specify the SSLREQUIRED parameter, the server is not automatically configured for SSL. You must follow the instructions for connecting with SSL in order for the example to work.

Example: Update all nodes to communicate with a server by using strict session security

Update all nodes to use the strictest security settings to authenticate with the server.

```
update node * sessionsecurity=strict
```

Example: Update a node with software release information for a future deployment

The client deployment feature helps you update a backup-archive client to a newer release. The information that is generated from the UPDATE NODE command can help you when you plan a deployment. The information is stored for a future deployment and can be viewed by issuing the QUERY NODE command. After a deployment, you can issue the QUERY NODE command to see the current level and the target level. For example, to update node `LARRY` to backup-archive client Version 6.3.0.0.

```
update node LARRY targetlevel=6.3.0.0
```

Example: Update a node backup to compress data and keep the client from deleting archived files

Update node LARRY so that the data on node LARRY is compressed when it is backed up or archived by IBM Spectrum Protect and so that the client cannot delete archived files.

```
update node larry compression=yes archdelete=no
```

Example: Update a node's number of files that can be transferred as a group

Update node LARRY and increase the TXNGroupmax value to 1,000.

```
update node larry txngroupmax=1000
```

Example: Update a node and allow it to deduplicate on the client

Update a node BOB so that it can deduplicate on the client.

```
update node bob deduplication=clientorserver
```

Example: Update the role of node BOB to a server-device for PVU estimation reporting

If you want to accumulate PVU values, only server device roles are recorded. You can update a node from client-device to server-device by issuing the UPDATE NODE command. For this example, node BOB is updated to a server-device.

```
update node bob role=server
```

Example: Update a node definition on a source replication server

NODE1 is defined to a source replication server. The data that belongs to NODE1 was previously exported to a target replication server. Update the replication rule for backup data that belongs to NODE1 so that active backup data is replicated with a high priority. Enable replication for the node. Set up data synchronization with the target replication server.

```
update node node1 bkreplruledefault=active_data_high_priority
replstate=enabled replmode=syncsend
```

Example: Update a node definition to enable recovery of damaged files

Update the PAYROLL node to enable the recovery of damaged files from a target replication server.

```
update node payroll recoverdamaged=yes
```

Related commands

Table 2. Commands related to UPDATE NODE

Command	Description
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY PVUESTIMATE	Displays an estimate of the client-devices and server-devices being managed.
QUERY REPLNODE	Displays information about the replication status of a client node.
REGISTER ADMIN	Defines a new administrator without granting administrative authority.
REGISTER NODE	Defines a client node to the server and sets options for that user.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.
REMOVE REPLNODE	Removes a node from replication.
RENAME NODE	Changes the name for a client node.

Command	Description
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
RESET PASSEXP	Resets the password expiration for nodes or administrators.
SET DEDUPVERIFICATIONLEVEL	Specifies the percentage of extents verified by the server during client-side deduplication.
SET PASSEXP	Specifies the number of days after which a password is expired and must be changed.
SET REPLRECOVERDAMAGED	Specifies whether node replication is enabled to recover damaged files from a target replication server.
UPDATE ADMIN	Changes the password or contact information associated with any administrator.
UPDATE FILESPACE	Changes file-space node-replication rules.

Related information:
Ssl client option

UPDATE NODEGROUP (Update a node group)

Use this command to modify the description of a node group.

Privilege class

To issue this command, you must have system or unrestricted policy privilege.

Syntax

```
>>-UPDate NODEGroup--group_name--DESCription--=--description--->< 
```

Parameters

group_name
: Specifies the name of the node group whose description you want to update.

DESCription (Required)
: Specifies a description of the node group. This parameter is required. The maximum length of the description is 255 characters. If the description contains any blanks, enclose the entire description in quotation marks.

Example: Update a node group's description

Update the node group, `group1`, with a new description.

```
update nodegroup group1 description="Human Resources"
```

Related commands

Table 1. Commands related to UPDATE NODEGROUP

Command	Description
DEFINE BACKUPSET	Defines a previously generated backup set to a server.
DEFINE NODEGROUP	Defines a group of nodes.
DEFINE NODEGROUPMEMBER	Adds a client node to a node group.
DELETE BACKUPSET	Deletes a backup set.
DELETE NODEGROUP	Deletes a node group.
DELETE NODEGROUPMEMBER	Deletes a client node from a node group.

Command	Description
GENERATE BACKUPSET	Generates a backup set of a client's data.
QUERY BACKUPSET	Displays backup sets.
QUERY NODEGROUP	Displays information about node groups.
UPDATE BACKUPSET	Updates a retention value associated with a backup set.

UPDATE PATH (Change a path)

Use this command to update a path definition.

Syntax and parameter descriptions are available for the following path types.

- UPDATE PATH (Change a path when the destination is a drive)
- UPDATE PATH (Change a path when the destination is a library)
- AIX Linux UPDATE PATH (Update a path when the destination is a ZOSMEDIA library)

For detailed and current device support information, see the Supported Devices website for your operating system:

- AIX Windows Supported devices for AIX and Windows
- Linux Supported devices for Linux

Related commands

Table 1. Commands related to UPDATE PATH

Command	Description
DEFINE DATAMOVER	Defines a data mover to the IBM Spectrum Protect server.
DEFINE DRIVE	Assigns a drive to a library.
DEFINE LIBRARY	Defines an automated or manual library.
DEFINE PATH	Defines a path from a source to a destination.
DELETE PATH	Deletes a path from a source to a destination.
QUERY PATH	Displays information about the path from a source to a destination.
UPDATE DATAMOVER	Changes the definition for a data mover.

UPDATE PATH (Change a path when the destination is a drive)

Use this syntax when updating a path definition to a drive.

Privilege class

To issue this command you must have system privilege or unrestricted storage privilege.

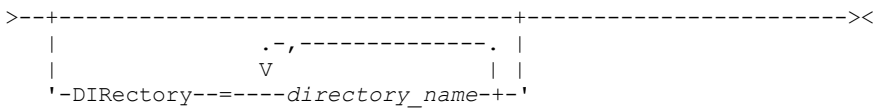
Syntax

```
>>-UPDate PATH--source_name--destination_name------------------>

>--SRCType--=--+-DATAMover-+--+------------------------+-------->
               '-SERVer----'  '-AUTODetect--=--+-No--+-'
                                               '-Yes-'

>--DESTType--=--DRive--LIBRary--=--library_name----------------->

>--+-----------------------+--+--------------------+---------->
   '-DEVIce--=--device_name-'  '-ONLine--=--+-Yes-+-'
                                            '-No--'
```



Parameters

source_name (Required)
Specifies the name of source for the path. This parameter is required.

destination_name (Required)
Specifies the name of the destination. This parameter is required.

SRCType (Required)
Specifies the type of the source. This parameter is required. Possible values are:

DATAMover
Specifies that a data mover is the source.

SERVer
Specifies that a server or a storage agent is the source.

AUTODetect
Specifies whether the serial number for a drive or library will be automatically detected, reported, and updated in IBM Spectrum Protect™. This parameter is optional. This parameter is only valid for paths defined from the local server to a drive or a library. Possible values are:

No
Specifies that the serial number is not automatically updated.

Yes
Specifies that the serial number is automatically updated to reflect the same serial number that the drive reports to IBM Spectrum Protect.
Important:

1. If you have not previously entered a serial number, then AUTODETECT defaults to YES. If you have previously entered a serial number, then AUTODETECT defaults to NO.
2. AUTODETECT=YES in this command overrides the serial number set in the DEFINE DRIVE command.
3. If you set DESTTYPE=DRIVE and AUTODETECT=YES, then the drive element number in the IBM Spectrum Protect database will be automatically changed to reflect the same element number that corresponds to the serial number of that drive. This is true for drives in a SCSI library. For more information about the element number, see the DEFINE DRIVE command.
4. Depending on the capabilities of the device, the AUTODETECT parameter may not be supported.

DESTType=DRive (Required)
Specifies that a drive is the destination. When the destination is a drive, you must specify a library name. This parameter is required.

LIBRary
Specifies the name of the library to which the drive is assigned. The library and its drives must already be defined to the server. If the path is from a NAS data mover to a library, the library must have LIBTYPE of SCSI, 349x, or ACSLS.

DEVIce
Specifies the name of the device as known to the source, or FILE if the device is a logical drive in a FILE library.
AIX The source uses the device name to access the drive. See Table 1 for examples.

Table 1. Examples of device names

Source to destination	Example
Server to a drive (not a FILE drive)	AIX `/dev/rmt3`
Storage agent to a drive (not a FILE drive)	`mt3`
Storage agent to a drive when the drive is a logical drive in a FILE library	`FILE`
NAS data mover to a drive	NetApp NAS file server: `rst01` EMC Celerra NAS file server: `c436t011` IBM® System Storage® N Series: `rst01`

Linux The source uses the device name to access the drive. See Table 2 for examples.

Table 2. Examples of device names

Source to destination	Example
Server to a drive (not a FILE drive)	`/dev/tsmscsi/mt3`
Storage agent to a drive (not a FILE drive)	`/dev/tsmscsi/mt3`
Storage agent to a drive when the drive is a logical drive in a FILE library	`FILE`
NAS data mover to a drive	NetApp NAS file server: `rst01` EMC Celerra NAS file server: `c436t011` IBM System Storage N Series: `rst01`

Windows The source uses the device name to access the drive. See Table 3 for examples.

Table 3. Examples of device names

Source to destination	Example
Server to a drive (not a FILE drive)	Windows `mt3`
Server to a drive (REMOVABLEFILE drive)	`e:`
Storage agent to a drive (not a FILE drive)	`mt3`
Storage agent to a drive when the drive is a logical drive in a FILE library	`FILE`
NAS data mover to a drive	NetApp NAS file server: `rst01` EMC Celerra NAS file server: `c436t011` IBM System Storage N Series: `rst01`

Important:

- For 349X libraries, the alias name is a symbolic name that is specified in the /etc/ibmatl.conf file. For more information, see *IBM Tape Device Drivers Installation and User's Guide*, which can be downloaded from the IBM Systems support site at http://www.ibm.com/support/docview.wss?uid=ssg1S7002972.
- For information about how to obtain names for devices that are connected to a NAS file server, consult the product information for the file server. For example, for a NetApp file server, connect to the file server using Telnet and issue the SYSCONFIG command. Use this command to determine device names for drives:

  ```
  sysconfig -t
  ```

ONLine
Specifies whether the path is available for use. This parameter is optional. Possible values are:

Yes
Specifies that the path is available for use.

No
Specifies that the path is not available for use.

The source and the destination must both be available to use the path.

For example, if the path from a data mover to a drive is online, but either the data mover or the drive is offline, you cannot use the path.

DIRectory
Specifies the directory location or locations for a storage agent to access the files in a FILE library. The DIRECTORY parameter is also used for devices of type REMOVABLEFILE. For REMOVABLEFILE devices, the DIRECTORY parameter provides information for the server (not a storage agent) along with the DRIVE parameter to describe access to the device. This parameter is optional.
On storage agents, this parameter is only valid when *all* of the following conditions are true:

- The source type is SERVER (meaning a storage agent that has been defined as a server to this server).
- The source name is the name of a storage agent, *not* the server.
- The destination is a logical drive that is part of a FILE library.
- If multiple directories were specified for the device class associated with the FILE library, the same number of directories must be specified with the DIRectory parameter of the DEFINE PATH command, for each drive in the FILE

library. Storage agent directories are not validated on the server. Specifying incorrect directories can cause a run-time failure.

The directory name or names identify the locations where the storage agent reads and writes the files that represent storage volumes for the FILE device class that is associated with the FILE library. The default value for DIRECTORY is the directory of the server at the time the command is issued.

Use a naming convention that you can use to associate the directory with a particular physical drive. This can help ensure that your configuration is valid for sharing the FILE library between the server and storage agent. If the storage agent is on a Windows system, use a universal naming convention (UNC) name. When the storage agent lacks permission to access remote storage, the storage agent will experience mount failures.

Windows The account associated with the storage agent service must be either an account within the local administrator's group or an account within the domain administrator's group. If the account is in the local administrator's group, the user ID and password must match that of an account with permissions to access storage as provided by the machine which administers the remote share. For example, if a SAMBA server is providing access to remote storage, the user ID and password in the SAMBA configuration must match that of the local administrator user ID and password associated with the storage agent service.

```
define devclass file devtype=file shared=yes mountlimit=1
directory=d:\filedir\dir1
define path sta1 file1 srctype=server desttype=drive
library=file1 device=file directory=\\192.168.1.10\filedir\dir1
```

In the previous example, the DEFINE DEVCLASS command establishes the shared file system in the directory accessed by the server as D:\FILEDIR\DIR1. The storage agent, however, is using UNC name \\192.168.1.10\FILEDIR\DIR1. This means that the machine with TCP/IP address 192.168.1.10 is sharing the same directory using FILEDIR as the shared name. Also, the storage agent service has an account which can access this storage. It can access it either because it is associated with a local account with the same user ID and password as 192.168.1.10 or it is associated with a domain account which is available on both the storage agent and on 192.168.1.10. If appropriate to the installation, you can replace the 192.168.1.10 with a symbolic name such as:

```
example.yourcompany.com
```

Important:

- IBM Spectrum Protect does not create shares or permissions, or mount the target file system. You must perform these actions before starting the storage agent.
- You can modify a list of directories only by replacing the entire list.
- You must ensure that storage agents can access newly created FILE volumes. To access FILE volumes, storage agents replace names from the directory list in the device-class definition with the names in the directory list for the associated path definition. The following illustrates the importance of matching device classes and paths to ensure that storage agents can access newly created FILE volumes.
  Suppose you want to use these three directories for a FILE library: Windows
  - c:\server
  - d:\server
  - e:\server

  AIX Linux
  - /opt/tivoli1
  - /opt/tivoli2
  - /opt/tivoli3

  1. You use the following command to set up a FILE library named CLASSA with one drive named *CLASSA1* on *SERVER1*: Windows

     ```
     define devclass classa devtype=file
     directory="c:\server,d:\server,e:\server"
     shared=yes mountlimit=1
     ```

     AIX Linux

     ```
     define devclass classa devtype=file
     directory="/opt/tivoli1,/opt/tivoli2,/opt/tivoli3"
     shared=yes mountlimit=1
     ```

  2. You want the storage agent `STA1` to be able to use the FILE library, so you define the following path for storage agent `STA1`: Windows

```
define path server1 sta1 srctype=server desttype=drive device=file
directory="\\192.168.1.10\c\server,\\192.168.1.10\d\server,
\\192.168.1.10\e\server" library=classa
```

Windows In this scenario, the storage agent, STA1, will replace the directory name c:\server with the directory name \\192.168.1.10\c\server to access FILE volumes that are in the c:\server directory on the server.

AIX Linux

```
define path server1 sta1 srctype=server desttype=drive device=file
directory="/opt/ibm1,/opt/ibm2,/opt/ibm3" library=classa
```

AIX Linux In this scenario, the storage agent, STA1, will replace the directory name /opt/tivoli1 with the directory name /opt/ibm1/ to access FILE volumes that are in the /opt/tivoli1 directory on the server.

3. Windows File volume c:\server\file1.dsm is created by SERVER1. If you later change the first directory for the device class with the following command:

   ```
   update devclass classa directory="c:\otherdir,d:\server,e:\server"
   ```

   SERVER1 will still be able to access file volume c:\server\file1.dsm, but the storage agent STA1 will not be able to access it because a matching directory name in the PATH directory list no longer exists. If a directory name is not available in the directory list associated with the device class, the storage agent can lose access to a FILE volume in that directory. Although the volume will still be accessible from the server for reading, failure of the storage agent to access the FILE volume can cause operations to be retried on a LAN-only path or to fail.
4. AIX Linux If file volume /opt/tivoli1/file1.dsm is created on *SERVER1*, and if the following command is issued,

   ```
   update devclass classa directory="/opt/otherdir,/opt/tivoli2,
   /opt/tivoli3"
   ```

   SERVER1 will still be able to access file volume /opt/tivoli1/file1.dsm, but the storage agent STA1 will not be able to access it because a matching directory name in the PATH directory list no longer exists. If a directory name is not available in the directory list associated with the device class, the storage agent can lose access to a FILE volume in that directory. Although the volume will still be accessible from the server for reading, failure of the storage agent to access the FILE volume can cause operations to be retried on a LAN-only path or to fail.

Example: Update a path from a data mover NAS file server to a tape drive

Update a path from a data mover that is a NAS file server to the drive *TAPEDRV2* that the data mover uses for backup and restore operations. In this example, the NAS data mover is *NAS1*, the library is *NASLIB*, and the device name for the drive is *rst0l*.

```
update path nas1 tapedrv2 srctype=datamover desttype=drive library=naslib
    device=rst0l
```

UPDATE PATH (Change a path when the destination is a library)

Use this syntax when updating a path definition to a library.

Privilege class

To issue this command you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate PATH--source_name--destination_name------------------->

>--SRCType--=--+-DATAMover-+--+-----------------------+-------->
               '-SERVer----'  '-AUTODetect--=--+-No--+-'
                                               '-Yes-'

>--DESTType--=--LIBRary--+-------------------------------+------>
                         +-DEVIce--=--device_name--------+
```

```
                          '-EXTERNALManager--=--path_name-'

>--+--------------------+-------------------------------------><
   '-ONLine--=--+-Yes-+-'
                '-No--'
```

Parameters

source_name (Required)
: Specifies the name of source for the path. This parameter is required.

destination_name (Required)
: Specifies the name of the destination. This parameter is required.
Important: To define a path from a NAS data mover to a library, the library must have LIBTYPE of SCSI, 349X, or Automated Cartridge System Library Software (ACSLS).

SRCType (Required)
: Specifies the type of the source. This parameter is required. Possible values are:

  DATAMover
  : Specifies that a data mover is the source.

  SERVer
  : Specifies that a server or a storage agent is the source.

AUTODetect
: Specifies whether the serial number for a drive or library is automatically detected, reported, and updated in IBM Spectrum Protect™. This parameter is optional. This parameter is only valid for paths defined from the local server to a library.
Possible values are:

  No
  : Specifies that the serial number is not automatically updated.

  Yes
  : Specifies that the serial number is automatically updated to reflect the same serial number that the drive reports to IBM Spectrum Protect.
  Important:

    1. If you have not previously entered a serial number, then AUTODETECT defaults to YES. If you have previously entered a serial number, then AUTODETECT defaults to NO.
    2. AUTODETECT=YES in this command overrides the serial number set in the DEFINE DRIVE command.
    3. Depending on the capabilities of the device, the AUTODETECT parameter may not be supported.

DESTType=LIBRary (Required)
: Specifies that a library is the destination.. This parameter is required.

DEVIce
: Specifies the name of the device as known to the source, or FILE if the device is a logical drive in a FILE library.
AIX The source uses the device name to access the drive or library. See Table 1 for examples.

Table 1. Examples of device names

Source to destination	Example
Server to a library	AIX `/dev/lb4` Linux `/dev/tsmscsi/lb4`
NAS data mover to a library	`mc0`

Linux The source uses the device name to access the drive or library. See Table 2 for examples.

Table 2. Examples of device names

Source to destination	Example
Server to a library	`/dev/tsmscsi/lb4`
NAS data mover to a library	`mc0`

Windows The source uses the device name to access the drive or library. See Table 3 for examples.

Table 3. Examples of device names

Source to destination	Example
Server to a library	Windows `lb4.1`

Source to destination	Example
NAS data mover to a library	`mc0`

Important:

- For 349X libraries, the alias name is a symbolic name that is specified in the /etc/ibmatl.conf file. For more information, see *IBM Tape Device Drivers Installation and User's Guide*, which can be downloaded from the IBM® Systems support site at http://www.ibm.com/support/docview.wss?uid=ssg1S7002972.
- For information about how to obtain names for devices that are connected to a NAS file server, consult the product information for the file server. For example, for a NetApp file server, connect to the file server using Telnet and issue the SYSCONFIG command. Use this command to determine the device name for a library:

  ```
  sysconfig -m
  ```

EXTERNALManager
: Specifies the location of the external library manager where IBM Spectrum Protect can send media access requests. Use single quotation marks around the value of this parameter. For example, enter: AIX

  ```
  /usr/lpp/GESedt-acsls/bin/elmdt
  ```

  Linux

  ```
  /opt/GESedt-acsls/bin/elmdt
  ```

  Windows

  ```
  C:\Program Files\GES\EDT-ACSLS\bin\elmdt.exe
  ```

  This parameter is required when the library name is an external library.

ONLine
: Specifies whether the path is available for use. This parameter is optional. Possible values are:

  Yes
  : Specifies that the path is available for use.

  No
  : Specifies that the path is not available for use.

  The source and the destination must both be available to use the path.

  Important: If the path to a library is offline, the server will not be able to access the library. If the server is halted and restarted while the path to the library is offline, the library will not be initialized.

AIX | Linux

UPDATE PATH (Update a path when the destination is a ZOSMEDIA library)

Use this syntax when you update a path to a ZOSMEDIA library.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-UPDate PATH--source_name--destination_name------------------>

>--SRCType--=--SERVer--DESTType--=--LIBRary--------------------->

>--ZOSMEDIASERVER--=--server_name--+--------------------+------><
                                   '-ONLine--=--+-Yes-+-'
                                                '-No--'
```

Parameters

source_name (Required)
: Specifies the name of source for the path.

destination_name (Required)
: Specifies the name of the destination.

SRCType=SERVer (Required)
: Specifies that the IBM Spectrum Protect™ server or a storage agent is the source.

DESTType=LIBRary (Required)
: Specifies that a library is the destination.

ZOSMEDIAServer (Required)
: Specifies the server name that represents a Tivoli® Storage Manager for z/OS® Media server.

ONLine
: Specifies whether the path is available for use. This parameter is optional. Possible values are:

  Yes
  : Specifies that the path is available for use.

  No
  : Specifies that the path is not available for use.

  The source and the destination must both be available to use the path.

  Important: If the path to a library is offline, the server cannot access the library. If the server is halted and restarted while the path to the library is offline, the library is not initialized during server initialization. The path must be updated to ONLINE=YES to access the library.

UPDATE POLICYSET (Update a policy set description)

Use this command to change the description of a policy set. You cannot change the description of the ACTIVE policy set.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the policy set belongs.

Syntax

```
>>-UPDate POlicyset--domain_name--policy_set_name--------------->

>--DESCription--=--description--------------------------------><
```

Parameters

domain_name (Required)
: Specifies the policy domain to which the policy set belongs.

policy_set_name (Required)
: Specifies the policy set to update. You cannot change the ACTIVE policy set.

DESCription (Required)
: Specifies text that describes the policy set. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters. To remove a previously defined description, specify a null string ("").

Example: Update a policy set

Update a policy set called `VACATION` for the `EMPLOYEE_RECORDS` policy domain with a description of "Schedule Planning Information."

```
update policyset employee_records vacation
description="schedule planning information"
```

Related commands

Table 1. Commands related to UPDATE POLICYSET

Command	Description
ACTIVATE POLICYSET	Validates and activates a policy set.
COPY MGMTCLASS	Creates a copy of a management class.
DEFINE DOMAIN	Defines a policy domain that clients can be assigned to.
DEFINE MGMTCLASS	Defines a management class.
DEFINE POLICYSET	Defines a policy set within the specified policy domain.
DELETE POLICYSET	Deletes a policy set, including its management classes and copy groups, from a policy domain.
QUERY POLICYSET	Displays information about policy sets.
VALIDATE POLICYSET	Verifies and reports on conditions the administrator must consider before activating the policy set.

UPDATE PROFILE (Update a profile description)

Use this command on a configuration manager to update a profile description.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-UPDate PROFIle--profile_name--DESCription--=--description--->< 
```

Parameters

profile_name (Required)
: Specifies the profile to update.

DESCription (Required)
: Specifies a description for the profile. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters. To remove a description, specify a null string ("").

Example: Update a profile's description

Update the description for profile DELTA.

```
update profile delta description="PAYROLL domain"
```

Related commands

Table 1. Commands related to UPDATE PROFILE

Command	Description
COPY PROFILE	Creates a copy of a profile.
DEFINE PROFASSOCIATION	Associates objects with a profile.
DEFINE PROFILE	Defines a profile for distributing information to managed servers.
DELETE PROFASSOCIATION	Deletes the association of an object with a profile.
DELETE PROFILE	Deletes a profile from a configuration manager.

Command	Description
LOCK PROFILE	Prevents distribution of a configuration profile.
QUERY PROFILE	Displays information about configuration profiles.
SET CONFIGMANAGER	Specifies whether a server is a configuration manager.
UNLOCK PROFILE	Enables a locked profile to be distributed to managed servers.

UPDATE RECOVERYMEDIA (Update recovery media)

Use this command to update information about recovery media.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-UPDate RECOVERYMedia--media_name----------------------------->

>--+---------------------------------+-------------------------->
   |                 .-,-----------. |
   |                 V             | |
   '-VOLumenames--=----volume_name-+-'

>--+-----------------------------+--+-----------------------+--->
   '-DESCription--=--description-'  '-LOcation--=--location-'

>--+--------------------+--+-------------------------+--------->
   '-Type--=--+-BOot--+-'  '-PROduct--=--product_name-'
              '-OTher-'

>--+---------------------------------------+---------------------><
   '-PRODUCTInfo--=--product_information-'
```

Parameters

media_name (Required)
: Specifies the name of the recovery media to be updated.

VOLumenames
: Specifies the names of volumes that contain the recoverable data (for example, operating system image copies). If you specify a TYPE=BOOT, you must specify the boot media volume names in the order in which they are to be loaded at recovery time. The volume names list can be up to 255 characters. Enclose the list in quotation marks if it contains any blank characters. To remove all volume names, specify a null string ("").

DESCription
: Specifies the description of the recovery media. This parameter is optional. You can use up to 255 characters. Enclose the text in quotation marks if it contains any blank characters.

LOcation
: Describes the location of the recovery media. This parameter is optional. You can use up to 255 characters. Enclose the text in quotation marks if it contains any blank characters. To remove a location description, specify a null string ("") for the value.

Type
: Specifies the type of recovery media. This parameter is optional. Possible values are:

  BOot
  : Specifies that this is boot media. You must specify volume names if the type is BOOT.

  OTher
  : Specifies that this is not boot media. For example, a CD that contains operating system manuals.

PROduct
: Specifies the name of the product that wrote to this media. This parameter is optional. You can use up to 16 characters. Enclose the text in quotation marks if it contains any blank characters. To remove a product name, specify a null string ("")

for the value.

PRODUCTInfo
: Specifies any information about the product that wrote to the media that you may need to restore the machine. This parameter is optional. You can use up to 255 characters. Enclose the text in quotation marks if it contains any blank characters. To remove previously defined product information, specify a null string ("") for the value.

Example: Update a recovery media's location description

Update the location description for recovery media DIST5RM to "Corporate Headquarters Data Vault."

```
update recoverymedia dist5rm
location="Corporate Headquarters Data Vault"
```

Related commands

Table 1. Commands related to UPDATE RECOVERYMEDIA

Command	Description
DEFINE RECOVERYMEDIA	Defines the media required to recover a machine.
DELETE RECOVERYMEDIA	Deletes recovery media.
QUERY RECOVERYMEDIA	Displays media available for machine recovery.

UPDATE REPLRULE (Update replication rules)

Use this command to enable or disable a replication rule.

Issue this command on the server that acts as a source for replicated data.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-UPDate REPLRule--rule_name----STate--=--+-ENabled--+--------><
                                            '-DISabled-'
```

Parameters

rule_name (Required)

Specifies the name of the replication rule to be updated. You can use wildcard characters to specify one or more rules. You can specify one of the following rules:

- ALL_DATA
- ACTIVE_DATA
- ALL_DATA_HIGH_PRIORITY
- ACTIVE_DATA_HIGH_PRIORITY

STate (Required)
: Specifies whether replication is allowed for the rule. You can specify one of the following values:

  ENabled
  : Specifies that the data to which the rule applies is ready to be replicated

  DISabled
  : Specifies that replication does not occur until you enable it.

Example: Disable replication for backup data

Disable replication of normal-priority, active-backup data for all file spaces in all client nodes that are configured for replication:

```
update replrule active_data state=disabled
```

Related commands

Table 1. Commands related to UPDATE REPLRULE

Command	Description
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY REPLICATION	Displays information about node replication processes.
QUERY REPLRULE	Displays information about node replication rules.
SET ARREPLRULEDEFAULT	Specifies the server node-replication rule for archive data.
SET BKREPLRULEDEFAULT	Specifies the server node-replication rule for backup data.
SET SPREPLRULEDEFAULT	Specifies the server node-replication rule for space-managed data.
UPDATE FILESPACE	Changes file-space node-replication rules.
UPDATE NODE	Changes the attributes that are associated with a client node.
VALIDATE REPLICATION	Verifies replication for file spaces and data types.

UPDATE SCHEDULE (Update a schedule)

Use this command to update a client or administrative command schedule.

The UPDATE SCHEDULE command takes two forms, depending on whether the schedule applies to client operations or administrative commands. Within these two forms, you can select either classic or enhanced style schedules. The syntax and parameters for each form are defined separately.

Table 1. Commands related to UPDATE SCHEDULE

Command	Description
COPY SCHEDULE	Creates a copy of a schedule.
DEFINE SCHEDULE	Defines a schedule for a client operation or an administrative command.
DELETE SCHEDULE	Deletes a schedule from the database.
QUERY EVENT	Displays information about scheduled and completed events for selected clients.
QUERY SCHEDULE	Displays information about schedules.
SET MAXCMDRETRIES	Specifies the maximum number of retries after a failed attempt to execute a scheduled command.
SET MAXSCHEDSESSIONS	Specifies the maximum number of client/server sessions available for processing scheduled work.
SET RETRYPERIOD	Specifies the time between retry attempts by the client scheduler.

- UPDATE SCHEDULE (Update a client schedule)
  Use the UPDATE SCHEDULE to update selected parameters for a client schedule.
- UPDATE SCHEDULE (Update an administrative schedule)
  Use this command to update selected parameters for an administrative command schedule.

UPDATE SCHEDULE (Update a client schedule)

Use the UPDATE SCHEDULE to update selected parameters for a client schedule.

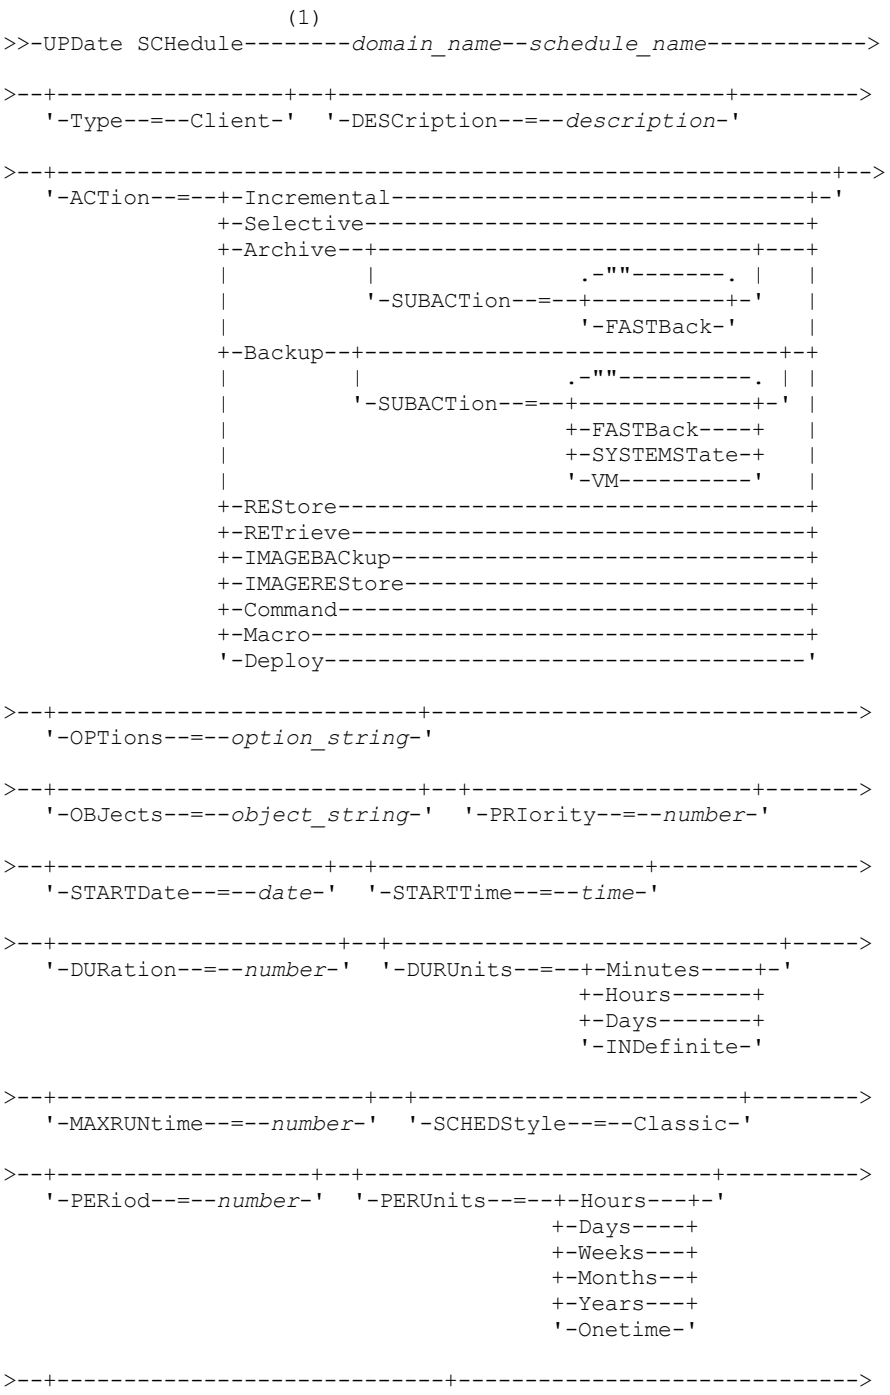
This command does not change the client associations that have been made to this schedule. Any clients that are associated with the original schedule, process the modified schedule.

Not all clients can run all scheduled operations, even though you can define the schedule on the server and associate it with the client. For example, a Macintosh client cannot run a schedule when the action is to restore or retrieve files, or run an executable script. An executable script is also known as a command file, a batch file, or a script on different client operating systems.

Privilege class

To update a client schedule, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the schedule belongs.

Syntax for a classic client schedule



```
   '-DAYofweek--=--+-ANY-------+-'
                   +-WEEKDay---+
                   +-WEEKEnd---+
                   +-SUnday----+
                   +-Monday----+
                   +-TUesday---+
                   +-Wednesday-+
                   +-THursday--+
                   +-Friday----+
                   '-SAturday--'

>--+-------------------------+-------------------------------><
   '-EXPiration--=--+-Never-+-'
                    '-date--'
```

Notes:

1. You must specify at least one optional parameter on this command.

Syntax for an enhanced client schedule

```
                      (1)
>>-UPDate SCHedule--------domain_name--schedule_name------------>

>--+-----------------+--+----------------------------+--------->
   '-Type--=--Client-'  '-DESCription--=--description-'

>--+-------------------------------------------------------------+-->
   '-ACTion--=--+-Incremental--------------------------------+-'
                +-Selective----------------------------------+
                +-Archive--+-----------------------------+---+
                |          '-SUBACTion--=--+-""-------+-'   |
                |                          '-FASTBack-'     |
                +-Backup--+-------------------------------+-+
                |         '-SUBACTion--=--+-""----------+-' |
                |                         +-FASTBack----+   |
                |                         +-SYSTEMSTate-+   |
                |                         +-VApp--------+   |
                |                         '-VM----------'   |
                +-REStore------------------------------------+
                +-RETrieve-----------------------------------+
                +-IMAGEBACkup--------------------------------+
                +-IMAGEREStore-------------------------------+
                +-Command------------------------------------+
                '-Macro--------------------------------------'

>--+--------------------------+-------------------------------->
   '-OPTions--=--option_string-'

>--+--------------------------+--+--------------------+------->
   '-OBJects--=--object_string-'  '-PRIority--=--number-'

>--+--------------------+--+--------------------+--------------->
   '-STARTDate--=--date-'  '-STARTTime--=--time-'

>--+--------------------+--+-------------------------+-------->
   '-DURation--=--number-'  '-DURUnits--=--+-Minutes-+-'
                                           +-Hours---+
                                           '-Days----'

>--+----------------------+--+-----------------------+------->
   '-MAXRUNtime--=--number-'  '-SCHEDStyle--=--Enhanced-'

>--+-------------------------+--+----------------------+------>
   '-MONth--=--+-ANY-------+-'  '-DAYOFMonth--=--+-ANY-+-'
               +-JAnuary---+                    '-Day-'
               +-February--+
               +-MARch-----+
               +-APril-----+
               +-May-------+
               +-JUNe------+
```

```
                +-JULy------+
                +-AUgust----+
                +-September-+
                +-October---+
                +-November--+
                '-December--'

>--+---------------------------+-------------------------------->
   '-WEEKofmonth--=--+-ANY----+-'
                     +-FIrst--+
                     +-Second-+
                     +-Third--+
                     +-FOurth-+
                     '-Last---'

>--+---------------------------+-------------------------------->
   '-DAYofweek--=--+-ANY-------+-'
                   +-WEEKDay---+
                   +-WEEKEnd---+
                   +-SUnday----+
                   +-Monday----+
                   +-TUesday---+
                   +-Wednesday-+
                   +-THursday--+
                   +-Friday----+
                   '-SAturday--'

>--+-------------------------+-------------------------------><
   '-EXPiration--=--+-Never-+-'
                    '-date--'
```

Notes:

1. You must specify at least one optional parameter on this command.

Parameters

domain_name (Required)
: Specifies the name of the policy domain to which this schedule belongs.

schedule_name (Required)
: Specifies the name of the schedule to be updated.

Type=Client
: Specifies that a client schedule is updated. This parameter is optional. The default is CLIENT.

DESCription
: Specifies a description of the schedule. This parameter is optional. You can specify up to 255 characters for the description. Enclose the description in quotation marks if it contains blank characters. To remove a previously defined description, specify a null string ("") for this value.

ACTion
: Specifies the action that occurs when this schedule is processed. Possible values are:

  Incremental
  : Specifies that the schedule backs up all files that are new or that have changed since the last incremental backup. Incremental also backs up any file for which all existing backups might have expired.

  Selective
  : Specifies that the schedule backs up only files that are specified with the OBJECTS parameter.

  Archive
  : Specifies that the schedule archives files that are specified with the OBJECTS parameter.

  Backup
  : Specifies that the schedule backs up files that are specified with the OBJECTS parameter.

  REStore
  : Specifies that the schedule restores files that are specified with the OBJECTS parameter.

    When you specify ACTION=RESTORE for a scheduled operation, and the REPLACE option is set to PROMPT, no prompting occurs. If you set the option to PROMPT, the files are skipped.

    If you specify a second file specification, this second file specification acts as the restore destination. If you need to restore multiple groups of files, schedule one for each file specification that you need to restore.

RETrieve
Indicates that the schedule retrieves files that are specified with the OBJECTS parameter.
Remember: A second file that is specified acts as the retrieve destination. If you need to retrieve multiple groups of files, create a separate schedule for each group of files.

IMAGEBACkup
Specifies that the schedule backs up logical volumes that are specified with the OBJECTS parameter.

IMAGEREStore
Specifies that the schedule restores logical volumes that are specified with the OBJECTS parameter.

Command
Specifies that the schedule processes a client operating system command or script that is specified with the OBJECTS parameter.

Macro
Specifies that a client processes a macro whose file name is specified with the OBJECTS parameter.

SUBACTion
You can specify one of the following values:

""
When a null string (two double quotes) is specified with ACTION=BACKUP the backup is an incremental.

FASTBAck
Specifies that a FastBack client operation that is identified by the ACTION parameter is to be scheduled for processing. The ACTION parameter must be either ARCHIVE or BACKUP.

SYSTEMSTate
Specifies that a client Systemstate backup is scheduled.

VApp
Specifies that a client vApp backup is scheduled. A vApp is a collection of pre-deployed virtual machines.

VM
Specifies that a client VMware backup operation is scheduled.

Deploy
Specifies whether to update client workstations with deployment packages that are specified with the OBJECTS parameter. The OBJECTS parameter must contain two specifications, the package files to retrieve and the location from which to retrieve them. Ensure that the objects are in the order *files location*. For example:

```
define schedule standard deploy_1 action=DEPLOY objects=
"\\IBM_ANR_WIN\c$\tsm\maintenance\client\v6r2\Windows\X32\v620\v6200\*
..\IBM_ANR_WIN\"
```

Values for the following options are restricted when you specify ACTION=DEPLOY:

PERUNITS
Specify `PERUNITS=ONETIME`. If you specify `PERUNITS=PERIOD`, the parameter is ignored.

DURUNITS
Specify `MINUTES`, `HOURS`, or `DAYS` for the DURUNITS parameter. Do not specify INDEFINITE.

SCHEDSTYLE
Specify the default style, CLASSIC.

The SCHEDULE command fails if the parameters do not conform to the required parameter values, such as the V.R.M.F.

OPTions
Specifies the client options that you specify to the scheduled command at the time the schedule is processed. This parameter is optional.
Only those options that are valid on the scheduled command can be specified for this parameter. Refer to the appropriate client manual for information about options that are valid from the command line. All options described there as valid only on the initial command line result in an error or are ignored when running the schedule from the server. For example, do not include the following options because they have no effect when the client processes the scheduled command:

- MAXCMDRETRIES
- OPTFILE
- QUERYSCHEDPERIOD
- RETRYPERIOD
- SCHEDLOGNAME
- SCHEDMODE
- SERVERNAME

- TCPCLIENTADDRESS
- TCPCLIENTPORT

Windows When you define a scheduler service by using the DSMCUTIL command or the backup-archive client GUI wizard, you specify an options file. You cannot override the options in that options file by issuing the scheduled command. You must modify the options in your scheduler service.

If the option string contains multiple options or options with embedded spaces, surround the entire option string with one pair of apostrophes. Enclose individual options that contain spaces in quotation marks. A leading minus sign is required in front of the option. Errors can occur if the option string contains spaces that are not quoted correctly.

The following examples show how to specify some client options:

- To specify `subdir=yes` and `domain all-local -systemobject`, enter:
  - `options='-subdir=yes -domain="all-local -c: -systemobject"'`
- To specify `domain all-local -c: -d:`, enter:
  - `options='-domain="all-local -c: -d:"'`

Windows Tip:

For Windows clients running in batch mode, if the use of quotation marks is necessary, use interactive mode or operating system escape characters. For additional information, see the following topics:

- Processing a series of commands from the administrative client
- Processing individual commands from the administrative client

OBJects

Specifies the objects for which the specified action is performed. Use a single space between each object. This parameter is required except when ACTION=INCREMENTAL. If the action is a backup, archive, retrieve, or restore operation, the objects are file spaces, directories, or logical volumes. If the action is to run a command or macro, the object is the name of the command or macro to run.

When you specify ACTION=INCREMENTAL without specifying a value for this parameter, the scheduled command is invoked without specified objects and attempts to process the objects as defined in the client option file. To select all file spaces or directories for an action, explicitly list them in the object string. Entering only an asterisk in the object string causes the backup to occur only for the directory where the scheduler was started.

Important:

- If you specify a second file specification, and it is not a valid destination, you receive this error:

  ```
  ANS1082E Invalid destination file specification <filespec> entered.
  ```

- If you specify more than two file specifications, you receive this error:

  ```
  ANS1102E Excessive number of command line arguments passed to the
  program!
  ```

When you specify ACTION=ARCHIVE, INCREMENTAL, or SELECTIVE for this parameter, you can list a maximum of twenty (20) file specifications.

Enclose the object string in double quotes if it contains blank characters (spaces), and then surround the double quotes with single quotes. If the object string contains multiple file names, enclose each file name with its own pair of double quotes, then surround the entire string with one pair of single quotes. Errors can occur if file names contain a space that is not quoted correctly.

Windows If you are using characters that have a special meaning for Windows users, such as commas, surround the entire argument in two pairs of double quotes, then surround the entire string with single quotes. The following examples show you how to specify some file names:

- To specify C:\FILE 2, D:\GIF FILES, and E:\MY TEST FILE, enter:
  - `OBJECTS='"C:\FILE 2" "D:\GIF FILES" "E:\MY TEST FILE"'`
- To specify D:\TEST FILE, enter:
  - `OBJECTS='"D:\TEST FILE"'`
- To specify D:TEST,FILE:
  - `OBJECTS='""D:\TEST,FILE""'`

AIX Linux The following examples show how to specify some file names:

- To specify /home/file 2, /home/gif files, and /home/my test file, enter:
  - `OBJECTS='"/home/file 2" "/home/gif files" "/home/my test file"'`
- To specify /home/test file, enter:
  - `OBJECTS='"/home/test file"'`

Windows Tip:

For Windows clients running in batch mode, if the use of double quotes is necessary, use interactive mode or operating system escape characters. For additional information, see the following topics:

- Processing a series of commands from the administrative client
- Processing individual commands from the administrative client

PRIority

Specifies the priority value for a schedule. This parameter is optional. You can specify an integer from 1 to 10, with 1 being the highest priority and 10 being the lowest. The default is 5.

If two or more schedules have the same window start time, the value you specify determines when IBM Spectrum Protect™ processes the schedule. The schedule with the highest priority starts first. For example, a schedule with PRIORITY=3 starts before a schedule with PRIORITY=5.

STARTDate

Specifies the date for the beginning of the window in which the schedule is first processed. This parameter is optional. The default is the current date. Use this parameter with the STARTTIME parameter to specify when the initial startup window of the schedule starts.

You can specify the date using one of the values below:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY+days **or** +days	The current date plus days specified. The maximum number of days you can specify is 9999.	TODAY +3 **or** +3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

STARTTime

Specifies the time for the beginning of the window in which the schedule is first processed. This parameter is optional. The default is the current time. This parameter is used in conjunction with the STARTDATE parameter to specify when the initial startup window begins.

You can specify the time using one of the values below:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW

Value	Description	Example
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes specified	NOW+02:00 **or** +02:00. If you issue this command at 5:00 with STARTTIME=NOW+02:00 or STARTTIME=+02:00, the beginning of the startup window is at 7:00.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes specified	NOW-02:00 **or** -02:00. If you issue this command at 5:00 with STARTTIME=NOW-02:00 or STARTTIME=-02:00, the beginning of the startup window is at 3:00.

DURation

Specifies the number of units that define the length of the startup window of the scheduled operation. This parameter is optional. This value must be from 1 to 999. The default is 1.

Use this parameter with the DURUNITS parameter to specify the length of the startup window. For example, if you specify DURATION=20 and DURUNITS=MINUTES, the schedule must be started within 20 minutes of the start date and start time. The default length of the startup window is 1 hour. The duration of the window must be shorter than the period between windows.

This value is ignored if you specify DURUNITS=INDEFINITE.

Tip: Define schedules with durations longer than 10 minutes. Doing this will give the IBM Spectrum Protect scheduler enough time to process the schedule and prompt the client.

DURUnits

Specifies the time units used to determine the duration of the window in which the schedule can start. This parameter is optional. The default is HOURS.

Use this parameter with the DURATION parameter to specify how long the startup window remains open to process the schedule. For example, if DURATION=20 and DURUNITS=MINUTES, the schedule must be started within 20 minutes of the start date and start time. The schedule may not necessarily complete processing within this window. If the schedule needs to be retried for any reason, the retry attempts must begin before the startup window elapses, or the operation does not restart.

The default value for the length of the startup window is 1 hour. You can specify one of the following values:

Minutes
: Specifies that the duration of the window is defined in minutes.

Hours
: Specifies that the duration of the window is defined in hours.

Days
: Specifies that the duration of the window is defined in days.

INDefinite
: Specifies that the startup window of the scheduled operation has an indefinite duration. The schedule can run any time after the scheduled start time, until the schedule expires. You cannot specify DURUNITS=INDEFINITE, unless you specify PERUNITS=ONETIME. The INDEFINITE value is not allowed with enhanced schedules.

MAXRUNtime

Specifies the maximum run time, which is the number of minutes during which all client sessions that are started by the scheduled operation should be completed. If sessions are still running after the maximum run time, the server issues a warning message, but the sessions continue to run.
Tip: The maximum run time is calculated from the beginning of the startup window and not from the time that sessions start within the startup window.
Restrictions:

- The value of the parameter is not distributed to servers that are managed by an enterprise configuration manager.
- The value of the parameter is not exported by the EXPORT command.

The parameter is optional. You can specify a number in the range 0-1440. A value of 0 means that the maximum run time is indefinite, and no warning message is issued. The maximum run time must be greater than the startup window duration, which is defined by the DURATION and DURUNITS parameters.

For example, if the start time of a scheduled operation is 9:00 PM, and the duration of the startup window is 2 hours, the startup window is 9:00 PM - 11:00 PM. If the maximum run time is 240 minutes, that is, 4 hours, all client sessions for this operation should be completed by 1:00 AM. If one or more sessions are still running after 1:00 AM, the server issues a warning message.
Tip: Alternatively, you can specify a *run time alert* value of 1:00 AM in the IBM Spectrum Protect Operations Center.

SCHEDStyle

This parameter is optional. SCHEDSTYLE defines either the interval between times when a schedule can run, or the days on which it can run. The style can be either classic or enhanced. This parameter must be specified when you change a schedule from classic to enhanced or back to classic. Otherwise, the value for the existing schedule is used.

For classic schedules, these parameters are allowed: PERIOD, PERUNITS, and DAYOFWEEK. These parameters are not allowed: MONTH, DAYOFMONTH, and WEEKOFMONTH. If the previous schedule style was enhanced, the MONTH, DAYOFMONTH, WEEKOFMONTH, and DAYOFWEEK parameters are reset. DAYOFWEEK, PERIOD, and PERUNITS are set to default values unless they are specified with the update command.

For enhanced schedules, these parameters are allowed: MONTH, DAYOFMONTH, WEEKOFMONTH, and DAYOFWEEK. These parameters are not allowed: PERIOD and PERUNITS. If the previous schedule style was classic, the DAYOFWEEK, PERIOD, and PERUNITS parameters are reset. MONTH, DAYOFMONTH, WEEKOFMONTH, and DAYOFWEEK are set to default values unless they are specified with the update command.

PERiod

Specifies the length of time between startup windows for this schedule. This parameter is optional. This parameter is used only with classic schedules. You can specify an integer from 1 to 999. The default is 1.

Use this parameter with the PERUNITS parameter to specify the period between startup windows. For example, if you specify PERIOD=5 and PERUNITS=DAYS (assuming that DAYOFWEEK=ANY), the operation is scheduled every five days after the initial start date and start time. The period between startup windows must exceed the duration of each window. The default is 1 day.

This value is ignored if you specify PERUNITS=ONETIME.

PERUnits

Specifies the time units used to determine the period between startup windows for this schedule. This parameter is optional. This parameter is used only with classic schedules. The default is DAYS.
Use this parameter with the PERIOD parameter to specify the period between startup windows. For example, if you specify PERIOD=5 and PERUNITS=DAYS (assuming that DAYOFWEEK=ANY), the operation is scheduled every 5 days after the initial start date and start time. The default is 1 day. You can specify one of the following values:

Hours
: Specifies that the time between startup windows is in hours.

Days
: Specifies that the time between startup windows is in days.

Weeks
: Specifies that the time between startup windows is in weeks.

Months
: Specifies that the time between startup windows is in months.

  When you specify PERUNITS=MONTHS, the scheduled operation will be processed each month on the same date. For example, if the start date for the scheduled operation is 02/04/1998, the schedule will process on the 4th of every month thereafter. However, if the date is not valid for the next month, then the scheduled operation will be processed on the last valid date in the month. Thereafter, subsequent operations are based on this new date. For example, if the start date is 03/31/1998, the next month's operation will be scheduled for 04/30/1998. Thereafter, all subsequent operations will be on the 30th of the month until February. Because February has only 28 days, the operation will be scheduled for 02/28/1999. Subsequent operations will be processed on the 28th of the month.

Years
: Specifies that the time between startup windows for the schedule is in years.

  When you specify PERUNITS=YEARS, the scheduled operation will be processed on the same month and date of each year. For example, if the start date for the scheduled operation is 02/29/2004, the next year's scheduled operation will be 02/28/2005 because February only has 28 days. Thereafter, subsequent operations will be scheduled for February 28th.

Onetime

Specifies that the schedule processes once. This value overrides the value you specified for the PERIOD parameter.

DAYofweek

Specifies the day of the week on which the startup window for the schedule begins. This parameter is optional. You can specify different options for the DAYofweek parameter, depending on whether the schedule style was defined as Classic or Enhanced:

Classic Schedule

Specifies the day of the week on which the startup window for the schedule begins. This parameter is optional. You can either specify one day of the week, or WEEKDAY, WEEKEND, or ANY. If the start date and start time fall on a day that does not correspond to a day you specify, the start date and start time will be shifted forward in 24-hour increments until the DAYOFWEEK parameter is satisfied.

If you select a value for DAYOFWEEK other than ANY, and depending on the values for PERIOD and PERUNITS, schedules may not be processed when you would expect. The default is ANY.

Enhanced Schedule

Specifies the days of the week on which to run the schedule. You can either specify multiple days separated by commas and no intervening blanks, or WEEKDAY, WEEKEND, or ANY. If you specify multiple days, the schedule will run on each of the specified days. If you specify WEEKDAY or WEEKEND, you must also specify either WEEKOFMONTH=FIRST or WEEKOFMONTH=LAST, and the schedule will run just once per month.

The default value is ANY, meaning the schedule will run every day of the week or on the day or days determined by other enhanced schedule parameters. DAYOFWEEK must have a value of ANY (either by default or specified with the command) when used with the DAYOFMONTH parameter.

Possible values for the DAYofweek parameter are:

ANY
: Specifies that the startup window can begin on any day of the week.

WEEKDay
: Specifies that the startup window can begin on Monday, Tuesday, Wednesday, Thursday, or Friday.

WEEKEnd
: Specifies that the startup window can begin on Saturday or Sunday.

SUnday
: Specifies that the startup window begins on Sunday.

Monday
: Specifies that the startup window begins on Monday.

TUesday
: Specifies that the startup window begins on Tuesday.

Wednesday
: Specifies that the startup window begins on Wednesday.

THursday
: Specifies that the startup window begins on Thursday.

Friday
: Specifies that the startup window begins on Friday.

SAturday
: Specifies that the startup window begins on Saturday.

MONth

Specifies the months of the year during which to run the schedule. This parameter is used only with enhanced schedules. Specify multiple values by using commas and no intervening blanks. The default value is ANY, which means that the schedule runs during every month of the year.

DAYOFMonth

Specifies the day of the month to run the schedule. This parameter is used only with enhanced schedules. You can either specify ANY or a number from -31 through 31, excluding zero. Negative values are a day from the end of the month, counting backwards. For example, the last day of the month is -1, the next-to-the-last day of the month is -2. You can specify multiple values separated by commas and no intervening blanks. If you specify multiple values, the schedule runs on each of the specified days of the month. If multiple values resolve to the same day, the schedule runs only once that day.

The default value is ANY, which means that the schedule runs on every day of the month or on the days determined by other enhanced schedule parameters. DAYOFMONTH must have a value of ANY (either by default or specified with the

command) when used with the DAYOFWEEK or WEEKOFMONTH parameters.

If an existing schedule specifies a value other than ANY for DAYOFWEEK and WEEKOFMONTH, and DAYOFMONTH is updated, DAYOFWEEK and WEEKOFMONTH are reset to ANY.

WEEKofmonth
Specifies the week of the month in which to run the schedule. This parameter is used only with enhanced schedules. A week is considered any seven-day period which does not start on a particular day of the week. You can specify FIRST, SECOND, THIRD, FOURTH, LAST, or ANY. You can specify multiple values separated by commas and no intervening blanks. If you specify multiple values, the schedule runs during each of the specified weeks of the month. If multiple values resolve to the same week, the schedule runs only once during that week.

The default value is ANY. ANY means that the schedule runs during every week of the month or on the day or days determined by other enhanced schedule parameters. WEEKOFMONTH must have a value of ANY (either by default or specified with the command) when used with the DAYOFMONTH parameter.

EXPiration
Specifies the date after which this schedule is no longer used. This parameter is optional. The default is NEVER. You can specify one of the following values:

Never
Specifies that the schedule never expires.

expiration_date
Specifies the date on which this schedule expires, in MM/DD/YYYY format. If you specify an expiration date, the schedule expires at 23:59:59 on the date you specify.

Example: Update the priority of a schedule

Update the MONTHLY_BACKUP schedule that belongs to the STANDARD policy domain by setting its priority value to 1.

```
update schedule standard monthly_backup priority=1
```

Example: Update the expiration date of a schedule

Update the WEEKLY_BACKUP schedule that belongs to the EMPLOYEE_RECORDS policy domain to expire on March 29, 1999 (03/29/1999).

```
update schedule employee_records weekly_backup expiration=03/29/1999
```

Example: Update a schedule to archive on the last Friday of a month

Update a schedule from archiving files quarterly on the last Friday of the month to archiving on the last day of the specified months.

```
update schedule employee_records quarterly_archive dayofmonth=-1
```

WEEKOFMONTH and DAYOFWEEK are reset to ANY.

UPDATE SCHEDULE (Update an administrative schedule)

Use this command to update selected parameters for an administrative command schedule.

You cannot schedule MACRO or QUERY ACTLOG commands.

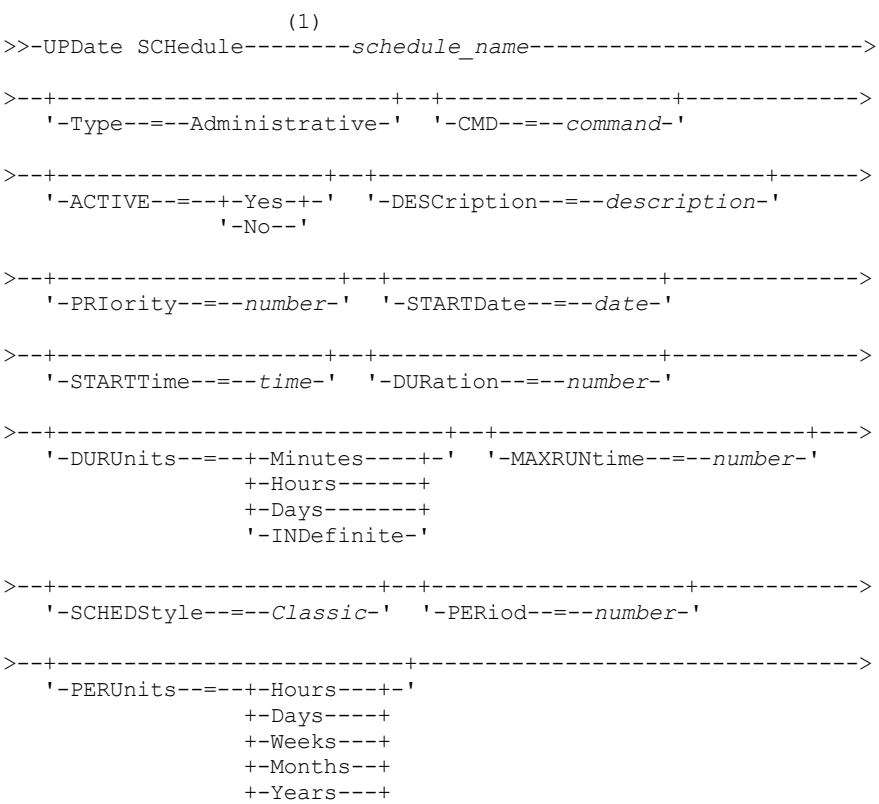
A managed administrative schedule that is updated by a configuration manager is set to an inactive state on the managed servers during configuration refresh processing. It remains in an inactive state until it is updated to an active state on those servers.

Privilege class

To update an administrative schedule, you must have system privilege.

Syntax

Classic administrative schedule



Notes:

1. You must specify at least one optional parameter on this command.

Notes:

1. You must specify at least one optional parameter on this command.

Parameters

schedule_name (Required)
: Specifies the name of the schedule to be updated.

Type=Administrative (Required)
: Specifies that an administrative command schedule is updated.

CMD
: Specifies the administrative command to be scheduled for processing. This parameter is optional. The command you specify can contain up to 512 characters. Enclose the command in quotation marks if it contains blanks.

  You cannot specify redirection characters with this parameter.

ACTIVE
: Specifies whether the administrative command is eligible for processing. This parameter is optional. An administrative command schedule will not be processed unless it is set to the active state. Possible values are:

  YES

Specifies that the administrative command is eligible for processing.

NO

Specifies that the administrative command is not eligible for processing.

DESCription

Specifies a description of the schedule. This parameter is optional. You can specify up to 255 characters for the description. Enclose the description in quotation marks if it contains blanks. To remove a previously defined description, specify a null string ("") for this value.

PRIority

Specifies the priority value for a schedule. This parameter is optional. You can specify an integer from 1 to 10, with 1 being the highest priority and 10 being the lowest. The default is 5.

If two or more schedules have the same window start time, the value you specify determines when IBM Spectrum Protect™ processes the schedule. The schedule with the highest priority starts first. For example, a schedule with PRIORITY=3 starts before a schedule with PRIORITY=5.

STARTDate

Specifies the date for the beginning of the window in which the schedule is first processed. This parameter is optional. The default is the current date. Use this parameter with the STARTTIME parameter to specify when the initial startup window of the schedule starts.

You can specify the date using one of the values below:

Value	**Description**	**Example**
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY+days **or** +days	The current date plus days specified. The maximum number of days you can specify is 9999.	TODAY +3 **or** +3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

STARTTime

Specifies the time for the beginning of the window in which the schedule is first processed. This parameter is optional. The default is the current time. This parameter is used in conjunction with the STARTDATE parameter to specify when the initial startup window begins.

You can specify the time using one of the values below:

Value	**Description**	**Example**
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes specified	NOW+02:00 **or** +02:00. If you issue this command at 5:00 with STARTTIME=NOW+02:00 or STARTTIME=+02:00, the beginning of the startup window is at 7:00.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes specified	NOW-02:00 **or** -02:00. If you issue this command at 5:00 with STARTTIME=NOW-02:00 or STARTTIME=-02:00, the beginning of the startup window is at 3:00.

DURation
Specifies the number of units that define the length of the startup window of the scheduled operation. This parameter is optional. This value must be from 1 to 999. The default is 1.

Use this parameter with the DURUNITS parameter to specify the length of the startup window. For example, if you specify DURATION=20 and DURUNITS=MINUTES, the schedule must be started within 20 minutes of the start date and start time. The default length of the startup window is 1 hour. The duration of the window must be shorter than the period between windows.

This value is ignored if you specify DURUNITS=INDEFINITE.

DURUnits
Specifies the time units used to determine the duration of the window in which the schedule can start. This parameter is optional. The default is HOURS.

Use this parameter with the DURATION parameter to specify how long the startup window remains open to process the schedule. For example, if DURATION=20 and DURUNITS=MINUTES, the schedule must be started within 20 minutes of the start date and start time. The schedule may not necessarily complete processing within this window. If the schedule needs to be retried for any reason, the retry attempts must begin before the startup window elapses, or the operation does not restart.

The default value for the length of the startup window is 1 hour. You can specify one of the following values:

Minutes
Specifies that the duration of the window is defined in minutes.
Hours
Specifies that the duration of the window is defined in hours.
Days
Specifies that the duration of the window is defined in days.
INDefinite
Specifies that the startup window of the scheduled operation has an indefinite duration. The schedule can run any time after the scheduled start time, until the schedule expires. You cannot specify DURUNITS=INDEFINITE, unless you specify PERUNITS=ONETIME. The INDEFINITE value is not allowed with enhanced schedules.

MAXRUNtime
Specifies the maximum run time, which is the number of minutes during which server processes that are started by the scheduled commands must be completed. If processes are still running after the maximum run time, the central scheduler cancels the processes.
Tips:

- The processes might not end immediately when the central scheduler cancels them; they end when they register the cancellation notification from the central scheduler.
- The maximum run time is calculated beginning from when the server process starts. If the schedule command starts more than one process, each process maximum run time is calculated from when the process starts.
- This parameter does not apply to some processes, such as duplicate-identification processes, which can continue to run after the maximum run time.
- This parameter does not apply if the scheduled command does not start a server process.
- Another cancel time might be associated with some commands. For example, the MIGRATE STGPOOL command can include a parameter that specifies the length of time that the storage pool migration runs before the migration is automatically canceled. If you schedule a command for which a cancel time is defined, and you also define a maximum run time for the schedule, the processes are canceled at whichever cancel time is reached first.

Restrictions:

- The value of the parameter is not distributed to servers that are managed by an enterprise configuration manager.
- The value of the parameter is not exported by the EXPORT command.

This parameter is optional. You can specify a number in the range 0-1440. A value of 0 means that the maximum run time is indefinite, and the central scheduler does not cancel processes. The maximum run time must be greater than the startup window duration, which is defined by the DURATION and DURUNITS parameters.

For example, if the start time of a scheduled command is 9:00 PM, and the duration of the startup window is 2 hours, the startup window is 9:00 PM - 11:00 PM. If the maximum run time is 240 minutes, that is, 4 hours, all applicable server processes that are started by the command must be completed by 1:00 AM. If one or more applicable processes are still running after 1:00 AM, the central scheduler cancels the processes.

Tip: Alternatively, you can specify an *end time* of 1:00 AM in the IBM Spectrum Protect Operations Center.

SCHEDStyle

This parameter is optional. SCHEDSTYLE defines either the interval between times when a schedule should run, or the days on which it should run. The style can be either classic or enhanced. This parameter must be specified when you change a schedule from classic to enhanced or back to classic. Otherwise, the value for the existing schedule is used.

For classic schedules, these parameters are allowed: PERIOD, PERUNITS, and DAYOFWEEK. These parameters are not allowed: MONTH, DAYOFMONTH, and WEEKOFMONTH. If the previous schedule style was enhanced, the MONTH, DAYOFMONTH, WEEKOFMONTH, and DAYOFWEEK parameters will be reset. DAYOFWEEK, PERIOD, and PERUNITS will be set to default values unless they are specified with the update command.

For enhanced schedules, these parameters are allowed: MONTH, DAYOFMONTH, WEEKOFMONTH, and DAYOFWEEK. These parameters are not allowed: PERIOD and PERUNITS. If the previous schedule style was classic, the DAYOFWEEK, PERIOD, and PERUNITS parameters will be reset. MONTH, DAYOFMONTH, WEEKOFMONTH, and DAYOFWEEK will be set to default values unless they are specified with the update command.

PERiod

Specifies the length of time between startup windows for this schedule. This parameter is optional. This parameter is used only with classic schedules. You can specify an integer from 1 to 999. The default is 1.

Use this parameter with the PERUNITS parameter to specify the period between startup windows. For example, if you specify PERIOD=5 and PERUNITS=DAYS (assuming that DAYOFWEEK=ANY), the operation is scheduled every five days after the initial start date and start time. The period between startup windows must exceed the duration of each window. The default is 1 day.

This value is ignored if you specify PERUNITS=ONETIME.

PERUnits

Specifies the time units used to determine the period between startup windows for this schedule. This parameter is optional. This parameter is used only with classic schedules. The default is DAYS.
Use this parameter with the PERIOD parameter to specify the period between startup windows. For example, if you specify PERIOD=5 and PERUNITS=DAYS (assuming that DAYOFWEEK=ANY), the operation is scheduled every 5 days after the initial start date and start time. The default is 1 day. You can specify one of the following values:

Hours
: Specifies that the time between startup windows is in hours.

Days
: Specifies that the time between startup windows is in days.

Weeks
: Specifies that the time between startup windows is in weeks.

Months
: Specifies that the time between startup windows is in months.

  When you specify PERUNITS=MONTHS, the scheduled operation will be processed each month on the same date. For example, if the start date for the scheduled operation is 02/04/1998, the schedule will process on the 4th of every month thereafter. However, if the date is not valid for the next month, then the scheduled operation will be processed on the last valid date in the month. Thereafter, subsequent operations are based on this new date. For example, if the start date is 03/31/1998, the next month's operation will be scheduled for 04/30/1998. Thereafter, all subsequent operations will be on the 30th of the month until February. Because February has only 28 days, the operation will be scheduled for 02/28/1999. Subsequent operations will be processed on the 28th of the month.

Years
: Specifies that the time between startup windows for the schedule is in years.

  When you specify PERUNITS=YEARS, the scheduled operation will be processed on the same month and date of each year. For example, if the start date for the scheduled operation is 02/29/2004, the next year's scheduled operation will be 02/28/2005 because February only has 28 days. Thereafter, subsequent operations will be scheduled for February 28th.

Onetime
: Specifies that the schedule processes once. This value overrides the value you specified for the PERIOD parameter.

DAYofweek

Specifies the day of the week on which the startup window for the schedule begins. This parameter is optional. You can specify different options for the DAYofweek parameter, depending on whether the schedule style was defined as Classic or

Enhanced:

Classic Schedule
: Specifies the day of the week on which the startup window for the schedule begins. This parameter is optional. You can either specify one day of the week, or WEEKDAY, WEEKEND, or ANY. If the start date and start time fall on a day that does not correspond to a day you specify, the start date and start time will be shifted forward in 24-hour increments until the DAYOFWEEK parameter is satisfied.

  If you select a value for DAYOFWEEK other than ANY, and depending on the values for PERIOD and PERUNITS, schedules may not be processed when you would expect. The default is ANY.

Enhanced Schedule
: Specifies the days of the week on which to run the schedule. You can either specify multiple days separated by commas and no intervening blanks, or WEEKDAY, WEEKEND, or ANY. If you specify multiple days, the schedule will run on each of the specified days. If you specify WEEKDAY or WEEKEND, you must also specify either WEEKOFMONTH=FIRST or WEEKOFMONTH=LAST, and the schedule will run just once per month.

  The default value is ANY, meaning the schedule will run every day of the week or on the day or days determined by other enhanced schedule parameters. DAYOFWEEK must have a value of ANY (either by default or specified with the command) when used with the DAYOFMONTH parameter.

Possible values for the DAYofweek parameter are:

ANY
: Specifies that the startup window can begin on any day of the week.

WEEKDay
: Specifies that the startup window can begin on Monday, Tuesday, Wednesday, Thursday, or Friday.

WEEKEnd
: Specifies that the startup window can begin on Saturday or Sunday.

SUnday
: Specifies that the startup window begins on Sunday.

Monday
: Specifies that the startup window begins on Monday.

TUesday
: Specifies that the startup window begins on Tuesday.

Wednesday
: Specifies that the startup window begins on Wednesday.

THursday
: Specifies that the startup window begins on Thursday.

Friday
: Specifies that the startup window begins on Friday.

SAturday
: Specifies that the startup window begins on Saturday.

MONth
: Specifies the months of the year during which to run the schedule. This parameter is used only with enhanced schedules. Specify multiple values by using commas and no intervening blanks. The default value is ANY. This means the schedule will run during every month of the year.

DAYOFMonth
: Specifies the day of the month to run the schedule. This parameter can only be specified with enhanced schedules. You can either specify ANY or a number from -31 through 31, excluding zero. Negative values are a day from the end of the month, counting backwards. For example, the last day of the month is -1, the next-to-the-last day of the month is -2, etc. You can specify multiple values separated by commas and no intervening blanks. If you specify multiple values, the schedule will run on each of the specified days of the month. If multiple values resolve to the same day, the schedule will run only once that day.

  The default value is ANY. This means the schedule will run on every day of the month or on the days determined by other enhanced schedule parameters. DAYOFMONTH must have a value of ANY (either by default or specified with the command) when used with the DAYOFWEEK or WEEKOFMONTH parameters.

WEEKofmonth
: Specifies the week of the month in which to run the schedule. This parameter can only be specified with enhanced schedules. A week is considered any seven-day period which does not start on a particular day of the week. You can specify FIRST, SECOND, THIRD, FOURTH, LAST, or ANY. You can specify multiple values separated by commas and no intervening

blanks. If you specify multiple values, the schedule will run during each of the specified weeks of the month. If multiple values resolve to the same week, the schedule will run only once during that week.

The default value is ANY, meaning the schedule will run during every week of the month or on the day or days determined by other enhanced schedule parameters. WEEKOFMONTH must have a value of ANY (either by default or specified with the command) when used with the DAYOFMONTH parameter.

EXPiration
Specifies the date after which this schedule is no longer used. This parameter is optional. The default is NEVER. You can specify one of the following values:

Never
Specifies that the schedule never expires.

expiration_date
Specifies the date on which this schedule expires, in MM/DD/YYYY format. If you specify an expiration date, the schedule expires at 23:59:59 on the date you specify.

Example: Update a backup schedule to every three days

Update existing administrative schedule named BACKUP_BACKUPPOOL so that starting today, the BACKUPPOOL primary storage pool is backed up to the COPYSTG copy storage pool every three days at 10:00 p.m.

