3. To delete a storage pool resource from a resource group, run the delete_mount.sh script by issuing the ./delete_mount.sh command. For example, the following command deletes the `/inst1stg1` mount point from the `inst1` IBM Spectrum Protect server instance.

   ```
   ./delete_mount.sh /inst1stg1 inst1
   ```

4. Unlock the resource group by issuing the rgreq -o unlock command. For example, the following command unlocks the `Sample_Resourcegroup_X` resource group.

   ```
   rgreq -o unlock Sample_Resourcegroup_X
   ```

Linux

Deleting a mount point from a resource group

You might want to delete a mount point that is no longer required.

Procedure

To delete a mount point, complete the following steps:

1. Check whether the tsm-$INST_NAME-rg resource group is online by issuing the lssam command.
2. If the tsm-$INST_NAME-rg resource group is online, take it offline by issuing the following command:

   ```
   chrg -o offline tsm-$INST_NAME-rg
   ```

3. Move to the bin directory by issuing the cd command.
4. To delete a mount point, run the delete_mount.sh script. For example, the following command deletes the `/tsminst1` mount point from the `inst1` IBM Spectrum Protect™ server instance resource group.

   ```
   ./delete_mount.sh /tsminst1 inst1
   ```

5. Bring the tsm-$INST_NAME-rg resource group online by issuing the following command:

   ```
   chrg -o online tsm-$INST_NAME-rg
   ```

Linux

Upgrading a server that is configured with Tivoli System Automation

You can upgrade a server that is configured with Tivoli® System Automation from Version 6.3 or Version 7.1.

Procedure

To upgrade the server on each node in the cluster, log in to the server and complete the following steps. These steps start the upgrade on the primary node and then the latter part of this procedure upgrades the secondary node.

1. Stop the server resources by issuing the chrg -o Offline command. For example, the following command stops the resources in the tsm-tsminst1-rg resource group:

   ```
   chrg -o Offline tsm-tsminst1-rg
   ```

2. Stop the Tivoli System Automation domain by issuing the stoprpdomain command. For example, the following command stops the tsm_domain:

   ```
   stoprpdomain tsm_domain
   ```

3. Mount the server mount points on the primary node.
4. To upgrade the server on the primary node, see Upgrading IBM Spectrum Protect™.
5. After the upgrade is finished, complete the post upgrade steps to verify that the upgrade is successful on the primary node.
6. Stop the server and unmount the server mount points on the primary node.
7. Mount the server mount points on the secondary node.
8. If you are upgrading a server from V6 to V7, complete the following steps:
    a. Uninstall the server.

       For instructions, see Uninstalling the V6.3 server.

    b. Install the server on the secondary node. Follow the instructions in Linux: Installing the server components.
9. To upgrade the server on the secondary node, see Upgrading the server.
10. After the upgrade is complete, complete the post upgrade steps to verify that the upgrade is successful on the secondary node.
11. Unmount the server mount points on the secondary node.
12. Start the Tivoli System Automation domain by issuing the startrpdomain command. For example, the following command starts the tsa_domain:

    ```
    startrpdomain tsa_domain
    ```

13. Start the server resources by issuing the chrg -o Online command. For example, the following command starts the resources in the tsm-tsminst1-rg resource group:

    ```
    chrg -o Online tsm-tsminst1-rg
    ```

Windows

Configuring a Windows clustered environment

You can configure an IBM Spectrum Protect™ server for Windows in a Microsoft failover cluster environment. Windows cluster environments consist of components such as IBM Spectrum Protect servers, hardware, and software. When these components are connected to the same disk system, downtime is minimized.

Microsoft software helps configure, monitor, and control applications and hardware components that are deployed on a Windows cluster. The administrator uses the Microsoft Cluster Administrator interface and IBM Spectrum Protect to designate cluster arrangements and define the failover pattern.

IBM Spectrum Protect supports tape failover for a cluster environment by using a Fibre or SCSI connection. Although Microsoft failover clusters do not support the failover of tape devices, the failover configuration can be monitored through the Microsoft Cluster Administrator interface after it is set up through IBM Spectrum Protect.

- Windows Microsoft Failover Cluster environment overview
  With a Microsoft Failover Cluster Manager, you can place IBM Spectrum Protect server cluster resources into a cluster group. The IBM Spectrum Protect cluster group has a network name, an IP address, one or more physical disks, a Tivoli® server, and an IBM Spectrum Protect server service.
- Windows Tape failover for nodes in a cluster
  Groups in a cluster can be transferred to other nodes when the node that is hosting the groups fails.
- Windows Planning for a clustered environment
  Configuration in a clustered environment takes planning to ensure the optimal performance of your system. Whether you configure your system to include clusters depends on your business needs.
- Windows Setting up IBM Spectrum Protect in a Microsoft Failover Cluster
  You must ensure that your cluster is properly installed and configured before you install IBM Spectrum Protect.
- Windows Maintaining the clustered environment
  After you set up your initial cluster or clusters, maintenance needs are minimal.

Windows

Microsoft Failover Cluster environment overview

With a Microsoft Failover Cluster Manager, you can place IBM Spectrum Protect™ server cluster resources into a cluster group. The IBM Spectrum Protect cluster group has a network name, an IP address, one or more physical disks, a Tivoli® server, and an IBM Spectrum Protect server service.

The IBM Spectrum Protect instance network name is independent of the name of the physical node on which the IBM Spectrum Protect cluster group runs. Clients connect to an IBM Spectrum Protect server by using the instance network name, rather than the Windows node name. The instance network name maps to a primary or backup node. The mapping depends on which node owns the cluster group. Any client that uses Windows Internet Name Service (WINS) or directory services to locate servers can automatically track the IBM Spectrum Protect clustered server as it moves between nodes. You can automatically track the clustered server without modifying or reconfiguring the client.

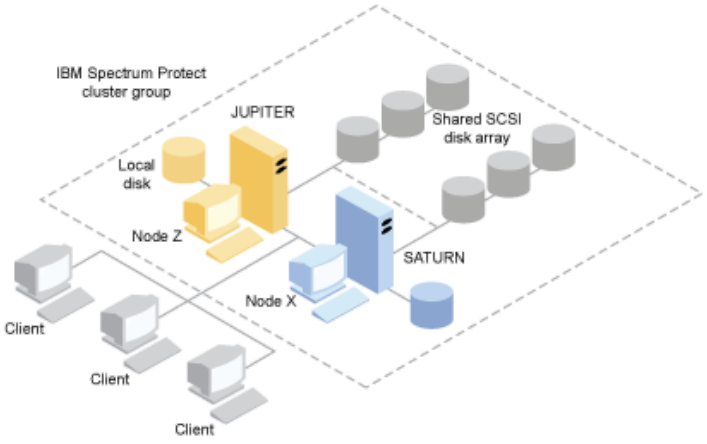
Each IBM Spectrum Protect cluster group has its own disk as part of a cluster resource group. IBM Spectrum Protect cluster groups cannot share data between the cluster groups. Each IBM Spectrum Protect server that is configured in a cluster group has its database, active logs, recovery logs, and set of storage pool volumes on a separate disk. This disk is owned by the cluster group where the server is configured.

Remember: Microsoft Failover Cluster Manager supports an IP address only as a resource. Hence, any IBM Spectrum Protect server that runs on a cluster must limit its supported communication method to just TCP/IP. Any client that does not use TCP/IP as a communication method is not able to reach the IBM Spectrum Protect cluster group if it fails over to the other cluster node.

The following example demonstrates the way that a Microsoft Failover Cluster Manager for an IBM Spectrum Protect cluster server works.

Assume that a clustered IBM Spectrum Protect server that is named JUPITER is running on Node Z and a clustered IBM Spectrum Protect server that is named SATURN is running on Node X. Clients connect to the IBM Spectrum Protect server JUPITER and the IBM Spectrum Protect server SATURN without knowing which node hosts their server.

Figure 1. Clustering with JUPITER as Node Z and SATURN as Node X



When one of the software or hardware resources fails, failover occurs. Resources such as applications, disks, and an IP address move from the failed node to the remaining node. The remaining node:

- Takes over the IBM Spectrum Protect cluster group
- Brings the disk resources, the network resources, and the DB2 resource online
- Restarts the IBM Spectrum Protect service
- Provides access to administrators and clients

If Node X fails, Node Z assumes the role of running SATURN. To a client, it is exactly as if Node X were turned off and immediately turned back on again. Clients experience the loss of all connections to SATURN and all active transactions are rolled back to the client. Clients must reconnect to SATURN after the connection is lost. The location of SATURN is not apparent to the client.

Windows

Tape failover for nodes in a cluster

Groups in a cluster can be transferred to other nodes when the node that is hosting the groups fails.

A node can host physical or logical units, referred to as resources. Administrators organize these cluster resources into functional units that are called groups and assign these groups to individual nodes. If a node fails, the server cluster transfers the groups that were being hosted by the node to other nodes in the cluster. This transfer process is called *failover*. The reverse process,

failback, occurs when the failed node becomes active again and the groups that were failed over to the other nodes are transferred back to the original node.

- Windows Fiber tape failover
  IBM Spectrum Protect can manage the failover of Fibre Channel direct-attached tape and library devices on a Microsoft Windows system in a clustered environment without extra hardware.

Windows

Planning for a clustered environment

Configuration in a clustered environment takes planning to ensure the optimal performance of your system. Whether you configure your system to include clusters depends on your business needs.

Plan for a cluster configuration that accommodates your environment. In addition to assuring the correct type of hardware and the applicable software, you must set up a failover pattern.

When a node fails or needs to be taken offline, which node or nodes in the cluster picks up the transaction processing? In a two-node cluster, there is little planning necessary. In a more complex arrangement, you want to consider how your transaction processing is best handled. A form of load balancing among your nodes needs to be accounted for so that you maintain peak performance. Another consideration is to ensure that your customers do not see any lag and little drop in productivity.

Microsoft Cluster Servers and Microsoft Failover Clusters require each IBM Spectrum Protect™ server instance to have a private set of disk resources. Although nodes can share disk resources, only one node can actively control a disk at a time.

Attention: Ensure that the same level of Windows (Windows 2012, Windows 2012 R2, and Windows 2016) is installed on all computers in the cluster.

Is one configuration better than the other? To determine your best installation, you need to look at the differences in performance and cost. Assume that you have an IBM Spectrum Protect server-dedicated cluster whose nodes have comparable power. During failover, the performance of a configuration might degrade because one node must manage both IBM Spectrum Protect cluster instances. If each node handles 100 clients in a normal operation, one node must handle 200 clients during a failure.

- Windows Cluster configuration worksheet
  Record your answers to the following planning questions before you set up the cluster configuration.
- Windows Planning for cluster hardware and software configuration
  Cluster hardware and software configuration is determined during the planning stage and before the actual installation.
- Windows Configuring IBM Spectrum Protect in Microsoft Failover Cluster
  The IBM Spectrum Protect cluster configuration procedure must be completed on the set of nodes that hosts an IBM Spectrum Protect cluster group.

Related information:
IBM Spectrum Protect Supported Operating Systems
Windows

Cluster configuration worksheet

Record your answers to the following planning questions before you set up the cluster configuration.

1. What type of cluster solution best fits your business needs?
2. What type of failover pattern do you need?

   The use of tape failover support also affects the pattern.

3. Is tape failover support be needed?

   Consider how tape devices are used by the IBM Spectrum Protect™ cluster instances. The way that tape devices are used by cluster instances can limit the number of nodes in the failover pattern to two.

4. What are the resources to be dedicated to IBM Spectrum Protect?

Resource type	Resource name
Cluster Resource Group	

Resource type	Resource name
Physical Disk Resources	
IP address	
Subnet Mask	
Network	
Network Name (server name)	
Nodes	
Tape Failover (optional): device name - both nodes	

Windows

Planning for cluster hardware and software configuration

Cluster hardware and software configuration is determined during the planning stage and before the actual installation.

Procedure

The following guidelines help determine what resources are needed for a successful IBM Spectrum Protect™ cluster:

1. Decide which cluster configuration you must use with servers that use disk devices. Each IBM Spectrum Protect cluster instance needs a separate set of disk resources on the shared disk subsystem. You might have problems if you configure the I/O subsystem as one large array. For example, when you configure a two server cluster and later decide to expand to a four server cluster.
2. Identify the disk resources to be dedicated to IBM Spectrum Protect. Do not divide a shared disk into multiple partitions with each partition assigned to a different application and thus a different cluster group.

   For example, Application A, a stable application, might be forced to fail over because of a software problem with Application B. This failover might occur if both applications use partitions that are part of the same physical disk. This problem causes the Cluster Services to fail over Application B and its corequisite disk resource. Because the partitions exist on the same physical drive, Application A is also forced to fail over. Therefore, when you install and configure an IBM Spectrum Protect application, dedicate a shared disk as a resource that can fail if necessary.

3. Ensure that you have an IP address and network name for each IBM Spectrum Protect server instance that you configure. For a cluster that involves two IBM Spectrum Protect cluster instances, you must have two network names.
4. Create a cluster resource group and move disk resources to it. Each IBM Spectrum Protect server instance requires a cluster resource group. Initially, the group must contain only disk resources. You might choose just to rename an existing resource group that contains only disk resources.
5. IBM Spectrum Protect is installed to a local disk on each node in the cluster. Determine the disk to be used on each node. Use the same drive letter on each system. When IBM Spectrum Protect server is installed in a cluster environment, the SANDISCOVERY option must be set to ON. By default, this option is set to OFF.
6. If you choose not to use IBM Spectrum Protect tape failover support, you can attach tape devices in either of the following configurations:

Configuration	Advantages and disadvantages	The required disk space	How to enable migration	What to do when a failover occurs
Attach to the node on which the IBM Spectrum Protect server instance is active.	This configuration allows high-performance backup and restore operations. However, it is not entirely automated because operator intervention is required to service a failover when repair delays occur.	Define enough volume space for which data is disk-based to keep more than two days worth of average data.	Set up a storage pool hierarchy so that data is moved efficiently to the tape device.	Manually disconnect the tape device and reattach it to the node on which the server was activated.

Configuration	Advantages and disadvantages	The required disk space	How to enable migration	What to do when a failover occurs
Attach to a third, non-clustered system on which an extra instance of the IBM Spectrum Protect server is active.	This configuration might not be feasible in installations with low-bandwidth communications between the servers in the cluster and the tape-device controller server.	Define enough volume space for which data is disk-based to keep more than two days worth of average data.	Use the virtual volumes to move the data from the local disk volumes to the tape device.	No action is needed; the activated server continues to use the virtual volumes.

Windows

Configuring IBM Spectrum Protect in Microsoft Failover Cluster

The IBM Spectrum Protect™ cluster configuration procedure must be completed on the set of nodes that hosts an IBM Spectrum Protect cluster group.

Steps for the procedure vary depending upon which node you are currently configuring. When you configure the primary node in the set, the IBM Spectrum Protect server instance is created and configured. When you configure the remaining nodes in the set, each node is updated by using a specific method. The way the node is updated allows it to host the IBM Spectrum Protect server instance that is created on the primary node. An IBM Spectrum Protect server must be installed and configured on the first node in the set before you configure the remaining nodes in the set. Violating this requirement causes the configuration to fail.

Ensure that you completely configure one IBM Spectrum Protect cluster group before you move on to the next when you are configuring multiple IBM Spectrum Protect cluster groups. Because you are dealing with separate IP addresses and network names for each IBM Spectrum Protect cluster group, you lessen the possibility of mistakes by configuring each cluster group separately.

Windows

Setting up IBM Spectrum Protect in a Microsoft Failover Cluster

You must ensure that your cluster is properly installed and configured before you install IBM Spectrum Protect™.

Procedure

To configure IBM Spectrum Protect in a Microsoft Failover Cluster, complete the following steps:

1. Ensure that the Windows operating system is installed on all computers that are part of the cluster. For the most current information about supported Windows operating systems, see technote 1243309.
2. Log on with the domain user ID. The domain user must be in the same domain as the IBM Spectrum Protect server.
3. Ensure that the failover cluster is installed and configured for all the computers in the cluster.
   If you plan to install the IBM Spectrum Protect server on the Windows Server 2012 operating system, install the failover cluster automation server and the failover cluster command interface first. To install these components, issue the following commands from Windows 2.0 PowerShell:

   ```
   Install-WindowsFeature -Name RSAT-Clustering-AutomationServer
   Install-WindowsFeature -Name RSAT-Clustering-CmdInterface
   ```

4. Verify that each node and shared disk in the cluster is operational.
5. Ensure that the shared tape devices are operational if IBM Spectrum Protect tape failover support is being used.

- Windows Preparing a Microsoft Failover Cluster group for a basic virtual server
  Each IBM Spectrum Protect server instance requires a cluster resource group.
- Windows Installing IBM Spectrum Protect in a Microsoft Failover Cluster
  Install the IBM Spectrum Protect server on every node in the cluster that hosts an IBM Spectrum Protect clustered server.
- Windows Initializing the IBM Spectrum Protect server for a Microsoft Failover Cluster on the primary node
  After you install IBM Spectrum Protect on the nodes in the cluster, you must initialize the server on the primary node.
- Windows Verifying the configuration of IBM Spectrum Protect in a Microsoft Failover Cluster
  When you finish configuring IBM Spectrum Protect in a Microsoft Failover Cluster, you can review the Failover Cluster Manager summary window. Verify that clustering is completed successfully and the IBM Spectrum Protect server is started.

- Windows Completing a failover test for your cluster
  After you complete the cluster configuration, run a failover test to ensure that the nodes are working properly.

Windows

Preparing a Microsoft Failover Cluster group for a basic virtual server

Each IBM Spectrum Protect™ server instance requires a cluster resource group.

Before you begin

Use the Failover Cluster Manager program on the computer that owns the shared disk or tape resource to prepare your resource group. Initially, the group must contain only disk resources. You can create a group and move disk resources to it. You can also choose to rename an existing resource group that contains only disk resources.

As you construct your resource groups, consider the following items:

- Ensure that each resource group has a distinctive name. Do not change the names after the group is created because it can cause a corrupted configuration.
- Ensure that all nodes in the cluster are online.
- Ensure that the group is online and owned by the node where the initial server instance is installed.

Procedure

To prepare a resource group for cluster configuration, complete the following steps:

1. Open the Failover Cluster Manager program. Right-click Services and Applications and then choose More Actions > Create Empty Service or Application.
2. Right-click New Service or Application, select Change the name and choose a new name for the resource group such as TSMGROUP.
3. Right-click the resource group TSMGROUP and select Add storage.
4. On the Add storage area panel, select the shared volume or volumes for IBM Spectrum Protect and click OK. The resource group TSMGROUP, which contains the disk volumes you just added, is displayed.

Windows

Installing IBM Spectrum Protect in a Microsoft Failover Cluster

Install the IBM Spectrum Protect™ server on every node in the cluster that hosts an IBM Spectrum Protect clustered server.

Procedure

Complete the following steps for each node in your cluster to install the IBM Spectrum Protect server:

1. Log in with an administrator or domain user ID. The domain user must be a member of the Domain Administrators group.
2. Install the IBM Spectrum Protect server to a local disk on each node. Use the same local disk drive letter for each node.
3. Restart the system after the server installation completes.

Windows

Initializing the IBM Spectrum Protect server for a Microsoft Failover Cluster on the primary node

After you install IBM Spectrum Protect™ on the nodes in the cluster, you must initialize the server on the primary node.

Procedure

1. Ensure that all systems are restarted after the installation. Verify that all systems are running correctly.
2. Log in with an administrator or domain user ID. The domain user must be in the same domain as the IBM Spectrum Protect server.
3. Open the Failover Cluster Manager program and verify that the resources are online and available to the primary node.

4. Begin the initialization procedure on the primary node in your cluster. In the Failover Cluster Manager program, verify that the owner of the resource group is the primary node in your cluster.
5. From the Start menu, click All programs > IBM Spectrum Protect server > Configuration wizard.
6. Follow the wizard directions, clicking Next to step through the wizard. When you are prompted to enter the user ID, enter the name of the domain account to associate with the cluster.
7. If the initialization completed, click Done.

Windows

Verifying the configuration of IBM Spectrum Protect in a Microsoft Failover Cluster

When you finish configuring IBM Spectrum Protect™ in a Microsoft Failover Cluster, you can review the Failover Cluster Manager summary window. Verify that clustering is completed successfully and the IBM Spectrum Protect server is started.

Procedure

To verify that the IBM Spectrum Protect server instance in a Microsoft Failover Cluster is created and configured correctly, complete the following steps:

1. From the Failover Cluster Manager, select the server instance. The network name that you configured is displayed in the Server Name pane.
2. In the Other Resources pane, confirm that the server instance and the IBM® DB2® server resource are displayed.
3. Right-click the IBM Spectrum Protect server instance and select Bring this resource online.

Windows

Completing a failover test for your cluster

After you complete the cluster configuration, run a failover test to ensure that the nodes are working properly.

Procedure

1. Open Failover Cluster Manager. Under Other Resources, right-click the IBM Spectrum Protect™ Instance(x) resource. Select Bring this resource online.
2. To test the failover, right-click the IBM Spectrum Protect cluster resource group and select Move this service or application to another node.
3. Verify that the failover from the second node to the first node completes successfully.

Windows

Maintaining the clustered environment

After you set up your initial cluster or clusters, maintenance needs are minimal.

Check your Windows Event log on a regular, if not daily, basis to monitor the activity of the nodes in the cluster. Use the log to check whether a node fails and needs maintenance.

The following list of topics describes situations that might affect the configuration or format of your cluster after it is operational.

- Windows Migrating an existing IBM Spectrum Protect server into a cluster
  The reason for moving client data into a cluster is similar to the reason for adding a server to a cluster. You want to increase the availability and reliability of data to all your users. By having the server as part of the cluster, you provide an extra level of security by ensuring that no transactions are missed due to a failed server. The failover pattern that you establish prevents future failures.
- Windows Adding an IBM Spectrum Protect server with backup and restore
  If your hardware resources are limited, you can add an existing IBM Spectrum Protect server to a cluster by using a backup and restore procedure.
- Windows Managing a virtual IBM Spectrum Protect server on a cluster
  For most tasks, you can administer a virtual IBM Spectrum Protect server as you would a non-clustered server. To complete

tasks such as starting and stopping the server or moving a resource group to another node to complete system maintenance, you must use the Microsoft Cluster Administrator interface.

- Windows Managing tape failover in a cluster
  As part of your regular routine, check the event log to ensure that the configuration is operating properly. If a server fails, the error is logged. The log provides you with information to understand why the failure took place.
- Windows Troubleshooting with IBM Spectrum Protect cluster log
  The IBM Spectrum Protect Cluster Resource DLL reports events and errors to the cluster log. The cluster log is a useful troubleshooting tool. When this log is enabled, it records the actions of each component of the Cluster service as the result of each action.

Windows

Migrating an existing IBM Spectrum Protect server into a cluster

The reason for moving client data into a cluster is similar to the reason for adding a server to a cluster. You want to increase the availability and reliability of data to all your users. By having the server as part of the cluster, you provide an extra level of security by ensuring that no transactions are missed due to a failed server. The failover pattern that you establish prevents future failures.

About this task

To migrate an existing IBM Spectrum Protect™ server into a cluster, you can either move the clients or complete a backup and restore procedure. The choice depends primarily on the availability and capacity of other IBM Spectrum Protect server computers in your site and your familiarity with the backup and restore procedure.

- Windows Moving the clients
  If you move clients from a non-clustered IBM Spectrum Protect server computer to a clustered one, you can slowly move your users to the new system and not interrupt services. However, you must have the correct hardware to run two IBM Spectrum Protect servers simultaneously.

Related tasks:
Installing and upgrading the server
Windows

Adding an IBM Spectrum Protect server with backup and restore

If your hardware resources are limited, you can add an existing IBM Spectrum Protect™ server to a cluster by using a backup and restore procedure.

About this task

For example, suppose that you have no hardware other than the two server systems to be clustered. You plan to use the computer that is running the IBM Spectrum Protect server as a node. Complete this procedure to remove IBM Spectrum Protect from the computer and reinstall it in the cluster:

Procedure

1. Back up all disk storage pools to a copy storage pool.
2. Back up the database of the existing IBM Spectrum Protect server.
3. Perform the installation and configuration of the cluster.
4. Restore the database to the clustered IBM Spectrum Protect server.
5. Restore the disk storage pool volumes from the copy storage pool.
6. After you verify that all of your data is on the clustered server, delete the old server.

Windows

Managing a virtual IBM Spectrum Protect server on a cluster

For most tasks, you can administer a virtual IBM Spectrum Protect™ server as you would a non-clustered server. To complete tasks such as starting and stopping the server or moving a resource group to another node to complete system maintenance, you must use the Microsoft Cluster Administrator interface.

About this task

The Microsoft Cluster Administrator interface is available through the Administrative Tools program group. The interface is a detailed view of a virtual server configuration. The virtual server configuration includes details such as the physical Windows servers that are part of the cluster and their resources, network connections, and status. View the components of a virtual server configuration and start, stop, or fail back a virtual server by using this interface. Manage a virtual IBM Spectrum Protect server by using the Microsoft Cluster Administrator interface to avoid server failures and error messages. For example, if you use the Windows Service Control Manager to shut down the server, you might receive messages that the server failed.

You might want to move a virtual IBM Spectrum Protect server when the Windows server acts as the primary node and this server requires hardware or system maintenance. Use the Microsoft Cluster Administrator interface to move the management of the virtual IBM Spectrum Protect server to the secondary node until the maintenance is completed.

Windows

Managing tape failover in a cluster

As part of your regular routine, check the event log to ensure that the configuration is operating properly. If a server fails, the error is logged. The log provides you with information to understand why the failure took place.

About this task

Sometimes a node must rejoin the cluster, for example:

- When a node failed
- When a new Host Bus Adapter fiber card is added (equipment changes)

Procedure

Complete the following tasks in any order to ensure that a node can successfully join the cluster:

- Update, if necessary, the drive and library that use the IBM Spectrum Protect™ cluster tool.
- Take the IBM Spectrum Protect server offline until the failed node rejoins the cluster. This action helps ensure that the IBM Spectrum Protect server that is running on the other node is not affected.

Windows

Troubleshooting with IBM Spectrum Protect cluster log

The IBM Spectrum Protect™ Cluster Resource DLL reports events and errors to the cluster log. The cluster log is a useful troubleshooting tool. When this log is enabled, it records the actions of each component of the Cluster service as the result of each action.

In comparison with the Microsoft Windows Event Log, the cluster log is a complete record of cluster activity. The cluster log records the cluster service activity that is recorded in the event log. Although the event log can point you to a problem, the cluster log helps you resolve the problem.

The cluster log is enabled by default in Windows. Its output is printed as a log file in %SystemRoot%\Cluster. For more information, see the Windows online help documentation.

Configuring clients for applications, virtual machines, and systems

The server protects data for clients, which can include applications, virtual machines, and systems. To start protecting client data, register the client node with the server and select a backup schedule to protect the client data.

- Adding clients
  After you implement a data protection solution with IBM Spectrum Protect™, you can expand the solution by adding clients.
- Customizing policies
  An organization's goals for how data is protected and retained are typically defined by corporate executives, legal advisors, or other people in lead roles. *Policies* are the means to align the operation of IBM Spectrum Protect with the data protection and retention goals of your organization.

Adding clients

After you implement a data protection solution with IBM Spectrum Protect™, you can expand the solution by adding clients.

About this task

The procedure describes basic steps for adding a client. For more specific instructions about configuring clients, see the documentation for the product that you install on the client node. You can have the following types of client nodes:

Application client nodes
: Application client nodes include email servers, databases, and other applications. For example, any of the following applications can be an application client node:

  - IBM Spectrum Protect Snapshot
  - IBM Spectrum Protect for Databases
  - IBM Spectrum Protect for Enterprise Resource Planning
  - IBM Spectrum Protect for Mail
  - IBM Spectrum Protect for Virtual Environments

System client nodes
: System client nodes include workstations, network-attached storage (NAS) file servers, and API clients.

Virtual machine client nodes
: Virtual machine client nodes consist of an individual guest host within a hypervisor. Each virtual machine is represented as a file space.

Procedure

To add a client, complete the following steps:

1. Select the software to install on the client node and plan the installation. Follow the instructions in Selecting the client software and planning the installation.
2. Specify how to back up and archive client data. Follow the instructions in Specifying rules for backing up and archiving client data.
3. Specify when to back up and archive client data. Follow the instructions in Scheduling backup and archive operations.
4. To allow the client to connect to the server, register the client. Follow the instructions in Registering clients.
5. To start protecting a client node, install and configure the selected software on the client node. Follow the instructions in Installing and configuring clients.

Selecting the client software and planning the installation

Different types of data require different types of protection. Identify the type of data that you must protect and select the appropriate software.

About this task

The preferred practice is to install the backup-archive client on all client nodes so that you can configure and start the client acceptor on the client node. The client acceptor is designed to efficiently run scheduled operations.

The client acceptor runs schedules for the following products: the backup-archive client, IBM Spectrum Protect™ for Databases, IBM Spectrum Protect for Enterprise Resource Planning, IBM Spectrum Protect for Mail, and IBM Spectrum Protect for Virtual Environments. If you install a product for which the client acceptor does not run schedules, you must follow the configuration instructions in the product documentation to ensure that scheduled operations can occur.

Procedure

Based on your goal, select the products to install and review the installation instructions.
Tip: If you install the client software now, you must also complete the client configuration tasks that are described in Installing and configuring clients before you can use the client.

Goal	Product and description	Installation instructions

Goal	Product and description	Installation instructions
Protect a file server or workstation	The backup-archive client backs up and archives files and directories from file servers and workstations to storage. You can also restore and retrieve backup versions and archived copies of files.	• Backup-archive client requirements • Installing the UNIX and Linux backup-archive clients • Installing the Windows backup-archive client
Protect applications with snapshot backup and restore capabilities	IBM Spectrum Protect Snapshot protects data with integrated, application-aware snapshot backup and restore capabilities. You can protect data that is stored by IBM DB2® database software and SAP, Oracle, Microsoft Exchange, and Microsoft SQL Server applications.	• Installing and upgrading IBM Spectrum Protect Snapshot for UNIX and Linux • Installing and upgrading IBM Spectrum Protect Snapshot for VMware • Installing and upgrading IBM Spectrum Protect Snapshot for Windows
Protect an email application on an IBM Domino® server	IBM Spectrum Protect for Mail: Data Protection for IBM® Domino automates data protection so that backups are completed without shutting down IBM Domino servers.	• Installation of Data Protection for IBM Domino on a UNIX, AIX, or Linux system (V7.1.0) • Installation of Data Protection for IBM Domino on a Windows system (V7.1.0)
Protect an email application on a Microsoft Exchange server	IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server automates data protection so that backups are completed without shutting down Microsoft Exchange servers.	Installing, upgrading, and migrating IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server
Protect an IBM DB2 database	The application programming interface (API) of the backup-archive client can be used to back up DB2 data to the IBM Spectrum Protect server.	Installing the IBM Spectrum Protect backup-archive clients (UNIX, Linux, and Windows)
Protect an IBM Informix® database	The API of the backup-archive client can be used to back up Informix data to the IBM Spectrum Protect server.	Installing the IBM Spectrum Protect backup-archive clients (UNIX, Linux, and Windows)
Protect a Microsoft SQL database	IBM Spectrum Protect for Databases: Data Protection for Microsoft SQL Server protects Microsoft SQL data.	Installing Data Protection for SQL Server on Windows Server Core
Protect an Oracle database	IBM Spectrum Protect for Databases: Data Protection for Oracle protects Oracle data.	Data Protection for Oracle installation
Protect an SAP environment	IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP provides protection that is customized for SAP environments. The product is designed to improve the availability of SAP database servers and reduce administration workload.	• Installing IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for DB2 • Installing IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for Oracle

Goal	Product and description	Installation instructions
Protect a virtual machine	IBM Spectrum Protect for Virtual Environments provides protection that is tailored for Microsoft Hyper-V and VMware virtual environments. You can use IBM Spectrum Protect for Virtual Environments to create incremental forever backups that are stored on a centralized server, create backup policies, and restore virtual machines or individual files. Alternatively, use the backup-archive client to back up and restore a full VMware or Microsoft Hyper-V virtual machine. You can also back up and restore files or directories from a VMware virtual machine.	• Installing Data Protection for Microsoft Hyper-V • Installing and upgrading Data Protection for VMware • Installing the IBM Spectrum Protect backup-archive clients (UNIX, Linux, and Windows)

Tip: To use the client for space management, you can install IBM Spectrum Protect for Space Management or IBM Spectrum Protect HSM for Windows.

Specifying rules for backing up and archiving client data

Before you add a client, ensure that appropriate rules are specified for backing up and archiving the client data. During the client registration process, you assign the client node to a policy domain, which has the rules that control how and when client data is stored.

Before you begin

Determine how to proceed:

- If you are familiar with the policies that are configured for your solution and you know that they do not require changes, continue with Scheduling backup and archive operations.
- If you are not familiar with the policies, follow the steps in this procedure.

About this task

Policies affect how much data is stored over time, and how long data is retained and available for clients to restore. To meet objectives for data protection, you can update the default policy and create your own policies. A policy includes the following rules:

- How and when files are backed up and archived to server storage
- The number of copies of a file and the length of time copies are kept in server storage

During the client registration process, you assign a client to a *policy domain*. The policy for a specific client is determined by the rules in the policy domain to which the client is assigned. In the policy domain, the rules that are in effect are in the active *policy set*.

When a client backs up or archives a file, the file is bound to a management class in the active policy set of the policy domain. A *management class* is the key set of rules for managing client data. The backup and archive operations on the client use the settings in the default management class of the policy domain unless you further customize policy. A policy can be customized by defining more management classes and assigning their use through client options.

Client options can be specified in a local, editable file on the client system and in a client option set on the server. The options in the client option set on the server can override or add to the options in the local client option file.

Procedure

1. Review the policies that are configured for your solution by following the instructions in Viewing policies.
2. If you need to make minor changes to meet data retention requirements, follow the instructions in Editing policies.
3. Optional: If you need to create policy domains or make extensive changes to policies to meet data retention requirements, see Customizing policies.

Viewing policies

View policies to determine whether they must be edited to meet your requirements.

Procedure

1. To view the active policy set for a policy domain, complete the following steps:
   a. On the Services page of the Operations Center, select a policy domain and click Details.
   b. On the Summary page for the policy domain, click the Policy Sets tab.
2. To view inactive policy sets for a policy domain, complete the following steps:
   a. On the Policy Sets page, click the Configure toggle. You can now view and edit the policy sets that are inactive.
   b. Scroll through the inactive policy sets by using the forward and back arrows. When you view an inactive policy set, the settings that differentiate the inactive policy set from the active policy set are highlighted.
   c. Click the Configure toggle. The policy sets are no longer editable.

Editing policies

To change the rules that apply to a policy domain, edit the active policy set for the policy domain. You can also activate a different policy set for a domain.

Before you begin

Changes to policy can affect data retention. Ensure that you continue to back up data that is essential to your organization so that you can restore that data if a disaster occurs. Also, ensure that your system has sufficient storage space for planned backup operations.

About this task

You edit a policy set by changing one or more management classes within the policy set. If you edit the active policy set, the changes are not available to clients unless you reactivate the policy set. To make the edited policy set available to clients, activate the policy set.

Although you can define multiple policy sets for a policy domain, only one policy set can be active. When you activate a different policy set, it replaces the currently active policy set.

To learn about preferred practices for defining policies, see Customizing policies.

Procedure

1. On the Services page of the Operations Center, select a policy domain and click Details.
2. On the Summary page for the policy domain, click the Policy Sets tab.

   The Policy Sets page indicates the name of the active policy set and lists all of the management classes for that policy set.

3. Click the Configure toggle. The policy set is editable.
4. Optional: To edit a policy set that is not active, click the forward and back arrows to locate the policy set.
5. Edit the policy set by completing any of the following actions:

Option	Description
Add a management class	a. In the Policy Sets table, click +Management Class. b. To specify the rules for backing up and archiving data, complete the fields in the Add Management Class window. c. To make the management class the default management class, select the Make default check box. d. Click Add.
Delete a management class	In the Management Class column, click -. Tip: To delete the default management class, you must first assign a different management class as the default.

Option	Description
Make a management class the default management class	In the Default column for the management class, click the radio button. Tip: The default management class manages client files when another management class is not assigned to, or appropriate for managing, a file. To ensure that clients can always back up and archive files, choose a default management class that contains rules for both backing up and archiving files.
Modify a management class	To change the properties of a management class, update the fields in the table.

6. Click Save.
   Attention: When you activate a new policy set, data might be lost. Data that is protected under one policy set might not be protected under another policy set. Therefore, before you activate a policy set, ensure that the differences between the previous policy set and the new policy set do not cause data to be lost.
7. Click Activate. A summary of the differences between the active policy set and the new policy set is displayed. Ensure that the changes in the new policy set are consistent with your data retention requirements by completing the following steps:
   a. Review the differences between corresponding management classes in the two policy sets, and consider the consequences for client files. Client files that are bound to management classes in the active policy set will be bound to the management classes with the same names in the new policy set.
   b. Identify management classes in the active policy set that do not have counterparts in the new policy set, and consider the consequences for client files. Client files that are bound to these management classes will be managed by the default management class in the new policy set.
   c. If the changes to be implemented by the policy set are acceptable, select the I understand that these updates can cause data loss check box and click Activate.

Scheduling backup and archive operations

Before you register a new client with the server, ensure that a schedule is available to specify when backup and archive operations take place. During the registration process, you assign a schedule to the client.

Before you begin

Determine how to proceed:

- If you are familiar with the schedules that are configured for the solution and you know that they do not require modification, continue with Registering clients.
- If you are not familiar with the schedules or the schedules require modification, follow the steps in this procedure.

About this task

Typically, backup operations for all clients must be completed daily. Carefully schedule client and server workloads to achieve the best performance for your storage environment. To avoid the overlap of client and server operations, consider scheduling client backup and archive operations so that they run at night. If client and server operations overlap or are not given enough time and resources to be processed, you might experience decreased system performance, failed operations, and other issues.

Procedure

1. Review available schedules by hovering over Clients on the Operations Center menu bar. Click Schedules.
2. Optional: Modify or create a schedule by completing the following steps:

Option	Description
Modify a schedule	a. In the Schedules view, select the schedule and click Details. b. On the Schedule Details page, view details by clicking the blue arrows at the beginning of the rows. c. Modify the settings in the schedule, and click Save.
Create a schedule	In the Schedules view, click +Schedule and complete the steps to create a schedule.

3. Optional: To configure schedule settings that are not visible in the Operations Center, use a server command. For example, you might want to schedule a client operation that backs up a specific directory and assigns it to a management class other than the default.
   a. On the Overview page of the Operations Center, hover over the settings icon and click Command Builder.

b. Issue the DEFINE SCHEDULE command to create a schedule or the UPDATE SCHEDULE command to modify a schedule. For details about the commands, see DEFINE SCHEDULE (Define a schedule for an administrative command) or UPDATE SCHEDULE (Update a client schedule).

Related tasks:
Tuning the schedule for daily operations

Registering clients

Register a client to ensure that the client can connect to the server, and the server can protect client data.

Before you begin

Determine whether the client requires an administrative user ID with client owner authority over the client node. To determine which clients require an administrative user ID, see technote 7048963.
Restriction: For some types of clients, the client node name and the administrative user ID must match. You cannot authenticate those clients by using the Lightweight Directory Access Protocol authentication method that was introduced in V7.1.7. For details about this authentication method, sometimes referred to as integrated mode, see Authenticating users by using an Active Directory database.

Procedure

To register a client, complete one of the following actions.

- If the client requires an administrative user ID, register the client by using the REGISTER NODE command and specify the USERID parameter:

  ```
  register node node_name password userid=node_name
  ```

  where *node_name* specifies the node name and *password* specifies the node password. For details, see Register a node.
- If the client does not require an administrative user ID, register the client by using the Operations Center Add Client wizard. Complete the following steps:
  a. On the Operations Center menu bar, click Clients.
  b. In the Clients table, click +Client.
  c. Complete the steps in the Add Client wizard:
     i. Specify that redundant data can be eliminated on both the client and server. In the Client-side data deduplication area, select the Enable check box.
     ii. In the Configuration window, copy the TCPSERVERADDRESS, TCPPORT, NODENAME, and DEDUPLICATION option values.
     Tip: Record the option values and keep them in a safe place. After you complete the client registration and install the software on the client node, use the values to configure the client.
     iii. Follow the instructions in the wizard to specify the policy domain, schedule, and option set.
     iv. Set how risks are displayed for the client by specifying the at-risk setting.
     v. Click Add Client.

Installing and configuring clients

To start protecting a client node, you must install and configure the selected software.

Procedure

If you already installed the software, start at step 2.

1. Take one of the following actions:
   - To install software on an application or client node, follow the instructions.

Software	Link to instructions
IBM Spectrum Protect™ backup-archive client	■ Installing the UNIX and Linux backup-archive clients ■ Installing the Windows backup-archive client For information about manual deployment of client updates from the server, see the following documents: ■ For IBM Spectrum Protect 8.1.2 or later servers, see technote 2004596. ■ For IBM® Tivoli® Storage Manager V7.1 servers and IBM Spectrum Protect V8.1.0 and V8.1.1 servers, see technote 1673299.
IBM Spectrum Protect for Databases	■ Data Protection for Oracle installation ■ Installing Data Protection for SQL Server on Windows Server Core
IBM Spectrum Protect for Mail	■ Installation of Data Protection for IBM Domino on a UNIX, AIX, or Linux system (V7.1.0) ■ Installation of Data Protection for IBM Domino on a Windows system (V7.1.0) ■ Installing, upgrading, and migrating IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server
IBM Spectrum Protect Snapshot	■ Installing and upgrading IBM Spectrum Protect Snapshot for UNIX and Linux ■ Installing and upgrading IBM Spectrum Protect Snapshot for VMware ■ Installing and upgrading IBM Spectrum Protect Snapshot for Windows
IBM Spectrum Protect for Enterprise Resource Planning	■ Installing IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for DB2® ■ Installing IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for Oracle

- To install software on a virtual machine client node, follow the instructions for the selected backup type.

Backup type	Link to instructions
If you plan to create full VMware backups of virtual machines, install and configure the IBM Spectrum Protect backup-archive client.	■ Installing the UNIX and Linux backup-archive clients ■ Installing the Windows backup-archive client
If you plan to create incremental forever full backups of virtual machines, install and configure IBM Spectrum Protect for Virtual Environments and the backup-archive client on the same client node or on different client nodes.	■ IBM Spectrum Protect for Virtual Environments online product documentation Tip: You can obtain the software for IBM Spectrum Protect for Virtual Environments and the backup-archive client in the IBM Spectrum Protect for Virtual Environments installation package.

2. To allow the client to connect to the server, add or update the values for the TCPSERVERADDRESS, TCPPORT, and NODENAME options in the client options file. Use the values that you recorded when you registered the client (Registering clients).
   - For clients that are installed on an AIX®, Linux, Mac OS X, or Oracle Solaris operating system, add the values to the client system-options file, dsm.sys.
   - For clients that are installed on a Windows operating system, add the values to the dsm.opt file.

   By default, the options files are in the installation directory.
3. If you installed a backup-archive client on a Linux or Windows operating system, install the client management service on the client. Follow the instructions in Collecting diagnostic information with client management services.
4. Configure the client to run scheduled operations. Follow the instructions in Configuring the client to run scheduled operations.
5. Optional: Configure communications through a firewall. Follow the instructions in Configuring client/server communications through a firewall.
6. Run a test backup to verify that data is protected as you planned. For example, for a backup-archive client, complete the following steps:
   a. On the Clients page of the Operations Center, select the client that you want to back up, and click Back Up.
   b. Verify that the backup completes successfully and that there are no warning or error messages.
7. Monitor the results of the scheduled operations for the client in the Operations Center.

What to do next

If you need to change what is getting backed up from the client, follow the instructions in Modifying the scope of a client backup.

Configuring the client to run scheduled operations

You must configure and start a client scheduler on the client node. The client scheduler enables communication between the client and server so that scheduled operations can occur. For example, scheduled operations typically include backing up files from a client.

About this task

The preferred method is to install the backup-archive client on all client nodes so that you can configure and start the client acceptor on the client node. The client acceptor is designed to efficiently run scheduled operations. The client acceptor manages the client scheduler so that the scheduler runs only when required:

- When it is time to query the server about the next scheduled operation
- When it is time to start the next scheduled operation

By using the client acceptor, you can reduce the number of background processes on the client and help to avoid memory retention problems.

The client acceptor runs schedules for the following products: the backup-archive client, IBM Spectrum Protect™ for Databases, IBM Spectrum Protect for Enterprise Resource Planning, IBM Spectrum Protect for Mail, and IBM Spectrum Protect for Virtual Environments. If you installed a product for which the client acceptor does not run schedules, follow the configuration instructions in the product documentation to ensure that scheduled operations can occur.

If your business uses a third-party scheduling tool as standard practice, you can use that scheduling tool as an alternative to the client acceptor. Typically, third-party scheduling tools start client programs directly by using operating system commands. To configure a third-party scheduling tool, see the product documentation.

Procedure

To configure and start the client scheduler by using the client acceptor, follow the instructions for the operating system that is installed on the client node:

AIX® and Oracle Solaris

a. From the backup-archive client GUI, click Edit > Client Preferences.
b. Click the Web Client tab.
c. In the Managed Services Options field, click Schedule. If you also want the client acceptor to manage the web client, click the Both option.
d. To ensure that the scheduler can start unattended, in the dsm.sys file, set the passwordaccess option to `generate`.
e. To store the client node password, issue the following command and enter the client node password when prompted:

```
dsmc query sess
```

f. Start the client acceptor by issuing the following command on the command line:

```
/usr/bin/dsmcad
```

g. To enable the client acceptor to start automatically after a system restart, add the following entry to the system startup file (typically, /etc/inittab):

```
tsm::once:/usr/bin/dsmcad > /dev/null 2>&1 # Client Acceptor Daemon
```

Linux

a. From the backup-archive client GUI, click Edit > Client Preferences.
b. Click the Web Client tab.
c. In the Managed Services Options field, click Schedule. If you also want the client acceptor to manage the web client, click the Both option.
d. To ensure that the scheduler can start unattended, in the dsm.sys file, set the passwordaccess option to `generate`.

e. To store the client node password, issue the following command and enter the client node password when prompted:

```
dsmc query sess
```

f. Start the client acceptor by logging in with the root user ID and issuing the following command:

```
service dsmcad start
```

g. To enable the client acceptor to start automatically after a system restart, add the service by issuing the following command at a shell prompt:

```
# chkconfig --add dsmcad
```

MAC OS X

a. In the backup-archive client GUI, click Edit > Client Preferences.
b. To ensure that the scheduler can start unattended, click Authorization, select Password Generate, and click Apply.
c. To specify how services are managed, click Web Client, select Schedule, click Apply, and click OK.
d. To ensure that the generated password is saved, restart the backup-archive client.
e. Use the IBM Spectrum Protect Tools for Administrators application to start the client acceptor.

Windows

a. In the backup-archive client GUI, click Utilities > Setup Wizard > Help me configure the Client Scheduler. Click Next.
b. Read the information on the Scheduler Wizard page and click Next.
c. On the Scheduler Task page, select Install a new or additional scheduler and click Next.
d. On the Scheduler Name and Location page, specify a name for the client scheduler that you are adding. Then, select Use the Client Acceptor daemon (CAD) to manage the scheduler and click Next.
e. Enter the name that you want to assign to this client acceptor. The default name is Client Acceptor. Click Next.
f. Complete the configuration by stepping through the wizard.
g. Update the client options file, dsm.opt, and set the passwordaccess option to generate.
h. To store the client node password, issue the following command at the command prompt:

```
dsmc query sess
```

Enter the client node password when prompted.
i. Start the client acceptor service from the Services Control page. For example, if you used the default name, start the Client Acceptor service. Do not start the scheduler service that you specified on the Scheduler Name and Location page. The scheduler service is started and stopped automatically by the client acceptor service as needed.

Configuring client/server communications through a firewall

If a client must communicate with a server through a firewall, you must enable client/server communications through the firewall.

Before you begin

If you used the Add Client wizard to register a client, find the option values in the client options file that you obtained during that process. You can use the values to specify ports.

About this task

Attention: Do not configure a firewall in a way that might cause termination of sessions that are in use by a server or storage agent. Termination of a valid session can cause unpredictable results. Processes and sessions might appear to stop due to input/output errors. To help exclude sessions from timeout restrictions, configure known ports for IBM Spectrum Protect™ components. Ensure that the KEEPALIVE server option remains set to the default value of YES. In this way, you can help to ensure that client/server communication is uninterrupted. For instructions about setting the KEEPALIVE server option, see KEEPALIVE.

Procedure

Open the following ports to allow access through the firewall:

TCP/IP port for the backup-archive client, command-line administrative client, and the client scheduler

Specify the port by using the tcpport option in the client options file. The tcpport option in the client options file must match the TCPPORT option in the server options file. The default value is 1500. If you decide to use a value other than the default, specify a number in the range 1024 - 32767.

HTTP port to enable communication between the web client and remote workstations
Specify the port for the remote workstation by setting the httpport option in the client options file of the remote workstation. The default value is 1581.

TCP/IP ports for the remote workstation
The default value of 0 (zero) causes two free port numbers to be randomly assigned to the remote workstation. If you do not want the port numbers to be randomly assigned, specify values by setting the webports option in the client options file of the remote workstation.

TCP/IP port for administrative sessions
Specify the port on which the server waits for requests for administrative client sessions. The value of the client tcpadminport option must match the value of the TCPADMINPORT server option. In this way, you can secure administrative sessions within a private network.

Customizing policies

An organization's goals for how data is protected and retained are typically defined by corporate executives, legal advisors, or other people in lead roles. *Policies* are the means to align the operation of IBM Spectrum Protect™ with the data protection and retention goals of your organization.

About this task

To automatically manage data protection and retention, you define policies, which are rules that you set on the server. Policies affect how much data is stored over time, and how long data is retained and available for clients to restore. Customize policies to meet the data protection goals for your organization.

You choose the policy that manages a client's data by assigning the client to a policy domain. Clients of different types have different retention requirements, and customizing and creating policies is typically necessary.

When a server is installed, by default it has one policy, in one policy domain. You can customize that policy and create your own policy.

- Policy concepts
  The policy for a specific client is determined by the settings in the policy domain to which a client is added.
- Customizing a policy
  You can customize existing policies to meet new or revised data retention requirements for your organization. Modifying a policy domain or copying an existing policy domain is a typical way to start customizing policy.
- Creating a policy by copying an existing policy
  You can create new policies by copying an existing policy and then updating the parts that you want to change.
- Creating a policy domain
  You might want to create a new policy domain for each type of client that is protected by the server. You might also want to divide responsibilities for clients among several administrators by giving them authority for specific policy domains.
- Controlling client operations through client option sets
  You can use client option sets to centrally control the processing options that clients use for operations such as backup. Client option sets can help ensure that data is consistently protected according to your requirements. A client option set can override options in a local client options file, and can add options that might not be in a local client options file.

Policy concepts

The policy for a specific client is determined by the settings in the policy domain to which a client is added.

During the client registration process, you assign a client to a *policy domain*. The policy for each client is determined by the rules in the policy domain to which the client is assigned. In the policy domain, the rules that are in effect are in the active *policy set*.

When a client backs up or archives a file, the file is bound to a management class in the active policy set of the policy domain. A *management class* is the key set of rules for managing client data. The backup and archive operations on the client use the settings in the default management class of the policy domain unless you customize policy.

A policy can be customized by defining more management classes in the policy set, activating the policy set, and assigning the use of the new management classes through client options.

Client options can be specified in a local, editable file on the client system and in a client option set on the server. The options in the client option set on the server can override or add to the options in the local client option file.

The server uses the policy in management classes to manage files based on whether file versions are active or inactive. The most recent backup or archived copy of a file is the *active version*. Active versions are never deleted from server storage.

Backup versions other than the most recent version are called *inactive versions*. An active version of a file becomes inactive when one of the following events occur:

- The file is backed up again, creating a more recent version of the file in server storage.
- The file is deleted from storage on the client node and then an incremental backup operation runs. An *incremental backup*, the typical backup operation for a client, backs up only those files that changed since the last backup.

The settings in the management class that is bound to a file determine how long and how many inactive versions of the file are retained.

Expiration processing uses policies to determine when inactive versions are no longer needed, that is, when the versions are expired. The process of expiration on the server enforces policies that you define for data retention, and you must ensure that you schedule expiration to run regularly. For example, if you have a policy that requires only four versions of a file be kept, the fifth and oldest version is expired. During expiration processing, the server removes entries for expired versions from the database, which in effect deletes the versions from server storage.

- Retention and expiration of backup versions
  Multiple versions of file backups are important because users can continually update files and might need to restore a file from different points in time. Policy settings control the backup versions that the server retains in server storage, and affects what users can restore.
- Policy activation after updates
  When you make updates to policy, the updates do not go into effect until you activate the policy set that you updated.

Related concepts:
Full incremental backup and partial incremental backup

Retention and expiration of backup versions

Multiple versions of file backups are important because users can continually update files and might need to restore a file from different points in time. Policy settings control the backup versions that the server retains in server storage, and affects what users can restore.

You can specify the versions that the server retains in server storage with settings in the management class:

- Specify the number of days to keep backup versions.
  You specify the number of days to keep backup versions with settings in the Operations Center:
  - Keep Extra Backups, which is how many days to keep inactive backup versions. The days are counted from the day that the version becomes inactive.

    If you use commands, use the DEFINE COPYGROUP command with the RETEXTRA parameter.

  - Keep Deleted Backups, which is how many days to keep the last backup version of a file that is deleted from the client file system.

    If you use commands, use the DEFINE COPYGROUP command with the RETONLY parameter.

- Specify the number of versions to keep.
  You specify the number of backup versions to keep with settings in the Operations Center:
  - Backups, which is the number of versions to keep of a file that still exists on the client file system.

    If you use commands, use the DEFINE COPYGROUP command with the VEREXISTS parameter.

  - Deleted Backups, which is the number of versions to keep of a file that is deleted from the client file system.

    If you use commands, use the DEFINE COPYGROUP command with the VERDELETED parameter.

- Specify a combination of the number of versions and the days to keep them.

The settings interact to determine the backup versions that the server retains. Ensure that you understand which settings take precedence and what interactions can occur:

- When the number of inactive backup versions exceeds the number in the Backups and Deleted Backups settings, the oldest version expires and the server deletes the version from the database the next time expiration processing runs.
- The number of inactive versions that the server keeps is also affected by the Keep Extra Backups setting. Inactive versions expire when the number of days that they are inactive exceeds the value that is specified for retaining extra versions, even when the number of versions is not exceeded.

- File expiration and expiration processing
  Files expire as they exceed the retention criteria that is specified in the policy. Expiration processing on the server removes expired files from the server database and the files are deleted from server storage.
- Example: Retention when a policy uses only time controls
  The simplest way to manage data retention is to use only time-based policy controls. With only time-based controls in the policy, the file versions are retained based on the days since the versions become inactive.
- Example: Retention when a policy uses both version and time controls
  Using both the version and the time controls in a policy gives you flexibility in managing data retention but also causes complexity. To understand the interactions among the controls, review example policies and their effects on the retention of one file's backup versions during one month.
- Interactions among policy settings
  Time-based and version-based policy settings interact when used together in a management class for a policy. The frequency of client backups also affects the backup versions that are stored for a client.

File expiration and expiration processing

Files expire as they exceed the retention criteria that is specified in the policy. Expiration processing on the server removes expired files from the server database and the files are deleted from server storage.

Files expire under the following conditions:

- Users delete file spaces from client nodes
- Users expire files by using the EXPIRE command on the client
- A backup version of a file exceeds the criteria for backup retention (how long a file is kept and how many inactive versions of a file are kept)
- An archived file exceeds the time criteria for retention of archived files (how long archived copies are kept)
- A backup set exceeds the retention time that is specified for the backup set

The server deletes expired files from the server database only during expiration processing. After expired files are deleted from the database, the server can reuse the space in the storage pools that was occupied by expired files. Ensure that expiration processing runs periodically to allow the server to reuse space.

Restrictions on expiration processing

The use of some functions affects expiration processing.

Replication
: If you are using dissimilar policies on the source and target servers, files that are marked for immediate expiration on the source replication server are not deleted until they are replicated to the target replication server. If you are not using dissimilar policies, files that are marked for immediate expiration on the source replication server are deleted immediately.

  For the target replication server, if files are marked as expired, they are deleted when the target replication server runs expiration processing.

Event-based retention for archive data
: An archive file is not eligible for expiration if there is a deletion hold on it. If a file is not held, it is handled according to existing expiration processing.

Related tasks:
Expiration/deletion hold and release

Example: Retention when a policy uses only time controls

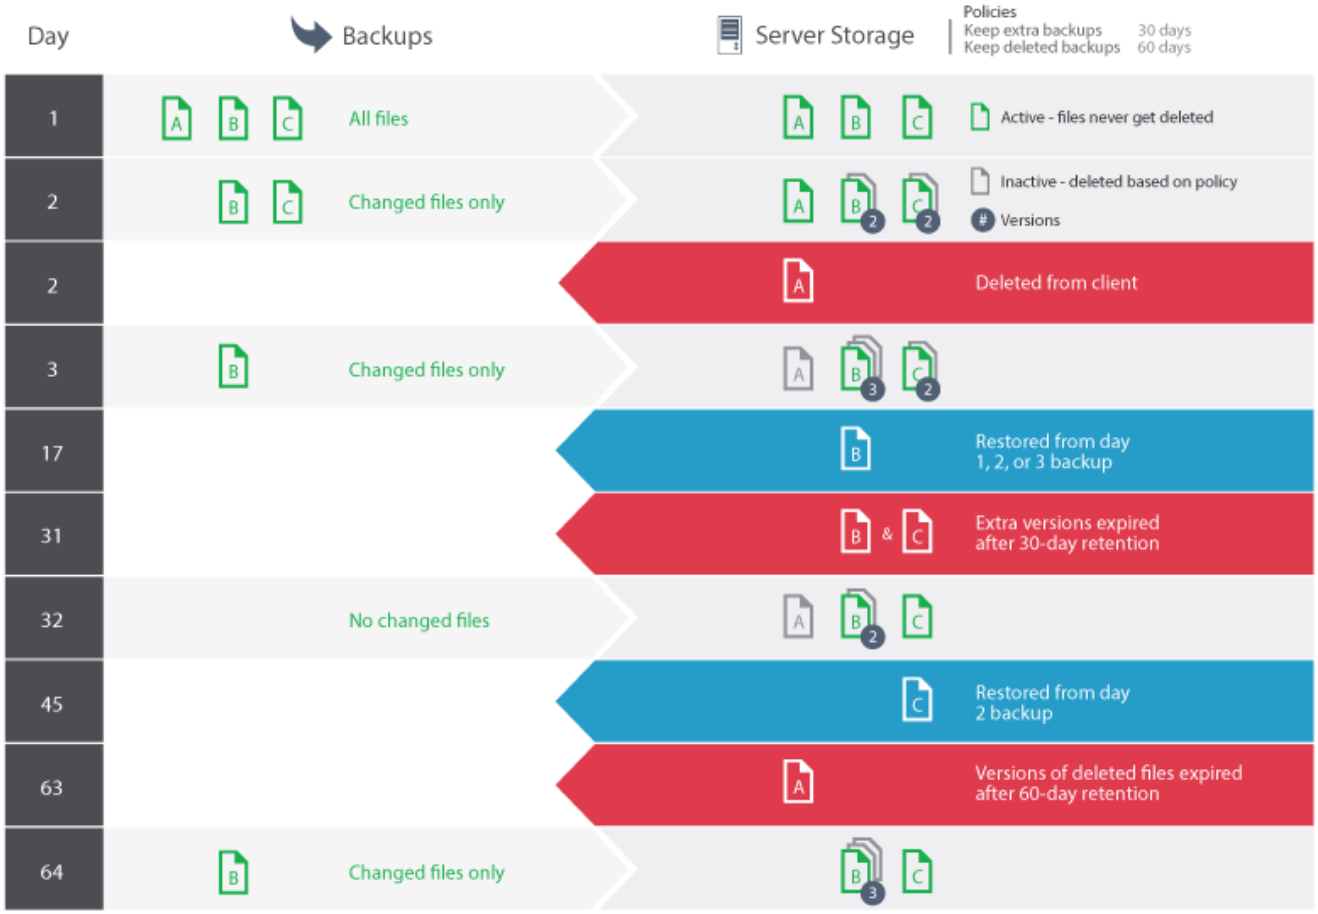
The simplest way to manage data retention is to use only time-based policy controls. With only time-based controls in the policy, the file versions are retained based on the days since the versions become inactive.

For a policy that is based only on time, you use the Keep Extra Backups and Keep Deleted Backups controls. This type of policy does not limit the number of versions of files. If clients back up frequently, ensure that server storage can handle the potential number of file versions.

The following figure shows how files from a client are handled by the server over time as the client runs a daily incremental backup operation.

In this example, the policy has the following characteristics:

- The latest version of a file is always retained, as long as the file still exists on the client system. The latest version is the active version. This characteristic is part of every policy on the server.
- Keep Extra Backups is set to 30 days. After a more recent backup is made, a file version becomes inactive and is kept in server storage for 30 days.
- Keep Deleted Backups is set to 60 days. When a file is deleted from the client system, all versions of the file in server storage become inactive. These inactive versions are kept for 60 days after the file versions become inactive.



Example: Retention when a policy uses both version and time controls

Using both the version and the time controls in a policy gives you flexibility in managing data retention but also causes complexity. To understand the interactions among the controls, review example policies and their effects on the retention of one file's backup versions during one month.

See Table 1 and Figure 1. A client backs up the file REPORT.TXT four times in one month, from 23 March to 23 April. The settings in the backup copy group of the management class to which REPORT.TXT is bound determine how the server treats these backup versions. Table 2 shows how different copy group settings can affect the versions, as of 24 April (one day after the file was last backed up).

Table 1. Status of REPORT.TXT backup versions as of 24 April

Version	Date created	Days since the version became inactive
Active	23 April	(not applicable)
Inactive 1	13 April	1 (since 23 April)
Inactive 2	31 March	11 (since 13 April)
Inactive 3	23 March	24 (since 31 March)

Figure 1. Active and inactive versions of REPORT.TXT

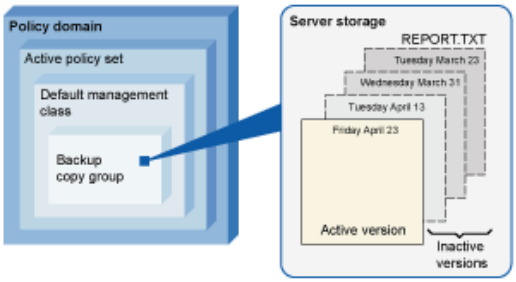


Table 2. Effects of the policy on retention of backup versions for REPORT.TXT as of 24 April

Backups	Deleted Backups	Keep Extra Backups	Keep Deleted Backups	Results
4 versions	2 versions	60 days	180 days	Backups and Keep Extra Backups settings control the expiration of the versions. The version that is created on 23 March is retained until the file is backed up again (creating a fourth inactive version), or until that version is inactive for 60 days. If the user deletes the REPORT.TXT file from the client file system, the server notes the deletion at the next full incremental backup operation by the client. From that point, the Deleted Backups and Keep Deleted Backups settings also affect the retention. All versions are now inactive. Two of the four versions expire immediately (the 23 March and 31 March versions expire). The 13 April version expires when it is inactive for 60 days (on 23 June). The server keeps the last remaining inactive version, the 23 April version, for 180 days after it becomes inactive.
No limit	2 versions	60 days	180 days	Keep Extra Backups setting controls expiration of the versions. The inactive versions (other than the last remaining version) are expired when they are inactive for 60 days. If the user deletes the REPORT.TXT file from the client node, the server notes the deletion at the next full incremental backup operation by the client. From that point, the Deleted Backups and Keep Deleted Backups settings also affect the retention. All versions are now inactive. Two of the four versions expire immediately (the 23 March and 31 March versions expire) because only two versions are allowed. The 13 April version expires when it is inactive for 60 days (on 22 June). The server keeps the last remaining inactive version, the 23 April version, for 180 days after it becomes inactive.

Backups	Deleted Backups	Keep Extra Backups	Keep Deleted Backups	Results
No limit	No limit	60 days	180 days	Keep Extra Backups setting controls expiration of the versions. The server does not expire inactive versions based on the maximum number of backup copies. The inactive versions (other than the last remaining version) are expired when they are inactive for 60 days. If the user deletes the REPORT.TXT file from the client node, the server notes the deletion at the next full incremental backup operation by the client node. From that point, the Keep Deleted Backups setting also affects the retention. All versions are now inactive. Three of the four versions expire after each of them is inactive for 60 days. The server keeps the last remaining inactive version, the 23 April version, for 180 days after it becomes inactive.
4 versions	2 versions	No limit	No limit	Backups setting controls the expiration of the versions until a user deletes the file from the client node. The server does not expire inactive versions based on age. If the user deletes the REPORT.TXT file from the client node, the server notes the deletion at the next full incremental backup operation by the client node. From that point, the Deleted Backups setting controls expiration. All versions are now inactive. Two of the four versions expire immediately (the 23 March and 31 March versions expire) because only two versions are allowed. The server keeps the two remaining inactive versions indefinitely.

Related concepts:
Full incremental backup and partial incremental backup

Interactions among policy settings

Time-based and version-based policy settings interact when used together in a management class for a policy. The frequency of client backups also affects the backup versions that are stored for a client.

For a client system that must back up twice a day, consider the effects of the following policy choices on a file that changes frequently:

- You set Keep Extra Backups to 30 days. You set Backups to No limit so that the policy does not limit the number of versions. After 30 days, the server might have 60 backup versions of the file, if the file changes between each of the two daily backup operations. The client can choose to restore any of the 60 versions from the past 30 days.
- You set Keep Extra Backups to No limit, and set Backups to 30 versions. If the file changes between each of the two daily backup operations, the server has 30 backup versions after 15 days. After 30 days, the server still has only 30 backup versions because of the limit on the number of versions. If the file continues to change between each of the two daily backup operations, the backup versions might be from as few as the last 15 days. The client can choose to restore one of the 30 versions, which might be no older than 15 days.

The examples show that if backup versions must be available for a specific number of days, the simplest way to implement that requirement is to use a time-based policy. Set Keep Extra Backups to the specific number of days and set Backups to No limit.

The effect of the No limit value in the policy settings varies according to what other policy controls are set:

Keep Extra Backups

If you specify No limit, inactive backup versions are deleted based on the Backups or Deleted Backups settings.

To enable client nodes to restore files to a specific point in time, set the Backups or Deleted Backups to No limit. Set Keep Extra Backups to the number of days that you expect clients might need versions of files available for possible point-in-time restoration. For example, to enable clients to restore files from a point in time 60 days in the past, set Keep Extra Backups to 60.

Keep Deleted Backups

If you specify No limit, the last version is retained forever unless a user or an administrator deletes the file from server storage.

Backups

Setting the value to No limit can require increased storage, but that value might be necessary to specify for some situations. For example, to enable client nodes to restore files to a specific point in time, set the value for Backups to No limit. By not setting a limit on versions, you ensure that the server retains versions according to the Keep Extra Backups setting.

Deleted Backups

Setting the value to No limit can require increased storage, but that value might be necessary to specify for some situations. For example, set the value for Deleted Backups to No limit to enable clients to restore files to a specific point in time. By not setting a limit on versions, you ensure that the server retains versions according to the Keep Extra Backups setting.

Cross-reference for Operations Center fields and server command parameters

The following table shows the Operations Center fields with the equivalent parameter to use with the `DEFINE COPYGROUP TYPE=BACKUP` command.

Field name in Operations Center views	**Parameter to use with the `DEFINE COPYGROUP TYPE=BACKUP` command**
Keep Extra Backups	RETEXTRA
Keep Deleted Backups	RETONLY
Backups	VEREXISTS
Deleted Backups	VERDELETED

Policy activation after updates

When you make updates to policy, the updates do not go into effect until you activate the policy set that you updated.

Policy set activation puts into effect updates that you made. For example, the following types of updates go into effect after you activate the policy set:

- You define a new policy domain with a policy set and one or more management classes
- You add a management class to a policy set
- You change the backup retention settings in an existing management class

Policy set validation before activation

In the Operations Center, validation is not a separate step. If you are using commands, validation is an optional command that gives you an opportunity to preview the effect of activating a changed policy set. When you validate a policy set, the server reports on conditions that might cause problems if the policy set is activated.
Validation fails if the policy set does not contain a default management class. Validation results in warning messages if any of the conditions that are shown in Table 1 exist.

Table 1. Conditions that cause warnings during policy set validation

Condition	**Reason for warning**
The storage destinations that are specified for backup, archive, or migration operations are not defined storage pools.	A storage pool must exist before you can specify it as a destination.
A storage destination that is specified for backup, archive, or migration operations is a copy storage pool or an active-data pool.	The storage destination must be a primary storage pool.
The default management class does not contain backup or archive settings.	When the default management class does not contain backup or archive settings, any files that are bound to the default management class are not backed up or archived.

Condition	Reason for warning
The current active policy set names a management class that is not defined in the policy set that is being validated.	When you back up files that were bound to a management class that no longer exists in the active policy set, backup versions are rebound to the default management class. When the management class to which an archive copy is bound no longer exists and the default management class does not contain archive settings, the server uses the archive retention grace period to manage the retention of the archive copy. The archive retention grace period is set for a policy domain, and that setting is used only when no other policy setting is available to manage an archive copy.
The current active policy set contains backup settings that are not defined in the policy set that is being validated.	When a client backs up a file and the management class to which the file is bound no longer has backup settings, backup versions are managed by the default management class. If the default management class does not contain any backup settings, the server uses the backup retention grace period to manage file versions. However, the file is not backed up in the next backup operation. The backup retention grace period is set for a policy domain, and that setting is used only when no other policy setting is available to manage a backup version.
A management class specifies that a backup version must exist before a file can be migrated from a client node, but the management class does not contain backup settings.	This warning applies only if you are using the IBM Spectrum Protect™ for Space Management product. The conflicts within the management class can cause problems for IBM Spectrum Protect for Space Management clients.

Policy set activation

When you activate a policy set, the server validates the contents of the policy set and copies the policy set to be the active policy set. To later change the contents of the active policy set, you must create or change another policy set and then activate that policy set.

Some updates to a policy have an immediate effect when it is activated, but some other updates do not:

- Updates to Keep Extra Backups and Keep Deleted Backups settings are immediately applied to data already in server storage, and to future backups.

  If you use commands, these settings are the RETEXTRA and RETONLY parameters for the DEFINE COPYGROUP or UPDATE COPYGROUP commands.

- Updates to Backups and Deleted Backups settings do not take effect for client data until the clients complete the next backup operation.

  If you use commands, these settings are the VEREXISTS and VERDELETED parameters for the DEFINE COPYGROUP or UPDATE COPYGROUP commands.

Restrictions for servers that use the feature for data retention protection

If the feature for data retention protection is active, more rules apply when you validate and activate a policy set. The feature for data retention protection is activated by using the SET ARCHIVERETENTIONPROTECTION command on a server that does not yet have any client data.

If data retention protection is active for a server, more rules must be satisfied before the policy is activated:

- If a management class exists in the active policy set, a management class with the same name must exist in the policy set that is being activated.
- All management classes in the policy set that is being activated must contain archive retention settings.
- If the active policy set includes archive retention settings in a management class, the policy set that is being activated must have archive retention values at least as large as the corresponding values in the active policy set.

If the server is a managed server in an enterprise configuration, the server might receive policy updates from the server that is the configuration manager. Policy updates that are received by the managed server from the configuration manager must also satisfy the preceding rules.

SET ARCHIVERETENTIONPROTECTION (Activate data retention protection)

Customizing a policy

You can customize existing policies to meet new or revised data retention requirements for your organization. Modifying a policy domain or copying an existing policy domain is a typical way to start customizing policy.

About this task

The key policy settings are in management classes. In the management classes, you can control both the number of backup versions and the number of days that backup versions are kept in server storage. When you use both types of controls, the policy is more complex. By controlling only the number of days that backup versions are kept, you can more simply define how long backed-up data is kept.

Ensure that the default management class in a policy domain has appropriate settings for data retention for most or all of the clients that are assigned to the domain. The retention settings in the default management class are applied to data when client operations do not specify a management class.

You can work on updates to a policy and save the changes until a later time. When you are satisfied that the draft changes are ready, you can activate the updated policy set to put the changes into effect.

Procedure

1. On the Overview page of the Operations Center, click the Services menu.
2. Select the policy domain and click Details. Click Policy Sets.
3. Click the Configure toggle so that you can update the settings.
4. Customize the settings in the management class.
    a. Make selections for backup services. For example, update the following items so that inactive backup versions for the clients are retained for 30 days:
        - Backups: No limit
        - Keep Extra Backups: 30 days
        - Deleted Backups: 1
        - Keep Deleted Backups: No limit
    b. Optional: Make selections for archive services. For example, change the Keep Archives setting to 1 year.
    c. Click Save.
5. Optional: Click +Management Class to add a management class.
    a. Make selections for the basic settings, and click Add.
    b. Customize more settings in the new management class. For backup services, make selections in the following columns: Backup Destination, Backups, Keep Extra Backups, Deleted Backups, and Keep Deleted Backups. For archive services, make selections in the Archive Destination and Keep Archives columns.
    c. Click Save.
6. In the Default column, ensure that an appropriate management class is selected as the default. The retention settings in the default management class are applied when client operations do not specify a management class. A management class can be specified when a client operation is run. A management class can also be specified in a client option file that is on the client system, or in a client option set that is defined on the server.
7. Activate the policy set by clicking Activate.
8. Assign client nodes to the new policy domain by either updating existing client nodes or registering new nodes.
    - To add new clients to the policy domain, click +Client.
    - To move an existing client to the policy domain, select the client, click Details, and then click the Properties tab. Select the new policy domain and click Save.

    Data retention for the client that you assign to the policy domain is now controlled by that policy.
    Requirement: If a client is running when you assign it to a new domain, you must stop and restart the client for the change to take effect.

Related tasks:

Creating a policy by copying an existing policy

You can create new policies by copying an existing policy and then updating the parts that you want to change.

Procedure

You can create a policy by copying a policy domain, updating the management classes, and then assigning clients to the new domain.

1. On the Overview page of the Operations Center, hover over the settings icon and click Command Builder.
2. Copy a policy domain by using the COPY DOMAIN command. For example, copy the default policy domain, STANDARD, to a new policy domain, NEWDOMAIN:

   ```
   copy domain standard newdomain
   ```

   This operation copies the policy domain and all associated policy sets and management classes. In this example, the operation copies the following items into the NEWDOMAIN policy domain:
   - A policy set, named STANDARD.
   - The management class that is named STANDARD, which is in the STANDARD policy set.
   - The copy groups that the STANDARD management class contains:
     - The backup copy group, named STANDARD
     - The archive copy group, named STANDARD
3. On the Overview page of the Operations Center, click the Services menu.
4. Select the new policy domain and click Details. Click Policy Sets.
5. Click the Configure toggle so that you can update the settings.
6. Customize the settings in the management classes.
   a. Make selections for backup services. For example, update the following items so that inactive backup versions for the clients are retained for 30 days:
      - Backups: No limit
      - Keep Extra Backups: 30 days
      - Deleted Backups: 1
      - Keep Deleted Backups: No limit

   b. Optional: Make selections for archive services. For example, change the Keep Archives setting to 1 year.
   c. Click Save.
7. Optional: Make other updates and additions, such as adding a management class.
   a. Click +Management Class to add a management class. Make selections for the basic settings, and click Add.
   b. Customize more settings in the new management class. For backup services, make selections in the following columns: Backup Destination, Backups, Keep Extra Backups, Deleted Backups, and Keep Deleted Backups. For archive services, make selections in the Archive Destination and Keep Archives columns.
   c. Click Save.
8. Select the default management class that clients use, which is indicated in the Default column. Click Save. The retention settings in the default management class are applied when client operations do not specify a management class. A management class can be specified when a client operation is run. A management class can also be specified in a client option file that is on the client system, or in a client option set that is defined on the server.
9. Activate the policy set by clicking Activate.
10. Assign client nodes to the new policy domain by either updating existing client nodes or registering new nodes.
    - To add new clients to the policy domain, click +Client.
    - To move an existing client to the policy domain, select the client, click Details, and then click the Properties tab. Select the new policy domain and click Save.