```
update schedule backup_backuppool type=administrative cmd="backup stgpool
    backuppool copystg" active=yes starttime=22:00 period=3
```

Example: Update a backup schedule to every first and third Friday

Update a schedule named BACKUP_ARCHIVEPOOL that backs up the primary storage pool ARCHIVEPOOL to the copy storage pool RECOVERYPOOL. The existing schedule runs on the first and tenth day of every month. Update it to run the first and third Friday of every month.

```
update schedule backup_archivepool
dayofweek=friday weekofmonth=first,third
```

DAYOFMONTH will be reset to ANY.

UPDATE SCRATCHPADENTRY (Update a scratch pad entry)

Use this command to update data on a line in the scratch pad.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-UPDate SCRATCHPadentry--major_category--minor_category------->

>--subject--Line---=--number--Data--=--data--------------------><
```

Parameters

major_category (Required)
Specifies the major category in which data is to be updated. This parameter is case sensitive.

minor_category (Required)
Specifies the minor category in which data is to be updated. This parameter is case sensitive.

subject (Required)
Specifies the subject under which data is to be updated. This parameter is case sensitive.

Line (Required)
Specifies the number of the line on which data is to be updated.

Data (Required)

Specifies the new data to be stored on the line. Previous data is deleted. You can enter up to 1000 characters. Enclose the data in quotation marks if the data contains one or more blanks. The data is case sensitive.

Example: Update a scratch pad entry

Update the vacation contact details of an administrator, Jane, in a database that stores information about the location of all administrators:

```
update scratchpadentry admin_info location jane line=2 data=
"Out of the office until 18 Nov."
```

Related commands

Table 1. Commands related to UPDATE SCRATCHPADENTRY

Command	Description
DEFINE SCRATCHPADENTRY	Creates a line of data in the scratch pad.
DELETE SCRATCHPADENTRY	Deletes a line of data from the scratch pad.
QUERY SCRATCHPADENTRY	Displays information that is contained in the scratch pad.
SET SCRATCHPADRETENTION	Specifies the amount of time for which scratch pad entries are retained.

UPDATE SCRIPT (Update an IBM Spectrum Protect script)

Use this command to change a command line or to add a new command line to an IBM Spectrum Protect™ script.

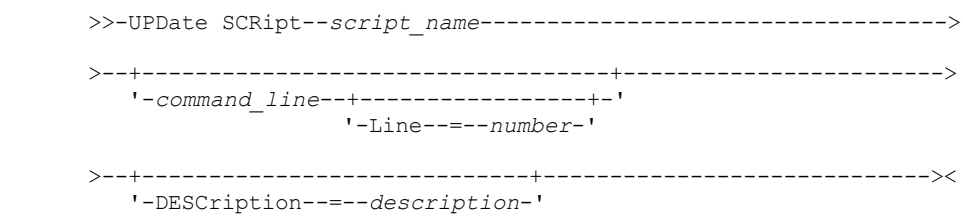
Restriction: You cannot redirect the output of a command within an IBM Spectrum Protect script. Instead, run the script and then specify command redirection. For example, to direct the output of script1 to the c:\temp\test.out directory, run the script and specify command redirection as in the following example:

```
run script1 > c:\temp\test.out
```

Privilege class

To issue this command, the administrator must have previously defined the script or must have system privilege.

Syntax



Parameters

script_name (Required)
: Specifies the name of the script to be updated.

command_line
: Specifies a new or updated command to be processed in a script. You must update a command, a description, or both when you issue this command.

  Command can contain substitution variables and may be continued across multiple lines if you specify a continuation character (-) as the last character in the command. You can specify up to 1200 characters for the command. Enclose the command in quotation marks if it contains blanks. If you specify this parameter, you can optionally specify the following parameter.

You have the options of running commands serially, in parallel, or serially and in parallel by specifying the SERIAL or PARALLEL script commands for this parameter. You can run multiple commands in parallel and wait for them to complete before proceeding to the next command. Commands will run serially until the parallel command is encountered.

Conditional logic flow statements can be used. These statements include IF, EXIT, and GOTO.

Line
: Specifies the line number for the command. If you do not specify a line number, the command line is appended to the existing series of command lines. The appended command line is assigned a line number of five greater than the last command line number in the sequence. For example, if the last line in your script is 015, the appended command line is assigned a line number of 020.

  If you specify a line number, the command will replace an existing line (if the number is the same as an existing line). Or the command will insert the specified line (if the line number does not correspond to an existing line number for the command line sequence).

DESCription
: Specifies a description for the script. You can specify up to 255 characters for the description. Enclose the description in quotation marks if it contains blank characters.

Example: Add a command to the end of a script

Assume that you have defined the following three line script, named QSAMPLE, and that you want to add the QUERY SESSION command to the end of the script.

```
 001  /* This is a sample script */
 005  QUERY STATUS
 010  QUERY PROCESS
```

```
update script qsample "query session"
```

After the command processes, the script now consists of the following lines:

```
 001  /* This is a sample script */
 005  QUERY STATUS
 010  QUERY PROCESS
 015  QUERY SESSION
```

Example: Update a specific line a script

Using the script from the prior example, change line 010 so that it processes the QUERY STGPOOL command instead of the QUERY PROCESS command:

```
update script qsample "query stgpool" line=010
```

After the command processes, the script now consists of the following lines:

```
 001  /* This is a sample script */
 005  QUERY STATUS
 010  QUERY STGPOOL
 015  QUERY SESSION
```

Example: Insert a command in the middle of a script

Using the script from the prior example, insert a new command line (QUERY NODE) after the QUERY STATUS command line in the QSAMPLE script:

```
update script qsample "query node"
line=007
```

After the command processes, the script now consists of the following lines:

```
 001  /* This is a sample script */
 005  QUERY STATUS
 007  QUERY NODE
```

```
010  QUERY STGPOOL
015  QUERY SESSION
```

Related commands

Table 1. Commands related to UPDATE SCRIPT

Command	Description
COPY SCRIPT	Creates a copy of a script.
DEFINE SCRIPT	Defines a script to the IBM Spectrum Protect server.
DELETE SCRIPT	Deletes the script or individual lines from the script.
QUERY SCRIPT	Displays information about scripts.
RENAME SCRIPT	Renames a script to a new name.
RUN	Runs a script.

Related tasks:
Running commands in parallel or serially
Including logic flow statements in a script
Performing tasks concurrently on multiple servers
Defining a server script
Related reference:
Return codes for use in IBM Spectrum Protect scripts

UPDATE SERVER (Update a server defined for server-to-server communications)

Use this command to update a server definition.

Restriction: If this server is a source server for a virtual volume operation, changing any of these values can affect the ability of the source server to access and manage the data that is stored on the corresponding target server. Changing the server name by using the SET SERVERNAME command might have additional implications, varying by operating system. The following are some examples:

- Passwords might be invalidated
- Device information might be affected
- Registry information about Windows operating systems might change

Privilege class

To issue this command, you must have system privilege.

Syntax for:

- **Enterprise configuration**
- **Enterprise event logging**
- **Command routing**
- **Storage agent**
- **Node replication source and target servers**
- AIX | Linux **z/OS® media server**

```
>>-UPDate--SERver--server_name---------------------------------->

>--+-----------------------------+------------------------------>
   '-SERVERPAssword--=--password-'

>--+--------------------------+--+-----------------------+----->
   '-HLAddress--=--ip_address-'  '-LLAddress--=--tcp_port-'

>--+----------------------+--+-------------+-------------------->
   '-COMMmethod--=--TCPIP-'  '-URL--=--url-'
```

Notes:

1. The VALIDATEPROTOCOL parameter is deprecated and applies only to storage agent definitions.
2. Linux The TRANSFERMETHOD parameter is available only on Linux x86_64 operating systems.

Syntax for virtual volumes

Parameters

server_name (Required)
: Specifies the name of the server to be updated. This parameter is required.

PAssword
: Specifies the password that is used to sign on to the target server for virtual volumes. This parameter is optional.

SERVERPAssword
: Specifies the server password, which is used for enterprise configuration, command routing, and server-to-server event logging functions. The password must match the server password set by the SET SERVERPASSWORD command. This parameter is optional.

HLAddress

Specifies the IP address (in dotted decimal format) of the server. This parameter is optional.

LLAddress

Specifies the low-level address of the server. This address is usually the same as the address in the TCPPORT server option of the target server. When SSL=YES, the port must already be designated for SSL communications on the target server.

COMMmethod

Specifies the communication method that is used to connect to the server. This parameter is optional.

URL

Specifies the URL address that is used to access this server from the Administration Center. The parameter is optional.

DELgraceperiod

Specifies a number of days that an object remains on the target server after it was marked for deletion. You can specify a value 0 - 9999. The default is 5. This parameter is optional.

NODEName

Specifies a node name to be used by the server to connect to the target server. This parameter is optional.

DESCription

Specifies a description of the server. This parameter is optional. The description can be up to 255 characters. Enclose the description in quotation marks if it contains blank characters. To remove an existing description, specify a null string ('').

FORCESync

Specifies whether to reset the server verification key when the source server next signs on to the target server. A valid verification key enables a source server to put objects on the target server, manage the grace deletion period value, and update the password, if the current password is known and the verification key matches. The parameter is optional. You can specify one of the following values:

Yes

Specifies that a new verification key will be sent to and accepted by the target server if a valid password is received.

No

Specifies that a new verification key will not be sent to the target server.

VALIdateprotocol (deprecated)

Specifies whether a cyclic redundancy check validates the data sent between the storage agent and the IBM Spectrum Protect™ server. The parameter is optional. The default is NO.

Important: Beginning with IBM Spectrum Protect Version 8.1.2, validation that is enabled by this parameter is replaced by the TLS 1.2 protocol, which is enforced by the SESSIONSECURITY parameter. The VALIDATEPROTOCOL parameter is ignored. Update your configuration to use the SESSIONSECURITY parameter.

ALLOWReplace

Specifies whether a server definition that was defined by a managed server can be replaced with a definition from the configuration manager. This parameter is optional. You can specify one of the following values:

Yes

Specifies that a server definition can be replaced by a definition from the configuration manager.

No

Specifies that a server definition cannot be replaced by the definition from the configuration manager.

SSL

Specifies the communication mode of the server.

Important: Beginning with V8.1.2, SSL is used to encrypt some communication with the specified server even when you specify NO.

The following conditions and considerations apply when you specify the SSL parameter:

- Before starting the servers, self-signed certificates of the partner servers must be in the key database file (cert.kdb) of each of the servers.
- You can define multiple server names with different parameters for the same target server.

You can specify one of the following values:

No

Specifies an SSL session for all communication with the specified server, except when the server is sending or receiving object data. Object data is sent and received by using TCP/IP. By choosing not to encrypt the object data, server performance is similar to communication over a TCP/IP session and the session is secure.

Yes

Specifies an SSL session for all communication with the specified server, even when the server is sending and receiving object data.

SESSIONSECurity

Specifies whether the server that you are defining must use the most secure settings to communicate with an IBM Spectrum Protect server. This parameter is optional.

You can specify one of the following values:

STRict
: Specifies that the strictest security settings are enforced for the server that you are defining. The STRICT value uses the most secure communication protocol available, which is currently TLS 1.2. The TLS 1.2 protocol is used for SSL sessions between the specified server and an IBM Spectrum Protect server.
To use the STRICT value, the following requirements must be met to ensure that the specified server can authenticate with the IBM Spectrum Protect server:

  - Both the server that you are defining and the IBM Spectrum Protect server must be using IBM Spectrum Protect software that supports the SESSIONSECURITY parameter.
  - The server that you are defining must be configured to use the TLS 1.2 protocol for SSL sessions between itself and the IBM Spectrum Protect server.

  Servers set to STRICT that do not meet these requirements are unable to authenticate with the IBM Spectrum Protect server.

TRANSitional
: Specifies that the existing security settings are enforced for the server. This is the default value. This value is intended to be used temporarily while you update your security settings to meet the requirements for the STRICT value.

  If SESSIONSECURITY=TRANSITIONAL and the server has never met the requirements for the STRICT value, the server will continue to authenticate by using the TRANSITIONAL value. However, after a server meets the requirements for the STRICT value, the SESSIONSECURITY parameter value automatically updates from TRANSITIONAL to STRICT. Then, the server can no longer authenticate by using a version of the client or an SSL/TLS protocol that does not meet the requirements for STRICT. In addition, after a server successfully authenticates by using a more secure communication protocol, the server can no longer authenticate by using a less secure protocol. For example, if a server that is not using SSL is updated and successfully authenticates by using TLS 1.2, the server can no longer authenticate by using no SSL protocol or TLS 1.1. This restriction also applies when you use functions such as virtual volumes, command routing, or server-to-server export, when a node or administrator authenticates to the IBM Spectrum Protect server as a node or administrator from another server.

Linux TRANSFERMethod
: Linux Specifies the method that is used for server-to-server data transfer. This parameter is optional. You can specify one of the following values:

Tcpip
: Specifies that TCP/IP is used to transfer data. This is the default.

Fasp
: Specifies that Aspera® Fast Adaptive Secure Protocol (FASP®) technology is used to transfer data. Aspera FASP technology can help you optimize data transfer in a wide area network (WAN).
Restrictions:

  - Before you enable Aspera FASP technology, determine whether the technology is appropriate for your system environment and install the appropriate licenses. For instructions, see Determining whether Aspera FASP technology can optimize data transfer in your system environment. If the licenses are missing or expired, data transfer operations fail.
  - If WAN performance meets your business needs, do not enable Aspera FASP technology.
  - If you specify TRANSFERMETHOD=FASP on the PROTECT STGPOOL or REPLICATE NODE command, that value overrides the TRANSFERMETHOD parameter on the DEFINE SERVER and UPDATE SERVER commands.

Example: Update a deletion grace period for a server

Update the definition of SERVER2 to specify that objects remain on the target server for 10 days after they were marked for deletion.

```
update server server2 delgraceperiod=10
```

Example: Update the URL for a server

Update the definition of NEWSERVER to specify its URL address to be http://newserver:1580/.

```
update server newserver url=http://newserver:1580/
```

Example: Update all servers to communicate with an IBM Spectrum Protect server by using strict session security

Update the definition of all servers to use the strictest security settings to authenticate with the IBM Spectrum Protect server.

```
update server * sessionsecurity=strict
```

Related commands

Table 1. Commands related to UPDATE SERVER

Command	Description
DEFINE DEVCLASS	Defines a device class.
DEFINE SERVER	Defines a server for server-to-server communications.
DELETE DEVCLASS	Deletes a device class.
DELETE FILESPACE	Deletes data associated with client file spaces. If a file space is part of a collocation group and you remove the file space from a node, the file space is removed from the collocation group.
DELETE SERVER	Deletes the definition of a server.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY SERVER	Displays information about servers.
RECONCILE VOLUMES	Reconciles source server virtual volume definitions and target server archive objects.
REGISTER NODE	Defines a client node to the server and sets options for that user.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.
UPDATE DEVCLASS	Changes the attributes of a device class.
UPDATE NODE	Changes the attributes that are associated with a client node.

UPDATE SERVERGROUP (Update a server group description)

Use this command to update the description of a server group.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-UPDate SERVERGroup--group_name------------------------------>

>--DESCription--=--description---------------------------------><
```

Parameters

group_name (Required)
: Specifies the server group to update.

DESCription (Required)
: Specifies a description of the server group. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains blank characters.

Example: Update the description of a server group

Update the description of the server group named WEST_COMPLEX to "Western Region Complex".

```
update servergroup west_complex
 description="western region complex"
```

Related commands

Table 1. Commands related to UPDATE SERVERGROUP

Command	Description
COPY SERVERGROUP	Creates a copy of a server group.
DEFINE SERVERGROUP	Defines a new server group.
DELETE SERVERGROUP	Deletes a server group.
QUERY SERVERGROUP	Displays information about server groups.
RENAME SERVERGROUP	Renames a server group.

UPDATE SPACETRIGGER (Update the space triggers)

Use this command to update settings for triggers that determine when and how the server resolves space shortages in storage pools that use sequential-access FILE and random-access DISK device classes.

For storage pools with a parameter RECLAMATIONTYPE=SNAPLOCK, space triggers are not enabled.

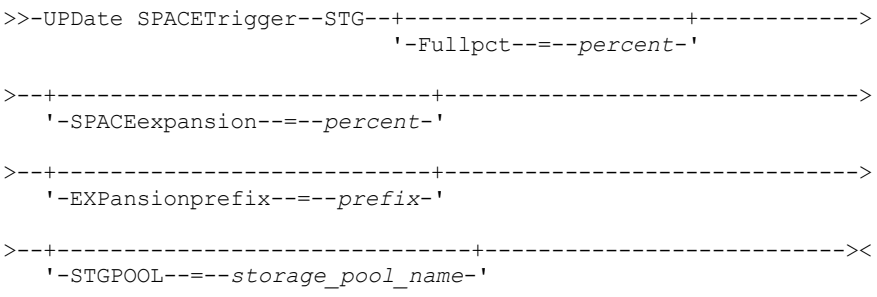
Important: Space trigger functions and storage pool space calculations take into account the space remaining in each directory. Ideally, you associate each directory with a separate file system. If you specify multiple directories for a device class and the directories reside in the same file system, the server calculates space by adding values representing the space remaining in each directory. These space calculations will be inaccurate. Rather than choosing a storage pool with sufficient space for an operation, the server might choose the wrong storage pool and run out of space prematurely. For space triggers, an inaccurate calculation might result in a failure to expand the space available in a storage pool. Failure to expand space in a storage pool is one of the conditions that can cause a trigger to become disabled. If a trigger is disabled because the space in a storage pool could not be expanded, you can re-enable the trigger by specifying the following command: `update spacetrigger stg`. No further changes are required to the space trigger.

See the DEFINE SPACETRIGGER command for more information.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax



Parameters

STG (Required)
: Specifies a storage pool space trigger

Fullpct

This parameter specifies the utilization percentage of the storage pool.

When this value is exceeded, the space trigger creates new volumes.

You can determine storage pool utilization by issuing the QUERY STGPOOL command with FORMAT=DETAILED. The percentage of storage pool utilization for the storage pool is displayed in the field "Space Trigger Util." The calculation for this percentage does not include potential scratch volumes. The calculation for the percentage utilization used for migration and reclamation, however, does include potential scratch volumes.

SPACEexpansion

For space triggers for sequential-access FILE-type storage pools, this parameter is used in determining the number of additional volumes that are created in the storage pool. Volumes are created using the MAXCAPACITY value from the storage pool's device class. For space triggers for random-access DISK storage pools, the space trigger creates a single volume using the EXPANSIONPREFIX.

EXPansionprefix

This specifies the prefix that the server uses to create new storage pool files. This parameter is optional and applies only to random-access DISK device classes. The default prefix is the server installation path.
The prefix can include one or more directory separator characters, for example: AIX Linux

```
/opt/tivoli/tsm/server/bin/
```

Windows

```
c:\program files\tivoli\tsm\
```

AIX Linux You can specify up to 250 characters. If you specify a prefix that is not valid, automatic expansion can fail.

Windows You can specify up to 200 characters. If the server is running as a Windows service, the default prefix is the c:\wnnt\system32 directory. If you specify a prefix that is not valid, automatic expansion can fail.

This parameter is not valid for space triggers for sequential-access FILE storage pools. Prefixes are obtained from the directories specified with the associated device class.

STGPOOL

Specifies the storage pool associated with this space trigger. If the STGPOOL parameter is not specified, the default storage pool space trigger is updated.

This parameter does not apply to storage pools with the parameter RECLAMATIONTYPE=SNAPLOCK.

Example: Increase the amount of space for a storage pool

Increase the amount of space in a storage pool by 50 percent when it is filled to 80 percent utilization of existing volumes. Space will be created in the directories associated with the device class.

```
update spacetrigger stg spaceexpansion=50 stgpool=file
```

Related commands

Table 1. Commands related to UPDATE SPACETRIGGER

Command	Description
DEFINE SPACETRIGGER	Defines a space trigger to expand the space for a storage pool.
DELETE SPACETRIGGER	Deletes the storage pool space trigger.
QUERY SPACETRIGGER	Displays information about a storage pool space trigger.

UPDATE STATUSTHRESHOLD (Update a status monitoring threshold)

Use this command to update an existing status monitoring threshold.

Status monitoring thresholds compare the defined conditions to the status monitoring server queries and inserts the results in the status monitoring table.

Multiple thresholds can be defined for an activity. For example, you can create a threshold that provides a warning status if storage pool capacity utilization is greater than 80%. You can then create another threshold that provides error status if storage pool capacity utilization is greater than 90%.

Note: If a threshold is already defined for an EXISTS condition, you cannot define another threshold with one of the other condition types.

Syntax

```
>>-UPDate STAtusthreshold--threshold_name--+----------------------------+-->
                                           '-Activity--=--activity_name-'

>--+-------------------------+--+-----------------+------------>
   '-Condition--=--+-EXists-+-'  '-Value--=--value-'
                   +-GT-----+
                   +-GE-----+
                   +-LT-----+
                   +-LE-----+
                   '-EQual--'

>--+-----------------------+--------------------------------><
   '-STatus--=--+-Normal--+-'
                +-Warning-+
                '-Error---'
```

Parameters

threshold_name (Required)
: Specifies the threshold name that you want to update. The name cannot exceed 48 characters in length.

activity
: Specify this value to change the activity for an existing threshold. This parameter is optional. Specify one of the following values:

  PROCESSSUMMARY
  : Specifies the number of processes that are currently active.

  SESSIONSUMMARY
  : Specifies the number of sessions that are currently active.

  CLIENTSESSIONSUMMARY
  : Specifies the number of client sessions that are currently active.

  SCHEDCLIENTSESSIONSUMMARY
  : Specifies the number of scheduled client sessions.

  DBUTIL
  : Specifies the database utilization percentage. The default warning threshold value is 80%, and the default error threshold value is 90%.

  DBFREESPACE
  : Specifies the free space available in the database in gigabytes.

  DBUSEDSPACE
  : Specifies the amount of database space that is used, in gigabytes.

  ARCHIVELOGFREESPACE
  : Specifies the free space that is available in the archive log, in gigabytes.

  STGPOOLUTIL
  : Specifies the storage pool utilization percentage. The default warning threshold value is 80%, and the default error threshold value is 90%.

  STGPOOLCAPACITY
  : Specifies the storage pool capacity in gigabytes.

  AVGSTGPOOLUTIL
  : Specifies the average storage pool utilization percentage across all storage pools. The default warning threshold value is 80%, and the default error threshold value is 90%.

  TOTSTGPOOLCAPACITY
  : Specifies the total storage pool capacity in gigabytes for all available storage pools.

  TOTSTGPOOLS
  : Specifies the number of defined storage pools.

  TOTRWSTGPOOLS

Specifies the number of defined storage pools that are readable or writeable.

TOTNOTRWSTGPOOLS
Specifies the number of defined storage pools that are not readable or writeable.

STGPOOLINUSEANDDEFINED
Specifies the total number of defined volumes that are in use.

ACTIVELOGUTIL
Specifies the current percent utilization of the active log. The default warning threshold value is 80%, and the default error threshold value is 90%.

ARCHLOGUTIL
Specifies the current utilization of the archive log. The default warning threshold value is 80%, and the default error threshold value is 90%.

CPYSTGPOOLUTIL
Specifies the percent utilization for a copy storage pool. The default warning threshold value is 80%, and the default error threshold value is 90%.

PMRYSTGPOOLUTIL
Specifies the percent utilization for a primary storage pool. The default warning threshold value is 80%, and the default error threshold value is 90%.

DEVCLASSPCTDRVOFFLINE
Specifies the percent utilization of drives that are offline, by device class. The default warning threshold value is 25%, and the default error threshold value is 50%.

DEVCLASSPCTDRVPOLLING
Specifies the drives polling, by device class. The default warning threshold value is 25%, and the default error threshold value is 50%.

DEVCLASSPCTLIBPATHSOFFLINE
Specifies the library paths that are offline, by device class. The default warning threshold value is 25%, and the default error threshold value is 50%.

DEVCLASSPCTPATHSOFFLINE
Specifies the percentage of device class paths that are offline, by device class. The default warning threshold value is 25%, and the default error threshold value is 50%.

DEVCLASSPCTDISKSNOTRW
Specifies the percentage of disks that are not writable for the disk device class. The default warning threshold value is 25%, and the default error threshold value is 50%.

DEVCLASSPCTDISKSUNAVAILABLE
Specifies the percentage of the disk volumes that are unavailable, by device class. The default warning threshold value is 25%, and the default error threshold value is 50%.

FILEDEVCLASSPCTSCRUNALLOCATABLE
Specifies the percentage of scratch volumes that the server cannot allocate for a given non-shared file device class. The default warning threshold value is 25%, and the default error threshold value is 50%.

Condition
Specify this value to change the condition of an existing threshold. This parameter is optional. Specify one of the following values:

EXists
Creates a status monitoring indicator if the activity exists.

GT
Creates a status monitoring indicator if the activity outcome is greater than the specified value.

GE
Creates a status monitoring indicator if the activity outcome is greater than or equal to the specified value.

LT
Creates a status monitoring indicator if the activity outcome is less than the specified value.

LE
Creates a status monitoring indicator if the activity outcome is less than or equal to the specified value.

EQual
Creates a status monitoring indicator if the activity outcome is equal to the specified value.

Value
Specify this parameter to change the value that is compared with the activity output for the specified condition. You can specify an integer in the range 0 - 999999999999999.

STatus
Specify this value to change the status of the indicator that is created in status monitoring if the condition that is being evaluated passes. This parameter is optional. Specify one of the following values:

Normal
: Specifies that the status indicator has a normal status value.

Warning
: Specifies that the status indicator has a warning status value.

Error
: Specifies that the status indicator has an error status value.

Update an existing status threshold

Update a status threshold for average storage pool utility percentage by issuing the following command:

```
update statusthreshold avgstgpl "AVGSTGPOOLUTIL" value=90 condition=gt status=error
```

Related commands

Table 1. Commands related to UPDATE STATUSTHRESHOLD

Command	Description
DELETE STATUSTHRESHOLD (Delete a status monitoring threshold)	Deletes a status monitoring threshold.
QUERY MONITORSTATUS (Query the monitoring status)	Displays information about monitoring alerts and server status settings.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
QUERY STATUSTHRESHOLD (Query status monitoring thresholds)	Displays information about a status monitoring thresholds.
SET STATUSMONITOR (Specifies whether to enable status monitoring)	Specifies whether to enable status monitoring.
SET STATUSATRISKINTERVAL (Specifies whether to enable client at-risk activity interval evaluation)	Specifies whether to enable client at-risk activity interval evaluation
SET STATUSREFRESHINTERVAL (Set refresh interval for status monitoring)	Specifies the refresh interval for status monitoring.
SET STATUSSKIPASFAILURE (Specifies whether to use client at-risk skipped files as failure evaluation)	Specifies whether to use client at-risk skipped files as failure evaluation
UPDATE STATUSTHRESHOLD (Update a status monitoring threshold)	Changes the attributes of an existing status monitoring threshold.

UPDATE STGPOOL (Update a storage pool)

Use this command to change a storage pool.

Restriction: If a client is using the simultaneous-write function and data deduplication, the data deduplication feature is disabled during backups to a storage pool.

The UPDATE STGPOOL command takes seven forms. The syntax and parameters for each form are defined separately.

Table 1. Commands related to UPDATE STGPOOL

Command	Description
BACKUP STGPOOL	Backs up a primary storage pool to a copy storage pool.
COPY ACTIVEDATA	Copies active backup data.
DEFINE COLLOCGROUP	Defines a collocation group.
DEFINE COLLOCMEMBER	Adds a client node or file space to a collocation group.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.

Command	Description
DELETE COLLOCGROUP	Deletes a collocation group.
DELETE COLLOCMEMBER	Deletes a client node or file space from a collocation group.
DELETE STGPOOL	Deletes a storage pool from server storage.
MOVE DRMEDIA	Moves DRM media onsite and offsite.
MOVE MEDIA	Moves storage pool volumes that are managed by an automated library.
QUERY COLLOCGROUP	Displays information about collocation groups.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY NODEDATA	Displays information about the location and size of data for a client node.
QUERY SHREDSTATUS	Displays information about data waiting to be shredded.
QUERY STGPOOL	Displays information about storage pools.
RESTORE STGPOOL	Restores files to a primary storage pool from copy storage pools.
RESTORE VOLUME	Restores files stored on specified volumes in a primary storage pool from copy storage pools.
SET DRMDBBACKUPEXPIREDAYS	Specifies criteria for database backup series expiration.
SHRED DATA	Manually starts the process of shredding deleted data.
UPDATE COLLOCGROUP	Updates the description of a collocation group.

- UPDATE STGPOOL (Update a cloud-container storage pool)
  Use this command to update a container storage pool in a cloud environment. Cloud storage pools are not supported on Linux on System z®.
- UPDATE STGPOOL (Update a directory-container storage pool)
  Use this command to update a directory-container storage pool.
- UPDATE STGPOOL (Update a container-copy storage pool)
  Use this command to update a container-copy storage pool.
- UPDATE STGPOOL (Update a primary random access storage pool)
  Use this command to update a random access storage pool.
- UPDATE STGPOOL (Update a primary sequential access pool)
  Use this command to update a primary sequential access storage pool.
- UPDATE STGPOOL (Update a copy sequential access storage pool)
  Use this command to update a copy sequential access storage pool.
- UPDATE STGPOOL (Update an active-data sequential access)
  Use this command to update an active-data pool.

UPDATE STGPOOL (Update a cloud-container storage pool)

Use this command to update a container storage pool in a cloud environment. Cloud storage pools are not supported on Linux on System z®.

The preferred way to define and configure a cloud-container storage pool is to use the Operations Center. For instructions and tips for the Operations Center and the command-line interface, see Configuring a cloud-container storage pool for data storage.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege.

Syntax

```
>>-UPDate STGpool--pool_name--+------------------------------+--->
                              '-DESCription--=--description-'
```

Notes:

1. If you specified CLOUDTYPE=AZURE, do not specify the IDENTITY parameter.
2. This parameter is valid only if you specify CLOUDTYPE=S3.

Parameters

pool_name (Required)
: Specifies the storage pool to update. This parameter is required.

DESCription
: Specifies a description of the storage pool. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains blank characters. To remove an existing description, specify a null string ("").

CLOUDType
: Specifies the type of cloud environment where you are configuring a storage pool. This parameter is optional. Specify one of the following values:

  SOftlayer
  : Specifies that the storage pool uses an IBM® SoftLayer® (IBM Bluemix) cloud computing system with an OpenStack Swift cloud computing system.

  SWift
  : Specifies that the storage pool uses an OpenStack Swift cloud computing system. This value also specifies that the storage pool uses Version 2 of the protocol for authentication to the cloud. The URL of the cloud usually contains the version number of the protocol it is using.

  V1Swift

Specifies that the storage pool uses an OpenStack Swift cloud computing system. This value also specifies that the storage pool uses Version 1 of the protocol for authentication to the cloud. The URL of the cloud usually contains the version number of the protocol it is using.

Restriction: If you used the DEFINE STGPOOL command to define a storage pool with CLOUDTYPE=S3 (Simple Storage Service), you cannot change to a different cloud type by using the UPDATE STGPOOL command. Additionally, you cannot change the cloud type of a non-S3 storage pool to S3 by using the UPDATE STGPOOL command.

CLOUDUrl

Specifies the URL of the cloud environment where you are configuring the storage pool. Based on your cloud provider, you can use a region endpoint URL, an accesser IP address, a public authentication endpoint, or a similar value for this parameter. Be sure to include the protocol, such as `https://` or `http://`, at the beginning of the URL. The maximum length of the web address is 870 characters. The CLOUDURL parameter is not validated until the first backup begins.
For more information about how to locate these values, select your cloud service provider from the list on the Configuring a cloud-container storage pool for data storage page.
Tip: To use more than one IBM Cloud Object Storage accesser, list the accesser IP addresses separated by a vertical bar (|), with no spaces, such as in the following example:

```
CLOUDURL=<accesser_URL1>|<accesser_URL2>|<accesser_URL3>
```

Use multiple accessers to improve performance. If you are using the IBM SoftLayer Cloud Object Store S3 solution, only one accesser is needed.

IDentity

Specifies the user ID for the cloud that is specified in the STGTYPE=CLOUD parameter. This parameter is required for all supported cloud computing systems except Azure. If you specified CLOUDTYPE=AZURE, do not specify the IDENTITY parameter. Based on your cloud provider, you can use an access key ID, a user name, a tenant name and user name, or a similar value for this parameter. The maximum length of the user ID is 255 characters.

PAssword (Required)

Specifies the password for the cloud that is specified in the STGTYPE=CLOUD parameter. Based on your cloud provider, you can use a shared access signature (SAS) token, secret access key, an API key, a password, or a similar value for this parameter. This parameter is required. The maximum length of the password is 255 characters. The IDENTITY and PASSWORD parameters are not validated until the first backup begins.

CLOUDLocation

Specifies the physical location of the cloud that is specified in the CLOUD parameter. This parameter is optional. You can specify one of the following values:

- OFfpremise
- ONpremise

BUCKETName

Specifies the name for an Amazon Web Services (AWS) bucket or IBM Cloud Object Storage vault to use with this storage pool. AWS buckets and IBM Cloud Object Storage vaults are used in the same manner as containers in a cloud-container storage pool. This parameter is optional, and is valid only if this storage pool has a cloud type of S3. If the name that you specify does not exist, the server creates a bucket or vault with the specified name before using the bucket or vault. Follow the naming restrictions for your cloud provider when specifying this parameter. Review the permissions for the bucket or vault and ensure that the credentials for this storage pool have permission to read, write, list, and delete objects in this bucket or vault.
Restriction: You cannot change the bucket or vault if any cloud containers exist in this storage pool.

ACCess

Specifies how client nodes and server processes access the storage pool. This parameter is optional. You can specify one of the following values:

READWrite
: Specifies that client nodes and server processes can read and write to the storage pool.

READOnly
: Specifies that client nodes and server processes can read only from the storage pool.

UNAVailable
: Specifies that client nodes and server processes cannot access the storage pool. As a result, backups and restore fail for this storage pool. You can use this value to specify that the cloud service provider is temporarily unavailable.

DESTroyed
: Specifies that client nodes and server processes cannot access the storage pool because the cloud service provider is permanently unavailable. Backups and restores fail for this storage pool, but any attempts to delete objects and containers from this storage pool finish successfully.

MAXWriters

Specifies the maximum number of writing sessions that can run concurrently on the storage pool. Specify a maximum number of writing sessions to control the performance of the cloud storage pool from negatively impacting other system resources. This parameter is optional. You can specify one of the following values:

NOLimit
: Specifies that no maximum size limit exists for the number of writers that you can use. This value is the default.

maximum_writers
: Limits the maximum number of writers that you can use. Specify an integer in the range 1 - 99999.

REUsedelay
: Specifies the number of days that must elapse after all deduplicated extents are removed from a cloud storage pool. This parameter controls the duration that deduplicated extents are associated with a cloud storage pool. When the value that is specified for the parameter expires, the deduplicated extents are deleted from the cloud storage pool. This parameter is optional. You can specify one of the following values:

  1
  : Specifies that deduplicated extents are deleted from a cloud storage pool after one day.

  days
  : You can specify an integer in the range 0 - 9999.

  Tip: Set this parameter to a value that is greater than the number specified for the SET DRMDBBACKUPEXPIREDAYS command. By setting this parameter to a higher value, you can ensure that when you restore the database to an earlier level, the references to files in the storage pool are still valid.

ENCRypt
: Specifies whether the server encrypts client data before it writes it to the storage pool. You can specify the following values:

  Yes
  : Specifies that client data is encrypted by the server.

  No
  : Specifies that client data is not encrypted by the server.

  This parameter is optional. The default depends on the physical location of the cloud, which is specified by the CLOUDLOCATION parameter. If the cloud is off premise, the server encrypts data by default. If the cloud is on premises, the server does not encrypt data by default.

COMPRession
: Specifies whether data is compressed in the storage pool. This parameter is optional. You can specify one of the following values:

  No
  : Specifies that data is not compressed in the storage pool.

  Yes
  : Specifies that data is compressed in the storage pool. This is the default.

Example 1: Update a cloud storage pool to specify a maximum number of data sessions

Update a cloud storage pool that is named STGPOOL1 and specify a maximum of 10 data sessions.

```
update stgpool stgpool1 maxwriters=10
```

Example 2: Update the description of a cloud-container storage pool

Update a cloud-container storage pool that is named STGPOOL2. Remove the existing description from the storage pool.

```
update stgpool stgpool2 cloudurl=http://123.234.123.234:5000/v2.0
identity=admin:admin password=protect8991 description=""
```

```

Parameters

pool_name (Required)
: Specifies the storage pool to update. This parameter is required. The maximum length of the name is 30 characters.

DESCription
: Specifies a description of the storage pool. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters. To remove an existing description, specify a null string ("").

ACCess
: Specifies how client nodes and server processes access files in the storage pool. This parameter is optional. You can specify one of the following values:

  READWrite
  : Specifies that client nodes and server processes can read and write to the storage pool. This is the default.

  READOnly
  : Specifies that client nodes and server processes can only read from the storage pool.

  UNAVailable
  : Specifies that client nodes and server processes cannot access the storage pool.

MAXSIze
Specifies the maximum size for a physical file that the server can store in the storage pool. This parameter is optional. The default value is NOLIMIT. Specify one of the following values:

NOLimit
Specifies that there is no maximum size limit for physical files that are stored in the storage pool.

maximum_file_size
Limits the maximum physical file size. Specify an integer in the range 1 - 999999, followed by a scale factor. For example, MAXSIZE=5G specifies that the maximum file size for this storage pool is 5 GB. Use one of the following scale factors:

Table 1. Scale factor for the maximum file size

Scale factor	Meaning
K	kilobyte
M	megabyte
G	gigabyte
T	terabyte

Tip: If you do not specify a unit of measurement for the maximum file size, the value is specified in bytes.

When the physical size of the storage pool exceeds the MAXSIZE parameter, the following table shows where files are typically stored.

Table 2. The location of a file according to the file size and the pool that is specified

Pool that is specified	Result
No pool is specified as the next storage pool in the hierarchy.	The server does not store the file.
A pool is specified as the next storage pool in the hierarchy.	The server stores the file in the storage pool that you specified.

Tip: If you also specify the NEXTstgpool parameter, update one storage pool in your hierarchy to have no limit on the maximum file size by specifying the MAXSIze=NOLimit parameter. When you have at least one pool with no size limit, you ensure that no matter what its size, the server can store the file.

For multiple files that are sent during data deduplication processing, the server considers the size of the data deduplication process to be the file size. If the total size of all files in the process is larger than the maximum size limit, the server does not store the files in the storage pool.

MAXWriters
Specifies the maximum number of I/O threads that can run concurrently on the storage pool. Specify a maximum number of I/O threads to control the number of I/O threads that are written simultaneously to the directory-container storage pool. This parameter is optional. As a best practice, use the default value of NOLIMIT. You can specify one of the following values:

NOLimit
Specifies that no maximum number of I/O threads are written to the storage pool.

maximum_writers
Limits the maximum number of I/O threads that you can use. Specify an integer in the range 1 - 99999.

NEXTstgpool
Specifies the name of a random-access or primary sequential storage pool to which files are stored when the directory-container storage pool is full. This parameter is optional.
Restrictions:

- To ensure that you do not create a chain of storage pools that leads to an endless loop, specify at least one storage pool in the hierarchy with no value.
- If you specify a sequential-access pool as the next storage pool, the pool must be in either NATIVE or NONBLOCK data format.
- Do not specify a directory-container or cloud-container storage pool.
- Do not use this parameter to specify a storage pool for data migration.

PROTECTstgpool
: Specifies the name of the directory-container storage pool on the target server where the data is backed up when you use the PROTECT STGPOOL command for this storage pool. This parameter is optional.

PROTECTLOCalstgpools
: Specifies the name of the container-copy storage pool on a local device where the data is backed up. This container-copy storage pool will be a local target storage pool when you use the PROTECT STGPOOL command. You can specify a maximum of two container-copy storage pool names to update. Separate multiple names with commas and no intervening spaces. The maximum length of each name is 30 characters. This parameter is optional.
To add or remove container-copy storage pools, specify the container-copy storage pool names to include. For example, if the existing container-copy storage pool includes COPY1 and you want to add COPY2, specify PROTECTLOCALSTGPOOLS=COPY1,COPY2. To remove all existing container-copy storage pools that are associated with the primary storage pool, specify a null string (""). For example, COPYSTGPOOLS="".

REUsedelay
: Specifies the number of days that must elapse before all deduplicated extents are removed from a directory-container storage pool. This parameter controls the duration that deduplicated extents are associated with a directory-container storage pool. When the value that is specified for the parameter expires, the deduplicated extents are deleted from the directory-container storage pool. The default is 1. Specify one of the following values:

  days
  : Specify an integer in the range 0 - 9999.

  1
  : Specifies that deduplicated extents are deleted from a directory-container storage pool after one day.

  Tip: Set this parameter to a value greater than the number that is specified as your database backup period to ensure that data extents are still valid when you restore the database to another level.

ENCRypt
: Specifies whether the server encrypts client data before the server writes the data to the storage pool. You can specify the following values:

  Yes
  : Specifies that client data is encrypted by the server.

  No
  : Specifies that client data is not encrypted by the server.

COMPRession
: Specifies whether data is compressed in the storage pool. This parameter is optional. You can specify one of the following values:

  No
  : Specifies that data is not compressed in the storage pool.

  Yes
  : Specifies that data is compressed in the storage pool. This is the default.

Example: Update a storage pool to specify a maximum number of data sessions

Update a storage pool that is named STGPOOL1 and specify a maximum of 10 data sessions.

```
update stgpool stgpool1 maxwriters=10
```

Example: Update a storage pool to specify the maximum size

Update a storage pool that is named STGPOOL2. The storage pool specifies the maximum file size that the server can store in the storage pool as 100 megabytes.

```
update stgpool stgpool2 maxsize=100M
```

Example: Update the description of a storage pool

Update a storage pool that is named STGPOOL3. Remove the existing description from the storage pool.

```
update stgpool stgpool3 description=""
```

Table 3. Commands related to UPDATE STGPOOL

Command	Description

Command	Description
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DEFINE STGPOOLDIRECTORY	Defines a storage pool directory to a directory-container or cloud-container storage pool.
PROTECT STGPOOL	Protects a directory-container storage pool.
QUERY CONTAINER	Displays information about a container.
QUERY STGPOOL	Displays information about storage pools.
REPAIR STGPOOL	Repairs a directory-container storage pool.
AIX Linux Windows UPDATE STGPOOLDIRECTORY	Changes the attributes of a storage pool directory.

AIX Linux Windows

UPDATE STGPOOL (Update a container-copy storage pool)

Use this command to update a container-copy storage pool.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the storage pool to be updated.

Syntax

```
>>-UPDate STGpool--pool_name--+-----------------------+--------->
                              '-MAXSCRatch--=--number-'

>--+-----------------------------+------------------------------>
   '-DESCription--=--description-'

>--+-----------------------------+------------------------------>
   '-ACCess--=--+-READWrite---+-'
                +-READOnly----+
                '-UNAVailable-'

>--+---------------------------+--+--------------------+------->
   '-PROTECTPRocess--=--number-'  '-RECLaim--=--percent-'

>--+---------------------------------+--------------------------->
   '-RECLAIMLIMit--=--+-NOLimit---+-'
                      '-vol_limit-'

>--+--------------------+-------------------------------------><
   '-REUsedelay--=--days-'
```

Parameters

pool_name (Required)
: Specifies the name of the storage pool to be updated.

MAXSCRatch
: Specifies the maximum number of scratch volumes that the server can request for this storage pool. You can specify an integer in the range 0 - 100000000. If the server can request scratch volumes as needed, you do not have to define each volume to be used.

  The value of this parameter is used to estimate the total number of volumes that are available in the storage pool and the corresponding estimated capacity for the storage pool.

DESCription
: Specifies a description of the storage pool. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters. To remove an existing

description, specify a null string ("").

ACCess

Specifies how server processes such as storage-pool protection and repair can access data in the storage pool. This parameter is optional. You can specify one of the following values:

READWrite

Specifies that the server can read and write to volumes in the storage pool.

READOnly

Specifies that the server can only read volumes in the storage pool. The server can use data in the storage pool to restore extents to directory-container storage pools. No operations that write to the container-copy storage pool are allowed.

UNAVailable

Specifies that the server cannot access data that is stored on volumes in the storage pool.

PROTECTPRocess

Specifies the maximum number of parallel processes that are used when you issue the PROTECT STGPOOL command to copy data to this pool from a directory-container storage pool. This parameter is optional. Enter a value in the range 1 - 20.

The time that is required to complete the copy operation might be decreased by using multiple, parallel processes. However, in some cases when multiple processes are running, one or more of the processes must wait to use a volume that is already in use by a different process.

When you select this value, consider the number of logical and physical drives that can be dedicated to this operation. To access a tape volume, the server uses a mount point and a drive. The number of available mount points and drives depends on the mount limit of the device class for the storage pool, and on other server and system activity.

If you use the preview option on the PROTECT STGPOOL command, only one process is used and no mount points or drives are needed.

RECLaim

Specifies when a volume becomes eligible for reclamation and reuse. Specify eligibility as the percentage of a volume's space that is occupied by extents that are no longer stored in the associated directory-container storage pool. Reclamation moves any extents that are still stored in the associated directory-container storage pool from eligible volumes to other volumes. Reclamation occurs only when a PROTECT STGPOOL command stores data into this storage pool.

This parameter is optional. You can specify an integer in the range 1 - 100. The value 100 specifies that volumes in this storage pool are not reclaimed.

The server determines that the volume is a candidate for reclamation if the percentage of reclaimable space on a volume is greater than the reclamation threshold of the storage pool.

By setting the reclaim value to 50 percent or greater, data that is moved from two reclaimed volumes uses no more than the equivalent of one new volume.

Use caution when you use reclamation with container-copy storage pools that have offsite volumes. When an offsite volume becomes eligible for reclamation, in effect the server moves the extents on the volume back to the onsite location. If a disaster occurs onsite, the server can obtain extents from the offsite volume if the restored database refers to extents on the offsite volume. Therefore, for disaster recovery purposes, ensure that you schedule database backups to run after storage pool protection schedules and DRM move schedules have run, and ensure that all database backup volumes are taken offsite along with the DRM volumes.

Tip: Set different reclamation values for offsite container-copy storage pools and onsite container-copy storage pools. Because container-copy storage pools store deduplicated data, the data extents are spread across multiple tape volumes. When you choose a reclamation threshold for an offsite copy, carefully consider the number of available mount points and the number of tape volumes that you must retrieve if a disaster occurs. Setting a higher threshold means that you must retrieve more volumes than you would if your reclamation value was lower. Using a lower threshold reduces the number of mount points that are required in a disaster. The preferred method is to set the reclamation value for offsite copies to 60, and for onsite copies, in the range 90 - 100.

RECLAIMLIMit

Specifies the maximum number of volumes that the server reclaims when you issue the PROTECT STGPOOL command and specify the RECLAIM=YESLIMITED or RECLAIM=ONLYLIMITED option. This parameter is valid only for container-copy storage pools. This parameter is optional. You can specify one of the following values:

NOLimit

Specifies that all volumes in the container-copy storage pool are processed for reclamation.

vol_limit
Specifies the maximum number of volumes in the container-copy storage pool that are reclaimed. The value that you specify determines how many new scratch tapes are available after reclamation processing completes. You can specify a number in the range 1 - 100000.

REUsedelay
Specifies the number of days that must elapse after all extents are deleted from a volume before the volume can be rewritten or returned to scratch status. This parameter is optional. You can specify an integer in the range 0 - 9999. A value of 0 means that a volume can be rewritten or returned to scratch status as soon as all the extents are deleted from the volume.
Tip: Use this parameter to ensure that when you restore the database to an earlier level, database references to extents in the storage pool are still valid. You must set this parameter to a value greater than the number of days you plan to retain the oldest database backup. If you use disaster recovery manager, the number of days that are specified for this parameter must be the same as the number specified for the SET DRMDBBACKUPEXPIREDAYS command.

Example: Update a container-copy storage pool to delay volume reuse for 30 days

Update the storage pool that is named CONTAINER1_COPY2 to change the delay for volume reuse to 30 days.

```
update stgpool container1_copy2 reusedelay=30
```

Example: Update a container-copy storage pool to limit the number of reclaimed tape volumes to 10

Update the storage pool that is named CONTAINER1_COPY2 to change the reclaim limit to 10 volumes.

```
update stgpool container1_copy2 reclaimlimit=10
```

Table 1. Commands related to UPDATE STGPOOL (Update a container-copy storage pool)

Command	Description
DEFINE STGPOOL (container-copy)	Define a container-copy storage pool that stores copies of data from a directory-container storage pool.
PROTECT STGPOOL	Protects a directory-container storage pool.
QUERY STGPOOL	Displays information about storage pools.
REPAIR STGPOOL	Repairs a directory-container storage pool.
UPDATE STGPOOL (directory-container)	Update a directory-container storage pool.

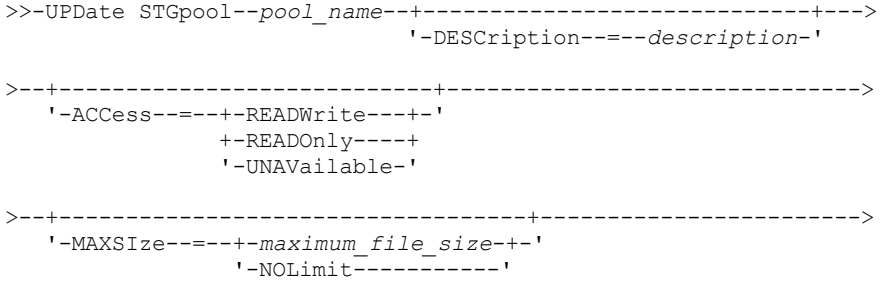
UPDATE STGPOOL (Update a primary random access storage pool)

Use this command to update a random access storage pool.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the storage pool to be updated.

Syntax



Parameters

pool_name (Required)
: Specifies the storage pool to update. This parameter is required.

DESCription
: Specifies a description of the storage pool. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters. To remove an existing description, specify a null string ("").

ACCess
: Specifies how client nodes and server processes (such as migration and reclamation) can access files in the storage pool. This parameter is optional. You can specify the following values:

  READWrite
  : Specifies that client nodes and server processes can read and write to files stored on volumes in the storage pool.

  READOnly
  : Specifies that client nodes can only read files from the volumes in the storage pool.

    Server processes can move files within the volumes in the storage pool. However, no new writes are permitted to volumes in the storage pool from volumes outside the storage pool.

    If this storage pool was specified as a subordinate storage pool (with the NEXTSTGPOOL parameter) and is defined as *readonly*, the storage pool is skipped when server processes attempt to write files to the storage pool.

  UNAVailable
  : Specifies that client nodes cannot access files stored on volumes in the storage pool.

    Server processes can move files within the volumes in the storage pool and can also move or copy files from this storage pool to another storage pool. However, no new writes are permitted to volumes in the storage pool from volumes outside the storage pool.

If this storage pool was specified as a subordinate storage pool (with the NEXTSTGPOOL parameter) and is defined as *unavailable*, the storage pool is skipped when server processes attempt to write files to the storage pool.

MAXSIze
Specifies the maximum size for a physical file that the server can store in the storage pool. This parameter is optional. You can specify the following values:

NOLimit
Specifies that there is no maximum size limit for physical files stored in the storage pool.

maximum_file_size
Limits the maximum physical file size. Specify an integer from 1 to 999999 terabytes, followed by a scale factor. For example, MAXSIZE=5G specifies that the maximum file size for this storage pool is 5 gigabytes. Scale factors are:

Scale factor	Meaning
K	kilobyte
M	megabyte
G	gigabyte
T	terabyte

The client estimates the size of files that are sent to the server. The client estimate is used rather than the actual amount of data that is sent to the server. Client options, such as deduplication, compression, and encryption, can cause the actual amount of data that is sent to the server to be larger or smaller than the size estimate. For example, the compression of a file might be smaller in size than the estimate, thus sending less data than the estimate. Furthermore, a binary file might be larger in size after the compression processing, thus sending more data than the estimate.

See the following table for information about where a file is stored when its size exceeds the MAXSIZE parameter.

Table 1. Where a file is stored according to the file size and the pool that is specified

File size	Pool specified	Result
Exceeds the maximum size	No pool is specified as the next storage pool in the hierarchy	The server does not store the file
	A pool is specified as the next storage pool in the hierarchy	The server stores the file in the next storage pool that can accept the file size

If you specify the next storage pool parameter, define one storage pool in your hierarchy to have no limit on the maximum file size. By having no limit on the size for at least one pool, you ensure that no matter what its size, the server can store the file.

For multiple files that are sent in a single transaction, the server considers the size of the transaction to be the file size. If the total size of all files in the transaction is larger than the maximum size limit, the server does not store the files in the storage pool.

CRCData
Specifies whether a cyclic redundancy check (CRC) validates storage pool data when audit volume processing occurs on the server. This parameter is optional. The default value is NO. By setting CRCDATA to YES and scheduling an AUDIT VOLUME command, you can continually ensure the integrity of data that is stored in your storage hierarchy. You can specify the following values:

Yes
Specifies that data is stored containing CRC information, allowing for audit volume processing to validate storage pool data. This mode impacts performance because more expenditure is required to calculate and compare CRC values between the storage pool and the server.

No
Specifies that data is stored without CRC information.

NEXTstgpool
Specifies a primary storage pool to which files are migrated. This parameter is optional.

To remove an existing storage pool from the storage hierarchy, specify a null string ("") for this value.

If you do not specify a next storage pool, the following actions occur:

- The server cannot migrate files from this storage pool
- The server cannot store files that exceed the maximum size for this storage pool in another storage pool

Restrictions:

- To ensure that you do not create a chain of storage pools that leads to an endless loop, specify at least one storage pool in the hierarchy with no value.
- If you specify a sequential-access pool as the next storage pool, the pool must be in either NATIVE or NONBLOCK data format.
- Do not specify a directory-container or cloud-container storage pool.
- Do not use this parameter to specify a storage pool for data migration.

HIghmig
: Specifies that the server starts migration for this storage pool when the amount of data in the pool reaches this percentage of the pool's estimated capacity. This parameter is optional. You can specify an integer 0 - 100.

When the storage pool exceeds the high migration threshold, the server can start migration of files by node to the next storage pool, as defined with the NEXTSTGPOOL parameter. You can specify HIGHMIG=100 to prevent migration for this storage pool.

LOwmig
: Specifies that the server stops migration for this storage pool when the amount of data in the pool reaches this percentage of the pool's estimated capacity. You can specify an integer 0 - 99 for this optional parameter.

When migration is by node or file space, depending upon collocation, the level of the storage pool can fall below the value that you specified for this parameter. To empty the storage pool, set LOWMIG=0.

CAChe
: Specifies whether the migration process leaves a cached copy of a file in this storage pool after you migrate the file to the next storage pool. This parameter is optional. You can specify the following values:

Yes
: Specifies that caching is enabled.

No
: Specifies that caching is disabled.

Using cache might improve your ability to retrieve files, but might affect the performance of other processes.

MIGPRocess
: Specifies the number of processes that are used for migrating files from this storage pool. This parameter is optional. You can specify an integer 1 - 999.

During migration, these processes are run in parallel to provide the potential for improved migration rates.

Tips:

- The number of migration processes is dependent upon the following settings:
  - The setting of the MIGPROCESS parameter
  - The collocation setting of the next pool
  - The number of nodes or the number of collocation groups with data in the storage pool that is being migrated

  For this example, `MIGPROCESS =6`, the next pool COLLOCATE parameter is NODE, but there are only two nodes with data on the storage pool. Migration processing consists of only two processes, not six. If the COLLOCATE parameter is GROUP group and both nodes are in the same group, migration processing consists of only one process. If the COLLOCATE parameter is NO or FILESPACE group, and each node has two file spaces with backup data, then migration processing consists of only four processes.
- When you specify this parameter, consider whether the simultaneous-write function is enabled for server data migration. Each migration process requires a mount point and a drive for each copy storage pool and active-data pool that is defined to the target storage pool.

MIGDelay
: Specifies the minimum number of days a file must remain in a storage pool before it becomes eligible for migration. To calculate a value to compare to the specified MIGDELAY value, the server counts the following items:

- The number of days that the file was in the storage pool
- The number of days, if any, since the file was retrieved by a client

The lesser of the two values are compared to the specified MIGDELAY value. For example, if all the following conditions are true, a file is not migrated:

- A file was in a storage pool for five days.
- The file was accessed by a client within the past three days.
- The value that is specified for the MIGDELAY parameter is four days.

This parameter is optional. You can specify an integer 0 - 9999. The default is 0, which means that you do not want to delay migration.

If you want the server to count the number of days that are based on when a file was stored and not when it was retrieved, use the NORETRIEVEDATE server option.

MIGContinue
Specifies whether you allow the server to migrate files that do not satisfy the migration delay time. This parameter is optional.

Because you can require that files remain in the storage pool for a minimum number of days, the server may migrate all eligible files to the next storage pool yet not meet the low migration threshold. This parameter allows you to specify whether the server is allowed to continue the migration process by migrating files that do not satisfy the migration delay time.

You can specify one of the following values:

Yes
Specifies that, when necessary to meet the low migration threshold, the server continues to migrate files that do not satisfy the migration delay time.

If you allow more than one migration process for the storage pool, some files that do not satisfy the migration delay time may be migrated unnecessarily. As one process migrates files that satisfy the migration delay time, a second process could begin migrating files that do not satisfy the migration delay time to meet the low migration threshold. The first process that is still migrating files that satisfy the migration delay time might have, by itself, caused the low migration threshold to be met.

No
Specifies that the server stops migration when no eligible files remain to be migrated, even before reaching the low migration threshold. The server does not migrate files unless the files satisfy the migration delay time.

AUTOCopy
Specifies when IBM Spectrum Protect™ runs simultaneous-write operations to copy storage pools and active-data pools. This parameter affects the following operations:

- Client store sessions
- Server import processes
- Server data-migration processes

If an error occurs while data is being simultaneously written to a copy storage pool or active-data pool during a migration process, the server stops writing to the failing storage pools for the remainder of the process. However, the server continues to store files into the primary storage pool and any remaining copy storage pools or active-data pools. These pools remain active for the duration of the migration process. Copy storage pools are specified using the COPYSTGPOOLS parameter. Active-data pools are specified using the ACTIVEDATAPOOLS parameter.

You can specify one of the following values:

None
Specifies that the simultaneous-write function is disabled.

CLient
Specifies that data is written simultaneously to copy storage pools and active-data pools during client store sessions or server import processes. During server import processes, data is written simultaneously to only copy storage pools. Data is not written to active-data pools during server import processes.

MIGRation
Specifies that data is written simultaneously to copy storage pools and active-data pools only during migration to this storage pool. During server data-migration processes, data is written simultaneously to copy storage pools and active-data pools only if the data does not exist in those pools. Nodes whose data is being migrated must be in a

domain associated with an active-data pool. If the nodes are not in a domain associated with an active pool, the data cannot be written to the pool.

All

Specifies that data is written simultaneously to copy storage pools and active-data pools during client store sessions, server import processes, or server data-migration processes. Specifying this value ensures that data is written simultaneously whenever this pool is a target for any of the eligible operations.

COPYSTGpools

Specifies the names of copy storage pools where the server simultaneously writes data. You can specify a maximum of three copy pool names that are separated by commas. Spaces between the names of the copy pools are not allowed. To add or remove one or more copy storage pools, specify the pool name or names that you want to include in the updated list. For example, if the existing copy pool list includes COPY1 and COPY2 and you want to add COPY3, specify COPYSTGPOOLS=COPY1,COPY2,COPY3. To remove all existing copy storage pools that are associated with the primary storage pool, specify a null string ("") for the value (for example, COPYSTGPOOLS="").

When you specify a value for the COPYSTGPOOLS parameter, you can also specify a value for the COPYCONTINUE parameter. For more information, see the COPYCONTINUE parameter.

The combined total number of storage pools that are specified in the COPYSGTPOOLS and ACTIVEDATAPOOLS parameters cannot exceed three.

When a data storage operation switches from a primary storage pool to a next storage pool, the next storage pool inherits the list of copy storage pools and the COPYCONTINUE value from the primary storage pool. The primary storage pool is specified by the copy group of the management class that is bound to the data.

The server can write data simultaneously to copy storage pools for the following operations:

- Back up and archive operations by IBM Spectrum Protect backup-archive clients or application clients that are using the IBM Spectrum Protect API
- Migration operations by IBM Spectrum Protect for Space Management clients
- Import operations that involve copying exported file data from external media to a primary storage pool associated with a copy storage pool list

Restrictions: The simultaneous-write function is not supported for the following store operations:

- When the operation is using LAN-free data movement. Simultaneous-write operations take precedence over LAN-free data movement, causing the operations to go over the LAN. However, the simultaneous-write configuration is accepted.
- NAS backup operations. If the primary storage pool specified in the DESTINATION or TOCDESTINATION in the copy group of the management class has copy storage pools that are defined:
  - The copy storage pools are ignored
  - The data is stored into the primary storage pool only

Attention: The function that is provided by the COPYSTGPOOLS parameter is not intended to replace the BACKUP STGPOOL command. If you use the COPYSTGPOOLS parameter, continue to use the BACKUP STGPOOL command to ensure that the copy storage pools are complete copies of the primary storage pool. There are cases when a copy might not be created. For more information, see the COPYCONTINUE parameter description.

COPYContinue

Specifies how the server reacts to a copy storage pool write failure for any of the copy storage pools that are listed in the COPYSTGPOOLS parameter. This parameter is optional. When you specify the COPYCONTINUE parameter, either a COPYSTGPOOLS list must exist or the COPYSTGPOOLS parameter must also be specified.
You can specify the following values:

Yes

If the COPYCONTINUE parameter is set to YES, the server will stop writing to the failing copy pools for the remainder of the session, but continue storing files into the primary pool and any remaining copy pools. The copy storage pool list is active only for the life of the client session and applies to all the primary storage pools in a particular storage pool hierarchy.

No

If the COPYCONTINUE parameter is set to NO, the server will fail the current transaction and discontinue the store operation.

Restrictions:

- The setting of the COPYCONTINUE parameter does not affect active-data pools. If a write failure occurs for any of the active-data pools, the server stops writing to the failing active-data pool for the remainder of the session, but continues storing files into the primary pool and any remaining active-data pools and copy storage pools. The active-data pool list is active only for the life of the session and applies to all the primary storage pools in a particular storage pool hierarchy.
- The setting of the COPYCONTINUE parameter does not affect the simultaneous-write function during server import. If data is being written simultaneously and a write failure occurs to the primary storage pool or any copy storage pool, the server import process fails.
- The setting of the COPYCONTINUE parameter does not affect the simultaneous-write function during server data migration. If data is being written simultaneously and a write failure occurs to any copy storage pool or active-data pool, the failing storage pool is removed and the data migration process continues. Write failures to the primary storage pool cause the migration process to fail.

ACTIVEDATApools
Specifies the names of active-data pools where the server simultaneously writes data during a client backup operation. The ACTIVEDATAPOOLS parameter is optional. Spaces between the names of the active-data pools are not allowed.

The combined total number of storage pools that are specified in the COPYSGTPOOLS and ACTIVEDATAPOOLS parameters cannot exceed three.

When a data storage operation switches from a primary storage pool to a next storage pool, the next storage pool inherits the list of active-data pools from the destination storage pool that is specified in the copy group. The primary storage pool is specified by the copy group of the management class that is bound to the data.

The server can write data simultaneously to active-data pools only during backup operations by IBM Spectrum Protect backup-archive clients or application clients that use the IBM Spectrum Protect API.
Restrictions:

1. This parameter is available only to primary storage pools that use "NATIVE" or "NONBLOCK" data format. This parameter is not available for storage pools that use the following data formats:
    - NETAPPDUMP
    - CELERRADUMP
    - NDMPDUMP
2. Writing data simultaneously to active-data pools is not supported when you use LAN-free data movement. Simultaneous-write operations take precedence over LAN-free data movement, causing the operations to go over the LAN. However, the simultaneous-write configuration is followed.
3. The simultaneous-write function is not supported when a NAS backup operation is writing a TOC file. If the primary storage pool specified in the TOCDESTINATION in the copy group of the management class has active-data pools that are defined:
    - The active-data pools are ignored
    - The data is stored into the primary storage pool only
4. You cannot use the simultaneous-write function with CENTERA storage devices.
5. Data that is being imported is not stored in active-data pools. After an import operation, use the COPY ACTIVEDATA command to store the imported data in an active-data pool.

Attention: The function that is provided by the ACTIVEDATAPOOLS parameter is not intended to replace the COPY ACTIVEDATA command. If you use the ACTIVEDATAPOOLS parameter, use the COPY ACTIVEDATA command to ensure that the active-data pools contain all active data of the primary storage pool.

SHRED
Specifies whether data is physically overwritten when it is deleted. This parameter is optional. You can specify an integer 0 - 10.

If you specify a value of zero, the server deletes the data from the database. However, the storage that is used to contain the data is not overwritten, and the data exists in storage until that storage is reused for other data. It might be possible to discover and reconstruct the data after it is deleted. Changing the value (for example, resetting it to 0) does not affect data that was deleted and is waiting to be overwritten.

If you specify a value greater than 0, the server deletes the data both logically and physically. The server overwrites the storage that is used to contain the data the specified number of times. This overwriting increases the difficulty of discovering and reconstructing the data after it is deleted.

To ensure that all copies of the data are shredded, specify a SHRED value greater than zero for the storage pool that is specified in the NEXTSTGPOOL parameter. Do not specify either the COPYSTGPOOLS or ACTIVEDATAPOOLS. Specifying

relatively high values for the overwrite count generally improves the level of security, but might affect performance adversely.

Overwriting of deleted data is done asynchronously after the delete operation is complete. Therefore, the space that is occupied by the deleted data remains occupied for some time. The space is not available as free space for new data.

A SHRED value greater than zero cannot be used if the value of the CACHE parameter is YES. If you want to enable shredding for an existing storage pool for which caching is already enabled, you must change the value of the CACHE parameter to NO. Existing cached files remain in storage so that subsequent retrieval requests can be satisfied quickly. If space is needed to store new data, the existing cached files are erased so that the space they occupied can be used for the new data. The existing cached files are not shredded when they are erased.
Important: After an export operation finishes and identifies files for export, any change to the storage pool SHRED value is ignored. An export operation that is suspended retains the original SHRED value throughout the operation. You might want to consider canceling your export operation if changes to the storage pool SHRED value jeopardize the operation. You can reissue the export command after any needed cleanup.

Example: Update a random access storage pool to allow caching

Update the random access storage pool that is named BACKUPPOOL to allow caching when the server migrates files to the next storage pool.

```
update stgpool backuppool cache=yes
```

UPDATE STGPOOL (Update a primary sequential access pool)

Use this command to update a primary sequential access storage pool.

Restrictions:

1. You cannot use this command to change the data format for the storage pool.
2. If the value for DATAFORMAT is NETAPPDUMP, CELERRADUMP, or NDMPDUMP, you can modify only the following attributes:
   - DESCRIPTION
   - ACCESS
   - COLLOCATE
   - MAXSCRATCH
   - REUSEDELAY

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the storage pool to be updated.

Notes:

1. This parameter is not available for storage pools that use the data formats NETAPPDUMP, CELERRADUMP, or NDMPDUMP.
2. This parameter is not available for CENTERA storage pools.
3. This parameter is valid only for storage pools that are defined with a FILE-type device class.
4. This parameter is only available if the value of the DEDUPLICATE parameter is YES.

Parameters

pool_name (Required)
: Specifies the name of the storage pool to be updated.

DESCription
: Specifies a description of the storage pool. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters. To remove an existing description, specify a null string ("").

ACCess
: Specifies how client nodes and server processes (such as migration and reclamation) can access files in the storage pool. This parameter is optional. You can specify the following values:

  READWrite
  : Specifies that client nodes and server processes can read and write to files stored on volumes in the storage pool.

  READOnly
  : Specifies that client nodes can only read files from the volumes in the storage pool.

    Server processes can move files within the volumes in the storage pool. However, no new writes are permitted to volumes in the storage pool from volumes outside the storage pool.

    If this storage pool was specified as a subordinate storage pool (with the NEXTSTGPOOL parameter) and is defined as *readonly*, the storage pool is skipped when server processes attempt to write files to the storage pool.

  UNAVailable
  : Specifies that client nodes cannot access files stored on volumes in the storage pool.

    Server processes can move files within the volumes in the storage pool and can also move or copy files from this storage pool to another storage pool. However, no new writes are permitted to volumes in the storage pool from volumes outside the storage pool.

    If this storage pool was specified as a subordinate storage pool (with the NEXTSTGPOOL parameter) and is defined as *unavailable*, the storage pool is skipped when server processes attempt to write files to the storage pool.

MAXSIze
: Specifies the maximum size for a physical file that the server can store in the storage pool. This parameter is optional. You can specify the following values:

  NOLimit
  : Specifies that there is no maximum size limit for physical files stored in the storage pool.

  maximum_file_size
  : Limits the maximum physical file size. Specify an integer from 1 to 999999 terabytes, followed by a scale factor. For example, MAXSIZE=5G specifies that the maximum file size for this storage pool is 5 gigabytes. Scale factors are:

Scale factor	Meaning
K	kilobyte
M	megabyte
G	gigabyte
T	terabyte

The client estimates the size of files that are sent to the server. The client estimate is used rather than the actual amount of data that is sent to the server. Client options, such as deduplication, compression, and encryption, can cause the actual amount of data that is sent to the server to be larger or smaller than the size estimate. For example, the compression of a file might be smaller in size than the estimate, thus sending less data than the estimate. Furthermore, a binary file might be larger in size after the compression processing, thus sending more data than the estimate.

When the physical size of the storage pool exceeds the MAXSIZE parameter, the following table shows where files are typically stored.

Table 1. The location of a file according to the file size and the pool that is specified

File size	Pool specified	Result
Exceeds the maximum size	No pool is specified as the next storage pool in the hierarchy	The server does not store the file
	A pool is specified as the next storage pool in the hierarchy	The server stores the file in the next storage pool that can accept the file size

Tip: If you also specify the NEXTstgpool parameter, define one storage pool in your hierarchy to have no limit on the maximum file size by specifying the MAXSIze=NOLimit parameter. When you have at least one pool with no size limit, you ensure that no matter what its size, the server can store the file.

For multiple files that are sent in a single transaction, the server considers the size of the transaction to be the file size. If the total size of all files in the transaction is larger than the maximum size limit, the server does not store the files in the storage pool.

Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

CRCData

Specifies whether a cyclic redundancy check (CRC) validates storage pool data when audit volume processing occurs on the server. This parameter is only valid for NATIVE data format storage pools. This parameter is optional. The default value is NO. By setting CRCDATA to YES and scheduling an AUDIT VOLUME command, you can continually ensure the integrity of data that is stored in your storage hierarchy. You can specify the following values:

Yes
: Specifies that data is stored containing CRC information, allowing for audit volume processing to validate storage pool data. This mode impacts performance because more processing is required to calculate and compare CRC values between the storage pool and the server.

No
: Specifies that data is stored without CRC information.

Tip:

For storage pools that are associated with the 3592, LTO, or ECARTRIDGE device type, logical block protection provides better protection against data corruption than CRC validation for a storage pool. If you specify CRC validation for a storage pool, data is validated only during volume auditing operations. Errors are identified after data is written to tape.

To enable logical block protection, specify a value of READWRITE for the LBPROTECT parameter on the DEFINE DEVCLASS and UPDATE DEVCLASS commands for the 3592, LTO, or ECARTRIDGE device types. Logical block protection is supported only on the following types of drives and media:

- IBM® LTO5 and later.
- IBM 3592 Generation 3 drives and later with 3592 Generation 2 media and later.
- Oracle StorageTek T10000C and T10000D drives.

NEXTstgpool

Specifies a primary storage pool to which files are migrated. You cannot migrate data from a sequential access storage pool to a random access storage pool. This parameter is optional. The next storage pool must be a primary storage pool.

To remove an existing value, specify a null string ("").

If this storage pool does not have a next storage pool, the server cannot migrate files from this storage pool and cannot store files that exceed the maximum size for this storage pool in another storage pool.

When there is insufficient space available in the current storage pool, the NEXTSTGPOOL parameter for sequential access storage pools does not allow data to be stored into the next pool. In this case, the server issues a message and the transaction fails.

For next storage pools with a device type of FILE, the server completes a preliminary check to determine whether sufficient space is available. If space is not available, the server skips to the next storage pool in the hierarchy. If space is available, the server attempts to store data in that pool. However, it is possible that the storage operation might fail because, at the time the actual storage operation is attempted, the space is no longer available.

Restrictions:

- To ensure that you do not create a chain of storage pools that leads to an endless loop, specify at least one storage pool in the hierarchy with no value.
- If you specify a sequential-access pool as the next storage pool, the pool must be in either NATIVE or NONBLOCK data format.
- Do not specify a directory-container or cloud-container storage pool.
- Do not use this parameter to specify a storage pool for data migration.
- This parameter is not available for storage pools that use the following data formats:
  - NETAPPDUMP
  - CELERRADUMP
  - NDMPDUMP

HIghmig
: Specifies that the server starts migration when storage pool utilization reaches this percentage. For sequential-access disk (FILE) storage pools, utilization is the ratio of data in a storage pool to the pool's total estimated data capacity, including the capacity of all scratch volumes specified for the pool. For storage pools that use tape media, utilization is the ratio of volumes that contain data to the total number of volumes in the storage pool. The total number of volumes includes the maximum number of scratch volumes. This parameter is optional. You can specify an integer 0 - 100.

  When the storage pool exceeds the high migration threshold, the server can start migration of files by volume to the next storage pool defined for the storage pool. You can set the high migration threshold to 100 to prevent migration for the storage pool.

  Restriction: This parameter is not available for storage pools that use the following data formats:

  - NETAPPDUMP
  - CELERRADUMP
  - NDMPDUMP

LOwmig
: Specifies that the server stops migration when storage pool utilization is at or below this percentage. For sequential-access disk (FILE) storage pools, utilization is the ratio of data in a storage pool to the pool's total estimated data capacity, including the capacity of all scratch volumes specified for the pool. For storage pools that use tape media, utilization is the ratio of volumes that contain data to the total number of volumes in the storage pool. The total number of volumes includes the maximum number of scratch volumes. This parameter is optional. You can specify an integer 0 - 99.

  When the storage pool reaches the low migration threshold, the server does not start migration of files from another volume. You can set the low migration threshold to 0 to allow migration to empty the storage pool.

  Restriction: This parameter is not available for storage pools that use the following data formats:

  - NETAPPDUMP
  - CELERRADUMP
  - NDMPDUMP

RECLaim
: Specifies when the server reclaims a volume, which is based on the percentage of reclaimable space on a volume. Reclaimable space is the amount of space that is occupied by files that are expired or deleted from the IBM Spectrum Protect™ database.

  Reclamation makes the fragmented space on volumes usable again by moving any remaining unexpired files from one volume to another volume, thus making the original volume available for reuse. This parameter is optional. You can specify an integer 1 - 100.

The server determines that the volume is a candidate for reclamation if the percentage of reclaimable space on a volume is greater than the reclamation threshold of the storage pool.

Specify a value of 50 percent or greater for this parameter so that files stored on two volumes can be combined onto a single output volume.

AIX Windows For storage pools that use a WORM device class, you can lower the value from the default of 100. Lowering the value allows the server to consolidate data onto fewer volumes when needed. Volumes that are emptied by reclamation can be checked out of the library, freeing slots for new volumes. Because the volumes are write-once, the volumes cannot be reused.

Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

RECLAIMPRocess
Specifies the number of parallel processes to use for reclaiming the volumes in this storage pool. This parameter is optional. Enter a value 1 - 999. You can specify one or more reclamation processes for each primary sequential-access storage pool.
When you calculate the value for this parameter, consider the following resources that are required for reclamation processing:

- The number of sequential storage pools.
- The number of logical and physical drives that can be dedicated to the operation.

To access sequential volumes, IBM Spectrum Protect uses a mount point and, if the device type is not FILE, a physical drive.

For example, suppose that you want to reclaim the volumes from two sequential storage pools simultaneously and that you want to specify four processes for each of the storage pools. The storage pools have the same device class. Assuming that the RECLAIMSTGPOOL parameter is not specified or that the reclaim storage pool has the same device class as the storage pool that is being reclaimed, each process requires two mount points and, if the device type is not FILE, two drives. (One of the drives is for the input volume, and the other drive is for the output volume.) To run eight reclamation processes simultaneously, you need a total of at least 16 mount points and 16 drives. The device class for the two storage pools must have a mount limit of at least 16.

Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

RECLAIMSTGpool
Specifies another primary storage pool as a target for reclaimed data from this storage pool. This parameter is optional. When the server reclaims volumes for the storage pool, unexpired data is moved from the volumes that are being reclaimed to the storage pool named with this parameter.

To remove an existing value, specify a null string ("").

A reclaim storage pool is most useful for a storage pool that has only one drive in its library. When you specify this parameter, the server moves all data from reclaimed volumes to the reclaim storage pool regardless of the number of drives in the library.

To move data from the reclaim storage pool back to the original storage pool, use the storage pool hierarchy. Specify the original storage pool as the next storage pool for the reclaim storage pool.

Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

COLlocate

Specifies whether the server attempts to keep data, which is stored on as few volumes as possible, that belong to one of the following candidates:

- A single client node
- A group of file spaces
- A group of client nodes
- A client file space

This parameter is optional.

Collocation reduces the number of sequential access media mounts for restore, retrieve, and recall operations. However, collocation increases both the amount of server time that is needed to collocate files for storing and the number of volumes required. Collocation can also impact the number of processes that are migrating disks to sequential pool.

You can specify one of the following options:

No
: Specifies that collocation is disabled. During migration from disk, processes are created at a file space level.

GRoup
: Specifies that collocation is enabled at the group level for client nodes or file spaces. For collocation groups, the server attempts to put data for nodes or file spaces that belong to the same collocation group on as few volumes as possible.

  If you specify COLLOCATE=GROUP but do not define any collocation groups, or if you do not add nodes or file spaces to a collocation group, data is collocated by node. Consider tape usage when you organize client nodes or file spaces into collocation groups.

  For example, if a tape-based storage pool consists of data from nodes and you specify COLLOCATE=GROUP, the server completes the following actions:

  - Collocates the data by group for grouped nodes. Whenever possible, the server collocates data that belongs to a group of nodes on a single tape or on as few tapes as possible. Data for a single node can also be spread across several tapes that are associated with a group.
  - Collocates the data by node for ungrouped nodes. Whenever possible, the server stores the data for a single node on a single tape. All available tapes that already have data for the node are used before available space on any other tape is used.
  - During migration from disk, the server creates migration processes at the collocation group level for grouped nodes, and at the node level for ungrouped nodes.

  If a tape-based storage pool consists of data from grouped file spaces and you specify COLLOCATE=GROUP, the server completes the following actions:

  - Collocates by group, the data for grouped file spaces only. Whenever possible, the server collocates data that belongs to a group of file spaces on a single tape or on as few tapes as possible. Data for a single file space can also be spread across several tapes that are associated with a group.
  - Collocates the data by node (for file spaces that are not explicitly defined to a file space collocation group). For example, node1 has file spaces that are named A, B, C, D, and E. File spaces A and B belong to a file space collocation group but C, D, and E do not. File spaces A and B are collocated by file space collocation group, while C, D, and E are collocated by node.
  - During migration from disk, the server creates migration processes at the collocation group level for grouped file spaces.

  Data is collocated on the least number of sequential access volumes.

NODe
: Specifies that collocation is enabled at the client node level. For collocation groups, the server attempts to put data for one node on as few volumes as possible. If the node has multiple file spaces, the server does not try to collocate those file spaces. For compatibility with an earlier version, COLLOCATE=YES is still accepted by the server to specify collocation at the client node level.

  If a storage pool contains data for a node that is a member of a collocation group and you specify COLLOCATE=NODE, the data is collocated by node.

  For COLLOCATE=NODE, the server creates processes at the node level when you migrate data from disk.

FIlespace

Specifies that collocation is enabled at the file space level for client nodes. The server attempts to place data for one node and file space on as few volumes as possible. If a node has multiple file spaces, the server attempts to place data for different file spaces on different volumes.

For COLLOCATE=FILESPACE, the server creates processes at the file space level when you migrate data from disk.

MAXSCRatch
Specifies the maximum number of scratch volumes that the server can request. This parameter is optional. You can specify an integer 0 - 100000000. By allowing the server to request scratch volumes, you avoid having to define each volume to be used.

The value that is specified for this parameter is used to estimate the total number of volumes available in the storage pool and the corresponding estimated capacity for the storage pool.

Scratch volumes are automatically deleted from the storage pool when they become empty. When scratch volumes with the device type of FILE are deleted, the space that the volumes occupied is freed by the server and returned to the file system.

Tip: For server-to-server operations that use virtual volumes and that store a small amount of data, consider specifying a value for the MAXSCRATCH parameter that is higher than the value you typically specify for write operations to other types of volumes. After a write operation to a virtual volume, IBM Spectrum Protect marks the volume as FULL, even if the value of the MAXCAPACITY parameter on the device-class definition is not reached. The server does not keep virtual volumes in FILLING status and does not append to them. If the value of the MAXSCRATCH parameter is too low, server-to-server operations can fail.

REUsedelay
Specifies the number of days that must elapse after all files are deleted from a volume before the volume can be rewritten or returned to the scratch pool. This parameter is optional. You can specify an integer 0 - 9999. The value 0 means that a volume can be rewritten or returned to the scratch pool as soon as all files are deleted from the volume.

By specifying this parameter, you can ensure that the database can be restored to an earlier level and database references to files in the storage pool would still be valid.

OVFLOcation
Specifies the overflow location for the storage pool. The server assigns this location name to a volume that is ejected from the library by the MOVE MEDIA command. This parameter is optional. The location name can be a maximum length of 255 characters. Enclose the location name in quotation marks if the location name contains any blank characters.

To remove an existing value, specify a null string ("").

Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

MIGDelay
Specifies the minimum number of days a file must remain in a storage pool before it becomes eligible for migration. All files on a volume must be eligible for migration before the server selects the volume for migration. To calculate a value to compare to the specified MIGDELAY, the server counts the number of days that the file has been in the storage pool.

This parameter is optional. You can specify an integer 0 - 9999.

If you want the server to count the number of days that are based only on when a file was stored and not when it was retrieved, use the NORETRIEVEDATE server option.

Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

MIGContinue
Specifies whether you allow the server to migrate files that do not satisfy the migration delay time. This parameter is optional.

Because you can require that files remain in the storage pool for a minimum number of days, the server may migrate all eligible files to the next storage pool yet not meet the low migration threshold. This parameter allows you to specify whether the server is allowed to continue migration by migrating files that do not satisfy the migration delay time.

You can specify one of the following values:

Yes
: Specifies that, when necessary to meet the low migration threshold, the server continues to migrate files that have not been stored in the storage pool for the number of days specified by the migration delay period.

No
: Specifies that the server stops migration when no eligible files remain to be migrated, even before reaching the low migration threshold. The server does not migrate files unless the files have been stored in the storage pool for the number of days specified by the migration delay period.

Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

MIGPRocess
: Specifies the number of parallel processes to use for migrating the files from the volumes in this storage pool. This parameter is optional. Enter a value 1 - 999.

When calculating the value for this parameter, consider the number of sequential storage pools that will be involved with the migration, and the number of logical and physical drives that can be dedicated to the operation. To access a sequential-access volume, IBM Spectrum Protect uses a mount point and, if the device type is not FILE, a physical drive. The number of available mount points and drives depends on other IBM Spectrum Protect and system activity and on the mount limits of the device classes for the sequential access storage pools that are involved in the migration.

For example, suppose you want to simultaneously migrate the files from volumes in two primary sequential storage pools and that you want to specify three processes for each of the storage pools. The storage pools have the same device class. Assuming that the storage pool to which files are being migrated has the same device class as the storage pool from which files are being migrated, each process requires two mount points and, if the device type is not FILE, two drives. (One drive is for the input volume, and the other drive is for the output volume.) To run six migration processes simultaneously, you need a total of at least 12 mount points and 12 drives. The device class for the storage pools must have a mount limit of at least 12.

If the number of migration processes you specify is more than the number of available mount points or drives, the processes that do not obtain mount points or drives will wait for mount points or drives to become available. If mount points or drives do not become available within the MOUNTWAIT time, the migration processes will end. For information about specifying the MOUNTWAIT time, see DEFINE DEVCLASS (Define a device class).

The IBM Spectrum Protect server will start the specified number of migration processes regardless of the number of volumes that are eligible for migration. For example, if you specify ten migration processes and only six volumes are eligible for migration, the server will start ten processes and four of them will complete without processing a volume.

Note: When you specify this parameter, consider whether the simultaneous-write function is enabled for server data migration. Each migration process requires a mount point and a drive for each copy storage pool and active-data pool that is defined to the target storage pool.

AUTOCopy
: Specifies when IBM Spectrum Protect completes simultaneous-write operations. This parameter affects the following operations:

- Client store sessions
- Server import processes
- Server data-migration processes

If the AUTOCOPY option is set to `ALL` or `CLIENT`, and there is at least one storage pool that is listed in the COPYSTGPOOLS or ACTIVEDATAPOOLS options, any client-side deduplication is disabled.

If an error occurs while data is being simultaneously written to a copy storage pool or active-data pool during a migration process, the server stops writing to the failing storage pools for the remainder of the process. However, the server continues to store files into the primary storage pool and any remaining copy storage pools or active-data pools. These

pools remain active for the duration of the migration process. Copy storage pools are specified using the COPYSTGPOOLS parameter. Active-data pools are specified using the ACTIVEDATAPOOLS parameter.

You can specify one of the following values:

None
: Specifies that the simultaneous-write function is disabled.

CLient
: Specifies that data is written simultaneously to copy storage pools and active-data pools during client store sessions or server import processes. During server import processes, data is written simultaneously to only copy storage pools. Data is not written to active-data pools during server import processes.

MIGRation
: Specifies that data is written simultaneously to copy storage pools and active-data pools only during migration to this storage pool. During server data-migration processes, data is written simultaneously to copy storage pools and active-data pools only if the data does not exist in those pools. Nodes whose data is being migrated must be in a domain associated with an active-data pool. If the nodes are not in a domain associated with an active pool, the data cannot be written to the pool.

All
: Specifies that data is written simultaneously to copy storage pools and active-data pools during client store sessions, server import processes, or server data-migration processes. Specifying this value ensures that data is written simultaneously whenever this pool is a target for any of the eligible operations.

COPYSTGpools
: Specifies the names of copy storage pools where the server simultaneously writes data. You can specify a maximum of three copy pool names that are separated by commas. Spaces between the names of the copy pools are not allowed. To add or remove one or more copy storage pools, specify the pool name or names that you want to include in the updated list. For example, if the existing copy pool list includes COPY1 and COPY2 and you want to add COPY3, specify COPYSTGPOOLS=COPY1,COPY2,COPY3. To remove all existing copy storage pools that are associated with the primary storage pool, specify a null string ("") for the value (for example, COPYSTGPOOLS="").

  When you specify a value for the COPYSTGPOOLS parameter, you can also specify a value for the COPYCONTINUE parameter. For more information, see the COPYCONTINUE parameter.

  The combined total number of storage pools that are specified in the COPYSGTPOOLS and ACTIVEDATAPOOLS parameters cannot exceed three.

  When a data storage operation switches from a primary storage pool to a next storage pool, the next storage pool inherits the list of copy storage pools and the COPYCONTINUE value from the primary storage pool. The primary storage pool is specified by the copy group of the management class that is bound to the data.

  The server can write data simultaneously to copy storage pools during the following operations:

  - Back up and archive operations by IBM Spectrum Protect backup-archive clients or application clients that use the IBM Spectrum Protect API
  - Migration operations by IBM Spectrum Protect for Space Management clients
  - Import operations that involve copying exported file data from external media to a primary storage pool associated with a copy storage pool list

  Restrictions:

  1. This parameter is available only to primary storage pools that use NATIVE or NONBLOCK data format. This parameter is not available for storage pools that use the following data formats:
     - NETAPPDUMP
     - CELERRADUMP
     - NDMPDUMP
  2. Simultaneous-write operations takes precedence over LAN-free data movement, causing the operations to go over the LAN. However, the simultaneous-write configuration is accepted.
  3. The simultaneous-write function is not supported for NAS backup operations. If the primary storage pool specified in the DESTINATION or TOCDESTINATION in the copy group of the management class has copy storage pools defined, the copy storage pools are ignored and the data is stored into the primary storage pool only.
  4. You cannot use the simultaneous-write function with CENTERA storage devices.

  Attention: The function that is provided by the COPYSTGPOOLS parameter is not intended to replace the BACKUP STGPOOL command. If you use the COPYSTGPOOLS parameter, continue to use the BACKUP STGPOOL command to ensure that the

copy storage pools are complete copies of the primary storage pool. There are cases when a copy might not be created. For more information, see the COPYCONTINUE parameter description.

COPYContinue

Specifies how the server reacts to a copy storage pool write failure for any of the copy storage pools that are listed in the COPYSTGPOOLS parameter. This parameter is optional. The default is YES. When you specify the COPYCONTINUE parameter, either a COPYSTGPOOLS list must exist or the COPYSTGPOOLS parameter must also be specified.

The COPYCONTINUE parameter has no effect on the simultaneous-write function during migration.

You can specify the following values:

Yes

If the COPYCONTINUE parameter is set to YES, the server will stop writing to the failing copy pools for the remainder of the session, but continue storing files into the primary pool and any remaining copy pools. The copy storage pool list is active only for the life of the client session and applies to all the primary storage pools in a particular storage pool hierarchy.

No

If the COPYCONTINUE parameter is set to NO, the server will fail the current transaction and discontinue the store operation.

Restrictions:

- The setting of the COPYCONTINUE parameter does not affect active-data pools. If a write failure occurs for any of the active-data pools, the server stops writing to the failing active-data pool for the remainder of the session, but continues storing files into the primary pool and any remaining active-data pools and copy storage pools. The active-data pool list is active only for the life of the session and applies to all the primary storage pools in a particular storage pool hierarchy.
- The setting of the COPYCONTINUE parameter does not affect the simultaneous-write function during server import. If data is being written simultaneously and a write failure occurs to the primary storage pool or any copy storage pool, the server import process fails.
- The setting of the COPYCONTINUE parameter does not affect the simultaneous-write function during server data migration. If data is being written simultaneously and a write failure occurs to any copy storage pool or active-data pool, the failing storage pool is removed and the data migration process continues. Write failures to the primary storage pool cause the migration process to fail.

ACTIVEDATApools

Specifies the names of active-data pools where the server simultaneously writes data during a client backup operation. The ACTIVEDATAPOOLS parameter is optional. Spaces between the names of the active-data pools are not allowed.

The combined total number of storage pools that are specified in the COPYSGTPOOLS and ACTIVEDATAPOOLS parameters cannot exceed three.

When a data storage operation switches from a primary storage pool to a next storage pool, the next storage pool inherits the list of active-data pools from the destination storage pool specified in the copy group. The primary storage pool is specified by the copy group of the management class that is bound to the data.

The server can write data simultaneously to active-data pools only during backup operations by IBM Spectrum Protect backup-archive clients or application clients that use the IBM Spectrum Protect API.
Restrictions:

1. This parameter is available only to primary storage pools that use NATIVE or NONBLOCK data format. This parameter is not available for storage pools that use the following data formats:
   - NETAPPDUMP
   - CELERRADUMP
   - NDMPDUMP
2. Writing data simultaneously to active-data pools is not supported when the operation is using LAN-free data movement. Simultaneous-write operations take precedence over LAN-free data movement, causing the operations to go over the LAN. However, the simultaneous-write configuration is accepted.
3. The simultaneous-write function is not supported when a NAS backup operation is writing a TOC file. If the primary storage pool specified in the TOCDESTINATION in the copy group of the management class has active-data pools defined, the active-data pools are ignored and the data is stored into the primary storage pool only.
4. You cannot use the simultaneous-write function with CENTERA storage devices.
5. Data being imported cannot be stored in active-data pools. After an import operation, use the COPY ACTIVEDATA command to store the imported data in an active-data pool.

Attention: The function that is provided by the ACTIVEDATAPOOLS parameter is not intended to replace the COPY ACTIVEDATA command. If you use the ACTIVEDATAPOOLS parameter, use the COPY ACTIVEDATA command to ensure that the active-data pools contain all active data of the primary storage pool.

DEDUPlicate
: Specifies whether the data that is stored in this storage pool is deduplicated. This parameter is optional and is valid only for storage pools that are defined with a FILE device class.

IDENTIFYPRocess
: Specifies the number of parallel processes to use for server-side data deduplication. This parameter is optional and is valid only for storage pools that are defined with a device class associated with the FILE device type. Enter a value 1 - 50.
Remember: Data deduplication processes can be either active or idle. Processes that are working on files are active. Processes that are waiting for files to work on are idle. Processes remain idle until volumes with data to be deduplicated become available. The output of the QUERY PROCESS command for data deduplication includes the total number of bytes and files that have been processed since the process first started. For example, if a data deduplication process processes four files, becomes idle, and then processes five more files, then the total number of files processed is nine. Processes end only when canceled or when the number of data-deduplication processes for the storage pool is changed to a value less than the number currently specified.

Example: Update the primary sequential storage pool's mountable scratch volumes

Update the primary sequential storage pool that is named TAPEPOOL1 to allow as many as 10 scratch volumes to be mounted.

```
update stgpool tapepool1 maxscratch=10
```

UPDATE STGPOOL (Update a copy sequential access storage pool)

Use this command to update a copy sequential access storage pool.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the storage pool to be updated.

Syntax

```
>>-UPDate STGpool--pool_name--+-----------------------------+--->
                              '-DESCription--=--description-'

>--+----------------------------+------------------------------->
   '-ACCess--=--+-READWrite---+-'
                +-READOnly----+
                '-UNAVailable-'

>--+--------------------------+--+--------------------+-------->
   '-OVFLOcation--=--location-'  '-CRCData--=--+-Yes-+-'
                                              '-No--'

>--+-----------------------------+----------------------------->
   '-DEDUPlicate--=--+-No------+-'
                     |      (1) |
                     '-Yes-----'
```

```
>--+-------------------------------+-------------------------><
   |                           (2) |
   '-IDENTIFYPRocess--=--number-----'
```

Notes:

1. This parameter is valid only for storage pools that are defined with a FILE-type device class.
2. This parameter is only available if the value of the DEDUPLICATE parameter is YES.

Parameters

pool_name (Required)
: Specifies the name of the copy storage pool to be updated.

DESCription
: Specifies a description of the copy storage pool. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters. To remove an existing description, specify a null string ("").

ACCess
: Specifies how client nodes and server processes (such as reclamation) can access files in the copy storage pool. This parameter is optional. You can specify the following values:

  READWrite
  : Specifies that files can be read from and written to the volumes in the copy storage pool.

  READOnly
  : Specifies that client nodes can read only files that are stored on the volumes in the copy storage pool.

    Server processes can move files within the volumes in the storage pool. The server can use files in the copy storage pool to restore files to primary storage pools. However, no new writes are allowed to volumes in the copy storage pool from volumes outside the storage pool. A storage pool cannot be backed up to the copy storage pool.

  UNAVailable
  : Specifies that client nodes cannot access files that are stored on volumes in the copy storage pool.

    Server processes can move files within the volumes in the storage pool. The server can use files in the copy storage pool to restore files to primary storage pools. However, no new writes are allowed to volumes in the copy storage pool from volumes outside the storage pool. A storage pool cannot be backed up to the copy storage pool.

COLlocate
: Specifies whether the server attempts to keep data, which is stored on as few volumes as possible, that belong to one of the following candidates:

  - A single client node
  - A group of file spaces
  - A group of client nodes
  - A client file space

  This parameter is optional.

  Collocation reduces the number of sequential access media mounts for restore, retrieve, and recall operations. However, collocation increases both the amount of server time that is needed to collocate files for storing and the number of volumes required.

  You can specify one of the following options:

  No
  : Specifies that collocation is disabled.

  GRoup
  : Specifies that collocation is enabled at the group level for client nodes or file spaces. For collocation groups, the server attempts to put data for nodes or file spaces that belong to the same collocation group on as few volumes as possible.

    If you specify COLLOCATE=GROUP but do not define any collocation groups, or if you do not add nodes or file spaces to a collocation group, data is collocated by node. Consider tape usage when you organize client nodes or file spaces into collocation groups.

For example, if a tape-based storage pool consists of data from nodes and you specify COLLOCATE=GROUP, the server completes the following actions:

- Collocates the data by group for grouped nodes. Whenever possible, the server collocates data that belongs to a group of nodes on a single tape or on as few tapes as possible. Data for a single node can also be spread across several tapes that are associated with a group.
- Collocates the data by node for ungrouped nodes. Whenever possible, the server stores the data for a single node on a single tape. All available tapes that already have data for the node are used before available space on any other tape is used.

If a tape-based storage pool consists of data from grouped file spaces and you specify COLLOCATE=GROUP, the server completes the following actions:

- Collocates by group, the data for grouped file spaces only. Whenever possible, the server collocates data that belongs to a group of file spaces on a single tape or on as few tapes as possible. Data for a single file space can also be spread across several tapes that are associated with a group.
- Collocates the data by node (for file spaces that are not explicitly defined to a file space collocation group). For example, node1 has file spaces named A, B, C, D, and E. File spaces A and B belong to a filespace collocation group but C, D, and E do not. File spaces A and B are collocated by filespace collocation group, while C, D, and E are collocated by node.

Data is collocated on the least amount of sequential access volumes.

NODe
: Specifies that collocation is enabled at the client node level. For collocation groups, the server attempts to put data for one node on as few volumes as possible. If the node has multiple file spaces, the server does not try to collocate those file spaces. For compatibility with an earlier version, COLLOCATE=YES is still accepted by the server to specify collocation at the client node level.

  If a storage pool contains data for a node that is a member of a collocation group and you specify COLLOCATE=NODE, the data is collocated by node.

FIlespace
: Specifies that collocation is enabled at the file space level for client nodes. The server attempts to place data for one node and file space on as few volumes as possible. If a node has multiple file spaces, the server attempts to place data for different file spaces on different volumes.

REClaim
: Specifies when the server reclaims a volume, which is based on the percentage of reclaimable space on a volume. Reclaimable space is the amount of space that is occupied by files that are expired or deleted from the IBM Spectrum Protect™ database.

  Reclamation makes the fragmented space on volumes usable again by moving any remaining active files from one volume to another volume, thus making the original volume available for reuse. This parameter is optional. You can specify an integer 1 - 100. The value 100 means that reclamation is not completed.

  The server determines that the volume is a candidate for reclamation if the percentage of reclaimable space on a volume is greater than the reclamation threshold of the storage pool.

  If you change the value from the default of 100, specify a value of 50 percent or greater so that files stored on two volumes can be combined onto a single output volume.

  When a copy pool volume that is offsite becomes eligible for reclamation, the reclamation process attempts to obtain the active files on the reclaimable volume from a primary or copy storage pool that is onsite. The process then writes these files to an available volume in the original copy storage pool. Effectively, these files are moved back to the onsite location. However, the files can be obtained from the offsite volume after a disaster if a database backup is used that references the files on the offsite volume. Because of the way reclamation works with offsite volumes, use it carefully with copy storage pools.

RECLAIMPRocess
: Specifies the number of parallel processes to use for reclaiming the volumes in this storage pool. This parameter is optional. Enter a value 1 - 999.
  When you calculate the value for this parameter, consider the following resources that are required for reclamation processing:

- The number of sequential storage pools.
- The number of logical and physical drives that can be dedicated to the operation.

To access sequential volumes, IBM Spectrum Protect uses a mount point and, if the device type is not FILE, a physical drive.

For example, suppose that you want to reclaim the volumes from two sequential storage pools simultaneously and that you want to specify four processes for each of the storage pools. The storage pools have the same device class. Each process requires two mount points and, if the device type is not FILE, two drives. (One of the drives is for the input volume, and the other drive is for the output volume.) To run eight reclamation processes simultaneously, you need a total of at least 16 mount points and 16 drives. The device class for each storage pool must have a mount limit of at least eight.

You can specify one or more reclamation processes for each copy storage pool. You can specify multiple concurrent reclamation processes for a single copy storage pool, which makes better use of your available tape drives or FILE volumes. If multiple concurrent processing is not necessary, specify a value of 1 for the RECLAIMPROCESS parameter.

OFFSITERECLAIMLimit
Specifies the number of offsite volumes that space is reclaimed from during reclamation for this storage pool. This parameter is optional. You can specify the following values:

NOLimit
Specifies that you want to reclaim the space in all of your offsite volumes.

number
Specifies the number of offsite volumes to reclaim space from. You can specify an integer 0 - 99999. A value of zero means that none of the offsite volumes are reclaimed.
Tip:

To determine the value for the OFFSITERECLAIMLIMIT, use the statistical information in the message that is issued at the end of the offsite volume reclamation operation. The statistical information includes the following items:

- The number of offsite volumes that were processed
- The number of parallel processes that were used
- The total amount of time required for the processing

The order in which offsite volumes are reclaimed is based on the amount of unused space in a volume. (Unused space includes both space that has never been used on the volume and space that has become empty because of file deletion.) Volumes with the largest amount of unused space are reclaimed first.

For example, suppose a copy storage pool contains three volumes: VOL1, VOL2, and VOL3. VOL1 has the largest amount of unused space, and VOL3 has the least amount of unused space. Suppose further that the percentage of unused space in each of the three volumes is greater than the value of the RECLAIM parameter. If you do not specify a value for the OFFSITERECLAIMLIMIT parameter, all three volumes will be reclaimed when the reclamation runs. If you specify a value of 2, only VOL1 and VOL2 will be reclaimed when the reclamation runs. If you specify a value of 1, only VOL1 will be reclaimed.

MAXSCRatch
Specifies the maximum number of scratch volumes that the server can request for this storage pool. This parameter is optional. You can specify an integer 0 - 100000000. By allowing the server to request scratch volumes as needed, you avoid having to define each volume to be used.

The value that is specified for this parameter is used to estimate the total number of volumes available in the copy storage pool and the corresponding estimated capacity for the copy storage pool.

Scratch volumes are automatically deleted from the storage pool when they become empty. However, if the access mode for a scratch volume is OFFSITE, the volume is not deleted from the copy storage pool until the access mode is changed. An administrator can query the server for empty, offsite scratch volumes and return them to the onsite location.

When scratch volumes with the device type of FILE become empty and are deleted, the space that the volumes occupied is freed by the server and returned to the file system.

Tip: For server-to-server operations that use virtual volumes and that store a small amount of data, consider specifying a value for the MAXSCRATCH parameter that is higher than the value you typically specify for write operations to other types of volumes. After a write operation to a virtual volume, IBM Spectrum Protect marks the volume as FULL, even if the value of the MAXCAPACITY parameter on the device-class definition is not reached. The IBM Spectrum Protect server does not

keep virtual volumes in FILLING status and does not append to them. If the value of the MAXSCRATCH parameter is too low, server-to-server operations can fail.

REUsedelay
: Specifies the number of days that must elapse after all files are deleted from a volume before the volume can be rewritten or returned to the scratch pool. This parameter is optional. You can specify an integer 0 - 9999. A value of 0 means that a volume can be rewritten or returned to the scratch pool as soon as all files are deleted from the volume.
Tip: Use this parameter to ensure that when you restore the database to an earlier level, database references to files in the copy storage pool are still valid. You must set this parameter to a value greater than the number of days you plan to retain the oldest database backup. The number of days that are specified for this parameter must be the same as the number specified for the SET DRMDBBACKUPEXPIREDAYS command.

OVFLOcation
: Specifies the overflow location for the storage pool. The server assigns this location name to a volume that is ejected from the library by the MOVE MEDIA command. This parameter is optional. The location name can be a maximum length of 255 characters. Enclose the location name in quotation marks if the location name contains any blank characters.

  To remove an existing value, specify a null string ("").

CRCData
: Specifies whether a cyclic redundancy check (CRC) validates storage pool data when audit volume processing occurs on the server. This parameter is only valid for NATIVE data format storage pools. This parameter is optional. The default value is NO. By setting CRCDATA to YES and scheduling an AUDIT VOLUME command, you can continually ensure the integrity of data that is stored in your storage hierarchy. You can specify the following values:

  Yes
  : Specifies that data is stored containing CRC information, allowing for audit volume processing to validate storage pool data. This mode impacts performance because more processing is required to calculate and compare CRC values between the storage pool and the server.

  No
  : Specifies that data is stored without CRC information.

  Tip:

  For storage pools that are associated with the 3592, LTO, or ECARTRIDGE device type, logical block protection provides better protection against data corruption than CRC validation for a storage pool. If you specify CRC validation for a storage pool, data is validated only during volume auditing operations. Errors are identified after data is written to tape.

  To enable logical block protection, specify a value of READWRITE for the LBPROTECT parameter on the DEFINE DEVCLASS and UPDATE DEVCLASS commands for the 3592, LTO, or ECARTRIDGE device types. Logical block protection is supported only on the following types of drives and media:

  - IBM® LTO5 and later.
  - IBM 3592 Generation 3 drives and later with 3592 Generation 2 media and later.
  - Oracle StorageTek T10000C and T10000D drives.

DEDUPlicate
: Specifies whether the data that is stored in this storage pool is deduplicated. This parameter is optional and is valid only for storage pools that are defined with a FILE-type device class.

IDENTIFYPRocess
: Specifies the number of parallel processes to use for server-side data deduplication. This parameter is optional and is valid only for storage pools that are defined with a FILE device class. Enter a value 1 - 50.
Remember: Data deduplication processes can be either active or idle. Processes that are working on files are active. Processes that are waiting for files to work on are idle. Processes remain idle until volumes with data to be deduplicated become available. The output of the QUERY PROCESS command for data deduplication includes the total number of bytes and files that have been processed since the process first started. For example, if a data deduplication process processes four files, becomes idle, and then processes five more files, then the total number of files processed is nine. Processes end only when canceled or when the number of data-deduplication processes for the storage pool is changed to a value less than the number currently specified.

Example: Update a copy storage pool to a 30-day volume reuse and to collocate files by client node

Update the copy storage pool that is named TAPEPOOL2 to change the delay for volume reuse to 30 days and to collocate files by client node.

```
update stgpool tapepool2 reusedelay=30 collocate=node
```

   |                              (2) |
   '-IDENTIFYPRocess--=--number-----'
```

Notes:

1. This parameter is valid only for storage pools that are defined with a FILE-type device class.
2. This parameter is only available if the value of the DEDUPLICATE parameter is YES.

Parameters

pool_name (Required)
: Specifies the name of the active-data pool to be updated.

DESCription
: Specifies a description of the active-data pool. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters. To remove an existing description, specify a null string ("").

ACCess
Specifies how client nodes and server processes (such as reclamation) can access files in the active-data pool. This parameter is optional. You can specify the following values:

READWrite
Specifies that files can be read from and written to the volumes in the active-data pool.
READOnly
Specifies that client nodes can read only files that are stored on the volumes in the active-data pool.

Server processes can move files within the volumes in the storage pool. The server can use files in the active-data pool to restore active versions of backup files to primary storage pools. However, no new writes are allowed to volumes in the active-data pool from volumes outside the storage pool. A storage pool cannot be copied to the active-data pool.

UNAVailable
Specifies that client nodes cannot access files that are stored on volumes in the active-data pool.

Server processes can move files within the volumes in the storage pool. The server can use files in the active-data pool to restore active versions of backup files to primary storage pools. However, no new writes are allowed to volumes in the active-data pool from volumes outside the storage pool. A storage pool cannot be copied to the active-data pool.

COLlocate
Specifies whether the server attempts to keep data, which is stored on as few volumes as possible, that belong to one of the following candidates:

- A single client node
- A group of file spaces
- A group of client nodes
- A client file space

This parameter is optional.

Collocation reduces the number of sequential access media mounts for restore, retrieve, and recall operations. However, collocation increases both the amount of server time that is needed to collocate files for storing and the number of volumes required.

You can specify one of the following options:

No
Specifies that collocation is disabled.
GRoup
Specifies that collocation is enabled at the group level for client nodes or file spaces. For collocation groups, the server attempts to put data for nodes or file spaces that belong to the same collocation group on as few volumes as possible.

If you specify COLLOCATE=GROUP but do not define any collocation groups, or if you do not add nodes or file spaces to a collocation group, data is collocated by node. Consider tape usage when you organize client nodes or file spaces into collocation groups.

For example, if a tape-based storage pool consists of data from nodes and you specify COLLOCATE=GROUP, the server completes the following actions:

- Collocates the data by group for grouped nodes. Whenever possible, the server collocates data that belongs to a group of nodes on a single tape or on as few tapes as possible. Data for a single node can also be spread across several tapes that are associated with a group.
- Collocates the data by node for ungrouped nodes. Whenever possible, the server stores the data for a single node on a single tape. All available tapes that already have data for the node are used before available space on any other tape is used.

If a tape-based storage pool consists of data from grouped file spaces and you specify COLLOCATE=GROUP, the server completes the following actions:

- Collocates by group, the data for grouped file spaces only. Whenever possible, the server collocates data that belongs to a group of file spaces on a single tape or on as few tapes as possible. Data for a single file space can also be spread across several tapes that are associated with a group.

- Collocates the data by node (for file spaces that are not explicitly defined to a file space collocation group). For example, node1 has file spaces named A, B, C, D, and E. File spaces A and B belong to a filespace collocation group but C, D, and E do not. File spaces A and B are collocated by filespace collocation group, while C, D, and E are collocated by node.

Data is collocated on the least amount of sequential access volumes.

NODe
: Specifies that collocation is enabled at the client node level. For collocation groups, the server attempts to put data for one node on as few volumes as possible. If the node has multiple file spaces, the server does not try to collocate those file spaces. For compatibility with an earlier version, COLLOCATE=YES is still accepted by the server to specify collocation at the client node level.

  If a storage pool contains data for a node that is a member of a collocation group and you specify COLLOCATE=NODE, the data is collocated by node.

FIlespace
: Specifies that collocation is enabled at the file space level for client nodes. The server attempts to place data for one node and file space on as few volumes as possible. If a node has multiple file spaces, the server attempts to place data for different file spaces on different volumes.

RECLaim
: Specifies when the server reclaims a volume, which is based on the percentage of reclaimable space on a volume. Reclaimable space is the amount of space that is occupied by files that are expired or deleted from the IBM Spectrum Protect™ database.

  Reclamation makes the fragmented space and space occupied by inactive backup files on volumes usable again by moving any remaining unexpired files and active backup files from one volume to another volume. This action makes the original volume available for reuse. This parameter is optional. You can specify an integer 1 - 100. The value 100 means that reclamation is not completed.

  The server determines that the volume is a candidate for reclamation if the percentage of reclaimable space on a volume is greater than the reclamation threshold of the storage pool.

  If you change the value from the default of 60, specify a value of 50 percent or greater so that files stored on two volumes can be combined onto a single output volume.

  When an active-data pool volume that is offsite becomes eligible for reclamation, the reclamation process attempts to obtain the active files on the reclaimable volume from a primary or active-data pool that is onsite. The process then writes these files to an available volume in the original active-data pool. Effectively, these files are moved back to the onsite location. However, the files can be obtained from the offsite volume after a disaster if a database backup is used that references the files on the offsite volume. Because of the way reclamation works with offsite volumes, use it carefully with active-data pools.

RECLAIMPRocess
: Specifies the number of parallel processes to use for reclaiming the volumes in this storage pool. This parameter is optional. Enter a value 1 - 999.
  When you calculate the value for this parameter, consider the following resources that are required for reclamation processing:

  - The number of sequential storage pools.
  - The number of logical and physical drives that can be dedicated to the operation.

  To access sequential volumes, IBM Spectrum Protect uses a mount point and, if the device type is not FILE, a physical drive.

  For example, suppose that you want to reclaim the volumes from two sequential storage pools simultaneously and that you want to specify four processes for each of the storage pools. The storage pools have the same device class. Each process requires two mount points and, if the device type is not FILE, two drives. (One of the drives is for the input volume, and the other drive is for the output volume.) To run eight reclamation processes simultaneously, you need a total of at least 16 mount points and 16 drives. The device class for each storage pool must have a mount limit of at least eight.

  You can specify one or more reclamation processes for each active-data pool. You can specify multiple concurrent reclamation processes for a single active-data pool, which makes better use of your available tape drives or FILE volumes. If multiple concurrent processing is not necessary, specify a value of 1 for the RECLAIMPROCESS parameter.

OFFSITERECLAIMLimit
Specifies the number of offsite volumes that space is reclaimed from during reclamation for this storage pool. This parameter is optional. You can specify the following values:

NOLimit
Specifies that you want to reclaim the space in all of your offsite volumes.

number
Specifies the number of offsite volumes to reclaim space from. You can specify an integer 0 - 99999. A value of zero means that none of the offsite volumes are reclaimed.
Tip:

To determine the value for the OFFSITERECLAIMLIMIT, use the statistical information in the message that is issued at the end of the offsite volume reclamation operation. The statistical information includes the following items:

- The number of offsite volumes that were processed
- The number of parallel processes that were used
- The total amount of time required for the processing

The order in which offsite volumes are reclaimed is based on the amount of unused space in a volume. (Unused space includes both space that has never been used on the volume and space that has become empty because of file deletion.) Volumes with the largest amount of unused space are reclaimed first.

For example, suppose an active-data pool contains three volumes: VOL1, VOL2, and VOL3. VOL1 has the largest amount of unused space, and VOL3 has the least amount of unused space. Suppose further that the percentage of unused space in each of the three volumes is greater than the value of the RECLAIM parameter. If you do not specify a value for the OFFSITERECLAIMLIMIT parameter, all three volumes are reclaimed when the reclamation runs. If you specify a value of 2, only VOL1 and VOL2 are reclaimed when the reclamation runs. If you specify a value of 1, only VOL1 is reclaimed.

MAXSCRatch
Specifies the maximum number of scratch volumes that the server can request for this storage pool. This parameter is optional. You can specify an integer 0 - 100000000. By allowing the server to request scratch volumes as needed, you avoid having to define each volume to be used.

The value that is specified for this parameter is used to estimate the total number of volumes available in the active-data pool and the corresponding estimated capacity for the active-data pool.

Scratch volumes are automatically deleted from the storage pool when they become empty. However, if the access mode for a scratch volume is OFFSITE, the volume is not deleted from the active-data pool until the access mode is changed. An administrator can query the server for empty, offsite scratch volumes and return them to the onsite location.

When scratch volumes with the device type of FILE become empty and are deleted, the space that the volumes occupied is freed by the server and returned to the file system.

Tip: For server-to-server operations that use virtual volumes and that store a small amount of data, consider specifying a value for the MAXSCRATCH parameter that is higher than the value you typically specify for write operations to other types of volumes. After a write operation to a virtual volume, IBM Spectrum Protect marks the volume as FULL, even if the value of the MAXCAPACITY parameter on the device-class definition is not reached. The IBM Spectrum Protect server does not keep virtual volumes in FILLING status and does not append to them. If the value of the MAXSCRATCH parameter is too low, server-to-server operations can fail.

REUsedelay
Specifies the number of days that must elapse after all files are deleted from a volume before the volume can be rewritten or returned to the scratch pool. This parameter is optional. You can specify an integer 0 - 9999. A value of 0 means that a volume can be rewritten or returned to the scratch pool as soon as all files are deleted from the volume.
Tip: Use this parameter to ensure that when you restore the database to an earlier level, database references to files in the active-data pool are still valid. You must set this parameter to a value greater than the number of days you plan to retain the oldest database backup. The number of days that are specified for this parameter must be the same as the number specified for the SET DRMDBBACKUPEXPIREDAYS command.

OVFLOcation
Specifies the overflow location for the storage pool. The server assigns this location name to a volume that is ejected from the library by the MOVE MEDIA command. This parameter is optional. The location name can be a maximum length of 255 characters. Enclose the location name in quotation marks if the location name contains any blank characters.

To remove an existing value, specify a null string ("").

CRCData

Specifies whether a cyclic redundancy check (CRC) validates storage pool data when audit volume processing occurs on the server. This parameter is only valid for NATIVE data format storage pools. This parameter is optional. The default value is NO. By setting CRCDATA to YES and scheduling an AUDIT VOLUME command, you can continually ensure the integrity of data that is stored in your storage hierarchy. You can specify the following values:

Yes
: Specifies that data is stored containing CRC information, allowing for audit volume processing to validate storage pool data. This mode impacts performance because more processing is required to calculate and compare CRC values between the storage pool and the server.

No
: Specifies that data is stored without CRC information.

Tip:

For storage pools that are associated with the 3592, LTO, or ECARTRIDGE device type, logical block protection provides better protection against data corruption than CRC validation for a storage pool. If you specify CRC validation for a storage pool, data is validated only during volume auditing operations. Errors are identified after data is written to tape.

To enable logical block protection, specify a value of READWRITE for the LBPROTECT parameter on the DEFINE DEVCLASS and UPDATE DEVCLASS commands for the 3592, LTO, or ECARTRIDGE device types. Logical block protection is supported only on the following types of drives and media:

- IBM® LTO5 and later.
- IBM 3592 Generation 3 drives and later with 3592 Generation 2 media and later.
- Oracle StorageTek T10000C and T10000D drives.

DEDUPlicate
: Specifies whether the data that is stored in this storage pool is deduplicated. This parameter is optional and is valid only for storage pools that are defined with a FILE-type device class.

IDENTIFYPRocess
: Specifies the number of parallel processes to use for server-side data deduplication. This parameter is optional and is valid only for storage pools that are defined with a FILE device class. Enter a value 1 - 50.
Remember: Data deduplication processes can be either active or idle. Processes that are working on files are active. Processes that are waiting for files to work on are idle. Processes remain idle until volumes with data to be deduplicated become available. The output of the QUERY PROCESS command for data deduplication includes the total number of bytes and files that have been processed since the process first started. For example, if a data deduplication process processes four files, becomes idle, and then processes five more files, then the total number of files processed is nine. Processes end only when canceled or when the number of data-deduplication processes for the storage pool is changed to a value less than the number currently specified.

Example: Update an active data pool

Update the active-data pool that is named TAPEPOOL2 to change the delay for volume reuse to 30 days and to collocate files by client node.

```
update stgpool tapepool3 reusedelay=30 collocate=node
```

Related reference:
SET DRMDBBACKUPEXPIREDAYS (Specify DB backup series expiration)
AIX | Linux | Windows

UPDATE STGPOOLDIRECTORY (Update a storage pool directory)

Use this command to update a storage pool directory.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege.

Syntax

```
>>-UPDate STGPOOLDIRectory--pool_name--directory----------------><
```

```
                                  .-MAXPRocess--==--4------.
>----ACCess--==--+-READWrite---+----+-----------------------+---->
                 +-READOnly----+    '-MAXProcess--==--number-'
                 +-DEStroyed---+
                 '-UNAVailable-'

   .-Wait--==--No------.
>--+------------------+---------------------------------------><
   '-Wait--==--+-No--+-'
               '-Yes-'
```

Parameters

pool_name (Required)
: Specifies the storage pool that contains the directory to update. This parameter is required.

directory (Required)
: Specifies a file system directory of the storage pool. This parameter is required.

ACCess (Required)
: Specifies how client nodes and server processes can access files in the storage pool directory. This parameter is required. The following values are possible:

  READWrite
  : Specifies that files can be read from and written to the storage pool directory.

  READOnly
  : Specifies that files can be read from the storage pool directory.

  DEStroyed
  : Specifies that files are permanently damaged and must be destroyed in the storage pool directory. Use this access mode to indicate that an entire storage pool directory must be recovered.
    Tips:

    - Mark storage pool directories as `DESTROYED` before you complete data recovery. When the storage pool directory is marked as destroyed, you can recover data extents on the target replication server.
    - Use the MAXPROCESS parameter to specify the number of parallel processes that you can use to update a storage pool directory.

  UNAVailable
  : Specifies that files cannot be accessed on the storage pool directory in the storage pool.

MAXPRocess
: Specifies the maximum number of parallel processes to use for updating a storage pool directory. This parameter is optional. You can enter a value in the range 1 - 99. The default value is 4.
  Restriction: You can use this parameter only when you specify the ACCESS=DESTROYED parameter.

  When you specify the ACCESS=DESTROYED parameter, each container in the storage pool directory is updated by one process. If the maximum number of parallel processes is larger than or equal to the number of containers that must be updated, only one process is created for each container. If the number of containers exceeds the value of the MAXPROCESS parameter, the command waits for the child processes to finish before any new processes can begin.

Wait
: This optional parameter specifies whether to wait for the IBM Spectrum Protect™ server to complete processing this command in the foreground. The default is NO. You can specify the following values:

  No
  : The server processes this command in the background and you can continue with other tasks while the command is processing. Messages that are related to the background process are shown either in the activity log file or the server console, depending on where the messages are logged.

  Yes
  : The server processes this command in the foreground. The operation must complete processing before you can continue with other tasks. Messages are shown either in the activity log file or the server console, or both, depending on where the messages are logged.
    Restriction: You cannot specify WAIT=YES from the server console.

Example: Update a storage pool directory to destroy it

Update a storage pool directory that is named DIR1 in storage pool POOL1 to mark it as destroyed.

```
update stgpooldirectory pool1 dir1 access=destroyed
```

Example: Update a storage pool directory to destroy it in a cloud-container storage pool

Update a storage pool directory that is named DIR3 in cloud-container storage pool CLOUDLOCALDISK1 to mark it as destroyed.

```
update stgpooldirectory cloudlocaldisk1 dir3 access=destroyed
```

Example: Update a storage pool directory to make it unavailable

When the storage pool directory is unavailable, the server does not read or write data to the directory. To update the access mode to unavailable for a storage pool directory, `dir1`, in a storage pool that is named `pool1`, issue the following command:

```
update stgpooldirectory pool1 dir1 access=unavailable
```

Table 1. Commands related to UPDATE STGPOOLDIRECTORY

Command	Description
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DEFINE STGPOOLDIRECTORY	Defines a storage pool directory to a directory-container or cloud-container storage pool.
DELETE STGPOOLDIRECTORY	Deletes a storage pool directory from a directory-container or cloud-container storage pool.
QUERY STGPOOLDIRECTORY	Displays information about storage pool directories.

UPDATE VIRTUALFSMAPPING (Update a virtual file space mapping)

Use this command to update a virtual file space mapping definition.

Restriction: You cannot use the UPDATE VIRTUALFSMAPPING command to update a virtual file space mapping for an EMC Celerra or EMC VNX NAS device. You must use the DEFINE VIRTUALFSMAPPING command.

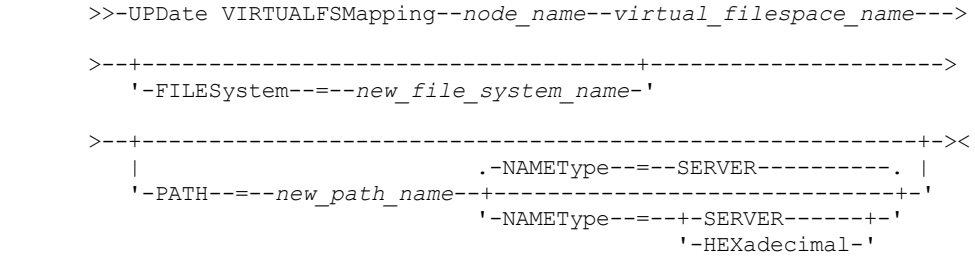
The NAS device needs an associated data mover definition because when the server updates a virtual file space mapping, the server contacts the NAS device to validate the virtual file system and file system name.

Privilege class

To issue this command, you must have one of the following privilege classes:

- System privilege
- Unrestricted policy privilege
- Restricted policy privilege for the domain to which the NAS node is assigned

Syntax



Parameters

node_name (Required)

Specifies the NAS node on which the file system and path reside. You cannot use wildcard characters or specify a list of names.

virtual_filespace_name (Required)

Specifies the virtual file space mapping to update. You cannot use wildcard characters or specify a list of names.

FILESystem

Specifies the new name of the file system in which the path is located. The file system name must exist on the specified NAS node. The file system name cannot contain wildcard characters. The file system name should only be modified when the file system name is modified on the NAS device or, for example, the directory is moved to a different file system. This parameter is optional.

PATH

Specifies the new path from the root of the file system to the directory. The path can only reference a directory. This should only be modified when the path on the NAS device has changed; for example, the directory is moved to a different path. The maximum length of the path is 1024 characters. The path name is case sensitive. This parameter is optional.

NAMEType

Specifies how the server should interpret the path name specified. Specify this parameter only if you specify a path. This parameter is useful when a path contains characters that are not part of the code page on which the server is running. The default value is SERVER.

Possible values are:

SERVER
: The code page in which the server is running is used to interpret the path.

HEXadecimal
: The server interprets the path that you enter as the hexadecimal representation of the path. This option should be used when a path contains characters that cannot be entered. For example, this could occur if the NAS file system is set to a language different from the one in which the server is running.

Example: Modify the path of a virtual file space mapping

Update the virtual file space mapping named /mikeshomedir for the NAS node NAS1 by modifying the path.