    Data retention for the client that you assign to the policy domain is now controlled by that policy. For example, if you implemented the example in step 6, inactive backup versions for the clients are retained for 30 days by default.
    Requirement: If a client is running when you assign it to a new domain, you must stop and restart the client for the change to take effect.

Related tasks:
Controlling client operations through client option sets

Creating a policy domain

You might want to create a new policy domain for each type of client that is protected by the server. You might also want to divide responsibilities for clients among several administrators by giving them authority for specific policy domains.

About this task

Creating a new policy domain can be useful in the following circumstances:

- Applications, systems, or virtual machines require different data-retention settings. You can create a policy domain for each type of client, with a default policy that is appropriate for that type.
- Administrators are responsible for different groups of clients. For each administrator, you can create a policy domain to which you assign the clients to be managed by that administrator.

Procedure

The following steps summarize how to create a policy domain.

1. On the Overview page of the Operations Center, hover over the settings icon  and click Command Builder.
2. Define a policy domain by using the DEFINE DOMAIN command.
3. Define a policy set for the domain by using the DEFINE POLICYSET command.
4. On the Overview page of the Operations Center, click the Services menu.
5. Select the policy domain and click Details. Click Policy Sets.
6. Click the Configure toggle so that you can update the settings.
7. Click +Management Class to add a management class. Make selections for the basic settings, and click Add.
8. Optional: Customize more settings in the new management class:
    a. For backup services, make selections in the following columns: Backup Destination, Backups, Keep Extra Backups, Deleted Backups, and Keep Deleted Backups.
    b. For archive services, make selections in the Archive Destination and Keep Archives columns.
    c. Click Save.
9. Optional: Click +Management Class to add more management classes.
10. In the Default column, ensure that a default management class is selected.
11. Activate the policy set by clicking Activate.
12. Assign clients to the new policy domain. From the Operations Center menu bar, click Clients.
    - To add new clients to the policy domain, click +Client.
    - To move an existing client to the policy domain, select the client, click Details, and then click the Properties tab. Select the new policy domain and click Save.

Controlling client operations through client option sets

You can use client option sets to centrally control the processing options that clients use for operations such as backup. Client option sets can help ensure that data is consistently protected according to your requirements. A client option set can override options in a local client options file, and can add options that might not be in a local client options file.

About this task

By creating and assigning client option sets, you reduce the need to update local client option files and reduce work for you or your users.

For example, you can define a client option set to specify an include-exclude list that determines what is backed up, what is excluded from backup, and what management classes are used to manage data retention. Other client options that might be useful to centrally control in a client option set are the compression and deduplication options.

You can create client option sets for clients that have similar requirements, such as clients on the same operating system, clients that use the same software, or clients that one department uses. For example, you might create client option sets for Windows workstations, or for the payroll department. After you create the client option set, you assign the client option set to all clients of the same type.

Not all client options can be specified in a client option set on the server. To learn about the client options that you can centrally control in a client option set, see Client options that can be set by the server.

Procedure

1. Define a client option set by using the DEFINE CLOPTSET command. For example, to define a client option set named PAYROLLBACKUP, issue the following command:

   ```
   define cloptset payrollbackup description='Backup options for the payroll department'
   ```

2. Add client options to the client option set by using the DEFINE CLIENTOPT command. For example, you want to add include and exclude options to the client option set named PAYROLLBACKUP to accomplish the following goals:
   - Exclude temporary Internet directory files from backup operations
   - Include for backup all files in the C:\Data directory and its subdirectories, and assign the files to the PAYCLASS management class for data retention

   Issue the following commands:

   ```
   define clientopt payrollbackup inclexcl "exclude.dir '*:\...\Temporary Internet Files'"
   define clientopt payrollbackup inclexcl "include C:\Data\...\* payclass"
   ```

3. To assign a client option set to a client, complete the following steps:
   a. On the Overview page of the Operations Center, click Clients.
   b. Select a client and click Details.
   c. Click Properties.
   d. In the General area, select an option set and click Save.

Configuring storage

Depending on the storage functionality that you require, choose the correct type of storage media. Optimize and control your storage pools for different types of data.

- Storage pool types
  To help you determine which storage pool type best meets your storage requirements, you should evaluate the characteristics of each storage pool type.
- Data deduplication options
  Use inline data deduplication to deduplicate data and write the data to a container storage pool at the same time. Use postprocess data deduplication to eliminate duplicate data from sequential access (FILE) storage pools.
- Configuring storage devices
  Configure storage devices by attaching devices, configuring device drivers, and creating the objects that represent the devices to the server.
- Configuring a directory-container storage pool for data storage
  You can configure directory-container storage pools to use inline data deduplication to store deduplicated data.
- Configuring a cloud-container storage pool for data storage
  You can store deduplicated data and non-deduplicated data in a cloud-container storage pool and restore the data as required. You can configure cloud-container storage pools to use one of the following service providers and protocols: Amazon Web Services (AWS) with Simple Storage Service (S3), IBM® Cloud Object Storage with Swift or S3 (and IBM SoftLayer), Microsoft Azure, and OpenStack with Swift using Keystone Version 1 or Version 2. Cloud-container storage pools are not supported on Linux on System z®.
- Optimizing performance for cloud object storage
  You can configure IBM Spectrum Protect™ to temporarily store data in one or more local storage pool directories during data ingestion. The data is then moved from local storage to the cloud. In this way, you can improve data backup and archive performance.
- Managing space in container storage pools
  After you configure IBM Spectrum Protect and add storage, manage your data and storage pool space effectively to ensure that it operates correctly. Use container storage pools to maximize your storage space and server performance.
- Auditing a storage pool container
  Audit a storage pool container to check for inconsistencies between database information and a container in a storage pool.
- Storage system requirements and reducing the risk of data corruption
  You can use many types of storage for the IBM Spectrum Protect server. If you use block disk storage, solid-state drives (SSD), or network-attached file systems for server storage, ensure that the storage meets requirements.

Storage pool types

To help you determine which storage pool type best meets your storage requirements, you should evaluate the characteristics of each storage pool type.

Use the following table to evaluate each type of storage pool.

Storage pool type	Description	Uses
Directory-container storage pool	A primary storage pool that a server uses to store data. Data that is stored in directory-container storage pools uses both inline data deduplication and client-side data deduplication.	Use when you want to deduplicate data inline. By using directory-container storage pools, you remove the need for volume reclamation, which improves server performance and reduces the cost of storage hardware. You cannot use this type of storage pool for storage pool backup, migration, reclamation, import or export operations.
Cloud-container storage pool	A primary storage pool that a server uses to store data. Use cloud-container storage pools to store data to an object-store based cloud storage provider. Data that is stored in cloud-container storage pools uses both inline data deduplication and client-side data deduplication.	By storing data in cloud-container storage pools, you can exploit the cost per unit advantages that clouds offer along with the scaling capabilities that cloud storage provides. You cannot use this type of storage pool for storage pool backup, migration, reclamation, encryption, import or export operations.
Random-access storage pool	A set of volumes that the server uses to store backup versions of files, files that are archive copies, and files that are migrated from client nodes. Files are stored on DISK devices.	Use this type of storage pool to keep a copy of your data on DISK devices. You can migrate data in or out of this storage pools.
Sequential-access storage pool	A set of volumes that the server uses to store backup versions of files, files that are archive copies, and files that are migrated from client nodes. Files are stored on tape or FILE devices. Data that is stored in sequential-access storage pools uses both postprocess and client-side data deduplication.	Use this type of storage pool to keep a copy of your data on TAPE devices. You can migrate data into this type of storage pool.
Copy storage pool	A named set of volumes that contain copies of files that reside in primary storage pools. Copy storage pools are used only to back up the data that is stored in primary storage pools. A copy storage pool cannot be a destination for a backup copy group, an archive copy group, or a management class (for space-managed files).	Use copy storage pools to have a copy of active and inactive data that you can restore to a primary storage pool after a disaster or outage. You cannot use inline data deduplication, compression, replication, or data deduplication with this type of storage pool.

Storage pool type	Description	Uses
Container-copy storage pool	A set of tape volumes that contain a copy of deduplicated extents that reside in a directory-container storage pool. Container-copy storage pools are used only to protect the data that is stored in directory-container storage pools. Container-copy storage pools are used to repair damage in a directory-container storage pool or to restore a directory-container storage pool if a disaster occurs. Container-copy storage pools are stored on sequential media.	Use container-copy storage pools to store copies of directory-container storage pools onsite or offsite. Damaged data in directory-container storage pools can be repaired by using the deduplicated extents in a container-copy storage pool.
Active-data storage pool	A named set of storage pool volumes that contain only active versions of client backup data.	Use active-data storage pools to restore active only data to primary storage pools after a disaster or outage. By restoring active only data you can restore client data quicker and you use less bandwidth. You cannot use inline data deduplication, compression, replication, or data deduplication with this type of storage pool.

Use the following table to compare storage pool capabilities and choose the storage pool that most suits your business needs based on your storage requirements.

User goal	Directory-container storage pool	Cloud-container storage pool	Random-access storage pool	Sequential-access storage pool	Copy storage pool	Container-copy storage pool	Active-data storage pool
Protect storage pool data through node replication.	✓		✓	✓	✓		✓
Reduce storage needs by using inline compression.	✓	✓					
Reduce storage needs by using inline data deduplication.	✓	✓					
Reduce storage needs by using client-side data deduplication.	✓	✓		✓			
Reduce storage needs by using postprocess data deduplication.				✓			

User goal	Directory-container storage pool	Cloud-container storage pool	Random-access storage pool	Sequential-access storage pool	Copy storage pool	Container-copy storage pool	Active-data storage pool
Protect storage pool data through storage pool protection.	✓					✓	
Back up storage pool data by using copy storage pools on disk or tape.			✓	✓			
Store data in a cloud.		✓					

Data deduplication options

Use inline data deduplication to deduplicate data and write the data to a container storage pool at the same time. Use postprocess data deduplication to eliminate duplicate data from sequential access (FILE) storage pools.

You must use directory-container storage pools or cloud-container storage pools for inline data deduplication. By using directory-container or cloud-container storage pools, you reduce the need for offline reorganization, which improves server performance and reduces the cost of storage hardware. You do not use device classes or volumes with these types of storage pool.

By using postprocess data deduplication, the server identifies the data first and then removes the duplicate data to the storage pool. Only one instance of the data is retained on storage media. Other instances of the same data are replaced with a pointer to the retained instance. When you remove the duplicate data, you can reclaim space in the storage pool.

For more information about postprocess data deduplication, see Deduplicating data (V7.1.1).

In client-side data deduplication, only compressed, deduplicated data is sent to the server. Processing is distributed between the server and the client during a backup process.

Use the following table to compare data deduplication options.

Type of data deduplication	Advantages	Disadvantages
Post-process Restriction: You can use postprocess data deduplication only with sequential access (FILE) storage pools.	• After data deduplication, you can reclaim the storage pool.	• Longer processing times because the data must be identified first before the duplicate data is removed from the storage pool.
Inline Restriction: You can use inline data deduplication only with directory-container and cloud-container storage pools.	• Deduplicates data as the data is written to a container storage pool. • Reduces the need for offline reorganization which improves server performance. • Reduced cost of storage hardware.	• Higher processor usage by the server.
Client-side	• Processing is distributed between the server and the client during a backup process.	• Higher processor usage by the client. • Longer elapsed time for client operations such as backup. • Only compressed, deduplicated data is sent to the server.

Related tasks:
Configuring data deduplication (multisite disk solution)

Configuring data deduplication (single-site disk solution)
Comparing storage pools

Configuring storage devices

Configure storage devices by attaching devices, configuring device drivers, and creating the objects that represent the devices to the server.

About this task

If you are not using the single-site disk or multisite disk solution, configure and manage storage devices by following the instructions in the V7.1.1 documentation:

- AIX Linux Configuring and managing storage devices
- Windows Configuring and managing storage devices

Configuring a directory-container storage pool for data storage

You can configure directory-container storage pools to use inline data deduplication to store deduplicated data.

Procedure

To store data in a directory-container storage pool, complete the following steps:

1. Create a directory-container storage pool by completing the following steps:
   a. On the Operations Center menu bar, click Storage > Storage Pools.
   b. On the Storage Pools page, click + Storage Pool.
   c. Complete the steps in the Add Storage Pool wizard. Select Directory for the type of container-based storage.
2. After the wizard creates the storage pool, update your management classes and policy sets to use the new pool. To update a management class to use the new pool, complete the following steps:
   a. On the Operations Center menu bar, click Services.
   b. On the Policies page, select a policy domain and click Details.
   c. On the Details page, click the Policy Sets tab.
   d. Click the Configure toggle. The policy sets are editable.
   e. Optional: To edit a policy set that is not active, click the forward and back arrows to locate the policy set.
   f. Update one or more management classes to use the new pool by editing the Backup Destination field of the table.
   g. Click Save.
3. Activate the changed policy set by completing the following steps:
   a. Click Activate. Because changing the active policy set might result in data loss, a summary of the differences between the active policy set and the new policy set is displayed.
   b. Look at the differences between corresponding management classes in the two policy sets, and consider the consequences on client files. Client files that are bound to management classes in the currently active policy set are, after activation, bound to the management classes with the same names in the new policy set.
   c. Identify management classes in the currently active policy set that do not have counterparts in the new policy set, and consider the consequences on client files. Client files that are bound to these management classes are, after activation, managed by the default management class in the new policy set.
   d. If the changes implemented by the policy set are acceptable, select the I understand that these updates can cause data loss check box and click Activate.
4. Click the Configure toggle. The policy sets are no longer editable.

What to do next

To protect a directory-container storage pool, issue the PROTECT STGPOOL command. For instructions, see PROTECT STGPOOL (Protect data that belongs to a storage pool) and Copying directory-container storage pools to tape.

Linux If you are protecting a directory-container storage pool by copying the data to a remote server, and you experience network issues, see Determining whether Aspera FASP technology can optimize data transfer in your system environment.

- Copying directory-container storage pools to tape
  You can protect data in a directory-container storage pool by copying the data to container-copy storage pools, which are represented by tape volumes. The tape copy is used to repair damage to a directory-container storage pool.

- Rotating tape volumes offsite when DRM is not configured
  If your storage solution includes container-copy storage pools that are represented by tape volumes, but you did not configure the disaster recovery manager (DRM) function, you can follow a manual procedure to rotate the tape volumes offsite. By maintaining copies of data in offsite tape volumes, you can restore the data if a disaster occurs onsite.
- Changing the volume reclamation threshold for container-copy storage pools
  By default, tape volume reclamation is enabled for container-copy storage pools. To ensure that tape volumes are used efficiently, you can change the threshold for volume reclamation.
- Reclaiming tape volumes in container-copy storage pools
  You can reclaim tape volumes in container-copy storage pools without running a protection operation when you don't have time to allow both protection and reclamation operations.
- Determining whether to use container-copy storage pools for disaster protection
  Determine whether container-copy storage pools meet your requirements for disaster protection.

Copying directory-container storage pools to tape

You can protect data in a directory-container storage pool by copying the data to container-copy storage pools, which are represented by tape volumes. The tape copy is used to repair damage to a directory-container storage pool.

Before you begin

Define at least one tape library to the server by using the DEFINE LIBRARY command. Provision enough tape drives and scratch volumes to meet your storage requirements. For more information about managing backup media and configuring disaster recovery manager (DRM), see Disaster recovery manager (V7.1.1).

About this task

To copy the data in directory-container storage pools to tape, the Operations Center creates a schedule to run the PROTECT STGPOOL command. When the protection schedule runs, one tape copy is created. At least one volume must be available when the protection schedule runs. Otherwise, the operation fails.

You can create up to two tape copies, but you must use the command-line interface to create a second container-copy storage pool. One tape copy can be taken to an offsite disaster recovery location. The other copy can be kept onsite to expedite recovery from less-critical failures.

Restrictions:

- Virtual tape libraries are not supported, regardless of which library type is defined. Only physical tape is supported.
- Container-copy storage pools can be used to repair minor to moderate storage pool damage, which includes damaged containers or directories. Container-copy storage pools can also be used for disaster protection, but you must ensure that recovery times meet your requirements. For more information, see Determining whether to use container-copy storage pools for disaster protection.
- You cannot use replication to target a container-copy storage pool.
  Tip: You can create a tape copy of the directory-container storage pool data at a disaster recovery site by using this procedure to create a container-copy storage pool on the target replication server. Then, schedule the PROTECT STGPOOL and REPLICATE NODE commands to run on the source replication server to protect your data to the target replication server.
- You cannot use the following procedure if the directory-container storage pool already has an associated container-copy storage pool. To create a second container-copy storage pool, follow the instructions in step 5.

If you created a container-copy storage pool as part of the Add Storage Pool wizard, you do not have to use this procedure. When you completed the wizard, the Operations Center configured the container-copy storage pool and a protection schedule.

Procedure

To configure storage pool protection to tape for an existing directory-container storage pool, complete the following steps:

1. On the Operations Center menu bar, click Storage > Storage Pools.
2. On the Storage Pools page, select the directory-container storage pool that you want to protect to tape.
3. Click More > Add Container-Copy Pool.
4. Follow the instructions in the Add Container-Copy Pool window to schedule protection to tape.
5. After you complete the previous steps, you can add a second container-copy storage pool by using the command-line interface. Optionally, complete the following steps to add a container-copy storage pool:

a. Create a container-copy storage pool by issuing the DEFINE STGPOOL command.
b. Assign the container-copy storage pool to the directory-container storage pool by issuing the UPDATE STGPOOL command for the directory-container pool.

Results

After you complete the configuration, data in the directory-container storage pool is copied to a container-copy storage pool based on the defined protection schedule.

What to do next

1. If you created a tape copy to store offsite, enable the offsite container-copy storage pool for DRM operations by issuing the SET DRMCOPYCONTAINERSTGPOOL command. Ensure that the tape volumes are added to your offsite tape rotation schedules. If DRM is not configured, you must do so or use the alternative method to rotate tapes offsite. For instructions about the alternative method, see Rotating tape volumes offsite when DRM is not configured. To verify that offsite container-copy storage pools are enabled for DRM, use the QUERY DRMSTATUS command.

   For instructions about configuring DRM, see Disaster recovery manager (V7.1.1).

2. Confirm that the reclamation threshold for your container-copy storage pool meets your requirements.

   By default, tape volume reclamation is enabled for new container-copy storage pools that are created by using the Operations Center. Volume reclamation occurs when the reclamation threshold for the container-copy storage pool is less than 100%. However, tape volumes are not a candidate for reclamation until they are 75% full. Be careful when you use reclamation with container-copy storage pools that have offsite volumes. When an offsite volume becomes eligible for reclamation, in effect the server moves the extents on the volume back to the onsite location. If a disaster occurs onsite, the server can obtain extents from the offsite volume if the restored database refers to extents on the offsite volume. To prevent volumes from being rewritten immediately after all extents are deleted, use the REUSEDELAY parameter to specify a value that is greater than 0. The Operations Center sets the reclamation threshold at 60% for onsite container-copy storage pools.

   For instructions about changing the reclamation threshold, see Changing the volume reclamation threshold for container-copy storage pools.

3. Protect the metadata for your container-copy storage pool.
   When the protection schedule runs, data extents in the container-copy storage pools are copied to tape volumes without the associated metadata. This metadata is required to restore the tape copies. To protect the metadata, you must separately back up the server database along with its volume history, server options, and device configuration files. If you use reclamation with container-copy storage pools that have offsite tape volumes, ensure that the following requirements are met to provide disaster recovery protection:
   - Database backup operations run after storage pool protection schedules and DRM move schedules finish.
   - All database backup volumes and DRM volumes are taken offsite together.

   For instructions about backing up the server database and related files, see Defining schedules for server maintenance activities.

4. Optionally, change the protection schedule for a directory-container storage pool that has one or more associated container-copy storage pools by using the UPDATE SCHEDULE command. The schedule that is created by the Operations Center is named CONTAINER_COPY.

Rotating tape volumes offsite when DRM is not configured

If your storage solution includes container-copy storage pools that are represented by tape volumes, but you did not configure the disaster recovery manager (DRM) function, you can follow a manual procedure to rotate the tape volumes offsite. By maintaining copies of data in offsite tape volumes, you can restore the data if a disaster occurs onsite.

Procedure

1. Check out the storage volume that must be rotated offsite by using the CHECKOUT LIBVOLUME command.
2. Update the volume to indicate that it is moved offsite by using the UPDATE VOLUME command and specifying `ACCESS=UNAVAILABLE`. Optionally, indicate the offsite location by using the LOCATION parameter. For example, specify `LOCATION=SITE1`.
3. Reclaim space by taking one of the following actions:
   - To reclaim space without protecting the storage pool, run the PROTECT STGPOOL command and specify `TYPE=LOCAL` and `RECLAIM=ONLY`.
   - To reclaim space while protecting the storage pool, run the PROTECT STGPOOL command without specifying `RECLAIM=ONLY`.
4. Monitor the volume by using the QUERY VOLUME command. If the volume is shown to be unavailable and empty, return the volume onsite and check it into the library by using the CHECKIN LIBVOLUME command.
5. Update the volume by using the UPDATE VOLUME command and specifying `ACCESS=READWRITE`.

Related reference:
CHECKOUT LIBVOLUME (Check a storage volume out of a library)

UPDATE VOLUME (Change a storage pool volume)

Changing the volume reclamation threshold for container-copy storage pools

By default, tape volume reclamation is enabled for container-copy storage pools. To ensure that tape volumes are used efficiently, you can change the threshold for volume reclamation.

Procedure

1. On the Operations Center Overview page, click Storage > Storage Pools.
2. Select the storage pool and click Details, and then Properties.
3. In the Reclamation section, set the reclamation percentage and click Save.
   Tip: Alternatively, change the reclamation threshold by issuing the UPDATE STGPOOL command and specifying the RECLAIM parameter. For details about the RECLAIM parameter, see the commands for defining and updating container-copy storage pools.
   Restriction: You cannot use the RECLAIM STGPOOL command to reclaim volumes in container-copy storage pools. For details about reclaiming volumes in container-copy storage pools, see the RECLAIM parameter in the PROTECT STGPOOL command.

Reclaiming tape volumes in container-copy storage pools

You can reclaim tape volumes in container-copy storage pools without running a protection operation when you don't have time to allow both protection and reclamation operations.

About this task

When you issue the PROTECT STGPOOL command and the target storage pool is a container-copy storage pool, both protection and reclamation operations run by default. The preferred practice is to allow both protection and reclamation operations to run. However, to save time, you can run only the storage pool protection operation or only reclamation, or you can limit the number of tape volumes that are reclaimed. Use this procedure only when you have to reclaim tape volumes quickly or when you have to reclaim a limited number of tape volumes.

Procedure

To reclaim tape volumes without running a storage pool protection operation, complete the following steps:

1. Optional: To maximize the amount of space that is reclaimed, start the inventory expiration process by issuing the EXPIRE INVENTORY command.
2. Determine whether you want reclamation to run to completion or limit the number of tape volumes that are reclaimed.
3. To run reclamation to completion, issue the PROTECT STGPOOL command and specify the TYPE=LOCAL and RECLAIM=ONLY parameters. For example, to reclaim space in a local container-copy storage pool that is defined as the target protection pool for SPOOL1, issue the following command:

   ```
   protect stgpool spool1 type=local reclaim=only
   ```

4. To reclaim a limited number of tape volumes, complete the following steps:
   a. Set a reclamation limit for the container-copy storage pool by issuing the UPDATE STGPOOL command and specifying the RECLAIMLIMIT parameter. This parameter limits the number of volumes in the container-copy storage pool that are reclaimed.
   b. Issue the PROTECT STGPOOL command and specify the TYPE=LOCAL parameter along with either the RECLAIM=YESLIMITED or RECLAIM=ONLYLIMITED parameter.
   Tip: When you specify RECLAIM=YESLIMITED, both reclamation and storage pool protection operations run when the PROTECT STGPOOL command is issued. When you specify RECLAIM=ONLYLIMITED, reclamation is the only operation that runs. When you specify either of these values, reclamation runs only until it reaches the reclamation limit that is defined for the container-copy storage pool. The reclamation limit is defined with the RECLAIMLIMIT parameter on the DEFINE STGPOOL or UPDATE STGPOOL command.

   For example, to reclaim a limit of five tape volumes in a container-copy storage pool that is named CCPOOL1 without running a protection operation on the source directory-container storage pool that is named SPOOL1, issue the following commands:

   ```
   update stgpool ccpool1 reclaimlimit=5
   protect stgpool spool1 type=local reclaim=onlylimited
   ```

   For example, to protect a storage pool that is named SPOOL1 and to reclaim a maximum of 10 tape volumes in the associated container-copy storage pool, issue the following commands:

   ```
   update stgpool spool1 reclaimlimit=10
   protect stgpool spool1 type=local reclaim=yeslimited
   ```

Results

Reclamation processing for the container-copy storage pool is completed. The storage pool protection operation did not run, so data in the directory-container storage pool that was updated since the last protection operation is not protected.

What to do next

1. Protect the data in the directory-container storage pool to the container-copy storage pool by issuing the PROTECT STGPOOL command and specifying the TYPE=LOCAL parameter. The protection process runs with the default RECLAIM=YES parameter. The protection operation takes less time because reclamation already ran.
   For example, to protect the data in a directory-container storage pool that is named SPOOL1, issue the following command:

   ```
   protect stgpool spool1 type=local
   ```

   Alternatively, protect the data in a directory-container storage pool that is named SPOOL1 without running reclamation by issuing the following command:

   ```
   protect stgpool spool1 type=local reclaim=no
   ```

2. Back up the server database and run scheduled maintenance operations. For instructions, see Defining schedules for server maintenance activities.

EXPIRE INVENTORY (Manually start inventory expiration processing)

Determining whether to use container-copy storage pools for disaster protection

Determine whether container-copy storage pools meet your requirements for disaster protection.

About this task

You can create an offsite copy of your container-copy storage pool for disaster recovery protection or to satisfy regulatory and business requirements for offsite tape copies. Before you decide to use offsite tape copies for disaster protection, carefully consider whether the solution meets your recovery time objective.

Using container-copy storage pools for disaster recovery is suitable when the amount of data in your environment is equal to or less than the following values:

- 200 TB of total managed data
- 50 TB of back-end data
- 37 TB of front-end data

Total managed data
: All data that is stored in the directory-container storage pool on the server. This includes active and inactive versions of the data. The number of versions is determined by retention policies.

Back-end data
: All data that is stored in the container-copy storage pool.

Front-end data
: The current active data that is stored in the container-copy storage pool. This is the active data that is used to restore data on client nodes. In a disaster, all or part of the front-end data is required to reestablish production. Front-end data is a percentage of total managed data and is less than or equal to the total managed data, depending on the policy settings in use.

To recover from a disaster within 48 hours, the system environment at the recovery site must meet the minimum hardware requirements for the actions in the following table.

Action	Time required	Minimum requirements
Configure a new IBM Spectrum Protect™ server at a disaster recovery site. To configure the new server, you must complete the following steps: 1. Provision disks for the server. 2. Restore the server from backup. 3. Start the server. 4. Update the storage and device configurations.	Time to restore the server: 6 hours	Use a solid-state drive (SSD) for the server database, with the following requirements: • A minimum of 100 MB per second average combined read/write throughput • A minimum of 12,862 average input/output operations per second (IOPS)
Audit the directory-container storage pool and repair the data from tape. Tip: If the system meets the minimum hardware requirements, you can repair up to 50 TB of back-end data within 48 hours.	Time to audit the storage pool: 2 hours Time to repair the storage pool by using a tape copy: 28 hours Note: The time estimate applies if you have a maximum of 200 TB of total managed data in the storage pool.	Use Nearline SAS (NL-SAS) drives, as in a medium blueprint server configuration, with a minimum of 700 MB per second write performance to storage pool disk. Use new generation tape technology such as LTO-7 or better, with a minimum of six drives to allow concurrent read operations from tape volumes.
Restore data on client nodes. Tip: If the system meets the minimum hardware requirements, you can restore up to 37 TB of front-end data within 48 hours.	Time for client restore operations: 12 hours	Use NL-SAS drives, as in a medium blueprint server configuration, with a minimum of 10 restore sessions achieving 3102 GB per hour.

Procedure

1. Estimate the disaster recovery time for your environment by using the following table. Determine whether the recovery time meets your requirements.

Table 1. Recovery time estimate for differing amounts of total managed data

Recovery time objective	Total managed data (TB)	Number of hours to repair a directory-container storage pool (First Byte Restored)	Hours until client nodes are restored (Disaster Recovery complete)
Up to 1 day	25	10	12
	50	13	16
	75	17	22
Up to 2 days	100	20	26
	200	34	46
Up to 4 days	300	48	66
	400	62	86
More than 4 days	500	76	106

Notes:

- Achievable rates are highly dependent on the workload and the configured environment.
- The front-end data percentage is relative to the total managed data. Increasing the amount of front-end data increases the total recovery time. Decreasing the amount of front-end data decreases the total recovery time.

2. Estimate the recovery time for your environment by using the following formulas:
   - Estimate the value **Hours until directory-container storage pool is repaired (First Byte Restored)**:

     ```
     Time to Client First Byte Restore =
     6 hours + 14 hours for every 100 TB of Total Managed Data
     ```

   - Estimate the value **Hours until client nodes are restored (Disaster Recovery complete)**:

     ```
     Time to Client Restore Complete =
     Time to Client First Byte Restore + ((Total Managed Data * Front-End Data) / Restore
     Rate)
     ```

   Restore Rate: The rate at which clients can restore data from the server back to their local computer or storage device.

3. Complete test procedures for disaster recovery to ensure that container-copy storage pools can be used to restore your environment in a time frame that meets your requirements.

Repairing storage pools after a disaster

Configuring a cloud-container storage pool for data storage

You can store deduplicated data and non-deduplicated data in a cloud-container storage pool and restore the data as required. You can configure cloud-container storage pools to use one of the following service providers and protocols: Amazon Web Services (AWS) with Simple Storage Service (S3), IBM® Cloud Object Storage with Swift or S3 (and IBM SoftLayer), Microsoft Azure, and OpenStack with Swift using Keystone Version 1 or Version 2. Cloud-container storage pools are not supported on Linux on System z®.

Before you begin

Complete the following steps:

1. Obtain the configuration information for your cloud service provider:
   - Amazon with S3 (off-premises)
   - Microsoft Azure
   - IBM Cloud Object Storage with S3 (off-premises, with IBM SoftLayer®)
   - IBM Cloud Object Storage with Swift (off-premises, with IBM SoftLayer)
   - IBM Cloud Object Storage with S3 (on-premises)
   - OpenStack with Swift (on-premises or off-premises)
2. Specify a device class to use for database backup operations. When you use encryption for cloud-container storage pools, the server master encryption key is used to protect the cloud encryption key in a database backup.
   a. On the Operations Center menu bar, select Servers.

b. Select a server row and click Back Up.
c. Select a device class to use for database backup operations and click Back Up.

Tip: Alternatively, use the SET DBRECOVERY command to specify a device class for the database backup.

Procedure

To store data in a cloud-container storage pool, complete the following steps:

1. Create a cloud-container storage pool. You must provide configuration information that identifies the cloud service.
   a. On the Operations Center menu bar, click Storage > Storage Pools.
   b. On the Storage Pools page, click + Storage Pool.
   c. Complete the steps in the Add Storage Pool wizard. Select On-premises cloud or Off-premises cloud for the type of container-based storage.
2. Update your management classes and policy sets to use the new storage pool. To update a management class to use the new storage pool, complete the following steps:
   a. On the Operations Center menu bar, click Services.
   b. On the Policies page, select a policy domain and click Details.
   c. On the Details page, click the Policy Sets tab.
   d. Click the Configure toggle. The policy sets are editable.
   e. Optional: To edit a policy set that is not active, click the forward and back arrows to locate the policy set.
   f. Update one or more management classes to use the new storage pool by editing the Backup Destination field of the table.
   g. Click Save.
3. Activate the changed policy set by completing the following steps:
   a. Click Activate. Because changing the active policy set might result in data loss, a summary of the differences between the active policy set and the new policy set is displayed.
   b. Look at the differences between corresponding management classes in the two policy sets, and consider the consequences on client files. Client files that are bound to management classes in the currently active policy set are, after activation, bound to the management classes with the same names in the new policy set.
   c. Identify management classes in the currently active policy set that do not have counterparts in the new policy set, and consider the consequences on client files. Client files that are bound to these management classes are, after activation, managed by the default management class in the new policy set.
   d. If the changes implemented by the policy set are acceptable, select the I understand that these updates can cause data loss check box and click Activate.
4. Click the Configure toggle. The policy sets are no longer editable.
5. To take advantage of local storage, create a storage pool directory for this storage pool using the DEFINE STGPOOLDIRECTORY command. For more information, see Optimizing performance for cloud object storage.

SET DBRECOVERY (Set the device class for automatic backups)

Preparing to configure cloud-container storage pools for AWS with S3 (off premises)

Before you configure cloud-container storage pools to use Amazon Web Services (AWS) off premises with the Simple Storage Service (S3) protocol, you must obtain information from Amazon that is required for the configuration process.

About this task

AWS account credentials are different from Amazon account credentials. Use the credentials for your AWS account when you configure storage pools in the Operations Center or with the DEFINE STGPOOL command.

AWS uses *buckets* to store data. AWS buckets are used in the same manner as containers in a cloud-container storage pool. IBM Spectrum Protect™ automatically creates a bucket in Amazon for an instance of IBM Spectrum Protect, and that bucket is shared by all pools for that instance.

Restriction: Edit an AWS bucket only with IBM Spectrum Protect, and do not change the data in the bucket or edit the configuration settings for the bucket.

Procedure

1. Sign up for an AWS account by going to the Amazon S3 page and clicking Create an AWS Account.
2. Obtain your AWS credentials:
   a. Go to the Amazon S3 page and click Sign In to the Console.
   b. Select your name and select Security Credentials.
   c. Go to the Access Keys section to locate the Access Key ID and the Secret Access Key fields. Record the values so that you can use them when you configure storage pools.
3. If you plan to configure storage pools by using the Add Storage Pool wizard in the Operations Center, use the following values for the parameters:
   - Cloud type: `Amazon - S3 API`
   - Access key ID: *access_key_id*
   - Secret access key: *secret_access_key*
   - Region: Select the region endpoint that best fits your location, based on the AWS Regions and Endpoints page. If you select `Other`, specify a region endpoint URL in the URL field, and include the protocol, usually https://. Typically, you can use the region that is closest to your physical location for the Region parameter. Because an Amazon bucket exists in only one region, you can specify only one endpoint URL for a region. If you require a GovCloud region, specify a URL from the AWS GovCloud (US) Endpoints page.
     Warning: Be sure to use only the AWS endpoint URL for the Region value, such as `https://s3-us-west-1.amazonaws.com`. Do not use the static website hosting URL for this value.
   - Bucket name: Use the default bucket name generated by the server, or specify a new bucket name.
4. To define the cloud-container storage pool, issue the DEFINE STGPOOL command with the following values:
   - CLOUDTYPE: S3
   - IDENTITY: *access_key_id*
   - PASSWORD: *secret_access_key*
   - CLOUDURL: Specify the region endpoint URL that best fits your location, based on the AWS Regions and Endpoints page.

     Typically, you can use the region that is closest to your physical location for the CLOUDURL parameter. If you require a GovCloud region, specify a URL from the AWS GovCloud (US) Endpoints page.

     Warning: Be sure to use only the AWS endpoint URL for the CLOUDURL value, such as `https://s3-us-west-1.amazonaws.com`. Do not use the static website hosting URL for this value.

What to do next

Configure cloud-container storage pools for AWS by following the instructions in Configuring a cloud-container storage pool for data storage.

Configuring an Amazon S3 compatible device as a cloud-container storage pool

You can configure a storage device that is compatible with the Amazon Simple Storage Service (S3) protocol so that the device can be used as an IBM Spectrum Protect™ cloud-container storage pool.

About this task

Amazon S3 uses *buckets* to store data. You must create a bucket on the S3 compatible storage device for use by an IBM Spectrum Protect server. After you create the bucket, use the credentials from the account on your Amazon S3 compatible cloud object storage device when you configure storage pools with the DEFINE STGPOOL command.

Restriction: Do not change the data in the bucket or edit the configuration settings for the bucket.

Procedure

1. Create a bucket on the cloud object storage device. Follow the instructions in the device documentation.
2. Create a user account on the cloud object storage device. The account is used by IBM Spectrum Protect to access the device by using the access key ID and secret access key. Ensure that the account has permissions to store data in and delete data from the bucket that you created in Step 1. Record the access key ID and the secret access key values so that you can use them when you configure storage pools.
3. Identify the URL value that will be used by IBM Spectrum Protect to access the cloud object storage device. For instructions, see the documentation for your cloud object storage device.
4. To define the cloud-container storage pool, issue the DEFINE STGPOOL command with the following values:
    - CLOUDTYPE: S3
    - IDENTITY: *access_key_id*
    - PASSWORD: *secret_access_key*
    - CLOUDURL: http://*cloud_object_storage_endpoint_IP_address* or https://*cloud_object_storage_endpoint_IP_address*. If you use more than one endpoint, list the endpoint IP addresses separated by a vertical bar (|), with no spaces, as shown in the following example:

      ```
      CLOUDURL=endpoint_URL1|endpoint_URL2|endpoint_URL3
      ```

    - BUCKETNAME: *name_of_bucket_on_device*

      To optimize performance, use multiple endpoints or a load balancer.

What to do next

Configure cloud-container storage pools in a similar way as you would configure a cloud-container storage pool for IBM Cloud Object Storage by following the instructions in Configuring a cloud-container storage pool for data storage.

Preparing to configure cloud-container storage pools for Microsoft Azure (off premises)

Before you configure cloud-container storage pools to use the Microsoft Azure cloud computing system, you must obtain information for the configuration process from Microsoft.

About this task

IBM Spectrum Protect™ supports the following Azure storage tiers:

- *Hot storage tier* for data that is accessed frequently
- *Cool storage tier* for data that is accessed less frequently

You can use a cool storage tier for cost-effective, long-term storage. However, it is more costly to restore data from a cool storage tier than from a hot storage tier.

Procedure

1. Sign up for a Microsoft Azure account by going to the Azure portal and creating an account.
2. Create a storage account. Typically, select the location that is nearest to your IBM Spectrum Protect server for the storage account location.
3. Obtain your Azure credentials:
    a. Go to the Azure portal and click Storage accounts.
    b. Open the new storage account, go to the container section of the Blob Service pane, and record the blob service endpoint value so that you can use it when you configure storage pools. The blob service endpoint looks like these examples: https://*name* .blob.core.windows.net and http://*name* .blob.core.windows.net.
    c. Create a shared access signature (SAS) token by opening the Shared access signature tab and completing the fields . Ensure that the Allowed services section includes Blob and that the Allowed resource types section includes Container and Object. Ensure that the SAS token has read, write, delete, list, add, and create permissions. Click Generate SAS.
    d. Record the SAS token value so that you can use it when you configure storage pools. IBM Spectrum Protect does not monitor the SAS token expiration date, so ensure that you select a date that best suits your needs. If the token expires, the IBM Spectrum Protect server loses access to the storage account until you provide a new SAS token. Tip: If you would like to less frequently update the SAS token, set an expiration date that is several years away. Also, ensure that you verify the start date and time fields.

4. If you plan to configure storage pools by using the Add Storage Pool wizard in the Operations Center, use the following values for the parameters:
    - Cloud type: `Azure`
    - SAS token: *SAS_token_value*. Look for a string that is similar to this example:

      ```
      ?sv=2016-05-31&ss=b&srt=sco&sp=rwdlac&se=2017-04-05T18:26:
      12Z&st=2017-04-05T10:26:12Z&spr=https&sig=
      XUangS%2FcXXXXXXXXXXXXXXXXXXXXXXXXXXXELsuWp106Cmq7o%3D
      ```

    - Blob service endpoint: Specify the blob service endpoint from your Azure storage account, for example, https://*name* .blob.core.windows.net or http://*name* .blob.core.windows.net.
5. If you plan to configure storage pools by using the DEFINE STGPOOL command, use the following values for the command parameters:
    - CLOUDTYPE: Azure
    - PASSWORD: *SAS_token_value*. Look for a string that is similar to this example:

      ```
      ?sv=2016-05-31&ss=b&srt=sco&sp=rwdlac&se=2017-04-05T18:26:
      12Z&st=2017-04-05T10:26:12Z&spr=https&sig=
      XUangS%2FcXXXXXXXXXXXXXXXXXXXXXXXXXXXELsuWp106Cmq7o%3D
      ```

    - CLOUDURL: Specify the blob service endpoint from your Azure storage account, for example, https://*name* .blob.core.windows.net or http://*name* .blob.core.windows.net.

What to do next

Configure cloud-container storage pools for Azure by following the instructions in Configuring a cloud-container storage pool for data storage.

Preparing to configure cloud-container storage pools for IBM Cloud Object Storage with Swift (off premises)

Before you configure cloud-container storage pools to use IBM® Cloud Object Storage and IBM SoftLayer® off premises using Swift, you must obtain configuration information from the SoftLayer Object Storage page.

About this task

Use the credentials from your IBM SoftLayer account when you configure the storage pools in the Operations Center or with the DEFINE STGPOOL command.

Procedure

1. Create a SoftLayer account by following the instructions in the SoftLayer documentation.
2. Obtain your SoftLayer credentials:
    a. Go to the SoftLayer Object Storage page and log in with your account credentials.
    b. Select the account and cluster that you want to configure.
    c. In the Account section, click View Credentials
    d. In the Account Credentials section, locate the Public Authentication Endpoint, Username, and API Key fields. Record the values in those fields so that you can use them when you configure storage pools.
3. If you plan to configure storage pools by using the Add Storage Pool wizard in the Operations Center, use the following values for the parameters:
    - Cloud type: `IBM Cloud Object Storage - Swift API (SoftLayer)`
    - User name: *username*
    - Password: *API_key*
    - URL: *public_authentication_endpoint*
4. If you plan to configure storage pools by using the DEFINE STGPOOL command, use the following values for the command parameters:
    - CLOUDTYPE: SOFTLAYER
    - IDENTITY: *username*
    - PASSWORD: *API_key*
    - CLOUDURL: *public_authentication_endpoint*

What to do next

Configure cloud-container storage pools for IBM SoftLayer by following the instructions in Configuring a cloud-container storage pool for data storage.

Preparing to configure cloud-container storage pools for IBM Cloud Object Storage with S3 (off premises)

You can set up cloud storage pools to use IBM® Cloud Object Storage off premises with the Simple Storage Service (S3) protocol.

About this task

The off premises implementation of IBM Cloud Object Storage is managed through SoftLayer® or IBM Bluemix. In this setup, only the owner of the SoftLayer or Bluemix account can create buckets and administrators.

Use the credentials from your IBM SoftLayer or IBM Bluemix account when you configure the storage pools in the Operations Center or with the DEFINE STGPOOL command. For more information, see the SoftLayer Object Storage page. To use this configuration, select Cloud Object Storage - S3 API from the SoftLayer Order Object Storage page.

Procedure

1. Log into the SoftLayer Customer Portal.
2. Click the Storage menu and select Object Storage.
3. From the Object Storage page, select an S3 account.
4. From the Cloud Object Storage page, click Manage Buckets and then click the + symbol to create the bucket you want to use with the new cloud-container storage pool.
5. Click Show Credentials to create administrator credentials for your new bucket.
6. Click Add Credential.
7. Locate the Access Key ID, the Secret Access Key, and the Public Authentication Endpoint. Record the values in those fields so that you can use them when you configure storage pools. If you are inside the SoftLayer network, you can use a private authentication endpoint.
8. To configure storage pools by using the Add Storage Pool wizard in the Operations Center, select Off-premises cloud. Use the following values for the parameters:
   - Cloud type: `IBM Cloud Object Storage - S3 API (SoftLayer)`
   - Access key ID: *access_key_ID*
   - Secret access key: *secret_access_key*
   - Bucket name: *bucket_name* (from step 4)
   - URL: *us-geo_authentication_endpoint*
     Note: Only one cloud provider endpoint is needed with this configuration. If all of your servers are inside the SoftLayer network, you can use a private authentication endpoint.
9. If you configure storage pools by using the DEFINE STGPOOL command, use the following values for the command parameters:
   - CLOUDTYPE: S3
   - IDENTITY: *access_key_ID*
   - BUCKETNAME: *bucket_name* (from step 4)
   - PASSWORD: *secret_access_key*
   - CLOUDURL: *us-geo_authentication_endpoint*
     Note: Only one cloud provider endpoint is needed with this configuration. If all of your servers are inside the SoftLayer network, you can use a private authentication endpoint.

What to do next

Configure cloud-container storage pools for IBM SoftLayer Cloud Object Storage by following the instructions in Configuring a cloud-container storage pool for data storage.

Preparing to configure cloud-container storage pools for IBM Cloud Object Storage with S3 (on premises)

Before you configure cloud-container storage pools to use IBM® Cloud Object Storage on premises with S3, you must set up an IBM Cloud Object Storage vault template and an IBM Cloud Object Storage user account, and then obtain configuration information.

About this task

IBM Cloud Object Storage vaults are used in the same manner as containers in a cloud-container storage pool. Set up a vault template to quickly create vaults with your preferred settings.

After you create a vault template, use the credentials from your IBM Cloud Object Storage user account to configure the storage pools in the Operations Center or with the DEFINE STGPOOL command. IBM Spectrum Protect™ uses the Simple Storage Service (S3) protocol to communicate with IBM Cloud Object Storage.

Tip: You can skip the first four steps in the procedure if you want to configure a vault that already exists by using the BUCKETNAME parameter in the DEFINE STGPOOL or UPDATE STGPOOL commands.

Procedure

1. Create a vault template:
    a. Log in to IBM Cloud Object Storage and click the Configure tab.
    b. In the dsNet navigation pane, expand Storage Pools.
    c. Select the IBM Cloud Object Storage storage pool where you want to create the vault template, and click the Storage Pool link in the General section.
    d. In the Vault Templates section, click Create Vault Template.
    e. Select the settings for the default vault template. You might be able to optimize performance by not selecting the Enable SecureSlice Technology or the Name Index Enabled options, and selecting the Recovery Listing Enabled option.
    f. In the Deployment section, select the access pool or pools that you want to use for the template and click Save.
2. Set the vault template as the default for your IBM Cloud Object Storage dsNet:
    a. Click the Configure tab.
    b. In the Default Vault Template Configuration section, click Configure.
    c. Select a vault template to use as the default, and click Update to set that template as the default.
3. If this is your first time configuring a vault template, enable the vault provisioning role so you can create new vaults:
    a. Click the Administration tab.
    b. In the Provisioning API Configuration section, click Configure.
    c. Select Create Only or Create and Delete to let users create new vaults using the Provisioning API.
    d. Click Update to save the settings.
4. Use an IBM Cloud Object Storage account with administration authority to create a user account on the IBM Cloud Object Storage instance in your environment. Ensure that the new user account has the Vault Provisioner role.
5. Click the Security tab and select the new user account.
6. Generate an access key for the new user:
    a. In the Access Key Authentication section, click Change Keys.
    b. On the Edit Access Keys page, click Generate New Access Key.
    c. Click Back.
7. In the Access Key Authentication section, locate the Access Key ID and Secret Access Key values. Record the values so that you can use them when you configure storage pools.
8. Locate the URL value:
    a. Click the Configure tab.
    b. In the dsNet navigation pane, expand the Devices and Accesser sections.
    c. Select the IBM Cloud Object Storage accesser. Verify that the accesser belongs to an access pool to which the default vault template is deployed.
    d. In the Device Configuration section for the accesser, record the IP Address value so that you can use it when you configure storage pools. Use `http://` before the IP address value to prevent certificate security errors.
9. If you configure storage pools by using the Add Storage Pool wizard in the Operations Center, use the following values for the parameters:
    - Cloud type: `IBM Cloud Object Storage - S3 API`
    - Access key ID: *access_key_ID*
    - Secret access key: *secret_access_key*
    - Bucket name: Use the default bucket name generated by the server, or specify a new bucket name.
    - URL: `http://`*Cloud_Object_Store_accesser_IP_address*
      Important: If you use more than one accesser, type an accesser IP address and then press Enter to add additional IP addresses. Use multiple accessers or a load balancer for optimal performance.
10. If you configure storage pools by using the DEFINE STGPOOL command, use the following values for the command parameters:
    - CLOUDTYPE: S3
    - IDENTITY: *access_key_ID*

- PASSWORD: *secret_access_key*
- CLOUDURL: `http://`*Cloud_Object_Store_accesser_IP_address*
  Important: If you use more than one accesser, list the accesser IP addresses separated by a vertical bar (|), with no spaces, such as *CLOUDURL=<accesser_URL1>|<accesser_URL2>|<accesser_URL3>*. Use multiple accessers or a load balancer for optimal performance.

What to do next

Configure cloud-container storage pools for IBM Cloud Object Storage by following the instructions in Configuring a cloud-container storage pool for data storage.

Preparing to configure cloud-container storage pools for OpenStack with Swift

Before you configure cloud-container storage pools to use OpenStack on premises or off premises with Swift, you must obtain configuration information from the OpenStack Swift computer.

About this task

Use the credentials from your OpenStack Swift account when you configure the storage pools by using the Operations Center or the DEFINE STGPOOL command.

Procedure

1. Create an OpenStack Swift account by following the instructions in the OpenStack Swift documentation.
2. Obtain your OpenStack Swift credentials:
   a. On the OpenStack Swift computer, type the following command:

      ```
      swift auth -v
      ```

   b. In the output, locate the `OS_AUTH_URL`, the `OS_TENANT_NAME`, the `OS_USERNAME`, and the `OS_PASSWORD` values. Record the values so that you can use them when you configure storage pools.
3. If you plan to configure storage pools by using the Add Storage Pool wizard in the Operations Center, use the following values for the parameters:
   - Cloud type: `OpenStack Swift`
   - User name: *OS_TENANT_NAME:OS_USERNAME*
   - Password: *OS_PASSWORD*
   - URL: *OS_AUTH_URL*
4. If you plan to configure storage pools by using the DEFINE STGPOOL command, use the following values for the command parameters:
   - CLOUDTYPE: SWIFT or V1SWIFT
   - IDENTITY: *OS_TENANT_NAME:OS_USERNAME*
   - PASSWORD: *OS_PASSWORD*
   - CLOUDURL: *OS_AUTH_URL*
5. If you plan to use a specific tenant or user name, record the values in the following format: *TENANT_NAME:USERNAME*.
6. To prevent data loss, configure OpenStack Swift to create replicas of the data that is written to its object storage. For more information, see the OpenStack Swift documentation.

What to do next

Configure cloud-container storage pools for OpenStack Swift by following the instructions in Configuring a cloud-container storage pool for data storage.

Encrypting data for cloud-container storage pools

Data that is stored in off-premises cloud-container pools is encrypted by default. You can optionally encrypt data in on-premises cloud-container storage pools.

About this task

For information about encrypting cloud-container storage pool data and for performance considerations related to the encryption of data, see technote 1963635.

Optimizing performance for cloud object storage

You can configure IBM Spectrum Protect™ to temporarily store data in one or more local storage pool directories during data ingestion. The data is then moved from local storage to the cloud. In this way, you can improve data backup and archive performance.

Before you begin

To optimize backup and archive performance, ensure that IBM Spectrum Protect Version 8.1 is installed.

About this task

After you define a storage pool directory, the IBM Spectrum Protect server uses that directory as a temporary landing spot for the data that you are transferring to cloud object storage. The server uses an automated background process to transfer data from local storage in the directory to cloud object storage. You do not need to take any additional steps to start or manage this transfer process. After the server successfully moves the data from local storage to cloud object storage, the server deletes the data from the directory and releases space for more incoming data.

If storage pool directories contain no more free space, backup operations stop prematurely. To avoid this situation, you can allocate more storage pool directories. You can also wait for the data to be automatically removed from the local directories after the data moves to the cloud. The required number of storage pool directories you need to define depends on your disk configuration on the server. When the initial backups occur, the server spreads the data across all the directories you defined.

The amount of space you need for local storage is based on the amount of data you expect to back up each day after data deduplication and compression. If you have a stable network connection to the cloud object storage, the required amount of space is similar to the amount that is required for a daily backup.

For additional planning information, see the topic for your operating system:

- AIX®: Planning for directory-container and cloud-container storage pools
- Linux: Planning for directory-container and cloud-container storage pools
- Windows: Planning for directory-container and cloud-container storage pools

Procedure

1. Create a cloud-container storage pool by using the Add Storage Pool wizard in the Operations Center. Alternatively, create the pool by using the DEFINE STGPOOL command.
2. Define one or more storage pool directories by using the DEFINE STGPOOLDIRECTORY command. Ensure that each storage pool directory has its own file system. On Linux systems, use xfs or ext4 as the file system instead of ext3 because deleting large files takes more time with ext3. Ensure that the new storage pool directories do not share the root file system, nor should they share the same file systems that are used by other IBM Spectrum Protect resources, such as the database or the logs.

Related reference:
DEFINE STGPOOLDIRECTORY (Define a storage pool directory)
AIX | Linux | Windows

Managing space in container storage pools

After you configure IBM Spectrum Protect™ and add storage, manage your data and storage pool space effectively to ensure that it operates correctly. Use container storage pools to maximize your storage space and server performance.

About this task

Container storage pools are primary storage pools that you use for inline data deduplication, inline compression, and cloud storage.
Restriction: You cannot use any of the following functions with container storage pools:

- Migration

- Reclamation
- Aggregation
- Collocation
- Export
- Import
- Simultaneous-write
- Storage pool backup
- Virtual volumes

Procedure

1. Create a directory-container storage pool by completing the following steps:
    a. Open the Operations Center.
    b. On the Operations Center menu bar, click Storage > Storage Pools.
    c. Click +Storage Pool.
    d. Complete the steps in the Add Storage Pool wizard:
        - To use inline data deduplication, select a Directory storage pool under Container-based storage.
        - When you configure directories for the directory-container storage pool, specify the directory paths that you created for storage during system setup.
    e. After you configure the new directory-container storage pool, click Close & View Policies to update a management class and start using the storage pool.
2. For optimal performance of container storage pools, complete the following tasks:

Task	Procedure	More information
Protect the storage pool	When you create a directory-container storage pool in the Operations Center, you can configure storage pool protection in the schedule that you assign to the storage pool. Alternatively, use the PROTECT STGPOOL command from the source server to back up data extents in a directory-container storage pool. By protecting a storage pool, you do not use resources that replicate existing data and metadata, which improves server performance.	○ Protecting data in directory-container storage pools ○ PROTECT STGPOOL (Protect data that belongs to a storage pool)
Repair a storage pool	When a storage pool is protected, you can use the REPAIR STGPOOL command to repair damaged data extents. Use the REPAIR STGPOOL command to repair a directory-container storage pool. Restriction: If you replicate client nodes but do not protect the directory-container storage pool, you cannot repair the storage pool.	○ Repairing storage pools ○ REPAIR STGPOOL (Repair a directory-container storage pool)
Delete containers	Containers are deleted in the inventory as file data is removed or expired. Use the DEFINE STGPOOL command and specify the REUSEDELAY parameter to control the duration that deduplicated extents are associated with a directory-container storage pool after they are no longer referenced. If a container is damaged, use the AUDIT CONTAINER command to recover or remove data.	○ DEFINE STGPOOL (Define a directory-container storage pool) ○ AUDIT CONTAINER (Verify the consistency of database information for a directory-container)

Convert a primary storage pool that uses a FILE device class, a tape device class, or a virtual tape library (VTL)	You can convert an existing storage pool to a directory-container storage pool by completing the steps in Converting a primary storage pool to a container storage pool. Restriction: You cannot convert the following types of storage pool: ◦ Primary storage pools that use random-access device classes (DISK) ◦ Copy storage pools ◦ Active-data storage pools	◦ CONVERT STGPOOL (Convert a storage pool to a container storage pool)
Monitor container storage pool occupancy	Monitor the storage solution to identify existing and potential issues. For more information, see Monitoring storage solutions.	

- Converting a primary storage pool to a container storage pool
  Convert a primary storage pool that uses a FILE device class, a tape device class, or a virtual tape library (VTL) to a container storage pool. Data that is stored in a container storage pool can use both inline data deduplication and inline compression.
- Cleaning up data in a source storage pool
  To convert a storage pool to a directory-container storage pool, you might have to clean up damaged data or files that are in the source storage pool.

AIX | Linux | Windows

Converting a primary storage pool to a container storage pool

Convert a primary storage pool that uses a FILE device class, a tape device class, or a virtual tape library (VTL) to a container storage pool. Data that is stored in a container storage pool can use both inline data deduplication and inline compression.

Before you begin

To ensure that volumes in a source storage pool and associated copy storage pools are not reused during a conversion process, specify a value for the REUSEDELAY parameter on the UPDATE STGPOOL command. Specify a value for the REUSEDELAY parameter that is greater than the conversion duration. You might have to delay reuse of volumes for the following reasons:

- You inadvertently delete the data during storage pool conversion.
- You need source storage pool functionality that is not available in container storage pools.

Tip: When you specify the REUSEDELAY parameter and a conversion operation is in progress, some storage space is unavailable in the source storage pool until the value of the parameter expires.
Create a container storage pool where data will be moved by completing the following steps:

1. On the Storage Pools page of the Operations Center, click + Storage Pool.
2. Complete the steps in the Add Storage Pool wizard. Select the type of container-based storage that you require.

About this task

By converting a storage pool to a container storage pool, you remove the need for volume reclamation. The omission of volume reclamation operations can help to improve server performance and reduce the amount of required storage hardware.

As files are converted, any copies that are stored in copy pools or active-data pools are deleted.
Restrictions:

- If the source pool is specified as a backup, archive, or migration destination in an active policy set that has pending changes, you must activate those changes before you can convert the pool.
- To ensure that the destination specifies a storage pool that is not converted or undergoing conversion, you must update all policies that reference the source storage pool.
- If the source storage pool is specified as a next storage pool, you must update the NEXTSTGPOOL parameter on the UPDATE STGPOOL command to specify a random-access or sequential-access storage pool that is not being converted.

- The following data types are not eligible for conversion: table of contents (TOC) backups, virtual volumes, and Network Data Management Protocol (NDMP) data. Before you start the conversion process, manually delete these data types from the storage pool, move the data types to a different primary storage pool, or allow the data types to expire based on policy settings.
- When you convert a storage pool with a FILE device class to a directory-container pool, the target storage pool should be approximately 30% larger than the source storage pool. Additional space is not typically required when you convert other storage pool types.

  For more information about best practices for storage pool conversion, see Best practices for IBM Spectrum Protect storage pool conversion.

- If the source storage pool is used to store TOC backups, ensure that another primary storage pool is available to store new TOC backups. Existing TOC backups are not moved during conversion.

  The TOC pool must use a NATIVE or NONBLOCK data format and a device class other than Centera. To avoid mount delays, use a DISK or FILE device class.

Procedure

1. On the Storage Pools page of the Operations Center, select a storage pool that uses a FILE device class, a tape device class, or VTL.
2. Click More > Convert and complete the steps in the Convert Storage Pool wizard.
   Tip: Schedule conversion for at least 2 hours for a storage pool that uses a FILE device class and at least 4 hours for VTL.

What to do next

When the conversion process is complete, the source storage pool might contain damaged data or data that is incompatible with container storage pools. Clean up the source storage pool by completing the steps in Cleaning up objects after storage pool conversion.

Related tasks:
Restoring the database
AIX | Linux | Windows

Cleaning up data in a source storage pool

To convert a storage pool to a directory-container storage pool, you might have to clean up damaged data or files that are in the source storage pool.

Procedure

Use the following options to recover or repair damaged data:

- Recover an undamaged version of the data from a copy or active-data storage pool by issuing the RESTORE STGPOOL command.
- Recover an undamaged version of the data from a target replication server by issuing the REPLICATE NODE command and specifying the RECOVERDAMAGED=YES parameter.
- Remove data that cannot be repaired after storage pool conversion by issuing the REMOVE DAMAGED command.
  The REMOVE DAMAGED command might not remove volumes that are marked as destroyed on the source storage pool. To remove these volumes, complete the following steps:
  a. Issue the DELETE VOLUME command and specify the DISCARDDATA=YES parameter.
  b. Issue the CONVERT STGPOOL command to convert the storage pool again.
  c. If damaged data is identified during storage pool conversion, reissue the REMOVE DAMAGED command.
- Complete the analysis tasks that are described in technote 1666371.

What to do next

After you have recovered or repaired the damaged data, retry conversion by issuing the CONVERT STGPOOL command.
To view information about damaged files that remain in the source storage pool, issue the QUERY CLEANUP command.
Tip: If a Cleanup status is shown for a storage pool that contains no data, you can delete the storage pool by using the DELETE STGPOOL command.
Related reference:

DELETE VOLUME (Delete a storage pool volume)
QUERY CLEANUP (Query the cleanup that is required in a source storage pool)
REMOVE DAMAGED (Remove damaged data from a source storage pool)
REPLICATE NODE (Replicate data in file spaces that belong to a client node)
RESTORE STGPOOL (Restore storage pool data from a copy pool or an active-data pool)

Auditing a storage pool container

Audit a storage pool container to check for inconsistencies between database information and a container in a storage pool.

About this task

You audit a storage pool container in the following situations:

- When you issue the QUERY DAMAGED command and a problem is detected
- When the server displays messages about damaged data extents
- Your hardware reports an issue and error messages that are associated with the storage pool container are displayed

Procedure

1. To audit a storage pool container, issue the AUDIT CONTAINER command. For example, issue the following command to audit a container, 000000000000076c.dcf:

   ```
   audit container c:\tsm-storage\07\000000000000076c.dcf
   ```

2. Review the output from the ANR4891I message for information about any damaged data extents.

What to do next

If you detect problems with the storage pool container, you can restore data based on your configuration. You can repair the contents in the storage pool by using the REPAIR STGPOOL command.
Restriction: You can repair the contents of the storage pool only if you protected the storage pool by using the PROTECT STGPOOL command.
Related reference:
AUDIT CONTAINER (Verify the consistency of database information for a directory-container storage pool)
QUERY DAMAGED (Query damaged data in a directory-container or cloud-container storage pool)

Storage system requirements and reducing the risk of data corruption

You can use many types of storage for the IBM Spectrum Protect™ server. If you use block disk storage, solid-state drives (SSD), or network-attached file systems for server storage, ensure that the storage meets requirements.

The following requirements apply to storage for the server database, active log, and archive log; for storage pools that use DISK or FILE device classes; and for directory-container storage pools.

Storage can be connected to the server system by any method that is valid for the operating system. For example, the storage can be attached directly, or by using Fibre Channel or iSCSI technology.

Because of the many storage systems that can meet the requirements for server storage, a list of such devices is not available. Contact the vendor if you have questions about whether a system meets IBM Spectrum Protect requirements.

For details about file system requirements, see technote 1902417. For details about network file system (NFS) requirements, see technote 1470193.

Storage and file systems must report write and commit results synchronously and accurately to the IBM Spectrum Protect server. Unreported or asynchronously reported write errors that result in data not being permanently committed to the storage system can cause data corruption. Data corruption can cause operational failures, including failure to start the server, and data recovery is typically required.

You can reduce the risk of data corruption with the following tips:

Write cache

Disk systems use write cache to improve system performance. To reduce the risk of data corruption, the storage system must reliably commit the data in the write cache to permanent storage.

The write cache typically has a battery to prevent loss of data from the cache during short power outages. For critical systems, consider backup power sources to protect the cache from extended power outages.

Direct I/O
: Direct I/O meets the server's need for synchronous and accurate reporting on data write and commit operations. Attention: Do not disable direct I/O in situations where the method of write caching has a potential to cause data loss. Disabling direct I/O can greatly increase the potential for data loss because more data is cached by the file system, in addition to the disk system.

Storage replication
: Environments that replicate IBM Spectrum Protect storage must use features such as maintenance of write order between the source (local server) and the target (remote server). The database, active log, archive logs, and storage pools must be part of a consistency group. A consistency group maintains relationships among volumes to preserve write order so that they can be recovered. Any I/O to the members of the target consistency group must be written in the same order as the source and maintain the same volatility characteristics.

  To maintain synchronization between IBM Spectrum Protect servers at local and remote sites, do not start a server at the remote site except in a failover situation. Monitor for synchronization of data at the local and remote locations. If synchronization is lost, you must restore the server at the remote location by using IBM Spectrum Protect restore commands for the database and storage pools.

Tips on storage configuration

For tips on storage configuration to optimize system performance, see the following topics from the V7.1.1 product documentation. The information in the checklists can be applied to later releases.

- Checklist for server database disks
- Checklist for server recovery log disks
- Checklist for storage pools that use DISK or FILE device classes

Monitoring storage solutions

After you implement an IBM Spectrum Protect™ solution, monitor the solution to ensure that it operates correctly. By monitoring the solution on a daily and periodic basis, you can identify existing and potential issues. The information that you gather can be used to troubleshoot problems and optimize system performance.

About this task

The preferred way to monitor a solution is by using the Operations Center, which provides overall and detailed system status in a graphical user interface. In addition, you can configure the Operations Center to generate email reports that summarize system status.

Procedure

1. Complete daily monitoring tasks. For instructions, see Daily monitoring checklist.
2. Complete periodic monitoring tasks. For instructions, see Periodic monitoring checklist.
3. To verify that your system complies with licensing requirements, follow the instructions in Verifying license compliance.
4. Optional: Set up email reports of system status. For instructions, see Tracking system status by using email reports
5. Optional: In some cases, you might want to use advanced monitoring tools to complete specific monitoring or troubleshooting tasks. To select and configure advanced monitoring tools, see Selecting, configuring, and using monitoring tools.

What to do next

To help you diagnose issues with backup-archive clients, install IBM Spectrum Protect client management services on backup-archive client systems that support it. When the client management service is installed on a system, in the Operations Center you can click Diagnose to get help with diagnosing issues with the backup-archive client. To install the client management service, follow the instructions in Collecting diagnostic information with IBM Spectrum Protect client management services.

Troubleshooting

Daily monitoring checklist

Review the checklist to ensure that you complete important daily monitoring tasks.

Complete the daily monitoring tasks from the Operations Center Overview page. You can access the Overview page by opening the Operations Center and clicking Overviews.

The following figure shows the location for completing each task.

Tip: To run administrative commands for advanced monitoring tasks, use the Operations Center command builder. The command builder provides a type-ahead function to guide you as you enter commands. To open the command builder, go to the Operations Center Overview page. On the menu bar, hover over the settings icon and click Command Builder.

The following table lists the daily monitoring tasks and provides instructions for completing each task.

Table 1. Daily monitoring tasks

Task	Basic procedures	Advanced procedures and troubleshooting information
1 Determine whether clients are at risk of being unprotected due to failed or missed backup operations.	To verify whether clients are at risk, in the Clients area, look for an At risk notification. To view details, click the Clients area. If you installed the client management service on a backup-archive client, you can view and analyze the client error and schedule logs by completing the following steps: 1. In the Clients table, select the client and click Details. 2. To diagnose an issue, click Diagnosis.	For clients that do not have the client management service installed, access the client system to review the client error logs.

Task	Basic procedures	Advanced procedures and troubleshooting information
2 Determine whether client-related or server-related errors require attention.	To determine the severity of any reported alerts, in the Alerts area, hover over the columns.	To view additional information about alerts, complete the following steps: 1. Click the Alerts area. 2. In the Alerts table, select an alert. 3. In the Activity Log pane, review the messages. The pane displays related messages that were issued before and after the selected alert occurred.
3 Determine whether servers that are managed by the Operations Center are available to provide data protection services to clients.	1. To verify whether servers are at risk, in the Servers area, look for an Unavailable notification. 2. To view additional information, click the Servers area. 3. Select a server in the Servers table and click Details.	Tip: If you detect an issue that is related to server properties, update the server properties: 1. In the Servers table, select a server and click Details. 2. To update server properties, click Properties.
4 Determine whether sufficient space is available for the server inventory, which consists of the server database, active log, and archive log.	1. Click the Servers area. 2. In the Status column of the table, view the status of the server and resolve any issues: ○ Normal Sufficient space is available for the server database, active log, and archive log. ○ Critical Insufficient space is available for the server database, active log, or archive log. You must add space immediately, or the data protection services that are provided by the server will be interrupted. ○ Warning The server database, active log, or archive log is running out of space. If this condition persists, you must add space. ○ Unavailable Status cannot be obtained. Ensure that the server is running, and that there are no network issues. This status is also shown if the monitoring administrator ID is locked or otherwise unavailable on the server. This ID is named IBM-OC-hub_server_name. ○ Unmonitored Unmonitored servers are defined to the hub server, but are not configured for management by the Operations Center. To configure an unmonitored server, select the server, and click Monitor Spoke.	You can also look for related alerts on the Alerts page. For additional instructions about troubleshooting, see Resolving server problems.

Task	Basic procedures	Advanced procedures and troubleshooting information
5 Verify server database backup operations.	To determine when a server was most recently backed up, complete the following steps: 1. Click the Servers area. 2. In the Servers table, review the Last Database Backup column.	To obtain more detailed information about backup operations, complete the following steps: 1. In the Servers table, select a row and click Details. 2. In the DB Backup area, hover over the check marks to review information about backup operations. If a database was not backed up recently (for example, in the last 24 hours), you can start a backup operation: 1. On the Operations Center Overview page, click the Servers area. 2. In the table, select a server and click Back Up. To determine whether the server database is configured for automatic backup operations, complete the following steps: 1. On the menu bar, hover over the settings icon  and click Command Builder. 2. Issue the QUERY DB command: `query db f=d` 3. In the output, review the `Full Device Class Name` field. If a device class is specified, the server is configured for automatic database backups.
6 Monitor other server maintenance tasks. Server maintenance tasks can include running administrative command schedules, maintenance scripts, and related commands.	To search for information about processes that failed because of server issues, complete the following steps: 1. Click Servers > Maintenance. 2. To obtain the two-week history of a process, view the History column. 3. To obtain more information about a scheduled process, hover over the check box that is associated with the process.	For more information about monitoring processes and resolving issues, see the Operations Center online help.
7 Verify that the amount of data that was recently sent to and from servers is within the expected range.	• To obtain an overview of activity in the last 24 hours, view the Activity area. • To compare activity in the last 24 hours with activity in the previous 24 hours, review the figures in the Current and Previous areas.	• If more data was sent to the server than you expected, determine which clients are backing up more data and investigate the cause. It is possible that client-side data deduplication is not working correctly. • If less data was sent to the server than you expected, investigate whether client backup operations are proceeding on schedule.

Task	Basic procedures	Advanced procedures and troubleshooting information
8 Verify that storage pools are available to back up client data.	1. If problems are indicated in the Storage & Data Availability area, click Pools to view the details: ○ If the Critical status is displayed, insufficient space is available in the storage pool, or its access status is unavailable. ○ If the Warning status is displayed, the storage pool is running out of space, or its access status is read-only. 2. To view the used, free, and total space for your selected storage pool, hover over the entries in the Capacity Used column.	To view the storage-pool capacity that was used over the past two weeks, select a row in the Storage Pools table and click Details.
9 Verify that storage devices are available for backup operations.	In the Storage & Data Availability area, in the Volumes section, under the capacity bars, review the status that is reported next to Devices. If a Critical or Warning status is displayed for any device, investigate the issue. To view details, click Devices.	Disk devices might have a critical or warning status for the following reasons: • For DISK device classes, volumes might be offline or have a read-only access status. The Disk Storage column of the Disk Devices table shows the state of volumes. • For FILE device classes that are not shared, directories might be offline. Also, insufficient free space might be available for allocating scratch volumes. The Disk Storage column of the Disk Devices table shows the state of directories. • For FILE device classes that are shared, drives might be unavailable. A drive is unavailable if it is offline, if it stopped responding to the server, or if its path is offline. Other columns of the Disk Devices table show the state of the drives and paths. Tape devices might have a warning or critical status if drives are unavailable. A drive is unavailable if it is offline, if it stopped responding to the server, or if its path is offline. A tape device might also have a critical status if the library is offline. Other columns of the Tape Devices table show the state of the library robotics, drives, and paths. For tape backup operations, verify that sufficient scratch tapes are available. If you are not certain whether the number of available scratch tapes is sufficient, open the details notebook to view tape usage and an estimate of scratch tape availability. To open the details notebook, select a library in the table and click Details.

Task	Basic procedures	Advanced procedures and troubleshooting information
10 Monitor node replication processes.	1. To obtain the overall status of node replication processes, view the Replication area on the Operations Center Overview page. 2. To view information about each replicated server pair, click the Replication area. 3. To view the amount of data that was replicated over the last two weeks and the speed of replication, select a server pair and click Details. 4. To view replication information for a client, on the Operations Center Overview page, click Clients. View the information in the Replication Workload column.	For advanced monitoring, view information about running and ended node replication processes by using commands: 1. On the Operations Center Overview page, hover over the settings icon and click Command Builder. 2. Issue the QUERY REPLICATION command. For instructions, see QUERY REPLICATION (Query node replication processes). If the replication operation was completed successfully, the `Total Files To Replicate` value matches the `Total Files Replicated` value. To display messages that are related to a node replication process on a source or target replication server, complete the following steps: 1. On the Operations Center Overview page, click Servers. 2. Select the source or target replication server and click Details: ○ To view active tasks, click Active Tasks, select the task, and verify that the Running status is displayed. For details, view the related activity logs. ○ To view completed tasks, click Completed Tasks, select the task, and ensure that the Completed status is displayed. For details, view the related activity logs.

Periodic monitoring checklist

To help ensure operations run correctly, complete the tasks in the periodic monitoring checklist. Schedule periodic tasks frequently enough so that you can detect potential issues before they become problematic.

Tip: To run administrative commands for advanced monitoring tasks, use the Operations Center command builder. The command builder provides a type-ahead function to guide you as you enter commands. To open the command builder, go to the Operations Center Overview page. On the menu bar, hover over the settings icon and click Command Builder.

Table 1. Periodic monitoring tasks

Task	Basic procedures	Advanced procedures and troubleshooting

Task	Basic procedures	Advanced procedures and troubleshooting
Monitor system performance.	Determine the length of time that is required for client backup operations: 1. On the Operations Center Overview page, click Clients. Find the server that is associated with the client. 2. Click Servers. Select the server and click Details. 3. To view the duration of completed tasks in the last 24 hours, click Completed Tasks. 4. To view the duration of tasks that were completed more than 24 hours ago, use the QUERY ACTLOG command. Follow the instructions in QUERY ACTLOG (Query the activity log). 5. If the duration of client backup operations is increasing and the reasons are not clear, investigate the cause. If you installed the client management service on a backup-archive client, you can diagnose performance issues for the backup-archive client by completing the following steps: 1. On the Operations Center Overview page, click Clients. 2. Select a backup-archive client and click Details. 3. To retrieve client logs, click Diagnosis.	For instructions about reducing the time that it takes for the client to back up data to the server, see Resolving common client performance problems. Look for performance bottlenecks. For instructions, see Identifying performance bottlenecks. For information about identifying and resolving other performance issues, see Performance.
Determine the disk savings that are provided by data deduplication.	1. On the Operations Center Overview page, click Pools. 2. Select a pool and click Quick Look. 3. In the Data Deduplication area, view the Space saved row.	For advanced monitoring, to obtain detailed statistics about the data-deduplication process for a specific directory-container storage pool or cloud-container storage pool, complete the following steps: 1. On the Operations Center Overview page, hover over the settings icon and click Command Builder. 2. Obtain a statistical report by issuing the GENERATE DEDUPSTATS command. Follow the instructions in GENERATE DEDUPSTATS (Generate data deduplication statistics for a directory-container storage pool). 3. View the statistical report by issuing the QUERY DEDUPSTATS command. Follow the instructions in QUERY DEDUPSTATS (Query data deduplication statistics).