```
update virtualfsmapping nas1 /mikeshomedir path=/new/home/mike
```

Related commands

Table 1. Commands related to UPDATE VIRTUALFSMAPPING

Command	Description
DEFINE VIRTUALFSMAPPING	Define a virtual file space mapping.
DELETE VIRTUALFSMAPPING	Delete a virtual file space mapping.
QUERY VIRTUALFSMAPPING	Query a virtual file space mapping.

UPDATE VOLHISTORY (Update sequential volume history information)

Use this command to update volume history information for a volume produced by a database backup or an export operation. This command does not apply to storage pool volumes.

Use the UPDATE BACKUPSET command to update specified backup set volume information in the volume history file. Do not use this UPDATE VOLHISTORY command to update backup set volume information in the volume history file.

Privilege class

You must have system privilege or unrestricted storage privilege to issue this command.

Syntax

```
>>-UPDate VOLHistory--volume_name------------------------------>

>--DEVclass--=--device_class_name--+-----------------------+---->
                                   '-LOcation--=--location-'

>--+-----------------------------------+------------------------><
   '-ORMSTate--=--+-MOuntable-------+-'
                  +-NOTMOuntable----+
                  +-COUrier---------+
                  +-VAult-----------+
                  '-COURIERRetrieve-'
```

Parameters

volume_name (Required)
: Specifies the volume name. The volume must have been used for a database backup or an export operation.

DEVclass (Required)
: Specifies the name of the device class for the volume.

LOcation
: Specifies the volume location. This parameter is required if the ORMSTATE parameter is not specified. The maximum text length is 255 characters. Enclose the text in quotation marks if it contains any blank characters.
  Tip: The UPDATE VOLHISTORY command supports updates to the location information and ORMSTATE for snapshot database backup volumes.

ORMSTate
: Specifies a change to the state of a database backup volume. This parameter is required if the LOCATION parameter is not specified. This parameter is only supported for systems licensed with Disaster Recovery Manager. Possible states are:

  MOuntable
  : The volume contains valid data and is accessible for on-site processing.

  NOTMOuntable
  : The volume is on-site, contains valid data, and is not accessible for on-site processing.

  COUrier
  : The volume is being moved off-site.

  VAult
  : The volume is off-site, contains valid data, and is not accessible for on-site processing.

  COURIERRetrieve
  : The volume is being moved on-site.

Example: Update the location of a volume used for database backup

Update the location of a volume used for database backup, BACKUP1, to show that it has been moved to an off-site location.

```
update volhistory backup1 devclass=tapebkup
location="700 w. magee rd."
```

Related commands

Table 1. Commands related to UPDATE VOLHISTORY

Command	Description
BACKUP VOLHISTORY	Records volume history information in external files.
DELETE VOLHISTORY	Removes sequential volume history information from the volume history file.
MOVE DRMEDIA	Moves DRM media onsite and offsite.
PREPARE	Creates a recovery plan file.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY VOLHISTORY	Displays sequential volume history information that has been collected by the server.

UPDATE VOLUME (Change a storage pool volume)

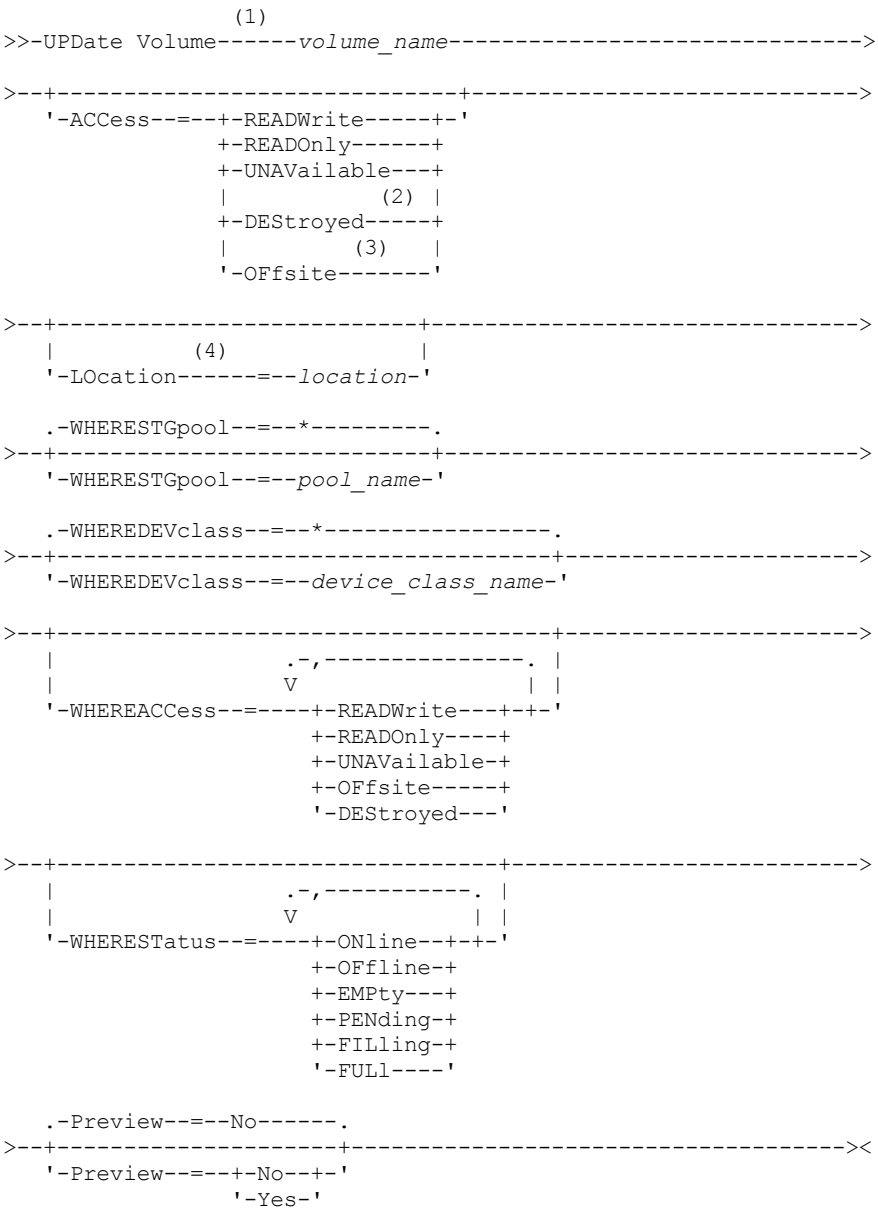
Use this command to change the access mode for one or more volumes in storage pools.

You can correct an error condition associated with a volume by updating the volume to an access mode of READWRITE. You can also use this command to change the location information for one or more volumes in sequential access storage pools.

Privilege class

To issue this command, you must have system privilege or operator privilege.

Syntax



Notes:

1. You must update at least one attribute (ACCESS or LOCATION).
2. This value is valid only for volumes in primary storage pools.
3. This value is valid only for volumes in copy storage pools.
4. This parameter is valid only for volumes in sequential access storage pools.

Parameters

volume_name (Required)
Specifies the storage pool volume to update. You can use wildcard characters to specify names.

ACCess
Specifies how client nodes and server processes (such as migration) can access files in the storage pool volume. This parameter is optional. Possible values are:

READWrite
Specifies that client nodes and server processes can read from and write to files stored on the volume.

If the volume being updated is an empty scratch volume that had an access mode of offsite, the server deletes the volume from the database.

READOnly
Specifies that client nodes and server processes can only read files stored on the volume.

If the volume being updated is an empty scratch volume that had an access mode of offsite, the server deletes the volume from the database.

UNAVailable
Specifies that neither client nodes nor server processes can access files stored on the volume.

Before making a random access volume unavailable, you must vary the volume offline. After you make a random access volume unavailable, you cannot vary the volume online.

If you make a sequential access volume unavailable, the server does not attempt to mount the volume.

If the volume being updated is an empty scratch volume that had an access mode of offsite, the server deletes the volume from the database.

DEStroyed
Specifies that a primary storage pool volume has been permanently damaged. Neither client nodes nor server processes can access files stored on the volume. Use this access mode to indicate an entire volume that needs to be restored by using the RESTORE STGPOOL command. After all files on a destroyed volume have been restored to other volumes, the server automatically deletes the destroyed volume from the database.

Only volumes in primary storage pools can be updated to DESTROYED.

Before updating a random access volume to DESTROYED access, you must vary the volume offline. After you update a random access volume to DESTROYED, you cannot vary the volume online.

If you update a sequential access volume to DESTROYED, the server does not attempt to mount the volume.

If a volume contains no files and you change the access mode to DESTROYED, the server deletes the volume from the database.

OFfsite
Specifies that a copy or active-data storage pool volume is at an offsite location from which it cannot be mounted. Only volumes in copy or active-data storage pools can have the access mode of OFFSITE.

If you specify values for both the ACCESS and LOCATION parameters but the access mode cannot be updated for a particular volume, the location attribute is also not updated for that volume. For example, if you specify ACCESS=OFFSITE and a LOCATION value for a primary storage pool volume, neither the access nor location values are updated because a primary storage pool volume cannot be given an access mode of OFFSITE.

LOcation
Specifies the location of the volume. This parameter is optional. It can be specified only for volumes in sequential access storage pools. The maximum length of the location is 255 characters. Enclose the location in quotation marks if it contains any blank characters. To remove a previously defined location, specify the null string ("").

WHERESTGpool
Specifies the name of the storage pool for volumes to be updated. Use this parameter to restrict the update by storage pool. This parameter is optional. You can use wildcard characters to specify names. If you do not specify a storage pool name, volumes belonging to any storage pool are updated.

WHEREDEVclass

Specifies the name of the device class for volumes to be updated. Use this parameter to restrict the update by device class. This parameter is optional. You can use wildcard characters to specify names. If you do not specify a device class name, volumes with any device class are updated.

WHEREACCess

Specifies the current access mode of volumes to be updated. Use this parameter to restrict the update to volumes that currently have the specified access mode. This parameter is optional. You can specify multiple access modes by separating the modes with commas and no intervening spaces. If you do not specify a value for this parameter, the update is not restricted by the current access mode of a volume. Possible values are:

READWrite
: Update volumes with an access mode of READWRITE.

READOnly
: Update volumes with an access mode of READONLY.

UNAVailable
: Update volumes with an access mode of UNAVAILABLE.

OFfsite
: Update volumes with an access mode of OFFSITE.

DEStroyed
: Update volumes with an access mode of DESTROYED.

WHERESTatus

Specifies the status of volumes to be updated. Use this parameter to restrict the update to volumes that have a specified status. This parameter is optional. You can specify multiple status values by separating the values with commas and no intervening spaces. If you do not specify a value for this parameter, the update is not restricted by volume status. Possible values are:

ONline
: Update volumes with a status of ONLINE.

OFfline
: Update volumes with a status of OFFLINE.

EMPty
: Update volumes with a status of EMPTY.

PENding
: Update volumes with a status of PENDING. These are volumes from which all files have been deleted, but the time specified by the REUSEDELAY parameter has not elapsed.

FILling
: Update volumes with a status of FILLING.

FULl
: Update volumes with a status of FULL.

Preview

Specifies whether you want to preview the update operation without actually updating volumes. This parameter is optional. The default value is NO. Possible values are:

No
: Specifies that volumes are actually updated.

Yes
: Specifies that you want only to preview the update operation. This option displays the volumes that will be updated if you actually perform the update operation.

Example: Make a tape volume unavailable

Update a tape volume named DSMT20 to make it unavailable to client nodes and server processes.

```
update volume dsmt20 access=unavailable
```

Example: Update the access mode of all offsite volumes in a specific storage pool

Update all empty, offsite volumes in the TAPEPOOL2 storage pool. Set the access mode to READWRITE and delete the location information for the updated volumes.

```
update volume * access=readwrite location="" wherestgpool=tapepool2
    whereaccess=offsite wherestatus=empty
```

Related commands

Table 1. Commands related to UPDATE VOLUME

Command	Description
DEFINE VOLUME	Assigns a volume to be used for storage within a specified storage pool.
DELETE VOLUME	Deletes a volume from a storage pool.
QUERY VOLUME	Displays information about storage pool volumes.
VARY	Specifies whether a disk volume is available to the server for use.

VALIDATE commands

Use the VALIDATE command to verify that an object is complete or valid for IBM Spectrum Protect™.

- Linux VALIDATE ASPERA (Validate an Aspera FASP configuration)
- AIX Linux Windows VALIDATE CLOUD (Validate cloud credentials)
- VALIDATE LANFREE (Validate LAN-Free paths)
- VALIDATE POLICYSET (Verify a policy set)
- VALIDATE REPLICATION (Validate replication for a client node)
- VALIDATE REPLPOLICY (Verify the policies on the target replication server)

Linux

VALIDATE ASPERA (Validate an Aspera FASP configuration)

Use this command to determine whether Aspera® Fast Adaptive Secure Protocol (FASP®) technology can be used to optimize data transfer in your system environment. Specifically, you can determine whether Aspera FASP technology would result in better network throughput than TCP/IP technology.

This command verifies the following additional items:

- Whether the system environment is correctly configured to use Aspera FASP technology
- Whether the required licenses for enabling Aspera FASP technology are installed

Aspera FASP technology is used to optimize data transfer for node replication or storage pool protection in a wide area network (WAN). However, you are not required to configure your system for node replication or storage pool protection to run the VALIDATE ASPERA command. If your system is configured for node replication or storage pool protection in a local environment, you can issue the command to evaluate whether the data can be successfully replicated to a remote server.

This command is available only on Linux x86_64 operating systems.

Before you issue the command, complete the following tasks:

1. Ensure that at least one server is defined in your system environment. Issue the PING SERVER command to ensure that you have connectivity to the defined server. For example, if the server is named VMRH6T, issue the following command:

   ```
   ping server vmrh6t
   ```

2. To use the VALIDATE ASPERA command to determine the speed of network throughput, install 30-day evaluation licenses or full, unlimited licenses on the source and target servers. For example, install licenses on the source and target servers, VMRH6 and VMRH6T. For instructions about obtaining and installing licenses, see Determining whether Aspera FASP technology can optimize data transfer in your system environment.

To simulate an environment that uses multiple sessions, you can run several instances of the VALIDATE ASPERA command simultaneously. If you plan to run multiple sessions, you might want to limit the bandwidth of each network connection to ensure that sufficient bandwidth is available for all network connections. To limit the bandwidth, specify the FASPTARGETRATE server option as described in FASPTARGETRATE.

You can query the current transferred amount by issuing the QUERY PROCESS command:

```
query process
```

You can obtain the process number from the output of the QUERY PROCESS command. You can cancel the process by issuing the CANCEL PROCESS command and specifying the process number, for example:

```
cancel process 3
```

Privilege class

Any administrator can issue this command.

Syntax

```
>>-VALidate ASPera--+------------------------+------------------>
                    '---target_server_name---'

                              .-Wait--=--No------.
>--+----------------------+--+------------------+-------------><
   '-DURation--=--seconds-'  '-Wait--=--+-No--+-'
                                        '-Yes-'
```

Parameters

target_server_name
: Specifies a previously defined server. This parameter is optional. To specify this parameter, follow the guidelines:

  - To determine whether Aspera FASP can optimize a node replication process, specify a target server that is configured for node replication.
  - To determine whether Aspera FASP can optimize a storage pool protection process, specify a target server that is configured for storage pool protection.
  - To determine whether Aspera FASP can optimize data transfer to a remote server that is defined but not configured for storage pool protection or node replication, specify that target server.
  - If you do not specify a target server, the command output indicates whether the source server is correctly configured for Aspera FASP data transmission. The output also indicates whether a valid license for Aspera FASP is installed on the source server.

DURation
: Specifies the allotted time, in seconds, for transferring data across the network to evaluate throughput. This parameter is optional. The default value is 120 seconds. You can specify a value in the range 120 - 3600000 seconds. The allotted time is divided between the Aspera FASP and TCPIP data transfers.

Wait
: Specifies whether to wait for the server to complete the command processing. This parameter is optional. The default value is NO. You can specify one of the following values:

  No
  : Specifies that the server processes the command in the background. You can continue with other tasks while the command is being processed. If you specify NO, the output messages are displayed in the activity log.

  Yes
  : Specifies that the server processes the command in the foreground. The operation must complete processing before you can continue with other tasks. If you specify YES, the output messages are displayed in the administrative command-line client.
    Restriction: You cannot specify WAIT=YES from the server console.

Example: Display information about the status of an Aspera FASP configuration

On the source server, run the `VALIDATE ASPERA` command. To ensure that messages are displayed in the administrative command-line client, specify WAIT=YES. See Field descriptions for field descriptions.

```
validate aspera wait=yes

ANR3836I Validation of the Aspera FASP connection from VMRH6 to localhost.
Amount transferred using FASP: 0 MB per second. Amount transferred using
TCP/IP: 0 MB per second. Latency: 0 microseconds. Status: OK. Days until
```

```
license expires: Never.
```

Example: Verify whether the required licenses are installed

On the source server, run the `VALIDATE ASPERA` command and specify the target replication server. To ensure that messages are displayed in the administrative command-line client, specify WAIT=YES. See Field descriptions for field descriptions.

```
validate aspera vmrh6t wait=yes

ANR0984I Process 8 for VALIDATE ASPERA started in the FOREGROUND at 09:35:21 AM.
ANR3672E The license file that is required to enable Aspera Fast Adaptive
Secure Protocol (FASP) technology was not found on the VMRH6 server.
ANR3836I Validation of the Aspera FASP connection from VMRH6 to localhost.
Amount transferred using FASP: 0 MB per second. Amount transferred using
TCP/IP: 0 MB per second. Latency: 0 microseconds. Status: Invalid
configuration. Days until license expires: Expired.
ANR0985I Process 8 for VALIDATE ASPERA running in the FOREGROUND completed with
completion state FAILURE at 09:35:21 AM.
ANR1893E Process 8 for VALIDATE ASPERA completed with a completion state of
FAILURE.
```

Field descriptions

Status
: The status of the configuration. The following values are possible:

- `OK` indicates that no issues are detected.
- `Invalid configuration` indicates that a configuration file, license file, or Aspera FASP library file is missing.
- `License issue` indicates that a license is missing, invalid, or expired.
- `Server failure` indicates that all ports are in use, a network read/write error occurred, or the Aspera FASP log file is unwritable.
- `Invalid target configuration` indicates that a configuration file, license file, or Aspera FASP library file is missing on the target server.
- `Failure on target server` indicates that all ports are in use, a network read/write error occurred, or the Aspera FASP log file is unwritable.
- `License issue on target server` indicates that a license is invalid or expired on the target server.
- `Unsupported operating system` indicates that an operating system other than Linux x86_64 is installed on one or both servers.
- `Unknown` indicates that an unexpected error occurred. To identify the error, review the log messages.

Days until license expires
: The following values are possible:

- `Never` indicates that a full, unlimited license is installed.
- `Today` indicates that a 30-day evaluation license is installed and it expires today.
- `Expired` indicates that a 30-day evaluation license is installed, but has expired.
- *Number* indicates that a 30-day evaluation license is installed and will expire in the specified number of days.
- `License not found` indicates that no license was found.

Amount transferred using TCP/IP
: The speed of data transfer, in megabytes per second, using TCP/IP technology.

Amount transferred using FASP
: The speed of data transfer, in megabytes per second, using Aspera FASP technology.

Latency
: The latency of data transfer in microseconds.

Related commands

Table 1. Commands related to VALIDATE ASPERA

Command	Description
CANCEL SESSION	Cancels active sessions with the server.

Command	Description
DEFINE SERVER	Defines a server for server-to-server communications.
PING SERVER	Tests the connections between servers.
AIX Linux Windows PROTECT STGPOOL	AIX Linux Windows Protects a directory-container storage pool.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.

VALIDATE CLOUD (Validate cloud credentials)

Before you define a storage pool, use this command to ensure that the credentials for a cloud-container storage pool are valid and that the necessary permissions are granted to the user.

Privilege class

Any administrator can issue this command.

Syntax

```
                    .-CLOUDType--=--SWift---------.
>>-VALidate CLOud--+-----------------------------+-------------->
                    '-CLOUDType--=--+-AZure-----+-'
                                    +-S3--------+
                                    +-SOftlayer-+
                                    +-SWift-----+
                                    '-V1Swift---'

                                                      (1)
>--CLOUDUrl--=--cloud_url--IDentity--=--cloud_identity---------->

>--PAssword--=--password--+--------------------------------+---><
                         |                          (2)   |
                         '-BUCKETName--=--bucket_name-----'
```

Notes:

1. If you specify CLOUDTYPE=AZURE, do not specify the IDENTITY parameter.
2. The BUCKETNAME parameter is valid only if you specify CLOUDTYPE=S3.

Parameters

CLOUDType
: Specifies the type of cloud environment where you are configuring the storage pool.
You can specify one of the following values:

AZure
: Specifies that the storage pool uses a Microsoft Azure cloud computing system.

S3
: Specifies that the storage pool uses a cloud computing system with the Simple Storage Service (S3) protocol, such as IBM® Cloud Object Storage or Amazon Web Services (AWS) S3.

SOftlayer
: Specifies that the storage pool uses an IBM SoftLayer® (IBM Bluemix) cloud computing system with an OpenStack Swift cloud computing system.

SWift
: Specifies that the storage pool uses an OpenStack Swift cloud computing system. This value also specifies that the storage pool uses Version 2 of the protocol for authentication to the cloud. The URL of the cloud usually contains the version number of the protocol that it is using.

V1Swift
: Specifies that the storage pool uses an OpenStack Swift cloud computing system. This value also specifies that the storage pool uses Version 1 of the protocol for authentication to the cloud. The URL of the cloud usually contains the version number of the protocol that it is using.

This parameter is optional. If you do not specify the parameter, the default value, SWIFT, is used.

CLOUDUrl (Required)

Specifies the URL of the cloud environment where you configure the storage pool. Based on your cloud provider, you can use a blob service endpoint, region endpoint URL, an accesser IP address, a public authentication endpoint, or a similar value for this parameter. Ensure that you include the protocol, such as `https://` or `http://`, at the beginning of the URL. The maximum length of the web address is 870 characters. The CLOUDURL parameter is validated when the first backup begins.

IDentity (Required)

Specifies the user ID for the cloud. This parameter is required for all supported cloud computing systems except Azure. If you specify CLOUDTYPE=AZURE, do not specify the IDENTITY parameter. Based on your cloud provider, you can use an access key ID, a user name, a tenant name and user name, or a similar value for this parameter. The maximum length of the user ID is 255 characters.

PAssword (Required)

Specifies the password for the cloud. Based on your cloud provider, you can use a shared access signature (SAS) token, secret access key, an API key, a password, or a similar value for this parameter. This parameter is required. The maximum length of the password is 255 characters.

BUCKETName

Specifies the name for an AWS S3 bucket or a IBM Cloud Object Storage vault to use with this storage pool, instead of using the default bucket name or vault name. This parameter is optional, and is valid only if you specify CLOUDTYPE=S3. If a bucket or vault exists with the name that you specify, that bucket or vault is tested to ensure that the proper permissions are set. If the bucket or vault does not exist, the parameter verifies only that a bucket or vault with that name does not exist. Follow the naming restrictions for your cloud provider when you specify this parameter. Review the permissions for the bucket or vault and make sure that the credentials have permission to read, write, list, and delete objects in this bucket or vault.

Tip: If you do not specify the BUCKETNAME parameter, the Replication Globally Unique ID is used as the default bucket name. The default is

```
ibmsp guid
```

where *guid* is the REPLICATION GLOBALLY UNIQUE ID value, minus the periods, in the output of the QUERY REPLSERVER command. For example, if the Replication Globally Unique ID is 52.82.39.20.64.d0.11.e6.9d.77.0a.00.27.00.00.00, the default bucket name is ibmsp.5282392064d011e69d770a0027000000.

Example: Verify the credentials of an S3 cloud-container storage pool

Validate the credentials of the cloud-container storage pool.

```
validate cloud
cloudtype=s3 cloudurl=http://123.234.123.234:5000/v2.0
password=protect8991 bucketname=ibmsp.5282392064d011e69d770a0027000000
```

Related commands

UPDATE STGPOOL (cloud-container)	Update a cloud-container storage pool.

VALIDATE LANFREE (Validate LAN-Free paths)

Use this command to determine which destinations for a given node using a specific storage agent are capable of LAN-Free data movement.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-VALidate LAnfree--node_name--stgagent_name------------------><
```

Parameters

node_name (Required)
: The name of the node to evaluate.

stgagent_name (Required)
: The name of the storage agent to evaluate.

Example: Validate a current LAN-Free configuration

Validate the current server definitions and configuration for node TIGER to use storage agent AIX_STA1 for LAN-free data operations.

```
validate lanfree tiger aix_sta1

Node  Storage  Operation Mgmt Class Destination LAN-Free Explanation

QUERY COPYGROUP	Displays the attributes of a copy group.
QUERY DEVCLASS	Displays information about device classes.
QUERY DOMAIN	Displays information about policy domains.
QUERY DRIVE	Displays information about drives.
QUERY LIBRARY	Displays information about one or more libraries.
QUERY MGMTCLASS	Displays information about management classes.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY PATH	Displays information about the path from a source to a destination.
QUERY POLICYSET	Displays information about policy sets.

Command	Description
QUERY SERVER	Displays information about servers.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
QUERY STGPOOL	Displays information about storage pools.

VALIDATE POLICYSET (Verify a policy set)

Use this command to verify that a policy set is complete and valid before you activate it. The command examines the management class and copy group definitions in the policy set and reports on conditions that you need to consider before activating the policy set.

The VALIDATE POLICYSET command fails if any of the following conditions exist:

- The policy set has no default management class.
- A copy group within the policy set specifies a copy storage pool as a destination.
- A management class specifies a copy storage pool as the destination for files that were migrated by an IBM Spectrum Protect™ for Space Management client.
- A TOCDESTINATION parameter is specified, and the storage pool is either a copy pool or has a data format other than NATIVE or NONBLOCK.

The server issues warning messages for the following conditions:

- A copy group specifies a storage pool that does not exist as a destination for backed-up or archived files.

  If you activate a policy set with copy groups that specify nonexistent storage pools, the client backup or archive operations fail.

- A management class specifies a storage pool that does not exist as a destination for files migrated by IBM Spectrum Protect for Space Management clients.
- The policy set does not have one or more management classes that exist in the current ACTIVE policy set.

  If you activate the policy set, backup files bound to the deleted management classes are rebound to the default management class in the new active policy set.

- The policy set does not have one or more copy groups that exist in the current ACTIVE policy set.

  If you activate the policy set, files bound to the management classes with deleted copy groups are no longer archived or backed up.

- The default management class for the policy set does not contain a backup or archive copy group.

  If you activate the policy set with this default management class, clients using the default cannot back up or archive files.

- A management class specifies that a backup version must exist before a file can be migrated from a client node (MIGREQUIRESBKUP=YES), but the management class does not contain a backup copy group.

If the server has data retention protection enabled, the following conditions must exist:

- All management classes in the policy set to be validated must contain an archive copy group.
- If a management class exists in the active policy set, a management class with the same name must exist in the policy set to be validated.
- If an archive copy group exists in the active policy set, the corresponding copy group in the policy set to be validated must have a RETVER value at least as large as the corresponding values in the active copy group.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the policy set belongs.

Syntax

```
>>-VALidate POlicyset--domain_name--policy_set_name------------><
```

Parameters

domain_name (Required)
: Specifies the name of the policy domain to which the policy set is assigned.

policy_set_name (Required)
: Specifies the name of the policy set to be validated.

Example: Validate a specific policy set

Validate the policy set `VACATION` located in the `EMPLOYEE_RECORDS` policy domain.

```
validate policyset employee_records vacation
```

Related commands

Table 1. Commands related to VALIDATE POLICYSET

Command	Description
ACTIVATE POLICYSET	Validates and activates a policy set.
COPY POLICYSET	Creates a copy of a policy set.
DEFINE COPYGROUP	Defines a copy group for backup or archive processing within a specified management class.
DEFINE MGMTCLASS	Defines a management class.
DELETE POLICYSET	Deletes a policy set, including its management classes and copy groups, from a policy domain.
QUERY POLICYSET	Displays information about policy sets.
UPDATE COPYGROUP	Changes one or more attributes of a copy group.
UPDATE POLICYSET	Changes the description of a policy set.

VALIDATE REPLICATION (Validate replication for a client node)

Use this command to identify the replication rules that apply to file spaces in client nodes that are configured for replication. You can also use this command to verify that the source replication server can communicate with the target replication server.

Before you begin replication processing, use the VALIDATE REPLICATION command to determine whether your replication configuration is correct.

Issue this command on the server that acts as a source for replicated data.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                        .-,-------------.
                        V               |
>>-VALidate REPLication------node_name---+----------------------->

   .-VERIFYconnection--=--No------.
>--+-----------------------------+----------------------------><
   '-VERIFYconnection--=--+-No--+-'
                          '-Yes-'
```

Parameters

node_name (Required)
: Specifies the name of the client node whose file spaces you want to display. To specify multiple client node names, separate the names with commas and no intervening spaces. You can use wildcard characters to specify names.

  Information is displayed only for client nodes that are either enabled or disabled for replication. The replication mode must be SEND. To determine whether a client node is enabled or disabled for replication and its mode, issue the QUERY NODE command. Look for values in the Replication State and Replication Mode fields.

VERIFYconnection
: Specifies whether to check the connection to a target replication server. The version of the target replication server is also checked to verify that it is Version 6.3 or later. This parameter is optional. The default is NO. You can specify one of the following values:

  No
  : The connection and version of the target replication server are not checked.

  Yes
  : The connection and version of the target replication server are checked.

Example: Validate replication for a client node

The name of the client node is NODE1. Verify the connection status between the source and the target replication servers.

```
validate replication node1 verifyconnection=yes

                  Node Name: NODE1
              Filespace Name: \\node1\c$
                        FSID: 1
                        Type: Bkup
Controlling Replication Rule: ACTIVE_DATA
      Replication Rule Level: System Level
                 Server Name: DRSRV
           Connection Status: Valid Connection

                  Node Name: NODE1
              Filespace Name: \\node1\c$
                        FSID: 1
                        Type: Arch
Controlling Replication Rule: ALL_DATA_HIGH_PRIORITY
      Replication Rule Level: Node Level
                 Server Name: DRSRV
           Connection Status: Valid Connection

                  Node Name: NODE1
              Filespace Name: \\node1\c$
                        FSID: 1
                        Type: SpMg
Controlling Replication Rule: ALL_DATA
      Replication Rule Level: System Level
                 Server Name: DRSRV
           Connection Status: Valid Connection
```

Output is displayed for all data types regardless of whether a file space contains the data types. For example, if a file space contains only backup and archive data, the output of the VALIDATE REPLICATION command also contains information that would be relevant to space-managed data.

Field descriptions

Node Name
: The node that owns the replicated data.

Filespace Name
: The name of the file space that belongs to the node.

  File space names can be in a different code page or locale than the server. If they are, the names in the Operations Center and the administrative command-line interface might not be displayed correctly. Data is backed up and can be restored normally, but the file space name or file name might be displayed with a combination of invalid characters or blank spaces.

If the file space name is Unicode-enabled, the name is converted to the server code page for display. The success of the conversion depends on the operating system, the characters in the name, and the server code page. Conversion can be incomplete if the string includes characters that are not available in the server code page or if the server cannot access system conversion routines. If the conversion is incomplete, the name might contain question marks, blanks, unprintable characters, or ellipses (...).

FSID
: The file space identifier for the file space. The server assigns a unique FSID when a file space is first stored on the server.

Type
: The type of data. The following values are possible:

  Arch
  : Archive data

  Bkup
  : Backup data

  SpMg
  : Data that was migrated by an IBM Spectrum Protect™ for Space Management client.

Controlling Replication Rule
: The name of the replication rule that controls replication for a data type in a file space. To determine whether the controlling rule is a file space rule, a client rule, or a server rule, check the Replication Rule Level field.

Replication Rule Level
: The level of the controlling rule in the replication-rule hierarchy. The following values are possible:

  Filespace
  : The controlling rule is assigned to a data type in the file space.

  Node
  : The controlling rule is assigned to a data type for a client node.

  Server
  : The controlling rule is assigned to a data type for all file spaces in all client nodes that are configured for replication.

Server Name
: The name of the target replication server to be queried.

Connection Status
: The connection status between the source and the target replication server. The following values are possible:

  Valid Connection
  : Communication with the target replication server was successful, and the target replication server is a V6.3 server.

  Target Server Not Set
  : The target replication server is not set. To set the target replication server, issue the SET REPLSERVER command.

  Communication Failure
  : The source replication server was unable to contact the target replication server. Examine the activity log for error messages about failed communications. Consider the following possible causes:

    - The replication configuration on the source replication server is not valid. One or more of the following problems might exist:
      - The server definition for the target replication server is incorrect.
      - If the target replication-server definition was deleted and redefined, issue the PING SERVER command to test the connection between the source and the target replication server. If the PING SERVER command is successful, issue the UPDATE SERVER command and specify FORCESYNC=YES to reset the server verification keys.
      - The server name, server low-level address, server high-level address, and server password do not match the values that are specified in the server definition on the target replication server.
    - The replication configuration on the target replication server is not valid. One or more of the following problems might exist:
      - The version of the target replication server is earlier than V6.3.
      - The server definition for the source replication server is incorrect.
      - The server name, server low-level address, server high-level address, and server password do not match the values that are specified in the server definition on the source replication server.
    - Network communications are unavailable. To test the connection between the source and target server, issue the PING SERVER command.
    - The target replication server is unavailable.
    - Sessions between the source and the target replication servers are disabled. To verify the status of sessions, issue the QUERY STATUS command.

Replication Suspended
: Replication processing is suspended when you restore the database on the source replication server or you disable replication processing on this server by issuing the DISABLE REPLICATION command.

Related commands

Table 1. Commands related to VALIDATE REPLICATION

Command	Description
DISABLE REPLICATION	Prevents outbound replication processing on a server.
ENABLE REPLICATION	Allows outbound replication processing on a server.
ENABLE SESSIONS	Resumes server activity following the DISABLE command or the ACCEPT DATE command.
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY REPLRULE	Displays information about node replication rules.
QUERY SERVER	Displays information about servers.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
SET ARREPLRULEDEFAULT	Specifies the server node-replication rule for archive data.
SET BKREPLRULEDEFAULT	Specifies the server node-replication rule for backup data.
SET REPLSERVER	Specifies a target replication server.
SET SPREPLRULEDEFAULT	Specifies the server node-replication rule for space-managed data.
UPDATE FILESPACE	Changes file-space node-replication rules.
UPDATE NODE	Changes the attributes that are associated with a client node.
UPDATE REPLRULE	Enables or disables replication rules.
UPDATE SERVER	Updates information about a server.

VALIDATE REPLPOLICY (Verify the policies on the target replication server)

Use this command to compare the policies for client nodes on the source replication server with the same policies on the target replication server where the client node data is being replicated.

The command displays the differences between these policies so that you can verify that any differences between the policies on the source and target replication servers are intended or you can modify the policies on the target replication server.

Ensure that IBM Spectrum Protect™, Version 7.1.1 or later, is installed on the source and target replication servers before you issue this command. Issue this command on the source replication server.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-VALidate REPLPolicy--+-------------+------------------------><
```

```
'-server_name-'
```

Parameters

server_name
: Specifies the name of the target replication server that has policies you want to verify. This parameter is optional. If you do not specify this parameter, the command sets the default replication server as the target replication server.

Example: Display the differences between the replication policies on a source and target replication server

To display the differences between the policies on the source replication server and the policies on the target replication server, CVTCVS_LXS_SRV2, where the client data is replicated, issue the following command on the source replication server:

```
VALIDATE REPLPOLICY CVTCVS_LXS_SRV2

Policy domain name          Policy domain name      Target
on this server              on target server        server name
--------------------------  ----------------------  -----------------
STANDARD                    STANDARD                CVTCVS_LXS_SRV2

Differences in policy set:
Change detected             Source server value     Target server value
--------------------------  ----------------------  -----------------
Mgmt class only on target   Not applicable          STANDARD2
Mgmt Class only on source   STANDARD1               Not applicable

Differences in backup       STANDARD in             STANDARD
copy group                  management class
Change detected             Source server value     Target server value
--------------------------  ----------------------  ------------------
Versions data exists        2                       20

Affected nodes
---------------------------------------------------------------------
NODE1,NODE2,NODE3,NODE4,NODE5
```

Field descriptions

Policy domain name on this server
: Specifies the policy domain name on the source replication server where the command is issued.

Policy domain name on target server
: Specifies the policy domain name on the target replication server.

Target server name
: Specifies the name of the target replication server.

Differences in policy set:
: Specifies the differences between the policies that are defined on the source and target replication servers. The differences between the policies are listed under the following fields:

  Change detected
  : Specifies the list of policy items that are different between the source and target replication servers.

  Source server value
  : Specifies the value for the policy item on the source replication server.

  Target server value
  : Specifies the value for the policy item on the target replication server.

Differences in backup copy group <backup_copy_group_name> in default management class OR Differences in archive copy group <archive_copy_group_name> in default management class
: Specifies the differences between the backup copy group or the archive copy group in the management class. The differences are listed under the following fields:

  Change Detected
  : Specifies the list of copy group fields that are different.

  Source server value

Specifies the value in the copy group field on the source replication server.

Target server value

Specifies the value in the copy group field on the target replication server.

Affected nodes

Specifies the names of all the client nodes that are affected by the changes that are shown in this output.

Related commands

Table 1. Commands related to VALIDATE REPLPOLICY

Command	Description
VALIDATE REPLICATION	Verifies replication for file spaces and data types.
QUERY REPLSERVER	Displays information about replicating servers.
SET DISSIMILARPOLICIES	Enable the policies on the target replication server to manage replicated data.
QUERY DOMAIN	Displays information about policy domains.
QUERY POLICYSET	Displays information about policy sets.
QUERY COPYGROUP	Displays the attributes of a copy group.
QUERY MGMTCLASS	Displays information about management classes.

VARY (Bring a random access volume online or offline)

Use this command to make a random access storage pool volume online or offline to the server.

Privilege class

This command is valid only for volumes on random access devices. For example, use this command during maintenance or corrective action of a random access volume. You cannot vary a random access volume online that is defined as unavailable.

To issue this command, you must have system privilege or operator privilege.

Syntax

```
                                  .-Wait--=--No------.
>>-VARy--+-ONline--+--volume_name--+------------------+--------><
         '-OFfline-'               '-Wait--=--+-No--+-'
                                              '-Yes-'
```

Parameters

ONline

Specifies that the server can use the random access volume.

OFfline

Specifies that the server cannot use the volume.

volume_name (Required)

Specifies the volume identifier. Volume names cannot contain embedded blanks or equal signs.

Wait

Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default is NO. Possible values are:

No

Specifies that the server processes this command in the background, while other tasks run. The server displays messages created from the background process either in the activity log or the server console, depending on where messages are logged.

Yes

Specifies that the server processes this command in the foreground. Wait for the command to complete before you continue with other tasks. The server displays the output messages to the administrative client when the command completes.

AIX Linux Windows You cannot specify WAIT=YES from the server console.

Example: Bring volume online

AIX Linux Make volume /adsm/stgvol/1 available to the server for use as a storage pool volume. AIX Linux

```
vary online /adsm/stgvol/1
```

Windows Make volume j:\storage\pool001 available to the server for use as a storage pool volume. Windows

```
vary online j:\storage\pool001
```

Related commands

Table 1. Commands related to VARY

Command	Description
CANCEL PROCESS	Cancels a background server process.
DEFINE VOLUME	Assigns a volume to be used for storage within a specified storage pool.
DELETE VOLUME	Deletes a volume from a storage pool.
QUERY PROCESS	Displays information about background processes.
QUERY VOLUME	Displays information about storage pool volumes.

Server options

At installation, IBM Spectrum Protect™ provides a server options file that contains a set of default options to start the server.

The file is:

- dsmserv.opt in the server instance directory

Server options let you customize the following:

- Communication
- Server storage
- Client-server
- Date, number, time, and language
- Database and recovery log
- Data transfer
- Message
- Event logging
- Security and licensing

Several other options are available for miscellaneous purposes. These undocumented options are intended to be used only by IBM® support.
To display the current option settings, enter:

```
query option
```

- Modifying server options
  The server reads the server options file at server initialization. When you update a server option by editing the file, you must stop and start the server to activate the updated server options file.
- Types of server options
  Server options let you customize how some functions and processes work.
- 3494SHARED
  The 3494SHARED option specifies whether an IBM 3494 library can share applications other than IBM Spectrum Protect.

- ACSACCESSID
  The ACSACCESSID option specifies the ID for the ACS access control for an ACSLS library.
- ACSLOCKDRIVE
  The ACSLOCKDRIVE option specifies if the drives within the ACSLS libraries are locked. Drive locking ensures the exclusive use of the drive in the ACSLS library in a shared environment. However, there is some performance gain if libraries are not locked. When other applications do not share the IBM Spectrum Protect drives, drive locking is not required.
- ACSQUICKINIT
  The ACSQUICKINIT option specifies whether, at server startup, the initialization of the ACSLS library is a quick or full initialization. The default is Yes. A quick initialization avoids the overhead associated with synchronizing the IBM Spectrum Protect server inventory with the ACSLS library inventory (through an audit of the library).
- ACSTIMEOUTX
  The ACSTIMEOUTX option specifies the multiple for the built-in timeout value for ACSLS APIs. The built-in timeout value for the ENTER, EJECT, and AUDIT ACS API is 1800 seconds; for all other ACSLS APIs it is 600 seconds. For example, if the multiple value specified is 5, the timeout value for audit API becomes 9000 seconds, and all other APIs become 3000 seconds.
- ACTIVELOGDIRECTORY
  The ACTIVELOGDIRECTORY option specifies the name of the directory where all active logs are stored.
- ACTIVELOGSIZE
  The ACTIVELOGSIZE option sets the total log size.
- ADMINCOMMTIMEOUT
  The ADMINCOMMTIMEOUT option specifies how long the server waits for an expected administrative client message during an operation that causes a database update.
- ADMINIDLETIMEOUT
  The ADMINIDLETIMEOUT option specifies the amount of time, in minutes, that an administrative client session can be idle before the server cancels the session.
- ADMINONCLIENTPORT
  The ADMINONCLIENTPORT option specifies whether the TCPPORT can be used by administrative sessions. The default is YES.
- Windows ADSMGROUPNAME
  The ADSMGROUPNAME option specifies the name of a Windows group. A client node must be a member of this group to use the IBM Spectrum Protect server through NT Unified Logon. The client node must also be a registered IBM Spectrum Protect client node.
- ALIASHALT
  The ALIASHALT option allows administrators to give the IBM Spectrum Protect **HALT** command a different name.
- ALLOWDESAUTH
  The ALLOWDESAUTH option specifies whether to allow use of the Data Encryption Standard (DES) algorithm for authentication between a server and a backup-archive client.
- ALLOWREORGINDEX
  The ALLOWREORGINDEX option specifies whether server-initiated index reorganization is enabled or disabled.
- ALLOWREORGTABLE
  The ALLOWREORGTABLE option specifies whether server-initiated table reorganization is enabled or disabled.
- ARCHFAILOVERLOGDIRECTORY
  The ARCHFAILOVERLOGDIRECTORY option specifies the directory which the server uses to store archive log files that cannot be stored in the archive log directory.
- ARCHLOGCOMPRESS
  You can enable or disable compression of archive logs on the IBM Spectrum Protect server. By compressing the archive logs, you reduce the amount of space that is required for storage.
- ARCHLOGDIRECTORY
  The ARCHLOGDIRECTORY option specifies a directory that the database manager can archive a log file into after all the transactions represented in that log file are completed.
- ARCHLOGUSEDTHRESHOLD
  The ARCHLOGUSEDTHRESHOLD option specifies when to start an automatic database backup in relation to the percentage of archive log file space used. The default is 80 percent.
- ASSISTVCRRECOVERY
  The ASSISTVCRRECOVERY option specifies whether IBM Spectrum Protect assists an IBM 3590 drive in recovering from a lost or corrupted Vital Cartridge Records (VCR) condition. If you specify YES (the default) and if IBM Spectrum Protect detects an error during the mount processing, it locates to the end-of-data during the dismount processing to allow the drives to restore the VCR. During the tape operation, there might be some small effect on performance because the drive cannot complete a fast locate with a lost or corrupted VCR. However, there is no loss of data.
- AUDITSTORAGE
  As part of a license audit operation, the server calculates, by node, the amount of server storage used for backup, archive, and space–managed files. For servers managing large amounts of data, this calculation can take a great deal of CPU time

and can stall other server activity. You can use the AUDITSTORAGE option to specify that storage is not to be calculated as part of a license audit.

- BACKUPINITIATIONROOT
  The BACKUPINITIATIONROOT option specifies whether the server overrides node parameter values for users who are not IBM Spectrum Protect authorized users.
- CHECKTAPEPOS
  The CHECKTAPEPOS option specifies whether the IBM Spectrum Protect server validates the position of data blocks on tape.
- CLIENTDEDUPTXNLIMIT
  The CLIENTDEDUPTXNLIMIT option specifies the maximum size of a transaction when client-side deduplicated data is backed up or archived.
- COMMMETHOD
  The COMMMETHOD option specifies a communication method to be used by the server.
- COMMTIMEOUT
  The COMMTIMEOUT option specifies how long the server waits for an expected client message during an operation that causes a database update. If the length of time exceeds this time-out, the server ends the session with the client. You may want to increase the time-out value to prevent clients from timing out. Clients may time out if there is a heavy network load in your environment or they are backing up large files.
- CONTAINERRESOURCETIMEOUT
  The CONTAINERRESOURCETIMEOUT option specifies how long the server waits to complete a data store operation to a container storage pool.
- Windows DATEFORMAT
  The DATEFORMAT option specifies the format in which dates are displayed by the server.
- DBDIAGLOGSIZE
  This option helps to control the amount of space that is used by diagnostic log files.
- DBDIAGPATHFSTHRESHOLD
  The DBDIAGPATHFSTHRESHOLD option specifies the threshold for free space on the file system or disk that contains the db2diag.log file.
- DBMEMPERCENT
  Use this option to specify the percentage of the virtual address space that is dedicated to the database manager processes.
- DBMTCPPORT
  The DBMTCPPORT option specifies the port number on which the TCP/IP communication driver for the database manager waits for requests for client sessions.
- DEDUPREQUIRESBACKUP
  The DEDUPREQUIRESBACKUP option specifies whether volumes in primary sequential-access storage pools that are set up for data deduplication can be reclaimed and whether duplicate data can be discarded before the storage pools are backed up.
- DEDUPTIER2FILESIZE
  The DEDUPTIER2FILESIZE option specifies at what file size IBM Spectrum Protect begins to use Tier 2 data deduplication.
- DEDUPTIER3FILESIZE
  The DEDUPTIER3FILESIZE option specifies at what file size IBM Spectrum Protect begins to use Tier 3 data deduplication.
- DEVCONFIG
  The DEVCONFIG option specifies the name of a file in which you want IBM Spectrum Protect to store a backup copy of device configuration information.
- DISABLEREORGTABLE
  The DISABLEREORGTABLE option specifies whether online table reorganization is disabled for table names that are specified in the tables list.
- DISABLESCHEDS
  The DISABLESCHEDS option specifies whether administrative and client schedules are disabled during IBM Spectrum Protect server recovery.
- DISPLAYLFINFO
  The DISPLAYLFINFO option specifies how the accounting records and summary table entries report the node name.
- DNSLOOKUP
  The DNSLOOKUP option specifies whether the server uses system API calls to determine the domain name server (DNS) names of systems that contact the server.
- DRIVEACQUIRERETRY
  The DRIVEACQUIRERETRY option lets you specify how many times the server retries the acquisition of a drive in an IBM 349x library. If the library is shared among multiple applications, its drives may appear to be available to the server (through the use of a background polling process) when they are not.
- ENABLENASDEDUP
  The ENABLENASDEDUP server option specifies whether the server deduplicates data that is stored by a network-attached storage (NAS) file server. This option applies only to NetApp file servers.

- EVENTSERVER
  The EVENTSERVER option specifies whether at startup the server should try to contact the event server.
- EXPINTERVAL
  The EXPINTERVAL option specifies the interval, in hours, between automatic inventory expiration processes by IBM Spectrum Protect. Inventory expiration removes client backup and archive file copies from the server as specified by the management classes to which the client files are bound. If expiration is not run periodically, storage pool space is not reclaimed from expired client files, and the server requires more storage space than required by policy.
- EXPQUIET
  The EXPQUIET option specifies whether IBM Spectrum Protect sends detailed messages during expiration processing.
- Linux Windows FASPBEGPORT
  The FASPBEGPORT option specifies the starting number in the range of port numbers that are used for network communications with Aspera® Fast Adaptive Secure Protocol (FASP®) technology.
- Linux Windows FASPENDPORT
  The FASPENDPORT option specifies the ending number in the range of port numbers that are used for network communications with Aspera Fast Adaptive Secure Protocol (FASP) technology.
- Linux Windows FASPTARGETRATE
  The FASPTARGETRATE option specifies the target rate for data transfer with Aspera Fast Adaptive Secure Protocol (FASP) technology. By specifying the target rate, you limit the bandwidth of each network connection that uses Aspera FASP technology. In this way, you can ensure that sufficient bandwidth is available for all network connections.
- FFDCLOGLEVEL
  The FFDCLOGLEVEL option specifies the type of general server messages that are displayed in the first failure data capture (FFDC) log.
- FFDCLOGNAME
  The FFDCLOGNAME option specifies a name for the first failure data capture (FFDC) log.
- FFDCMAXLOGSIZE
  The FFDCMAXLOGSIZE option specifies the size for the first failure data capture (FFDC) log file.
- FFDCNUMLOGS
  The FFDCNUMLOGS option specifies the number of log files that can be used for circular logging. The default value is 10.
- FILEEXIT
  The FILEEXIT option specifies a file to which enabled events are routed. Each logged event is a record in the file.
- FILETEXTEXIT
  The FILETEXTEXIT option specifies a file to which enabled events are routed. Each logged event is a fixed-size, readable line.
- FSUSEDTHRESHOLD
  The FSUSEDTHRESHOLD option specifies what percentage of the file system can be filled up by the database before an alert message is issued.
- IDLETIMEOUT
  The IDLETIMEOUT option specifies the amount of time, in minutes, that a client session can be idle before the server cancels the session. You may want to increase the time-out value to prevent clients from timing out if there is a heavy network load in your environment. Note, however, that a large number of idle sessions could prevent other users from connecting to the server.
- KEEPALIVE
  The KEEPALIVE option specifies whether the Transmission Control Protocol (TCP) keepalive function is enabled for outbound TCP sockets. The TCP keepalive function sends a transmission from one device to another to check that the link between the two devices is operating.
- KEEPALIVETIME
  The KEEPALIVETIME option specifies how often TCP sends a keepalive transmission when it receives a response. This option applies only if you set the KEEPALIVE option to YES.
- KEEPALIVEINTERVAL
  The KEEPALIVEINTERVAL option specifies how often a keepalive transmission is sent if no response is received. This option applies only if you set the KEEPALIVE option to YES.
- LANGUAGE
  The LANGUAGE option controls the initialization of locales. A locale includes the language and the date, time, and number formats to be used for the console and server.
- LDAPCACHEDURATION
  The LDAPCACHEDURATION option determines the amount of time that the IBM Spectrum Protect server caches LDAP password authentication information.
- LDAPURL
  The LDAPURL option specifies the location of a Lightweight Directory Access Protocol (LDAP) server. Set the LDAPURL option after you configure the LDAP server.
- MAXSESSIONS
  The MAXSESSIONS option specifies the maximum number of simultaneous client sessions that can connect with the

server.

- MESSAGEFORMAT
  The MESSAGEFORMAT option specifies whether a message number is displayed in all lines of a multi-line message.
- MIRRORLOGDIRECTORY
  The MIRRORLOGDIRECTORY option specifies the directory for mirroring the active log path.
- MOVEBATCHSIZE
  The MOVEBATCHSIZE option specifies the number of client files that are to be moved and grouped together in a batch, within the same server transaction. This data movement results from storage pool backups and restores, migration, reclamation, and MOVE DATA operations. This option works with the MOVESIZETHRESH option.
- MOVESIZETHRESH
  The MOVESIZETHRESH option specifies, in megabytes, a threshold for the amount of data moved as a batch, within the same server transaction. When this threshold is reached, no more files are added to the current batch, and a new transaction is started after the current batch is moved.
- MSGINTERVAL
  The MSGINTERVAL option specifies the time, in minutes, between messages prompting an operator to mount a tape for the server.
- Windows NAMEDPIPENAME
  The NAMEDPIPENAME option specifies a communication method that allows processes to communicate with one another without having to know where the sender and receiver processes are located. The name acts like an alias, connecting the two processes regardless of whether they are on the same computer or across connected domains.
- NDMPCONNECTIONTIMEOUT
  The NDMPCONNECTIONTIMEOUT server option specifies the time in hours that IBM Spectrum Protect server waits to receive status updates during NDMP restore operations across the LAN. NDMP restore operations of large NAS file systems can have long periods of inactivity. The default is 6 hours.
- NDMPCONTROLPORT
  The NDMPCONTROLPORT option specifies the port number to be used for internal communications for certain Network Data Management Protocol (NDMP) operations. The IBM Spectrum Protect server does not function as a general purpose NDMP tape server.
- NDMPENABLEKEEPALIVE
  The NDMPENABLEKEEPALIVE server option specifies whether the IBM Spectrum Protect server enables Transmission Control Protocol (TCP) keepalive on network data-management protocol (NDMP) control connections to network-attached storage (NAS) devices. The default is NO.
- AIX Linux Windows NDMPKEEPIDLEMINUTES
  The NDMPKEEPIDLEMINUTES server option specifies the amount of time, in minutes, before the operating system transmits the first Transmission Control Protocol (TCP) keepalive packet on a network data-management protocol (NDMP) control connection. The default is 120 minutes.
- NDMPPORTRANGE
  The NDMPPORTRANGE option specifies the range of port numbers through which IBM Spectrum Protect cycles to obtain a port number for accepting a session from a network-attached storage (NAS) device for data transfer. The default is 0,0 which means that IBM Spectrum Protect lets the operating system provide a port (ephemeral port).
- NDMPPREFDATAINTERFACE
  This option specifies the IP address that is associated with the interface in which you want the server to receive all Network Data Management Protocol (NDMP) backup data.
- NOPREEMPT
  The server allows certain operations to preempt other operations for access to volumes and devices. You can specify the NOPREEMPT option to disable preemption. When preemption is disabled, no operation can preempt another for access to a volume, and only a database backup operation can preempt another operation for access to a device.
- NORETRIEVEDATE
  The NORETRIEVEDATE option specifies that the server does not update the retrieve date of a file in a disk storage pool when a client restores or retrieves the file. This option and the MIGDELAY storage pool parameter control when the server migrates files.
- Windows NPAUDITFAILURE
  The NPAUDITFAILURE option specifies whether an event is sent to the event log when a node logs in to the server using a name that is in the Windows group but does not match the Windows account login name. To ensure that a node can access only its own data, the node name and the Windows account name must match.
- Windows NPAUDITSUCCESS
  The NPAUDITSUCCESS option specifies that an event is sent to the event log when a client node user is authenticated for access to the server through SECUREPIPE.
- Windows NPBUFFERSIZE
  The NPBUFFERSIZE option specifies the size of the Named Pipes communication buffer.
- Windows NUMBERFORMAT
  The NUMBERFORMAT option specifies the format in which the server displays numbers.

- NUMOPENVOLSALLOWED
  The NUMOPENVOLSALLOWED option specifies the number of input FILE volumes in a deduplicated storage pool that can be open at one time.
- PUSHSTATUS
  The PUSHSTATUS option is used on spoke servers to ensure that status information is sent to the hub server. Do not update this option unless you must restore the Operations Center configuration to the preconfigured state where the IBM Spectrum Protect servers are not defined as hub or spoke servers.
- QUERYAUTH
  The QUERYAUTH option specifies the administrative authority level required to issue QUERY or SQL SELECT commands. By default any administrator can issue QUERY and SELECT commands. You can use this option to restrict the use of these commands.
- RECLAIMDELAY
  This option delays the reclamation of a SnapLock volume, allowing remaining data to expire so that there is no need to reclaim the volume.
- RECLAIMPERIOD
  This option allows you to set the number of days for the reclamation period of a SnapLock volume.
- REORGBEGINTIME
  The REORGBEGINTIME option specifies the earliest time that the IBM Spectrum Protect server can start a table or index reorganization.
- REORGDURATION
  The REORGDURATION option specifies an interval during which server-initiated table or index reorganization can start.
- REPORTRETRIEVE
  The REPORTRETRIEVE option reports on restore or retrieve operations that are performed by client nodes or administrators. The default is NO.
- REPLBATCHSIZE
  The REPLBATCHSIZE option specifies the number of client files that are to be replicated in a batch, within the same server transaction. This option affects only the node replication processes and works with the REPLSIZETHRESH option to improve node replication processing.
- REPLSIZETHRESH
  The REPLSIZETHRESH option specifies, in megabytes, a threshold for the amount of data replicated, within the same server transaction.
- REQSYSAUTHOUTFILE
  The REQSYSAUTHOUTFILE option specifies if system authority is required for administrative commands that cause IBM Spectrum Protect to write to an external file.
- RESOURCETIMEOUT
  The RESOURCETIMEOUT option specifies how long the server waits for a resource before canceling the pending acquisition of a resource. When a timeout occurs the request for the resource will be canceled.
- RESTOREINTERVAL
  The RESTOREINTERVAL option specifies how long a restartable restore session can be saved in the server database. As long as the restore session is saved in the database, it can be restarted from the point at which it stopped.
- RETENTIONEXTENSION
  The RETENTIONEXTENSION option specifies the number of days to extend the retention date of a SnapLock volume. This option allows the server to extend the retention date of a SnapLock volume in order to avoid excessive reclamation.
- AIX Linux Windows SANDISCOVERY
  The SANDISCOVERY option specifies whether the IBM Spectrum Protect SAN discovery function is enabled.
- AIX Linux Windows SANDISCOVERYTIMEOUT
  The SANDISCOVERYTIMEOUT option specifies the amount of time allowed for host bus adapters to respond when they are queried by the SAN discovery process. Once the time specified for the SANDISCOVERYTIMEOUT is reached, the process times out.
- AIX Linux Windows SANREFRESHTIME
  The SANREFRESHTIME option specifies the amount of time that elapses before the cached SAN discovery information is refreshed. The SANREFRESHTIME option has a default value of 0, which means that there is no SAN discovery cache. The information is obtained directly from the host bus adapter (HBA) every time the server performs a SAN discovery operation.
- SEARCHMPQUEUE
  The SEARCHMPQUEUE option specifies the order in which the server satisfies requests in the mount queue. If the option is specified, the server first tries to satisfy requests for volumes that are already mounted. These requests may be satisfied before other requests, even if the others have been waiting longer for the mount point. If this option is not specified, the server satisfies requests in the order in which they are received.
- Windows SECUREPIPES
  When using the named pipes protocol, enabling SECUREPIPES forces the server to check the Windows group designated by ADSMGROUPNAME in order to authenticate a client node/user.

- SERVERDEDUPTXNLIMIT
  The SERVERDEDUPTXNLIMIT option specifies the maximum size of objects that can be deduplicated on the server.
- SHMPORT
  AIX Linux The SHMPORT option specifies the TCP/IP port address of a server when using shared memory. All shared memory communications start with a TCP/IP connection. Windows The SHMPORT option specifies the port that the server listens on for shared memory connections.
- SHREDDING
  The SHREDDING option specifies whether shredding of deleted sensitive data is performed automatically or manually. Shredding applies only to data in storage pools that have been explicitly configured to support shredding.
- SNMPHEARTBEATINTERVAL
  The SNMPHEARTBEATINTERVAL option specifies the interval in minutes between queries of the IBM Spectrum Protect server.
- SNMPMESSAGECATEGORY
  The SNMPMESSAGECATEGORY option specifies the trap types used when messages are forwarded from the server, through the Simple Network Management Protocol (SNMP) subagent, to the SNMP manager.
- SNMPSUBAGENT
  The SNMPSUBAGENT option specifies the parameters needed for the IBM Spectrum Protect subagent to communicate with the Simple Network Management Protocol (SNMP) daemon. This option is only to configure the SNMP subagent for communicating with the SNMP agent; it is ignored by the server.
- SNMPSUBAGENTHOST
  The SNMPSUBAGENTHOST option specifies the location of the IBM Spectrum Protect Simple Network Management Protocol (SNMP) subagent. The default for this option is 127.0.0.1.
- SNMPSUBAGENTPORT
  The SNMPSUBAGENTPORT option specifies the port number of the IBM Spectrum Protect Simple Network Management Protocol (SNMP) subagent.
- SSLFIPSMODE
  The SSLFIPSMODE option specifies whether the Federal Information Processing Standards (FIPS) mode is in effect for Secure Sockets Layer (SSL). The default is NO.
- SSLINITTIMEOUT
  The SSLINITTIMEOUT option specifies the time, in minutes, that the server waits for a Secure Sockets Layer (SSL) session to complete initialization before the server cancels the session.
- SSLTCPADMINPORT
  The SSLTCPADMINPORT option specifies the port address on which the server TCP/IP communication driver waits for requests for SSL-enabled sessions only. The sessions are for the command-line administrative client.
- SSLTCPPORT
  The SSLTCPPORT option specifies the Secure Sockets Layer (SSL) port number for SSL-enabled sessions only. The server TCP/IP communication driver waits for requests on this port for SSL-enabled sessions from the client.
- TCPADMINPORT
  The TCPADMINPORT option specifies the port number on which the server TCP/IP communication driver waits for requests for TCP/IP and SSL-enabled sessions other than client sessions. This includes administrative sessions, server-to-server sessions, storage agent sessions, library client sessions, managed server sessions, and event server sessions.
- AIX Linux TCPBUFSIZE
  The TCPBUFSIZE option specifies the size of the buffer used for TCP/IP send requests. During a restore, client data moves from the IBM Spectrum Protect session component to a TCP communication driver. The TCPBUFSIZE option determines if the server sends the data directly from the session buffer or copies the data to the TCP buffer. A 32 KB buffer size forces the server to copy data to its communication buffer and flush the buffer when it fills.
- TCPNODELAY
  The TCPNODELAY option specifies whether the server disables the delay of sending successive small packets on the network.
- TCPPORT
  The TCPPORT option specifies the port number on which the server TCP/IP communication driver waits for requests for client sessions. The server TCP/IP communication driver listens on this port for both TCP/IP and SSL-enabled sessions from the client.
- TCPWINDOWSIZE
  The TCPWINDOWSIZE option specifies, in kilobytes, the amount of receive data that can be buffered at one time on a TCP/IP connection. The sending host cannot send more data until it receives an acknowledgment and a TCP receive window update. Each TCP packet contains the advertised TCP receive window on the connection. A larger window lets the sender continue sending data, and may improve communication performance, especially on fast networks with high latency.
- TECBEGINEVENTLOGGING
  The TECBEGINEVENTLOGGING option specifies whether event logging for the Tivoli® receiver should begin when the server starts up. If the TECHOST option is specified, TECBEGINEVENTLOGGING defaults to YES.

- TECHOST
  The TECHOST option specifies the host name or IP address for the Tivoli event server.
- TECPORT
  The TECPORT option specifies the TCP/IP port address on which the Tivoli event server is listening. This option is only required if the Tivoli event server is on a system that does not have a Port Mapper service running.
- TECUTF8EVENT
  The TECUTF8EVENT option allows the IBM Spectrum Protect administrator to send information to the Tivoli Enterprise Console® (TEC) server in UTF–8 data format. The default is No. You can display whether or not this option is enabled by issuing the QUERY OPTION command.
- THROUGHPUTDATATHRESHOLD
  The THROUGHPUTDATATHRESHOLD option specifies a throughput threshold that a client session must reach to prevent being canceled after the time threshold is reached.
- THROUGHPUTTIMETHRESHOLD
  The THROUGHPUTTIMETHRESHOLD option specifies the time threshold for a session after which it may be canceled for low throughput.
- Windows TIMEFORMAT
  The TIMEFORMAT option specifies the format in which time is displayed by the server.
- TXNGROUPMAX
  The TXNGROUPMAX option specifies the number of objects that are transferred as a group between a client and the server between transaction commit points. The minimum value is 4 objects and the maximum value is 65000 objects. The default value is 4096 objects. The objects transferred are actual files, directories, or both. The server counts each file or directory as one object.
- UNIQUETDPTECEVENTS
  The UNIQUETDPTECEVENTS option generates a unique Tivoli Enterprise Console (TEC) event class for each individual IBM Spectrum Protect message, including client, server, and IBM Spectrum Protect Data Protection client messages. The default is No.
- UNIQUETECEVENTS
  The UNIQUETECEVENTS option generates a unique Tivoli Enterprise Console (TEC) event class for each individual IBM Spectrum Protect message. The default is No.
- USEREXIT
  The USEREXIT option specifies a user-defined exit that will be given control to manage an event.
- VERBCHECK
  The VERBCHECK option specifies that the server will do additional error checking on the structure of commands sent by the client. This option should only be enabled when the client sends incorrectly formed requests to the server, causing the server to crash. When this option is enabled, you will get a protocol error instead of a server crash.
- VOLUMEHISTORY
  The VOLUMEHISTORY option specifies the name of files to be automatically updated whenever server sequential volume history information is changed. There is no default for this option.

Modifying server options

The server reads the server options file at server initialization. When you update a server option by editing the file, you must stop and start the server to activate the updated server options file.

About this task

You can change some options dynamically without stopping and starting the server, by using the SETOPT command. See SETOPT (Set a server option for dynamic update) for details.

AIX Linux The dsmserv.opt.smp file (also provided at installation) contains the format of the options file and all the default settings. You can change any options in the dsmserv.opt.smp file. To have the server use the changed options, you must rename the file to dsmserv.opt. To activate an option within the server options file, remove the *>>> that precedes the option. The server ignores any options preceded by *>>>.

Windows You can modify server options by using the options file editor included in the IBM Spectrum Protect™ Console. This editor provides communications parameter detection, value validation, and help for all options. The options file editor is the preferred way to change server options, but you can also use a text editor.

Types of server options

Server options let you customize how some functions and processes work.

- Server communication options
  You can use server options to specify server communication methods and their characteristics.
- Server storage options
  IBM Spectrum Protect provides a number of options that you can specify to configure certain device and server storage operations.
- Client-server options
  You can use server options to control client-server processing.
- Date, number, time, and language options
  You can use server options to specify display formats for the dates, times, numbers, and national language.
- Database options
  You can use server options to control some aspects of database processing.
- Data transfer options
  You can use server options to control how IBM Spectrum Protect groups and transfers data.
- Message options
  You can use server options to give you more flexibility in the way IBM Spectrum Protect issues messages.
- Event logging options
  Options can help you manage event logging receivers.
- Security options and licensing options
  You can use server options to customize server security and license audits.
- Miscellaneous options
  You can use a variety of miscellaneous server options to customize IBM Spectrum Protect.

Server communication options

You can use server options to specify server communication methods and their characteristics.

Table 1. Communication options

Option	Description
ADMINCOMMTIMEOUT	The amount of time that the server waits for an administrative client message during an operation that causes a database update
ADMINIDLETIMEOUT	The amount of time an administrative client session can be idle
ADMINONCLIENTPORT	The port that determines whether administrative sessions can use the port specified in the TCPPORT option
COMMMETHOD	The server communication method
DBMTCPPORT	The port number on which the TCP/IP communication driver for the database manager waits for client session requests
DNSLOOKUP	Control of use of Domain Name Services to lookup names of systems contacting the server
LDAPCACHEDURATION	Determines the amount of time that authentication sessions, to the same node or administrator, are skipped. You might see a slight performance boost when skipping sessions.
LDAPURL	Specifies the LDAP directory server. Each setting must have the LDAP directory server name, a port number, and the base distinguished name of the namespace or suffix that the server maintains.
Windows NAMEDPIPENAME	Windows The named pipes communication method

Option	Description
NDMPCONTROLPORT	The internal communications port used for certain Network Data Management Protocol (NDMP) operations
NDMPENABLEKEEPALIVE	The TCP keepalive mechanism
AIX Linux Windows NDMPKEEPIDLEMINUTES	AIX Linux Windows The amount of idle time before the first TCP keepalive packet is sent
Windows NPBUFFERSIZE	Windows The size of the Named Pipes communication buffer
SHMPORT	AIX Linux The TCP/IP port address of a server when using shared memory Windows The port that the server listens on for shared memory connections
SNMPHEARTBEATINTERVAL	The interval in minutes between queries of the IBM Spectrum Protect server
SNMPMESSAGECATEGORY	The trap types used when messages are forwarded from the server
SNMPSUBAGENT	The parameters needed for the IBM Spectrum Protect subagent to communicate with the SNMP daemon
SNMPSUBAGENTHOST	The location of the IBM Spectrum Protect SNMP subagent
SNMPSUBAGENTPORT	The port address of the IBM Spectrum Protect SNMP subagent
SSLFIPSMODE	Specifies whether the Federal Information Processing Standards (FIPS) mode is in effect for Secure Sockets Layer (SSL)
SSLTCPADMINPORT	The port address on which the server's TCP/IP communication driver waits for requests for SSL-enabled sessions for the command-line administrative client
SSLTCPPORT	The SSL-only port number on which the server's TCP/IP communication driver waits for requests for SSL-enabled sessions from the following sources: • Command line backup-archive client • Backup-archive GUI • Administrative client • Application programming interface (API)
TCPADMINPORT	The TCP/IP port number for administrative sessions
AIX Linux TCPBUFSIZE	AIX Linux The size of the buffer used for TCP/IP send requests
TCPPORT	The TCP/IP port number for client sessions

Option	Description
TCPWINDOWSIZE	The client node TCP/IP sliding window

Server storage options

IBM Spectrum Protect™ provides a number of options that you can specify to configure certain device and server storage operations.

Table 1. Server storage options

Option	Description
3494SHARED	Enables sharing of a 3494 library with applications other than IBM Spectrum Protect.
ACSACCESSID	The ID for the ACS access control.
ACSLOCKDRIVE	Allows the drives within the ACSLS libraries to be locked.
ACSQUICKINIT	Allows a quick or full initialization of the ACSLS library.
ACSTIMEOUTX	The multiple for the built-in timeout value for the ACSLS API.
ASSISTVCRRECOVERY	Specifies whether the server assists an IBM 3590 drive in recovering from a lost or corrupted Vital Cartridge Records (VCR) condition.
CHECKTAPEPOS	Specifies whether the server validates data position on tape.
CLIENTDEDUPTXNLIMIT	Specifies the maximum size of a transaction when client-side deduplicated data is backed up or archived.
DEDUPREQUIRESBACKUP	Specifies whether volumes in primary sequential-access storage pools that are set up for data deduplication can be reclaimed and whether duplicate data can be discarded before the storage pools are backed up.
DEDUPTIER2FILESIZE	File size at which Tier 2 processing is used for data deduplication.
DEDUPTIER3FILESIZE	File size at which Tier 3 processing is used for data deduplication.
DEVCONFIG	The name of the file that store backup copies of device configuration information.
DRIVEACQUIRERETRY	The number of times that the server retries the acquisition of a drive in an IBM 349x library that is shared among multiple applications.
ENABLENASDEDUP	Specifies whether the server deduplicates data that is stored by a NetApp network-attached storage (NAS) file server.
NUMOPENVOLSALLOWED	The number of input FILE volumes in a deduplicated storage pool that can be open at one time.
RECLAIMDELAY	The number of days that the reclamation of a SnapLock volume is delayed.
RECLAIMPERIOD	The number of days for the reclamation period of a SnapLock volume
RESOURCETIMEOUT	The length of time that the server waits for a resource before canceling the pending acquisition of the resource.
RETENTIONEXTENSION	The number of days to extend the retention date of a SnapLock volume.
AIX Linux Windows SANDISCOVERY	AIX Linux Windows Whether the IBM Spectrum Protect SAN discovery function is enabled.
AIX Linux Windows SANDISCOVERYTIMEOUT	AIX Linux Windows Amount of time before the SAN discovery process times out.
AIX Linux Windows SANREFRESHTIME	AIX Linux Windows Amount of time before cached SAN discovery information is refreshed.
SEARCHMPQUEUE	The order in which the server satisfies requests in the mount queue.
SERVERDEDUPTXNLIMIT	Specifies the maximum size of objects that can be deduplicated on the server.

Client-server options

You can use server options to control client-server processing.

Table 1. Client-Server options

Option	Description
COMMTIMEOUT	The number of seconds the server waits for a response from a client before timing out the client session
DISABLESCHEDS	Whether administrative and client schedules are disabled during the IBM Spectrum Protect server recovery scenario
IDLETIMEOUT	The number of minutes the server allows a client session to remain idle before timing out the client session
MAXSESSIONS	The maximum number of simultaneous client sessions with the server
THROUGHPUTDATATHRESHOLD	The throughput threshold that a client session must reach to prevent being canceled after the time threshold is reached
THROUGHPUTTIMETHRESHOLD	The time threshold for a session after which it may be canceled for low throughput
VERBCHECK	Whether additional error checking is done for commands sent by the client

Date, number, time, and language options

You can use server options to specify display formats for the dates, times, numbers, and national language.

Table 1. Date, number, time, and language options

Option	Description
Windows DATEFORMAT	Windows The format by which dates are displayed
LANGUAGE	The national language is used to present client messages
Windows NUMBERFORMAT	Windows The format for displaying numbers
Windows TIMEFORMAT	Windows The format displaying times

Database options

You can use server options to control some aspects of database processing.

Table 1. Database options

Option	Description
ACTIVELOGDIRECTORY	The new directory for the location where the active log is stored. Use this option to change the location of the active log.
ACTIVELOGSIZE	The maximum size of the active log.
ALLOWREORGINDEX	Server-initiated index reorganization.
ALLOWREORGTABLE	Server-initiated table reorganization.
ARCHLOGDIRECTORY	The directory that the database manager can archive a log file into after all the transactions represented in that log file are completed.
ARCHFAILOVERLOGDIRECTORY	The directory in which the server tries to store archive log files that cannot be stored in the archive log directory.
DBDIAGLOGSIZE	The maximum size of the database manager diagnostic log files.
DBDIAGPATHFSTHRESHOLD	The threshold for free space on the file system or disk that contains the database manager diagnostic log files.
DBMEMPERCENT	The percentage of system memory that is dedicated to the database.
DISABLEREORGTABLE	Disables table reorganization for specific tables.

Option	Description
FSUSEDTHRESHOLD	The percentage of the file system that can be used by the database before an alert message is issued.
MIRRORLOGDIRECTORY	The directory for mirroring the active log path.
REORGBEGINTIME	The earliest time that the IBM Spectrum Protect server can start a table or index reorganization.
REORGDURATION	The interval during which server-initiated table or index reorganization can start.

Data transfer options

You can use server options to control how IBM Spectrum Protect™ groups and transfers data.

Table 1. Group options

Option	Description
MOVEBATCHSIZE	The number of files that are to be moved and grouped in a batch, within a transaction
MOVESIZETHRESH	The threshold for the amount of data moved as a batch, within the same server transaction
NDMPPORTRANGE	The IP address associated with the interface in which the server receives all Network Data Management Protocol (NDMP) backup data
NDMPPREFDATAINTERFACE	The IP address associated with the interface in which the server receives all Network Data Management Protocol (NDMP) backup data
REPLBATCHSIZE	The number of files that are to be replicated in a batch, within the same server transaction
REPLSIZETHRESH	The threshold for the amount of data replicated as a batch, within the same server transaction
TXNGROUPMAX	The number of files that are transferred as a group between a client and the server between transaction commit points

Message options

You can use server options to give you more flexibility in the way IBM Spectrum Protect™ issues messages.

Table 1. Message options

Option	Description
EXPQUIET	Whether IBM Spectrum Protect sends detailed informational messages during expiration processing
MESSAGEFORMAT	Whether a message number is displayed in all lines of a multi-line message
MSGINTERVAL	The time, in minutes, between messages prompting an operator to mount a tape for IBM Spectrum Protect

Event logging options

Options can help you manage event logging receivers.

Table 1. Event logging options

Option	Description
EVENTSERVER	Whether the server should try to contact the event server when the server starts up
FILEEXIT	A file to which enabled events are routed (binary format)
FILETEXTEXIT	A file to which enabled events are routed (readable format)

Option	Description
REPORTRETRIEVE	Record client restore and retrieve operations
TECBEGINEVENTLOGGING	Whether event logging for the TIVOLI receiver should begin when the server starts up
TECHOST	The host name or IP address for the Tivoli Enterprise Console (TEC) event server
TECPORT	The TCP/IP port address on which the Tivoli Enterprise Console event server is listening
TECUTF8EVENT	A Tivoli Enterprise Console event sent from the IBM Spectrum Protect server in UTF8 format
UNIQUETDPTECEVENTS	Events from an IBM Spectrum Protect Data Protection client that are sent to the Tivoli Enterprise Console as unique events
UNIQUETECEVENTS	Events sent to the Tivoli Enterprise Console as unique
USEREXIT	A user-defined exit that will be given control to manage an event

Security options and licensing options

You can use server options to customize server security and license audits.

Table 1. Security and licensing options

Option	Description
Windows ADSMGROUPNAME	Windows The name of a Windows group
AUDITSTORAGE	Specifies that during a license audit operation, the server calculates, by node, the amount of backup, archive, and space management storage in use
BACKUPINITIATIONROOT	Specifies whether the server overrides node parameter values for users who are not IBM Spectrum Protect authorized users
LDAPURL	Specifies the LDAP directory server. Each setting must have the LDAP directory server name, a port number, and the base distinguished name of the namespace or suffix that the server maintains.
Windows NPAUDITFAILURE	Windows Specifies that a node can access only its own data
Windows NPAUDITSUCCESS	Windows Specifies that an event is sent to the event log when a client node user is authenticated for access to the server through SECUREPIPE
QUERYAUTH	The administrative authority level required to issue QUERY or SQL SELECT commands
REQSYSAUTHOUTFILE	Specifies if system authority is required for administrative commands that cause IBM Spectrum Protect to write to an external file
Windows SECUREPIPES	Windows With named pipes protocol, specifies that the server checks the Windows group to authenticate a client
SHREDDING	Specifies whether shredding of deleted sensitive data is done automatically or manually

Related reference:
Server communication options

Miscellaneous options

You can use a variety of miscellaneous server options to customize IBM Spectrum Protect™.

Table 1. Miscellaneous options

Option	Description

Option	Description
ALIASHALT	Allows administrators to give the IBM Spectrum Protect HALT command a different name
DISPLAYLFINFO	Specifies whether accounting records and summary table entries report the storage agent name
EXPINTERVAL	The interval between automatic inventory expiration processes
FFDCLOGNAME	The name for the first failure data capture (FFDC) log
FFDCMAXLOGSIZE	The maximum size of the first failure data capture (FFDC) log
NOPREEMPT	Specifies that no operation can preempt another for access to a volume and that only a database backup operation can preempt another operation for access to a device
NORETRIEVEDATE	Specifies that the server does not update the retrieve date of a file in a disk storage pool when a client restores or retrieves the file
RESTOREINTERVAL	The length of time that a restartable restore session can be saved in the server database
VOLUMEHISTORY	The name of the file to be automatically updated whenever server sequential volume history information is changed

3494SHARED

The 3494SHARED option specifies whether an IBM® 3494 library can share applications other than IBM Spectrum Protect™.

The default is NO, meaning that no application other than IBM Spectrum Protect can share the 3494. When you set this option to YES, for every mount request, IBM Spectrum Protect determines if each drive is in use. After the query completes, IBM Spectrum Protect selects an available drive that is not in use by another application. Enable sharing only if you have more than two drives in your library. If you are currently sharing an IBM 3494 library with other applications, you must specify this option.

Syntax

```
>>-3494SHARED--+-Yes-+----------------------------------------><
               '-No--'
```

Parameters

Yes
: Specifies that other applications can share the 3494 library.

No
: Specifies that no other applications can share the 3494 library.

Examples

Enable sharing of a 3494 library:

```
3494shared yes
```

ACSACCESSID

The ACSACCESSID option specifies the ID for the ACS access control for an ACSLS library.

Syntax

```
>>-ACSACCESSID--name-----------------------------------------><
```

Parameters

name
: Specifies a 1 to 64 character ID. The default ID is your local host name.

Examples

```
acsaccessid region
```

ACSLOCKDRIVE

The ACSLOCKDRIVE option specifies if the drives within the ACSLS libraries are locked. Drive locking ensures the exclusive use of the drive in the ACSLS library in a shared environment. However, there is some performance gain if libraries are not locked. When other applications do not share the IBM Spectrum Protect™ drives, drive locking is not required.

Syntax

```
>>-ACSLOCKDRIVE--+-Yes-+---------------------------------------><
                 '-No--'
```

Parameters

Yes
: Specifies that drives are locked.

No
: Specifies that drives are not locked.

Examples

```
acslockdrive yes
```

ACSQUICKINIT

The ACSQUICKINIT option specifies whether, at server startup, the initialization of the ACSLS library is a quick or full initialization. The default is Yes. A quick initialization avoids the overhead associated with synchronizing the IBM Spectrum Protect™ server inventory with the ACSLS library inventory (through an audit of the library).

Syntax

```
>>-ACSQUICKINIT--+-Yes-+---------------------------------------><
                 '-No--'
```

Parameters

Yes

Specifies that a quick initialization of the ACSLS library is performed. When the option is set to Yes, IBM Spectrum Protect bypasses library inventory verification, initializing the library quickly, and making it available to IBM Spectrum Protect sooner than if a full initialization is done.

This option should be set to Yes when it is known that the physical library inventory and the IBM Spectrum Protect library inventory have not changed and an audit is not needed.

No

Specifies that a full initialization of the ACSLS library and library inventory is performed. When the option is set to No, IBM Spectrum Protect synchronizes its library volume inventory with what is reported by the ACSLS library manager.

Examples

```
acsquickinit yes
```

ACSTIMEOUTX

The ACSTIMEOUTX option specifies the multiple for the built-in timeout value for ACSLS APIs. The built-in timeout value for the ENTER, EJECT, and AUDIT ACS API is 1800 seconds; for all other ACSLS APIs it is 600 seconds. For example, if the multiple value specified is 5, the timeout value for audit API becomes 9000 seconds, and all other APIs become 3000 seconds.

Syntax

```
>>-ACSTIMEOUTX--value-----------------------------------------><
```

Parameters

value
Specifies the multiple for the built-in timeout value for ACSLS API. The range is from 1 to 100. The default is 1.

Examples

```
acstimeoutx 1
```

ACTIVELOGDIRECTORY

The ACTIVELOGDIRECTORY option specifies the name of the directory where all active logs are stored.

This option is appended to the options file when the DSMSERV FORMAT command is run. Under normal operating conditions, the option does not need to be changed. See DSMSERV FORMAT (Format the database and log) for guidance on this option.

Syntax

```
>>-ACTIVELOGDirectory--dir_name-------------------------------><
```

Parameters

dir_name
Specifies a fully qualified directory name. The directory must exist, it must be empty, and it must be accessible by the user ID of the database manager. If you change the active log directory, IBM Spectrum Protect™ moves the existing active logs to the location that is specified by this directory. The maximum number of characters is 175.

Examples

AIX | Linux

```
activelogdirectory /tsm/activelogdir
```

Windows

```
activelogdirectory c:\tsmserv1\activelogdir
```

ACTIVELOGSIZE

The ACTIVELOGSIZE option sets the total log size.

This option is appended to the options file when the DSMSERV FORMAT command is run. Under normal operating conditions the option does not need to be changed. See DSMSERV FORMAT (Format the database and log) for guidance on this option.

Syntax

```
                  .-16GB------.
>>-ACTIVELOGSize--+-megabytes-+-------------------------------><
```

Parameters

megabytes
: Specifies the size of the active log file in megabytes. The minimum value is 2048 MB (2 GB); the maximum is 524,288 MB (512 GB). If an odd number is specified, the value is rounded up to the next even number. The default is 16,384 MB (16 GB).
The size of an active log file is based on the value of the ACTIVELOGSIZE option. Guidelines for space requirements are in the following table:

Table 1. How to estimate volume and file space requirements

ACTIVELOGSize option value	**Reserve this much free space in the active log directory, in addition to the ACTIVELOGSize space**
16 GB - 128 GB	5120 MB
129 GB - 256 GB	10240 MB
257 GB - 512 GB	20480 MB

Examples

```
activelogsize 8192
```

ADMINCOMMTIMEOUT

The ADMINCOMMTIMEOUT option specifies how long the server waits for an expected administrative client message during an operation that causes a database update.

If the length of time exceeds this time-out period, the server ends the session with the administrative client. You may want to increase the time-out value to prevent administrative client sessions from timing out.

You can update this server option without stopping and restarting the server by using the SETOPT command. See SETOPT (Set a server option for dynamic update).

Syntax

```
                    .-60------.
>>-ADMINCOMMTimeout--+-seconds-+-------------------------------><
```

Parameters

seconds
: Specifies the maximum number of seconds that a server waits for an administrative client response. The default value is 60. The minimum value is 1.

Examples

```
admincommtimeout 60
```

ADMINIDLETIMEOUT

The ADMINIDLETIMEOUT option specifies the amount of time, in minutes, that an administrative client session can be idle before the server cancels the session.

If there is a heavy network load in your environment, you might want to increase the time-out value to prevent administrative clients from timing out. However, a large number of idle sessions could prevent other users from connecting to the server.

You can update this server option without stopping and restarting the server by using the SETOPT command. See SETOPT (Set a server option for dynamic update).

Syntax

```
                     .-15------.
>>-ADMINIDLETIMEOUT--+-minutes-+------------------------------><
```

Parameters

minutes
: Specifies the maximum number of minutes that a server waits for an idle administrative client. The default value is 15 minutes. The minimum value is 1 minute.

Examples

```
adminidletimeout 20
```

ADMINONCLIENTPORT

The ADMINONCLIENTPORT option specifies whether the TCPPORT can be used by administrative sessions. The default is YES.

Syntax

```
>>-ADMINONCLIENTPORT--+-YES-+-----------------------------------><
                      '-NO--'
```

Parameters

YES
: If the option is set to YES, or if the TCPPORT and TCPADMINPORT are the same value (the default), administrative sessions can use the TCPPORT.

NO
: If the option is set to NO, and if the TCPADMINPORT value is different than the TCPPORT value, administrative sessions cannot use the TCPPORT.

Examples

Specify that the TCPPORT can be used by administrative sessions.

```
adminonclientport yes
```

Windows

ADSMGROUPNAME

The ADSMGROUPNAME option specifies the name of a Windows group. A client node must be a member of this group to use the IBM Spectrum Protect™ server through NT Unified Logon. The client node must also be a registered IBM Spectrum Protect client node.

Syntax

```
>>-ADSMGROUPname--group_name---------------------------------><
```

Parameters

group_name
: Specifies a Windows group name.

Examples

Specify IDD as a Windows group:

```
adsmgroup idd
```

ALIASHALT

The ALIASHALT option allows administrators to give the IBM Spectrum Protect™ **HALT** command a different name.

The administrative client recognizes an alias for the HALT command when the client is started with the CHECKALIASHALT option specified. See Administrative client options for details.

Syntax

```
>>-ALIASHALT--newname-----------------------------------------><
```

Parameters

newname
: Specifies the alias of the HALT command for shutting down the IBM Spectrum Protect server. Minimum length of *newname* is 1; maximum length is 16.

Examples

```
aliashalt tsmhalt
```

ALLOWDESAUTH

The ALLOWDESAUTH option specifies whether to allow use of the Data Encryption Standard (DES) algorithm for authentication between a server and a backup-archive client.

To prevent the use of DES, specify a value of NO for the ALLOWDESAUTH option.
To configure the IBM Spectrum Protect™ server to be in compliance with the NIST SP800-131A standard, set this option to NO.
Restrictions:

- The backup-archive client must be running Version 6.3 or later if you authenticate to a server with the ALLOWDESAUTH option set to NO.
- Automatic deployment of the backup-archive client fails if this option is set to NO.

Syntax

```
   .-ALLOWDESAUTH--Yes-----.
>>-+-----------------------+---------------------------------><
   '-ALLOWDESAUTH--+-No--+-'
```

```
                    '-Yes-'
```

Parameters

Yes
: Specifies that the server allows authentication with any backup-archive clients that use DES-based encryption. The default is YES.

No
: Specifies that the server rejects any backup-archive clients that attempt to authenticate with DES-based encryption.

Examples

Specify that the server rejects any backup-archive clients that attempt to authenticate with DES encryption:

```
allowdesauth no
```

Specify that the server allows authentication with any backup-archive clients that use DES encryption:

```
allowdesauth yes
```

ALLOWREORGINDEX

The ALLOWREORGINDEX option specifies whether server-initiated index reorganization is enabled or disabled.

The default is YES.

Syntax

```
>>-ALLOWREORGINDEX--+-Yes-+-----------------------------------><
                    '-No--'
```

Parameters

Yes
: Specifies that server-initiated index reorganization is enabled.

No
: Specifies that server-initiated index reorganization is disabled.

Example

Specify that server-initiated index reorganization is enabled.

```
allowreorgindex yes
```

ALLOWREORGTABLE

The ALLOWREORGTABLE option specifies whether server-initiated table reorganization is enabled or disabled.

The default is YES.

Syntax

```
>>-ALLOWREORGTABLE--+-Yes-+-----------------------------------><
                    '-No--'
```

Parameters

Yes

Specifies that server-initiated table reorganization is enabled.

No
Specifies that server-initiated table reorganization is disabled.

Examples

Specify that server-initiated table reorganization is disabled.

```
allowreorgtable no
```

ARCHFAILOVERLOGDIRECTORY

The ARCHFAILOVERLOGDIRECTORY option specifies the directory which the server uses to store archive log files that cannot be stored in the archive log directory.

This option is appended to the options file when the DSMSERV FORMAT command is run. Typically the directory does not need to be changed.

Syntax

```
>>-ARCHFailoverlogdirectory--dir_name--------------------------><
```

Parameters

dir_name
Specifies a fully qualified directory name. The maximum number of characters is 175.

Examples

AIX | Linux

```
archfailoverlogdirectory /tsm/archfailoverlog
```

Windows

```
archfailoverlogdirectory c:\tsmserv1\archfailoverlog
```

ARCHLOGCOMPRESS

You can enable or disable compression of archive logs on the IBM Spectrum Protect™ server. By compressing the archive logs, you reduce the amount of space that is required for storage.

The ARCHLOGCOMPRESS server option specifies whether log files that are written to the archive directory for logs are compressed.

Syntax

```
                    .-No--.
>>-ARCHLOGCOMPress--+-----+-----------------------------------><
                    '-Yes-'
```

Parameters

No
Specifies that log files that are written to the archive log directory are not compressed. The default is No.

Yes
Specifies that log files that are written to the archive log directory are compressed.

Restriction: Use caution when you enable the ARCHLOGCOMPRESS server option on systems with sustained high volume usage and heavy workloads. Enabling this option in this system environment can cause delays in archiving log files from the active log

file system to the archive log file system. This delay can cause the active log file system to run out of space. Be sure to monitor the available space in the active log file system after archive log compression is enabled. If the active log directory file system usage nears out of space conditions, the ARCHLOGCOMPRESS server option must be disabled. You can use the SETOPT command to disable archive log compression immediately without halting the server.

Example

To enable compression of log files that are written to the archive log directory, specify the following option:

```
archlogcompress yes
```

ARCHLOGDIRECTORY

The ARCHLOGDIRECTORY option specifies a directory that the database manager can archive a log file into after all the transactions represented in that log file are completed.

This option is appended to the options file when the DSMSERV FORMAT command is run.

Syntax

```
>>-ARCHLOGDirectory--dir_name-----------------------------------><
```

Parameters

dir_name
: Specifies a fully qualified directory name. The maximum number of characters is 175.

Examples

AIX | Linux

```
archlogdirectory /tsm/archlog
```

Windows

```
archlogdirectory d:\tsmserv1\archlog
```

ARCHLOGUSEDTHRESHOLD

The ARCHLOGUSEDTHRESHOLD option specifies when to start an automatic database backup in relation to the percentage of archive log file space used. The default is 80 percent.

The ARCHLOGUSEDTHRESHOLD option prevents frequent automatic backups. For example, if the archive log file directory resides on a file system or drive that is 400 GB, a database backup is triggered if there is less than 80 GB of free space. Repeated database backups might cause the server to use an excessive amount of scratch tapes.

Syntax

```
                          .-80----.
>>-ARCHLOGUSEDTHRESHOLD--+-value-+----------------------------><
```

Parameters

value
: The percentage of archive log file space used before an automatic backup starts.

Specify to start an automatic backup when 90 percent of archive log file space is used.

```
archlogusedthreshold 90
```

ASSISTVCRRECOVERY

The ASSISTVCRRECOVERY option specifies whether IBM Spectrum Protect™ assists an IBM® 3590 drive in recovering from a lost or corrupted Vital Cartridge Records (VCR) condition. If you specify YES (the default) and if IBM Spectrum Protect detects an error during the mount processing, it locates to the end-of-data during the dismount processing to allow the drives to restore the VCR. During the tape operation, there might be some small effect on performance because the drive cannot complete a fast locate with a lost or corrupted VCR. However, there is no loss of data.

Syntax

```
>>-ASSISTVCRRECovery--+-Yes-+-----------------------------------><
                      '-No--'
```

Parameters

Yes
: Specifies server assistance in recovery.

No
: Specifies no server assistance in recovery.

Examples

Turn off recovery assistance:

```
assistvcrrecovery no
```

AUDITSTORAGE

As part of a license audit operation, the server calculates, by node, the amount of server storage used for backup, archive, and space–managed files. For servers managing large amounts of data, this calculation can take a great deal of CPU time and can stall other server activity. You can use the AUDITSTORAGE option to specify that storage is not to be calculated as part of a license audit.

Note: This option was previously called NOAUDITSTORAGE.

Syntax

```
>>-AUDITSTorage--+-Yes-+---------------------------------------><
                 '-No--'
```

Parameters

Yes
: Specifies that storage is to be calculated as part of a license audit. The default is Yes.

No
: Specifies that storage is not to be calculated as part of a license audit.

Examples

```
auditstorage    yes
```

BACKUPINITIATIONROOT

The BACKUPINITIATIONROOT option specifies whether the server overrides node parameter values for users who are not IBM Spectrum Protect™ authorized users.

You can update this server option without stopping and restarting the server by using the SETOPT command. See SETOPT (Set a server option for dynamic update).

Syntax

```
>>-BACKUPINITIATIONROOT--+-ON--+------------------------------><
                         '-OFf-'
```

Parameters

ON
: Specifies that sessions from clients on AIX®, Linux, Mac OS X, and Solaris operating systems, where the users are not IBM Spectrum Protect authorized users, are prevented from initiating backup operations. This is the default. The server overrides the value for the BACKUPINITIATION parameter that is specified in the REGISTER NODE and UPDATE NODE commands.
Tip: For an overview of IBM Spectrum Protect authorized users, see UNIX and Linux client root and authorized user tasks.

OFf
: Specifies that the node value for the BACKUPINITIATION parameter is used. The BACKUPINITIATION parameter is specified in the REGISTER NODE and UPDATE NODE commands.

Example

Specify that the node value for the BACKUPINITIATION parameter is used.

```
backupinitiationroot off
```

CHECKTAPEPOS

The CHECKTAPEPOS option specifies whether the IBM Spectrum Protect™ server validates the position of data blocks on tape.

The CHECKTAPEPOS option applies only to operations that use tape drives. It does not apply to non-tape, sequential-access device classes such as FILE. If the server information about position does not match the position that is detected by the drive, an error message is displayed, the transaction is rolled back, and the data is not committed to the database.

Using the CHECKTAPEPOS option, you can enable append-only mode for IBM LTO Generation 5 and later drives, and for any drives that support this feature. When it is enabled, the drive issues an error after it receives instructions to overwrite any data on the currently mounted volume. The IBM Spectrum Protect server repositions the tape to the correct block and continues writing data. Append-only mode provides added protection by preventing most data overwrite situations. If you are using a drive that supports this feature, you can validate data position on tape by using both IBM Spectrum Protect and the drive or you can enable one or the other.

Note: When you use SAN Tape acceleration functions in the fabric, set CHECKTAPEPOS to DRIVEonly or No to avoid false positive positioning errors. The IBM Spectrum Protect CHECKTAPEPOS server option does not require an append-only capable drive.

Changes to the CHECKTAPEPOS option affect mounts only after the update to the drive is complete.

The default is YES.

Syntax

```
>>-CHECKTAPEPOS--+-Yes-------+--------------------------------><
                 +-No--------+
                 +-TSMonly---+
                 '-DRIVEonly-'
```

Parameters

Yes
: Specifies that the IBM Spectrum Protect server validates data position on tape. For drives that support append-only mode, this parameter specifies that IBM Spectrum Protect enables the drive to also validate the data position during each WRITE

operation to prevent data overwrite. Yes is the default.

No
: Specifies that all data position validation is turned off.

TSMonly
: Specifies that the IBM Spectrum Protect server validates data position on tape. The server does not use append-only mode even if the drive supports the feature

DRIVEonly
: Specifies that the IBM Spectrum Protect server enables append-only mode for drives that support this feature. The server does not validate the data position on tape.

Example

Validate data position on tape and enable append-only mode for a supported drive:

```
checktapepos yes
```

CLIENTDEDUPTXNLIMIT

The CLIENTDEDUPTXNLIMIT option specifies the maximum size of a transaction when client-side deduplicated data is backed up or archived.

When you use client-side deduplication for large objects, intensive database activity can result from long-running transactions that are required to update the database. High levels of database activity can produce the following symptoms:

- Reduced throughput for client backup and archive operations
- Resource contention resulting from concurrent server operations
- Excessive recovery log activity

The extent to which these symptoms occur depends on the number and size of objects being stored using client-side data deduplication, the intensity and type of concurrent operations taking place on the IBM Spectrum Protect™ server, and the IBM Spectrum Protect server configuration.

With the CLIENTDEDUPTXNLIMIT server option, you can specify a maximum size, in gigabytes, for transactions when client-side deduplicated data is backed up or archived. If an object or set of objects in a single transaction exceeds the limit specified by CLIENTDEDUPTXNLIMIT, the objects are not deduplicated by the client, and the transaction can fail. You can specify a value 32 - 102400 GB. The default value is 5120 GB.

If an object or set of objects in a single transaction exceeds the limit specified by CLIENTDEDUPTXNLIMIT, the objects or set of objects is not deduplicated by the client. However, the objects are sent to the server. These objects can be deduplicated on the server, depending on whether the destination storage pool is configured for data deduplication and on the value of the SERVERDEDUPTXNLIMIT option. Objects in a deduplication-enabled storage pool that are less than the value of the SERVERDEDUPTXNLIMIT are deduplicated by a server duplicate-identification process.

The appropriate value for this option depends on the IBM Spectrum Protect server configuration and concurrent server activity. You can specify a high value for this option if you minimize resource contention. To minimize resource contention, perform operations, such as backup, archive, duplicate identification (the IDENTIFY DUPLICATES command), and reclamation, at different times.

To update this server option without stopping and restarting the server, use the SETOPT command.

Syntax

Parameters

gigabytes
: Specifies the maximum size, in gigabytes, of objects that can be backed up or archived using client-side data deduplication. You can specify a value 32 - 102400. The default value is 5120.

Examples

Disable client-side data deduplication for all objects over 80 GB:

```
clientdeduptxnlimit 80
```

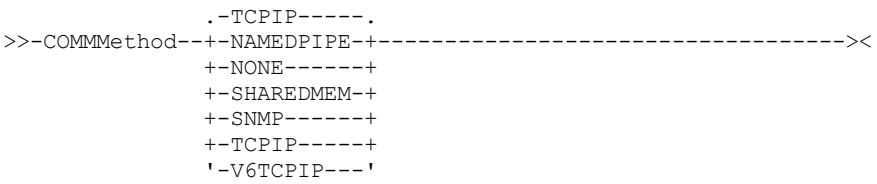
COMMMETHOD

The COMMMETHOD option specifies a communication method to be used by the server.

You can configure the server to use multiple communication methods. The more commonly used are the TCPIP, V6TCPIP, and SHAREDMEM communication methods. To specify multiple communication methods, enable each method by adding a COMMMETHOD stanza to the dsmserv.opt options file.

Important: When you enable a communication method, you must also add the options that are specific to the communication method to the options file.

Syntax



Parameters

You can choose one of the following communication methods:

Windows NAMEDPIPES
Windows Specifies the named pipes communication method option.

NONE
Specifies that no communication method is used. This option does not allow users to connect to the server and is useful for experimenting with policy commands.

SHAREDMEM
Specifies the shared memory communication method option. This method uses the same area of memory to send data between several applications at the same time. Both the server and the backup-archive client must be configured to support the shared memory communication method, and they must be installed on the same computer.

SNMP
Specifies the SNMP communication method option.

TCPIP
Specifies the TCP/IP communication method option. This option is the default. When TCPIP is specified, TCP/IP Version 4 is used exclusively.

V6TCPIP
Specifies the TCP/IP communication method option. If TCP/IP Version 4 and Version 6 are both configured, IBM Spectrum Protect™ uses both protocols simultaneously. If both COMMMETHOD TCPIP and COMMMETHOD V6TCPIP are specified, V6TCPIP overrides the specification of TCPIP. A valid domain name server (DNS) environment must be present to use either TCP/IP V4 or TCP/IP V6 if this option is specified.

Examples

Example of specifying multiple communication methods to be used by the server (TCP/IP and TCP/IP Version 6):

```
commmethod tcpip
commmethod v6tcpip
```

COMMTIMEOUT

The COMMTIMEOUT option specifies how long the server waits for an expected client message during an operation that causes a database update. If the length of time exceeds this time-out, the server ends the session with the client. You may want to increase the time-out value to prevent clients from timing out. Clients may time out if there is a heavy network load in your environment or they are backing up large files.

The COMMTIMEOUT server option is used for non-administrative sessions. See the ADMINCOMMTIMEOUT option for administrative client sessions.

You can update this server option without stopping and restarting the server by using the SETOPT command.

Syntax

```
                .-60------.
>>-COMMTimeout--+-seconds-+-----------------------------------><
```

Parameters

seconds
: Specifies the maximum number of seconds that a server waits for a client response. The default value is 60. The minimum value is 1.

Examples

```
commtimeout 60
```

AIX | Linux | Windows

CONTAINERRESOURCETIMEOUT

The CONTAINERRESOURCETIMEOUT option specifies how long the server waits to complete a data store operation to a container storage pool.

Syntax

When a timeout occurs, any data that was stored in the container storage pool remains there. The data store operation ends, and the request for the container resource is canceled.

```
                             .-180-----.
>>-CONTAINERRESOURCETimeout--+-minutes-+----------------------><
```

Parameters

minutes
: Specifies the maximum number of minutes that a server waits before an operation is canceled. The default value is 180 minutes. The minimum value is 1 minute.

Example

Specify that the server waits for 4 hours before a data store operation to a container storage pool is canceled.

```
containerresourcetimeout 240
```

Windows

DATEFORMAT

The DATEFORMAT option specifies the format in which dates are displayed by the server.

The DATEFORMAT value is overridden by the locale format if the locale is initialized at server startup. The locale is specified in the LANGUAGE option.

Syntax

```
>>-DATEformat--n-------------------------------------------------><
```

Parameters

n
: Select a number from 1 to 5 to identify the date format used by the server. The default value is 1.

  1
  : MM/DD/YYYY

  2
  : DD-MM-YYYY

  3
  : YYYY-MM-DD

  4
  : DD.MM.YYYY

  5
  : YYYY.MM.DD

Examples

```
dateformat 4
```

DBDIAGLOGSIZE

This option helps to control the amount of space that is used by diagnostic log files.

The database manager uses diagnostic log files to log messages. You must control the size of the log files so that they do not fill the file system. Use the DBDIAGLOGSIZE option to set the amount of space that is used by the log files.
If you set a value in the range 2 - 9999, a maximum of 10 rotating diagnostic log files are retained. Each file name indicates the order in which the file was created. After a file is full, the next file is created. When the 10th file is full, the oldest file is deleted, and a new file is created. The following example shows how the rotating log files might look:

```
db2diag.14.log, db2diag.15.log, ... , db2diag.22.log, db2diag.23.log
```

When db2diag.23.log is full, db2diag.14.log is deleted, and db2diag.24.log is created.
The server checks the file space that contains the diagnostic log files every hour. Messages are displayed every 12 hours if either of the following conditions occur:

- The available space in the file system where the diagnostic log files are located is less than 20% of the total file system space.
- The available space in the file system where the server instance directory is located is less than 1 GB.

If you specify a value of 0, only one log file, db2diag.log, is used for all diagnostic messages. No limits are imposed on the size of the log file.
Restriction: You must monitor the size of the diagnostic log files to ensure that they do not use all the available space in the file system. If there is not enough available space, the server might fail to respond.

Syntax

```
                    .-1024------.
>>-DBDIAGLOGSize--+-megabytes-+-------------------------------><
```

Parameters

megabytes
: Specifies the amount of space that is used by diagnostic log files in megabytes. Specify a value in the range 2 - 9999, or a value of 0. The default value is 1024.

If you specify a value in the range 2 - 9999, rotating log files are used, and the value specifies the total size in megabytes of all 10 log files. The value is reset to 1024 whenever the server is restarted.

If you specify a value of 0, one log file is used, and no limits are imposed on the size of the log file.

If you want to archive messages, specify a value of 0 to ensure that the db2diag.log file can use all the available space without using rotating log files.

After you set the value of the megabytes parameter to 0 by using the DBDIAGLOGSIZE option, messages are initially written to rotating log files. After the server is restarted, messages are written to the db2diag.log file.

Tip: If you specify a value in the range 2 - 9999 by using the server options file, dsmserv.opt, the value is not reset automatically at server startup. The value remains the same until it is changed or removed from the dsmserv.opt file, by using the SETOPT command.

Example: Specify a maximum size of 5120 megabytes

Specify the size of the diagnostic log files as 5120 megabytes (5 GB):

```
dbdiaglogsize 5120
```

Example: Archive messages in a single log file

Archive messages by specifying that the messages are written to the db2diag.log file:

```
dbdiaglogsize 0
```

Related information:
DB2 V10.5 product information

DBDIAGPATHFSTHRESHOLD

The DBDIAGPATHFSTHRESHOLD option specifies the threshold for free space on the file system or disk that contains the db2diag.log file.

When the amount of free space is equal to or less than the specified threshold, the ANR1545W error message is shown. By default, the message is shown when the file system or disk has 20% or less of free disk space.

You can update this server option without stopping and restarting the server by using the SETOPT command. See SETOPT (Set a server option for dynamic update).

Syntax

```
>>-DBDIAGPATHFSTHreshold--percent-----------------------------><
```

Parameter

percent
Specifies the percentage of available space in the file system. Valid values are in the range 0 - 100. The default is 20.
Tip: For best results, do not set a low or high value for the percent parameter. A low value might cause the file system to become full before you can correct the issue. A full file system might corrupt the server database. A high value might result in many ANR1545W messages in the server activity log.

Example

Set the threshold value to 10%.

```
setopt DBDIAGPATHFSTH 10
```

DBMEMPERCENT

Use this option to specify the percentage of the virtual address space that is dedicated to the database manager processes.

If applications other than IBM Spectrum Protect™ server are running on the system, ensure that the value allows adequate memory for the other applications.

Syntax

```
>>-DBMEMPERCENT--+-percent-+-----------------------------------><
                 '-AUTO----'
```

Parameters

percent
: Set a value from 10 to 99.

AUTO
: The database manager sets the percentage automatically to a value that is between 75 percent and 95 percent of system RAM. The default value is AUTO.

Examples

```
dbmempercent 50
```

DBMTCPPORT

The DBMTCPPORT option specifies the port number on which the TCP/IP communication driver for the database manager waits for requests for client sessions.

The specified port number must be reserved for use by the database manager.

By default, the IBM Spectrum Protect™ server uses interprocess communications (IPC) to establish connections for the first two connection pools, with a maximum of 480 connections for each pool. After the first 960 connections are established, the IBM Spectrum Protect server uses TCP/IP for any additional connections.

Syntax

```
>>-DBMTCPPort--port_number-------------------------------------><
```

Parameters

port_number
: Specifies the number of the TCP/IP port on which the database manager waits for communications from the server. Valid values are integers from 1024 to 65535.

  The default port number is the value of the server TCPPORT option plus 50,000. For example, if the server TCPPORT option is 1500, the default DBMTCPPORT port number would be 51500.

  If the TCPPORT server option is greater than 9999, add the last four digits of its value to 50000. For example, if the TCPPORT option is 11500, 1550 is added to 50000, resulting in a DBMTCPPORT port number of 51500.

Example

```
dbmtcpport 51500
```

DEDUPREQUIRESBACKUP

The DEDUPREQUIRESBACKUP option specifies whether volumes in primary sequential-access storage pools that are set up for data deduplication can be reclaimed and whether duplicate data can be discarded before the storage pools are backed up.

If the value of this option is YES (the default), you must back up data to copy storage pools that are not set up for data deduplication. Use the BACKUP STGPOOL command to back up data to copy storage pools.

Be aware that reclamation of a volume in a storage pool that is set up for data deduplication might not occur when the volume first becomes eligible. The server makes additional checks to ensure that data from a storage pool that is set up for data deduplication has been backed up to a copy storage pool. These checks require more than one BACKUP STGPOOL instance before the server reclaims a volume. After the server verifies that the data was backed up, the volume is reclaimed.

You can change this option dynamically using the SETOPT command.

Attention: To minimize the possibility of data loss, do not change the default setting for this server option. Specify a value of NO only if you do not have any copy storage pools and are not performing storage pool backups.

Syntax

```
>>-DEDUPREQUIRESBACKUP--+-Yes-+--------------------------------><
                        '-No--'
```

Parameters

Yes
: Specifies that the storage pool must be backed up before volumes can be reclaimed and before duplicate data can be discarded. This is the default.

No
: Specifies that volumes in primary sequential-access storage pools that are set up for data deduplication can be reclaimed and duplicate data can be discarded if the storage pools are not backed up.

Examples

Specify that primary sequential-access storage pools that are set up for data deduplication do not have to be backed up.

```
deduprequiresbackup no
```

DEDUPTIER2FILESIZE

The DEDUPTIER2FILESIZE option specifies at what file size IBM Spectrum Protect™ begins to use Tier 2 data deduplication.

Syntax

```
>>-DEDUPTIER2FILESIZE--nnn-------------------------------------><
```

Parameters

nnn
: Specifies the file size, in gigabytes, at which point the IBM Spectrum Protect server begins to use Tier 2 processing for data deduplication. You can specify a value 20 - 9999. The default is 100.
Note: If the value specified or defaulted to for this option is greater than the value for the SERVERDEDUPTXNLIMIT option, then this option is ignored for server data deduplication. If the value specified or defaulted to for this option is greater than the value for CLIENTDEDUPTXNLIMIT, then this option is ignored for client data deduplication.

Examples

```
deduptier2filesize 550
```

DEDUPTIER3FILESIZE

The DEDUPTIER3FILESIZE option specifies at what file size IBM Spectrum Protect™ begins to use Tier 3 data deduplication.

Syntax

```
>>-DEDUPTIER3FILESIZE--nnn-------------------------------------><
```

Parameters

nnn
: Specifies the file size, in gigabytes, at which point the IBM Spectrum Protect server begins to use Tier 3 processing for data deduplication. You can specify a value 90 - 9999. The default is 400.

  - If the value specified or defaulted to for this option is greater than the value for the SERVERDEDUPTXNLIMIT option, then this option is ignored for server data deduplication.
  - If the value specified or defaulted to for this option is greater than the value for CLIENTDEDUPTXNLIMIT, then this option is ignored for client data deduplication.
  - If the value specified or defaulted to for this option is less than the value specified or defaulted to for DEDUPTIER2FILESIZE, then the value of DEDUPTIER2FILESIZE is used for this option.

Examples

```
deduptier3filesize 1150
```

DEVCONFIG

The DEVCONFIG option specifies the name of a file in which you want IBM Spectrum Protect™ to store a backup copy of device configuration information.

IBM Spectrum Protect stores the following information in the device configuration file:

- Device class definitions created by using the DEFINE DEVCLASS command
- Drive definitions created by using the DEFINE DRIVE command
- Library definitions created by using the DEFINE LIBRARY command
- Library inventory information for the LIBTYPE=SCSI automated libraries
- Path definitions created by using the DEFINE PATH command
- Server definitions created with the DEFINE SERVER command
- Server name created with the SET SERVERNAME command
- Server password created with the SET SERVERPASSWORD command

Note:

- Only path definitions with SRCTYPE=SERVER are backed up to the device configuration file. Paths of SRCTYPE=DATAMOVER are not written to the file.
- Library volume location information is stored as comments (/*...*/) in the device configuration file whenever CHECKIN LIBVOLUME, CHECKOUT LIBVOLUME, and AUDIT LIBRARY commands are issued for SCSI libraries.

Attention: To restore the database after a disaster, you must have a copy of the current device configuration file. The device configuration file cannot be recreated.

You can include one or more DEVCONFIG options in the server options file. When you use multiple DEVCONFIG options, IBM Spectrum Protect automatically updates and stores a backup copy of device configuration information in each file you specify.

Syntax

```
>>-DEVCONFig--file_name-----------------------------------------><
```

Parameters

file_name
: Specifies the name of a file in which to store a backup copy of device configuration information.

Examples

```
devconfig devices.sav
```

DISABLEREORGTABLE

The DISABLEREORGTABLE option specifies whether online table reorganization is disabled for table names that are specified in the tables list.

To use the DISABLEREORGTABLE option, you must halt the server, update the options file, and then restart the server.

Syntax

```
>>-DISABLEREORGTable----tablelist------------------------------><
```

Parameters

tablelist
: Specifies a list of table names for which table reorganization is disabled. If you do not specify any table names with the option, or if the option is not in the options file, no tables are disabled.
Restriction: The following tables are already excluded from table reorganization processing and cannot be specified for this option:

- STAGED_EXPIRING_OBJECTS
- STAGED_OBJECT_IDS
- BF_DEREFERENCED_CHUNKS
- BF_QUEUED_CHUNKS

Example

```
DISABLEREORGTABLE BF_BITFILE_EXTENTS,REPLICATING_OBJECTS
```

DISABLESCHEDS

The DISABLESCHEDS option specifies whether administrative and client schedules are disabled during IBM Spectrum Protect™ server recovery.

Syntax

```
>>-DISABLESCheds--+-Yes-+-------------------------------------><
                  '-No--'
```

Parameters

Yes
: Specifies that administrative and client schedules are disabled.

No
: Specifies that administrative and client schedules are enabled.

Examples

```
disablescheds no
```

DISPLAYLFINFO

The DISPLAYLFINFO option specifies how the accounting records and summary table entries report the node name.

When this option is enabled, the accounting records and summary table entries report node_name(storage_agent_name) for the node name. If the option is not enabled, the accounting records and summary table entries simply report node_name for the node name. The default is No.

Syntax

```
>>-DISPLAYLFINFO--+-Yes-+-------------------------------------><
                  '-No--'
```

Parameters

Yes
: Specifies that the accounting records and summary table entries will report the storage agent name.

No
: Specifies that the accounting records and summary table entries will not report the storage agent name. This is the default.

Examples

```
displaylfinfo yes
```

The result shows the following accounting record with the storage agent name displayed (STA53):

```
5,0,ADSM,07/13/2004,15:35:14,COLIND-TUC(STA53),,WinNT,1,Tcp/Ip,1,0,0,0,
0,223,4063,0,0,222,7,8,3,1,4,0,0,0,0,3,0
```

The corresponding summary table also displays the storage agent name:

```
      START_TIME: 2004-07-13 15:35:07.000000
        END_TIME: 2004-07-13 15:35:14.000000
        ACTIVITY: BACKUP
          NUMBER: 8
          ENTITY: COLIND-TUC(STA53)
        COMMMETH: Tcp/Ip
         ADDRESS: colind-tuc:2229
   SCHEDULE_NAME:
        EXAMINED: 0
        AFFECTED: 223
          FAILED: 0
           BYTES: 4160875
            IDLE: 8
          MEDIAW: 1
      PROCESSES: 1
     SUCCESSFUL: YES
    VOLUME_NAME:
     DRIVE_NAME:
   LIBRARY_NAME:
       LAST_USE:
      COMM_WAIT: 3
NUM_OFFSITE_VOLS:
```

DNSLOOKUP

The DNSLOOKUP option specifies whether the server uses system API calls to determine the domain name server (DNS) names of systems that contact the server.

Syntax

```
>>-DNSLOOKUP--+-Yes-+----------------------------------------><
              '-No--'
```

Parameters

Yes

Specifies that the server obtains the DNS names of contacting systems. Yes is the default.

No

Specifies that the server does not obtain the DNS names of contacting systems.

Examples

```
dnslookup yes
```

DRIVEACQUIRERETRY

The DRIVEACQUIRERETRY option lets you specify how many times the server retries the acquisition of a drive in an IBM® 349x library. If the library is shared among multiple applications, its drives may appear to be available to the server (through the use of a background polling process) when they are not.

This option is only valid if you specified 3494SHARED YES in the dsmserv.opt file. If you specified DRIVEACQUIRERETRY NEVER, you need to monitor how long jobs have been waiting for drives and how long the server has been polling the drives. You may also need to check the status of these drives in the other IBM Spectrum Protect™ servers. There may be cartridges stuck in the drives, and the other IBM Spectrum Protect servers may have marked the drives as *offline*. If this is the case, you need to mark the drives *offline* in the IBM Spectrum Protect server that is polling the drives. If necessary, also cancel any waiting jobs.

Syntax

```
>>-DRIVEACQuireretry--+-Forever-----------+------------------><
                      +-Never-------------+
                      '-number_of_retries-'
```

Parameters

Forever

The acquisition of a drive is retried until one is successfully acquired. This is the default.

Never

The server does not retry the acquisition of a drive and fails the operation.

number_of_retries

Specifies the maximum number of times, from 1 to 9999, that the server retries the acquisition of a drive.

Examples

Specify that the server should attempt no more than 10 times to acquire the drive:

```
driveacquireretry 10
```

ENABLENASDEDUP

The ENABLENASDEDUP server option specifies whether the server deduplicates data that is stored by a network-attached storage (NAS) file server. This option applies only to NetApp file servers.

If the value of this option is NO, the data stored by the file server is skipped during duplicate-identification processing. If the value of this option is YES, the value of the DEDUPLICATE parameter in the storage pool definition must be YES.

Syntax

```
>>-ENABLENASDEDUP--+-No--+-------------------------------------><
                   '-Yes-'
```

Parameters

Yes

Specifies that IBM Spectrum Protect™ server deduplicates data stored by a NetApp file server.

No
: Specifies that the server does not deduplicate data stored by a NetApp file server.

Example

Specify that the server deduplicates data stored by a NetApp file server.

```
enablenasdedup yes
```

EVENTSERVER

The EVENTSERVER option specifies whether at startup the server should try to contact the event server.

Syntax

```
>>-EVENTSERVer--+-Yes-+----------------------------------------><
                '-No--'
```

Parameters

Yes
: Specifies that, at startup, the server tries to contact the event server. Contact occurs only if a DEFINE EVENTSERVER command has already been issued. This is the default.

No
: Specifies that, at startup, the server does not try to contact the event server.

Examples

```
eventserver yes
```

EXPINTERVAL

The EXPINTERVAL option specifies the interval, in hours, between automatic inventory expiration processes by IBM Spectrum Protect™. Inventory expiration removes client backup and archive file copies from the server as specified by the management classes to which the client files are bound. If expiration is not run periodically, storage pool space is not reclaimed from expired client files, and the server requires more storage space than required by policy.

You can also use the EXPIRE INVENTORY command to start inventory expiration. Expiration can make space available in your storage pools for additional client backup or archive files.

You can update this server option without stopping and restarting the server by using the SETOPT command. See SETOPT (Set a server option for dynamic update).

Syntax

```
                .-24----.
>>-EXPINterval--+-hours-+--------------------------------------><
```

Parameters

hours
: Specifies the time, in hours, between automatic inventory expiration processes. You can specify from 0 to 336 (14 days). A value of 0 means that expiration must be started with the EXPIRE INVENTORY command. The default is 24.

Examples

```
expinterval 5
```

EXPQUIET

The EXPQUIET option specifies whether IBM Spectrum Protect™ sends detailed messages during expiration processing.

You can update this server option without stopping and restarting the server by using the SETOPT command. See SETOPT (Set a server option for dynamic update).

Syntax

```
>>-EXPQUiet--+- --No--+---------------------------------------><
             '- --Yes-'
```

Parameters

No
: Specifies that the server sends detailed messages. This is the default.

Yes
: Specifies that the server sends only minimal messages. These messages are sent only for files that have expired based on the copy group in the default management class or retention grace period for the domain.

Examples

```
expquiet no
```

Linux

FASPBEGPORT

The FASPBEGPORT option specifies the starting number in the range of port numbers that are used for network communications with Aspera® Fast Adaptive Secure Protocol (FASP®) technology.

To define the range of port numbers, specify both the FASPBEGPORT and FASPENDPORT options.

Syntax

```
                .-15100----------------.
>>-FASPBEGPort--+-starting_port_number-+----------------------><
```

Parameters

starting_port_number
: Specifies the starting port number for network communications that use Aspera FASP technology. The default value is 15100.
Ask your network administrator to help you define the range of port numbers:

- If you did not enable the Secure Sockets Layer (SSL) protocol for the server pair, ensure that the ports can be used for Transmission Control Protocol (TCP) sockets.
- Ensure that the ports can be used for User Datagram Protocol (UDP) connections.
- Ensure that the ports are compatible with firewall rules.

Example

If firewall rules require port numbers to be greater than 1800, you would specify a minimum port number of 1801:

```
faspbegport 1801
```

Related reference:
FASPENDPORT

Linux

FASPENDPORT

The FASPENDPORT option specifies the ending number in the range of port numbers that are used for network communications with Aspera® Fast Adaptive Secure Protocol (FASP®) technology.

To define the range of port numbers, specify both the FASPBEGPORT and FASPENDPORT options.

Syntax

```
                .-15199--------------.
>>-FASPENDPort--+-ending_port_number-+------------------------><
```

Parameters

ending_port_number
: Specifies the ending port number for network communications that use Aspera FASP technology. The default value is 15199.
Ask your network administrator to help you define the range of port numbers:

- If you did not enable the Secure Sockets Layer (SSL) protocol for the server pair, ensure that the ports can be used for Transmission Control Protocol (TCP) sockets.
- Ensure that the ports can be used for User Datagram Protocol (UDP) connections.
- Ensure that the ports are compatible with firewall rules.

Example

If firewall rules require port numbers to be less than 1900, you would specify a maximum port number of 1899:

```
faspendport 1899
```

Related reference:
FASPBEGPORT
Linux

FASPTARGETRATE

The FASPTARGETRATE option specifies the target rate for data transfer with Aspera® Fast Adaptive Secure Protocol (FASP®) technology. By specifying the target rate, you limit the bandwidth of each network connection that uses Aspera FASP technology. In this way, you can ensure that sufficient bandwidth is available for all network connections.

Syntax

```
                  .-250000------.
>>-FaspTargetRate--+-target_rate-+----------------------------><
```

Parameters

target_rate
: Specifies the maximum rate, in kilobits per second, for data transfer during a session. The default value is 250000. You can specify values in the range 100 - 100000000.

  For example, if you issue the PROTECT STGPOOL command to run two parallel operations at the default target rate, the aggregated throughput does not exceed 500,000 kbps. If your file system can support two operations to protect storage pools at much higher rates than 500,000 kbps of aggregated throughput, and sufficient network bandwidth is available, you can increase the target rate.

  To determine the appropriate target rate, consult your network administrator.

Examples

If the allotted network bandwidth is 150,000 kbps, you can set the target rate to 75,000 and use the default number of sessions (two) for the PROTECT STGPOOL command.

```
fasptargetrate 75000
```

In a large blueprint configuration, if the allotted network bandwidth is 6,000,000 kbps, you can set the target rate to 750,000 and use eight sessions for the PROTECT STGPOOL command.

```
fasptargetrate 750000
```

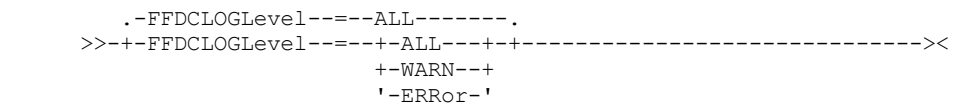
FFDCLOGLEVEL

The FFDCLOGLEVEL option specifies the type of general server messages that are displayed in the first failure data capture (FFDC) log.

The FFDC log contains three categories of general server messages. Setting the FFDCLOGLEVEL option affects the following categories:

- FFDC_GENERAL_SERVER_INFO
- FFDC_GENERAL_SERVER_WARNING
- FFDC_GENERAL_SERVER_ERROR

Syntax



Parameters

ALL

Specifies that all FFDC general server log messages are in the log. This value is the default.

WARN

Specifies that the FFDC_GENERAL_SERVER_WARNING and FFDC_GENERAL_SERVER_ERROR messages appear in the log.

ERRor

Specifies that only the FFDC_GENERAL_SERVER_ERROR messages appear in the log.

Example

```
ffdcloglevel warn
```

FFDCLOGNAME

The FFDCLOGNAME option specifies a name for the first failure data capture (FFDC) log.

The FFDC log file is used to gather diagnostic information about the server. When an error occurs, data about the error is written to the FFDC log file. This information can be provided to IBM Support to help diagnose problems. The FFDC log file is in the server instance directory.

Syntax

Parameters

file_name
: Specifies a file name for the FFDC log file. The file name can be a fully qualified file name or a file name relative to the server instance directory. The default value is dsmffdc.log.

Examples

```
ffdclogname /tsminst1/tsmffdc.log
ffdclogname tsmffdc.log
ffdclogname c:\tsmserv1\tsmffdc.log
```

Related reference:
FFDCMAXLOGSIZE
FFDCNUMLOGS

FFDCMAXLOGSIZE

The FFDCMAXLOGSIZE option specifies the size for the first failure data capture (FFDC) log file.

The FFDC log file is used to gather diagnostic information about the server. When an error occurs, data about the error is written to the FFDC log file. This information can be provided to IBM Support to help diagnose problems.

Syntax

Parameters

kilobytes
: Specifies the size to which the FFDC log file can grow before wrapping. The minimum value is 500. The maximum value is 2097151. The default value is 1024.

  To allow the size of the log file to grow indefinitely, specify a value of -1. To disable the log, specify 0.

Examples

```
ffdcmaxlogsize 2000
```

Related reference:
FFDCLOGNAME
FFDCNUMLOGS

FFDCNUMLOGS

The FFDCNUMLOGS option specifies the number of log files that can be used for circular logging. The default value is 10.

Circular logging uses a ring of log files to provide recovery from transaction failures and system crashes. For example, when the dsmffcd.log file is full, it is renamed to dsmffdc.log.1. If a dsmffdc.log.1 file exists, the dsmffdc.log.1 file is renamed to dsmffdc.log.2. If a dsmffdc.log.2 exists, the dsmffdc.log.2 file is renamed to dsmffdc.log.3, and so on, until the FFDCNUMLOGS value is reached. If there is a log file that is renamed as the FFDCNUMLOGS value is reached, that log file is deleted.

The minimum value is 1. The maximum value is 100. The default value is 10.

Syntax

Parameters

value
Specifies the number of log files that are used for circular logging.

If you specify a value of 1 and the log file size reaches the FFDCMAXLOGSIZE, the server continues to write to the log file. Any logging information is overwritten and the server continues to write to the log file.

Examples

```
ffdcnumlogs 20
```

FILEEXIT

The FILEEXIT option specifies a file to which enabled events are routed. Each logged event is a record in the file.

Syntax

```
>>-FILEEXIT--+-No--+--file_name--+-REPLACE--+-----------------><
             '-Yes-'             +-APPEND---+
                                 '-PRESERVE-'
```

Parameters

Yes
Specifies that event logging to the file exit receiver begins automatically at server startup.

No
Specifies that event logging to the file exit receiver does not begin automatically at server startup. When this parameter has been specified, you must begin event logging manually by issuing the BEGIN EVENTLOGGING command.

file_name
Specifies the name of the file in which the events are stored.

REPLACE
Specifies that if the file already exists, it will be overwritten.

APPEND
Specifies that if the file already exists, data is appended to it.

PRESERVE
Specifies that if the file already exists, it will not be overwritten.

Examples

Windows

```
fileexit yes \tsm\server\data replace
```

AIX | Linux

```
fileexit yes /tsm/server/data replace
```

FILETEXTEXIT

The FILETEXTEXIT option specifies a file to which enabled events are routed. Each logged event is a fixed-size, readable line.

Syntax

```
>>-FILETEXTEXIT--+-No--+--file_name--+-REPLACE--+--------------><
                 '-Yes-'             +-APPEND---+
                                     '-PRESERVE-'
```

Parameters

Yes

Specifies that event logging to the file exit receiver begins automatically at server startup.

No
: Specifies that event logging to the file exit receiver does not begin automatically at server startup. When this parameter has been specified, you must begin event logging manually by issuing the BEGIN EVENTLOGGING command.

file_name
: Specifies the name of the file in which the events are stored.

REPLACE
: Specifies that if the file already exists, it will be overwritten.

APPEND
: Specifies that if the file already exists, data will be appended to it.

PRESERVE
: Specifies that if the file already exists, it will not be overwritten.

Examples

Windows

```
filetextexit yes \tsm\server\data replace
```

AIX | Linux

```
filetextexit yes /tsm/server/data replace
```

FSUSEDTHRESHOLD

The FSUSEDTHRESHOLD option specifies what percentage of the file system can be filled up by the database before an alert message is issued.

You can update this server option without stopping and restarting the server by using the SETOPT command.

If this value is set to a low number, the activity log might be flooded with messages about the database space being filled, even if there is still space available. If the value is set too high, the database space might be filled before you can add more space to the file system.

Syntax

```
>>-FSUSEDTHreshold--percent-------------------------------------><
```

Parameters

percent
: Specifies the value of used space in the database. You can specify a value from 0 to 100. The default is 90.

Examples

```
fsusedthreshold 70
```

IDLETIMEOUT

The IDLETIMEOUT option specifies the amount of time, in minutes, that a client session can be idle before the server cancels the session. You may want to increase the time-out value to prevent clients from timing out if there is a heavy network load in your environment. Note, however, that a large number of idle sessions could prevent other users from connecting to the server.

The IDLETIMEOUT server option is used for non-administrative sessions. See the ADMINIDLETIMEOUT option for administrative client sessions.

You can update this server option without stopping and restarting the server by using the SETOPT command.

Syntax

```
                .-15------.
>>-IDLETimeout--+-minutes-+-------------------------------------><
```

Parameters

minutes
: Specifies the maximum number of minutes that a server waits for an idle client. The default value is 15 minutes. The minimum value is 1 minute.

Examples

```
idletimeout 15
```

KEEPALIVE

The KEEPALIVE option specifies whether the Transmission Control Protocol (TCP) keepalive function is enabled for outbound TCP sockets. The TCP keepalive function sends a transmission from one device to another to check that the link between the two devices is operating.

If you are using node replication, you can use the KEEPALIVE option on the source replication server to enable the TCP keepalive function. The KEEPALIVE option is not required on the target replication server unless you specify bidirectional replication, in which case the target server becomes the source replication server.

Syntax

```
              .-Yes-.
>>-KEEPALIVE--+-No--+-----------------------------------------><
```

Parameters

Yes
: Specifies that the TCP keepalive function is enabled for outbound TCP sockets. This value is the default.
If the KEEPALIVE option is enabled, default values are used for the KEEPALIVETIME and KEEPALIVEINTERVAL options.

No
: Specifies that the TCP keepalive function is not enabled for outbound TCP sockets.
If you specify a value of NO, it does not affect current TCP socket connections that originated from outbound connection requests while the KEEPALIVE option was set to YES. The YES value applies to those sockets until the related session ends and the socket is closed.

Example

Use the SETOPT command to enable the keepalive function without disabling or halting the server:

```
setopt keepalive yes
```

Related reference:
KEEPALIVEINTERVAL
KEEPALIVETIME

KEEPALIVETIME

The KEEPALIVETIME option specifies how often TCP sends a keepalive transmission when it receives a response. This option applies only if you set the KEEPALIVE option to YES.

Syntax

```
                .-300-----.
```

```
>>-KEEPALIVETIME--+-seconds-+--------------------------------><
```

Parameters

seconds
: Specifies how often TCP sends keepalive transmissions to verify that an idle connection is still active. The value is specified in seconds.
You can specify a value in the range 1 - 4294967. The default is 300 (5 minutes).

Example

Set the KEEPALIVETIME option to 120 seconds:

```
keepalivetime 120
```

Related reference:
KEEPALIVE
KEEPALIVEINTERVAL

KEEPALIVEINTERVAL

The KEEPALIVEINTERVAL option specifies how often a keepalive transmission is sent if no response is received. This option applies only if you set the KEEPALIVE option to YES.

Syntax

```
                      .-30------.
>>-KEEPALIVEINTERVAL--+-seconds-+----------------------------><
```

Parameters

seconds
: Specifies the length of time, in seconds, between keepalive transmissions when no response is received. The value is specified in seconds.
You can specify a value in the range 1 - 4294967. The default is 30 seconds.

Example

Set the KEEPALIVEINTERVAL option to 45 seconds:

```
keepaliveinterval 45
```

Related reference:
KEEPALIVE
KEEPALIVETIME

LANGUAGE

The LANGUAGE option controls the initialization of locales. A locale includes the language and the date, time, and number formats to be used for the console and server.

If your client and server are running different languages, the messages that are generated might not be understandable when messages are issued from the client to the server or if the server sends output to the client.

AIX Linux If initialization of the locale fails, the server defaults to American English.

Windows If the initialization of the locale fails, the server defaults to American English and uses the date, time, and number formats that are set by the DATEFORMAT, TIMEFORMAT, and NUMBERFORMAT server options.

Syntax

```
                    (1)
>>-LANGuage--+-AMENG------+-----------------------------------><
             |       (2)  |
             +-en_US------+
             |        (3) |
             '-locale-----'
```

Notes:

1. AMENG is available only on HP-UX, Solaris, Windows.
2. en_US is available only on AIX and Linux.
3. *locale* is available only on AIX, HP-UX, Solaris, Linux, and Windows.

Parameters

Windows AMENG

Windows Specifies that American English is used as the default language for the server.

AIX Linux en_US

AIX Linux Specifies that American English is used as the default language for the server.

locale

Specifies the name of the locale that is supported by the server. See the following tables for information on supported locales by operating system.

Note: IBM Spectrum Protect™ runs in any locale, but defaults to American English. For the locales listed, language support is available.

AIX

Table 1. Server languages for AIX®

Language	LANGUAGE option value
Chinese, Simplified	zh_CN
Chinese, Simplified	Zh_CN
Chinese, Simplified (UTF-8)	ZH_CN
Chinese, Traditional (Big5)	Zh_TW
Chinese, Traditional (UTF-8)	ZH_TW
Chinese, Traditional (euc_tw)	zh_TW

```

LDAPCACHEDURATION

The LDAPCACHEDURATION option determines the amount of time that the IBM Spectrum Protect™ server caches LDAP password authentication information.