Task	Basic procedures	Advanced procedures and troubleshooting
Verify that current backup files for device configuration and volume history information are saved.	Access your storage locations to ensure that the files are available. The preferred method is to save the backup files to two locations. To locate the volume history and device configuration files, complete the following steps: 1. On the Operations Center Overview page, hover over the settings icon  and click Command Builder. 2. To locate the volume history and device configuration files, issue the following commands: `query option volhistory` `query option devconfig` 3. In the output, review the Option Setting column to find the file locations. If a disaster occurs, both the volume history file and the device configuration file are required to restore the server database.	

Task	Basic procedures	Advanced procedures and troubleshooting
Determine whether sufficient space is available for the instance directory file system.	Verify that at least 20% of free space is available in the instance directory file system. Take the action that is appropriate for your operating system: • AIX To view available space in the file system, on the operating system command line, issue the following command: `df -g instance_directory` where *instance_directory* specifies the instance directory. • Linux To view available space in the file system, on the operating system command line, issue the following command: `df -h instance_directory` where *instance_directory* specifies the instance directory. • Windows In the Windows Explorer program, right-click the file system and click Properties. View the capacity information. The preferred location of the instance directory depends on the operating system where the server is installed: • AIX Linux /home/tsminst1/tsminst1 • Windows C:\tsminst1 Tip: If you completed a planning worksheet, the location of the instance directory is recorded in the worksheet.	
Identify unexpected client activity.	To monitor client activity to determine whether data volumes exceed expected amounts, complete the following steps: 1. On the Operations Center Overview page, click the Clients area. 2. To view activity over the past two weeks, double-click any client. 3. To view the number of bytes sent to the client, click the Properties tab. 4. In the Last Session area, view the Sent to client row.	When you double-click a client in the Clients table, the Activity over 2 Weeks area displays the amount of data that the client sent to the server each day.

Task	Basic procedures	Advanced procedures and troubleshooting
Monitor storage pool growth over time.	1. On the Operations Center Overview page, click the Pools area. 2. To view the capacity that was used over the last two weeks, select a pool and click Details.	Tips: • To specify the time period that must elapse before all deduplicated extents are removed from a directory-container storage pool or cloud-container storage pool after they are no longer referenced by the inventory, complete the following steps: 1. On the Storage Pools page of the Operations Center, select the storage pool. 2. Click Details > Properties. 3. Specify the duration in the `Delay period for container reuse` field. • To determine data deduplication performance for directory-container and cloud-container storage pools, use the GENERATE DEDUPSTATS command. • To view data deduplication statistics for a storage pool, complete the following steps: 1. On the Storage Pools page of the Operations Center, select the storage pool. 2. Click Details > Properties. Alternatively, use the QUERY EXTENTUPDATES command to display information about updates to data extents in directory-container or cloud-container storage pools. The command output can help you determine which data extents are no longer referenced and which ones are eligible to be deleted from the system. In the output, monitor the number of data extents that are eligible to be deleted from the system. This metric has a direct correlation to the amount of free space that will be available within the container storage pool. • To display the amount of physical space that is occupied by a file space after the removal of the data deduplication savings, use the select * from occupancy command. The command output includes the LOGICAL_MB value. LOGICAL_MB is the amount of space that is used by the file space.
Evaluate the timing of client schedules. Ensure that the start and end times of client schedules meet your business needs.	On the Operations Center Overview page, click Clients > Schedules. In the Schedules table, the Start column displays the configured start time for the scheduled operation. To see when the most recent operation was started, hover over the clock icon.	Tip: You can receive a warning message if a client operation runs longer than expected. Complete the following steps: 1. On the Operations Center Overview page, hover over Clients and click Schedules. 2. Select a schedule and click Details. 3. View the details of a schedule by clicking the blue arrow next to the row. 4. In the Run time alert field, specify the time when a warning message will be issued if the scheduled operation is not completed. 5. Click Save.

Task	Basic procedures	Advanced procedures and troubleshooting
Evaluate the timing of maintenance tasks. Ensure that the start and end times of maintenance tasks meet your business needs.	On the Operations Center Overview page, click Servers > Maintenance. In the Maintenance table, review the information in the Last Run Time column. To see when the last maintenance task was started, hover over the clock icon.	Tip: If a maintenance task is running too long, change the start time or the maximum run time. Complete the following steps: 1. On the Operations Center Overview page, hover over the settings icon and click Command Builder. 2. To change the start time or maximum run time for a task, issue the UPDATE SCHEDULE command. For instructions, see UPDATE SCHEDULE (Update a client schedule).

QUERY EXTENTUPDATES (Query updated data extents)

Verifying license compliance

Verify that your IBM Spectrum Protect™ solution complies with the provisions of your licensing agreement. By verifying compliance regularly, you can track trends in data growth or processor value unit (PVU) usage. Use this information to plan for future license purchasing.

About this task

The method that you use to verify that your solution complies with license terms varies depending on the provisions of your IBM Spectrum Protect licensing agreement.

Front-end capacity licensing
: The front-end model determines license requirements based on the amount of primary data that is reported as being backed up by clients. Clients include applications, virtual machines, and systems.

Back-end capacity licensing
: The back-end model determines license requirements based on the terabytes of data that are stored in primary storage pools and repositories.
Tips:

- To ensure the accuracy of front-end and back-end capacity estimates, install the most recent version of the client software on each client node.
- The front-end and back-end capacity information in the Operations Center is for planning and estimation purposes.

PVU licensing
: The PVU model is based on the use of PVUs by server devices.
Important: The PVU calculations that are provided by IBM Spectrum Protect are considered estimates and are not legally binding. The PVU licensing information that is reported by IBM Spectrum Protect is not considered an acceptable substitute for the IBM® License Metric Tool.

For the most recent information about licensing models, see the information about product details and licenses at the IBM Spectrum Protect product family website. If you have questions or concerns about licensing requirements, contact your IBM Spectrum Protect software provider.

Procedure

To monitor license compliance, complete the steps that correspond to the provisions of your licensing agreement.
Tip: The Operations Center provides an email report that summarizes front-end and back-end capacity usage. Reports can be sent automatically to one or more recipients regularly. To configure and manage email reports, click Reports on the Operations Center menu bar.

Option	Description

Option	Description
Front-end model	a. On the Operations Center menu bar, hover over the settings icon and click Licensing. The front-end capacity estimate is displayed on the Front-end Usage page. b. If a value is displayed in the Not Reporting column, click the number to identify clients that did not report capacity usage. c. To estimate capacity for clients that did not report capacity usage, go to the following FTP site, which provides measuring tools and instructions: ftp://public.dhe.ibm.com/storage/tivoli-storage-management/front_end_capacity_measurement_tools To measure front-end capacity by script, complete the instructions in the most recently available licensing guide. d. Add the Operations Center estimate and any estimates that you obtained by using a script. e. Verify that the estimated capacity complies with your licensing agreement.
Back-end model	Restriction: If the source and target replication servers do not use the same policy settings, you cannot use the Operations Center to monitor back-end capacity usage for replicated clients. For information about how to estimate capacity usage for these clients, see technote 1656476. a. On the Operations Center menu bar, hover over the settings icon and click Licensing. b. Click the Back-end tab. c. Verify that the estimated amount of data complies with your licensing agreement.
PVU model	For information about how to assess compliance with PVU licensing terms, see Assessing compliance with the PVU licensing model.

- Assessing compliance with the PVU licensing model
  If you purchased IBM Spectrum Protect under the processor value unit (PVU) licensing model, ensure that your solution complies with the license terms. Review the PVU estimates periodically to plan for future license purchasing. For example, if PVU estimates increase or you plan to install more servers, you might have to purchase more licenses.

Tracking system status by using email reports

Set up the Operations Center to generate email reports that summarize system status. You can configure a mail server connection, change report settings, and optionally create custom SQL reports.

Before you begin

Before you set up email reports, ensure that the following requirements are met:

- A Simple Mail Transfer Protocol (SMTP) host server is available to send and receive reports by email. The SMTP server must be configured as an open mail relay. You must also ensure that the IBM Spectrum Protect™ server that sends email messages has access to the SMTP server. If the Operations Center is installed on a separate computer, that computer does not require access to the SMTP server.
- To set up email reports, you must have system privilege for the server.
- To specify the recipients, you can enter one or more email addresses or administrator IDs. If you plan to enter an administrator ID, the ID must be registered on the hub server and must have an email address associated with it. To specify an email address for an administrator, use the EMAILADDRESS parameter of the UPDATE ADMIN command.

About this task

You can configure the Operations Center to send a general operations report, a license compliance report, and one or more custom reports, which use SQL SELECT statements to query managed servers.

Procedure

To set up and manage email reports, complete the following steps:

1. On the Operations Center menu bar, click Reports.
2. If an email server connection is not yet configured, click Configure Mail Server and complete the fields. After you configure the mail server, the general operations report and license compliance report are enabled.
3. To change report settings, select a report, click Details, and update the form.
4. Optional: To add a custom SQL report, click + Report, and complete the fields.
   Tip: To immediately run and send a report, select the report and click Send.

Results

Enabled reports are sent according to the specified settings.

Related reference:

UPDATE ADMIN (Update an administrator)

Related information:

Custom Report Examples

Selecting, configuring, and using monitoring tools

Use the Operations Center to obtain an overview of system status and to drill down to more detailed information. In some cases, you might want to use advanced tools to collect specific monitoring information.

Procedure

Select and configure the monitoring tools that are appropriate for your solution.

Table 1. Monitoring tools

Tool type	Use cases	Links to more information
Operations Center	• Use the graphical user interface to review system status and diagnose issues. • Set up the Operations Center to send daily email summary reports. • Optional: Customize the alerts that are displayed in the Operations Center and set up email notifications about the alerts. • Optional: Monitor the storage environment remotely by viewing the Overview page in the web browser of a mobile device. For example, you can use the Apple Safari web browser on an Apple iPad device. Other mobile devices can also be used. Tip: If you install IBM Spectrum Protect™ client management services on a backup-archive client, you can use the Operations Center to obtain troubleshooting information for the backup-archive client. The client management service can be installed only on Linux or Windows operating systems.	

Tool type	Use cases	Links to more information
IBM Spectrum Protect administrative commands	Review detailed information. Use the method that is appropriate for your solution: • To display messages that were generated by the server and client, use the QUERY ACTLOG command. Tip: You can run administrative commands from the Operations Center command builder. • To monitor activities such as server migration and client logons, use the administrative client in console mode. Run the dsmadmc -consolemode command.	• Administrative commands • QUERY ACTLOG (Query the activity log) • Monitoring server activities from the administrative client • Administrative client options
Event logging	Log server messages and most client messages as events to one or more repositories called receivers.	AIX Linux Windows For instructions about using event logging to monitor a solution, see Logging IBM Spectrum Protect events to receivers (V7.1.1). Linux For instructions about logging events to a Linux system log, see Logging events to the Linux system log (V7.1.4).
SQL queries	Create and format customized queries of the server database. For example, you can query the SQL activity summary table to view statistics about client operations and server processes. To display all information in the summary table, issue the following command from the administrative client: `select * from summary`	Using SELECT commands (V7.1.1)
Operating system tools	Monitor and test system performance.	
Device-monitoring tools	Monitor devices for availability, capacity, and performance. For example, use IBM Spectrum Control™ or tools that are included in device hardware packages.	To monitor overall device status by using IBM Spectrum Control, follow the instructions in Monitoring the status and condition of resources. To monitor performance by using IBM Spectrum Control, follow the instructions in Monitoring the performance of resources.
IBM® Tivoli® Monitoring for Tivoli Storage Manager	Monitor IBM Spectrum Protect servers and produce historical reports about server and client activities. Tip: The Operations Center is the preferred tool for monitoring. However, Tivoli Monitoring for Tivoli Storage Manager is useful for generating historical reports that are based on IBM Cognos® Business Intelligence technology.	Tivoli Monitoring for Tivoli Storage Manager

Managing operations

By effectively managing server and client operations, you can optimize the performance of your storage environment. To get started, monitor the environment by using the Operations Center. Then, take action to prevent potential issues and improve performance.

About this task

- Managing server operations
  You can start and stop the server, manage inventory capacity, and manage memory and processor usage. You can also optimize data transfer between servers, upgrade the server, and tune scheduled activities.
- Managing client operations
  You can evaluate and resolve errors that are related to a backup-archive client by using the Operations Center, which provides suggestions for resolving errors. For errors on other types of clients, you must examine the error logs on the client and review the product documentation.
- Managing the Operations Center
  The Operations Center provides web and mobile access to status information about the IBM Spectrum Protect™ environment. You can use the Operations Center to monitor multiple servers and to complete some administrative tasks. The Operations Center also provides web access to the IBM Spectrum Protect command line.

Managing server operations

You can start and stop the server, manage inventory capacity, and manage memory and processor usage. You can also optimize data transfer between servers, upgrade the server, and tune scheduled activities.

- Stopping and starting the server
  Before you complete maintenance or reconfiguration tasks, stop the server. Then, start the server in maintenance mode. When you are finished with the maintenance or reconfiguration tasks, restart the server in production mode.
- Managing inventory capacity
  Manage the capacity of the database, active log, and archive logs to ensure that the inventory is sized for the tasks, based on the status of the logs.
- Managing memory and processor usage
  Ensure that you manage memory requirements and processor usage to ensure that the server can complete data processes such as backup and data deduplication. Consider the impact on performance when you complete certain processes.
- Determining whether Aspera FASP technology can optimize data transfer in your system environment
  If your IBM Spectrum Protect™ server replicates nodes or protects storage pools to a remote server, determine whether Aspera® Fast Adaptive Secure Protocol (FASP®) technology can improve data throughput to the remote server. Before you enable Aspera FASP technology, you must obtain the appropriate licenses. Both evaluation and full licenses are available.
- Planning to upgrade the server
  When a fix pack or interim fix becomes available, you can upgrade the IBM Spectrum Protect server to take advantage of product improvements. Servers and clients can be upgraded at different times. Ensure that you complete the planning steps before you upgrade the server.
- Tuning scheduled activities
  Schedule maintenance tasks daily to ensure that your solution operates correctly. By tuning your solution, you maximize server resources and effectively use different functions available within your solution.

Stopping and starting the server

Before you complete maintenance or reconfiguration tasks, stop the server. Then, start the server in maintenance mode. When you are finished with the maintenance or reconfiguration tasks, restart the server in production mode.

Before you begin

You must have system or operator privilege to stop and start the IBM Spectrum Protect™ server.

- Stopping the server
  Before you stop the server, prepare the system by ensuring that all database backup operations are completed, and all other processes and sessions are ended. In this way, you can safely shut down the server and ensure that data is protected.
- Starting the server for maintenance or reconfiguration tasks
  Before you begin server maintenance or reconfiguration tasks, start the server in maintenance mode. When you start the

server in maintenance mode, you disable operations that might disrupt your maintenance or reconfiguration tasks.

Stopping the server

Before you stop the server, prepare the system by ensuring that all database backup operations are completed, and all other processes and sessions are ended. In this way, you can safely shut down the server and ensure that data is protected.

About this task

When you issue the HALT command to stop the server, the following actions occur:

- All processes and client node sessions are canceled.
- All current transactions are stopped. (The transactions will be rolled back when the server is restarted.)

Procedure

To prepare the system and stop the server, complete the following steps:

1. Prevent new client node sessions from starting by issuing the DISABLE SESSIONS command:

   ```
   disable sessions all
   ```

2. Determine whether any client node sessions or processes are in progress by completing the following steps:
   a. On the Overview page of the Operations Center, view the Activity area for the total numbers of processes and sessions that are currently active. If numbers differ significantly from the usual numbers that are displayed during your daily storage-management routine, view other status indicators in the Operations Center to check whether there is a problem.
   b. View the graph in the Activity area to compare the amount of network traffic over the following periods:
      - The current period, that is, the most recent 24-hour period
      - The previous period, that is, the 24 hours before the current period

      If the graph for the previous period represents the expected amount of traffic, significant differences on the graph for the current period might indicate a problem.
   c. On the Servers page, select a server for which you want to view processes and sessions, and click Details. If the server is not registered as a hub or spoke server in the Operations Center, obtain information about processes by using administrative commands. Issue the QUERY PROCESS command to query processes and obtain information about sessions by issuing the QUERY SESSION command.
3. Wait until the client node sessions are completed or cancel them. To cancel processes and sessions, complete the following steps:
   - On the Servers page, select a server for which you want to view processes and sessions, and click Details.
   - Click the Active Tasks tab, and select one or more processes, sessions, or a combination of both that you want to cancel.
   - Click Cancel.
   - If the server is not registered as a hub or spoke server in the Operations Center, cancel sessions by using administrative commands. Issue the CANCEL SESSION command to cancel a session and cancel processes by using the CANCEL PROCESS command.
     Tip: If the process that you want to cancel is waiting for a tape volume to be mounted, the mount request is canceled. For example, if you issue an EXPORT, IMPORT, or MOVE DATA command, the command might initiate a process that requires a tape volume to be mounted. However, if a tape volume is being mounted by an automated library, the cancel operation might not take effect until the mount process is complete. Depending on your system environment, this could take several minutes.
4. Stop the server by issuing the HALT command:

   ```
   halt
   ```

Starting the server for maintenance or reconfiguration tasks

Before you begin server maintenance or reconfiguration tasks, start the server in maintenance mode. When you start the server in maintenance mode, you disable operations that might disrupt your maintenance or reconfiguration tasks.

About this task

Start the server in maintenance mode by running the DSMSERV utility with the MAINTENANCE parameter.

The following operations are disabled in maintenance mode:

- Administrative command schedules
- Client schedules
- Reclamation of storage space on the server
- Inventory expiration
- Migration of storage pools

In addition, clients are prevented from starting sessions with the server.
Tips:

- You do not have to edit the server options file, dsmserv.opt, to start the server in maintenance mode.
- While the server is running in maintenance mode, you can manually start the storage-space reclamation, inventory expiration, and storage-pool migration processes.

Procedure

To start the server in maintenance mode, issue the following command:

```
dsmserv maintenance
```

Tip: To view a video about starting the server in maintenance mode, see Starting a server in maintenance mode.

What to do next

To resume server operations in production mode, complete the following steps:

1. Shut down the server by issuing the HALT command:

   ```
   halt
   ```

2. Start the server by using the method that you use in production mode. Follow the instructions for your operating system:
   - AIX Starting the server instance
   - Linux Starting the server instance
   - Windows Starting the server instance

Operations that were disabled during maintenance mode are reenabled.

Managing inventory capacity

Manage the capacity of the database, active log, and archive logs to ensure that the inventory is sized for the tasks, based on the status of the logs.

Before you begin

The active and archive logs have the following characteristics:

- The active log can be a maximum size of 512 GB. For more information about sizing the active log for your system, see Planning the storage arrays.
- The archive log size is limited to the size of the file system that it is installed on. The archive log size is not maintained at a predefined size like the active log. Archive log files are automatically deleted after they are no longer needed.

As a best practice, you can optionally create an archive failover log to store archive log files when the archive log directory is full.

Check the Operations Center to determine the component of the inventory that is full. Ensure that you stop the server before you increase the size of one of the inventory components.

Procedure

- To increase the size of the database, complete the following steps:
  - Create one or more directories for the database on separate drives or file systems.
  - Issue the EXTEND DBSPACE command to add the directory or directories to the database. The directories must be accessible to the instance user ID of the database manager. By default, data is redistributed across all database directories and space is reclaimed.

Tips:
    - The time that is needed to complete redistribution of data and reclaiming of space is variable, depending on the size of your database. Make sure that you plan adequately.
    - Ensure that the directories that you specify are the same size as existing directories to ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching and distribution of the database.
  - Halt and restart the server to fully use the new directories.
  - Reorganize the database if necessary. Index and table reorganization for the server database can help to avoid unexpected database growth and performance issues. For more information about reorganizing the database, see technote 1683633.
- To decrease the size of the database for V7.1 servers and later, issue the following DB2® commands from the server instance directory:
  Restriction: The commands can increase I/O activity, and might affect server performance. To minimize performance problems, wait until one command is completed before you issue the next command. The DB2 commands can be issued when the server is running.

```
db2 connect to tsmdb1
db2 set schema tsmdb1
db2 ALTER TABLESPACE USERSPACE1 REDUCE MAX
db2 ALTER TABLESPACE IDXSPACE1 REDUCE MAX
db2 ALTER TABLESPACE LARGEIDXSPACE1 REDUCE MAX
db2 ALTER TABLESPACE LARGESPACE1 REDUCE MAX
db2 ALTER TABLESPACE REPLTBLSPACE1 REDUCE MAX
db2 ALTER TABLESPACE REPLIDXSPACE1 REDUCE MAX
db2 ALTER TABLESPACE ARCHOBJDATASPACE REDUCE MAX
db2 ALTER TABLESPACE ARCHOBJIDXSPACE REDUCE MAX
db2 ALTER TABLESPACE BACKOBJDATASPACE REDUCE MAX
db2 ALTER TABLESPACE BACKOBJIDXSPACE REDUCE MAX
db2 ALTER TABLESPACE BFABFDATASPACE REDUCE MAX
db2 ALTER TABLESPACE BFABFIDXSPACE REDUCE MAX
db2 ALTER TABLESPACE BFBFEXTDATASPACE REDUCE MAX
db2 ALTER TABLESPACE BFBFEXTIDXSPACE REDUCE MAX
db2 ALTER TABLESPACE DEDUPTBLSPACE1 REDUCE MAX
db2 ALTER TABLESPACE DEDUPIDXSPACE1 REDUCE MAX
db2 ALTER TABLESPACE DEDUPTBLSPACE2 REDUCE MAX
db2 ALTER TABLESPACE DEDUPIDXSPACE2 REDUCE MAX
db2 ALTER TABLESPACE DEDUPTBLSPACE3 REDUCE MAX
db2 ALTER TABLESPACE DEDUPIDXSPACE3 REDUCE MAX
db2 ALTER TABLESPACE DEDUPTBLSPACE4 REDUCE MAX
db2 ALTER TABLESPACE DEDUPIDXSPACE4 REDUCE MAX
db2 ALTER TABLESPACE DEDUPTBLSPACE5 REDUCE MAX
db2 ALTER TABLESPACE DEDUPIDXSPACE5 REDUCE MAX
```

- To increase or decrease the size of the active log, complete the following steps:
  1. Ensure that the location for the active log has enough space for the increased log size. If a log mirror exists, its location must also have enough space for the increased log size.
  2. Halt the server.
  3. In the dsmserv.opt file, update the ACTIVELOGSIZE option to the new size of the active log, in megabytes.
     The size of an active log file is based on the value of the ACTIVELOGSIZE option. Guidelines for space requirements are in the following table:

     Table 1. How to estimate volume and file space requirements

ACTIVELOGSize option value	**Reserve this much free space in the active log directory, in addition to the ACTIVELOGSize space**
16 GB - 128 GB	5120 MB
129 GB - 256 GB	10240 MB
257 GB - 512 GB	20480 MB

     To change the active log to its maximum size of 512 GB, enter the following server option:

     ```
     activelogsize 524288
     ```

  4. If you plan to use a new active log directory, update the directory name that is specified in the ACTIVELOGDIRECTORY server option. The new directory must be empty and must be accessible to the user ID of the database manager.
  5. Restart the server.

- Compress the archive logs to reduce the amount of space that is required for storage. Enable dynamic compression of the archive log by issuing the following command:

  ```
  setopt archlogcompress yes
  ```

  Restriction: Use caution when you enable the ARCHLOGCOMPRESS server option on systems with sustained high volume usage and heavy workloads. Enabling this option in this system environment can cause delays in archiving log files from the active log file system to the archive log file system. This delay can cause the active log file system to run out of space. Be sure to monitor the available space in the active log file system after archive log compression is enabled. If the active log directory file system usage nears out of space conditions, the ARCHLOGCOMPRESS server option must be disabled. You can use the SETOPT command to disable archive log compression immediately without halting the server.

SETOPT (Set a server option for dynamic update)

Managing memory and processor usage

Ensure that you manage memory requirements and processor usage to ensure that the server can complete data processes such as backup and data deduplication. Consider the impact on performance when you complete certain processes.

Before you begin

- Ensure that your configuration uses the required hardware and software. For more information, see IBM Spectrum Protect™ Supported Operating Systems.
- For more information about managing resources such as the database and recovery log, see Planning the storage arrays.
- Add more system memory to determine whether there is a performance improvement. Monitor memory usage regularly to determine whether more memory is required.

Procedure

1. Release memory from the file system cache where possible.
2. To manage the system memory that is used by each server on a system, use the DBMEMPERCENT server option. Limit the percentage of system memory that can be used by the database manager of each server. If all servers are equally important, use the same value for each server. If one server is a production server and other servers are test servers, set the value for the production server to a higher value than the test servers.
3. Set the user data limit and private memory for the database to ensure that private memory is not exhausted. Exhausting private memory can result in errors, less than optimal performance, and instability.

Linux

Determining whether Aspera FASP technology can optimize data transfer in your system environment

If your IBM Spectrum Protect™ server replicates nodes or protects storage pools to a remote server, determine whether Aspera® Fast Adaptive Secure Protocol (FASP®) technology can improve data throughput to the remote server. Before you enable Aspera FASP technology, you must obtain the appropriate licenses. Both evaluation and full licenses are available.

Before you begin

Aspera FASP technology is used to transfer data extents from a container storage pool to a remote server. When Aspera FASP technology is enabled, the data extents are always encrypted during transfer regardless of whether the Secure Sockets Layer (SSL) protocol is enabled. However, if you want to secure the network connection, enable SSL. For information about SSL and how to enable it, see Secure Sockets Layer and Transport Layer Security communication.

About this task

Restrictions:

- Use Aspera FASP technology when your wide area network (WAN) shows signs of high packet loss, data transfer delays that are caused by network impairment, or both. If WAN performance meets your business needs, do not enable Aspera FASP technology.
- To enable Aspera FASP technology for node replication operations, the data must be stored in a directory-container storage pool.

Procedure

1. Determine whether Aspera FASP technology is appropriate for your system environment. If either of the following conditions occurs, enable Aspera FASP technology:
   - Average delays for data-transfer operations exceed 50 milliseconds.
   - Packet loss is greater than 0.01%.

   Network characteristics can vary widely. You might be able to improve network throughput by enabling Aspera FASP technology even if the data-transfer delay is less than 50 milliseconds and the packet loss is less than 0.01%.
2. Obtain and install the appropriate licenses. Take one of the following actions:

   Obtain and install evaluation licenses

   To obtain and install evaluation licenses, which expire in 30 days, complete the following steps:

   a. Request the licenses by sending an email to alliances@asperasoft.com:
      - Include your company name, address, phone number, and the email address of the primary contact at your company.
      - State that you require a 30-day evaluation license.
      - Indicate the number of licenses that you require.

      One license is required for each server that is used for data transfer with Aspera FASP technology. For example, if you are replicating a node from a source server to a target server, you require two licenses.

      If the license request is approved, the primary contact can expect to receive an email within 24 hours. The email will have license file attachments that are named according to the following convention:

      xxxxx-ConnectSrv-unlim.eval.aspera-license

      where *xxxxx* is a unique number.

   b. Copy one of the license files to the server bin directory of the source server. Select either license file. By default, the directory is in the following location:

      ```
      /opt/tivoli/tsm/server/bin
      ```

   c. Copy the remaining license file to the bin directory of the target server.
   d. On the source and target servers, set the permission level of each license file to 755. For example, if you are using the default installation directory and the unique license number is 47474, issue the following command on one line:

      ```
      chmod 755 /opt/tivoli/tsm/server/bin/
      47474-ConnectSrv-unlim.eval.aspera-license
      ```

   Obtain and install full licenses

   To obtain and install full, unlimited licenses, which do not expire, complete the following steps:

   a. Purchase the IBM Spectrum Protect High Speed Data Transfer product. The product identification number is 5725-Z10. You can obtain the product from Passport Advantage®.

      One instance of IBM Spectrum Protect High Speed Data Transfer is required for each server that is used to transfer data with Aspera FASP technology. For example, if you are replicating a node from a source server to a target server, you require two instances of IBM Spectrum Protect High Speed Data Transfer.

   b. Install IBM Spectrum Protect High Speed Data Transfer on each server by using the installation wizard.

   Restriction: If the required licenses are missing or expired, operations to replicate nodes and protect storage pools by using Aspera FASP technology fail.
3. Optional: Validate the Aspera FASP configuration by issuing the VALIDATE ASPERA command. You can use the VALIDATE ASPERA command to verify that your system environment is correctly configured for Aspera FASP and to verify that valid

licenses are installed. In addition, you can use the command to compare the speed of network throughput with Aspera FASP and TCP/IP technology.

What to do next

To enable Aspera FASP technology, follow the steps in Optimizing data transfer by enabling Aspera FASP technology.

- Optimizing data transfer by enabling Aspera FASP technology
  If you use a remote server for storage pool protection or node replication and you experience network issues, you might want to optimize data transfer by using Aspera Fast Adaptive Secure Protocol (FASP) technology.

Planning to upgrade the server

When a fix pack or interim fix becomes available, you can upgrade the IBM Spectrum Protect™ server to take advantage of product improvements. Servers and clients can be upgraded at different times. Ensure that you complete the planning steps before you upgrade the server.

About this task

Follow these guidelines:

- The preferred method is to upgrade the server by using the installation wizard. After you start the wizard, in the IBM Installation Manager window, click the Update icon; do not click the Install or Modify icon.
- If upgrades are available for both the server component and the Operations Center component, select the check boxes to upgrade both components.

Procedure

1. Review the list of fix packs and interim fixes. See technote 1239415.
2. Review product improvements, which are described in readme files.
   Tip: When you obtain the installation package file from the IBM Spectrum Protect support site, you can also access the readme file.
3. Ensure that the version that you upgrade your server to is compatible with other components, such as storage agents and library clients. See technote 1302789.
4. If your solution includes servers or clients at a level that is earlier than V7.1, review the guidelines to ensure that client backup and archive operations are not disrupted. See technote 1053218.
5. Review the upgrade instructions. Ensure that you back up the server database, the device configuration information, and the volume history file.

What to do next

To install a fix pack or interim fix, follow the instructions for your operating system:

- AIX Installing an IBM Spectrum Protect server fix pack
- Linux Installing an IBM Spectrum Protect server fix pack
- Windows Installing an IBM Spectrum Protect server fix pack

Tuning scheduled activities

Schedule maintenance tasks daily to ensure that your solution operates correctly. By tuning your solution, you maximize server resources and effectively use different functions available within your solution.

Procedure

1. Monitor system performance regularly to ensure that client backup and server maintenance tasks are completing successfully. Follow the instructions in Monitoring storage solutions.
2. Optional: If the monitoring information shows that the server workload increased, review the planning information. Review whether the capacity of the system is adequate in the following cases:
   - The number of clients increases
   - The amount of data that is being backed up increases

- The amount of time that is available for backups changes

3. Determine whether your solution is performing at the level you expect. Review the client schedules to check whether tasks are completing within the scheduled time frame:
   a. On the Clients page of the Operations Center, select the client.
   b. Click Details.
   c. From the client Summary page, review the Backed up and Replicated activity to identify any risks.

   Adjust the time and frequency of client backup operations, if necessary.
4. Schedule enough time for the following maintenance tasks to complete successfully within a 24-hour period:
   a. Protect storage pools.
   b. Replicate node data.
   c. Back up the database.
   d. Run expiration processing to remove client backups and archive file copies from server storage.

   Tip: Schedule maintenance tasks to start at an appropriate time and in the correct sequence. For example, schedule replication tasks after client backups complete successfully.

- Moving clients from one server to another
  To avoid running out of space on a server or to resolve workload issues, you might have to move client nodes from one server to another.

Deduplicating data (V7.1.1)

Managing client operations

You can evaluate and resolve errors that are related to a backup-archive client by using the Operations Center, which provides suggestions for resolving errors. For errors on other types of clients, you must examine the error logs on the client and review the product documentation.

About this task

In some cases, you can resolve client errors by stopping and starting the client acceptor. If client nodes or administrator IDs are locked, you can resolve the issue by unlocking the client node or administrator ID, and then resetting the password.

For detailed instructions about identifying and resolving client errors, see Resolving client problems.

- Modifying the scope of a client backup
  When you set up client backup operations, the preferred practice is to exclude objects that you do not require. For example, you typically want to exclude temporary files from a backup operation.
- Evaluating errors in client error logs
  You can resolve client errors by obtaining suggestions from the Operations Center or by reviewing error logs on the client.
- Stopping and restarting the client acceptor
  If you change the configuration of your solution, you must restart the client acceptor on all client nodes where a backup-archive client is installed.
- Resetting passwords
  If a password for a client node or an administrator ID is lost or forgotten, you can reset the password. Multiple attempts to access the system with an incorrect password can cause a client node or administrator ID to be locked. You can take steps to resolve the issue.
- Decommissioning a client node
  If a client node is no longer required, you can start a process to remove it from the production environment. For example, if a workstation was backing up data to the IBM Spectrum Protect™ server, but the workstation is no longer used, you can decommission the workstation.
- Deactivating data to free storage space
  In some cases, you can deactivate data that is stored on the IBM Spectrum Protect server. When you run the deactivation process, any backup data that was stored before the specified date and time is deactivated and will be deleted as it expires. In this way, you can free space on the server.
- Managing client upgrades
  When a fix pack or interim fix becomes available for a client, you can upgrade the client to take advantage of product improvements. Servers and clients can be upgraded at different times and can be at different levels with some restrictions.

Modifying the scope of a client backup

When you set up client backup operations, the preferred practice is to exclude objects that you do not require. For example, you typically want to exclude temporary files from a backup operation.

About this task

When you exclude unnecessary objects from backup operations, you get better control of the amount of storage space that is required for backup operations, and the cost of storage. Depending on your licensing package, you also might be able to limit licensing costs.

Procedure

How you modify the scope of backup operations depends on the product that is installed on the client node:

- For a backup-archive client, you can create an include-exclude list to include or exclude a file, groups of files, or directories from backup operations. To create an include-exclude list, follow the instructions in Creating an include-exclude list.

  To ensure consistent use of an include-exclude list for all clients of one type, you can create a client option set on the server that contains the required options. Then, you assign the client option set to each of the clients of the same type. For details, see Controlling client operations through client option sets.

- For a backup-archive client, you can specify the objects to include in an incremental backup operation by using the domain option. Follow the instructions in Domain client option.
- For other products, to define which objects are included in and excluded from backup operations, follow the instructions in the product documentation.

Evaluating errors in client error logs

You can resolve client errors by obtaining suggestions from the Operations Center or by reviewing error logs on the client.

Before you begin

To resolve errors in a backup-archive client on a Linux or Windows operating system, ensure that the client management service is installed and started. For installation instructions, see Collecting diagnostic information with client management services.

Procedure

To diagnose and resolve client errors, take one of the following actions:

- If the client management service is installed on the client node, complete the following steps:
  1. On the Operations Center Overview page, click Clients and select the client.
  2. Click Details.
  3. On the client Summary page, click the Diagnosis tab.
  4. Review the retrieved log messages.
     Tips:
     - To show or hide the Client Logs pane, double-click the Client Logs bar.
     - To resize the Client Logs pane, click and drag the Client Logs bar.

     If suggestions are displayed on the Diagnosis page, select a suggestion. In the Client Logs pane, client log messages to which the suggestion relates are highlighted.

  5. Use the suggestions to resolve the problems that are indicated by the error messages.
     Tip: Suggestions are provided for only a subset of client messages.
- If the client management service is not installed on the client node, review the error logs for the installed client.

Stopping and restarting the client acceptor

If you change the configuration of your solution, you must restart the client acceptor on all client nodes where a backup-archive client is installed.

About this task

In some cases, you can resolve client scheduling problems by stopping and restarting the client acceptor. The client acceptor must be running to ensure that scheduled operations can occur on the client. For example, if you change the IP address or domain name of the server, you must restart the client acceptor.

Procedure

Follow the instructions for the operating system that is installed on the client node:

AIX and Oracle Solaris

- To stop the client acceptor, complete the following steps:
  a. Determine the process ID for the client acceptor by issuing the following command on the command line:

     ```
     ps -ef | grep dsmcad
     ```

     Review the output. In the following sample output, 6764 is the process ID for the client acceptor:

     ```
     root  6764     1   0 16:26:35 ?           0:00 /usr/bin/dsmcad
     ```

  b. Issue the following command on the command line:

     ```
     kill -9 PID
     ```

     where *PID* specifies the process ID for the client acceptor.
- To start the client acceptor, issue the following command on the command line:

  ```
  /usr/bin/dsmcad
  ```

Linux

- To stop the client acceptor (and not restart it), issue the following command:

  ```
  # service dsmcad stop
  ```

- To stop and restart the client acceptor, issue the following command:

  ```
  # service dsmcad restart
  ```

MAC OS X

Click Applications > Utilities > Terminal.

- To stop the client acceptor, issue the following command:

  ```
  /bin/launchctl unload -w com.ibm.tivoli.dsmcad
  ```

- To start the client acceptor, issue the following command:

  ```
  /bin/launchctl load -w com.ibm.tivoli.dsmcad
  ```

Windows

- To stop the client acceptor service, complete the following steps:
  a. Click Start > Administrative Tools > Services.
  b. Double-click the client acceptor service.
  c. Click Stop and OK.
- To restart the client acceptor service, complete the following steps:
  a. Click Start > Administrative Tools > Services.
  b. Double-click the client acceptor service.
  c. Click Start and OK.

Related reference:
Resolving client scheduling problems

Resetting passwords

If a password for a client node or an administrator ID is lost or forgotten, you can reset the password. Multiple attempts to access the system with an incorrect password can cause a client node or administrator ID to be locked. You can take steps to resolve the issue.