After a successful LDAP bind, the value that you enter determines the amount of time that information about the LDAP directory server is kept available. The higher the number, the better the performance of the LDAP directory server. During the cache period, though, changes on the LDAP directory server do not take immediate effect on the node. For example, old passwords might be available for some time, even after they were changed or locked on the LDAP server.

Include the LDAPCACHEDURATION option in a SETOPT command to have the option take effect immediately.

Restriction: The LDAPCACHEDURATION option does not apply to storage agents.

Syntax

```
>>-LDAPCACHEDURATION--minutes----------------------------------><
```

Parameters

minutes
: Specifies the maximum amount of time after a successful LDAP bind, that subsequent sessions to the same node or administrator skip secondary LDAP bind operations. Values range from zero to 360 minutes.

Example: Set the LDAPCACHEDURATION value to 6 hours (maximum)

In the dsmserv.opt file, specify the following value:

```
ldapcacheduration 360
```

After a node or administrator authenticates with an external directory server, the LDAP bind is skipped for 360 minutes on all sessions.

LDAPURL

The LDAPURL option specifies the location of a Lightweight Directory Access Protocol (LDAP) server. Set the LDAPURL option after you configure the LDAP server.

Tip: The information in this documentation applies to the LDAP authentication method that is preferred for IBM Spectrum Protect™ V7.1.7 or later servers. For instructions about using the previous LDAP authentication method, see Managing passwords and logon procedures.
The following restrictions apply:

- The LDAPURL option cannot be used in combination with the SETOPT command.
- The LDAPURL option does not apply to storage agents.

Syntax

```
>>-LDAPURL--ldap_url_value-------------------------------------><
```

Parameters

ldap_url_value
: Specifies the URL of one LDAP server, or the URLs of multiple LDAP servers. You can enter multiple values, with each URL value up to 1024 characters. The port number is optional and defaults to 389. Each URL value must contain an LDAP server name. For example, the format of the server name is `server1.storage.us.ibm.com` and the LDAP port is `341`. The value of the LDAPURL option must conform to the following specifications:

  - If you specify multiple URLs, each URL must be on a separate line.
  - If you specify multiple URLs, each URL must point to a different external directory, and all external directories must contain the same data.
  - Each URL must begin with `ldap://`.
    Restriction: The URL that you designate cannot begin with ldaps://.

    IBM Spectrum Protect supports LDAP connections that are secured with the standard LDAPv3 StartTLS operation, which establishes a secure Transport Layer Security (TLS) exchange on an existing LDAP connection. The LDAP Simple Bind operation that IBM Spectrum Protect uses does not protect the password when it is sent. A secure TLS connection is required to protect the password.

Example: Set the port value for an LDAP server

In the dsmserv.opt file, specify the port value as 341 for an LDAP server:

```
ldapurl ldap://server1.storage.us.ibm.com:341/dc=storage,dc=us,dc=ibm,dc=com
```

MAXSESSIONS

The MAXSESSIONS option specifies the maximum number of simultaneous client sessions that can connect with the server.

You can update this server option without stopping and restarting the server by using the SETOPT command. See SETOPT (Set a server option for dynamic update).

Syntax

```
                .-25-----------------.
>>-MAXSessions--+-number_of_sessions-+------------------------><
```

Parameters

number_of_sessions
: Specifies the maximum number of simultaneous client sessions. The default value is 25 client sessions. The minimum value is 2 client sessions. The maximum value is limited only by available virtual storage size or communication resources.

Examples

```
maxsessions 25
```

MESSAGEFORMAT

The MESSAGEFORMAT option specifies whether a message number is displayed in all lines of a multi-line message.

Syntax

```
>>-MESsageformat--number----------------------------------------><
```

Parameters

number
: Select a number to specify if a message number is to be displayed only on the first line of a multi-line message or is to be displayed on all lines.

  1
  : The message number for a message is displayed only in the first line of the message. This is the default.

  2
  : The message number for a message is displayed in all lines of a message.

Examples

```
messageformat 2
```

MIRRORLOGDIRECTORY

The MIRRORLOGDIRECTORY option specifies the directory for mirroring the active log path.

All changes made to the active log directory are also written to this mirror directory. This option is appended to the options file when the DSMSERV FORMAT command is run. Typically, the directory does not need to be changed.

Syntax

```
>>-MIRRorlogdirectory--dir_name--------------------------------><
```

Parameters

dir_name
: Specifies a fully qualified directory name for the active log mirror. The maximum number of characters is 175.

Examples

AIX Linux

```
mirrorlogdirectory /tsm/mirrorlog
```

Windows

```
mirrorlogdirectory c:\tsmserv1\mirrorlog
```

MOVEBATCHSIZE

The MOVEBATCHSIZE option specifies the number of client files that are to be moved and grouped together in a batch, within the same server transaction. This data movement results from storage pool backups and restores, migration, reclamation, and MOVE DATA operations. This option works with the MOVESIZETHRESH option.

Syntax

```
                  .-1000------------.
>>-MOVEBatchsize--+-number_of_files-+-------------------------><
```

Parameters

number_of_files
Specifies a number of files between 1 and 1000. The default is 1000.

Examples

```
movebatchsize 100
```

MOVESIZETHRESH

The MOVESIZETHRESH option specifies, in megabytes, a threshold for the amount of data moved as a batch, within the same server transaction. When this threshold is reached, no more files are added to the current batch, and a new transaction is started after the current batch is moved.

Syntax

```
                    .-4096-------.
>>-MOVESizethresh--+- megabytes-+------------------------------><
```

Parameters

megabytes
Specifies the number of megabytes as an integer from 1 to 32768. The default value is 4096. This option is used with the MOVEBATCHSIZE option.

Examples

```
movesizethresh 500
```

MSGINTERVAL

The MSGINTERVAL option specifies the time, in minutes, between messages prompting an operator to mount a tape for the server.

Syntax

```
                 .-1-------.
>>-MSGINTerval--+-minutes-+----------------------------------><
```

Parameters

minutes
Specifies the time interval at which the operator is prompted by the server to mount a tape. The default value is 1 minute. The minimum value is 1 minute.

Examples

```
msginterval 2
```

Windows

NAMEDPIPENAME

The NAMEDPIPENAME option specifies a communication method that allows processes to communicate with one another without having to know where the sender and receiver processes are located. The name acts like an alias, connecting the two processes regardless of whether they are on the same computer or across connected domains.

Syntax

```
>>-NAMEDpipename--name----------------------------------------><
```

Parameters

name
: Specifies the named pipes name for the server to use. Named pipes are ideal for running in an environment where client and server are on the same machine. No communication software is required and no setup is required.

Examples

```
namedpipename     \\.\PIPE\TSMPIPE
```

AIX | Linux | Windows

NDMPCONNECTIONTIMEOUT

The NDMPCONNECTIONTIMEOUT server option specifies the time in hours that IBM Spectrum Protect™ server waits to receive status updates during NDMP restore operations across the LAN. NDMP restore operations of large NAS file systems can have long periods of inactivity. The default is 6 hours.

Syntax

```
                          .-6-----.
>>-NDMPCONNECTIONTIMEOUT--+-hours-+---------------------------><
```

Parameters

hours
: The number of hours that the IBM Spectrum Protect server waits to receive status updates during an NDMP restore operation over the LAN. The default value is 6. The minimum is 1 hour. The maximum is 48 hours.

Example

Specify a timeout of 10 hours before the NDMP connection times out:

```
ndmpconnectiontimeout  10
```

NDMPCONTROLPORT

The NDMPCONTROLPORT option specifies the port number to be used for internal communications for certain Network Data Management Protocol (NDMP) operations. The IBM Spectrum Protect™ server does not function as a general purpose NDMP tape server.

Syntax

```
                    .-10000-------.
>>-NDMPControlport--+-port_number-+---------------------------><
```

Parameters

port_number
: The port number to be used for internal communications for certain NDMP operations. The port number must be from 1024 to 32767. The default is 10000.

Examples

```
ndmpcontrolport 9999
```

NDMPENABLEKEEPALIVE

The NDMPENABLEKEEPALIVE server option specifies whether the IBM Spectrum Protect™ server enables Transmission Control Protocol (TCP) keepalive on network data-management protocol (NDMP) control connections to network-attached storage (NAS) devices. The default is NO.

TCP keepalive is implemented within the network support of an operating system. TCP keepalive prevents a long-running, inactive connection from being closed by firewall software that detects and closes inactive connections.
Restriction: To prevent errors, do not enable TCP keepalive in certain types of environments. One example is environments that do not have firewalls between the IBM Spectrum Protect server and a NAS device. Another example is environments with firewalls that tolerate long-running, inactive connections. Enabling TCP keepalive in this type of environment can cause an idle connection to be inadvertently closed if the connection partner temporarily fails to respond to TCP keepalive packets.

Syntax

```
>>-NDMPENABLEKEEPALIVES--+-NO--+------------------------------><
                         '-YES-'
```

Parameters

NO
: Disable TCP keepalive on all NDMP control connections. NO is the default.

YES
: Enable TCP keepalive on all NDMP control connections. The default idle time before the first TCP keepalive packet is sent is 120 minutes.

AIX Linux Windows To change the idle time, use the NDMPKEEPIDLEMINUTES server option.

Example

Enable TCP keepalive on all NDMP control connections so that inactive NDMP connections are not closed:

```
ndmpenablekeepalive yes
```

AIX Linux Windows

NDMPKEEPIDLEMINUTES

The NDMPKEEPIDLEMINUTES server option specifies the amount of time, in minutes, before the operating system transmits the first Transmission Control Protocol (TCP) keepalive packet on a network data-management protocol (NDMP) control connection. The default is 120 minutes.

Prerequisite: Use this option only after you set the value of the NDMPENABLEKEEPALIVES server option to YES.

Syntax

```
                          .-120-----.
>>-NDMPKEEPIDLEMINUTES--+-minutes-+----------------------------><
```

Parameters

minutes
: The number of minutes of inactivity on NDMP control connections before TCP keepalive packets are transmitted. The default value is 120. The minimum is 1 minute. The maximum is 600 minutes.

Example

Specify an idle time of 15 minutes before the first TCP keepalive packet is sent:

```
ndmpkeepidleminutes  15
```

NDMPPORTRANGE

The NDMPPORTRANGE option specifies the range of port numbers through which IBM Spectrum Protect™ cycles to obtain a port number for accepting a session from a network-attached storage (NAS) device for data transfer. The default is 0,0 which means that IBM Spectrum Protect lets the operating system provide a port (ephemeral port).

If all ports specified are in use when a NAS device attempts to connect to the server, the operation fails. If a single port number is chosen (no comma and no port number for the high value), the default for the high port number is the low port number plus 100.

When Network Data Management Protocol (NDMP) data is directed to an IBM Spectrum Protect native pool, communication can be initiated from either the NDMP systems or the IBM Spectrum Protect server. If a firewall separates the server and NAS devices, it may be necessary to specify port numbers in firewall rules to allow traffic to pass to and from the NAS devices. NAS devices communicate to the IBM Spectrum Protect server the port numbers that they will use when contacting the server. The port numbers of the server are controlled with the NDMPPortrange options. Port number control for NAS devices is specific to vendors. Consult your vendor documentation.

Syntax

```
>>-NDMPPortrange--port_number_low-+--------------------+-------><
                                  '-,port_number_high-'
```

Parameters

port_number_low
: The low port number from which IBM Spectrum Protect starts to cycle when needing a port number for accepting session from a NAS device for data transfer. The minimum port number value is 1024.

port_number_high
: The high port number to which IBM Spectrum Protect can cycle when needing a port number for accepting session from a NAS device for data transfer. The maximum port number value is 32767. The high port number must be the same or larger than the low port number.

Examples

Specify that IBM Spectrum Protect can cycle from port numbers 1024 - 2024.

```
ndmpportrange 1024,2024
```

NDMPPREFDATAINTERFACE

This option specifies the IP address that is associated with the interface in which you want the server to receive all Network Data Management Protocol (NDMP) backup data.

This option affects all subsequent NDMP filer-to-server operations, but does not affect NDMP control connections, which use the system's default network interface. The value for this option is a host name or IPV4 address that is associated with one of the active network interfaces of the system on which the IBM Spectrum Protect™ server is running. This interface must be IPV4 enabled.

You can update this server option without stopping and restarting the server by using the SETOPT command.

Syntax

```
>>-NDMPPREFDATAINTERFACE--ip_address--------------------------><
```

Parameters

ip_address

Specify an address in either dotted decimal or host name format. If you specify a dotted decimal address, it is not verified with a domain name server. If the address is not correct, it can cause failures when the server attempts to open a socket at the start of an NDMP filer-to-server backup.

Host name format addresses are verified with a domain name server. There is no default value. If a value is not set, all NDMP operations use the IBM Spectrum Protect server's network interface for receiving backup data during NDMP filer-to-server backup operations.

To clear the option value, specify the SETOPT command with a null value, "".

Examples:

```
ndmpprefdatainterface  net1.tucson.ibm.com

ndmpprefdatainterface  9.11.152.89
```

NOPREEMPT

The server allows certain operations to preempt other operations for access to volumes and devices. You can specify the NOPREEMPT option to disable preemption. When preemption is disabled, no operation can preempt another for access to a volume, and only a database backup operation can preempt another operation for access to a device.

For example, a client data restore operation preempts a client data backup for use of a specific device or access to a specific volume.

Syntax

```
>>-NOPREEMPT-------------------------------------------------><
```

Parameters

None

Examples

Disable preemption among server operations:

```
nopreempt
```

NORETRIEVEDATE

The NORETRIEVEDATE option specifies that the server does not update the retrieve date of a file in a disk storage pool when a client restores or retrieves the file. This option and the MIGDELAY storage pool parameter control when the server migrates files.

If you do not specify NORETRIEVEDATE, the server migrates files after they have been in the storage pool for the number of days specified by the MIGDELAY parameter. The number of days is counted from the day that the file was stored in the storage pool or retrieved by a client, whichever is more recent. If you specify NORETRIEVEDATE, the server does not update the retrieve date of a file, and the number of days is counted from the day the file entered the disk storage pool.

If you specify this option and caching is enabled for a disk storage pool, reclamation of cached space is affected. When space is needed in a disk storage pool that contains cached files, the server gets the space by selectively erasing cached copies. Files that have the oldest retrieve dates and occupy the largest amount of space are selected for removal. When you specify NORETRIEVEDATE, the server does not update the retrieve date when a file is retrieved. This may cause cached copies to be removed even though they have recently been retrieved by a client.

Syntax

```
>>-NORETRIEVEDATE-------------------------------------------><
```

Parameters

None.

Examples

Specify that the retrieve dates of files in disk storage pools are not updated when clients restore and retrieve the files:

```
noretrievedate
```

Windows

NPAUDITFAILURE

The NPAUDITFAILURE option specifies whether an event is sent to the event log when a node logs in to the server using a name that is in the Windows group but does not match the Windows account login name. To ensure that a node can access only its own data, the node name and the Windows account name must match.

Syntax

```
>>-NPAUDITFailure--+-Yes-+-------------------------------------><
                   '-No--'
```

Parameters

Yes
: Specifies that an event is sent to the event log when a node logs in to the server using a name that is in the Windows group. But, this name does not match the Windows account login name.

No
: Specifies that an audit failure event is not sent to the event log.

Examples

Specify that an event is sent to the event log when a node logs in to the server using a name that is in the Windows group. But, this name does not match the Windows account login name.

```
npauditfailure yes
```

Windows

NPAUDITSUCCESS

The NPAUDITSUCCESS option specifies that an event is sent to the event log when a client node user is authenticated for access to the server through SECUREPIPE.

Syntax

```
>>-NPAUDITSuccess--+-Yes-+-------------------------------------><
                   '-No--'
```

Parameters

Yes
: Specifies that an event is sent to the event log when a client node user is authenticated for access to the server through SECUREPIPES.

No
: Specifies that an event is not sent to the Windows log.

Examples

Specify that an event is sent to the event log when a client node is authenticated for access to the server.

```
npauditsuccess yes
```

Windows

NPBUFFERSIZE

The NPBUFFERSIZE option specifies the size of the Named Pipes communication buffer.

Syntax

Parameters

kilobytes
: Specifies the size, in kilobytes, of the Named Pipes communication buffer. The default is 8.

Examples

Specify a 16 KB Named Pipes communication buffer:

```
npbuffersize 16
```

Windows

NUMBERFORMAT

The NUMBERFORMAT option specifies the format in which the server displays numbers.

The value of NUMBERFORMAT is overridden by the number formatting definition of the locale if the locale is successfully initialized at server startup. The locale is specified in the LANGUAGE option.

Syntax

Parameters

number
: Select a number from 1 to 6 to identify the number format used by the server. The default is 1.

1
: 1,000.00

2
: 1,000,00

3
: 1 000,00

4
: 1 000.00

5
: 1.000,00

6
: 1'000,00

Examples

```
numberformat 4
```

NUMOPENVOLSALLOWED

The NUMOPENVOLSALLOWED option specifies the number of input FILE volumes in a deduplicated storage pool that can be open at one time.

Input volumes contain data to be read during client-restore operations and server processes, such as reclamation and migration. Use this option to improve performance by reducing the frequency with which volumes are opened and closed.

Each session within a client operation or server process can have as many open FILE volumes as specified by this option. A session is initiated by a client operation or by a server process. Multiple sessions can be started within each.

During a client restore operation, volumes can remain open for the duration of a client restore operation and as long a client session is active. During a no-query restore operation, the volumes remain open until the no-query restore completes. At that time, all volumes are closed and released. However, for a classic restore operation started in interactive mode, the volumes might remain open at the end of the restore operation. The volumes are closed and released when the next classic restore operation is requested.

Set this value in the server options file or use the SETOPT command.

Tip: This option can significantly increase the number of volumes and mount points in use at any one time. To optimize performance, follow these steps:

- To set NUMOPENVOLSALLOWED, select a beginning value (the default is recommended). Monitor client sessions and server processes. Note the highest number of volumes open for a single session or process. Increase the setting of NUMOPENVOLSALLOWED if the highest number of open volumes is equal to the value specified by NUMOPENVOLSALLOWED.
- To prevent sessions or processes from having to wait for a mount point, increase the value of the MOUNTLIMIT parameter in the device-class definition. Set the value of the MOUNTLIMIT parameter high enough to allow all client sessions and server processes using deduplicated storage pools to open the number of volume specified by the NUMOPENVOLSALLOWED option. For client sessions, check the destination in the copy group definition to determine how many nodes are storing data in the deduplicated storage pool. For server processes, check the number of processes allowed for each process for the storage pool.
- A situation might occur in which a node backs up and restores or archives and retrieves concurrently to and from a deduplicated storage pool. All the mount points required for these operations increase the total number of mount points required by the node.

  As a result, the node might not be able to start additional backup sessions if it already has more mount points open than what the MAXNUMMP parameter in the client-node definition allows. This can occur even though the MOUNTLIMIT for the device class was not exceeded.

  To prevent backup and retrieve operations from failing, set the value of the MAXNUMMP parameter in the client-node definition to a value at least as high as the NUMOPENVOLSALLOWED option. Increase this value if you notice that the node is failing backup or retrieve operations because the MAXNUMMP value is being exceeded.

Syntax

```
>>-NUMOPENVOLSallowed--number_of_open_volumes------------------><
```

Parameters

number_of_open_volumes
: Specifies the number of input FILE volumes in a deduplicated storage pool that can be open at one time. The default is 10. The minimum value is 3. The maximum value is 999.

Examples

Specify that up to 5 volumes in a deduplicated storage pool can be open at one time.

```
numopenvolsallowed 5
```

AIX | Linux | Windows

PUSHSTATUS

The PUSHSTATUS option is used on spoke servers to ensure that status information is sent to the hub server. Do not update this option unless you must restore the Operations Center configuration to the preconfigured state where the IBM Spectrum Protect™ servers are not defined as hub or spoke servers.

If you must restore the Operations Center configuration to the preconfigured state, you must issue the following command on each spoke server:

```
SETOPT PUSHSTATUS NO
```

QUERYAUTH

The QUERYAUTH option specifies the administrative authority level required to issue QUERY or SQL SELECT commands. By default any administrator can issue QUERY and SELECT commands. You can use this option to restrict the use of these commands.

Syntax

```
>>-QUERYAuth--+-NOne-----+-------------------------------------><
              +-SYstem---+
              +-POlicy---+
              +-STorage--+
              '-OPerator-'
```

Parameters

NOne
: Any administrator can issue QUERY or SELECT commands without requiring any administrative authority.

SYstem
: Administrators must have SYSTEM authority to issue QUERY or SELECT commands.

POlicy
: Administrators must have POLICY authority over one or more policy domains or SYSTEM authority to issue QUERY or SELECT commands.

STorage
: Administrators must have STORAGE authority over one or more storage pools or SYSTEM authority to issue QUERY or SELECT commands.

OPerator
: Administrators must have OPERATOR or SYSTEM authority to issue QUERY or SELECT commands.

Examples

To restrict the use of QUERY and SELECT commands to administrators with system or storage authority, enter:

```
queryauth storage
```

RECLAIMDELAY

This option delays the reclamation of a SnapLock volume, allowing remaining data to expire so that there is no need to reclaim the volume.

Syntax

```
                .-4--------------.
>>-RECLAIMDELAY--+-number_of_days-+----------------------------><
```

Parameters

number_of_days
: Specifies the number of days to delay the reclamation of a SnapLock volume.
Before a SnapLock volume is reclaimed, the IBM Spectrum Protect™ server allows the specified number of days to pass, so that any files remaining on the volume have a chance to expire. The default reclaim delay period is 4 days and can be set anywhere from 1 to 120 days.

Examples

Specify that the number of days to delay reclamation is 30 days:

```
reclaimdelay 30
```

RECLAIMPERIOD

This option allows you to set the number of days for the reclamation period of a SnapLock volume.

Syntax

Parameters

number_of_days
: Specifies the number of days that are allowed for the reclamation period of a SnapLock volume.
After the retention of a SnapLock volume has expired, the IBM Spectrum Protect™ server will reclaim the volume within the specified number of days if there is still data remaining on the volume. The default reclaim period is 30 days and can be set anywhere from 7 to 365 days.

  The reclamation period does not begin until the RECLAIMDELAY period has expired.

Examples

Specify that the reclaim period is 45 days:

```
reclaimperiod 45
```

REORGBEGINTIME

The REORGBEGINTIME option specifies the earliest time that the IBM Spectrum Protect™ server can start a table or index reorganization.

Schedule server-initiated reorganizations to start during periods when server activity is low. Use this option together with the REORGDURATION option. The REORGDURATION specifies an interval during which reorganization can start.

Syntax

Parameters

hh:mm
: Specifies the time that the server can start a reorganization: The default start time 6:00 a.m. Use a 24-hour format to specify the time.

Time	Description	Values

Time	Description	Values
hh	The hour of the day	Specify a number 00 - 23.
mm	The minute of the hour	Specify a number 00 - 59.

Examples

Specify 6:00 a.m. as the earliest time that a reorganization can start.

```
reorgbegintime 06:00
```

Specify 8:30 p.m. as the earliest time that a reorganization can start.

```
reorgbegintime 20:30
```

Specify noon as the earliest time that a reorganization can start.

```
reorgbegintime 12:00
```

Specify 3:30 p.m. as the earliest time that a reorganization can start.

```
reorgbegintime 15:30
```

Specify midnight as the earliest time that a reorganization can start.

```
reorgbegintime 00:00
```

REORGDURATION

The REORGDURATION option specifies an interval during which server-initiated table or index reorganization can start.

Schedule server-initiated reorganizations to start during periods when server activity is low. Use this option together with the REORGBEGINTIME option. The REORGBEGINTIME option specifies the earliest time that the server can start a reorganization.

Syntax

```
>>-REORGDURation--nn-----------------------------------------><
```

Parameters

nn

Specifies the number of hours during which a reorganization can start. The minimum value is 1, the maximum value is 24. The default value is 24.

Example

Specify an interval of four hours during which a reorganization can start.

```
reorgduration 4
```

REPORTRETRIEVE

The REPORTRETRIEVE option reports on restore or retrieve operations that are performed by client nodes or administrators. The default is NO.

Syntax

```
>>-REPORTRETRIEVE--+-YES-+-----------------------------------><
                   '-NO--'
```

Parameters

YES
: Specifies that messages will be issued to the server console and stored in the activity log whenever files are restored or retrieved from the IBM Spectrum Protect™ server. The messages will specify the name of the objects being restored or retrieved and identify the client node or administrator performing the operation.

NO
: Specifies that messages will not be issued.

Examples

Specify that messages will be issued and stored in the activity log whenever files are restored or retrieved from the IBM Spectrum Protect server:

```
reportretrieve yes
```

The following message is issued for an administrator client session:

```
ANR0411I Session 8 for administrator COLIND-TUC logged in as node
COLIND-TUC restored or retrieved Backup object: node COLIND-TUC,
filespace \\colind-tuc\c$, object\CODE\TESTDATA\ XXX.OUT
```

REPLBATCHSIZE

The REPLBATCHSIZE option specifies the number of client files that are to be replicated in a batch, within the same server transaction. This option affects only the node replication processes and works with the REPLSIZETHRESH option to improve node replication processing.

The REPLBATCHSIZE option limits the number of files in a transaction and the REPLSIZETHRESH option limits the number of bytes in a transaction. The transaction ends when either the REPLBATCHSIZE threshold or the REPLSIZETHRESH threshold is reached.

Syntax

Parameters

number_of_files
: Specifies a number of files between 1 - 32768. The default is 4096.

Examples

```
replbatchsize 25000
```

REPLSIZETHRESH

The REPLSIZETHRESH option specifies, in megabytes, a threshold for the amount of data replicated, within the same server transaction.

The amount of data is based on the non-deduplicated size of the file, which is the original size of the file. The amount of data that is replicated is controlled by the threshold. When the amount of data exceeds the threshold, the server ends the transaction and no more files are added to the current batch. A new transaction is started after the current batch is replicated. This option is used with the REPLBATCHSIZE option.

For example, suppose that a file is 10 MB and is stored in a data-deduplication-enabled storage pool and only 2 MB of the file is transferred during replication. The amount of data replicated includes the 10 MB size of the file, and excludes the 2 MB transferred. When the amount of data replicated exceeds the value specified for the REPLSIZETHRESH threshold, the transaction ends.

Tip: If you are replicating data from a source server in the cloud and frequently get an ANR1880W server message on the target server, lower the value of the REPLSIZETHRESH option on the source server.

Syntax

```
                    .-4096------.
>>-REPLSizethresh--+-megabytes-+-------------------------------><
```

Parameters

megabytes
: Specifies the number of megabytes as an integer from 1 - 32768. The default value is 4096.

Examples

```
replsizethresh 2000
```

REQSYSAUTHOUTFILE

The REQSYSAUTHOUTFILE option specifies if system authority is required for administrative commands that cause IBM Spectrum Protect™ to write to an external file.

This option applies to the following commands:

- BACKUP DEVCONFIG with the FILENAMES parameter
- BACKUP VOLHISTORY with the FILENAMES parameter
- DEFINE BACKUPSET
- DELETE BACKUPSET
- GENERATE BACKUPSET
- MOVE DRMEDIA with the CMD parameter
- MOVE MEDIA with the CMD parameter
- QUERY DRMEDIA with the CMD parameter
- QUERY MEDIA with the CMD parameter
- QUERY SCRIPT with the OUTPUTFILE parameter

Syntax

```
>>-REQSYSauthoutfile--+-Yes-+---------------------------------><
                      '-No--'
```

Parameters

Yes
: System authority is required for administrative commands that cause IBM Spectrum Protect to write to an external file.

No
: System authority is not required for administrative commands that cause IBM Spectrum Protect to write to an external file. That is, there is no change to the authority level that is required to issue the command.

Examples

```
reqsysauthoutfile no
```

RESOURCETIMEOUT

The RESOURCETIMEOUT option specifies how long the server waits for a resource before canceling the pending acquisition of a resource. When a timeout occurs the request for the resource will be canceled.

Note: When managing a set of shared library resources, such as servers designated as library managers and clients, consider setting this option at the same time limit for all participants in the shared configuration. In any case of error recovery, IBM Spectrum Protect™ will always defer to the longest time limit.

Syntax

```
                    .-60------.
>>-RESOURCETimeout--+-minutes-+--------------------------------><
```

Parameters

minutes
: Specifies the maximum number of minutes that the server waits for a resource. The default value is 60 minutes. The minimum value is 1 minute.

Examples

Specify that the server will wait 15 minutes for a server resource:

```
resourcetimeout 15
```

RESTOREINTERVAL

The RESTOREINTERVAL option specifies how long a restartable restore session can be saved in the server database. As long as the restore session is saved in the database, it can be restarted from the point at which it stopped.

You can update this server option without stopping and restarting the server by using the SETOPT command. See SETOPT (Set a server option for dynamic update).

Syntax

```
                    .-1440----.
>>-RESTOREINTERVAL--+-minutes-+--------------------------------><
```

Parameters

minutes
: Specifies how long, in minutes, that a restartable restore session can be in the database before it can be expired. The minimum value is 0. The maximum is 10080 (one week). The default is 1440 minutes (24 hours). If the value is set to 0 and the restore is interrupted or fails, the restore is still put in the restartable state. However, it is immediately eligible to be expired.

Examples

```
restoreinterval 1440
```

RETENTIONEXTENSION

The RETENTIONEXTENSION option specifies the number of days to extend the retention date of a SnapLock volume. This option allows the server to extend the retention date of a SnapLock volume in order to avoid excessive reclamation.

Syntax

```
>>-RETENTIONEXTENSION--number_of_days--------------------------><
```

Parameters

number_of_days
Specifies the number of days to extend the retention date of a SnapLock volume. The minimum value is 30 days; the maximum value is 9999 days; the default is 365.
If you specify a value of 0 (zero) for the RETVER parameter of an archive copy group, the actual value that is used for RETVER is the value of the option RETENTIONEXTENSION, if one of the following conditions is also true:

- The destination storage pool for the archive copy group is a SnapLock storage pool.
- The storage pool that is the target for a storage pool migration or of a MOVE DATA or MOVE NODEDATA command is a SnapLock storage pool.

If a SnapLock volume is the target volume for data from another SnapLock volume and if the remaining retention of the data on the volume is less than the value specified, then the retention date is set using the value specified. Otherwise, the remaining retention of the data is used to set the retention of the volume.
If a SnapLock volume has entered the reclamation period but the percentage of reclaimable space of the volume has not exceeded the reclamation threshold of the storage pool or the value specified on the THRESHOLD parameter of a RECLAIM STGPOOL command, then the retention date of the SnapLock volume is extended by the amount specified in the RETENTIONEXTENSION option.

Examples

Specify that the retention date is extended by 60 days:

```
retentionextension 60
```

AIX | Linux | Windows

SANDISCOVERY

The SANDISCOVERY option specifies whether the IBM Spectrum Protect™ SAN discovery function is enabled.

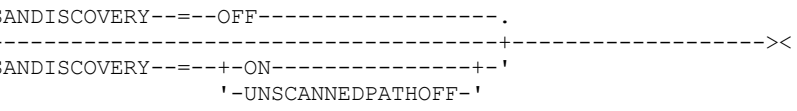
To use SAN discovery, all devices on the SAN must have a unique device serial number. When set to ON, the server completes SAN discovery in the following instances:

- When the device path is changed
- When the QUERY SAN command is issued

Using SAN discovery, the server can automatically correct the special file name for a device if it is changed for a specified tape device.

The IBM Spectrum Protect server does not require persistent binding with the SAN discovery function enabled. To display a list of devices that are seen by the server, you can issue the QUERY SAN command.

Syntax



Parameters

ON
Specifies that the server completes SAN discovery when the device path is changed, or when the QUERY SAN command is issued.
OFF
Specifies that the server does not complete SAN discovery when the device path is changed, or when the QUERY SAN command is issued. If the IBM Spectrum Protect server is not able to open a device, a message is issued but the path that is associated with the device is not taken offline. This value is the default.
UNSCANNEDPATHOFF
Specifies that the server does not complete SAN discovery when the device path is changed, or when the QUERY SAN command is issued. If the IBM Spectrum Protect server is not able to open a device, a message is issued and the path to the device is taken offline.

Examples

```
sandiscovery on
```

Related commands

Table 1. Commands related to SANDISCOVERY

Command	Description
PERFORM LIBACTION	Defines all drives and paths for a library.

AIX Linux Windows

SANDISCOVERYTIMEOUT

The SANDISCOVERYTIMEOUT option specifies the amount of time allowed for host bus adapters to respond when they are queried by the SAN discovery process. Once the time specified for the SANDISCOVERYTIMEOUT is reached, the process times out.

Syntax

```
>>-SANDISCOVERYTIMEOUT--value---------------------------------><
```

Parameters

value
: Specifies the amount of time to elapse before the SAN discovery process times out. The range is from 15 to 1800 seconds. The default is 15 seconds.

Examples

```
sandiscoverytimeout 45
```

AIX Linux Windows

SANREFRESHTIME

The SANREFRESHTIME option specifies the amount of time that elapses before the cached SAN discovery information is refreshed. The SANREFRESHTIME option has a default value of 0, which means that there is no SAN discovery cache. The information is obtained directly from the host bus adapter (HBA) every time the server performs a SAN discovery operation.

Note: The QUERY SAN server command always receives SAN information at the time that the command is issued and ignores any value specified for SANREFRESHTIME.

Syntax

```
                    .-0----.
>>-SANREFRESHTIME--+-time-+-----------------------------------><
```

Parameters

time
: The length of time, in seconds, before the cached SAN discovery information is refreshed. The default value is 0 and specifies that SAN discovery information is not cached. If a value other than 0 is specified, for example, 100 seconds, then the SAN discovery information is refreshed 100 seconds after the prior SAN discovery operation.

Examples

Refresh SAN discovery information after 100 seconds.

```
sanrefreshtime 100
```

Turn off the caching of SAN discovery information.

```
sanrefreshtime 0
```

SEARCHMPQUEUE

The SEARCHMPQUEUE option specifies the order in which the server satisfies requests in the mount queue. If the option is specified, the server first tries to satisfy requests for volumes that are already mounted. These requests may be satisfied before other requests, even if the others have been waiting longer for the mount point. If this option is not specified, the server satisfies requests in the order in which they are received.

Syntax

Parameters

None

Examples

Specify that the server tries to first satisfy a request for a volume that is already mounted:

```
searchmpqueue
```

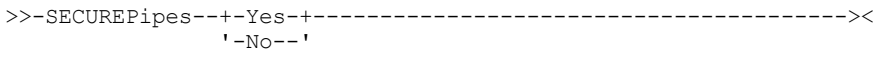
Windows

SECUREPIPES

When using the named pipes protocol, enabling SECUREPIPES forces the server to check the Windows group designated by ADSMGROUPNAME in order to authenticate a client node/user.

The user name and password defined in the Windows group are used to authenticate the node/user for access to the server data. The node/user must also be a registered IBM Spectrum Protect™ client node. However, the IBM Spectrum Protect client node password is ignored, and the Windows password associated with the user is used.

Syntax



Parameters

Yes
: Specifies that IBM Spectrum Protect checks the Windows group designated by ADSMGROUPNAME in order to authenticate a client node/user.

No
: Specifies that IBM Spectrum Protect does not check the Windows group designated by ADSMGROUPNAME in order to authenticate a client node/user.

Examples

Specify that IBM Spectrum Protect checks the Windows group to authenticate client nodes.

```
securepipes yes
```

SERVERDEDUPTXNLIMIT

The SERVERDEDUPTXNLIMIT option specifies the maximum size of objects that can be deduplicated on the server.

When you use duplicate-identification processes (the IDENTIFY DUPLICATES command) for large objects, intensive database activity can result from long-running transactions that are required to update the database. High levels of database activity can produce following symptoms:

- Reduced throughput for client backup and archive operations
- Resource contention resulting from concurrent server operations
- Excessive recovery log activity

The extent to which these symptoms occur depends on the number and size of objects being processed, the intensity and type of concurrent operations taking place on the IBM Spectrum Protect™ server, and the IBM Spectrum Protect server configuration.

With the SERVERDEDUPTXNLIMIT server option, you can specify a maximum size, in gigabytes, for objects that can be deduplicated on the server. If an object or set of objects in a single transaction exceeds the limit specified by SERVERDEDUPTXNLIMIT, the objects are not deduplicated by the server. You can specify a value 32 - 102400 GB. The default value is 5120 GB.

Increasing the value of this option causes the IBM Spectrum Protect server to search for objects previously deferred whose size falls below the new transaction limit.

Remember: The search for objects previously deferred can take time. Use care when increasing the value of SERVERDEDUPTXNLIMIT. Reducing the value of this option does not cause IBM Spectrum Protect to search for deferred objects.

The appropriate value for this option depends on the IBM Spectrum Protect server configuration and concurrent server activity. You can specify a high value for this option if you minimize resource contention. To minimize resource contention, perform operations, such as backup, archive, duplicate identification, and reclamation, at different times.

To update this server option without stopping and restarting the server, use the SETOPT command.

Syntax

```
                        .-5120------.
>>-SERVERDEDUPTXNlimit--+-gigabytes-+-------------------------><
```

Parameters

gigabytes
: Specifies the maximum size, in gigabytes, of objects that can be duplicated on the server. You can specify a value 32 - 102400. The default value is 5120.

Examples

Disable server-side deduplication for all objects over 120 GB:

```
serverdeduptxnlimit 120
```

SHMPORT

AIX | Linux The SHMPORT option specifies the TCP/IP port address of a server when using shared memory. All shared memory communications start with a TCP/IP connection. Windows The SHMPORT option specifies the port that the server listens on for shared memory connections.

Syntax

```
>>-SHMPort--port_number----------------------------------------><
```

Parameters

port_number
Specifies the port number. AIX Linux You can specify a value from 1024 to 32767. The default value is 1510. Windows You can specify a value from 1 to 32767. The default value is 1.

Examples

AIX Linux

```
shmport  1580
```

Windows

```
shmport  1
```

SHREDDING

The SHREDDING option specifies whether shredding of deleted sensitive data is performed automatically or manually. Shredding applies only to data in storage pools that have been explicitly configured to support shredding.

Syntax

```
>>-SHREDding--+-AUTOmatic-+-----------------------------------><
              '-MANual----'
```

Parameters

AUTOmatic
Specifies that shredding occurs automatically as sensitive data is deleted. Use this option to shred sensitive data as soon as possible after it is deleted. If the SHREDDING option is not specified, this is the default behavior. If there is an I/O error during automatic shredding, an error is reported, and shredding of the current object halts. If the I/O error cannot be corrected, you might need to run shredding manually and use the IOERROR keyword.

MANual
Specifies that shredding occurs manually, only when the SHRED DATA command is invoked. Use this option to control when shredding takes place, in order to ensure that it does not interfere with other server activities.
Tip: If you specify manual shredding, run the SHRED DATA command regularly, at least as often as you perform other routine server-maintenance tasks (for example, expiration, reclamation, and so on). Doing so can prevent performance degradation of certain server processes (in particular, migration). For best results, run SHRED DATA after any operation (for example, expiration and migration) that deletes files from a shred pool.

Examples

Specify that IBM Spectrum Protect™ automatically shreds data in a storage pool configured for shredding after that data is deleted:

```
shredding automatic
```

SNMPHEARTBEATINTERVAL

The SNMPHEARTBEATINTERVAL option specifies the interval in minutes between queries of the IBM Spectrum Protect™ server.

Syntax

```
                          .-5-------.
>>-SNMPHEARTBEATINTERVAL--+-minutes-+--------------------------><
```

Parameters

minutes
Specifies the heartbeat interval in minutes. Valid values are from 0 to 1440 (one day). The default is 5 minutes.

Examples

```
snmpheartbeatinterval 20
```

SNMPMESSAGECATEGORY

The SNMPMESSAGECATEGORY option specifies the trap types used when messages are forwarded from the server, through the Simple Network Management Protocol (SNMP) subagent, to the SNMP manager.

Syntax

```
>>-SNMPMESSAGECATEGORY--+-SEVERITY---+------------------------><
                        '-INDIVIDUAL-'
```

Parameters

SEVERITY
: Specifies that there are four trap types based on message severity level:

  1
  : Severe

  2
  : Error

  3
  : Warning

  4
  : Information

  This is the default.

INDIVIDUAL
: Specifies that a separate trap type is used for each message. The numeric part of the message identifier indicates the trap type.

Examples

```
snmpmessagecategory individual
```

SNMPSUBAGENT

The SNMPSUBAGENT option specifies the parameters needed for the IBM Spectrum Protect™ subagent to communicate with the Simple Network Management Protocol (SNMP) daemon. This option is only to configure the SNMP subagent for communicating with the SNMP agent; it is ignored by the server.

Syntax

```
>>-SNMPSUBAGENT--+---------------------+------------------------>
                 '-HOSTname--host_name-'

>--+-------------------------------+--+------------------+-----><
   '-COMMunityname--community_name-'  '-TIMEOUT--seconds-'
```

Parameters

HOSTname host_name
: Specifies the TCP/IP name or number of the host running the SNMP agent that the IBM Spectrum Protect SNMP subagent connects to. This parameter is optional. The default name is *localhost*.

COMMunityname community_name

Specifies the configured community name on the system running the SNMP agent. This parameter is optional. The default name is *public*.

TIMEOUT seconds

Specifies the time, in seconds, in which a request must be received. This parameter is optional. The default value is 600.

Examples

```
snmpsubagent hostname jimbo communityname public timeout 2600
```

SNMPSUBAGENTHOST

The SNMPSUBAGENTHOST option specifies the location of the IBM Spectrum Protect™ Simple Network Management Protocol (SNMP) subagent. The default for this option is 127.0.0.1.

Syntax

```
>>-SNMPSUBAGENTHOST--host_name---------------------------------><
```

Parameters

host_name

Specifies the TCP/IP host name or number on which the IBM Spectrum Protect SNMP subagent is located. The subagent and server must be on the same node.

Examples

```
snmpsubagenthost 9.116.23.450
```

SNMPSUBAGENTPORT

The SNMPSUBAGENTPORT option specifies the port number of the IBM Spectrum Protect™ Simple Network Management Protocol (SNMP) subagent.

Syntax

```
>>-SNMPSUBAGENTPORT--port_number-------------------------------><
```

Parameters

port_number

Specifies the port number of the IBM Spectrum Protect SNMP subagent. Valid values are 1000 - 32767. The default is 1521.

Examples

```
snmpsubagentport 1525
```

SSLFIPSMODE

The SSLFIPSMODE option specifies whether the Federal Information Processing Standards (FIPS) mode is in effect for Secure Sockets Layer (SSL). The default is NO.

Because SSLv3 is not supported by FIPS mode, when you are using SSL with Version 6.1 or V5.5 clients, you must turn off FIPS mode.

Syntax

```
   .-SSLFIPSMODE--=--No------.
>>-+-------------------------+--------------------------------><
   '-SSLFIPSMODE--=--+-No--+-'
                     '-Yes-'
```

Parameters

No
: Specifies that SSL FIPS mode is not active on the server. This setting is required when Backup-Archive Client versions previous to IBM Spectrum Protect™ 6.3 are to connect to the server with SSL.

Yes
: A value of YES indicates that SSL FIPS mode is active on the server. This setting restricts SSL session negotiation to use FIPS-approved cipher suites. Specifying YES is suggested when SSL communication is activated and all Backup-Archive Clients are at V6.3 or later.

To disable SSL FIPS mode on the server:

```
SSLFIPSMODE no
```

SSLINITTIMEOUT

The SSLINITTIMEOUT option specifies the time, in minutes, that the server waits for a Secure Sockets Layer (SSL) session to complete initialization before the server cancels the session.

When you specify this option, an SSL session is canceled if a client, server, or storage agent is not configured for SSL and tries to start an SSL session. Similarly, an SSL session is canceled if a client SSL session and a server are not configured with the same Transport Layer Security (TLS) version. In these situations, the SSL session might fail to completely initialize. The server cancels the session when the specified timeout is reached.

Syntax

```
                    .-2-------.
>>-SSLINITTIMEout--+-minutes-+--------------------------------><
```

Parameters

minutes
: Specifies the maximum number of minutes that a server waits for an SSL session to complete initialization. The default value is 2 minutes. The minimum value is 1 minute.

Example

```
sslinittimeout 1
```

SSLTCPADMINPORT

The SSLTCPADMINPORT option specifies the port address on which the server TCP/IP communication driver waits for requests for SSL-enabled sessions only. The sessions are for the command-line administrative client.

Note: Beginning with IBM Spectrum Protect™ Version 8.1.2, you are no longer required to use the SSLTCPPORT or SSLTCPADMINPORT option to allow SSL-enabled sessions from the client. The port number that is specified in the TCPPORT or TCPADMINPORT option listens for both TCP/IP and SSL-enabled client sessions.
The following types of sessions do not use the Secure Sockets Layer (SSL) protocol:

- Network Data Management Protocol (NDMP)
- Automated Cartridge System Library Software (ACSLS)
- Database restore operations

If the ADMINONCLIENTPORT option is set to NO, SSL-enabled sessions for the administrative client require that different port numbers are set for the SSLTCPADMINPORT and SSLTCPPORT options.

The TCP/IP communications driver must be enabled with COMMMETHOD TCPIP or COMMMETHOD V6TCPIP.

Syntax

```
>>-SSLTCPADMINPort--port_number--------------------------------><
```

Parameters

port_number
: Specifies the port number of the server. Valid values are 1024 - 32767. There is no default.

Examples

```
ssltcpadminport 1543
```

SSLTCPPORT

The SSLTCPPORT option specifies the Secure Sockets Layer (SSL) port number for SSL-enabled sessions only. The server TCP/IP communication driver waits for requests on this port for SSL-enabled sessions from the client.

Important: Beginning with IBM Spectrum Protect™ Version 8.1.2, you are no longer required to use the SSLTCPPORT or SSLTCPADMINPORT option to allow SSL-enabled sessions from the client. The port number that is specified in the TCPPORT or TCPADMINPORT option listens for both TCP/IP and SSL-enabled client sessions.
The following types of sessions do not use SSL:

- Network Data Management Protocol (NDMP)
- Automated Cartridge System Library Software (ACSLS)
- Database restore operations

If the ADMINONCLIENTPORT option is set to NO, SSL-enabled sessions for the administrative client require that different port numbers are specified for the SSLTCPADMINPORT and SSLTCPPORT options.

If you specify the same port number for the SSLTCPPORT and TCPPORT options, only SSL connections are accepted and TCP/IP connections are disabled for the port.

The TCP/IP communications driver must be enabled with COMMMETHOD TCPIP or COMMMETHOD V6TCPIP.

Syntax

```
>>-SSLTCPPort--port_number-------------------------------------><
```

Parameters

port_number
: Specifies the port number of the server. Valid values are 1024 - 32767. There is no default.

Examples

```
ssltcpport 1542
```

TCPADMINPORT

The TCPADMINPORT option specifies the port number on which the server TCP/IP communication driver waits for requests for TCP/IP and SSL-enabled sessions other than client sessions. This includes administrative sessions, server-to-server sessions, storage agent sessions, library client sessions, managed server sessions, and event server sessions.

Using different port numbers for the options TCPPORT and TCPADMINPORT enables you to create one set of firewall rules for client sessions and another set for the previously listed session types. By using the SESSIONINITIATION parameter of REGISTER NODE and UPDATE NODE commands, you can close the port specified by TCPPORT at the firewall, and specify nodes whose scheduled sessions will be started from the server. If the two port numbers are different, separate threads are used to service client sessions and the session types. If you allow the two options to use the same port number (by default or by explicitly setting them to the same port number), a single server thread is used to service all session requests.

Client sessions attempting to use the port specified by TCPADMINPORT are terminated (if TCPPORT and TCPADMINPORT specify different ports). Administrative sessions are allowed on either port, (unless the ADMINONCLIENTPORT option is set to NO) but by default administrative sessions use the port that is specified by TCPADMINPORT.

SSL-enabled sessions that use the TCPADMINPORT option have the same limitations as the SSLTCPADMINPORT option. The following types of sessions do not use the Secure Sockets Layer (SSL) protocol:

- Network Data Management Protocol (NDMP)
- Automated Cartridge System Library Software (ACSLS)
- Database restore operations

If the ADMINONCLIENTPORT option is set to NO, SSL-enabled sessions for the administrative client require that different port numbers are specified for the TCPADMINPORT andTCPPORT options.

Syntax

```
>>-TCPADMINPort--port_number-----------------------------------><
```

Parameters

port_number
: Specifies the port number of the server. Valid values are 1024 - 32767. The default is the value of TCPPORT.

Examples

```
tcpadminport 1502
```

AIX Linux

TCPBUFSIZE

The TCPBUFSIZE option specifies the size of the buffer used for TCP/IP send requests. During a restore, client data moves from the IBM Spectrum Protect™ session component to a TCP communication driver. The TCPBUFSIZE option determines if the server sends the data directly from the session buffer or copies the data to the TCP buffer. A 32 KB buffer size forces the server to copy data to its communication buffer and flush the buffer when it fills.

Note: This option is not related to the TCPWINDOWSIZE option.

Syntax

```
>>-TCPBufsize--kilobytes---------------------------------------><
```

Parameters

kilobytes
: Specifies the size, in kilobytes, of the buffer used for TCP/IP send requests.

  AIX The value range is from 1 to 64. The default is 32.

  Linux The value range is from 1 to 64. The default is 16.

Examples

```
tcpbufsize 5
```

TCPNODELAY

The TCPNODELAY option specifies whether the server disables the delay of sending successive small packets on the network.

Change the value from the default of YES only under one of these conditions:

- You are directed to change the option by your service representative.
- You fully understand the effects of the TCP Nagle algorithm on network transmissions. Setting the option to NO enables the Nagle algorithm, which delays sending small successive packets.

Syntax

```
>>-TCPNodelay--+-Yes-+-----------------------------------------><
               '-No--'
```

Parameters

Yes
: Specifies that the server allows successive small packets to be sent immediately over the network. Setting this option to YES might improve performance in some high-speed networks. The default is YES.

No
: Specifies that the server does not allow successive small packets to be sent immediately over the network.

Examples

```
tcpnodelay no
```

TCPPORT

The TCPPORT option specifies the port number on which the server TCP/IP communication driver waits for requests for client sessions. The server TCP/IP communication driver listens on this port for both TCP/IP and SSL-enabled sessions from the client.

Using different port numbers for the options TCPPORT and TCPADMINPORT enables you to create one set of firewall rules for client sessions and another set for other session types (administrative sessions, server-to-server sessions, storage agent sessions, library client sessions, managed server sessions, and event server sessions). If the two port numbers are different, separate threads are used to service client sessions and the other session types. If you allow the two options to use the same port number (by default or by explicitly setting them to the same port number), a single server thread is used to service all session requests.

SSL-enabled client sessions that use the TCPPORT option have the same limitations as the SSLTCPPORT option. The following types of sessions do not use SSL:

- Network Data Management Protocol (NDMP)
- Automated Cartridge System Library Software (ACSLS)
- Database restore operations

If the ADMINONCLIENTPORT option is set to NO, SSL-enabled sessions for the administrative client require that different port numbers are specified for the TCPADMINPORT and TCPPORT options.
If you specify the same port number for both the SSLTCPPORT and TCPPORT options, only SSL connections are accepted and TCP/IP connections are disabled for the port.

Windows You can change this option with the SETOPT command. When you change a port, the IBM Spectrum Protect™ server starts listening on the new port immediately. All current connections remain in use until closed.

Syntax

```
>>-TCPPort--port_number-----------------------------------------><
```

Parameters

port_number
: Specifies the port number of the server. Valid values are 1024 - 32767. The default value is 1500.

```
tcpport 1500
```

TCPWINDOWSIZE

The TCPWINDOWSIZE option specifies, in kilobytes, the amount of receive data that can be buffered at one time on a TCP/IP connection. The sending host cannot send more data until it receives an acknowledgment and a TCP receive window update. Each TCP packet contains the advertised TCP receive window on the connection. A larger window lets the sender continue sending data, and may improve communication performance, especially on fast networks with high latency.

Note:

- To improve backup performance, increase the TCPWINDOWSIZE on the server. To improve restore performance, increase the TCPWINDOWSIZE on the client.
- The TCP window acts as a buffer on the network.
- A window size larger than the buffer space on the network adapter might degrade throughput due to resending packets that were lost on the adapter.
- AIX Linux The TCPWINDOWSIZE option is not related to the TCPBUFFSIZE option nor to the send and receive buffers allocated in client or server memory.

Syntax

```
>>-TCPWindowsize--kilobytes-----------------------------------><
```

Parameters

kilobytes

Specifies the size you want to use, in kilobytes, for the TCP/IP sliding window for your client node. You can specify a value from 0 to 2048. The default is 63. If you specify 0, the server uses the default window size set by the operating system. Values from 1 to 2048 indicate that the window size is in the range of 1 KB to 2 MB.

Examples

```
tcpwindowsize 63
```

TECBEGINEVENTLOGGING

The TECBEGINEVENTLOGGING option specifies whether event logging for the Tivoli® receiver should begin when the server starts up. If the TECHOST option is specified, TECBEGINEVENTLOGGING defaults to YES.

Syntax

```
>>-TECBegineventlogging--+-Yes-+------------------------------><
                         '-No--'
```

Parameters

Yes
: Specifies that event logging begins when the server starts up and if a TECHOST option is specified.

No
: Specifies that event logging should not begin when the server starts up. To later begin event logging to the TIVOLI receiver (if the TECHOST option has been specified), you must issue the BEGIN EVENTLOGGING command.

Examples

```
tecbegineventlogging yes
```

TECHOST

The TECHOST option specifies the host name or IP address for the Tivoli® event server.

Syntax

```
>>-TECHost--host_name-----------------------------------------><
```

Parameters

host_name
: Specifies the host name or IP address for the Tivoli event server.

Examples

```
techost 9.114.22.345
```

TECPORT

The TECPORT option specifies the TCP/IP port address on which the Tivoli® event server is listening. This option is only required if the Tivoli event server is on a system that does not have a Port Mapper service running.

Syntax

```
>>-TECPort--port_number---------------------------------------><
```

Parameters

port_number
: Specifies the Tivoli event server port address. The value must be between 0 and 32767. AIX Linux This option is not required.

Examples

```
tecport 1555
```

TECUTF8EVENT

The TECUTF8EVENT option allows the IBM Spectrum Protect™ administrator to send information to the Tivoli Enterprise Console® (TEC) server in UTF–8 data format. The default is No. You can display whether or not this option is enabled by issuing the QUERY OPTION command.

Syntax

```
>>-TECUTF8event--+-Yes-+---------------------------------------><
                 '-No--'
```

Parameters

Yes

Specifies that the IBM Spectrum Protect server will encode the TEC event into UTF–8 before issuing the event to the TEC server.

No

Specifies that IBM Spectrum Protect server will not encode the TEC event into UTF–8 and it will be issued to the TEC server in ASCII format.

Examples

```
tecutf8event yes
```

THROUGHPUTDATATHRESHOLD

The THROUGHPUTDATATHRESHOLD option specifies a throughput threshold that a client session must reach to prevent being canceled after the time threshold is reached.

This option is used in conjunction with the THROUGHPUTTIMETHRESHOLD server option, which sets the value for the time threshold plus the media wait time. The time threshold starts when the client begins sending data to the server for storage (as opposed to setup or session housekeeping data).

You can update this server option without stopping and restarting the server by using the SETOPT command. See SETOPT (Set a server option for dynamic update).

Syntax

```
>>-THROUGHPUTDatathreshold-- kilobytes_per_second--------------><
```

Parameters

kilobytes_per_second

Specifies the throughput that client sessions must achieve to prevent cancellation after THROUGHPUTTIMETHRESHOLD minutes have elapsed. This threshold does not include time spent waiting for media mounts. A value of 0 prevents examining client sessions for insufficient throughput. Throughput is computed by adding send and receive byte counts and dividing by the length of the session. The length does not include time spent waiting for media mounts and starts at the time a client sends data to the server for storage. The default is 0. The minimum value is 0; the maximum is 99999999.

Examples

Specify that the server is to wait until 90 minutes plus the media wait time after a session has started sending data before storage examines it as a candidate for cancellation due to low throughput. If a session is not achieving 50 KB per second in transfer rates, it will be canceled.

```
throughputtimethreshold 90
Throughputdatathreshold 50
```

THROUGHPUTTIMETHRESHOLD

The THROUGHPUTTIMETHRESHOLD option specifies the time threshold for a session after which it may be canceled for low throughput.

You can update this server option without stopping and restarting the server by using the SETOPT command. See SETOPT (Set a server option for dynamic update).

Syntax

```
>>-THROUGHPUTTimethreshold--minutes----------------------------><
```

Parameters

minutes
: Specifies the threshold for examining client sessions and canceling them if the data throughput threshold is not met (see the THROUGHPUTDATATHRESHOLD server option). This threshold does not include time spent waiting for media mounts. The time threshold starts when a client begins sending data to the server for storage (as opposed to setup or session housekeeping data). A value of 0 prevents examining client sessions for low throughput. The default is 0. The minimum value is 0; the maximum is 99999999.

Examples

Specify that the server is to wait until 90 minutes plus the media wait time after a session has started sending data before examining it as a candidate for cancellation. If a session is not achieving 50 thousand bytes per second in transfer rates, it will be canceled.

```
throughputtimethreshold 90
Throughputdatathreshold 50
```

Windows

TIMEFORMAT

The TIMEFORMAT option specifies the format in which time is displayed by the server.

The value for the TIMEFORMAT option is overridden by the time formatting definition of the locale if the locale is successfully initialized at server startup. The locale is specified in the LANGUAGE option.

Syntax

```
>>-TIMEformat--format_number---------------------------------><
```

Parameters

format_number
: Select a number from 1 to 4 to identify the time format used by the server. The default is 1.

1
: hh:mm:ss

2
: hh,mm,ss

3
: hh.mm.ss

4
: hh:mm:ss a.m or p.m.

5
: a.m or p.m. hh:mm:ss

Examples

```
timeformat 4
```

TXNGROUPMAX

The TXNGROUPMAX option specifies the number of objects that are transferred as a group between a client and the server between transaction commit points. The minimum value is 4 objects and the maximum value is 65000 objects. The default value is 4096 objects. The objects transferred are actual files, directories, or both. The server counts each file or directory as one object.

It is possible to affect the performance of client backup, archive, restore, and retrieve operations by using a larger value for this option:

1. If you increase the value of the TXNGROUPMAX option by a large amount, watch for possible effects on the recovery log. A larger value for the TXNGROUPMAX option can result in increased utilization of the recovery log, as well as an increased

length of time for a transaction to commit. If the effects are severe enough, they can lead to problems with operation of the server.
2. Increasing the value of the TXNGROUPMAX option can improve throughput for operations storing data directly to tape, especially when storing a large number of objects. However, a larger value of the TXNGROUPMAX option can also increase the number of objects that must be resent in the case where the transaction is stopped because an input file changed during backup, or because a new storage volume was required. The larger the value of the TXNGROUPMAX option, the more data must be resent.
3. Increasing the TXNGROUPMAX value will affect the responsiveness of stopping the operation and the client may will have to wait longer for the transaction to complete.

You can override the value of this option for individual client nodes. See the TXNGROUPMAX parameter in REGISTER NODE (Register a node) and UPDATE NODE (Update node attributes).

This option is related to the TXNBYTELIMIT option in the client options file. TXNBYTELIMIT controls the number of bytes, as opposed to the number of objects, that are transferred between transaction commit points. At the completion of transferring an object, the client commits the transaction if the number of bytes transferred during the transaction reaches or exceeds the value of TXNBYTELIMIT, regardless of the number of objects transferred.

Syntax

```
>>-TXNGroupmax--number_of_objects------------------------------><
```

Parameters

number_of_objects
Specifies a number from 4 to 65000 for the maximum number of objects per transaction. The default is 4096.

Examples

```
txngroupmax 4096
```

UNIQUETDPTECEVENTS

The UNIQUETDPTECEVENTS option generates a unique Tivoli Enterprise Console® (TEC) event class for each individual IBM Spectrum Protect™ message, including client, server, and IBM Spectrum Protect Data Protection client messages. The default is No.

Syntax

```
>>-UNIQUETDPtecevents--+-Yes-+---------------------------------><
                       '-No--'
```

Parameters

Yes
Specifies that unique IBM Spectrum Protect Data Protection messages are sent to the TEC event server. Dynamically sets UNIQUETECevents to YES.

No
Specifies that general messages are sent to the TEC event server.

Examples

```
uniquetdptecevents yes
```

UNIQUETECEVENTS

The UNIQUETECEVENTS option generates a unique Tivoli Enterprise Console® (TEC) event class for each individual IBM Spectrum Protect™ message. The default is No.

Syntax

```
>>-UNIQUETECevents--+-Yes-+-----------------------------------><
                    '-No--'
```

Parameters

Yes
: Specifies that unique messages are sent to the TEC event server.

No
: Specifies that general messages are sent to the TEC event server.

Examples

```
uniquetecevents yes
```

USEREXIT

The USEREXIT option specifies a user-defined exit that will be given control to manage an event.

Syntax

```
                                    (1)           (2)
>>-USEREXIT--+-Yes-+--module_name------DLL_name-----------------><
             '-No--'

            (3)
>--function-------------------------------------------------------><
```

Notes:

1. *module_name* is available only on AIX, HP-UX, Linux, Solaris, and z/OS.
2. *DLL_name* is available only on Windows.
3. *function* is available only on Windows.

Parameters

Yes
: Specifies that event logging to the user exit receiver begins automatically at server startup.

No
: Specifies that event logging to the user exit receiver does not begin automatically at server startup. When this parameter has been specified, you must begin event logging manually by issuing the BEGIN EVENTLOGGING command.

AIX Linux module_name
: AIX Linux Specifies the module name of the user exit.

  AIX Linux This is the name of a shared library containing the exit. The module name can be either a fully qualified path name or just the module name itself. If it is just the module name, it is loaded from the current directory.

Windows DLL_name
: Windows Specifies the DLL name that contains the user-exit function.

Windows function
: Windows Specifies the name of the user-exit function in the DLL.

Examples

Windows

```
userexit yes dllname.dll dllmodulename
```

AIX Linux

```
userexit yes fevent.exit
```

VERBCHECK

The VERBCHECK option specifies that the server will do additional error checking on the structure of commands sent by the client. This option should only be enabled when the client sends incorrectly formed requests to the server, causing the server to crash. When this option is enabled, you will get a protocol error instead of a server crash.

Syntax

```
>>-VERBCHECK-------------------------------------------------><
```

Parameters

None

Examples

Enable additional error checking for commands sent by the client:

```
verbcheck
```

VOLUMEHISTORY

The VOLUMEHISTORY option specifies the name of files to be automatically updated whenever server sequential volume history information is changed. There is no default for this option.

You can include one or more VOLUMEHISTORY options in the server options file. When you use multiple VOLUMEHISTORY options, the server automatically updates and stores a backup copy of the volume history information in each file you specify.

Syntax

```
>>-VOLUMEHistory--file_name-----------------------------------><
```

Parameters

file_name
: Specifies the name of the file where you want the server to store a backup copy of the volume history information that it collects.

Examples

```
volumehistory volhist.out
```

Server utilities

Use server utilities to perform special tasks on the server while the server is not running.

- Windows DSMMAXSG (Increase the block size for writing data)
  Use the DSMMAXSG utility to increase the maximum transfer length for host bus adapters (HBAs). As a result, the block size that is used by the IBM Spectrum Protect™ server for writing data to and getting data from certain types of tape drives is increased.
- DSMSERV (Start the server)
  Use this utility to start the IBM Spectrum Protect server.
- AIX Linux Server startup script: rc.dsmserv
  You can use the rc.dsmserv script in your system startup to automatically start a server instance under a specific user ID.

- Linux Server startup script: dsmserv.rc
  You can use the dsmserv.rc script to stop a server instance, or to manually or automatically start a server.
- DSMSERV DISPLAY DBSPACE (Display information about database storage space)
  Use this utility to display information about storage space that is defined for the database. The output of this utility is the same as the output of the QUERY DBSPACE command, but you can use this utility when the server is not running.
- DSMSERV DISPLAY LOG (Display recovery log information)
  Use this utility to display information about recovery logs including the active log, the mirror for the active log, the failover directory for the archive log, and the overflow location for logs. Use this utility when the server is not running.
- DSMSERV EXTEND DBSPACE (Increase space for the database)
  Use this utility to increase space for the database by adding directories for the database to use. This utility performs the same function as the EXTEND DBSPACE command, but you can use it when the server is not running.
- DSMSERV FORMAT (Format the database and log)
  Use the DSMSERV FORMAT utility to initialize the server database and recovery log. No other server activity is allowed while initializing the database and recovery log.
- DSMSERV INSERTDB (Move a server database into an empty database)
  Use the DSMSERV INSERTDB utility to move a server database into a new database. The database can be extracted from the original server and inserted into a new database on the new server by using a network connection between the two servers. The database can also be inserted from media that contains the extracted database.
- DSMSERV LOADFORMAT (Format a database)
  Use the DSMSERV LOADFORMAT utility when upgrading from Version 5. The utility formats an empty database in preparation for inserting an extracted database into the empty database.
- DSMSERV REMOVEDB (Remove a database)
  Use the DSMSERV REMOVEDB utility to remove an IBM Spectrum Protect server database.
- DSMSERV RESTORE DB (Restore the database)
  Use this utility to restore a database by using a database backup.
- Windows DSMSERV UPDATE (Create registry entries for a server instance)
  Use this utility to create registry entries for an IBM Spectrum Protect server instance if the entries were accidentally deleted.
- AIX DSMULOG (Capture IBM Spectrum Protect server messages to a user log file)
  Use this command to capture IBM Spectrum Protect server console messages to a user log file. You can specify that IBM Spectrum Protect write messages to more than one user log file.

Windows

DSMMAXSG (Increase the block size for writing data)

Use the DSMMAXSG utility to increase the maximum transfer length for host bus adapters (HBAs). As a result, the block size that is used by the IBM Spectrum Protect™ server for writing data to and getting data from certain types of tape drives is increased.

With this utility, the maximum block size that you can specify is 256 KB. Depending on your system environment, increasing the block size can improve the rate at which IBM Spectrum Protect processes data for backup and restore operations and for archive and retrieve operations. However, the utility does not affect the generation of backup sets.

You can use tape drives that are only attached to SCSI or Fibre Channel HBAs and that have the following device types:

- 3590
- 3592
- DLT
- ECARTRIDGE
- LTO

The utility runs automatically as part of the IBM Spectrum Protect server and storage agent installation. However, if you install a new HBA on your system after you install a server or storage agent, or if you install a new version of an existing HBA device driver that resets the value of the maximum transfer size, you must run the utility manually to take advantage of the larger block size.

When you run this utility, it modifies one registry key for every HBA driver on the system. The name of the key is MaximumSGList.

Restriction: If data is backed up or archived to tape using the 256 KB block size, the tape cannot be appended to or read from using an HBA that does not support the 256 KB block size. For example, if you use a 256 KB Windows system to back up client data to the IBM Spectrum Protect server, you cannot restore the data using a Windows system that supports a different transfer length. To append to or read from tape written to using a 256 KB transfer length, you must install an HBA that supports 256 KB transfers.

Syntax

```
>>-dsmmaxsg---------------------------------------------------><
```

Example: Increase the block size for writing data

Run the DSMMAXSG utility to increase the block size that is used by the IBM Spectrum Protect.

```
dsmmaxsg
```

DSMSERV (Start the server)

Use this utility to start the IBM Spectrum Protect™ server.

Restrictions:

- Do not enter more than 1022 characters in the DSMSERV console command-line interface. Text that exceeds 1022 characters is truncated.
- Windows The following parameters are mutually exclusive:
  - NOEXPIRE
  - RUNFILE
  - MAINTENANCE

AIX Linux Windows

Syntax

Notes:

1. This parameter applies only to AIX® and Linux servers.
2. This parameter applies only to Windows servers.
3. This parameter applies only to Windows servers.
4. This parameter applies only to AIX, Linux, and Windows servers.

AIX Linux Windows

Parameters

AIX Linux -u user_name

AIX Linux Specifies a user name to switch to before you start the server. To start the server from the root user ID, you must specify the -u parameter and follow the instructions in Starting the server from the root user ID.

AIX Linux -i instance_dir

AIX Linux Specifies an instance directory to use. The instance directory becomes the current working directory of the server.

Windows -k key_name

Windows Specifies the name of the Windows registry key from which to retrieve information about the server. The default is Server1.

AIX Linux -noexpire

AIX Linux Specifies that the server does not remove expired files from the server database. The files are not deleted from server storage when you start the server.

Windows NOEXPIRE

Windows Specifies that the server does not remove expired files from the server database. The files are not deleted from server storage when you start the server.

-o options_file

Specifies an options file to use.

AIX Linux -quiet

AIX Linux Specifies that messages to the console are suppressed.

AIX Linux Windows MAINTenance

AIX Linux Windows Specifies that the server is started in maintenance mode, and that administrative command schedules, client schedules, client sessions, storage-space reclamation, inventory expiration, and storage-pool migration are disabled.

Tip: Maintenance mode is the preferred method for running the server during maintenance or reconfiguration tasks. When you run the server in maintenance mode, operations that might disrupt maintenance or reconfiguration tasks are disabled automatically.

RUNFILE file_name

Specifies the name of a text file to be run on the server. The file contains a list of server commands.

Attention: Whenever the RUNFILE parameter is used, the server halts when processing is complete. You must restart the server by using the DSMSERV utility.

Example: Start the server

Start the server for normal operation. Issue the following command on one line:

AIX

```
LDR_CNTRL=TEXTPSIZE=64K@DATAPSIZE=64K@STACKPSIZE=64K@SHMPSIZE=64K
usr/bin/dsmserv
```

AIX Ensure that you include a space after `SHMPSIZE=64K`. By starting the server with this command, you enable 64 KB memory pages for the server. This setting helps you optimize server performance.

Linux

```
/opt/tivoli/tsm/server/bin/dsmserv
```

Windows

```
C:\Program Files\Tivoli\TSM\bin\dsmserv -k server2
```

Windows

Example: Start an additional server

Start an additional server by using the registry key named SERVER2.

```
dsmserv -k server2
```

AIX Linux Windows

Example: Load the sample script

Load the sample script file that is provided with the server.

```
dsmserv runfile scripts.smp
```

AIX Linux Windows

Example: Start the server in maintenance mode

Before you begin maintenance or reconfiguration tasks, start the server in maintenance mode.

```
dsmserv maintenance
```

Related tasks:
Starting the server in maintenance mode
AIX

Server startup script: rc.dsmserv

You can use the rc.dsmserv script in your system startup to automatically start a server instance under a specific user ID.

Syntax

```
>>-rc.dsmserv--+- -u--user_name-+--+-------------------+-------><
               '- -U--user_name-'  '- -i--instance_dir-'
```

Parameters

-u user_name
: Specifies the instance user ID for which the environment is set up. The server will run under this user ID.

-U user_name
: Specifies the instance user ID for which the environment is set up. The server will run under the user ID of the invoker of the command.

-i instance_dir
: Specifies an instance directory, which becomes the working directory of the server.

Related tasks:
AIX: Automatically starting servers
Linux

Server startup script: dsmserv.rc

You can use the dsmserv.rc script to stop a server instance, or to manually or automatically start a server.

Prerequisites

Before you issue the DSMSERV.RC command, complete the following steps:

1. Ensure that the server instance runs under a non-root user ID with the same name as the instance owner.
2. Copy the dsmserv.rc script to the /etc/rc.d/init.d directory. The dsmserv.rc script is in the server installation directory, for example, /opt/tivoli/tsm/server/bin.
3. Rename the script so that it matches the name of the server instance owner, for example, `tsminst1`.
4. If the server instance directory is not home_directory/tsminst1, locate the following line in the script copy:

   ```
   instance_dir="${instance_home}/tsminst1"
   ```

   Change the line so that it points to your server instance directory, for example:

   ```
   instance_dir="/tsminst1"
   ```

5. In the script copy, locate the following line:

   ```
   # pidfile: /var/run/dsmserv_instancename.pid
   ```

   Change the instance name value to the name of the server instance owner. For example, if the server instance owner is tsminst1, update the line as shown:

   ```
   # pidfile: /var/run/dsmserv_tsminst1.pid
   ```

6. Use tools such as the CHKCONFIG utility to configure the run level in which the server automatically starts. Specify a value that corresponds to a multiuser mode, with networking turned on. Typically, the run level to use is 3 or 5, depending on the operating system and its configuration. For details about run levels, see the documentation for your operating system.

Syntax

```
>>-dsmserv.rc--+---------+-------------------------------------><
               +-start---+
               +-stop----+
               +-status--+
               '-restart-'
```

Parameters

start
: Starts the server.

stop
: Stops the server.

status
: Shows the status of the server. If the status is `started`, the process ID of the server process is also shown.

restart
: Stops the server and starts it again.

Related tasks:
Linux: Automatically starting servers on Linux systems

DSMSERV DISPLAY DBSPACE (Display information about database storage space)

Use this utility to display information about storage space that is defined for the database. The output of this utility is the same as the output of the QUERY DBSPACE command, but you can use this utility when the server is not running.

Syntax

```
>>-DSMSERV -+----------------------+---------------------------->
            |  (1)                 |
            '------- -u--user_name-'

                                (2).- -k--Server1--.
>--+-------------------------+------+---------------+----------->
   |  (1)                    |      '- -k--key_name-'
   '------- -i--instance_dir-'

>--+-------------------+--+------------+--+---------+----------->
   '- -o--options_file-'  '- -noexpire-'  '- -quiet-'

>--DISPlay DBSPace-------------------------------------------><
```

Notes:

1. This parameter applies to AIX® and Linux servers only.
2. This parameter applies only to Windows servers.

Parameters

AIX Linux -u user_name
: AIX Linux Specifies a user name to switch to before initializing the server.

AIX Linux -i instance_dir
: AIX Linux Specifies an instance directory to use. This becomes the current working directory of the server.

Windows -k key_name
: Windows Specifies the name of a Windows registry key that is used to store information about this server. Use this parameter only when there is more than one server on the same system. The default value is SERVER1.

-o options_file
: Specifies an options file to use.

-noexpire
: Specifies that expiration processing is suppressed when starting.

-quiet
: Specifies that messages to the console are suppressed.

Example: Display database space information

Display information about database storage space. See Field descriptions for details about the information shown in the output. Issue the command.

```
dsmserv display dbspace
```

AIX Linux

```
Location         Total Space (MB)   Used Space (MB)   Free Space (MB)
-------------    ----------------   ---------------   ---------------
 /tsmdb001              46,080.00         20,993.12         25,086.88
 /tsmdb002              46,080.00         20,992.15         25,087.85
```

Windows

```
Location           Total Space (MB)   Used Space (MB)   Free Space (MB)
-------------    ----------------   ---------------   ---------------
d:\tsm\db001           46,080.00         20,993.12         25,086.88
d:\tsm\db002           46,080.00         20,993.15         25,087.85
```

Field descriptions

Location
: The directory or path that is used for storing the database

Total Space (MB)
: The total number of megabytes in the location

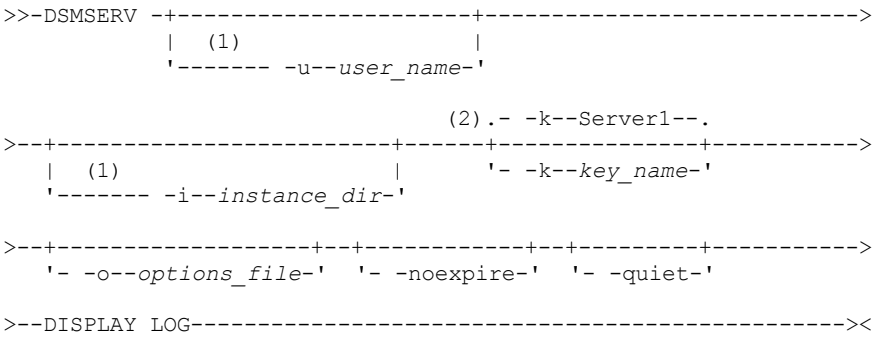
Used Space (MB)
: The number of megabytes in use in the location

Free Space (MB)
: AIX Linux The space remaining in the file system where the path is located
: Windows The space remaining on the drive where the directory is located

DSMSERV DISPLAY LOG (Display recovery log information)

Use this utility to display information about recovery logs including the active log, the mirror for the active log, the failover directory for the archive log, and the overflow location for logs. Use this utility when the server is not running.

Syntax



Notes:

1. This parameter applies to AIX® and Linux servers only.
2. This parameter applies only to Windows servers.

Parameters

AIX Linux -u user_name

AIX Linux Specifies a user name to switch to before initializing the server.

AIX Linux -i instance_dir

AIX Linux Specifies an instance directory to use. This becomes the current working directory of the server.

Windows -k key_name

Windows Specifies the name of the Windows registry key from which to retrieve information about the server. Use this parameter only when there is more than one server on the same system. The default is SERVER1.

-o options_file

Specifies an options file to use.

-noexpire

Specifies that expiration processing is suppressed when starting.

-quiet

Specifies that messages to the console are suppressed.

Examples: Display recovery log information

Display information about the recovery logs. See Field descriptions for details about the information shown in the output.

```
dsmserv display log
```

AIX Linux

```
               Total Space(MB): 38,912
                Used Space(MB): 401.34
                Free Space(MB): 38,358.65
          Active Log Directory: /activelog
         Archive Log Directory: /archivelog
          Mirror Log Directory: /mirrorlog
Archive Failover Log Directory: /archfailoverlog
```

Windows

```
               Total Space(MB): 38,912
                Used Space(MB): 401.34
                Free Space(MB): 38,358.65
          Active Log Directory: h:\tsm\activelog
         Archive Log Directory: k:\tsm\archivelog
          Mirror Log Directory: i:\tsm\mirrorlog
Archive Failover Log Directory: j:\tsm\archfailoverlog
```

Field descriptions

Total Space

Specifies the maximum size of the active log.

Used Space

Specifies the total amount of active log space currently used in the database, in megabytes.

Free Space

Specifies the amount of active log space in the database that is not being used by uncommitted transactions, in megabytes.

Active Log Directory

Specifies the location where active log files are stored. When you change the active log directory, the server moves all archived logs to the archive log directory and all active logs to a new active log directory.

Mirror Log Directory

Specifies the location where the mirror for the active log is maintained.

Archive Failover Log Directory

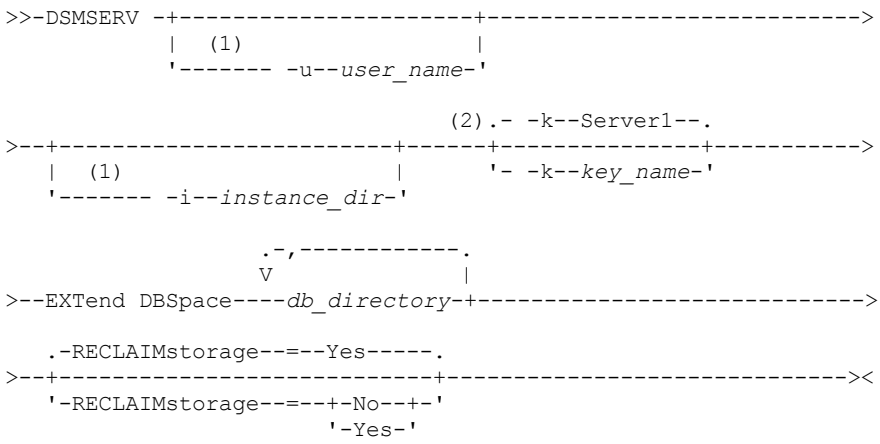
Specifies the location in which the server saves archive logs if the logs cannot be archived to the archive log destination.

DSMSERV EXTEND DBSPACE (Increase space for the database)

Use this utility to increase space for the database by adding directories for the database to use. This utility performs the same function as the EXTEND DBSPACE command, but you can use it when the server is not running.

Restriction: Redistribution of data and reclaiming of space as part of an operation to extend database space only works with DB2® Version 9.7 or later table spaces, which are created when you format a new Version 6.3 or later server.

Syntax



Notes:

1. This parameter applies to AIX® and Linux servers only.
2. This parameter applies only to Windows servers.

Parameters

AIX Linux -u user_name

AIX Linux Specifies a user name to switch to before you initialize the server.

AIX Linux -i instance_dir

AIX Linux Specifies an instance directory to use. This becomes the current working directory of the server.

Windows -k key_name

Windows Specifies the name of a Windows registry key that is used to store information about this server. Use this parameter only when there is more than one server on the same system. The default value is SERVER1.

db_directory (Required)

Specifies the directories for database storage. The directories must be empty and accessible by the user ID of the database manager. A directory name must be a fully qualified name and cannot exceed 175 characters in length. Enclose the name in quotation marks if it contains embedded blanks, an equal sign, or other special characters. If you are specifying a list of directories for database storage, the maximum length of the list can be 1400 characters.

Windows Restriction: You cannot specify Universal Naming Convention (UNC) paths.

Tip: Specify directories that are the same size as existing directories to ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching and distribution of the database.

RECLAIMstorage

Specifies whether data is redistributed across newly created database directories and space is reclaimed from the old storage paths when you add space to the database. This parameter is optional. The default value is Yes.

Yes

Specifies that data is redistributed so that new directories are available for immediate use.
Important: The redistribution process uses considerable system resources so ensure that you plan ahead. Also, the server might be offline for a while, until the process is completed.

No

Specifies that data is not redistributed across database directories and storage space is not reclaimed.

AIX Linux

Example: Increase space for the database

Add a directory named stg1 in the tsm_db directory for the database storage space and then redistribute data and reclaim space by issuing the following command:

```
dsmserv extend dbspace /tsm_db/stg1
```

Windows

Example: Increase space for the database

Add drive D to the storage space for the database and then redistribute data and reclaim space by issuing the following command:

```
dsmserv extend dbspace D:
```

Related reference:
EXTEND DBSPACE (Increase space for the database)

DSMSERV FORMAT (Format the database and log)

Use the DSMSERV FORMAT utility to initialize the server database and recovery log. No other server activity is allowed while initializing the database and recovery log.

The directories that are specified in this utility should be on fast, reliable storage. Do not place the directories on file systems that might run out of space. If certain directories (for example, the active log directory) become unavailable or full, the server stops.

Windows Restriction: If you are using a File Allocation Table (FAT or FAT32) or a New Technology File System (NTFS) format, you cannot specify the root directory of that system as the location of a database directory or log directory. Instead, you must create one or more subdirectories within the root directory. Then, create the database directories and log directories within the subdirectories.
Windows Important: The installation program creates a set of registry keys. One of these keys points to the directory where a default server, named SERVER1, is created. To install an extra server, create a directory and use the DSMSERV FORMAT utility, with the -k parameter, from that directory. That directory becomes the location of the server. The registry tracks the installed servers.

When a server is initially created by using the DSMSERV FORMAT utility or the configuration wizard, a server database and recovery log are created. In addition, files are created to hold database information that is used by the database manager.

Syntax

```
>>-DSMSERV -+----------------------+---------------------------->
            |  (1)                 |
            '------- -u--user_name-'

                                (2).- -k--Server1--.
>--+-------------------------+------+---------------+----------->
   |  (1)                    |      '- -k--key_name-'
   '------- -i--instance_dir-'

>--+--------------------+--+------------+--+---------+--FORMAT--->
   '- -o--options_file-'  '- -noexpire-'  '- -quiet-'

              .-,---------.
              V           |
>--+-DBDir--=----directory-+-+--------------------------------->
   '-DBFile--=--file---------'

   .-ACTIVELOGSize--=--16384-----.
>--+-----------------------------+----------------------------->
   '-ACTIVELOGSize--=--megabytes-'

>--ACTIVELOGDirectory--=--directory----------------------------->

>--ARCHLogdirectory--=--directory------------------------------->

>--+---------------------------------------+------------------->
   '-ARCHFailoverlogdirectory--=--directory-'

>--+-----------------------------------+------------------------><
   '-MIRRorlogdirectory--=--directory-'
```

Notes:

1. This parameter applies to AIX® and Linux servers only.
2. This parameter applies only to Windows servers.

Parameters

AIX Linux -u user_name

AIX Linux Specifies a user name to switch to before initializing the server. This parameter is optional.

AIX Linux -i instance_dir

AIX Linux Specifies an instance directory to use. This directory becomes the current working directory of the server. This parameter is optional.

Windows -k key_name

Windows Specifies the name of a Windows registry key that is used to store information about this server. Use this parameter only to install extra servers on the same system. After you install a server by using this parameter, you must always start it with the value of this parameter. This parameter is optional. The default is SERVER1.

Restriction: Additional instances of the IBM Spectrum Protect™ server that are running on the same system will compete for resources and impact overall performance of each IBM Spectrum Protect server.

-o options_file

Specifies an options file to use. This parameter is optional.

-noexpire

Specifies that expiration processing is suppressed when starting. This parameter is optional.

-quiet

Specifies that messages to the console are suppressed. This parameter is optional.

DBDir

Specifies the relative path names of one or more directories that are used to store database objects. Directory names must be separated by commas but without spaces. You can specify up to 128 directory names. You must specify either the DBDIR or the DBFILE parameter.

Tip: If you specify multiple directories, ensure that the underlying file systems are of equal size to ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching and distribution of the database.

DBFile

Specifies the name of a file that contains the relative path names of one or more directories that are used to store database objects. Each directory name must be on a separate line in the file. You can specify up to 128 directory names. You must specify either the DBDIR or the DBFILE parameter.

ACTIVELOGSize

Specifies the size of the active log file in megabytes. This parameter is optional. The minimum value is 2048 MB (2 GB); the maximum is 524,288 MB (512 GB). If an odd number is specified, the value is rounded up to the next even number. The default is 16384 MB.

The size of an active log file is based on the value of the ACTIVELOGSIZE option. Guidelines for space requirements are in the following table:

Table 1. How to estimate volume and file space requirements

ACTIVELOGSize option value	**Reserve this much free space in the active log directory, in addition to the ACTIVELOGSize space**
16 GB - 128 GB	5120 MB
129 GB - 256 GB	10240 MB
257 GB - 512 GB	20480 MB

ACTIVELOGDirectory (Required)

Specifies the directory in which the server writes and stores active log files. There is only one active log location. The name must be a fully qualified directory name. The directory must exist, it must be empty, and it must be accessible by the user ID of the database manager. The maximum number of characters is 175.

ARCHLogdirectory (Required)

Specifies the directory for the archive log files. The name must be a fully qualified directory name. The maximum number of characters is 175.

ARCHFailoverlogdirectory

Specifies the directory to be used as an alternative storage location if the ARCHLOGDIRECTORY directory is full. This parameter is optional. The maximum number of characters is 175.

MIRRorlogdirectory

Specifies the directory in which the server mirrors the active log (those files in the ACTIVELOGDIRECTORY directory). This parameter is optional. The directory must be a fully qualified directory name. The maximum number of characters is 175.

Example: Format a database

AIX Linux

```
dsmserv format dbdir=/tsmdb001 activelogsize=8192
activelogdirectory=/activelog archlogdirectory=/archlog
```

```
archfailoverlogdirectory=/archfaillog mirrorlogdirectory=/mirrorlog
```

Windows

```
dsmserv -k server2 format dbdir=d:\tsm\db001 activelogsize=8192
activelogdirectory=e:\tsm\activelog archlogdirectory=f:\tsm\archlog
archfailoverlogdirectory=g:\tsm\archfaillog mirrorlogdirectory=h:\tsm\mirrorlog
```

DSMSERV INSERTDB (Move a server database into an empty database)

Use the DSMSERV INSERTDB utility to move a server database into a new database. The database can be extracted from the original server and inserted into a new database on the new server by using a network connection between the two servers. The database can also be inserted from media that contains the extracted database.

Before you use the DSMSERV INSERTDB utility, complete the planning and preparation tasks, such as backing up the database and saving configuration information. Ensure that you meet all requirements before you move the server database.

Requirements for insertion by using media

Before you run the utility to insert the server database into an empty database, ensure that your system meets the following requirements.

- The manifest file from the DSMUPGRD EXTRACTDB operation must be available.
- If the manifest file does not contain device configuration information, or if you are specifying the CONFIGINFO=DEVCONFIG parameter, both of the following statements must be true:
  - The server options file must contain an entry for the device configuration file.
  - The device configuration file must have information about the device class that is specified in the manifest file.
- The media that contains the extracted database must be available to the V8 server. Also, the permissions must be set to grant access to the media for the user ID that owns the V8 server instance.

Syntax

```
>>-DSMSERV -+----------------------+---------------------------->
            |  (1)                 |
            '------- -u--user_name-'

                                (2).- -k--Server1--.
>--+-------------------------+------+---------------+----------->
   |  (1)                    |      '- -k--key_name-'
   '------- -i--instance_dir-'

>--+-------------------+--+------------+--+---------+----------->
   '- -o--options_file-'  '- -noexpire-'  '- -quiet-'

>--INSERTDB--+-| A: Insert from media |-----+------------------->
             '-| B: Insert over a network |-'

   .-PREview--=--No------.
>--+--------------------+-----------------------------------><
   '-PREview--=--+-Yes-+-'
                 '-No--'

A: Insert from media

|--+-------------------------------+--------------------------->
   '-DEVclass--=--device_class_name-'

   .-CONFiginfo--=--MANifest------.
>--+------------------------------+--MANifest--=--file_name-----|
   '-CONFiginfo--=--+-MANifest--+-'
                    '-DEVconfig-'

B: Insert over a network

   .-SESSWait--=--60------.
|--+----------------------+-------------------------------------|
   '-SESSWait--=--minutes-'
```

Notes:

1. This parameter applies to AIX® and Linux servers only.
2. This parameter applies only to Windows servers.

Parameters

AIX Linux -u user_name
AIX Linux Specifies a user name to switch to before initializing the server. This parameter is optional.

AIX Linux -i instance_dir
AIX Linux Specifies an instance directory to use. This directory becomes the current working directory of the server. This parameter is optional.

Windows -k key_name
Windows Specifies the name of the Windows registry key from which to retrieve information about the server. This parameter is optional. The default is SERVER1.

-o options_file
Specifies an options file to use. This parameter is optional.

-noexpire
Specifies that expiration processing is suppressed when starting. This parameter is optional.

-quiet
Specifies that messages to the console are suppressed. This parameter is optional.

DEVclass
Specifies a sequential-access device class. You can specify any device class except for the DISK device class. The definition for the device class must exist in either the manifest file or the device configuration file.
This parameter is optional and is used only when the database that you want to insert into the empty V8 database was extracted to media. If the database is on media and you do not specify a device class, the device class that is identified in the manifest file is used.
Restriction: You cannot use a device class with a device type of NAS or CENTERA.

MANifest
Specifies the location of the manifest file. Use a fully qualified file name, or place in a local directory. For example:
```
./manifest.txt
```

This parameter is required when the database that you want to insert into the empty V8 database was extracted to media.

CONFiginfo
Specifies the source of the device configuration information that is used by the DSMSERV INSERTDB operation. The default value for this parameter is MANIFEST. Possible values are as follows:

MANifest
Specifies that device configuration information is read from the manifest file. If the manifest file does not have device configuration information, the device configuration file is used instead.

DEVConfig
Specifies that device configuration information is read from the device configuration file.

SESSWait
Specifies the number of minutes that the V8 server waits to be contacted by the original server. The default value is 60 minutes.

Use this parameter only if the data that is inserted into the empty V8 database is transmitted from the source server with a network connection.

PREview
Specifies whether to preview the insertion operation. This parameter is optional. The default value is NO.

Use the PREVIEW=YES parameter to test a database. When you use this parameter, the operation includes all steps of the process, except for the actual insertion of data into the new database. When you preview the insertion operation, you can quickly verify that the source database is readable. You can also identify any data constraint violations that might prevent an upgraded database from being put into production.

DSMSERV LOADFORMAT (Format a database)

Use the DSMSERV LOADFORMAT utility when upgrading from Version 5. The utility formats an empty database in preparation for inserting an extracted database into the empty database.

Syntax

Notes:

1. This parameter applies to AIX® and Linux servers only.
2. This parameter applies only to Windows servers.

Parameters

AIX Linux -u user_name
AIX Linux Specifies a user name to switch to before initializing the server. This parameter is optional.

AIX Linux -i instance_dir
AIX Linux Specifies an instance directory to use. This directory becomes the current working directory of the server. This parameter is optional.

Windows -k key_name
Windows Specifies the name of a Windows registry key that is used to store information about this server. Use this parameter only to install additional servers on the same system. After you install a server by using this parameter, you must always start it with the value of this parameter. The default is SERVER1.

-o options_file
Specifies an options file to use. This parameter is optional.

-noexpire
Specifies that expiration processing is suppressed when the server starts. This parameter is optional.

-quiet
Specifies that messages to the console are suppressed. This parameter is optional.

DBDir
Specifies the relative path names of one or more directories that are used to store database objects. Directory names must be separated by commas but without spaces. You can specify up to 128 directory names. You must specify either the DBDIR or the DBFILE parameter.
Tip: If you specify multiple directories, ensure that the underlying file systems are of equal size to ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching and distribution of the database.

DBFile
Specifies the name of a file that contains the relative path names of one or more directories that are used to store database objects. Each directory name must be on a separate line in the file. You can specify up to 128 directory names. You must

specify either the DBDIR or the DBFILE parameter.

ACTIVELOGSize

Specifies the size of the active log file in megabytes. This parameter is optional. The minimum value is 2048 MB (2 GB); the maximum is 524,288 MB (512 GB). If an odd number is specified, the value is rounded up to the next even number. The default is 16384 MB.

The size of an active log file is based on the value of the ACTIVELOGSIZE option. Guidelines for space requirements are in the following table:

Table 1. How to estimate volume and file space requirements

ACTIVELOGSize option value	Reserve this much free space in the active log directory, in addition to the ACTIVELOGSize space
16 GB - 128 GB	5120 MB
129 GB - 256 GB	10240 MB
257 GB - 512 GB	20480 MB

ACTIVELOGDirectory (Required)

Specifies the directory in which the server writes and stores active log files. There is only one active log location. The name must be a fully qualified directory name. The directory must exist, it must be empty, and it must be accessible by the user ID of the database manager. The maximum number of characters is 175.

ARCHLogdirectory (Required)

Specifies the directory for the archive log files. The name must be a fully qualified directory name. The maximum number of characters is 175.

ARCHFailoverlogdirectory

Specifies the directory to be used as an alternative storage location if the ARCHLOGDIRECTORY directory is full. This parameter is optional. The maximum number of characters is 175.

MIRRorlogdirectory

Specifies the directory in which the server mirrors the active log (those files in the ACTIVELOGDIRECTORY directory). This parameter is optional. The directory must be a fully qualified directory name. The maximum number of characters is 175.

Example: Format a database

AIX Linux

```
dsmserv loadformat dbdir=/tsmdb001 activelogsize=8192
activelogdirectory=/activelog archlogdirectory=/archlog
archfailoverlogdirectory=/archfaillog mirrorlogdirectory=/mirrorlog
```

Windows

```
dsmserv -k server2 loadformat dbdir=d:\tsm\db001 activelogsize=8192
activelogdirectory=e:\tsm\activelog archlogdirectory=f:\tsm\archlog
archfailoverlogdirectory=g:\tsm\archfaillog mirrorlogdirectory=h:\tsm\mirrorlog
```

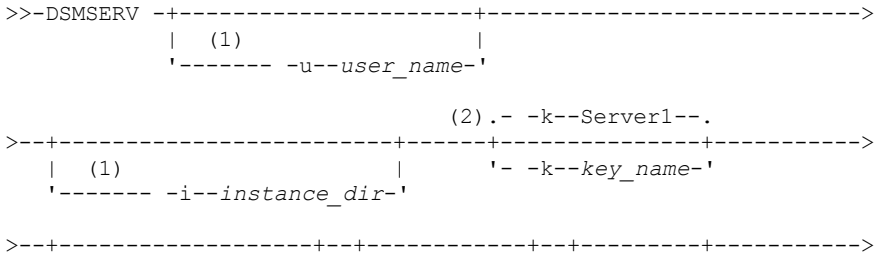
DSMSERV REMOVEDB (Remove a database)

Use the DSMSERV REMOVEDB utility to remove an IBM Spectrum Protect™ server database.

When you run this utility, you delete the server database, active log files, and active log mirror files. However, the archive log files and archive log failover log files are deleted only after you start a point-in-time database restore.

You must halt the IBM Spectrum Protect server before you issue this command.

Syntax



```
   '- -o--options_file-'  '- -noexpire-'  '- -quiet-'

                              .- -force--=--No------.
>--REMOVEDB--database_name--+---------------------+------------><
                              '- -force--=--+-No--+-'
                                            '-Yes-'
```

Notes:

1. This parameter applies to AIX® and Linux servers only.
2. This parameter applies only to Windows servers.

Parameters

AIX Linux -u user_name
AIX Linux Specifies a user name to switch to before initializing the server.
AIX Linux -i instance_dir
AIX Linux Specifies an instance directory to use. This becomes the current working directory of the server.
Windows -k key_name
Windows Specifies the name of the Windows registry key from which to retrieve information about the server. The default is SERVER1.
-o options_file
Specifies an options file to use.
-noexpire
Specifies that expiration processing is suppressed when starting.
-quiet
Specifies that messages to the console are suppressed.
database_name
The database name that was entered during installation. If the database was formatted manually, then this is the database name parameter in the DSMSERV FORMAT or DSMSERV LOADFORMAT utility. This database name can also be found in dsmserv.opt file. This parameter is required.
-force
Specifies whether the database is removed when there are open connections. The default is No. This parameter is optional. The values are as follows:

Yes
Specifies that the database is removed regardless of open connections
No
Specifies that the database is removed only when all connections are closed.

Example: Remove a database

Remove the IBM Spectrum Protect server database TSMDB1 and all of its references.

```
dsmserv removedb TSMDB1
```

Example: Remove a database with force parameter

Remove the IBM Spectrum Protect server database TSMDB1 and all of its references, even if it has open connections:

```
dsmserv removedb TSMDB1 force=yes
```

DSMSERV RESTORE DB (Restore the database)

Use this utility to restore a database by using a database backup.

Restriction: You cannot restore a server database if the release level of the server database backup is different from the release level of the server that is being restored. For example, an error occurs when you restore a Version 7.1.3 database and you are using a Version 8.1 IBM Spectrum Protect™ server.

The restore operation uses database backups created with the BACKUP DB command.

Important: After a point-in-time restore operation, issue the AUDIT VOLUME command to audit all DISK volumes and resolve any inconsistencies between database information and storage pool volumes. Before restoring the database, examine the volume history file to find out about any sequential access storage pool volumes that were deleted or reused since the point in time to which the database was restored.

- DSMSERV RESTORE DB (Restore a database to its most current state)
  Use the DSMSERV RESTORE DB utility to restore a database to its most current state under certain conditions.
- DSMSERV RESTORE DB (Restore a database to a point-in-time)
  Use this command to restore a database to a point in time. A volume history file and a device configuration file must be available.

DSMSERV RESTORE DB (Restore a database to its most current state)

Use the DSMSERV RESTORE DB utility to restore a database to its most current state under certain conditions.

The following conditions must be met:

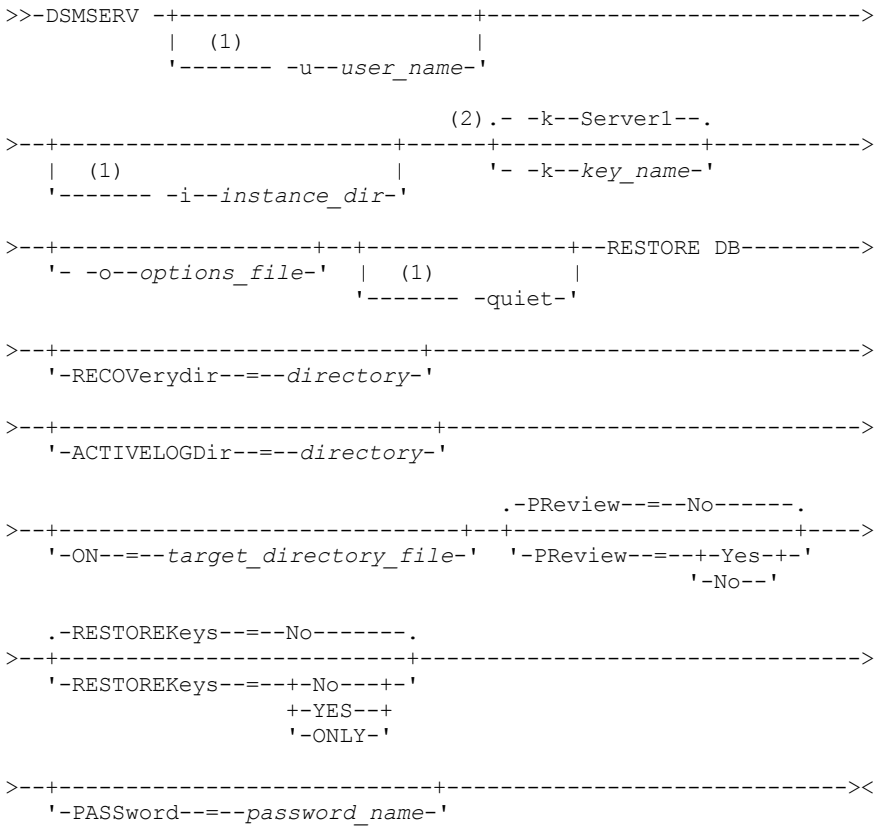
- An intact volume history file is available.
- The recovery logs are available.
- A device configuration file with the applicable device information is available.

Restriction: You cannot restore a server database if the release level of the server database backup is different from the release level of the server that is being restored. For example, an error occurs when you restore a Version 7.1.3 database and you are using a Version 8.1 IBM Spectrum Protect™ server.

IBM Spectrum Protect requests volume mounts to load the most recent backup series and then uses the recovery logs to update the database to its most current state.

Snapshot database backups cannot be used to restore a database to its most current state.

Syntax



Notes:

1. This parameter applies to AIX® and Linux servers only.
2. This parameter applies only to Windows servers.

Parameters

AIX Linux -u user_name

AIX Linux Specifies a user name to switch to before initializing the server.

AIX Linux -i instance_dir

AIX Linux Specifies an instance directory to use. This instance directory becomes the current working directory of the server.

Windows -k key_name

Windows Specifies the name of the Windows registry key from which to retrieve information about the server. The default is SERVER1.

-o options_file

Specifies an options file to use.

AIX Linux -quiet

AIX Linux Specifies that messages to the console are suppressed.

RECOVerydir

Specifies a directory in which to store recovery log information from the database backup media. This directory must have enough space to hold this transaction recovery information and must be an empty directory. If this parameter is not specified, the default is to the directory specified by one of the following parameters in the DSMSERV FORMAT or DSMSERV LOADFORMAT utility:

- ARCHFAILOVERLOGDIRECTORY, if specified
- ARCHLOGDIRECTORY, if ARCHFAILOVERLOGDIRECTORY is not specified

ACTIVELOGDir

Specifies a directory in which to store the log files that are used to track the active database operations. This directory must be specified only if the intent is to switch to an active log directory different from the one that had already been configured.

On

Specifies a file that lists the directories to which the database is restored. Specify each directory on a separate line in the file. For example, the ON parameter specifies the restorelist.txt file, which contains the following list: AIX Linux

```
/tsmdb001
/tsmdb002
/tsmdb003
```

Windows

```
e:\tsm\db001
f:\tsm\db002
g:\tsm\db003
```

If this parameter is not specified, the original directories that were recorded in the database backup are used.
Tip: If you specify multiple directories, ensure that the underlying file systems are of equal size to ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching and distribution of the database.

PReview

Specifies that the volume history files be examined and that the database backup volumes from the volume history file be evaluated.

1. Which set of database backup volumes best meets the most current criteria that are specified for restore processing? The volume history information provides details about the backup series ID, the operation ID (full, incremental 1, incremental 2, and so on), the date of the database backup, and the device class. This information and the parameters that are specified in the DSMSERV RESTORE DB command determine what to use to perform the restore. The volume history file is examined to find the most recent database backup and then to restore the data by using that backup.
2. Is self-describing data available for the selected set of database backup volumes? Cross-check the volume history information for this backup series. The reconciliation reports what the self-describing data contains compared to what was learned from the volume history entries. The cross-check involves mounting one or more of the volumes that are indicated by the volume history. Then, using the self-describing data that was included in the database backup volumes, that information is reconciled against what is in the volume history for the database backup. If the information from the volume history file is inconsistent with the self-describing data, then messages are issued to identify the problem. For example, not all values are specified and available, and no self-describing data is found.

If the volume history information is consistent with self-describing data from the database backup, a message is issued indicating that the database backup can be used for restore processing.

If the volume history information is inconsistent with the self-describing data from the database backup or if the self-describing data for the backup cannot be found, error messages are issued indicating what was checked and what was missing.

If the PREVIEW parameter is not specified or if it is set to NO, and if the volume history and self-describing data from the database backup are consistent, then the restore proceeds.

If the PREVIEW parameter is not specified or if it is set to NO, and the reconciliation and validation fail, the database restore is not performed. Make extra volumes available and referred to from the volume history file, or remove the incomplete backup series or operation so that the IBM Spectrum Protect server selects a different preferred series or operation and continues processing.

If the PREVIEW parameter is set to YES, the process performs only the evaluation of the volume history file and the reconciliation and validation against the selected database backup.

AIX Linux Windows RESTOREKeys

AIX Linux Windows Specifies whether to restore the server master encryption key that is used to encrypt storage pool data when the database is restored. This parameter is optional and only applies if you are using encrypted container storage pools in a cloud environment. If the server master key is protected when the database is restored, the default is YES. If the server master key is not protected when the database is restored, the default is NO. You can specify one of the following values:

No
: Specifies that the server master key is not restored when the database is restored.

Yes
: Specifies that the server master key is restored when the database is restored. You must specify a password with this parameter.

Only
: Specifies that only the server master key is restored. The database is not restored.

AIX Linux Windows PASSword

AIX Linux Windows Specifies the password that is used to protect the database backup. This parameter only applies if you are using encrypted container storage pools in a cloud environment. If you specify a password for database backup, you must specify the same password on the RESTORE DB command to restore the database. You must use a password if you specify the RESTOREKEYS=YES or RESTOREKEYS=ONLY parameter.

Example: Restore the database to its most current state

Restore the database to its most current state by using the already configured active log directory.

```
dsmserv restore db
```

Example: Restore the server master key without restoring the database

Restore the server master key without restoring the database by issuing the following command:

```
dsmserv restore db restorekeys=only
```

DSMSERV RESTORE DB (Restore a database to a point-in-time)

Use this command to restore a database to a point in time. A volume history file and a device configuration file must be available.

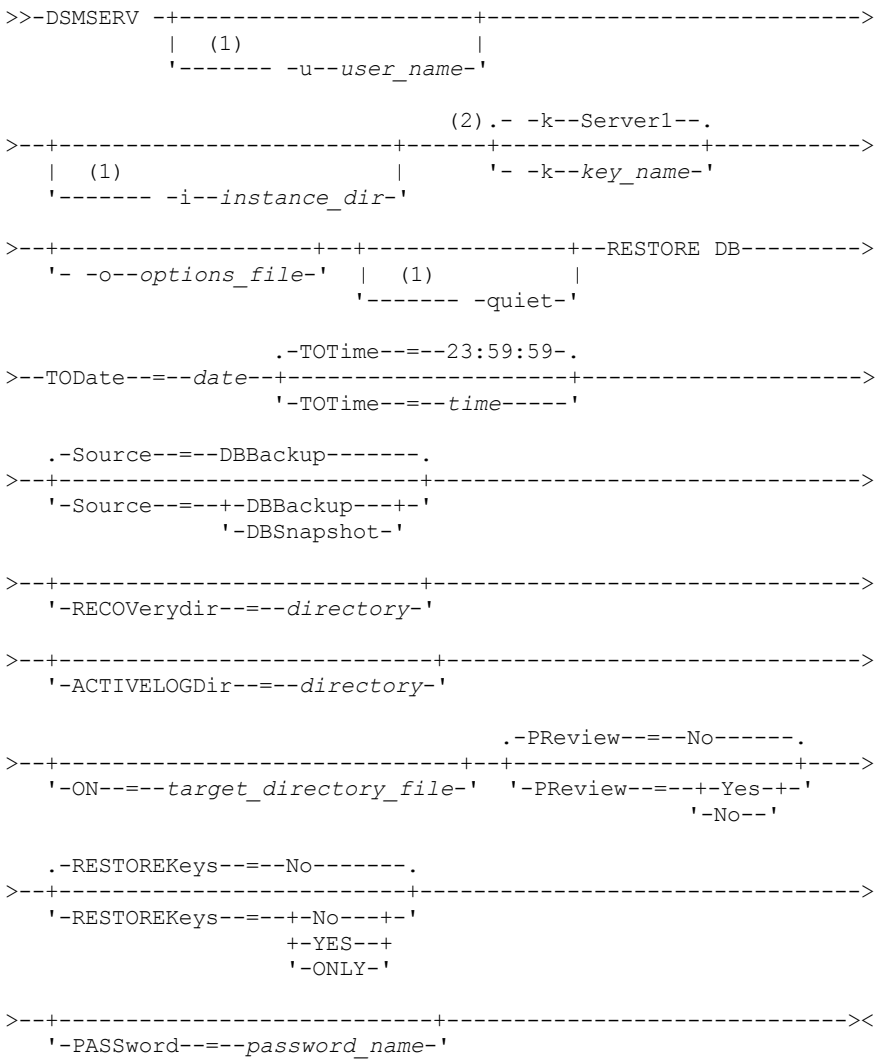
Restriction: You cannot restore a server database if the release level of the server database backup is different from the release level of the server that is being restored. For example, an error occurs when you restore a Version 7.1.3 database and you are using a Version 8.1 IBM Spectrum Protect™ server.

You can use full and incremental database backups, or snapshot database backups can be used to restore a database to a point in time.

Tip: When you restore a V7 or later IBM Spectrum Protect server database to a specific point in time, the preferred method is to issue the DSMSERV REMOVE DB command before you issue the DSMSERV RESTORE DB command. This ensures that the system

is in a clean state. The system drops and uncatalogs the database in the background. When you restore data to a specific point in time, all the required logs and the database image are retrieved from the backup media.

Syntax



Notes:

1. This parameter applies to only AIX® and Linux servers.
2. This parameter applies only to Windows servers.

Parameters

AIX Linux -u user_name

AIX Linux Specifies a user name to switch to before you initialize the server.

AIX Linux -i instance_dir

AIX Linux Specifies an instance directory to use. This becomes the current working directory of the server.

Windows -k key_name

Windows Specifies the name of the Windows registry key from which to retrieve information about the server. The default is SERVER1.

-o options_file

Specifies an options file to use.

AIX Linux -quiet

AIX Linux Specifies that messages to the console are suppressed.

TODate (Required)

Specifies the date to which to restore the database. The following values are possible:

MM/DD/YYYY
: Specifies that you want to restore a database by using the last backup series that was created before this specified date.

TODAY
: Specifies that you want to restore a database by using the most recent backup series that was created before today.

TODAY-numdays or -numdays
: Specifies that you want to restore a database by using the most recent backup series that was created the specified number of days before the current date.

TOTime
: Specifies the time of day to which to restore the database. This parameter is optional. The default is the end of the day (23:59:59). Possible values are:

HH:MM:SS
: Specifies that you want to restore the database by using the last backup series that is created on or before the specified time on the date that is specified on the TODATE parameter.

NOW
: Specifies that you want to restore the database by using a backup series that is created on or before the current time on the date that is specified on the TODATE parameter.

For example, if you issue the DSMSERV RESTORE DB utility at 9:00 with TOTIME=NOW, the database is restored by using the last backup series that is created on or before 9:00 on the date that is specified on the TODATE parameter.

NOW-numhours:numminutes or -numhours:numminutes
: Specifies that you want to restore the database by using a backup series that is created on or before the current time minus a specified number of hours and, optionally, minutes on the date that is specified on the TODATE parameter.

For example, if you issue the DSMSERV RESTORE DB utility at 9:00 with TOTIME=NOW-3:30 or TOTIME+-3:30, the database is restored by using the last backup series that is created on or before 5:30 on the date that is specified on the TODATE parameter.

Source
: Specifies whether the database is restored by using either database full and incremental backup volumes or snapshot database volumes. This parameter is optional. The default value is DBBackup. The following values are possible:

DBBackup
: Specifies that the database is restored as follows:

1. Reads the volume history file to locate the database full and incremental backup volumes that are needed.
2. Requests mounts and loads the data from the database full and incremental backup volumes as required to restore the database volume to the specified time.

DBSnapshot
: Specifies that the database is restored as follows:

1. Reads the volume history file to locate the snapshot database volumes that are needed,
2. Requests mounts and loads data from snapshot database volumes as required to restore the volume to the specified time.

RECOVerydir
: Specifies a directory in which to store recovery log information from the database backup media. This log information is used to establish transaction consistency of the server database as part of the recovery processing. This directory must have enough space to hold this transaction recovery information and must be an empty directory. If this parameter is not specified, the default is the directory that is specified by one of the following parameters in the DSMSERV FORMAT or DSMSERV LOADFORMAT utility:

- ARCHFAILOVERLOGDIRECTORY, if specified
- ARCHLOGDIRECTORY, if ARCHFAILOVERLOGDIRECTORY is not specified

ACTIVELOGDir
: Specifies a directory in which to store the log files that are used to track the active database operations. Specify this directory only if the intent is to switch to an active log directory that is different from the one that was already configured.

On
: Specifies a file that lists the directories to which the database is restored. Specify each directory on a separate line in the file. For example, the ON parameter specifies the restorelist.txt file, which contains the following list: AIX Linux

```
/tsmdb001
/tsmdb002
/tsmdb003
```

Windows

```
e:\tsm\db001
f:\tsm\db002
g:\tsm\db003
```

If this parameter is not specified, the original directories that were recorded in the database backup are used.
Tip: If you specify multiple directories, ensure that the underlying file systems are of equal size to ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching and distribution of the database.

PReview

Specifies that the volume history files be examined and that the database backup volumes from the volume history file be evaluated.

1. Which set of database backup volumes best meets the point-in-time criteria that are specified for restore processing? The volume history information provides details about the backup series ID, the operation ID (full, incremental 1, incremental 2, and so on), the date of the database backup, and the device class. This information and the parameters that are specified in the DSMSERV RESTORE DB command determine what to use to perform the restore. The volume history file is examined to find the best database backup that meets the specified point-in-time criteria and then perform the restore by using that backup.
2. Is self-describing data available for the selected set of database backup volumes? Cross-check the volume history information for this backup series. The reconciliation reports what the self-describing data contains compared to what was learned from the volume history entries. The cross-check involves mounting one or more of the volumes that are indicated by the volume history. Then, using the self-describing data that was included in the database backup volumes, that information is reconciled against what is in the volume history for the database backup. If the information from the volume history file is inconsistent with the self-describing data, then messages are issued to identify the problem. For example, not all values are specified and available, and no self-describing data is found.

If the volume history information is consistent with self-describing data from the database backup, a message is issued indicating that the database backup can be used for restore processing.

If the volume history information is inconsistent with the self-describing data from the database backup or if the self-describing data for the backup cannot be found, error messages are issued indicating what was checked and what was missing.

If the PREVIEW parameter is not specified or if it is set to NO, and if the volume history and self-describing data from the database backup are consistent, then the restore proceeds.

If the PREVIEW parameter is not specified or if it is set to NO, and the reconciliation and validation fail, the database restore is not performed. Make extra volumes available and referred to from the volume history file, or remove the incomplete backup series or operation so that the IBM Spectrum Protect server selects a different preferred series or operation and continues processing.

If the PREVIEW parameter is set to YES, the process performs only the evaluation of the volume history file and the reconciliation and validation against the selected database backup.

AIX Linux Windows RESTOREKeys

AIX Linux Windows Specifies whether to restore the server master encryption key that is used to encrypt storage pool data when the database is restored. This parameter is optional and only applies if you are using encrypted container storage pools in a cloud environment. If the server master key is protected when the database is restored, the default is YES. If the server master key is not protected when the database is restored, the default is NO. You can specify one of the following values:

No
: Specifies that the server master key is not restored when the database is restored.

Yes
: Specifies that the server master key is restored when the database is restored. You must specify a password with this parameter.

Only
: Specifies that only the server master key is restored. The database is not restored.

AIX Linux Windows PASSword

AIX | Linux | Windows Specifies the password that is used to protect the database backup. This parameter only applies if you are using encrypted container storage pools in a cloud environment. If you specify a password for database backup, you must specify the same password on the RESTORE DB command to restore the database. You must use a password if you specify the RESTOREKEYS=YES or RESTOREKEYS=ONLY parameter.

Example: Restore the database to a specific point in time

Restore the database to its state on May 12, 2011 at 2:25 PM.

```
dsmserv restore db todate=05/12/2011 totime=14:45
```

Example: Restore the server master key without restoring the database

Restore the server master key without restoring the database by issuing the following command:

```
dsmserv restore db restorekeys=only
```

Windows

DSMSERV UPDATE (Create registry entries for a server instance)

Use this utility to create registry entries for an IBM Spectrum Protect™ server instance if the entries were accidentally deleted.

Run this utility from the instance directory for the database (where files such as dsmserv.dsk are stored for the server). The utility re-creates the original registry entries for the server.

Syntax

Parameters

-k key_name
: Specifies the name of the Windows registry key in which to store information about the server. The default is Server1.

Example: Re-create registry entries for a server instance

Run the utility to re-create registry entries for the server instance, Server2.

```
"c:\Program Files\Tivoli\TSM\server\bin\dsmserv" -k server2 update
```

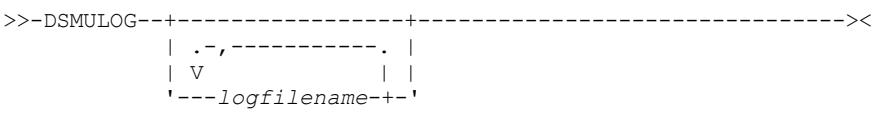
AIX | Linux

DSMULOG (Capture IBM Spectrum Protect server messages to a user log file)

Use this command to capture IBM Spectrum Protect™ server console messages to a user log file. You can specify that IBM Spectrum Protect write messages to more than one user log file.

Important: Do not place the user logs in the /usr or /opt file systems because space constraints in the file system can prevent the server from starting.

Syntax



Parameters

logfilename (Required)

Specifies the name of one or more user log files to which IBM Spectrum Protect writes server console messages. When you specify multiple file names, each file is written to for one day and then the server moves to the next file to capture log messages. When all the files in the list have been written to, the server begins writing to the first file again and any messages contained therein are overwritten.

Example: Capture console messages to a user log file

Use the DSMULOG command to log console messages to a user log file.
Specify the user log files to which you want to log console messages.

```
dsmulog /u/admin/log1 /u/admin/log2 /u/admin/log3
```

IBM Spectrum Protect server device utilities

You can use device utilities for tasks that are related to configuring storage devices for the server.

Device utilities

- AIX tsmdlst (Display information about devices)
- Linux autoconf (Auto configure devices)
- Windows tsmdlst (Display information about devices)

AIX

tsmdlst (Display information about devices)

Use the tsmdlst utility to view device names and other information about medium changer, and tape devices that are controlled by the IBM Spectrum Protect™ device driver.

The tsmdlst utility is part of the IBM Spectrum Protect device driver package that is the same for the server and the storage agent. You must install the IBM Spectrum Protect device driver to run the tsmdlst utility for the storage agent.

After devices are configured, you can run the tsmdlst utility to display device information. The utility saves this information in files that you can retrieve. The files are named lbinfo for medium changer devices, and mtinfo for tape devices. After a device is added or reconfigured, you can update these files by running the tsmdlst utility again.

The tsmdlst utility and the output files it generates are in the devices/bin directory, which is /opt/tivoli/tsm/devices/bin by default. Before you run the tsmdlst utility, make sure that either the IBM Spectrum Protect server is stopped or that all device activities are stopped. If a device is in use by the IBM Spectrum Protect server when the tsmdlst utility runs, a device busy error is issued.

Options

/t

Displays trace messages for the tsmdlst utility.

/?

Displays usage information about tsmdlst and its parameters.

AIX

Example: Display information about all devices

Display information about all devices that were configured by the IBM Spectrum Protect device driver:

```
tsmdlst

TSM Device Name Vendor   Product ID       Firmware World Wide Name         Serial Number

```

Linux

autoconf (Auto configure devices)

Use the autoconf utility to configure devices for use with the IBM Spectrum Protect™ server.

The autoconf utility performs the following tasks:

- Loads the driver to the kernel
- Creates the necessary files for the IBM Spectrum Protect device driver
- Creates device information files for libraries and tape devices

The autoconf utility is included in the device driver package and is installed to the /opt/tivoli/tsm/devices/bin directory.

Options

-a
: Adds read and write permissions to IBM Spectrum Protect device files to allow all users access to the devices. Specify this value to configure devices if the IBM Spectrum Protect server is started by a non-root user.

-g
: Adds read and write permissions to the IBM Spectrum Protect device files to allow anyone in the same group as a root user to use the devices.

-t
: Enables tracing for the autoconf utility.

-?
: Displays information about the autoconf utility and its parameters.

Example: Configure devices by using the autoconf utility

Run autoconf utility to configure IBM Spectrum Protect devices:

```
> /opt/tivoli/tsm/devices/bin/autoconf
```

Linux

Example: For a server that is started by a non-root user ID, configure devices by using the autoconf utility

Run autoconf to configure IBM Spectrum Protect devices. Use the a option because the server is started by a user ID that is not the root user.

```
> /opt/tivoli/tsm/devices/bin/autoconf -a

```

Windows

tsmdlst (Display information about devices)

Use the tsmdlst utility to view device names and other information about medium changer and tape devices on the system.

Options

After devices are configured, you can run the tsmdlst utility to display device information. The utility is in the devices server directory, which is \Program Files\Tivoli\TSM\server by default.

/computer=computer_name
: Specifies the name of the computer for which devices are listed. The default is the local system.

/detail
: Displays details on devices in the list. By default, a summary is shown.

/all
: Displays information about all types of devices. By default, only tape drives and tape libraries are included in the results.

/nogenerictapecheck
: Skips the step for opening detected drives to see whether they are supported for the IBM Spectrum Protect™ GENERICTAPE device type.

/nohbacheck
: Skips the step for host bus adapter (HBA) API detection, which might speed up processing. This option can be useful when debugging is needed.

/trace
: Used for diagnostic purposes. Stores trace output in the tsmdlst_trace.txt file.

/?
: Displays usage information about tsmdlst and its parameters.

/xinquiry
Provides an alternative way to obtain serial number and worldwide name information. This option is used only for devices that are supported by the IBM® tape device driver. The following parameters are specific to the /xinquiry option:

/processAll
Indicates that the process loops until all devices are processed.
/maxRetries=#
Indicates the maximum number of attempts to open each drive. This option requires the /processAll option.
/genpathfile
Use this option to generate a list of devices and serial numbers. The tsmdlst_pathfile.txt file is written with information for the /genmacropathsync and /genmacropathoffline options.
/includelib
If this parameter is specified with the /genpathfile option, the list of devices includes libraries in addition to drives.

/genmacropathsync
Generates a macro to synchronize IBM Spectrum Protect paths for the storage agent based on serial number. A drive must have a serial number that is defined to IBM Spectrum Protect for this option to work.
/genmacropathoffline
Generates a macro to update IBM Spectrum Protect paths for the storage agent to online or offline status based on drive accessibility. A drive is accessible if an operating system open call results in: ERROR_SUCCESS, ERROR_BUSY or ERROR_ACCESS_DENIED. This option works only for devices that are using the IBM device driver. A symbolic name, for example `\\.\tape0`, is required to open a device.
The following options are used only with the /genmacropathsync and /genmacropathoffline options:

/server=servername
Specifies the name of the server that the storage agent is using.
/stagent=stagentname
Specifies the name of the storage agent.
/tcps=address
Specifies the IBM Spectrum Protect server address.
/tcpp=port
Specifies the IBM Spectrum Protect server port. The default is 1500.
/id=id
Specifies the IBM Spectrum Protect administrative ID.
/pass=password
Specifies the IBM Spectrum Protect administrative password.
/devicetype=drivetype
Specifies the device type of the drive, for example, `LTO`. This option is case-sensitive and optional.
/libraryname=libname
Filters on the library name of the drive, for example `LTO3584`. This option is case-sensitive and optional.
/execmacropathsync
Issues the path synchronize macro to the IBM Spectrum Protect server.
/execmacropathoffline
Issues the path offline macro to the IBM Spectrum Protect server.
/addpaths
Adds define and update path statements. This option is used with the /genmacropathsync option.
/verbose
Lists both drive and path information returned from the IBM Spectrum Protect server and contents of the path file.
/encodednames
If a path is set to `online=no`, the device name encodes time stamp, error, and device as the updated device name.

Example: Display information about devices

Display information about tape devices and tape libraries for a local system, WANTON, by running the tsmdlst utility:

```
tsmdlst
```

The device name that is displayed is the alias name that can be used in the DEFINE PATH command and the UPDATE PATH command. The alias name is not the actual device name.

```
Computer Name:      WANTON
OS Version:         6.2
OS Build #:         9200
TSM Device Driver:  TSMScsi - Not Running
```

```
4 HBAs were detected.

Server scripts and macros for automation

You can automate common administrative tasks by creating IBM Spectrum Protect™ server scripts or administrative client macros. Server scripts are stored in the server database and can be scheduled to run with an administrative schedule command. Administrative client macros are stored as files on the administrative client. Macros cannot be distributed across servers and cannot be scheduled on the server.

- Server scripts
  You can automate common administrative tasks with scripts that are stored in the server database. You can schedule a script for processing by using the administrative command scheduler on the server.
- Administrative client macros
  A macro is a file that contains one or more administrative client commands. You can run a macro from the administrative client only in batch or interactive modes. Macros are stored as a file on the administrative client. Macros are not distributed across servers and cannot be scheduled on the server.

Server scripts

You can automate common administrative tasks with scripts that are stored in the server database. You can schedule a script for processing by using the administrative command scheduler on the server.

IBM Spectrum Protect™ scripts have the following capabilities and statements:

- Command parameter substitution.
- SELECT commands that you specify when the script is processed.
- Command execution control, such as PARALLEL and SERIAL processing options.
- Conditional logic flow statements. These logic flow statements include the following statements:
  - The IF clause; this clause determines how processing proceeds based on the current return code value.
  - The EXIT statement; this statement ends script processing.

    - The GOTO and LABEL statement. This statement directs logic flow to continue processing with the line that starts with the label specified.
- Comment lines.

Sample scripts are provided in the scripts.smp file. The sample scripts have an example order of execution for scheduling administrative commands.

If one of the specified commands in the script does not process successfully, the remaining commands are not processed.

- Defining a server script
  You can define a server script line-by-line, create a file that contains the command lines, or copy an existing script.
- Updating a script
  You can update a script to change a command line or to add a command line to a script.
- Querying a server script to create another server script
  You can create more server scripts by querying a script and specifying the FORMAT=RAW and OUTPUTFILE parameters. You can use the resulting output as input into another script without having to create a script line by line.
- Running a server script
  To process a script, use the RUN command. You can run a script that contains substitution variables by specifying them along with the RUN command.

Defining a server script

You can define a server script line-by-line, create a file that contains the command lines, or copy an existing script.

About this task

Restriction: You cannot redirect the output of a command within a server script. Instead, run the script and then specify command redirection. For example, to direct the output of script1 to the c:\temp\test.out directory, run the script and specify command redirection as in the following example:

```
run script1 > c:\temp\test.out
```

Procedure

1. Define a script with the DEFINE SCRIPT command. You can initially define the first line of the script with this command. For example:

   ```
   define script qaixc "select node_name from nodes where platform='aix'"
   desc='Display AIX clients'
   ```

   This example defines the script as QAIXC. When you run the script, all AIX® clients are displayed.
2. Define more lines in the script with the UPDATE SCRIPT command. For example, you want to add a QUERY SESSION command, enter:

   ```
   update script qaixc "query session *"
   ```

3. Optional: You can specify a WAIT parameter with the DEFINE CLIENTACTION command. By using this parameter, you can specify that the client action must complete before the next step in the command script or macro is processed.
4. Optional: To help you determine where a problem is within a command in a script, use the ISSUE MESSAGE command.

- Running commands in parallel or serially
  You have the options of running commands in a script serially, in parallel, or serially and in parallel. You can do so by using the SERIAL or PARALLEL script commands in the COMMAND_LINE parameter of DEFINE and UPDATE SCRIPT. Therefore, it is possible to run multiple commands in parallel and wait for them to complete before the next command is run.
- Continuing commands across multiple command lines
  You can continue long commands across multiple command lines by specifying the continuation character (-) as the last character for a command that is continued.
- Including substitution variables in a script
  You can include substitution variables in a script. Substitution variables are specified with a $ character followed by a number that represents the position of the parameter when the script is processed.
- Including logic flow statements in a script
  You can use conditional logic flow statements that are based on return codes that are issued from previous command processing. By using these logic statements, you can process your scripts according to the outcome of certain commands. You can use IF, EXIT, or GOTO (label) statements.

- Using SELECT commands in a script
  An IBM Spectrum Protect™ script is one or more commands that are stored as an object in the database. You can define a script that contains one or more SELECT commands.

Running commands in parallel or serially

You have the options of running commands in a script serially, in parallel, or serially and in parallel. You can do so by using the SERIAL or PARALLEL script commands in the COMMAND_LINE parameter of DEFINE and UPDATE SCRIPT. Therefore, it is possible to run multiple commands in parallel and wait for them to complete before the next command is run.

About this task

Running commands serially in a script ensures that any preceding commands are complete before proceeding and ensures that any following commands are run serially. When a script starts, all commands are run serially until a PARALLEL command is encountered. Multiple commands that are running in parallel and accessing common resources, such as tape drives, can run serially.

Script return codes remain the same before and after a PARALLEL command is run. When a SERIAL command is encountered, the script return code is set to the maximum return code from any previous commands that were run in parallel.

When you use server commands that support the WAIT parameter after a PARALLEL command, the behavior is as follows:

- If you specify (or use the default) WAIT=NO, a script does not wait for the completion of the command when a subsequent SERIAL command is encountered. The return code from that command reflects processing only up to the point that the command starts a background process. The final return code from the command is not available to your script.
- If you specify WAIT=YES, your script waits for the completion of the command when a subsequent SERIAL command is encountered. The return code from that command reflects processing for the entire command.

In most cases, you can use WAIT=YES on commands that are run in parallel.

Restriction: If the command starts a background process that does not have the WAIT parameter, the command is considered to be complete after the background thread is started. Therefore, the command can run only in parallel.

The following example illustrates how the PARALLEL command is used to back up, migrate, and reclaim storage pools.