Procedure

To resolve password issues, take one of the following actions:

- If a backup-archive client is installed on a client node, and the password is lost or forgotten, complete the following steps:
  1. Generate a new password by issuing the UPDATE NODE command:

     ```
     update node node_name new_password forcepwreset=yes
     ```

     where *node_name* specifies the client node and *new_password* specifies the password that you assign.
  2. Inform the client node owner about the changed password. When the owner of the client node logs in with the specified password, a new password is generated automatically. That password is unknown to users to enhance security.
     Tip: The password is generated automatically if you previously set the passwordaccess option to `generate` in the client options file.
- If an administrator is locked out because of password issues, complete the following steps:
  1. To provide the administrator with access to the server, issue the UNLOCK ADMIN command. For instructions, see UNLOCK ADMIN (Unlock an administrator).
  2. Set a new password by using the UPDATE ADMIN command:

     ```
     update admin admin_name new_password forcepwreset=yes
     ```

     where *admin_name* specifies the name of the administrator and *new_password* specifies the password that you assign.
- If a client node is locked, complete the following steps:
  1. Determine why the client node is locked and whether it must be unlocked. For example, if the client node is decommissioned, the client node is being removed from the production environment. You cannot reverse the decommission operation, and the client node remains locked. A client node also might be locked if the client data is the subject of a legal investigation.
  2. If you must unlock a client node, use the UNLOCK NODE command. For instructions, see UNLOCK NODE (Unlock a client node).
  3. Generate a new password by issuing the UPDATE NODE command:

     ```
     update node node_name new_password forcepwreset=yes
     ```

     where *node_name* specifies the name of the node and *new_password* specifies the password that you assign.
  4. Inform the client node owner about the changed password. When the owner of the client node logs in with the specified password, a new password is generated automatically. That password is unknown to users to enhance security.
     Tip: The password is generated automatically if you previously set the passwordaccess option to `generate` in the client options file.

Decommissioning a client node

If a client node is no longer required, you can start a process to remove it from the production environment. For example, if a workstation was backing up data to the IBM Spectrum Protect™ server, but the workstation is no longer used, you can decommission the workstation.

About this task

When you start the decommission process, the server locks the client node to prevent it from accessing the server. Files that belong to the client node are gradually deleted, and then the client node is deleted. You can decommission the following types of client nodes:

Application client nodes
: Application client nodes include email servers, databases, and other applications. For example, any of the following applications can be an application client node:

  - IBM Spectrum Protect Snapshot
  - IBM Spectrum Protect for Databases

- IBM Spectrum Protect for Enterprise Resource Planning
- IBM Spectrum Protect for Mail
- IBM Spectrum Protect for Virtual Environments

System client nodes
: System client nodes include workstations, network-attached storage (NAS) file servers, and API clients.

Virtual machine client nodes
: Virtual machine client nodes consist of an individual guest host within a hypervisor. Each virtual machine is represented as a file space.

The simplest method for decommissioning a client node is to use the Operations Center. The decommission process runs in the background. If the client is configured to replicate client data, the Operations Center automatically removes the client from replication on the source and target replication servers before it decommissions the client.
Tip: Alternatively, you can decommission a client node by issuing the DECOMMISSION NODE or DECOMMISSION VM command. You might want to use this method in the following cases:

- To schedule the decommission process for the future or to run a series of commands by using a script, specify the decommission process to run in the background.
- To monitor the decommission process for debugging purposes, specify the decommission process to run in the foreground. If you run the process in the foreground, you must wait for the process to be completed before you continue with other tasks.

Procedure

Take one of the following actions:

- To decommission a client in the background by using the Operations Center, complete the following steps:
  1. On the Operations Center Overview page, click Clients and select the client.
  2. Click More > Decommission.
- To decommission a client node by using an administrative command, complete the following steps:
  1. Determine whether the client node is configured for node replication by issuing the QUERY NODE command. For example, if the client node is named AUSTIN, run the following command:

     ```
     query node austin format=detailed
     ```

     Review the Replication State output field.
  2. If the client node is configured for replication, remove the client node from replication by issuing the REMOVE REPLNODE command. For example, if the client node is named AUSTIN, issue the following command:

     ```
     remove replnode austin
     ```

  3. Take one of the following actions:
     - To decommission an application or system client node in the background, issue the DECOMMISSION NODE command. For example, if the client node is named AUSTIN, issue the following command:

       ```
       decommission node austin
       ```

     - To decommission an application or system client node in the foreground, issue the DECOMMISSION NODE command and specify the `wait=yes` parameter. For example, if the client node is named AUSTIN, issue the following command:

       ```
       decommission node austin wait=yes
       ```

     - To decommission a virtual machine in the background, issue the DECOMMISSION VM command. For example, if the virtual machine is named AUSTIN, the file space is 7, and the file space name is specified by the file space ID, issue the following command:

       ```
       decommission vm austin 7 nametype=fsid
       ```

       If the virtual machine name includes one or more spaces, enclose the name in double quotation marks. For example:

       ```
       decommission vm "austin 2" 7 nametype=fsid
       ```

     - To decommission a virtual machine in the foreground, issue the DECOMMISSION VM command and specify the `wait=yes` parameter. For example, issue the following command:

```
decommission vm austin 7 nametype=fsid wait=yes
```

If the virtual machine name includes one or more spaces, enclose the name in double quotation marks. For example:

```
decommission vm "austin 2" 7 nametype=fsid wait=yes
```

What to do next

Watch for error messages, which might be displayed in the user interface or in the command output, immediately after you run the process.

You can verify that the client node is decommissioned:

1. On the Operations Center Overview page, click Clients.
2. In the Clients table, in the At risk column, review the state:
   - A DECOMMISSIONED state specifies that the node is decommissioned.
   - A null value specifies that the node is not decommissioned.
   - A PENDING state specifies that the node is being decommissioned, or the decommission process failed.

   Tip: If you want to determine the status of a pending decommission process, issue the following command:

   ```
   query process
   ```

3. Review the command output:
   - If status is provided for the decommission process, the process is in progress. For example:

     ```
     query process

      Process     Process Description           Process Status
       Number
     --------     --------------------     -------------------------------------------
            3          DECOMMISSION NODE        Number of backup objects deactivated
                                                for node NODE1: 8 objects deactivated.
     ```

   - If no status is provided for the decommission process, and you did not receive an error message, the process is incomplete. A process can be incomplete if files that are associated with the node are not yet deactivated. After the files are deactivated, run the decommission process again.
   - If no status is provided for the decommission process, and you receive an error message, the process failed. Run the decommission process again.

DECOMMISSION NODE (Decommission a client node)
DECOMMISSION VM (Decommission a virtual machine)
QUERY NODE (Query nodes)
REMOVE REPLNODE (Remove a client node from replication)

Deactivating data to free storage space

In some cases, you can deactivate data that is stored on the IBM Spectrum Protect™ server. When you run the deactivation process, any backup data that was stored before the specified date and time is deactivated and will be deleted as it expires. In this way, you can free space on the server.

About this task

Some application clients always save data to the server as active backup data. Because active backup data is not managed by inventory expiration policies, the data is not deleted automatically, and uses server storage space indefinitely. To free the storage space that is used by obsolete data, you can deactivate the data.

When you run the deactivation process, all active backup data that was stored before the specified date becomes inactive. The data is deleted as it expires and cannot be restored. The deactivation feature applies only to application clients that protect Oracle databases.

Procedure

1. From the Operations Center Overview page, click Clients.
2. In the Clients table, select one or more clients and click More > Clean Up.
   Command-line method: Deactivate data by using the DEACTIVATE DATA command.

Related reference:
DEACTIVATE DATA (Deactivate data for a client node)

Managing client upgrades

When a fix pack or interim fix becomes available for a client, you can upgrade the client to take advantage of product improvements. Servers and clients can be upgraded at different times and can be at different levels with some restrictions.

Before you begin

1. Review the client/server compatibility requirements in technote 1053218. If your solution includes servers or clients at a level that is earlier than V7.1, review the guidelines to ensure that client backup and archive operations are not disrupted.
2. Verify system requirements for the client in IBM Spectrum Protect™ Supported Operating Systems.
3. If the solution includes storage agents or library clients, review the information about storage-agent and library-client compatibility with servers that are configured as library managers. See technote 1302789.

   If you plan to upgrade a library manager and a library client, you must upgrade the library manager first.

Procedure

To upgrade the software, complete the instructions that are listed in the following table.

Software	Link to instructions
IBM Spectrum Protect backup-archive client	• Upgrading the backup-archive client
IBM Spectrum Protect Snapshot	• Installing and upgrading IBM Spectrum Protect Snapshot for UNIX and Linux • Installing and upgrading IBM Spectrum Protect Snapshot for VMware • Installing and upgrading IBM Spectrum Protect Snapshot for Windows
IBM Spectrum Protect for Databases	• Upgrading Data Protection for SQL Server • Data Protection for Oracle installation • Installing, upgrading, and migrating IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server
IBM Spectrum Protect for Enterprise Resource Planning	• Upgrading IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for DB2® • Upgrading IBM Spectrum Protect for Enterprise Resource Planning: Data Protection for SAP for Oracle
IBM Spectrum Protect for Mail	• Installation of Data Protection for IBM Domino on a UNIX, AIX, or Linux system (V7.1.0) • Installation of Data Protection for IBM Domino on a Windows system (V7.1.0) • Installing, upgrading, and migrating IBM Spectrum Protect for Mail: Data Protection for Microsoft Exchange Server
IBM Spectrum Protect for Virtual Environments	• Installing and upgrading Data Protection for VMware • Installing Data Protection for Microsoft Hyper-V

Managing the Operations Center

The Operations Center provides web and mobile access to status information about the IBM Spectrum Protect™ environment. You can use the Operations Center to monitor multiple servers and to complete some administrative tasks. The Operations Center also

provides web access to the IBM Spectrum Protect command line.

- Adding and removing spoke servers
  In a multiple-server environment, you can connect the other servers, called *spoke servers*, to the hub server.
- Starting and stopping the web server
  The web server of the Operations Center runs as a service and starts automatically. You might have to stop and start the web server, for example, to make configuration changes.
- Restarting the initial configuration wizard
  You might need to restart the initial configuration wizard of the Operations Center, for example, to make configuration changes.
- Changing the hub server
  You can use the Operations Center to remove the hub server of IBM Spectrum Protect, and configure another hub server.
- Restoring the configuration to the preconfiguration state
  If certain problems occur, you might want to restore the Operations Center configuration to the preconfigured state where the IBM Spectrum Protect servers are not defined as hub or spoke servers.

Adding and removing spoke servers

In a multiple-server environment, you can connect the other servers, called *spoke servers*, to the hub server.

About this task

The spoke servers send alerts and status information to the hub server. The Operations Center shows you a consolidated view of alerts and status information for the hub server and any spoke servers.

- Adding a spoke server
  After you configure the hub server for the Operations Center, you can add one or more spoke servers to the hub server.
- Removing a spoke server
  You can remove a spoke server from the Operations Center.

Adding a spoke server

After you configure the hub server for the Operations Center, you can add one or more spoke servers to the hub server.

Before you begin

Communication between the spoke server and the hub server must be secured by using the Transport Layer Security (TLS) protocol. To secure communication, add the certificate of the spoke server to the truststore file of the hub server.

Procedure

1. In the Operations Center menu bar, click Servers. The Servers page opens.

   In the table on the Servers page, a server might have a status of "Unmonitored." This status means that although an administrator defined this server to the hub server by using the DEFINE SERVER command, the server is not yet configured as a spoke server.

2. Complete one of the following steps:
   - Click the server to highlight it, and in the table menu bar, click Monitor Spoke.
   - If the server that you want to add is not shown in the table, and secure SSL/TLS communication is not required, click + Spoke in the table menu bar.
3. Provide the necessary information, and complete the steps in the spoke configuration wizard.
   Tip: If the event-record retention period of the server is less than 14 days, the period is automatically reset to 14 days if you configure the server as a spoke server.

Removing a spoke server

You can remove a spoke server from the Operations Center.

About this task

You might need to remove a spoke server in the following situations, for example:

- You want to move the spoke server from one hub server to another hub server.
- You want to decommission the spoke server.

Procedure

To remove the spoke server from the group of servers that are managed by the hub server, complete the following steps:

1. From the IBM Spectrum Protect™ command line, issue the following command on the hub server:

   ```
   QUERY MONITORSETTINGS
   ```

2. From the output of the command, copy the name that is in the Monitored Group field.
3. Issue the following command on the hub server, where *group_name* represents the name of the monitored group, and *member_name* represents the name of the spoke server:

   ```
   DELETE GRPMEMBER group_name member_name
   ```

4. Optional: If you want to move the spoke server from one hub server to another hub server, do **not** complete this step. Otherwise, you can disable alerting and monitoring on the spoke server by issuing the following commands on the spoke server:

   ```
   SET STATUSMONITOR OFF
   SET ALERTMONITOR OFF
   ```

5. Optional: If the spoke server definition is used for other purposes, such as enterprise configuration, command routing, storing virtual volumes, or library management, do **not** complete this step. Otherwise, you can delete the spoke server definition on the hub server by issuing the following command on the hub server:

   ```
   DELETE SERVER spoke_server_name
   ```

Starting and stopping the web server

The web server of the Operations Center runs as a service and starts automatically. You might have to stop and start the web server, for example, to make configuration changes.

Procedure

1. Stop the web server.
   - AIX From the */installation_dir*/ui/utils directory, where *installation_dir* represents the directory where the Operations Center is installed, issue the following command:

     ```
     ./stopserver.sh
     ```

   - Linux Issue the following command:

     ```
     service opscenter.rc stop
     ```

   - Windows From the Services window, stop the IBM Spectrum Protect™ Operations Center service.
2. Start the web server.
   - AIX From the */installation_dir*/ui/utils directory, where *installation_dir* represents the directory where the Operations Center is installed, issue the following command:

     ```
     ./startserver.sh
     ```

   - Linux Issue the following commands:

     Start the server:

     ```
     service opscenter.rc start
     ```

     Restart the server:

     ```
     service opscenter.rc restart
     ```

     Determine whether the server is running:

```
service opscenter.rc status
```

- Windows From the Services window, start the IBM Spectrum Protect Operations Center service.

Restarting the initial configuration wizard

You might need to restart the initial configuration wizard of the Operations Center, for example, to make configuration changes.

Before you begin

To change the following settings, use the Settings page in the Operations Center rather than restarting the initial configuration wizard:

- The frequency at which status data is refreshed
- The duration that alerts remain active, inactive, or closed
- The conditions that indicate that clients are at risk

The Operations Center help includes more information about how to change these settings.

About this task

To restart the initial configuration wizard, you must delete a properties file that includes information about the hub server connection. However, any alerting, monitoring, at-risk, or multiserver settings that were configured for the hub server are not deleted. These settings are used as the default settings in the configuration wizard when the wizard restarts.

Procedure

1. Stop the Operations Center web server.
2. On the computer where the Operations Center is installed, go to the following directory, where *installation_dir* represents the directory in which the Operations Center is installed:
   - AIX Linux *installation_dir*/ui/Liberty/usr/servers/guiServer
   - Windows *installation_dir*\ui\Liberty\usr\servers\guiServer

   For example:
   - AIX Linux /opt/tivoli/tsm/ui/Liberty/usr/servers/guiServer
   - Windows c:\Program Files\Tivoli\TSM\ui\Liberty\usr\servers\guiServer
3. In the guiServer directory, delete the serverConnection.properties file.
4. Start the Operations Center web server.
5. Open the Operations Center.
6. Use the configuration wizard to reconfigure the Operations Center. Specify a new password for the monitoring administrator ID.
7. On any spoke servers that were previously connected to the hub server, update the password for the monitoring administrator ID by issuing the following command from the IBM Spectrum Protect™ command-line interface:

   ```
   UPDATE ADMIN IBM-OC-hub_server_name new_password
   ```

   Restriction: Do not change any other settings for this administrator ID. After you specify the initial password, this password is managed automatically by the Operations Center.

Changing the hub server

You can use the Operations Center to remove the hub server of IBM Spectrum Protect™, and configure another hub server.

Procedure

1. Restart the initial configuration wizard of the Operations Center. As part of this procedure, you delete the existing hub server connection.
2. Use the wizard to configure the Operations Center to connect to the new hub server.

Related tasks:
Restarting the initial configuration wizard

Restoring the configuration to the preconfiguration state

If certain problems occur, you might want to restore the Operations Center configuration to the preconfigured state where the IBM Spectrum Protect™ servers are not defined as hub or spoke servers.

Procedure

To restore the configuration, complete the following steps:

1. Stop the Operations Center web server.
2. Unconfigure the hub server by completing the following steps:
   a. On the hub server, issue the following commands:

      ```
      SET MONITORINGADMIN ""
      SET MONITOREDSERVERGROUP ""
      SET STATUSMONITOR OFF
      SET ALERTMONITOR OFF
      REMOVE ADMIN IBM-OC-hub_server_name
      ```

      Tip: `IBM-OC-hub_server_name` represents the monitoring administrator ID that was automatically created when you initially configured the hub server.
   b. Reset the password for the hub server by issuing the following command on the hub server:

      ```
      SET SERVERPASSWORD ""
      ```

      Attention: Do not complete this step if the hub server is configured with other servers for other purposes, such as library sharing, exporting and importing of data, or node replication.
3. Unconfigure any spoke servers by completing the following steps:
   a. On the hub server, to determine whether any spoke servers remain as members of the server group, issue the following command:

      ```
      QUERY SERVERGROUP IBM-OC-hub_server_name
      ```

      Tip: `IBM-OC-hub_server_name` represents the name of the monitored server group that was automatically created when you configured the first spoke server. This server group name is also the same as the monitoring administrator ID that was automatically created when you initially configured the hub server.
   b. On the hub server, to delete spoke servers from the server group, issue the following command for each spoke server:

      ```
      DELETE GRPMEMBER IBM-OC-hub_server_name spoke_server_name
      ```

   c. After all spoke servers are deleted from the server group, issue the following commands on the hub server:

      ```
      DELETE SERVERGROUP IBM-OC-hub_server_name
      SET MONITOREDSERVERGROUP ""
      ```

   d. On each spoke server, issue the following commands:

      ```
      REMOVE ADMIN IBM-OC-hub_server_name
      SETOPT PUSHSTATUS NO
      SET ALERTMONITOR OFF
      SET STATUSMONITOR OFF
      ```

   e. On each spoke server, delete the definition of the hub server by issuing the following command:

      ```
      DELETE SERVER hub_server_name
      ```

      Attention: Do not complete this step if the definition is used for other purposes, such as library sharing, exporting and importing of data, or node replication.
   f. On the hub server, delete the definition of each spoke server by issuing the following command:

      ```
      DELETE SERVER spoke_server_name
      ```

      Attention: Do not complete this step if the server definition is used for other purposes, such as library sharing, exporting and importing of data, or node replication.
4. Restore the default settings on each server by issuing the following commands:

```
SET STATUSREFRESHINTERVAL 5
SET ALERTUPDATEINTERVAL 10
SET ALERTACTIVEDURATION 480
SET ALERTINACTIVEDURATION 480
SET ALERTCLOSEDDURATION 60
SET STATUSATRISKINTERVAL TYPE=AP INTERVAL=24
SET STATUSATRISKINTERVAL TYPE=VM INTERVAL=24
SET STATUSATRISKINTERVAL TYPE=SY INTERVAL=24
SET STATUSSKIPASFAILURE YES TYPE=ALL
```

5. Restart the initial configuration wizard of the Operations Center.

Configuring virtual tape libraries

A virtual tape library (VTL) does not use physical tape media. When you implement VTL storage, you can exceed the capacity of a physical tape library. The ability to define many volumes and drives can provide greater flexibility for the storage environment.

- Considerations for using virtual tape libraries
  There are some considerations for defining a library as a virtual tape library (VTL), including enhancements for performance and setup of your hardware.
- Adding a virtual tape library to your environment
  Define a virtual tape library (VTL) to take advantage of mount performance and scalability advantages.
- Defining all drives and paths for a single library
  Use the PERFORM LIBACTION command to set up a single SCSI or virtual tape library (VTL) in one step.
- AIX Linux Example: Configure a SCSI or virtual tape library with a single drive device type
  Configure a VTL or SCSI library that contains two LTO tape drives.
- AIX Linux Example: Configure a SCSI or virtual tape library with multiple drive device types
  You can configure a library with multiple drive device types, for example, a StorageTek L40 library that contains one DLT drive and one LTO Ultrium drive.

Considerations for using virtual tape libraries

There are some considerations for defining a library as a virtual tape library (VTL), including enhancements for performance and setup of your hardware.

About this task

Defining a VTL to the IBM Spectrum Protect™ server can help improve performance because the server handles mount point processing for VTLs differently than real tape libraries. The physical limitations for real tape hardware are not applicable to a VTL, affording options for better scalability.

You can use a VTL for any virtual tape library when the following conditions are true:

- There is no mixed media involved in the VTL. Only one type and generation of drive and media is emulated in the library.
- Every server and storage agent with access to the VTL has paths that are defined for all drives in the library.

If either of these conditions are not met, any mount performance advantage from defining a VTL library to the IBM Spectrum Protect server can be reduced or negated.

VTLs are compatible with earlier versions of both library clients and storage agents. The library client or storage agent is not affected by the type of library that is used for storage. If mixed media and path conditions are true for a SCSI library, it can be defined or updated as LIBTYPE=VTL.

- Storage capacity for virtual tape libraries
  Because virtual tape libraries (VTLs) do not have the physical limitations that real tape hardware does, their capacity for storage is more flexible.
- Drive configuration for virtual tape libraries
  Drive configuration in a virtual tape library (VTL) is variable, depending on the needs of your environment.

Storage capacity for virtual tape libraries

Because virtual tape libraries (VTLs) do not have the physical limitations that real tape hardware does, their capacity for storage is more flexible.

The concept of storage capacity in a virtual tape library is different from capacity in physical tape hardware. In a physical tape library, each volume has a defined capacity, and the library's capacity is defined in terms of the total number of volumes in the library. The capacity of a VTL, alternatively, is defined in terms of total available disk space. You can increase or decrease the number and size of volumes on disk.

This variability affects what it means to run out of space in a VTL. For example, a volume in a VTL can run out of space before reaching its assigned capacity if the total underlying disk runs out of space. In this situation, the server can receive an end-of-volume message without any warning, resulting in backup failures.

When out-of-space errors and backup failures occur, disk space is usually still available in the VTL. It is hidden in volumes that are not in use. For example, volumes that are logically deleted or returned to scratch status in the IBM Spectrum Protect™ server are deleted only in the server database. The VTL is not notified, and the VTL maintains the full size of the volume as allocated in its capacity considerations.

To help prevent out-of-space errors, ensure that any SCSI library that you update to LIBTYPE=VTL is updated with the RELABELSCRATCH parameter set to YES. The RELABELSCRATCH option enables the server to overwrite the label for any volume that is deleted and to return the volume to scratch status in the library. The RELABELSCRATCH parameter defaults to YES for any library defined as a VTL.

UPDATE LIBRARY (Update a library)

Drive configuration for virtual tape libraries

Drive configuration in a virtual tape library (VTL) is variable, depending on the needs of your environment.

Most VTL environments use as many drives as possible to maximize the number of concurrent tape operations. A single tape mount in a VTL environment is typically faster than a physical tape mount. However, using many drives increases the amount of time that the IBM Spectrum Protect™ server requires when a mount is requested. The selection process takes longer as the number of drives that are defined in a single library object in the server increases. Virtual tape mounts can take as long or longer than physical tape mounts depending on the number of drives in the VTL.

For best results when you create drives, check with your VTL vendor about device-specific recommendations. If more than 300-500 drives for each VTL are required, you can logically partition the VTL into multiple libraries and assign drives to each library. Operating system and SAN hardware configurations could impose limitations on the number of devices that can be utilized within the VTL library.

Adding a virtual tape library to your environment

Define a virtual tape library (VTL) to take advantage of mount performance and scalability advantages.

About this task

VTLs are identified by using the DEFINE LIBRARY command and specifying the LIBTYPE=VTL parameter. Because a VTL library functionally interacts with the server in the same way that a SCSI library does,you can use the UPDATE LIBRARY command to change the library type of a SCSI library that is already defined. You do not have to redefine the library.

Procedure

- Add a new VTL library. Define the library as a VTL to the server, as shown in the following example:

  ```
  define library chester libtype=vtl
  ```

  This sets up the new VTL library and enables the RELABELSCRATCH option to relabel volumes that have been deleted and returned to scratch status.

- Update a SCSI library to a VTL. If you have a SCSI library and you want to change it to a VTL, use the UPDATE LIBRARY command to change the library type:

  ```
  update library calzone libtype=vtl
  ```

  You can issue this command only if the library that is being updated is defined with the LIBTYPE=SCSI parameter.

Related reference:
DEFINE LIBRARY (Define a library)
UPDATE LIBRARY (Update a library)

Defining all drives and paths for a single library

Use the PERFORM LIBACTION command to set up a single SCSI or virtual tape library (VTL) in one step.

About this task

If you are setting up or modifying your hardware environment and must create or change large numbers of drive definitions, the PERFORM LIBACTION command can make this task much simpler. You can define a new library and then define all drives and paths to the drives. Or, if you have an existing library that you want to delete, you can delete all existing drives and their paths in one step.

The PREVIEW parameter allows you to view the output of commands before they are processed to verify the action that you want to perform. If you are defining a library, a path to the library must already be defined if you want to specify the PREVIEW parameter. You cannot use the PREVIEW and DEVICE parameters together.

The PERFORM LIBACTION command can be used only for SCSI and VTL libraries. If you are defining drives and paths for a library, the SANDISCOVERY option must be supported and enabled. The tape library must be able to return the drive serial number address association.

Procedure

To set up a VTL library named ODIN, complete these steps:

1. Define the library.

   ```
   define library odin libtype=vtl
   ```

2. Define two drives and their paths for your new library, ODIN.

   AIX

   ```
   perform libaction odin action=define device=/dev/lb3 prefix=dr
   ```

   The server then issues the following commands:

   ```
   define path tsmserver odin srct=server destt=library device=/dev/
    lb3 define drive odin dr0
   define path tsmserver dr0 srct=server destt=drive library=odin
    device=/dev/mt1 define drive odin dr1
   define path tsmserver dr1 srct=server destt=drive library=odin
    device=/dev/mt2
   ```

   Linux

   ```
   perform libaction odin action=define device=/dev/tsmscsi/lb3 prefix=dr
   ```

   The server then issues the following commands:

   ```
   define path tsmserver odin srct=server destt=library device=/dev/tsmscsi/lb3
    define drive odin dr0
   define path tsmserver dr0 srct=server destt=drive library=odin
    device=/dev/tsmscsi/mt1 define drive odin dr1
   define path tsmserver dr1 srct=server destt=drive library=odin
    device=/dev/tsmscsi/mt2
   ```

   Windows

   ```
   perform libaction odin action=define device=lb0.0.0.2 prefix=dr
   ```

The server then issues the following commands:

```
define path tsmserver odin srct=server destt=library device=lb0.0.0.2
 define drive odin dr0
define path tsmserver dr0 srct=server destt=drive library=odin
 device=mt0.1.0.2 define drive odin dr1
define path tsmserver dr1 srct=server destt=drive library=odin
 device=mt0.2.0.2
```

Related reference:
DEFINE LIBRARY (Define a library)
DEFINE PATH (Define a path when the destination is a drive)
PERFORM LIBACTION (Define or delete all drives and paths for a library)

Example: Configure a SCSI or virtual tape library with a single drive device type

Configure a VTL or SCSI library that contains two LTO tape drives.

About this task

This procedure is an example of configuring an automated SCSI library that contains two drives to the server system. The library is not shared with other IBM Spectrum Protect™ servers or with storage agents and is typically attached to the server system by using SCSI cables.

In this configuration, both drives in the library are the same device type. Define one device class. The procedure is the same for both SCSI libraries and VTLs, except for the step to define the library. For SCSI libraries, define the library with libtype=scsi. For VTL libraries, define the library with libtype=vtl.

Procedure

1. Define a SCSI library that is named AUTODLTLIB.

   ```
   define library autoltolib libtype=scsi
   ```

   If the library has a bar code reader and you would like to automatically label tapes before they are checked in, you can set the AUTOLABEL parameter to YES. For example:

   ```
   define library autoltolib libtype=scsi autolabel=yes
   ```

2. Define a path from the server to the library.
   AIX

   ```
   define path server1 autoltolib srctype=server desttype=library
   device=/dev/lb3
   ```

   Linux

   ```
   define path server1 autoltolib srctype=server desttype=library
   device=/dev/tsmscsi/lb3
   ```

   Windows

   ```
   define path server1 autoltolib srctype=server desttype=library
   device=lb0.0.0.3
   ```

3. Define the drives in the library. Both drives belong to the AUTODLTLIB library.

   ```
   define drive autoltolib drive01
   define drive autoltolib drive02
   ```

   Tip: You can use the PERFORM LIBACTION command to define drives and paths for a library in one step.
4. Define a path from the server to each drive.
   AIX

   ```
   define path server1 drive01 srctype=server desttype=drive
   library=autoltolib device=/dev/mt4
   define path server1 drive02 srctype=server desttype=drive
   library=autoltolib device=/dev/mt5
   ```

Linux

```
define path server1 drive01 srctype=server desttype=drive
library=autoltolib device=/dev/tsmscsi/mt4
define path server1 drive02 srctype=server desttype=drive
library=autoltolib device=/dev/tsmscsi/mt5
```

Windows

```
define path server1 drive01 srctype=server desttype=drive
library=autoltolib device=mt0.0.0.4
define path server1 drive02 srctype=server desttype=drive
library=autoltolib device=mt0.0.0.5
```

If you did not include the element address when you defined the drive, the server now queries the library to obtain the default element address for the drive.

5. Define a device class that is named AUTODLT_CLASS for the two drives in the AUTODLTLIB library.

```
define devclass autolto_class library=autodltlib devtype=lto
```

6. Define a storage pool that is named AUTOLTO_POOL associated with the device class named AUTOLTO_CLASS.

```
define stgpool autolto_pool autolto_class maxscratch=20
```

7. Label and check in library volumes.

```
label libvolume autoltolib search=yes labelsource=barcode checkin=scratch
```

8. Verify your definitions by issuing the following commands:

```
query library
query drive
query path
query devclass
query stgpool
query libvolume
```

Related reference:
DEFINE DEVCLASS (Define a device class)
DEFINE LIBRARY (Define a library)
DEFINE PATH (Define a path when the destination is a drive)

Example: Configure a SCSI or virtual tape library with multiple drive device types

You can configure a library with multiple drive device types, for example, a StorageTek L40 library that contains one DLT drive and one LTO Ultrium drive.

About this task

This procedure is an example of configuring an automated SCSI library that contains two drives to the server system. The library is not shared with other IBM Spectrum Protect™ servers or with storage agents and is typically attached to the server system by SCSI cables.

In this configuration, the drives are different device types. Define a device class for each drive device type. Drives with different device types are supported in a single library if you define a device class for each type of drive. If you are configuring this way, you must include the specific format for the drive's device type by using the FORMAT parameter with a value other than DRIVE.

The procedure is the same for both SCSI libraries and VTLs, except for the step to define the library. For SCSI libraries, define the library with libtype=scsi. For VTL libraries, define the library with libtype=vtl.

Procedure

1. Define a SCSI library named MIXEDLIB.

```
define library mixedlib libtype=scsi
```

2. Define a path from the server to the library.
   AIX

   ```
   define path server1 mixedlib srctype=server desttype=library
   device=/dev/lb3
   ```

   Linux

   ```
   define path server1 mixedlib srctype=server desttype=library
   device=/dev/tsmscsi/lb3
   ```

   Windows

   ```
   define path server1 mixedlib srctype=server desttype=library
   device=lb0.0.0.3
   ```

3. Define the drives in the library. Both drives belong to the MIXEDLIB library.

   ```
   define drive mixedlib dlt1
   define drive mixedlib lto1
   ```

4. Define a path from the server to each drive. The DEVICE parameter specifies the device driver's name for the drive, which is the device special file name.
   AIX

   ```
   define path server1 dlt1 srctype=server desttype=drive
   library=mixedlib device=/dev/mt4
   define path server1 lto1 srctype=server desttype=drive
   library=mixedlib device=/dev/mt5
   ```

   Linux

   ```
   define path server1 dlt1 srctype=server desttype=drive
   library=mixedlib device=/dev/tsmscsi/mt4
   define path server1 lto1 srctype=server desttype=drive
   library=mixedlib device=/dev/tsmscsi/mt5
   ```

   Windows

   ```
   define path server1 drive01 srctype=server desttype=drive
   library=autoltolib device=mt0.0.0.4
   define path server1 drive02 srctype=server desttype=drive
   library=autoltolib device=mt0.0.0.5
   ```

   If you did not include the element address when you defined the drive, the server now queries the library to obtain the element address for the drive.

5. Define device classes.
   Important: Do not use the DRIVE format, which is the default. Because the drives are different types, the server uses the format specification to select a drive. The results of using the DRIVE format in a mixed media library are unpredictable.

   ```
   define devclass dlt_class library=mixedlib devtype=dlt format=dlt40
   define devclass lto_class library=mixedlib devtype=lto format=ultriumc
   ```

6. Define storage pools that are associated with the device classes.

   ```
   define stgpool lto_pool lto_class maxscratch=20
   define stgpool dlt_pool dlt_class maxscratch=20
   ```

7. Label and check in library volumes.

   ```
   label libvolume mixedlib search=yes labelsource=barcode checkin=scratch
   ```

8. Verify your definitions by issuing the following commands:

   ```
   query library
   query drive
   query path
   query devclass
   query stgpool
   query libvolume
   ```

Protecting NAS file servers

You can configure and manage a backup environment that protects a network-attached storage (NAS) file server.

You can use the IBM Spectrum Protect™ server, the IBM Spectrum Protect backup-archive client, or IBM Spectrum Protect Snapshot to back up and restore a NAS file server as described in the following table.

Product	Description
IBM Spectrum Protect server	To back up and restore NAS file server data by using the IBM Spectrum Protect server, you must have IBM Spectrum Protect Extended Edition installed. You can configure the IBM Spectrum Protect server to use the network data management protocol (NDMP) to back up and restore data as described in the following topics in this section. To protect large NetApp file systems, you can alternatively configure IBM Spectrum Protect to use NetApp SnapMirror to Tape (also known as SMTape). SnapMirror to Tape uses a block-level copy of data for backup, which is faster than a traditional NDMP full backup and can be used when NDMP full backups are impractical. For information about using SnapMirror to Tape to back up and restore data, see Backup and restore operations by using the NetApp SnapMirror to Tape feature.
IBM Spectrum Protect backup-archive client	You can configure the backup-archive client to back up and restore file server data by using the Network File System (NFS) or Common Internet File System (CIFS) protocol. For information about using the backup-archive client to back up and restore data, see Back up and restore data with backup-archive clients.
IBM Spectrum Protect Snapshot	You can use IBM Spectrum Protect Snapshot to back up and restore file server data by using the advanced snapshot technologies of storage systems. For information about using IBM Spectrum Protect Snapshot to back up and restore data, see IBM Spectrum Protect Snapshot for UNIX and Linux overview or IBM Spectrum Protect Snapshot for VMware overview.

- NDMP requirements
  To use NDMP for operations with NAS file servers, you must have IBM Spectrum Protect Extended Edition installed and your file server environment must meet certain requirements.
- NDMP operations management
  There are several administrator activities for NDMP operations.
- Configuring IBM Spectrum Protect for NDMP operations
  You can configure IBM Spectrum Protect to back up and recover data on NAS file servers by using NDMP. The configuration procedure differs depending on whether you plan to back up data from a nonclustered or clustered NAS file server.
- Backing up and restoring NAS file servers using NDMP
  After you configure IBM Spectrum Protect for NDMP operations, you are ready to begin using NDMP.
- File-level backup and restore for NDMP operations
  When you back up data by using NDMP, you can specify that the IBM Spectrum Protect server collects and stores file-level information in a table of contents (TOC).
- Directory-level backup and restore operations
  If you have a large NAS file system, initiating a backup at a directory level reduces backup and restore times and provides more flexibility in configuring NAS backups. By defining virtual file spaces, a file system backup can be partitioned among several NDMP backup operations and multiple tape drives. You can also use different backup schedules to back up subtrees of a file system.
- Backup and restore operations by using the NetApp SnapMirror to Tape feature
  You can back up large NetApp file systems by using the NetApp SnapMirror to Tape feature (also known as SMTape). Using a block-level copy of data for backup, the SnapMirror to Tape method is faster than a traditional NDMP full backup and can be used when NDMP full backups are impractical.
- NDMP backup operations using Celerra file server-integrated checkpoints
  When the IBM Spectrum Protect server initiates an NDMP backup operation on a Celerra data mover, the backup of a large file system might take several hours to complete. Without Celerra integrated checkpoints, any changes that occur on the file system are written to the backup image.
- Replicating NAS nodes
  You can replicate a NAS node that uses NDMP for backup operations. Before you configure the replication operation, review the restrictions that apply.

NDMP requirements

To use NDMP for operations with NAS file servers, you must have IBM Spectrum Protect™ Extended Edition installed and your file server environment must meet certain requirements.

NAS file server
: The operating system on the file server must be supported by IBM Spectrum Protect. For information about the NAS file servers that are supported, see technote 1054144.

  The combination of file server model and operating system must be supported by the NAS file server. For more specifics, see the product information for the NAS file server.

Tape libraries
: This requirement is necessary only for a backup to a locally attached NAS device. The IBM Spectrum Protect server supports the following types of libraries for operations that use NDMP:

  SCSI
  : A SCSI library can be attached directly to the IBM Spectrum Protect server or to the NAS file server. When the library is attached directly to the IBM Spectrum Protect server, that server controls the library operations by passing the SCSI commands directly to the library. When the library is attached directly to the NAS file server, the IBM Spectrum Protect server controls the library by passing SCSI commands to the library through the NAS file server.

  ACSLS
  : An automated cartridge system library software (ACSLS) library can be directly connected only to the IBM Spectrum Protect server. The IBM Spectrum Protect server controls the library by passing the library request through TCP/IP to the library control server.
  Restriction: The IBM Spectrum Protect server does not include External Library support for the ACSLS library when the library is used for NDMP operations.

  VTL
  : A virtual tape library (VTL) can be attached directly either to the IBM Spectrum Protect server or to the NAS file server. A virtual tape library is essentially the same as a SCSI library, but is enhanced for virtual tape library characteristics and allows for better mount performance.
  If you are defining a VTL, your environment must not include mixed media. Paths must be defined between all drives in the library and all defined servers, including storage agents, that use the library. If these conditions are not met, the overall performance can degrade to the same levels as the SCSI library type, especially during times of high stress.

  349X
  : A 349X library can be directly connected only to the IBM Spectrum Protect server. The IBM Spectrum Protect server controls the library by passing the library request through TCP/IP to the library manager.

  Library sharing: The IBM Spectrum Protect server that runs NDMP operations can be a library manager for either an ACSLS, SCSI, VTL, or 349X library, but cannot be a library client. The IBM Spectrum Protect server can also be a library client in a configuration where the NAS file server sends data to the server by using TCP/IP rather than to a tape library attached to the file server. If the IBM Spectrum Protect server that runs NDMP operations is a library manager, that server must control the library directly and not by passing commands through the NAS file server.

Tape drives
: A tape drive is necessary only for backup to a locally attached NAS device. The NAS file server must be able to access the drives. A NAS device is not supported in a mixed device library. The drives must be supported for tape backup operations by the NAS file server and its operating system. For complete NDMP device support, refer to the NAS file server product documentation.
  Drive sharing: The tape drives can be shared by the IBM Spectrum Protect server and one or more NAS file servers. Also, when a SCSI, VTL, or a 349X library is connected to the server and not to the NAS file server, the drives can be shared by one or more NAS file servers. The drives can also be shared by one or more IBM Spectrum Protect library clients and storage agents.
  Drive reservations: When tape drives are attached to NAS devices and the RESETDRIVES=YES parameter for the DEFINE LIBRARY command is specified, the following limitations apply:

  - If a tape drive is shared by an IBM Spectrum Protect server and a NAS device, drive reservation preemption is supported when the NAS device supports persistent reserve and it is enabled. For more information about setting persistent reserve, see the documentation for your NAS device.
  - If a tape drive is attached only to a NAS device and not shared with an IBM Spectrum Protect server, drive reservation preemption is not supported. If you enable persistent reserve on the NAS device for these drives and a reservation is set by the NAS device but never cleared, you must use another method to clear the reservation.

Verify the compatibility of specific combinations of a NAS file server, tape devices, and SAN-attached devices with the hardware manufacturers.

Tip: IBM Spectrum Protect supports NDMP Version 4 for all NDMP operations. IBM Spectrum Protect continues to support all NDMP backup and restore operations with a NAS device that runs NDMP version 3. The IBM Spectrum Protect server negotiates the highest protocol level (either Version 3 or Version 4) with the NDMP server when it establishes an NDMP connection. If you experience any issues with Version 4, you might want to try Version 3.

- Interfaces for NDMP operations
  You can use several interfaces to run NDMP operations. You can schedule an NDMP operation by using the BACKUP NODE or RESTORE NODE command, and creating a schedule to process the command.
- Data formats for NDMP backup operations
  Data that is backed up using NDMP is not in the same format as the data that is used for typical IBM Spectrum Protect backup operations. The NAS file server controls the format of the backup data.

Interfaces for NDMP operations

You can use several interfaces to run NDMP operations. You can schedule an NDMP operation by using the BACKUP NODE or RESTORE NODE command, and creating a schedule to process the command.

Client interfaces:

- Backup-archive command-line client (on a Windows, 64-bit AIX®, or 64-bit Oracle Solaris system)
- Web client

Server interfaces:

- Server console
- Command line on the administrative client
  Tip: All examples for NDMP operations use server commands.

The IBM Spectrum Protect™ web client interface, available with the backup-archive client, displays the file systems of the NAS file server in a graphical view. The client function is not required, but you can use the client interfaces for NDMP operations. The client function is the preferred method for file-level restore operations. For more information about file-level restore operations, see File-level backup and restore for NDMP operations.

IBM Spectrum Protect prompts you for an administrator ID and password when you complete NDMP functions by using either of the client interfaces. For more information about installing and activating client interfaces, see Installing the IBM Spectrum Protect backup-archive clients.

To use the IBM Spectrum Protect backup-archive client or web client for NAS operations, the file system names on the NAS device must have a forward slash (/) as the first character. This restriction does not affect NAS operations that are initiated from the IBM Spectrum Protect server command line.

Data formats for NDMP backup operations

Data that is backed up using NDMP is not in the same format as the data that is used for typical IBM Spectrum Protect™ backup operations. The NAS file server controls the format of the backup data.

Data that is backed up to a library that is directly attached to the file server must be directed to a storage pool with the proper data format. When you define a storage pool for NDMP operations, you specify one of the following data formats:

- NETAPPDUMP if the NAS file server is a NetApp or an IBM® System Storage® N Series device.
- CELERRADUMP if the NAS file server is an EMC Celerra device.
- NDMPDUMP for all other devices.

Data that is backed up over the network to the local IBM Spectrum Protect hierarchy can be directed to any random-access or sequential-access primary storage pool. However, the format of the data does not change.

NDMP operations management

There are several administrator activities for NDMP operations.

- Managing NAS file server nodes
  You can query, update, rename, and remove NAS file server nodes.

- Managing data movers that are used in NDMP operations
  You can query, update, and delete the data movers that you define for NAS file servers.
- Dedicating an IBM Spectrum Protect drive to NDMP operations
  If you are already using a drive for IBM Spectrum Protect™ operations, you can dedicate that drive to NDMP operations.
- Storage pool management for NDMP operations
  When NETAPPDUMP, CELERRADUMP, or NDMPDUMP is designated as the storage-pool type, managing the storage pools that are produced by NDMP operations is different from managing storage pools that contain media for traditional IBM Spectrum Protect backups.
- Managing tables of contents
  You can use several commands to manage different aspects of your data contents.
- Preventing long-running, inactive NDMP connections from closing
  To prevent firewalls from closing NDMP connections that are long-running but inactive, you can enable Transmission Control Protocol (TCP) keepalive on the NDMP control connections.

Managing NAS file server nodes

You can query, update, rename, and remove NAS file server nodes.

Procedure

Use one of the following commands to manage NAS file server nodes:

Command	Procedure
QUERY NODE	To query a node, issue the QUERY NODE command with the appropriate parameters. For example, if you want to query the NAS node NASNODE1, issue the following command: `query node nasnode1 type=nas`
UPDATE NODE	To update a node, issue the UPDATE NODE command with the appropriate parameters. For example, if you created a new policy domain that is named NASDOMAIN for NAS nodes and you want to update the node NASNODE1 to include the node in the new domain, issue the following command: `update node nasnode1 domain=nasdomain`

Command	Procedure
RENAME NODE	To rename a NAS node, you must also rename the corresponding NAS data mover; both must have the same name. For example, to rename NASNODE1 to NAS1, complete the following steps: 1. Delete all paths between the data mover NASNODE1 and libraries and between the data mover NASNODE1 and drives. 2. Delete the data mover that is defined for the NAS node. 3. To rename NASNODE1 to NAS1, issue the following command: `rename node nasnode1 nas1` 4. Define the data mover by using the new node name. In this example, you must define a new data mover that is named NAS1 with the same parameters that were used to define NASNODE1. Important: When you define a new data mover for a node that you renamed, ensure that the data mover name matches the new node name. Also, ensure that the new data mover parameters are duplicates of the original data mover parameters. Any mismatch between a node name and a data mover name or between new data mover parameters and original data mover parameters can prevent you from establishing a session with the NAS file server. 5. For SCSI or 349X libraries, define a path between the NAS data mover and a library only if the tape library is physically connected directly to the NAS file server. 6. Define paths between the NAS data mover and any drives that are used for NDMP operations.
REMOVE NODE	To remove a node, complete the following steps: 1. Delete any virtual file space definitions for the node. 2. Delete all paths between the data mover and libraries and between the data mover and drives. 3. Delete the node. For example, if you want to remove a node that is named NAS1, issue the following command: `remove node nas1`

Related reference:
QUERY NODE (Query nodes)
UPDATE NODE (Update node attributes)
RENAME NODE (Rename a node)
REMOVE NODE (Delete a node or an associated machine node)

Managing data movers that are used in NDMP operations

You can query, update, and delete the data movers that you define for NAS file servers.

Procedure

Use one of the following commands to manage data movers:

Command	Procedure

Command	Procedure
QUERY DATAMOVER	To query a data mover, issue the QUERY DATAMOVER command with the appropriate parameters. For example, if you want to query the data mover NASNODE1, issue the following command: `query datamover nasnode1`
UPDATE DATAMOVER	To update a data mover, issue the UPDATE DATAMOVER command with the appropriate parameters. For example, if you shut down a NAS file server for maintenance and you want to take the data mover offline, issue the following command: `update datamover nasnode1 online=no`
DELETE DATAMOVER	To delete a data mover, issue the DELETE DATAMOVER command. For example, if you want to delete the data mover NASNODE1, issue the following command: `delete datamover nasnode1` Restriction: If the data mover has a path to a library, and you delete the data mover or take the data mover offline, you disable access to the library.

Related reference:
QUERY DATAMOVER (Display data mover definitions)
UPDATE DATAMOVER (Update a data mover)
DELETE DATAMOVER (Delete a data mover)

Dedicating an IBM Spectrum Protect drive to NDMP operations

If you are already using a drive for IBM Spectrum Protect™ operations, you can dedicate that drive to NDMP operations.

Procedure

Remove IBM Spectrum Protect server access by deleting the path definition. For example, if the server name is SERVER1 and the drive is NASDRIVE1, issue the following command:

```
delete path server1 nasdrive1 srctype=server desttype=drive library=naslib
```

Storage pool management for NDMP operations

When NETAPPDUMP, CELERRADUMP, or NDMPDUMP is designated as the storage-pool type, managing the storage pools that are produced by NDMP operations is different from managing storage pools that contain media for traditional IBM Spectrum Protect™ backups.

The following guidelines and restrictions apply to storage pools of the NETAPPDUMP, CELERRADUMP, and NDMPDUMP type that are produced by NDMP operations:

- You can query and update storage pools, but you cannot update the DATAFORMAT parameter.
- You cannot designate a CENTERA, directory-container, or cloud-container storage pool as a target pool of NDMP operations.
- Maintaining separate storage pools for data from different NAS vendors is the preferred practice, even when the data format for both is NDMPDUMP.
- The following DEFINE STGPOOL and UPDATE STGPOOL command parameters are ignored because storage pool hierarchies, reclamation, and migration are not supported for these storage pools:
  - MAXSIZE
  - NEXTSTGPOOL
  - LOWMIG
  - HIGHMIG
  - MIGDELAY
  - MIGCONTINUE
  - RECLAIMSTGPOOL

- OVFLOCATION

Important: Ensure that you do not accidentally use storage pools that were defined for NDMP operations in traditional IBM Spectrum Protect operations. Be especially careful when you assign the storage pool name as the value for the DESTINATION parameter of the DEFINE COPYGROUP command. Unless the destination is a storage pool with the appropriate data format, the backup fails.

Managing tables of contents

You can use several commands to manage different aspects of your data contents.

About this task

The SET TOCLOADRETENTION command can be used to specify the approximate number of minutes that an unreferenced table of contents (TOC) remains loaded in the IBM Spectrum Protect™ database. The IBM Spectrum Protect server-wide TOC retention value determines how long a loaded TOC is retained in the database after the latest access to information in the TOC.

Because TOC information is loaded into temporary database tables, this information is lost if the server is halted, even if the TOC retention period did not elapse. At installation, the retention time is set to 120 minutes. Use the QUERY STATUS command to see the TOC retention time.

Issue the QUERY NASBACKUP command to display information about the file system image objects that are backed up for a specific NAS node and file space. By issuing the command, you can see a display of all backup images that are generated by NDMP and whether each image has a corresponding TOC.
Tip: The IBM Spectrum Protect server can store a full backup in excess of the number of versions you specified if that full backup has dependent differential backups. Full NAS backups with dependent differential backups behave like other base files with dependent subfiles. Due to the retention time specified in the RETEXTRA setting, the full NAS backup is not expired, and the version is displayed in the output of a QUERY NASBACKUP command. For information about setting data retention policies, see Customizing policies.

Use the QUERY TOC command to display files and directories in a backup image that is generated by NDMP. By issuing the QUERY TOC server command, you can display all directories and files within a single specified TOC. The specified TOC is accessed in a storage pool each time the QUERY TOC command is issued because this command does not load TOC information into the IBM Spectrum Protect database. Then, use the RESTORE NODE command with the FILELIST parameter to restore individual files.

Preventing long-running, inactive NDMP connections from closing

To prevent firewalls from closing NDMP connections that are long-running but inactive, you can enable Transmission Control Protocol (TCP) keepalive on the NDMP control connections.

About this task

The IBM Spectrum Protect™ server initiates control connections to NAS devices during NDMP backup or restore operations. These control connections might remain open and inactive for an extended amount of time. For example, suppose that two NDMP operations are started for the same NAS device. The control connection for one NDMP operation might remain open but inactive if the operation requires a resource, for example, a tape drive or sequential volume, that is being used by the other NDMP operation.

Some firewall software is configured to automatically close network connections that are inactive for a specified length of time. If a firewall exists between an IBM Spectrum Protect server and a NAS device, it is possible that the firewall can close NDMP control connections unexpectedly and cause the NDMP operation to fail.

The IBM Spectrum Protect server provides a mechanism, TCP keepalive, that you can enable to prevent long-running, inactive connections from being closed. If TCP keepalive is enabled, small packets are sent across the network at predefined intervals to the connection partner.

Restriction: To prevent errors, do not enable TCP keepalive in certain types of environments. One example is environments that do not have firewalls between the IBM Spectrum Protect server and a NAS device. Another example is environments with firewalls that tolerate long-running, inactive connections. Enabling TCP keepalive in these types of environments can cause an idle connection to be inadvertently closed if the connection partner temporarily fails to respond to TCP keepalive packets.

- Enabling TCP keepalive
  To enable TCP keepalive, which keeps NDMP connections open, use the NDMPENABLEKEEPALIVE server option.

- AIX Linux Windows Specifying connection idle time for TCP keepalive
  To specify the amount of connection idle time, in minutes, before the first TCP keepalive packet is sent, use the NDMPKEEPIDLEMINUTES server option.

Enabling TCP keepalive

To enable TCP keepalive, which keeps NDMP connections open, use the NDMPENABLEKEEPALIVE server option.

Procedure

Add the option to the server options file dsmserv.opt:

```
ndmpenablekeepalive yes
```

Related reference:
NDMPENABLEKEEPALIVE
AIX Linux Windows

Specifying connection idle time for TCP keepalive

To specify the amount of connection idle time, in minutes, before the first TCP keepalive packet is sent, use the NDMPKEEPIDLEMINUTES server option.

Procedure

Add the option to the server options file dsmserv.opt:

```
ndmpkeepidleminutes minutes
```

Configuring IBM Spectrum Protect for NDMP operations

You can configure IBM Spectrum Protect™ to back up and recover data on NAS file servers by using NDMP. The configuration procedure differs depending on whether you plan to back up data from a nonclustered or clustered NAS file server.

- Configuring IBM Spectrum Protect for NDMP operations in a nonclustered environment
  Before you configure IBM Spectrum Protect for NDMP operations in a nonclustered environment, register the required license.
- Configuring IBM Spectrum Protect for NDMP operations in a NetApp clustered environment
  You can back up data from a NetApp cluster to a directly attached tape device or to an IBM Spectrum Protect server, which stores the data in a storage pool. You can back up the entire cluster to a single IBM Spectrum Protect node or parts of the cluster to multiple nodes.

Configuring IBM Spectrum Protect for NDMP operations in a nonclustered environment

Before you configure IBM Spectrum Protect™ for NDMP operations in a nonclustered environment, register the required license.

Procedure

1. Set up the tape library and media. See Configuring a tape library for NDMP operations, where the following steps are described in more detail.
   a. Attach the SCSI or virtual tape library (VTL) library to the NAS file server or to the IBM Spectrum Protect server, or attach the ACSLS library or 349X library to the IBM Spectrum Protect server.
   b. Define the library with a library type of SCSI, VTL, ACSLS, or 349X.
   c. Define a device class for the tape drives.
   d. Define a storage pool for NAS backup media.
   e. Optional: Define a storage pool for storing a table of contents.

2. Configure IBM Spectrum Protect policy for managing NAS image backups. See Configuring an IBM Spectrum Protect policy for NDMP operations.
3. Register a NAS file server node with the IBM Spectrum Protect server. See Registering NAS nodes with the IBM Spectrum Protect server.
4. Define a data mover for the NAS file server. See Defining a data mover for a NAS file server.
5. Define a path from either the IBM Spectrum Protect server or the NAS file server to the library. See Defining paths to libraries for NDMP operations.
6. Define the tape drives to IBM Spectrum Protect, and define the paths to those drives from the NAS file server and optionally from the IBM Spectrum Protect server. See Defining paths for NDMP operations.
7. Check tapes into the library and label them.

   AIX | Linux Tape volumes must be labeled before the server can use them. You can use the LABEL LIBVOLUME command, or you can use the AUTOLABEL parameter with the DEFINE LIBRARY and UPDATE LIBRARY commands.

   Windows All media must be labeled. Labeling media with an automated library requires you to check media into the library. To label volumes with the LABEL LIBVOLUME command, specify the CHECKIN parameter. To automatically label tape volumes in SCSI-type libraries, use the AUTOLABEL parameter on the DEFINE LIBRARY and UPDATE LIBRARY commands.

   For instructions, see LABEL LIBVOLUME, DEFINE LIBRARY, and UPDATE LIBRARY.

8. Optional: Set up scheduled backups for NAS file servers. See Scheduling NDMP operations.
9. Optional: Define a virtual file space name. See Defining virtual file spaces.
10. Optional: Configure for tape-to-tape copy to back up data. See Backing up data with the tape-to-tape function.
11. Optional: Configure for tape-to-tape copy to move data to a different tape technology. See Moving data with the tape-to-tape copy function.

- Configuring an IBM Spectrum Protect policy for NDMP operations
  With policies, you can manage the number and retention time of NDMP image backup versions.
- Tape libraries and drives for NDMP operations
  Most of the planning that is required to implement backup and recovery operations that use NDMP is related to device configuration. You have choices about how to connect and use the libraries and drives.
- Attaching tape library robotics for NAS-attached libraries
  If you plan to back up NAS data to a library that is directly attached to the NAS device and use a SCSI tape library, you must determine where to attach the library.
- Registering NAS nodes with the IBM Spectrum Protect server
  Register the NAS file server as an IBM Spectrum Protect node, specifying TYPE=NAS. This node name is used to track the image backups for the NAS file server.
- Defining a data mover for a NAS file server
  Define a data mover for each NAS file server by using NDMP operations in your environment. The data mover name must match the node name that you specified when you registered the NAS node to the IBM Spectrum Protect server.
- Defining paths for NDMP operations
  For NDMP operations, you create paths to drives and to libraries.
- Scheduling NDMP operations
  You can schedule backup or restore operations for images that are produced by NDMP operations. Use administrative schedules that process the BACKUP NODE or RESTORE NODE administrative commands.
- Defining virtual file spaces
  Use a virtual file space definition to complete NAS directory-level backups. To reduce backup and restore times for large file systems, map a directory path from a NAS file server to a virtual file space name on the IBM Spectrum Protect server.
- Backing up data with the tape-to-tape function
  When you use the NDMP tape-to-tape function to back up data, the library type can be SCSI, 349X, or ACSLS (automated cartridge system library software). Drives can be shared between the NAS devices and the IBM Spectrum Protect server.
- Moving data with the tape-to-tape copy function
  To move data from a previous tape technology to a new tape technology by using the NDMP tape-to-tape copy operation, you must complete the standard steps in your configuration setup and additional steps.

Configuring an IBM Spectrum Protect policy for NDMP operations

With policies, you can manage the number and retention time of NDMP image backup versions.

About this task

For more information, see Policies for backups initiated with an IBM Spectrum Protect server.

Procedure

Complete the following steps to configure a policy for NDMP operations:

1. Create a policy domain for NAS (network-attached storage) file servers. For example, to define a policy domain that is named NASDOMAIN, enter the following command:

   ```
   define domain nasdomain description='Policy domain for NAS file servers'
   ```

2. Create a policy set in that domain. For example, to define a policy set named STANDARD in the policy domain that is named NASDOMAIN, issue the following command:

   ```
   define policyset nasdomain standard
   ```

3. Define a management class, and then assign the management class as the default for the policy set. For example, to define a management class that is named MC1 in the STANDARD policy set, and assign it as the default, issue the following commands:

   ```
   define mgmtclass nasdomain standard mc1

   assign defmgmtclass nasdomain standard mc1
   ```

4. Define a backup copy group in the default management class. The destination must be the storage pool that you created for backup images that are produced by NDMP operations. In addition, you can specify the number of backup versions to retain. For example, to define a backup copy group for the MC1 management class where up to four versions of each file system are retained in the storage pool that is named NASPOOL, issue the following command:

   ```
   define copygroup nasdomain standard mc1 destination=naspool verexists=4
   ```

   If you want to create a table of contents for your backups, the TOCDESTINATION parameter of the copy group must contain the name of the primary storage pool.

   ```
   define copygroup nasdomain standard mc1 destination=naspool
   tocdestination=tocpool verexists=4
   ```

   Important: When you define a copy group for a management class to which a file system image produced by NDMP is bound, be sure that the DESTINATION parameter specifies the name of a storage pool that is defined for NDMP operations. If the DESTINATION parameter specifies an invalid storage pool, backups by NDMP fail.
5. Activate the policy set. For example, to activate the STANDARD policy set in the NASDOMAIN policy domain, issue the following command:

   ```
   activate policyset nasdomain standard
   ```

   The policy is ready to be used. Nodes are associated with a policy when they are registered. For more information, see Registering NAS nodes with the IBM Spectrum Protect server.

- Policies for backups initiated with an IBM Spectrum Protect server
  You can register a network-attached storage (NAS) file server as a node by using network data management protocol (NDMP) operations. Under the direction of the IBM Spectrum Protect server, the NAS file server backs up and restores a file system and directory images to a tape library.
- Policies for backups initiated with the client interface
  When a client node initiates a backup, the policy is affected by the option file for that client node.
- Determination of the NAS backup location
  When IBM Spectrum Protect uses NDMP to protect NAS file servers, the IBM Spectrum Protect server controls operations. During this time, the NAS file server transfers the data, either to an attached library or directly to the IBM Spectrum Protect server.

Policies for backups initiated with an IBM Spectrum Protect server

You can register a network-attached storage (NAS) file server as a node by using network data management protocol (NDMP) operations. Under the direction of the IBM Spectrum Protect™ server, the NAS file server backs up and restores a file system and directory images to a tape library.

The IBM Spectrum Protect server initiates the backup, allocates a drive, and selects and mounts the media. The NAS file server then transfers the data to tape.

Because the NAS file server backs up the data, the data is stored in its own format. For most NAS file servers, the data is stored in the NDMPDUMP data format. For NetApp file servers, the data is stored in the NETAPPDUMP data format. For EMC file servers, the data is stored in the CELERRADUMP data format. To manage NAS file server image backups, copy groups for NAS nodes must point to a storage pool that has a data format of NDMPDUMP, NETAPPDUMP, or CELERRADUMP.

The following backup copy group attributes are ignored for NAS images:

- Frequency
- Mode
- Retain Only Versions
- Serialization
- Versions Data Deleted

To set up the required policy for NAS nodes, you can define a new, separate policy domain.

When the IBM Spectrum Protect server creates a table of contents (TOC), you can view a collection of individual files and directories that are backed up by using NDMP. Then, you can select which file and directories to restore. To establish where to send data and store the table of contents, set the policy in the following way:

- Ensure that image backup data is sent to a storage pool with an NDMPDUMP, NETAPPDUMP, or CELERRADUMP format.
- Ensure that the table of contents is sent to a storage pool with a NATIVE or NONBLOCK format.

Policies for backups initiated with the client interface

When a client node initiates a backup, the policy is affected by the option file for that client node.

You can control the management classes that are applied to backup images produced by NDMP (network data management protocol) operations regardless of which node initiates the backup. You can complete this task by creating a set of options to be used by the client nodes. The option set can include an `include.fs.nas` statement to specify the management class for NAS (network-attached storage) file server backups.

Tip: You can define an option set by using the DEFINE CLOPTSET command. Then, add a client option to the option set by using the DEFINE CLIENTOPT command. You can assign an option set to a client by completing the following steps:

1. Open the Operations Center Overview page and click Clients.
2. Double-click the client and click Properties.
3. In the Option set field, select an option set and click Save.

For instructions about using the DEFINE CLOPTSET command, see DEFINE CLOPTSET (Define a client option set name). For instructions about using the DEFINE CLIENTOPT command, see DEFINE CLIENTOPT (Define an option to an option set).

Determination of the NAS backup location

When IBM Spectrum Protect™ uses NDMP to protect NAS file servers, the IBM Spectrum Protect server controls operations. During this time, the NAS file server transfers the data, either to an attached library or directly to the IBM Spectrum Protect server.

You can also use a backup-archive client to back up a NAS file server by mounting the NAS file system on the client computer and then backing up as usual. You can use either a Network File System (NFS) mount or a Common Internet File System (CIFS) map.

For a description of the backup-and-restore methods, see Table 1.

Tip: You can use a single method or a combination of methods in your individual storage environment.

Table 1. Comparing methods for backing up NDMP data

Property	NDMP: File server to server	NDMP: File server to attached library	Backup-archive client to server
Network data traffic	All backup data goes across the LAN from the NAS file server to the server.	The server controls operations remotely, but the NAS device moves the data locally.	All backup data goes across the LAN from the NAS device to the client and then to the server.

Property	NDMP: File server to server	NDMP: File server to attached library	Backup-archive client to server
File server processing during backup	Less file server processing is required, compared to the backup-archive client method, because the backup does not use file access protocols such as NFS and CIFS.	Less file server processing is required, compared to the backup-archive client method, because the backup does not use file access protocols such as NFS and CIFS.	File backup operations require more server processing resources for file access protocols such as NFS and CIFS.
Distance between devices	The IBM Spectrum Protect server must be within SCSI or Fibre Channel range of the tape library.	The IBM Spectrum Protect server can be distant from the NAS file server and the tape library.	The IBM Spectrum Protect server must be within SCSI or Fibre Channel range of the tape library.
Firewall considerations	More stringent than filer-to-attached-library because communications can be initiated by either the IBM Spectrum Protect server or the NAS file server.	Less stringent than filer-to-server because communications can be initiated only by the IBM Spectrum Protect server.	Client passwords and data are encrypted.
Security considerations	Data is sent decrypted from a NAS file server to an IBM Spectrum Protect server.	This method must be used in a trusted environment because port numbers are not secure.	Port number configuration allows for secure administrative sessions within a private network.
Load on the IBM Spectrum Protect server	Higher CPU workload is required to manage all back-end data processes (for example, migration).	CPU workload is reduced because migration and reclamation are not supported.	Higher CPU workload is required to manage all back-end data processes.
Backup of primary storage pools to copy storage pools	Data can be backed up only to copy storage pools that have the NATIVE data format.	Data can be backed up only to copy storage pools that have the same NDMP data format (NETAPPDUMP, CELERRADUMP, or NDMPDUMP).	Data can be backed up only to copy storage pools that have the NATIVE data format.
Restore of primary storage pools and volumes from copy storage pools	Data can be restored only to storage pools and volumes that have the NATIVE data format.	Data can be restored only to storage pools and volumes that have the same NDMP format.	Data can be restored only to storage pools and volumes that have the NATIVE data format.
Moving NDMP data from storage pool volumes	Data can be moved to another storage pool only if it has a NATIVE data format.	Data can be moved to another storage pool only if it has the same NDMP data format.	Data can be moved to another storage pool only if it has a NATIVE data format.
Migration from one primary storage pool to another	Supported	Not supported	Supported
Reclamation of a storage pool	Supported	Not supported	Supported
Simultaneous-write operations during backups	Not supported	Not supported	Supported
Export and import operations	Not supported	Not supported	Supported
Backup set generation	Not supported	Not supported	Supported
Cyclic Redundancy Checking (CRC) when data is moved by using IBM Spectrum Protect processes	Supported	Not supported	Supported
Validation by using IBM Spectrum Protect audit commands	Supported	Not supported	Supported

Property	NDMP: File server to server	NDMP: File server to attached library	Backup-archive client to server
Disaster recovery manager	Supported	Supported	Supported

Tape libraries and drives for NDMP operations

Most of the planning that is required to implement backup and recovery operations that use NDMP is related to device configuration. You have choices about how to connect and use the libraries and drives.

Many of the configuration choices you have for libraries and drives are determined by the hardware features of your libraries. You can set up NDMP operations with any supported library and drives. However, the more features your library has, the more flexibility you can exercise in your implementation.

You might start by answering the following questions:

- What type of library (SCSI, ACSLS, or 349X) will you use?
- If you are using a SCSI library, do you want to attach tape library robotics to the IBM Spectrum Protect™ server or to the network-attached storage (NAS) file server?
- Will you want to move your NDMP data to tape?
- How do you want to use the tape drives in the library?
    - Dedicate all tape drives to NDMP operations.
    - Dedicate some tape drives to NDMP operations and others to traditional IBM Spectrum Protect operations.
    - Share tape drives between NDMP operations and traditional IBM Spectrum Protect operations.
- Will you back up data tape-to-tape for disaster recovery functions?
- Will you send backup data to a single IBM Spectrum Protect server instead of attaching a tape library to each NAS device?
- Do you want to keep all hardware on the IBM Spectrum Protect server and send NDMP data over the LAN?

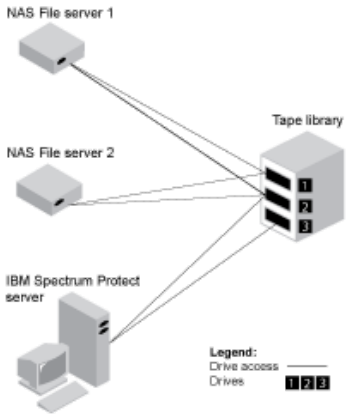
- Determining library drive usage when backing up to NAS-attached libraries
  Drives can be used for multiple purposes because of the flexible configurations that are allowed by IBM Spectrum Protect. For NDMP operations, the NAS file server must have access to the drive. The IBM Spectrum Protect server can also have access to the same drive, depending on your hardware connections and limitations.
- Configuring a tape library for NDMP operations
  You can configure a tape library to back up a network-attached storage (NAS) device to tape.

Determining library drive usage when backing up to NAS-attached libraries

Drives can be used for multiple purposes because of the flexible configurations that are allowed by IBM Spectrum Protect™. For NDMP operations, the NAS file server must have access to the drive. The IBM Spectrum Protect server can also have access to the same drive, depending on your hardware connections and limitations.

About this task

All drives are defined to the IBM Spectrum Protect server. However, the same drive can be defined for both traditional IBM Spectrum Protect operations and NDMP operations. Figure 1 illustrates one possible configuration. The IBM Spectrum Protect server has access to drives 2 and 3, and each NAS file server has access to drives 1 and 2.
Figure 1. IBM Spectrum Protect drive usage example



To create the configuration that is shown in Figure 1, complete the following steps:

Procedure

1. Define all three drives to IBM Spectrum Protect.
2. Define paths from the IBM Spectrum Protect server to drives 2 and 3. Because drive 1 is not accessed by the server, no path is defined.
3. Define each NAS file server as a separate data mover.
4. Define paths from each data mover to drive 1 and to drive 2.

Results

To use the IBM Spectrum Protect back-end data movement operations, the IBM Spectrum Protect server requires two available drive paths from a single NAS data mover. The drives can be in different libraries and can have different device types that are supported by NDMP. You can make copies between two different tape devices. For example, the source tape drive can be a DLT drive in a library and the target drive can be an LTO drive in another library.

During IBM Spectrum Protect back-end data movements, the IBM Spectrum Protect server locates a NAS data mover that supports the same data format as the data to be copied from and that has two available mount points and paths to the drives. If the IBM Spectrum Protect server cannot locate such a data mover, the requested data movement operation is not performed. The number of available mount points and drives depends on the mount limits of the device classes for the storage pools that are involved in the back-end data movements.

If the back-end data movement function supports multiprocessing, each concurrent IBM Spectrum Protect back-end data movement process requires two available mount points and two available drives. To run two IBM Spectrum Protect processes concurrently, at least four mount points and four drives must be available.

For more information, see Defining paths for NDMP operations.

Configuring a tape library for NDMP operations

You can configure a tape library to back up a network-attached storage (NAS) device to tape.

Procedure

Complete the following steps to set up tape libraries for NDMP operations:

1. Connect the library and drives to be used for NDMP operations.
   a. Connect the SCSI library. Before you set up a SCSI tape library for NDMP operations, determine whether you want to attach your library robotics control to the IBM Spectrum Protect™ server or to the NAS file server. See Tape libraries and drives for NDMP operations. Connect the SCSI tape library robotics to the IBM Spectrum Protect server or to the NAS file server. Refer to your device manufacturer documentation for instructions.

      If the library is connected to IBM Spectrum Protect, make a SCSI or Fibre Channel connection between the IBM Spectrum Protect server and the library robotics control port. Then, connect the NAS file server with the drives.

If the library is connected to the NAS file server, make a SCSI or Fibre Channel connection between the NAS file server and the library robotics and drives.

b. Connect the ACSLS Library. Connect the ACSLS tape library to the IBM Spectrum Protect server.
c. Connect the 349X Library. Connect the 349X tape library to the IBM Spectrum Protect server.

2. Define the library for your library device by issuing the DEFINE LIBRARY command. The library must be a single device type, not a mixed device. Issue one of the following commands to define the library depending on the type of device that you are configuring:

   SCSI Library

   ```
   define library tsmlib libtype=scsi
   ```

   ACSLS Library

   ```
   define library acslib libtype=acsls acsid=1
   ```

   349X Library

   ```
   define library tsmlib libtype=349x
   ```

3. Define a device class for your NDMP device by issuing the DEFINE DEVCLASS command.
   Tip: A device class that is defined with a device type of NAS is not explicitly associated with a specific drive type, for example, LTO. However, the preferred practice is to define a separate device class for different drive types.
   In the DEFINE DEVCLASS command, use the following parameters and values:
   - Specify `DEVTYPE=NAS`.
   - Specify `MOUNTRETENTION=0`. It is required for NDMP operations.
   - Specify a value for the ESTCAPACITY parameter.

   For example, to define a device class that is named NASCLASS for a library that is named NASLIB with an estimated capacity is 40 GB for the media, issue the following command:

   ```
   define devclass nasclass devtype=nas library=naslib mountretention=0
    estcapacity=40g
   ```

4. Define a storage pool for NDMP media by issuing the DEFINE STGPOOL command. When NETAPPDUMP, CELERRADUMP, or NDMPDUMP is designated as the type of storage pool, managing the storage pools that are produced by NDMP operations is different from managing storage pools that contain media for traditional IBM Spectrum Protect backups. IBM Spectrum Protect operations use storage pools that are defined with a NATIVE or NONBLOCK data format. If you select NETAPPDUMP, CELERRADUMP, or NDMPDUMP, NDMP operations require storage pools with a data format that matches the NAS file server and the selected backup method. Maintaining separate storage pools for data from different NAS vendors is optimal, even though the data format for both is NDMPDUMP. For example, to define a storage pool that is named NDMPPOOL for a file server, which is not a NetApp or a Celerra file server, issue the following command:

   ```
   define stgpool ndmppool nasclass maxscratch=10 dataformat=ndmpdump
   ```

   To define a storage pool that is named NASPOOL for a NetApp file server, issue the following command:

   ```
   define stgpool naspool nasclass maxscratch=10 dataformat=netappdump
   ```

   To define a storage pool that is named CELERRAPOOL for an EMC Celerra file server, issue the following command:

   ```
   define stgpool celerrapool nasclass maxscratch=10 dataformat=celerradump
   ```

   Attention: Ensure that you do not accidentally use storage pools that are defined for NDMP operations in traditional IBM Spectrum Protect operations. Be especially careful when you assign the storage pool name as the value for the DESTINATION parameter of the DEFINE COPYGROUP command. Unless the destination is a storage pool with the appropriate data format, the backup can fail.

5. Optional: Define a storage pool for a table of contents. If you plan to create a table of contents, you must also define a disk storage pool in which to store the table of contents. You must set up policy so that the IBM Spectrum Protect server stores the table of contents in a different storage pool from the one where the backup image is stored. The table of contents is treated like any other object in that storage pool. For example, to define a storage pool that is named TOCPOOL for a DISK device class, issue the following command:

   ```
   define stgpool tocpool disk
   ```

   Then define volumes for the storage pool.

AIX Linux For more information about defining volumes, see Configuring random access volumes on disk devices (V7.1.1).

Windows For more information about defining volumes, see Configuring random access volumes on disk devices (V7.1.1).

AIX Linux For more information about configuring libraries, see Configuring libraries for use by a server.

DEFINE DEVCLASS (Define a device class)

Attaching tape library robotics for NAS-attached libraries

If you plan to back up NAS data to a library that is directly attached to the NAS device and use a SCSI tape library, you must determine where to attach the library.

About this task

You must determine whether to attach the library robotics to the IBM Spectrum Protect™ server or to the NAS file server. Regardless of where you connect library robotics, tape drives must always be connected to the NAS file server for NDMP operations.

Distance and your available hardware connections are factors to consider for SCSI libraries. If the library does not have separate ports for robotics control and drive access, the library must be attached to the NAS file server because the NAS file server must have access to the drives. If your SCSI library has separate ports for robotics control and drive access, you can choose to attach the library robotics to either the IBM Spectrum Protect server or the NAS file server. If the NAS file server is at a different location from the IBM Spectrum Protect server, the distance might mean that you must attach the library to the NAS file server.

Whether you are using a SCSI, ACSLS, or 349X library, you have the option of dedicating the library to NDMP operations, or of using the library for NDMP operations. You can also use the library for most traditional IBM Spectrum Protect operations.