```
/*run multiple commands in parallel and wait for
them to complete before proceeding*/
PARALLEL
/*back up four storage pools simultaneously*/
BACKUP STGPOOL PRIMPOOL1 COPYPOOL1 WAIT=YES
BACKUP STGPOOL PRIMPOOL2 COPYPOOL2 WAIT=YES
BACKUP STGPOOL PRIMPOOL3 COPYPOOL3 WAIT=YES
BACKUP STGPOOL PRIMPOOL4 COPYPOOL4 WAIT=YES
/*wait for all previous commands to finish*/
SERIAL
/*after the backups complete, migrate stgpools
simultaneously*/
PARALLEL
MIGRATE STGPOOL PRIMPOOL1 DURATION=90 WAIT=YES
MIGRATE STGPOOL PRIMPOOL2 DURATION=90 WAIT=YES
MIGRATE STGPOOL PRIMPOOL3 DURATION=90 WAIT=YES
MIGRATE STGPOOL PRIMPOOL4 DURATION=90 WAIT=YES
/*wait for all previous commands to finish*/
SERIAL
/*after migration completes, relcaim storage
pools simultaneously*/
PARALLEL
RECLAIM STGPOOL PRIMPOOL1 DURATION=120 WAIT=YES
RECLAIM STGPOOL PRIMPOOL2 DURATION=120 WAIT=YES
RECLAIM STGPOOL PRIMPOOL3 DURATION=120 WAIT=YES
RECLAIM STGPOOL PRIMPOOL4 DURATION=120 WAIT=YES
```

DEFINE SCRIPT (Define a server script)
UPDATE SCRIPT (Update a server script)

Continuing commands across multiple command lines

You can continue long commands across multiple command lines by specifying the continuation character (-) as the last character for a command that is continued.

About this task

The following example continues an SQL statement across multiple command lines:

```
/*-----------------------------*/
/* Sample continuation example */
SELECT-
* FROM-
NODE WHERE-
PLATFORM='win32'
```

When this command is processed, it runs the following command:

```
select * from nodes where platform='win32'
```

Including substitution variables in a script

You can include substitution variables in a script. Substitution variables are specified with a $ character followed by a number that represents the position of the parameter when the script is processed.

About this task

The following example SQLSAMPLE script specifies substitution variables $1 and $2:

```
/*---------------------------------------------*/
/* Sample substitution example */
/* --------------------------------------------*/
SELECT-
$1 FROM-
NODES WHERE-
PLATFORM='$2'
```

When you run the script you must specify two values, one for $1 and one for $2. For example:

```
run sqlsample node_name aix
```

The command that is processed when the SQLSAMPLE script is run is the following command:

```
select node_name from nodes where platform='aix'
```

Including logic flow statements in a script

You can use conditional logic flow statements that are based on return codes that are issued from previous command processing. By using these logic statements, you can process your scripts according to the outcome of certain commands. You can use IF, EXIT, or GOTO (label) statements.

As each command is processed in a script, the return code is saved for possible evaluation before the next command is processed. The return code can be one of three severities: OK, WARNING, or ERROR. See Return codes for use in scripts for a list of valid return codes and severity levels.

- Specifying the IF clause
  You can use the IF clause at the beginning of a command line to determine how processing of the script proceeds based on the current return code value. In the IF clause, you specify a return code symbolic value or severity.
- Specifying the EXIT statement
  Use the EXIT statement to end script processing.
- Specifying the GOTO statement
  The GOTO statement is used with a label statement. The label statement is the target of the GOTO statement. The GOTO statement directs script processing to the line that contains the label statement to resume processing from that point.

Specifying the IF clause

You can use the IF clause at the beginning of a command line to determine how processing of the script proceeds based on the current return code value. In the IF clause, you specify a return code symbolic value or severity.

About this task

The server initially sets the return code at the beginning of the script to RC_OK. The return code is updated by each processed command. If the current return code from the processed command is equal to any of the return codes or severities in the IF clause, the remainder of the line is processed. If the current return code is not equal to one of the listed values, the line is skipped.

The following script example backs up the BACKUPPOOL storage pool only if there are no sessions currently accessing the server. The backup proceeds only if a return code of RC_NOTFOUND is received:

```
/* Backup storage pools if clients are not accessing the server */
select * from sessions
/* There are no sessions if rc_notfound is received */
if(rc_notfound) backup stg backuppool copypool
```

The following script example backs up the BACKUPPOOL storage pool if a return code with a severity of warning is encountered:

```
/* Backup storage pools if clients are not accessing the server */
select * from sessions
/* There are no sessions if rc_notfound is received */
if(warning) backup stg backuppool copypool
```

Specifying the EXIT statement

Use the EXIT statement to end script processing.

About this task

The following example uses the IF clause together with RC_OK to determine if clients are accessing the server. If an RC_OK return code is received, it indicates that client sessions are accessing the server. The script proceeds with the exit statement, and the backup does not start.

```
/* Back up storage pools if clients are not accessing the server */
select * from sessions
/* There are sessions if rc_ok is received */
if(rc_ok) exit
backup stg backuppool copypool
```

Specifying the GOTO statement

The GOTO statement is used with a label statement. The label statement is the target of the GOTO statement. The GOTO statement directs script processing to the line that contains the label statement to resume processing from that point.

About this task

The label statement always has a colon (:) after it and can be blank after the colon. The following example uses the GOTO statement to back up the storage pool only if there are no sessions currently accessing the server. In this example, the return code of RC_OK indicates that clients are accessing the server. The GOTO statement directs processing to the `done:` label, which contains the EXIT statement that ends the script processing:

```
/* Back up storage pools if clients are not accessing the server */
select * from sessions
/* There are sessions if rc_ok is received */
if(rc_ok) goto done
backup stg backuppool copypool
done:exit
```

Using SELECT commands in a script

An IBM Spectrum Protect™ script is one or more commands that are stored as an object in the database. You can define a script that contains one or more SELECT commands.

About this task

A script can be run from an administrative client or the server console. You can also include it in an administrative command schedule to run automatically. See Server scripts for details.

IBM Spectrum Protect is shipped with a file that contains a number of sample scripts. The file, scripts.smp, is in the server directory. To create and store the scripts as objects in your server's database, issue the DSMSERV RUNFILE command during installation:

```
> dsmserv runfile scripts.smp
```

You can also run the file as a macro from an administrative command line client:

```
macro scripts.smp
```

The sample scripts file contains commands. These commands first delete any scripts with the same names as those to be defined, then define the scripts. The majority of the samples create SELECT commands, but others do such things as back up storage pools. You can also copy and change the sample scripts file to create your own scripts.

Here are a few examples from the sample scripts file:

```
def script q_inactive_days '/* ------------------------------------------*/'
upd script q_inactive_days '/* Script Name:  Q_INACTIVE                   */'
upd script q_inactive_days '/* Description: Display nodes that have not    */'
upd script q_inactive_days '/*    accessed the backup server for a         */'
upd script q_inactive_days '/*    specified number of days                 */'
upd script q_inactive_days '/* Parameter 1: days                          */'
upd script q_inactive_days '/* Example:     run q_inactive_days 5          */'
upd script q_inactive_days '/* ------------------------------------------*/'
upd script q_inactive_days "select node_name,lastacc_time from nodes where -"
upd script q_inactive_days " cast((current_timestamp-lastacc_time)days as -"
upd script q_inactive_days " decimal) >= $1 "

/* Display messages in the activity log of severity X or Y               */

def script q_msg_sev desc='Show msgs in the activity log of severity X or Y'
upd script q_msg_sev '/* ------------------------------------------------*/'
upd script q_msg_sev '/* Script Name:  Q_MSG_SEV                         */'
upd script q_msg_sev '/* Description: Display messages in the            */'
upd script q_msg_sev '/*              activity log that have either      */'
upd script q_msg_sev '/*              of two specified severities.       */'
upd script q_msg_sev '/* Parameter 1: severity 1                         */'
upd script q_msg_sev '/* Parameter 2: severity 2                         */'
upd script q_msg_sev '/*  where severity is I, W, E, S, or D             */'
upd script q_msg_sev '/* Example:  run q_msg_sev S E                     */'
upd script q_msg_sev '/* ------------------------------------------------*/'
upd script q_msg_sev "select date_time,msgno,message from actlog -"
upd script q_msg_sev "  where severity=upper('$1') or severity=upper('$2')"
```

Updating a script

You can update a script to change a command line or to add a command line to a script.

- Appending a new command
  To append a command line to an existing script issue the UPDATE SCRIPT command without the LINE= parameter. The appended command line is assigned a line number of five greater than the last command line number in the command line sequence. For example, if your script ends with line 010, the appended command line is assigned a line number of 015.
- Replacing an existing command
  You can change an existing command line by specifying the LINE= parameter.
- Adding a command and line number
  You can change an existing script by adding new lines.
- Deleting a command from a server script
  You can delete an individual command line from a script. When you specify a line number, only the corresponding command line is deleted from the script.

Appending a new command

To append a command line to an existing script issue the UPDATE SCRIPT command without the LINE= parameter. The appended command line is assigned a line number of five greater than the last command line number in the command line sequence. For example, if your script ends with line 010, the appended command line is assigned a line number of 015.

About this task

The following is an example of the QSTATUS script. The script has lines 001, 005, and 010 as follows:

```
001 /* This is the QSTATUS script */
005 QUERY STATUS
010 QUERY PROCESS
```

To append the QUERY SESSION command at the end of the script, issue the following command:

```
update script qstatus "query session"
```

The QUERY SESSION command is assigned a command line number of 015 and the updated script is as follows:

```
001 /* This is the QSTATUS script */
005 QUERY STATUS
010 QUERY PROCESS
015 QUERY SESSION
```

Replacing an existing command

You can change an existing command line by specifying the LINE= parameter.

About this task

Line number 010 in the QSTATUS script contains a QUERY PROCESS command. To replace the QUERY PROCESS command with the QUERY STGPOOL command, specify the LINE= parameter as follows:

```
update script qstatus "query stgpool" line=10
```

The QSTATUS script is updated to contain the following lines:

```
001 /* This is the QSTATUS script */
005 QUERY STATUS
010 QUERY STGPOOL
015 QUERY SESSION
```

Adding a command and line number

You can change an existing script by adding new lines.

About this task

To add the QUERY NODE command as the new line 007 in the QSTATUS script, issue the following command:

```
update script qstatus "query node" line=7
```

The QSTATUS script is updated to contain the following lines:

```
001 /* This is the QSTATUS script */
005 QUERY STATUS
007 QUERY NODE
010 QUERY STGPOOL
015 QUERY SESSION
```

Deleting a command from a server script

You can delete an individual command line from a script. When you specify a line number, only the corresponding command line is deleted from the script.

About this task

For example, to delete the 007 command line from the QSTATUS script, issue the following command:

```
delete script qstatus line=7
```

Querying a server script to create another server script

You can create more server scripts by querying a script and specifying the FORMAT=RAW and OUTPUTFILE parameters. You can use the resulting output as input into another script without having to create a script line by line.

About this task

The following example shows how to query the SRTL2 script and direct the output to newscript.script:

```
query script srtl2 format=raw outputfile=newscript.script
```

You can then edit the newscript.script file with an editor that is available to you on your system. To create a new script by using the edited output from your query, issue:

```
define script srtnew file=newscript.script
```

Running a server script

To process a script, use the RUN command. You can run a script that contains substitution variables by specifying them along with the RUN command.

About this task

To stop a script that is running, an administrator must halt the server. You cannot cancel a script after it starts by using an IBM Spectrum Protect™ command.

Procedure

- Preview the commands in a script to evaluate the script before you run it. To preview the script without running the commands, enter the RUN command with the PREVIEW=YES parameter. If the script contains substitution variables, the commands are displayed with the substituted variables.
- Run a script that has no variables by entering the following command: `run qaixc` where `qaixc` is the name of the script.
- Run a script that contains substitution variables by specifying the variable values with the command. Contents of the script:

  ```
  /*---------------------------------------------*/
  /* Sample continuation and substitution example */
  /* --------------------------------------------*/
  SELECT-
  $1 FROM-
  NODES WHERE-
  PLATFORM='$2'
  ```

  To run this script, enter the following command:

  ```
  run qaixc node_name aix
  ```

  Where `node_name` is the value for the $1 variable and `aix` is the value for the $2 variable.

Related reference:
RUN (Run a server script)

Administrative client macros

A macro is a file that contains one or more administrative client commands. You can run a macro from the administrative client only in batch or interactive modes. Macros are stored as a file on the administrative client. Macros are not distributed across servers and cannot be scheduled on the server.

Macros can include the following elements:

- Administrative server commands

- Comments
- Continuation characters
- Variables

The name for a macro must follow the naming conventions of the administrative client that is running on your operating system.

In a macro that contains several commands, use the COMMIT and ROLLBACK commands to control command processing within the macro.

You can include the MACRO command within a macro file to call other macros up to 10 levels deep. A macro that is called from the administrative client command line is called a high-level macro. Any macros that are called from within the high-level macro are called *nested* macros.

- Writing commands in a macro
  Add administrative commands to a macro. The administrative client ignores any blank lines included in your macro. However, a blank line ends a command that is continued (with a continuation character).
- Writing comments in a macro
  Add comments to your macro file to describe the purpose or the commands in it.
- Including continuation characters in a macro
  You can use continuation characters in a macro file when you want to run a command that is longer than your screen or window width.
- Including substitution variables in a macro
  You can use substitution variables in a macro so that when you run the macro, you can provide values for items such as command parameters. When you use substitution variables, you can use a macro again and again, whenever you need to complete the same task for different objects or with different parameter values.
- Running a macro
  Use the MACRO command when you want to run a macro. You can enter the MACRO command in batch or interactive mode.
- Command processing in a macro
  When you issue a MACRO command, the server processes all commands in the macro file in order, including commands that are contained in any nested macros. The server commits all commands in a macro after successfully completing processing for the highest-level macro.

Writing commands in a macro

Add administrative commands to a macro. The administrative client ignores any blank lines included in your macro. However, a blank line ends a command that is continued (with a continuation character).

About this task

The following is an example of a macro that is called REG.MAC that registers and grants authority to a new administrator:

```
register admin pease mypasswd -
  contact='david pease, x1234'
grant authority pease -
  classes=policy,storage -
  domains=domain1,domain2 -
  stgpools=stgpool1,stgpool2
```

This example uses continuation characters in the macro file. For more information about continuation characters, see Including continuation characters in a macro.

After you create a macro file, you can update the information that it contains and use it again. You can also copy the macro file. After you have a copy of the macro, you can modify and run the copy.

Writing comments in a macro

Add comments to your macro file to describe the purpose or the commands in it.

About this task

To write a comment:

- Write a slash and an asterisk (/*) to indicate the beginning of the comment.

- Write the comment.
- Write an asterisk and a slash (*/) to indicate the end of the comment.

You can put a comment on a line by itself, or you can put it on a line that contains a command or part of a command.

For example, to use a comment to identify the purpose of a macro, write the following line:

```
/* auth.mac-register new nodes  */
```

Or you can write a comment to explain something about a command or part of a command:

```
domain=domain1            /*assign node to domain1  */
```

Comments cannot be nested and cannot span lines. Every line of a comment must contain the comment delimiters.

Including continuation characters in a macro

You can use continuation characters in a macro file when you want to run a command that is longer than your screen or window width.

About this task

Without continuation characters, you can enter up to 256 characters. With continuation characters, you can enter up to 1500 characters. In the MACRO command, values of substitution variables are included in the count of characters.

To use a continuation character, enter a dash or a backslash at the end of the line that you want to continue. With continuation characters, you can continue the following lines of a macro.

Examples

- Continue a command, for example:

  ```
  register admin pease mypasswd -
  contact="david, ext1234"
  ```

- Continue a list of values by entering a dash or a backslash, with no preceding blank spaces, after the last comma of the list that you enter on the first line. Then, enter the remaining items in the list on the next line with no preceding blank spaces. In the following example a list of storage pool names continues across lines:

  ```
  stgpools=stg1,stg2,stg3,-
  stg4,stg5,stg6
  ```

- Continue a string of values that are enclosed in quotation marks by entering the first part of the string in quotation marks, followed by a dash or a backslash at the end of the line. Then, enter the remainder of the string on the next line. Enclose the remainder of the string in the same type of quotation marks. The following example shows a string that continues across lines:

  ```
  contact="david pease, bldg. 100, room 2b, san jose,"-
  "ext. 1234, alternate contact-norm pass,ext 2345"
  ```

  The two strings are concatenated with no intervening blanks. You must use only this method to continue a quoted string of values across more than one line.

Including substitution variables in a macro

You can use substitution variables in a macro so that when you run the macro, you can provide values for items such as command parameters. When you use substitution variables, you can use a macro again and again, whenever you need to complete the same task for different objects or with different parameter values.

About this task

A substitution variable consists of a percent sign (%), followed by a unique number that identifies the substitution variable. When you run the file with the MACRO command, you must specify values for the variables.

Restrictions:

- If your system uses the percent sign as a wildcard character, the administrative client interprets a pattern-matching expression in a macro where the percent sign is immediately followed by a digit as a substitution variable.
- You cannot enclose a substitution variable in quotation marks. However, a value that you supply as a substitution for the variable can be a quoted string.

Example

Create a macro that is named AUTH.MAC to register new nodes. The macro has four substitution variables for parameters in the command:

```
/* register new nodes */
register node %1 %2 -      /*  userid password                */
  contact=%3 -             /* 'name, phone number'            */
  domain=%4                /*  policy domain                  */
```

When you run the macro, you must enter the values that you want to pass to the server to process the command.

For example, to use the macro to register the node that is named DAVID with a password of DAVIDPW, include a name and phone number as contact information, and assign it to the DOMAIN1 policy domain, enter the following command:

```
macro auth.mac david davidpw "david pease, x1234" domain1
```

Running a macro

Use the MACRO command when you want to run a macro. You can enter the MACRO command in batch or interactive mode.

About this task

If the macro does not contain substitution variables, run the macro by entering the MACRO command with the name of the macro file. For example:

```
macro reg.mac
```

If the macro contains substitution variables, include the values that you want to supply after the name of the macro. Each value is delimited by a space. For example:

```
macro auth.mac pease mypasswd "david pease, x1234" domain1
```

If you enter fewer values than there are substitution variables in the macro, the administrative client replaces the remaining variables with null strings.

If you want to omit one or more values between values, enter a null string ("") for each omitted value. For example, if you omit the contact information in the previous example, you must enter:

```
macro auth.mac pease mypasswd "" domain1
```

MACRO (Invoke a macro)

Command processing in a macro

When you issue a MACRO command, the server processes all commands in the macro file in order, including commands that are contained in any nested macros. The server commits all commands in a macro after successfully completing processing for the highest-level macro.

If an error occurs in any command in the macro or in any nested macro, the server stops processing and rolls back any changes that were caused by all previous commands.

If you specify the ITEMCOMMIT option when you enter the DSMADMC command, the server commits each command in a script or a macro individually after successfully completing processing for each command. If an error occurs, the server continues processing and rolls back only the changes caused by the failed command.

You can control precisely when commands are committed with the COMMIT command. If an error occurs while the server is processing the commands in a macro, the server stops processing the macro and rolls back any uncommitted changes. Uncommitted changes are commands that were processed since the last COMMIT command. Make sure that your administrative

client session is not running with the ITEMCOMMIT option if you want to control command processing with the COMMIT command.

You can test a macro before you implement it by using the ROLLBACK command. You can enter the commands (except the COMMIT command) you want to issue in the macro, and enter ROLLBACK as the last command. Then, you can run the macro to verify that all the commands process successfully. Any changes to the database caused by the commands are rolled back by the ROLLBACK command. Remember to remove the ROLLBACK command before you make the macro available for actual use. Also, make sure that your administrative client session is not running with the ITEMCOMMIT option if you want to control command processing with the ROLLBACK command.

Tip: Commands that start background processes cannot be rolled back.
If you have a series of commands that process successfully from the command line, but are unsuccessful when issued within a macro, there are probably dependencies between commands. It is possible that a command issued within a macro cannot be processed successfully until a previous command that is issued within the same macro is committed. Either of the following actions allows successful processing of these commands within a macro:

- Insert a COMMIT command before the command dependent on a previous command. For example, if COMMAND C is dependent upon COMMAND B, you would insert a COMMIT command before COMMAND C.

```
command a
command b
commit
command c/
```

- Start the administrative client session by using the ITEMCOMMIT option. This option causes each command within a macro to be committed before the next command is processed.

COMMIT (Control committing of commands in a macro)
ROLLBACK (Rollback uncommitted changes in a macro)

Return codes for use in IBM Spectrum Protect scripts

You can write IBM Spectrum Protect™ scripts that use return codes to determine how script processing proceeds. The return codes can be one of three severities: OK, WARNING, ERROR.

IBM Spectrum Protect scripts use the symbolic return code for processing, not the numeric value. The administrative client displays the numeric values when a command is run. The return codes are shown in the following table.

Table 1. Return codes

Return code	Severity	Numeric value	Description
RC_OK	OK	0	The command completed successfully.
RC_UNKNOWN	ERROR	2	The command is not found; not a known command.
RC_SYNTAX	ERROR	3	The command is valid, but one or more parameters were not specified correctly.
RC_ERROR	ERROR	4	An internal server error prevented the command from successfully completing.
RC_NOMEMORY	ERROR	5	The command could not be completed because of insufficient memory on the server.
RC_NOLOG	ERROR	6	The command could not be completed because of insufficient recovery log space on the server.
RC_NODB	ERROR	7	The command could not be completed because of insufficient database space on the server.
RC_NOSTORAGE	ERROR	8	The command could not be completed because of insufficient storage space on the server.
RC_NOAUTH	ERROR	9	The command failed because the administrator is not authorized to issue the command.

Return code	Severity	Numeric value	Description
RC_EXISTS	ERROR	10	The command failed because the specified object already exists on the server.
RC_NOTFOUND	WARNING	11	Returned by a QUERY or SQL SELECT command when no objects are found that match specifications.
RC_INUSE	ERROR	12	The command failed because the object to be operated upon was in use.
RC_ISREFERENCED	ERROR	13	The command failed because the object to be operated upon is still referenced by some other server construct.
RC_NOTAVAILABLE	ERROR	14	The command failed because the object to be operated upon is not available.
RC_IOERROR	ERROR	15	The command failed because an input/output (I/O) error was encountered on the server.
RC_NOTXN	ERROR	16	The command failed because a database transaction failed on the server.
RC_NOLOCK	ERROR	17	The command failed because a lock conflict was encountered in the server database.
RC_NOTHREAD	ERROR	19	The command could not be completed because of insufficient memory on the server.
RC_LICENSE	ERROR	20	The command failed because the server is not in compliance with licensing.
RC_INVDEST	ERROR	21	The command failed because a destination value was invalid.
RC_IFILEOPEN	ERROR	22	The command failed because an input file that was needed could not be opened.
RC_OFILEOPEN	ERROR	23	The command failed because it could not open a required output file.
RC_OFILEWRITE	ERROR	24	The command failed because it could not successfully write to a required output file.
RC_INVADMIN	ERROR	25	The command failed because the administrator was not defined.
RC_SQLERROR	ERROR	26	An SQL error was encountered during a SELECT statement query.
RC_INVALIDUSE	ERROR	27	The command failed because the command is used in an invalid manner.
RC_NOTABLE	ERROR	28	The command failed because of an unknown SQL table name.
RC_FS_NOTCAP	ERROR	29	The command failed because of incompatible file space name types.
RC_INVALIDADDR	ERROR	30	The command failed because of an incorrect high-level address or low-level address.
RC_INVALIDCG	ERROR	31	The command failed because the management class does not have an archive copy group.
RC_OVERSIZE_VOL	ERROR	32	The command failed because the volume size exceeds the maximum allowed.

Return code	Severity	Numeric value	Description
RC_DEFVOL_FAIL	ERROR	33	The command failed because volumes cannot be defined in RECLAMATIONTYPE=SNAPLOCK storage pools.
RC_DELVOL_FAIL	ERROR	34	The command failed because volumes cannot be deleted in RECLAMATIONTYPE=SNAPLOCK storage pools.
RC_CANCELED	WARNING	35	The command is canceled.
RC_INVPOLICY	ERROR	36	The command failed because there is an invalid definition in the policy domain.
RC_INVALIDPW	ERROR	37	The command failed because of an invalid password.
RC_UNSUPP_PARM	WARNING	38	The command failed because the command or the parameter is not supported.

Server documentation in PDF files

Prebuilt PDF files for IBM Spectrum Protect™ documentation are available for you to download.

Tip: Beginning with V7.1.3, the *Administrator's User Guide* is obsoleted. Use the solution guides to implement and manage a single-site disk solution and a multisite disk solution. Procedures for completing system administration tasks are available in the following topics:

- Configuring and managing the storage environment
- IBM Spectrum Protect data protection solutions

To complete the following tasks, see the PDF files in the following links.

Task	Components	Links
Learning about product concepts and solutions	• Server • Operations Center	Introduction to Data Protection Solutions
Deploying a best practice solution	• Server • Operations Center	• Single-Site Disk Solution Guide • Multisite Disk Solution Guide • Tape Solution Guide
Installing components	• Server • Operations Center	• AIX® • Linux • Windows

IBM Spectrum Protect backup-archive clients

To save copies of files and directories on workstations and file servers, use the IBM Spectrum Protect™ backup-archive client to store the data to the IBM Spectrum Protect server. You can recover those copies if the originals are ever damaged or lost. Depending on your reasons for saving data, you can either back up or archive the data.

- What's new for IBM Spectrum Protect backup-archive clients
  Read about new and changed features. Review the release notes before installing the product.
- Protection for workstations and file servers
  IBM Spectrum Protect is a client/server licensed product that provides storage management services in a multiplatform computer environment.
- Installing the IBM Spectrum Protect backup-archive clients (UNIX, Linux, and Windows)
  The IBM Spectrum Protect backup-archive client helps you protect information on your workstations.
- Configuring backup-archive clients
  You can configure the backup-archive client to use many of the available client features. Information for configuring the backup-archive client is provided.
- Back up and restore data with backup-archive clients
  If you want to save a copy of a file from your computer to the IBM Spectrum Protect server, use the *backup* function. If the original file is ever damaged or lost, you can *restore* the backup version from the server.
- Archive and retrieve data with backup-archive clients
  If you want to save a copy of a file to long-term storage on the IBM Spectrum Protect server for archival purposes, use the *archive* function.
- Schedule operations for backup-archive clients
  You can schedule backup operations that protect client data to ensure that the operations run on a regular basis.
- Storage management policies
  Storage management policies are rules your administrator defines in order to manage your backups and archives on the server.
- Backup-archive client options and commands
  Use the client options to tailor backup-archive client processing to meet your needs. Use the client command-line interface (CLI) as an alternative to the graphical user interface (GUI). Reference information for the client options, commands, and other supplemental information is provided.
- ANS 0000-9999 messages

What's new for IBM Spectrum Protect backup-archive clients

Read about new and changed features. Review the release notes before installing the product.

- Backup-archive client updates
  Learn about new features and updates for the backup-archive client in IBM Spectrum Protect Version 8.1.
- Release notes for IBM Spectrum Protect Backup-Archive Client Version 8.1
  IBM Spectrum Protect Backup-Archive Client V8.1 is available. Read this document to find important installation information. You can also learn about product updates, compatibility issues, limitations, and known problems.
- Readme files for IBM Spectrum Protect Version 8.1 backup-archive client fix packs
  Readme files for the IBM Spectrum Protect V8.1 backup-archive client fix packs are available in the Support knowledge base when there is a fix pack update.
- Late-breaking documentation updates
  Updates to the IBM Spectrum Protect backup-archive client documentation can occur after the documentation is published in IBM® Knowledge Center.

Backup-archive client updates

Learn about new features and updates for the backup-archive client in IBM Spectrum Protect™ Version 8.1.

Release	New features and updates
8.1.2	Protect your client with enhanced security settings

Release	New features and updates
	Beginning in IBM Spectrum Protect Version 8.1.2, several changes are introduced in the backup-archive client to work with the IBM Spectrum Protect V8.1.2 server, which provides enhancements to improve the security between client and server communications. After the IBM Spectrum Protect server is upgraded to V8.1.2 and configured with the improved security protocol, and the backup-archive client is upgraded to V8.1.2, the security settings for the client must be configured to work with the security enhancements on the server. For more information about the configuring the client for different security scenarios, see Configuring the client security settings to connect to the IBM Spectrum Protect server version 8.1.2 and later. The following changes are available in this release: New sslacceptcertfromserv option, changes to three existing SSL-related options To simplify the process of distributing server certificates, IBM Spectrum Protect now includes a new sslacceptcertfromserv option to control whether the backup-archive client or the API application accepts and trusts the IBM Spectrum Protect server's Secure Sockets Layer (SSL) public certificate the first time they connect. In addition, three SSL-related options ssl, ssldisablelegacytls, and sslarequired have changed. Their operation varies depending on whether operation is with IBM Spectrum Protect server V8.1.2 or with IBM Spectrum Protect server V8.1.1 and earlier V8 levels, and V7.1.7 and earlier levels. For a description of these option settings and important version information, see Sslacceptcertfromserv, Ssl, Ssldisablelegacytls, and Sslrequired. The IBM Spectrum Protect password location is changed Beginning in V8.1.2, the IBM® Global Security Kit (GSKit) keystores are used to store all IBM Spectrum Protect passwords. When you upgrade to IBM Spectrum Protect V8.1.2 backup-archive client, the existing passwords are automatically migrated to new locations on the client system. For more information about the new password location and related considerations, see Secure password storage. A new way of importing server certificates is available with the dsmcert utility. For information about importing server certificates, see Configuring IBM Spectrum Protect client/server communication with Secure Sockets Layer. Because of the use of the new secure password storage, new procedures for granting password access to non-administrative users are available. AIX Linux Mac OS X Solaris For UNIX and Linux clients, see Enable non-root users to manage their own data. Windows For Windows clients, see Backup-archive client operations and security rights. Automatically deploy backup-archive client updates The IBM Spectrum Protect server administrator can use server commands to schedule updates for one or more backup-archive clients. The updates can be fix packs or new releases. This feature was available in previous releases of IBM Spectrum Protect, but an improved procedure is available for V8.1.2. For more information, see Schedule automatic updates for backup-archive clients. Deprecated functions The following functions are deprecated in this release: lanfreessl and replsslport options Two SSL-related options, lanfreessl and replsslport, are deprecated and unavailable if you are connecting to an IBM Spectrum Protect server V8.1.2 and later. These options are still valid and available if you are connecting to an IBM Spectrum Protect server V8.1.1 and earlier V8 levels, and V7.1.7 and earlier levels. AIX Linux Mac OS X Solaris Trusted communications agent (TCA) AIX Linux Mac OS X Solaris The trusted communications agent (TCA), previously used by non-root users in V8.1.0 and V7.1.6 and older clients, is no longer available. Root users can use other methods to allow non-root users to manage their files. For more information, see:

Release	New features and updates
	• The trusted communications agent is no longer available • Enable non-root users to manage their own data IBM Spectrum Protect web client You can no longer use the web client to connect to the IBM Spectrum Protect V8.1.2 or later server. However, you can still use the web client to connect to IBM Spectrum Protect V8.1.1, V8.1.0, or V7.1.7 or earlier servers. For more information, see Using the web client in the new security environment. AIX Solaris Windows NDMP command-line and web client operations AIX Solaris Windows If you are connecting to IBM Spectrum Protect server V8.1.2 or later, you can no longer use the client command-line interface or web client to back up or restore NAS file servers using Network Data Management Protocol (NDMP). Alternatively, you can use IBM Spectrum Protect server commands with the administrative command-line client (dsmadmc) to restore NDMP data. For more information, see the NDMP information in Using the web client in the new security environment. Open registration If the client is connecting to IBM Spectrum Protect server V8.1.2 or later, the open registration feature is no longer available. To connect to the IBM Spectrum Protect server, you must use closed registration. For more information, see Closed registration. Open registration is still available if the client is connecting to IBM Spectrum Protect V8.1.1, V8.1.0, or V7.1.7 and earlier servers. For more information about security improvements on the server, see Protect your storage environment with an improved security protocol. Windows Enhanced support for Data Protection for Microsoft Hyper-V running on Windows Server 2016 Windows Back up virtual machines by using resilient change tracking (RCT) To improve the scalability and performance of virtual machine (VM) backups, resilient change tracking (RCT) is used for all VM backup operations of Hyper-V hosts that run on the Microsoft Windows Server 2016 operating system. For more information, see Virtual machine backups with resilient change tracking (RCT). Windows Exercise more control over backup operations on VMs with physical disks You can control whether full Hyper-V RCT VM backups are processed if the VM has one or more physical disks (pass-through disks) provisioned. For more information, see the following options: • Vmprocessvmwithphysdisks • Vmskipphysdisks Specify the number of snapshot attempts and the level of data consistency for backup operations To determine the total number of snapshot attempts to try for a virtual machine that fails during backup processing due to snapshot failure, use the INCLUDE.VMSNAPSHOTATTEMPTS option. You can choose to attempt application-consistent or crash-consistent snapshots. For more information, see INCLUDE.VMSNAPSHOTATTEMPTS. Exclude VM disks from or include VM disks in backup operations You can use the exclude.vmdisk option to exclude a VM disk (VHDX) from VM backup operations or use the include.vmdisk option to include a VM disk in VM backup operations. For more information, see the following topics: • Exclude.vmdisk • Include.vmdisk • Domain.vmfull • Backup VM

Release	New features and updates
	Windows Enhanced support for Data Protection for Microsoft Hyper-V running on Windows Server 2012 and 2012 R2 Windows Scalability and reliability of VM backups are improved VMs are logically grouped into a single snapshot to reduce or eliminate snapshot conflicts at the Hyper-V host level. Improved snapshot retry processing simplifies scheduling and improves reliability across cluster nodes. • To control the number of VMs to include in a snapshot, use the vmmaxpersnapshot option. For more information, see Vmmaxpersnapshot. • To control how many snapshot retries are attempted, use the vmmaxsnapshotretry option. For more information, see Vmmaxsnapshotretry . Use these grouping and retry improvements along with the vmmaxparallel option to help improve performance. For information, see Tuning scheduled VM backups for Windows Server 2012 and 2012 R2 clusters. Linux Windows Enhanced Virtual Volumes (VVOL) support Linux Windows VVOL support is enhanced to include support for persisted snapshots on the hardware storage and application protection. For more information about new VVOL support features, see IBM Spectrum Protect for Virtual Environments: Data Protection for VMware updates. To use enhanced VVOL features, use the options that are described in the following sections: Specify the location for virtual machine backup and restore operations: local, server, or both For virtual machines that are hosted on VVOL datastores, you can now specify one of the following backup locations for backup and restore operations: local, server, or both. A local backup is a persisted snapshot on the hardware storage. To specify the backup location for the Backup VM or Restore VM command, use the vmbackuplocation option. For more information, see Vmbackuplocation. You can also specify the backup location or locations to query when you run the Query VM command. For more information, see Query VM. The Local Backup Management (IBM Spectrum Protect) tags are available for local backups. For more information, see Supported data protection tags. Create a schedule group You can use the schedgroup option to create a group that contains multiple schedules. You can then use the IBM Spectrum Protect vSphere Client plug-in to assign the schedule group to an object in the VMware vSphere Web client rather than an individual schedule. An example of the use of this option is to group multiple daily local backup schedules with a single IBM Spectrum Protect server backup schedule. For more information, see Schedgroup. Linux Windows Restore multiple virtual disks simultaneously Linux Windows You can use the IBM Spectrum Protect client restore multiple virtual disks simultaneously on the Microsoft Windows and Linux operating systems by using the vmmaxrestoreparalleldisks option. For instructions about setting the option settings, see Vmmaxrestoreparalleldisks. Linux Windows The snapdiffchangelogdir client option is added for snapshot differential backup operations Linux Windows Snapshot differential backups no longer use the stagingdirectory option for storing snapshot differential change log files. Beginning with V8.1.2, use the new snapdiffchangelogdir option to specify the location where the client stores persistent change logs for snapshot differential backups. For a description of the option settings and important information about migrating from prior client versions, see Snapdiffchangelogdir. Mac OS X Support for Apple File System Mac OS X The Apple File System (APFS) is supported for backup, archive, restore, and retrieve operations. The Case Sensitive version and sparse files are not supported.

Release	New features and updates
8.1.0	IBM Tivoli® Storage Manager is now IBM Spectrum Protect IBM Spectrum Protect Version 8.1 is the next generation of Tivoli Storage Manager. This new release represents more than a name change in the user interface and documentation. It is an evolution to a higher level of data protection that is designed to meet the complex demands of today's world. For more information, see Meet IBM Spectrum Protect. An administrative user ID is no longer created by default with the REGISTER NODE server command Beginning with IBM Spectrum Protect V8.1, the REGISTER NODE server command does not automatically create an administrative user ID that matches the node name. This product update is designed to optimize user authentication to a Lightweight Directory Access Protocol (LDAP) server. This product update does not affect existing client nodes, but can affect the process of registering new client nodes, including but not limited to nodes for IBM Spectrum Protect backup-archive clients. In some cases, you might have to create an administrative user ID when you register a node. You can create the administrative user ID by issuing the REGISTER NODE command and specifying the USERID parameter. For information about the types of clients that are affected, see technote 7048963. If you plan to use the web client, you must manually create an administrative user ID when you register a new node. For more information, see Register your workstation with a server. Run the web client independently of the web browser Instead of running the IBM Spectrum Protect web client as a Java™ Applet, the web client is delivered as a Java Web Start application, which can be started and managed independently of the web browser. For more information about starting the web client, see Starting a web client session. Linux Windows Backup management enhancements, including new data protection tags, are available for tagging support Linux Windows New data protection tags are available for tagging support New data protection tags are added to help you manage virtual machine backup operations with the IBM Spectrum Protect vSphere Client plug-in in the VMware vSphere Web Client. In addition to using tags to exclude virtual machines from scheduled backup operations and assign retention or management classes, introduced in V7.1.6, you can assign the new tags to vSphere inventory objects to do the following tasks: • Include virtual machines in scheduled backup operations • Assign a data mover to a virtual machine • Specify a list of virtual disks to back up • Assign a backup schedule to virtual machines in a container • Specify the data consistency to achieve for snapshot attempts during virtual machine backup operations • Provide application protection to virtual machines that run Microsoft SQL Server or Microsoft Exchange Server software For more information, see Supported data protection tags. Set a default data mover for tagging You can set a default data mover for protecting virtual machines in vSphere inventory objects that are tagged with data protection tags. New virtual machines that are added to the tagged container and are protected by a schedule but do not have a data mover tag are backed up by the default data mover. For more information, see Vmtagdefaultdatamover. Data protection tags can be inherited from higher-level vSphere inventory objects You can use tag inheritance to manage data protection for virtual machines in your vSphere inventory. For more information, see Inheritance of data protection settings. Virtual machines can be added to a backup schedule by using the IBM Spectrum Protect vSphere Client plug-in

Release	New features and updates
	You can select a backup schedule for virtual machines from the IBM Spectrum Protect vSphere Client plug-in in the VMware vSphere Web Client. The backup schedule specifies how often and when to automatically back up the virtual machines in a vSphere inventory object. For more information, see Selecting a schedule for backing up virtual machines. You can also view and manage backup schedules from the IBM Spectrum Protect vSphere Client plug-in. For more information, see Managing backup schedules in the vCenter. Linux Windows Snapshot differential backup is no longer supported on AIX® Linux Windows You can no longer run snapshot differential backups of NetApp filer volumes on the backup-archive client on the IBM AIX operating system. You can run snapshot differential backups only on Linux and Microsoft Windows clients. Discontinued functions The following functions are discontinued in this release: Linux Windows Virtual machine operations on the backup-archive client Linux Windows Virtual machine operations are available only if you are using the client as a data mover for the IBM Spectrum Protect for Virtual Environments products (Data Protection for VMware or Data Protection for Microsoft Hyper-V). You can no longer run virtual machine operations without installing IBM Spectrum Protect for Virtual Environments. Linux Windows VMware vStorage API is no longer part of the client installation Linux Windows The VMware vStorage API runtime files component that is used for VMware operations is no longer part of the backup-archive client installation. It is installed as part of the Data Protection for VMware installation package. Linux Windows Virtual machine operations that are discontinued for the data mover Linux Windows File-level virtual machine backups You can no longer run file-level VMware virtual machine backups on the data mover. Instead, use incremental-forever full or incremental-forever incremental backup operations. Periodic full backups and incremental backups You can no longer run periodic full backups and incremental backups of virtual machines on the data mover. Instead, use incremental-forever full or incremental-forever incremental backup operations. VMware vCloud Director support You can no longer back up or restore vCloud vApps with the data mover. To back up or restore vApps, you must use Data Protection for VMware V7.1. Windows Online system state restores Windows You can no longer restore the system state on a system that is online. Instead, use the Automated System Recovery (ASR) based recovery method to restore the system state in offline Windows Preinstallation Environment (PE) mode. For more information, see: • Restoring the Windows operating system with Automated System Recovery • Restore Systemstate Windows Adaptive subfile backup Windows Adaptive subfile backup operations are discontinued, but you can still restore existing subfile backup data. Data Encryption Standard (DES) 56-bit data encryption For increased security, use Advanced Encryption Standard (AES) 128-bit or AES 256-bit data encryption for backup and archive operations. For more information, see Encryptiontype. Windows GPFS™ support for the Windows client Windows The Windows backup-archive client can no longer back up or restore files in a Windows only GPFS cluster. However, you can still use the AIX or Linux backup-archive client to protect data in GPFS clusters that contain mixed nodes, which can include AIX, Linux, and Windows.

Release	New features and updates
	Data Protection for IBM Domino® plug-in The Data Protection for IBM Domino plug-in is stabilized at V7.1.0 and is no longer supported by the backup-archive client. If the Data Protection for IBM Domino plug-in is installed and configured on the same server as the IBM Domino Server and the V8.1 backup-archive client, you can no longer back up and restore IBM Domino databases and transaction log files with the web client. The guitreeviewafterbackup option The guitreeviewafterbackup option is no longer supported in this release and is removed from the Preferences Editor. If this option is present in the client options file when you run the client, the option is ignored and no client error messages are displayed. Discontinued support of client operating systems To take advantage of new product features, install the V8.1 backup-archive client on one of the supported operating systems. For the current list of supported operating systems, see technote 1243309. The following operating systems are no longer supported by the backup-archive client: • Windows 32-bit operating systems (client and API). • Windows Server 2008, Windows Server 2008 R2, Windows 7, and Windows 8 operating systems. • HP-UX operating systems. You can still use the IBM Spectrum Protect API on an HP-UX operating system. • Linux on Power Systems™ (big endian). You can still use the IBM Spectrum Protect API on Linux on Power Systems (big endian). • Solaris SPARC operating systems. You can still use the IBM Spectrum Protect API on Solaris SPARC operating systems.

Release notes for IBM Spectrum Protect Backup-Archive Client Version 8.1

IBM Spectrum Protect™ Backup-Archive Client V8.1 is available. Read this document to find important installation information. You can also learn about product updates, compatibility issues, limitations, and known problems.

Contents

Description

IBM Spectrum Protect is a client/server licensed product that provides storage management services in a multiplatform computer environment. You can use the backup-archive client to back up and archive files from workstations or file servers to storage, and restore and retrieve backup versions and archive copies of files to local workstations.

For a list of the APARs that are fixed in this release, see technote 1993247.

Announcement

The announcement for the IBM Spectrum Protect V8.1 family of products includes the following information:

- Detailed product description, including a description of new functions
- Product-positioning statement
- Packaging and ordering details
- International compatibility information

To search for the product announcement, complete the following steps:

1. Go to the product announcement website.
2. In the Search for field, enter the product identifier (PID) for your product. The PID for IBM Spectrum Protect is 5725-W98.
3. In the Information Type field, select Announcement letters, and click Search.
4. From the Search in list, select Product Number.
5. Optional: In the Refine Your Search pane on the left side of the window, select the country where you reside.
6. In the Sort by section, select Newest first.

Compatibility with earlier versions

For compatibility with earlier versions, see IBM Spectrum Protect Server/Client Compatibility and Upgrade Considerations.

System requirements

For information about hardware and software compatibility, see the detailed system requirements document at the following websites:

Apple Macintosh client requirements
: Technote 1053584

IBM® AIX® client requirements
: Technote 1052226

Linux on Power® Systems client requirements
: Technote 1169963

Linux x86_64 client requirements
: Technote 1052223

Linux on z Systems™ client requirements
: Technote 1066436

Microsoft Windows client requirements
: Technote 1197133

Oracle Solaris x86_64 client requirements
: Technote 1232956

Installing the backup-archive client

If you download the product from IBM Passport Advantage®, follow the directions in the download document at technote 4042940.

For installation instructions, see Installing the IBM Spectrum Protect backup-archive clients (UNIX, Linux, and Windows).

Updates, limitations, and known problems

Documentation updates, limitations, and known problems are documented as technotes in the Support knowledge base at the IBM Support Portal for IBM Spectrum Protect. As problems are discovered and resolved, IBM Software Support updates the knowledge base. By searching the knowledge base, you can find workarounds or solutions to problems.

Limitations and known problems
: At the time of publication, the limitations and known problems are documented in the following technotes:

  - For AIX, Linux, Mac OS X, and Oracle Solaris operating systems, see technote 1993251.
  - For Windows operating systems, see technote 1993250.

Documentation updates
: For information that was not available at the time of publication, documentation updates are available in the following tech docs:

  - For AIX, Linux, Mac OS X, and Oracle Solaris operating systems, see technote 7048955.
  - For Windows operating systems, see technote 7048956.

Readme files for IBM Spectrum Protect Version 8.1 backup-archive client fix packs

Readme files for the IBM Spectrum Protect™ V8.1 backup-archive client fix packs are available in the Support knowledge base when there is a fix pack update.

View IBM Spectrum Protect V8.1 backup-archive client fix pack readme files

Late-breaking documentation updates

Updates to the IBM Spectrum Protect™ backup-archive client documentation can occur after the documentation is published in IBM® Knowledge Center.

Late-breaking documentation updates are available in the following documents in the IBM Support Portal:

- For AIX®, Linux, Mac OS X, and Oracle Solaris clients, see technote 7048955.
- For Windows clients, see technote 7048956.

Protection for workstations and file servers

IBM Spectrum Protect™ is a client/server licensed product that provides storage management services in a multiplatform computer environment.

The backup-archive client program enables users to back up and archive files from their workstations or file servers to storage, and restore and retrieve backup versions and archived copies of files to their local workstations.

In addition to the backup-archive client, IBM Spectrum Protect includes the following components:

- A server program that acts as a backup and archive server for distributed workstations and file servers.

  AIX Linux Solaris The server program also supplies hierarchical storage management (HSM) services, and enables systems to perform as a migration server.

- An administrative client program that you can access from a web browser or from the command line. The program enables the IBM Spectrum Protect administrator to control and monitor server activities, define storage management policies for backup, archive, and space management services, and set up schedules to perform those services at regular intervals.
- An application programming interface (API) that you can use to enhance an existing application with storage management services. When an application is registered with a server as a client node, the application can back up, restore, archive, and retrieve objects from storage.
- A web backup-archive client that enables an authorized administrator, help desk person, or other users to perform backup, restore, archive, and retrieve services by using a web browser on a remote system.

AIX Linux Solaris Associated with IBM Spectrum Protect, but sold separately, are the IBM Spectrum Protect for Space Management and IBM Spectrum Protect HSM for Windows client programs. These products automatically migrate eligible files to storage to maintain specific levels of free space on local file systems and automatically recall migrated files when they are accessed. It also enables users to migrate and recall specific files.

AIX Linux Solaris The terms *hierarchical storage management* and *space management* have the same meaning throughout this publication.

Installing the IBM Spectrum Protect backup-archive clients (UNIX, Linux, and Windows)

The IBM Spectrum Protect™ backup-archive client helps you protect information on your workstations.

You can maintain backup versions of your files that you can restore if the original files are damaged or lost. You can also archive infrequently used files, preserve them in their current state, and retrieve them when necessary.

The backup-archive client works in conjunction with the IBM Spectrum Protect server. Contact your IBM Spectrum Protect server administrator to obtain backup or archive access to the server, or refer to the server publications to install and configure the IBM Spectrum Protect server.

- Upgrading the backup-archive client
  The following sections explain what you need to do if you are upgrading to IBM Spectrum Protect backup-archive client Version 8.1.2 from a previous version.
- Client environment requirements
  Each of the IBM Spectrum Protect clients has hardware and software requirements.
- AIX Solaris Windows NDMP support requirements (Extended Edition only)
  You can use the Network Data Management Protocol (NDMP) to back up and restore network attached storage (NAS) file systems to tape drives or libraries that are locally attached to Network Appliance and EMC Celerra NAS file servers.
- Linux Windows Installation requirements for backing up and archiving Tivoli Storage Manager FastBack client data
  Before you can back up or archive your FastBack client data, you must install the required software.
- Windows Client configuration wizard for Tivoli Storage Manager FastBack
  The backup-archive client provides a wizard to configure the backup-archive client for Tivoli® Storage Manager FastBack.
- AIX Linux Solaris Mac OS X Install the UNIX and Linux backup-archive clients
  This section provides instructions to install and set up IBM Spectrum Protect UNIX and Linux clients.
- Windows Windows backup-archive client installation overview
  You can install the IBM Spectrum Protect Windows backup-archive client from the installation media.
- Linux Windows Installing the client management service to collect diagnostic information
  You can install IBM Spectrum Protect client management services to collect diagnostic information about the backup-archive client. The client management service makes the information available to the IBM Spectrum Protect Operations Center for basic monitoring capability.

Upgrading the backup-archive client

The following sections explain what you need to do if you are upgrading to IBM Spectrum Protect™ backup-archive client Version 8.1.2 from a previous version.

- Upgrade path for clients and servers
  IBM Spectrum Protect clients and servers can be upgraded at different times. The combination of servers and clients that you deploy must be compatible with each other.
- Additional upgrade information
  When you upgrade the backup-archive client, there is additional information to consider before you use the new client software.
- Automatic backup-archive client deployment
  The IBM Spectrum Protect server administrator can automatically deploy a backup-archive client to update workstations where the backup-archive client is already installed.

Upgrade path for clients and servers

IBM Spectrum Protect™ clients and servers can be upgraded at different times. The combination of servers and clients that you deploy must be compatible with each other.

To prevent disruption of your backup and archive activities while you upgrade from one release to another, follow the compatibility guidelines for IBM Spectrum Protect clients and servers in technote 1053218.

AIX For information about upgrading your current AIX® IBM® PowerHA® SystemMirror® setups, see Migrating legacy AIXIBM PowerHA SystemMirror setups.

Additional upgrade information

When you upgrade the backup-archive client, there is additional information to consider before you use the new client software.

Be aware of the following information when you upgrade a backup-archive client:

- Linux Solaris If you are upgrading from the IBM® Tivoli® Storage Manager Version 7.1.2 or earlier backup-archive client on the Oracle Solaris operating system, you must uninstall any previously installed language packages before you proceed with the upgrade.
- Mac OS X For Mac users, updates to the Mac OS X client contained in IBM Spectrum Protect™ V6.3, or newer versions, require you to consider the following items:
  - When you use the Mac OS X client that is provided in this release, ensure that the dsm.sys and dsm.opt files are encoded by using Unicode (UTF-8). UTF-8 encoding enables the use of characters from any language in the options files. If your dsm.sys or dsm.opt files were previously encoded as MacRoman (or anything other than UTF-8), open them in an editor like TextEdit and save them with UTF-8 encoding, and without the .txt extension. Your include-exclude lists can be encoded as either UTF-8 or UTF-16. For more information about using Unicode, see Considerations for Unicode-enabled clients.
  - IBM Spectrum Protect server file spaces that were created by Mac OS 9 clients cannot be managed by the Mac OS X client that was provided in IBM Spectrum Protect V6.3. Use `q file node f=d` on the server to list files stored for a node. Any Mac-platform files that do not start with a slash (/) were probably created by an older Mac client. You cannot restore or otherwise manage these files by using the Mac OS X client that is provided in this release. You can manage these files, but you must use a Mac client that is installed on a version 6.2.2 or older client node.
- Windows The size of the buffer to record change notifications for a particular journal file system (DirNotifyBufferSize) has changed. The default value is 16 KB.
- For a list of new and changed messages since the previous IBM Spectrum Protect release, see the client_message.chg file in the client package.

Automatic backup-archive client deployment

The IBM Spectrum Protect™ server administrator can automatically deploy a backup-archive client to update workstations where the backup-archive client is already installed.

The IBM Spectrum Protect server can be configured to automatically upgrade backup-archive clients on client workstations. The existing backup-archive clients must be at version 6.4.3 or later.

For more information about automatically deploying client upgrades from the server, see the following documents:

- For IBM Spectrum Protect 8.1.2 or later servers, see technote 2004596.
- For IBM® Tivoli® Storage Manager V7.1 servers and IBM Spectrum Protect V8.1.0 and V8.1.1 servers, see technote 1673299.

Restrictions: The following restrictions apply to automatic client deployment:

- The Windows cluster services environment is not supported.
- Only the backup-archive client can be deployed from the IBM Spectrum Protect server. Other related products such as IBM Spectrum Protect for Space Management, IBM Spectrum Protect HSM for Windows, IBM Spectrum Protect for Virtual Environments, and other Data Protection products are not supported. If a deployment of an unsupported product is attempted, the deployment process stops with a failure message.
- Do not schedule automatic client deployments to workstations that already have the IBM Spectrum Protect for ERP application installed on them.

  When the server administrator schedules automatic backup-archive client deployments, the updated client packages (which include the client components and the API library) are installed on the workstations that receive them. A dependency check is performed by the client installation program to ensure that the API library does not conflict with the client package that is already installed.

  IBM Spectrum Protect for ERP applications do not use the same installation technology that is used by the client installation program. Therefore, the client installation dependency check is not able to detect whether the API library that is being used by the IBM Spectrum Protect for ERP applications is compatible with the API library that will be installed by automatic client deployments. If a client package is automatically deployed to and installed on a workstation, the API library that is installed might not be compatible with the API library that was installed by the IBM Spectrum Protect for ERP application. The newly deployed API library can cause the IBM Spectrum Protect for ERP applications to fail.

How the autodeploy client option can affect client deployment

You can use the autodeploy option to conditionally enable automatic client deployment, if the deployment does not require a restart of the client workstation.

By default, the autodeploy option is enabled, and the client workstation is restarted if required.

To use automatic deployment but not restart the system, specify the autodeploy noreboot option.

To turn off automatic client deployment, add autodeploy no to the client options file.

You can set the autodeploy option in the following places:

- On a schedule definition on the IBM Spectrum Protect server. Schedule definitions that deploy client software updates have an `action=deploy` statement. On those schedules, you can include the autodeploy option as part of the command that you include on the –postnschedulecmd statement.
- On the client node, in an options file that is associated with the client scheduler or client acceptor. The deployment manager detects options files that are associated with the scheduler or client acceptor. If multiple scheduler or client acceptor processes are running on the same computer at the same time, and the processes use different options files, the deployment manager uses the autodeploy option value that is set in one of the options files.
- On the client in the client options file (dsm.opt). The autodeploy option that is set in the client options file overrides any other autodeploy setting.

- AIX Backup-archive client features that are available on AIX
  This topic lists the features that are supported on AIX.

AIX

AIX client installable components

The backup-archive client is comprised of several installable components.

The installable components for the AIX® client are as follows:

- Backup-archive command line client
- Administrative client
- Backup-archive client graphical user interface, which uses Oracle Java™ technology
- Backup-archive web client
- IBM Spectrum Protect™ 64-bit API

The API can be separately installed. The other components are all installed when you install the AIX package (tivoli.tsm.client.api.64bit).

AIX

System requirements for the AIX client

The IBM Spectrum Protect™ AIX® client requires a minimum amount of hardware, disk space, memory, and software.

For software and hardware requirements for all supported versions of AIX clients, including the most recent fix packs, see technote 1052226.

AIX

AIX client communication methods

The TCP/IP and shared memory communication methods are available for the AIX® backup-archive client.

You can use the following communication methods with the IBM Spectrum Protect™ Version 8.1.2 AIX client:

Table 1. AIX client communication methods

To use this communication method:	Install this software:	To connect to these IBM Spectrum Protect servers:

Mac OS X

Mac OS X client environment

This section contains client environment information, backup-archive client components, and hardware and software requirements for the Mac OS X client.

- Mac OS X Mac OS X client installable components
  The backup-archive client command-line, Java™ GUI, web backup-archive, and API comprise the Mac OS X backup-archive client installable components.
- Mac OS X System requirements for Mac OS X clients
  The IBM Spectrum Protect Mac OS X clients require a minimum amount of hardware, disk space, memory, and software.
- Mac OS X Mac OS X client communication methods
  The TCP/IP communication methods are available for the Mac OS X backup-archive client.

Mac OS X

Mac OS X client installable components

The backup-archive client command-line, Java™ GUI, web backup-archive, and API comprise the Mac OS X backup-archive client installable components.

The following components are installed with IBM Spectrum Protect™ Version 8.1.2:

- Backup-archive client
- Administrative client
- Web backup-archive client
- IBM Spectrum Protect API
- Backup-archive Java graphical user interface (GUI)

Tip: The `dsmj` shell script file for the Java GUI is installed in the following location:

```
/Library/Application Support/tivoli/tsm/client/ba/bin
```

Mac OS X

System requirements for Mac OS X clients

The IBM Spectrum Protect™ Mac OS X clients require a minimum amount of hardware, disk space, memory, and software.

For software and hardware requirements for all supported versions of Mac OS X clients, including the most recent fix packs, see technote 1053584.

Mac OS X

Mac OS X client communication methods

The TCP/IP communication methods are available for the Mac OS X backup-archive client.

You can use the following communication methods with the IBM Spectrum Protect™ Version 8.1.2 Mac OS X client:

Table 1. Mac OS X client communication methods

To use this communication method:	Install this software:	To connect to these IBM Spectrum Protect servers:
TCP/IP	TCP/IP (standard with Mac OS X)	AIX®, Linux, Windows

Solaris

Oracle Solaris client environment

Review client environment information, client components, and hardware and software requirements for the Oracle Solaris platform.

Starting in IBM Spectrum Protect™ Version 8.1.0, the Oracle Solaris backup-archive client is available only on the Oracle Solaris x86_64 platform. The Oracle Solaris API is available on the Oracle Solaris x86_64 and Oracle Solaris SPARC platforms.

- Solaris Oracle Solaris client installable components
  The IBM Spectrum Protect command-line, Java™ GUI, web backup-archive, and API comprise the Solaris backup-archive client installable components.
- Solaris System requirements for Oracle Solaris clients
  The IBM Spectrum Protect Oracle Solaris clients require a minimum amount of hardware, disk space, memory, and software.
- Solaris Oracle Solaris client communication methods
  The TCP/IP and shared memory communication methods are available for the Oracle Solaris backup-archive client.

Solaris

Oracle Solaris client installable components

The IBM Spectrum Protect™ command-line, Java™ GUI, web backup-archive, and API comprise the Solaris backup-archive client installable components.

You can install the following client components on Oracle Solaris x86_64:

- Backup-archive client
- Administrative client
- Backup-archive Java graphical user interface (GUI)
- Web backup-archive client
- IBM Spectrum Protect API

You can install the IBM Spectrum Protect API on Oracle Solaris SPARC.

Solaris

System requirements for Oracle Solaris clients

The IBM Spectrum Protect™ Oracle Solaris clients require a minimum amount of hardware, disk space, memory, and software.

For software and hardware requirements for all supported versions of IBM Spectrum Protect Oracle Solaris clients, including the most recent fix packs, see the following IBM® support pages:

- For Oracle Solaris x86_64 client requirements, see technote 1232956.
- For Oracle Solaris SPARC API requirements, see technote 1052211.

Solaris

Oracle Solaris client communication methods

The TCP/IP and shared memory communication methods are available for the Oracle Solaris backup-archive client.

You can use the following communication methods with the Oracle Solaris client:

Table 1. Oracle Solaris client communication methods

To use this communication method:	Install this software:	To connect to these IBM Spectrum Protect™ servers:
TCP/IP	TCP/IP (Standard with Solaris)	AIX®, Linux, Windows

Windows

Windows client environment requirements

This section contains client environment information, backup-archive client components, and hardware and software requirements for the supported Windows platforms.

- Windows Windows client installable components
  The backup-archive client is comprised of several installable components.
- Windows System requirements for Windows clients
  The backup-archive client on Windows requires a minimum amount of disk space for installation and a supported operating system.
- Windows Windows client communication methods
  The TCP/IP and shared memory communication methods are available for the Windows backup-archive client.
- Windows Backup-archive client features that are available on Windows platforms
  This topic lists which features are supported or not supported on the various Windows platforms.
- Windows Windows supported file systems
  The IBM Spectrum Protect Windows backup-archive client is supported on specific file systems.

Windows

Windows client installable components

The backup-archive client is comprised of several installable components.

The installable components for the Windows backup-archive client are as follows:

- Backup-archive command-line client
- Administrative client
- Backup-archive client graphical user interface, which uses Oracle Java™ technology
- Backup-archive web client
- IBM Spectrum Protect™ API (64-bit)

Windows

System requirements for Windows clients

The backup-archive client on Windows requires a minimum amount of disk space for installation and a supported operating system.

For software and hardware requirements for all supported versions of Windows clients, including the most recent fix packs, see technote 1197133.

Windows

Windows client communication methods

The TCP/IP and shared memory communication methods are available for the Windows backup-archive client.

You can use the following communication methods with the Windows backup-archive client:

Table 1. Windows client communication methods

To use this communication method:	Install this software:	To connect to these IBM Spectrum Protect™ servers:
TCP/IP	TCP/IP (Standard with all supported Windows	AIX®, Linux, Windows
Named Pipes	Named Pipes (Standard with all supported Windows platforms)	Windows
Shared Memory	TCP/IP (Standard with all supported Windows platforms)	Windows

Windows

Backup-archive client features that are available on Windows platforms

This topic lists which features are supported or not supported on the various Windows platforms.

Table 1 shows the supported and unsupported features on the various Windows platforms.

Table 1. Supported features on Windows platforms

Features	Windows 10	Windows Server 2012 Windows Server 2012 R2 Windows Server 2016
Journal-based backup	yes	yes
Online image backup	yes	yes
Offline image backup	yes	yes
System state support with Volume Shadowcopy Services (VSS)	yes	yes
LAN-free operations	yes	yes
Automated System Recovery (ASR)	yes	BIOS: yes UEFI: yes
Open File Support (OFS)	yes	yes

Windows

Windows supported file systems

The IBM Spectrum Protect™ Windows backup-archive client is supported on specific file systems.

The Windows backup-archive client supports the following types of file systems:

- File Allocation Table (FAT and FAT32)
- Microsoft New Technology File System (NTFS)
- Microsoft Resilient File System (ReFS). ReFS was introduced on Windows Server 2012 systems.

AIX Solaris Windows

NDMP support requirements (Extended Edition only)

You can use the Network Data Management Protocol (NDMP) to back up and restore network attached storage (NAS) file systems to tape drives or libraries that are locally attached to Network Appliance and EMC Celerra NAS file servers.

NDMP support is available only on IBM Spectrum Protect™ Extended Edition.

NDMP support requires the following hardware and software:

- IBM Spectrum Protect Extended Edition
- Tape drive and tape library. For supported combinations, go to: product information

Linux Windows

Installation requirements for backing up and archiving Tivoli Storage Manager FastBack client data

Before you can back up or archive your FastBack client data, you must install the required software.

You must install the following software:

- Tivoli® Storage Manager FastBack Version 6.1
- Tivoli Storage Manager client V6.1.3.x (where x is 1 or higher) or V6.2 or later
- Tivoli Storage Manager server V6.1.3 or higher
- Tivoli Storage Manager Administration Center V6.1.3
    - Required only if you want to use integrated Tivoli Storage Manager FastBack - administration.

      Starting with V7.1, the Administration Center component is no longer included in Tivoli Storage Manager or IBM Spectrum Protect™ distributions. FastBack users who have an Administration Center from a previous server release, can continue to use it to create and modify FastBack schedules. If you do not already have an Administration Center installed, you can download the previously-released version from ftp://public.dhe.ibm.com/storage/tivoli-storage-management/maintenance/admincenter/v6r3/. If you do not already have an Administration Center installed, you must create and modify FastBack schedules on the IBM Spectrum Protect server. For information about creating schedules on the server, see the IBM Spectrum Protect server documentation.

The Tivoli Storage Manager FastBack environment must be running. For information about installing and setting up Tivoli Storage Manager FastBack, see the product information at Tivoli Storage Manager FastBack.

For information about integrating IBM Spectrum Protect and Tivoli Storage Manager FastBack, see Integrating Tivoli Storage Manager FastBack and IBM Spectrum Protect.

You can install the IBM Spectrum Protect client in one of the following ways:

- Windows Install the backup-archive client on a workstation where the FastBack server is installed. In this case, the prerequisites are: the FastBack server, the FastBack shell, and the FastBack mount.
- Linux Install the backup-archive client on a workstation where the FastBack Disaster Recovery Hub is installed. In this case, the prerequisites are: the FastBack Disaster Recovery Hub setup, and the FastBack shell.
- Windows Install the backup-archive client on a workstation where the FastBack Disaster Recovery Hub is installed. In this case, the prerequisites are: the FastBack Disaster Recovery Hub setup, the FastBack shell, and the FastBack mount.
- Linux Install backup-archive client on a workstation where neither the FastBack server or the FastBack Disaster Recovery Hub is installed. In this case, the FastBack shell is still required.
- Windows Install the backup-archive client on a workstation where neither the FastBack server or the FastBack Disaster Recovery Hub is installed. In this case, ensure that the FastBack shell and the FastBack mount are installed.