Table 1. Summary of configurations for NDMP operations

Configuration	Distance between IBM Spectrum Protect server and library	Library sharing	Drive sharing between IBM Spectrum Protect and NAS file server	Drive sharing between NAS file servers	Drive sharing between storage agent and NAS file server
Configuration 1 (SCSI library that is connected to the IBM Spectrum Protect server)	Limited by SCSI or FC connection	Supported	Supported	Supported	Supported
Configuration 2 (SCSI library that is connected to the NAS file server)	No limitation	Not supported	Supported	Supported	Not supported
Configuration 3 (349X library)	Might be limited by 349X connection	Supported	Supported	Supported	Supported
AIX Windows Configuration 4 (ACSLS library)	AIX Windows Might be limited by ACSLS connection	AIX Windows Supported	AIX Windows Supported	AIX Windows Supported	AIX Windows Supported

- Configuration 1: SCSI library connected to the IBM Spectrum Protect server
  In this configuration, the tape library must have separate ports for robotics control and for drive access. In addition, the library must be within Fibre Channel range or SCSI bus range of both the IBM Spectrum Protect server and the NAS file server.
- Configuration 2: SCSI library connected to the NAS file server
  In this configuration, the library robotics and the drives must be physically connected directly to the NAS file server. Paths must be defined from the NAS data mover to the library and drives. No physical connection is required between the IBM Spectrum Protect server and the SCSI library.
- Configuration 3: 349x library connected to the IBM Spectrum Protect server
  For this configuration, you connect the tape library to the system as for traditional operations.

- Configuration 4: ACSLS library connected to the IBM Spectrum Protect server
  For this configuration, connect the tape library to the system as you do for traditional IBM Spectrum Protect operations.

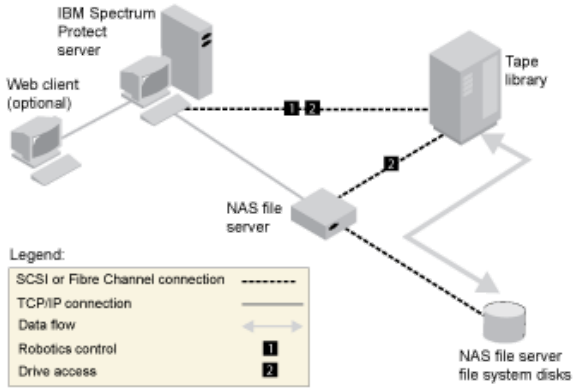
Configuration 1: SCSI library connected to the IBM Spectrum Protect server

In this configuration, the tape library must have separate ports for robotics control and for drive access. In addition, the library must be within Fibre Channel range or SCSI bus range of both the IBM Spectrum Protect™ server and the NAS file server.

In this configuration, the IBM Spectrum Protect server controls the SCSI library through a direct, physical connection to the library robotics control port. For NDMP operations, the drives in the library are connected directly to the NAS file server, and a path must be defined from the NAS data mover to each of the drives to be used. The NAS file server transfers data to the tape drive at the request of the IBM Spectrum Protect server. To also use the drives for IBM Spectrum Protect operations, connect the IBM Spectrum Protect server to the tape drives and define paths from the server to the tape drives.

This configuration also supports an IBM Spectrum Protect storage agent having access to the drives for its LAN-free operations, and the IBM Spectrum Protect server can be a library manager.

Figure 1. Configuration 1: SCSI library connected to IBM Spectrum Protect server

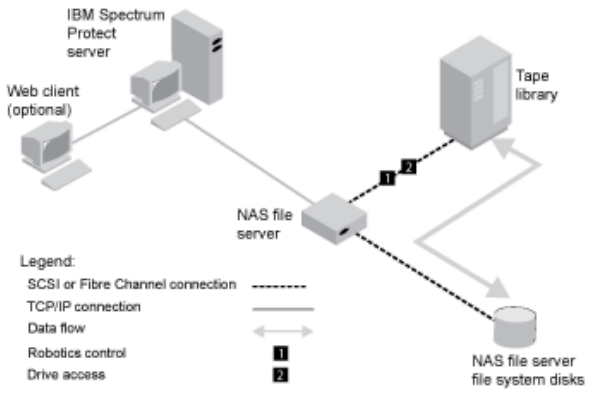


Configuration 2: SCSI library connected to the NAS file server

In this configuration, the library robotics and the drives must be physically connected directly to the NAS file server. Paths must be defined from the NAS data mover to the library and drives. No physical connection is required between the IBM Spectrum Protect™ server and the SCSI library.

The IBM Spectrum Protect server controls library robotics by sending library commands across the network to the NAS file server. The NAS file server passes the commands to the tape library. Any responses that are generated by the library are sent to the NAS file server, and passed back across the network to the IBM Spectrum Protect server. This configuration supports a physically distant IBM Spectrum Protect server and NAS file server. For example, the IBM Spectrum Protect server is in one city, while the NAS file server and tape library are in another city.

Figure 1. Configuration 2: SCSI library connected to the NAS file server



Configuration 3: 349x library connected to the IBM Spectrum Protect server

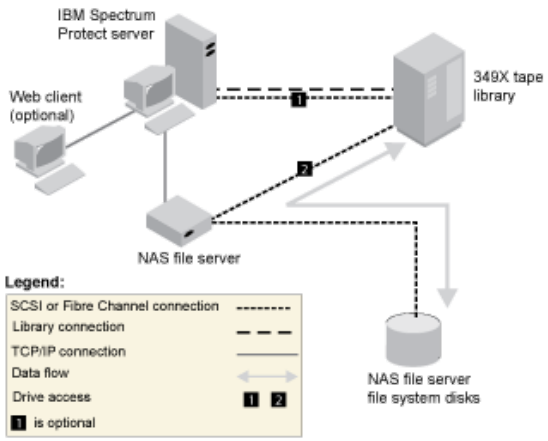
For this configuration, you connect the tape library to the system as for traditional operations.

In this configuration, the 349X tape library is controlled by the IBM Spectrum Protect™ server. The IBM Spectrum Protect server controls the library by passing the request to the 349X library manager through TCP/IP.

To complete NAS (network-attached storage) backup or restore operations, the NAS file server must be able to access one or more tape drives in the 349X library. Any tape drives used for NAS operations must be physically connected to the NAS file server, and paths need to be defined from the NAS data mover to the drives. The NAS file server transfers data to the tape drive at the request of the IBM Spectrum Protect server. Follow the manufacturer's instructions to attach the device to the server system.

This configuration supports a physically distant IBM Spectrum Protect server and NAS file server. For example, the IBM Spectrum Protect server might be in one city, while the NAS file server and tape library are in another city.

Figure 1. Configuration 3: 349x library connected to the IBM Spectrum Protect server



Related tasks:
Attaching devices for the server (V7.1.1)

Configuration 4: ACSLS library connected to the IBM Spectrum Protect server

For this configuration, connect the tape library to the system as you do for traditional IBM Spectrum Protect™ operations.

The ACSLS (automated cartridge system library software) tape library is controlled by the IBM Spectrum Protect server. The IBM Spectrum Protect server controls the library by passing the request to the ACSLS library server through TCP/IP. The ACSLS library supports library sharing and LAN-free operations.

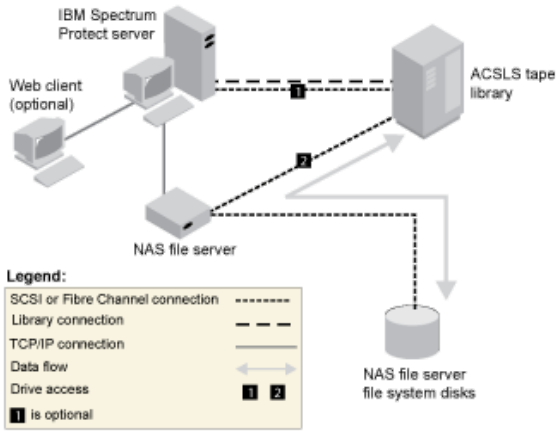
Windows Restriction: To use ACSLS functions, StorageTek Library Attach software must be installed. For more information, see ACSLS-managed libraries (V7.1.1).

To complete NAS (network-attached storage) backup or restore operations, the NAS file server must be able to access one or more tape drives in the ACSLS library. Any tape drives used for NAS operations must be physically connected to the NAS file server, and any paths need to be defined from the NAS data mover to the drives. The NAS file server transfers data to the tape drive at the request of the IBM Spectrum Protect server. Follow the manufacturer's instructions to attach the device to the server system.

This configuration supports a physically distant IBM Spectrum Protect server and NAS file server. For example, the IBM Spectrum Protect server might be in one city while the NAS file server and tape library are in another city.

To also use the drives for IBM Spectrum Protect operations, connect the IBM Spectrum Protect server to the tape drives and define paths from the IBM Spectrum Protect server to the tape drives.

Figure 1. Configuration 4: ACSLS library connected to the IBM Spectrum Protect server



Related tasks:
Attaching devices for the server (V7.1.1)

Registering NAS nodes with the IBM Spectrum Protect server

Register the NAS file server as an IBM Spectrum Protect™ node, specifying TYPE=NAS. This node name is used to track the image backups for the NAS file server.

Procedure

To register a NAS file server as a node named NASNODE1, with a password of NASPWD1, in a policy domain that is named NASDOMAIN, issue the following example command:

```
register node nasnode1 naspwd1 domain=nasdomain type=nas
```

If you are using a client option set, specify the option set when you register the node.
You can verify that this node is registered by issuing the following command:

```
query node type=nas
```

Remember: You must specify TYPE=NAS so that only NAS nodes are displayed.

Defining a data mover for a NAS file server

Define a data mover for each NAS file server by using NDMP operations in your environment. The data mover name must match the node name that you specified when you registered the NAS node to the IBM Spectrum Protect™ server.

About this task

IBM Spectrum Protect supports two types of data movers:

- For NDMP operations, data movers are NAS file servers. The definition for a NAS data mover contains the network address, authorization, and data formats that are required for NDMP operations. A data mover enables communication and ensures authority for NDMP operations between the IBM Spectrum Protect server and the NAS file server.
- For server-free data movement, data movers are devices such as the IBM® SAN Data Gateway, which move data between disk devices and tape devices on the SAN.

Procedure

To define a data mover, use the DEFINE DATAMOVER command.

Example

For example, define a data mover with these parameters:

- The NAS node is named NASNODE1.
- The high-level address is an IP address for the NAS file server, either a numerical address or a host name.
- The low-level address is the IP port for NDMP sessions with the NAS file server. The default is port number 10000.
- The user ID is the ID defined to the NAS file server that authorizes an NDMP session with the NAS file server. For this example, the user ID is the administrative ID for the NetApp file server.
- The password parameter is a valid password for authentication to an NDMP session with the NAS file server.
- The data format is NETAPPDUMP. This is the data format that the NetApp file server uses for tape backup. This data format must match the data format of the target storage pool.

Enter the following command:

```
define datamover nasnode1 type=nas hladdress=netapp2 lladdress=10000 userid=root
password=admin dataformat=netappdump
```

Related reference:
DEFINE DATAMOVER (Define a data mover)

Defining paths for NDMP operations

For NDMP operations, you create paths to drives and to libraries.

- Defining paths to drives for NDMP operations
  The method that you choose for creating paths to drives depends on whether the drives are accessed by a NAS file server and the IBM Spectrum Protect server or only by a NAS file server.
- Defining paths to libraries for NDMP operations
  Define a path to the SCSI library from either the IBM Spectrum Protect server or the NAS file server.

Defining paths to drives for NDMP operations

The method that you choose for creating paths to drives depends on whether the drives are accessed by a NAS file server and the IBM Spectrum Protect™ server or only by a NAS file server.

- Defining paths for drives attached to a NAS file server and to the IBM Spectrum Protect server
  If a tape drive must be accessed by a network-attached storage (NAS) file server and the IBM Spectrum Protect server, you must create two paths. One path exists between the tape drive and the NAS file server. The other path exists between the tape drive and the IBM Spectrum Protect server.
- Defining paths for drives attached only to NAS file servers
  If a tape drive must be accessed only by a NAS file server and not by the IBM Spectrum Protect server, only a single path between the tape drive and the NAS file server is required.
- Obtaining names for devices attached to NAS file servers
  For paths from a NAS data mover, the value of the DEVICE parameter in the DEFINE PATH command is the name by which the NAS file server knows a library or drive.

Defining paths for drives attached to a NAS file server and to the IBM Spectrum Protect server

If a tape drive must be accessed by a network-attached storage (NAS) file server and the IBM Spectrum Protect™ server, you must create two paths. One path exists between the tape drive and the NAS file server. The other path exists between the tape drive and the IBM Spectrum Protect server.

Procedure

Complete the following steps:

1. If the drive is not defined for the IBM Spectrum Protect server, create the drive definition. For example, to define a drive NASDRIVE1 for a library NASLIB, issue the following command:

   ```
   define drive naslib nasdrive1 element=autodetect
   ```

   Remember: If the drive is attached to the IBM Spectrum Protect server, the element address is automatically detected.
2. Map the NAS drive name to the corresponding drive definition on the IBM Spectrum Protect server:
   - On the IBM Spectrum Protect server, issue the QUERY DRIVE FORMAT=DETAILED command to obtain the worldwide name (WWN) and serial number for the drive that will be connected to the NAS file server.
   - On the NAS device, obtain the tape device name, serial number, and WWN for the drive.

   If the WWN or serial number matches, a drive on a NAS file server is the same as the drive on the IBM Spectrum Protect server.
3. Using the drive name, define a path to the drive from the NAS file server and a path to the drive from the IBM Spectrum Protect server.
   - For example, to define a path between a tape drive with a device name of rst01 and a NetApp file server, issue the following command:

     ```
     define path nasnode1 nasdrive1 srctype=datamover desttype=drive
       library=naslib device=rst01
     ```

   - To define a path between the tape drive and the IBM Spectrum Protect server, issue the following command:

     AIX

     ```
     define path server1 nasdrive1 srctype=server desttype=drive
      library=naslib device=/dev/rmt0
     ```

     Linux

     ```
     define path server1 nasdrive1 srctype=server desttype=drive
      library=naslib device=/dev/tsmscsi/mt0
     ```

     Windows

     ```
     define path server1 nasdrive1 srctype=server desttype=drive
      library=naslib device=mt3.0.0.2
     ```

Defining paths for drives attached only to NAS file servers

If a tape drive must be accessed only by a NAS file server and not by the IBM Spectrum Protect™ server, only a single path between the tape drive and the NAS file server is required.

Procedure

Complete the following steps:

1. Obtain the SCSI element addresses, worldwide name (WWN), and serial numbers for the drive to be connected to NAS file server.
   Restriction: If the SCSI drive is connected only to a NAS file server, the element address is not automatically detected, and you must supply it. If a library has more than one drive, you must specify an element address for each drive.
   To obtain a SCSI element address, go to the following device-support websites:
   - AIX Windows Supported devices for AIX and Windows
   - Linux Supported devices for Linux

   Element number assignment and device WWN assignments are also available from tape-library device manufacturers.
2. Create drive definitions by specifying the element addresses identified in the preceding step. Specify the element address in the ELEMENT parameter of the DEFINE DRIVE command. For example, to define a drive NASDRIVE1 with the element address 82 for the library NASLIB, issue the following command:

   ```
   define drive naslib nasdrive1 element=82
   ```

Attention: For a drive connected only to the NAS file server, do not specify ASNEEDED as the value for the CLEANFREQUENCY parameter of the DEFINE DRIVE command.

3. Obtain the device name, serial number, and WWN for the drive on the NAS device.
4. Using the information that is obtained in steps 1 and 3, map the NAS device name to the element address in the drive definition in the IBM Spectrum Protect server.
5. Define a path between the tape drive and the NAS file server. For example, to define a path between a NetApp file server and a tape drive with a device name of rst01, issue the following command:

```
define path nasnode1 nasdrive1 srctype=datamover desttype=drive
 library=naslib device=rst0l
```

Obtaining names for devices attached to NAS file servers

For paths from a NAS data mover, the value of the DEVICE parameter in the DEFINE PATH command is the name by which the NAS file server knows a library or drive.

About this task

You can obtain these device names, also known as *special file names*, by querying the NAS file server. For information about how to obtain names for devices that are connected to a NAS file server, see the product information for the file server.

Procedure

- To obtain the device names for tape libraries on a NetApp Release ONTAP 10.0 GX, or later, file server, connect to the file server by using telnet and issue the SYSTEM HARDWARE TAPE LIBRARY SHOW command. To obtain the device names for tape drives on a NetApp Release ONTAP 10.0 GX, or later, file server, connect to the file server by using telnet and issue the SYSTEM HARDWARE TAPE DRIVE SHOW command. For details about these commands, see the NetApp ONTAP GX file server product documentation.
- For releases earlier than NetApp Release ONTAP 10.0 GX, continue to use the SYSCONFIG command. For example, to display the device names for tape libraries, connect to the file server by using telnet and issue the following command:

  ```
  sysconfig -m
  ```

  To display the device names for tape drives, issue the following command:

  ```
  sysconfig -t
  ```

- For Fibre Channel attached drives and the Celerra data mover, complete the following steps:
  1. Log on to the EMC Celerra control workstation by using an administrative ID. Issue the following command:

     ```
     server_devconfig server_1 -l -s -n
     ```

     Tip: The -l option for this command lists only the device information that was saved in the database of the data mover. The command and option do not display changes to the device configuration that occurred after the last database refresh on the data mover. For details about how to obtain the most recent device configuration for your data mover, see the EMC Celerra documentation.
     The output for the server_devconfig command includes the device names for the devices that are attached to the data mover. The device names are listed in the *addr* column, for example:

     ```
     server_1:
     Scsi Device Table
     name         addr       type    info
     tape1        c64t0l0    tape    IBM ULT3580-TD2 53Y2
     ttape1       c96t0l0    tape    IBM ULT3580-TD2 53Y2
     ```

  2. Map the Celerra device name to the device worldwide name (WWN):
     a. To list the WWN, log on to the EMC Celerra control workstation and issue the following command. Remember to enter a period (.) as the first character in this command.

        ```
        .server_config server_# -v "fcp bind show"
        ```

        The output for this command includes the WWN, for example:

        ```
        Chain 0064: WWN 500507630f418e29 HBA 2 N_PORT Bound
        Chain 0096: WWN 500507630f418e18 HBA 2 N_PORT Bound
        ```

Tip: The .server_config command is an undocumented EMC Celerra command. For more information about how to use it, contact EMC.

b. Use the chain number to identify the tape device that was listed in the output of the server_devconfig command and that has the same WWN, for example:

Tape device name	Chain number	WWN
c64t0l0	0064	500507630f418e29
c96t0l0	0096	500507630f418e18

Celerra commands might behave differently on different EMC Celerra systems and operating system levels. For details, see the EMC Celerra documentation or contact EMC.

Defining paths to libraries for NDMP operations

Define a path to the SCSI library from either the IBM Spectrum Protect™ server or the NAS file server.

Procedure

1. For a SCSI library connected to IBM Spectrum Protect, issue the following example command to define a path from the server, named SERVER1, to the SCSI library named TSMLIB:

   AIX

   ```
   define path server1 tsmlib srctype=server desttype=library
            device=/dev/lb1
   ```

   Linux

   ```
   define path server1 tsmlib srctype=server desttype=library
            device=/dev/tsmscsi/lb1
   ```

   Windows

   ```
   define path server1 tsmlib srctype=server desttype=library
          device=lb0.0.0.2
   ```

2. For a SCSI library connected to a NAS file server, issue the following example command to define a path between a NetApp NAS data mover that is named NASNODE1 and a library named NASLIB:

   ```
   define path nasnode1 naslib srctype=datamover desttype=library device=mc0
   ```

3. For a 349X library, define a path to the library from the IBM Spectrum Protect server. For example, issue the following command to define a path from the server, named SERVER1, to the 349X library named TSMLIB:

   AIX

   ```
   define path server1 tsmlib srctype=server desttype=library
            device=/dev/lmcp0
   ```

   Linux | Windows

   ```
   define path server1 tsmlib srctype=server desttype=library
    device=library1
   ```

   Tip: The DEFINE PATH command is not required for an automated cartridge system library software (ACSLS) library.

Scheduling NDMP operations

You can schedule backup or restore operations for images that are produced by NDMP operations. Use administrative schedules that process the BACKUP NODE or RESTORE NODE administrative commands.

Procedure

Create an administrative schedule by using the DEFINE SCHEDULE command. For example, to create an administrative schedule that is named NASSCHED to back up all file systems for node NASNODE1, enter the following command:

```
define schedule nassched type=administrative cmd='backup node nasnode1' active=yes
starttime=20:00 period=1 perunits=days
```

The schedule is active, and is set to run at 8 p.m. every day.
Restriction: The BACKUP NODE and RESTORE NODE commands can be used only for nodes of TYPE=NAS.
Related tasks:
Tuning the schedule for daily operations
Related reference:
BACKUP NODE (Back up a NAS node)
RESTORE NODE (Restore a NAS node)
DEFINE SCHEDULE (Define a schedule for an administrative command)

Defining virtual file spaces

Use a virtual file space definition to complete NAS directory-level backups. To reduce backup and restore times for large file systems, map a directory path from a NAS file server to a virtual file space name on the IBM Spectrum Protect™ server.

Procedure

To create a virtual file space name for the directory path on the NAS device, issue the DEFINE VIRTUALFSMAPPING command:

```
define virtualfsmapping nas1 /mikesdir /vol/vol1 /mikes
```

This command defines a virtual file space name of /MIKESDIR on the server, which represents the directory path of /VOL/VOL1/MIKES on the NAS file server that is represented by node NAS1. For more information, see Directory-level backup and restore for NDMP operations.

Backing up data with the tape-to-tape function

When you use the NDMP tape-to-tape function to back up data, the library type can be SCSI, 349X, or ACSLS (automated cartridge system library software). Drives can be shared between the NAS devices and the IBM Spectrum Protect™ server.

About this task

When you use the NDMP tape-to-tape copy function, your configuration setup might affect the performance of the IBM Spectrum Protect back-end data movement.

Procedure

To have one NAS device with paths to four drives in a library, use the MOVE DATA command after you complete your configuration setup. This moves data on the volume VOL1 to any available volumes in the same storage pool as VOL1:

```
move data vol1
```

Moving data with the tape-to-tape copy function

To move data from a previous tape technology to a new tape technology by using the NDMP tape-to-tape copy operation, you must complete the standard steps in your configuration setup and additional steps.

About this task

When you use the NDMP tape-to-tape copy function, your configuration setup might affect the performance of the IBM Spectrum Protect™ back-end data movement.

Procedure

In addition to the standard steps in your configuration setup, complete the following steps:

1. Define one drive in the library, lib1, that has previous tape technology:

   ```
   define drive lib1 drv1 element=1035
   ```

2. Define one drive in the library, lib2, that has new tape technology:

```
define drive lib2 drv1 element=1036
```

3. Define paths from the NAS file server to each drive:

```
define path nas1 drv1 sourcetype=datamover desttype=drive library=lib1 device=rst11
define path nas1 drv1 sourcetype=datamover desttype=drive library=lib2 device=rst21
```

4. Move data on volume vol1 in the primary storage pool to the volumes in another primary storage pool, nasprimpool2:

```
move data vol1 stgpool=nasprimpool2
```

Configuring IBM Spectrum Protect for NDMP operations in a NetApp clustered environment

You can back up data from a NetApp cluster to a directly attached tape device or to an IBM Spectrum Protect™ server, which stores the data in a storage pool. You can back up the entire cluster to a single IBM Spectrum Protect node or parts of the cluster to multiple nodes.

Before you begin

For an overview of NDMP functionality in IBM Spectrum Protect and NetApp file servers, see technote 7046965. This technote also lists system requirements.

About this task

You can back up data in a NetApp clustered environment to the following storage media:

Tape device that is directly attached to a NAS file server
: You can back up data to a tape device that is directly attached to a NAS file server. This is the preferred method. Typically, it is faster to back up data to a directly attached tape device than it is to back up data to an IBM Spectrum Protect storage pool by using a network connection.

Storage pool in the local IBM Spectrum Protect hierarchy
: You can back up data to an IBM Spectrum Protect server, which stores the data in a storage pool of type DISK, FILE, or tape. The advantage of storing data in a storage pool is that you can replicate the data for added data protection. You can use existing storage pools or create storage pools. You must have a network connection between the NAS file server and the IBM Spectrum Protect server. The network connection must have sufficient bandwidth to transfer the NAS backup data.
  Tip: This type of backup is sometimes called a filer-to-server backup.

You can use one of the following backup methods:

Full cluster backup
: When you apply this method, the backup data of the entire cluster is owned by a single IBM Spectrum Protect node. Even if you move the volumes within the cluster, full cluster backup operations continue and you do not have to reconfigure backup operations. This is the preferred method.

Partial cluster backup
: When you apply this method, you specify a NetApp storage virtual machine (SVM), which determines the scope of the backup operation. The SVM is a virtual server that provides access to part of a cluster. You can specify that each SVM in the cluster backs up data to a separate IBM Spectrum Protect node. This method requires more configuration than the full cluster backup method, and it requires a network connection to transfer data from the SVM to the IBM Spectrum Protect node.
  Restriction: You cannot use this method to back up data to a tape device because SVMs do not have direct access to tape devices.

Procedure

1. Select the storage media based on the following questions:

Question	Storage media
Based on your business requirements, is it necessary to back up data to a local tape device?	If the answer is yes, use a directly attached tape device. If the answer is no, use either a directly attached tape device or a local IBM Spectrum Protect storage pool.

Question	Storage media
Does your organization require high-speed backup operations?	If the answer is yes, use a directly attached tape device. If the answer is no, use either a directly attached tape device or a local IBM Spectrum Protect storage pool.
Does your organization have sufficient network bandwidth for NAS backup data?	If the answer is yes, use either a directly attached tape device or a local IBM Spectrum Protect storage pool. If the answer is no, use a directly attached tape device.
Does your organization want to enhance data protection by using replication?	If the answer is yes, use a local IBM Spectrum Protect storage pool. If the answer is no, use either a directly attached tape device or a local IBM Spectrum Protect storage pool.
Are your NAS file servers at remote locations without access to directly attached tape libraries?	If the answer is yes, use a local IBM Spectrum Protect storage pool. If the answer is no, use either a directly attached tape device or a local IBM Spectrum Protect storage pool.

2. Select a backup method based on the following questions:

Question	Backup method
Based on your business requirements, is it necessary to back up data to a directly attached tape device?	If the answer is yes, use the full backup method. If the answer is no, use either the full or partial backup method.
Does your system have sufficient network bandwidth to back up several SVMs without affecting network performance?	If the answer is yes, use either the full or partial backup method. If the answer is no, use the full backup method. The partial backup method might adversely affect system performance.
Are the SVMs distributed across several organizations? For example, are any SVMs controlled by third parties, such as cloud-platform providers?	If the answer is yes, use the partial backup method because SVM owners can control backup operations for individual SVMs. If an SVM owner also owns an IBM Spectrum Protect server, the owner can set up backup operations from the SVM to a server node. In this way, the owner can control the end-to-end process. If the answer is no, use either the full or partial backup method.

3. Configure the system environment based on the storage media and backup method that you chose. Follow the instructions for your selected method:
    - Configuring full cluster backups to directly attached tape devices
    - Configuring full cluster backups to an IBM Spectrum Protect server
    - Configuring partial cluster backups to an IBM Spectrum Protect server

    Tip: If you configured IBM Spectrum Protect to back up NetApp clusters by using node-scoped NDMP, consider reconfiguring IBM Spectrum Protect to use NDMP Cluster Aware Backup (CAB). In this way, you can optimize backup operations for NetApp clusters. Follow the instructions in Reconfiguring IBM Spectrum Protect to optimize clustered backups.

- Configuring full cluster backups to directly attached tape devices
  You can configure IBM Spectrum Protect to back up all volumes in a NetApp cluster to a directly attached tape device.
- Configuring full cluster backups to an IBM Spectrum Protect server
  You can configure IBM Spectrum Protect to back up all volumes in a NetApp cluster to an IBM Spectrum Protect server, which stores the data in a storage pool. Even if you move volumes within the cluster, backup operations continue and no reconfiguration is required.
- Configuring partial cluster backups to an IBM Spectrum Protect server
  You can configure IBM Spectrum Protect to complete a partial backup of a NetApp cluster. This method is useful when multiple organizations own data in the cluster. Each organization can manage backup operations for its data.
- Reconfiguring IBM Spectrum Protect to optimize clustered backups
  If you configured IBM Spectrum Protect to back up NetApp clusters by using node-scoped NDMP, you can reconfigure IBM Spectrum Protect to use NDMP Cluster Aware Backup (CAB). In this way, you can optimize backup operations for NetApp clusters.

Configuring full cluster backups to directly attached tape devices

You can configure IBM Spectrum Protect™ to back up all volumes in a NetApp cluster to a directly attached tape device.

Before you begin

For an overview of NDMP functionality in IBM Spectrum Protect and NetApp file servers, see technote 7046965. This technote also lists system requirements.

If the NetApp Clustered Data ONTAP 8.2 or later, or 9.1 or later, operating system is installed on your NetApp file server, use the following procedure. After you configure your NetApp file server to work with IBM Spectrum Protect, you can use the NetApp Cluster Aware Backup (CAB) extension to back up all volumes.

If the NetApp Clustered Data ONTAP 8.2 or later, or 9.1 or later, operating system is not installed on your NetApp file server, back up data by following the instructions in Configuring IBM Spectrum Protect for NDMP operations in a nonclustered environment.

About this task

The preferred method is to back up the full cluster by using a node and data mover that are associated with the clusterwide network. In this way, you ensure that the backup data is owned by a single IBM Spectrum Protect node. Even if you move volumes within the cluster, backup operations continue and no reconfiguration is required.

Procedure

To configure full cluster backup operations to a directly attached tape device, complete the following steps:

1. Verify that IBM Spectrum Protect Extended Edition is installed, and that the license is registered. If the license is not registered, issue the following IBM Spectrum Protect command:

   ```
   register license file=tsmee.lic
   ```

2. Obtain cluster administrator privileges for the NetApp file server. This step is required to access the cluster console.
3. On the NetApp file server, enable the use of NDMP by following the instructions in the *Clustered Data ONTAP® Data Protection Tape Backup and Recovery Guide*. Complete the following steps:
   a. Enable SVM-scoped NDMP backup operations at the cluster level. In this way, you disable node-scoped NDMP backup operations on the NAS file server. Ensure that the node-scoped-ndmp option on the NAS file server is set to OFF.
   b. Create a backup user ID for NDMP operations.
   c. Configure a network interface for NDMP control connections at the cluster level.
4. Register the IBM Spectrum Protect node that will own all backup data for the cluster. On the IBM Spectrum Protect server, issue the REGISTER NODE command:

   ```
   register node node_name password domain=nas_domain type=nas
   ```

   where *node_name* specifies the node name, *password* specifies the node password, and *nas_domain* specifies the domain of the node. Assign the node to a domain that has a policy to back up data to an appropriate storage pool.
5. Determine the IP address of the NetApp cluster management interface on the NAS file server. The interface provides access to the entire cluster. On the NAS file server, issue the following Data ONTAP operating system command:

   ```
   network interface show -role cluster-mgmt
   ```

   The IP address that is shown in the command output is required when you specify the HLADDRESS parameter in step 6.
6. Define a data mover for the IBM Spectrum Protect node that will own the backup data. On the IBM Spectrum Protect server, issue the DEFINE DATAMOVER command on one line:

   ```
   define datamover data_mover_name type=nascluster
   hladdress=cluster_management_interface lladdress=port
   USER=user_name password=password dataformat=netappdump
   ```

   where *cluster_management_interface* is the value that you obtained in step 5 and *data_mover_name* is the node name that you registered in step 4. For information about specifying the other parameters, see DEFINE DATAMOVER (Define a data mover).
   Tip: After you define the data mover, additional data movers are defined automatically for each node in the cluster. The name of each data mover matches the name of the physical node in the cluster. You will use these data movers when you define paths to tape drives in step 3 of Configuring tape devices for full cluster backups.

What to do next

To configure the tape device for the full cluster backup, follow the instructions in Configuring tape devices for full cluster backups.

- Configuring tape devices for full cluster backups
  If you plan to back up all volumes in a NetApp cluster to a directly attached tape device, you must configure the tape device.

REGISTER NODE (Register a node)

Configuring full cluster backups to an IBM Spectrum Protect server

You can configure IBM Spectrum Protect™ to back up all volumes in a NetApp cluster to an IBM Spectrum Protect server, which stores the data in a storage pool. Even if you move volumes within the cluster, backup operations continue and no reconfiguration is required.

Before you begin

For an overview of NDMP functionality in IBM Spectrum Protect and NetApp file servers, see technote 7046965. This technote also lists system requirements.

If the NetApp Clustered Data ONTAP 8.2 or later, or 9.1 or later, operating system is installed on your NetApp file server, use the following procedure. After you configure your NetApp file server to work with IBM Spectrum Protect, you can use the NetApp Cluster Aware Backup (CAB) extension to back up all volumes in the cluster. All backed-up data will be owned by a single IBM Spectrum Protect node.

If the NetApp Clustered Data ONTAP 8.2 or later, or 9.1 or later, operating system is not installed on your NetApp file server, back up data by following the instructions in Configuring IBM Spectrum Protect for NDMP operations in a nonclustered environment.

Procedure

1. Verify that IBM Spectrum Protect Extended Edition is installed, and that the license is registered. If the license is not registered, issue the following IBM Spectrum Protect command:

   ```
   register license file=tsmee.lic
   ```

2. Obtain cluster administrator privileges for the NetApp file server. This step is required to access the cluster console.
3. Enable the use of NDMP by following the instructions in the *Clustered Data ONTAP® Data Protection Tape Backup and Recovery Guide*. Complete the following steps:
   a. Enable the NetApp SVM to control NDMP backup operations at the cluster level.
   b. Create a backup user ID for NDMP operations.
   c. Configure a network interface for NDMP control connections at the cluster level.
4. Register the IBM Spectrum Protect node that will own all backup data for the cluster. On the IBM Spectrum Protect server, issue the REGISTER NODE command:

   ```
   register node node_name password domain=nas_domain type=nas
   ```

   where *node_name* specifies the node name, *password* specifies the node password, and *nas_domain* specifies the domain of the node.
5. Determine the numerical IP address or the domain name that is used to access the NAS file server. The interface provides access to the entire cluster. On the NAS file server, issue the following Data ONTAP operating system command:

   ```
   network interface show -role cluster-mgmt
   ```

   The IP address in the output is required when you specify a value for the HLADDRESS parameter in step 6.
6. Define a data mover for the node by issuing the DEFINE DATAMOVER command and specifying `TYPE=NASCLUSTER`. On the IBM Spectrum Protect server, issue the following command on one line:

   ```
   define datamover data_mover_name type=nascluster
   hladdress=cluster_management_interface lladdress=port
   USER=user_name password=password dataformat=netappdump
   ```

   where *cluster_management_interface* is the value that you obtained in step 5 and *data_mover_name* is the node name that you registered in step 4. For information about specifying the other parameters, see DEFINE DATAMOVER (Define a data mover).

7. Configure an IBM Spectrum Protect policy for managing NAS image backups. Follow the instructions in Configuring an IBM Spectrum Protect policy for NDMP operations.
8. Update the cluster node that you registered in step 4 to the domain that was configured in step 7. On the IBM Spectrum Protect server, issue the UPDATE NODE command:

   ```
   update node node_name domain=domain_name
   ```

9. Optional: Identify the volumes in the cluster and schedule backups for the volumes:
   a. On the NAS file server, identify the volumes in the cluster by issuing the following Data ONTAP command:

      ```
      volume show
      ```

   b. Schedule backup operations by following the instructions in Scheduling NDMP operations.

What to do next

The following tasks are optional:

- To verify that volumes in the NetApp cluster are backed up, complete the following steps:
  1. On the Operations Center menu bar, click Clients.
  2. Double-click a NAS device client and click Volumes.
  3. To determine when the last full volume backup was completed, review the information in the Last Full column. To determine when the most recent differential backup was completed, review the information in the Last Differential column.
- To set up copy storage pools for added data protection, configure the tape-to-tape function to back up data. For instructions, see Backing up data with the tape-to-tape function.

REGISTER NODE (Register a node)

Configuring partial cluster backups to an IBM Spectrum Protect server

You can configure IBM Spectrum Protect™ to complete a partial backup of a NetApp cluster. This method is useful when multiple organizations own data in the cluster. Each organization can manage backup operations for its data.

Before you begin

For an overview of NDMP functionality in IBM Spectrum Protect and NetApp file servers, see technote 7046965. This technote also lists system requirements.

If the NetApp Clustered Data ONTAP 8.2 or later, or 9.1 or later, operating system is installed on your NetApp file server, use the following procedure. After you configure your NetApp file server to work with IBM Spectrum Protect, you can use the NetApp Cluster Aware Backup (CAB) extension to back up a partial cluster. When you configure a partial cluster backup, you determine the scope of the backup by specifying a virtual server, the NetApp storage virtual machine (SVM). The SVM provides access to part of a cluster.

If the NetApp Clustered Data ONTAP 8.2 or later, or 9.1 or later, operating system is not installed on your NetApp file server, back up data by following the instructions in Configuring IBM Spectrum Protect for NDMP operations in a nonclustered environment.

Procedure

1. Verify that IBM Spectrum Protect Extended Edition is installed, and that the license is registered. If the license is not registered, issue the following IBM Spectrum Protect command:

   ```
   register license file=tsmee.lic
   ```

2. Obtain cluster administrator privileges for the NetApp file server. This step is required to access the cluster console.
3. On the NetApp file server, enable the use of NDMP by following the instructions in the *Clustered Data ONTAP® Data Protection Tape Backup and Recovery Guide*. Complete the following steps:
   a. Enable the NetApp SVM to control NDMP backup operations.
   b. Create a backup user ID for NDMP operations.
   c. Configure a network interface for NDMP control connections at the SVM level.
4. Register the IBM Spectrum Protect node that will own the backed-up data. On the IBM Spectrum Protect server, issue the REGISTER NODE command:

```
register node node_name password domain=nas_domain type=nas
```

where *node_name* specifies the node name, *password* specifies the node password, and *nas_domain* specifies the domain of the node.

5. Determine the numerical IP address or the domain name of the cluster interface that is used by the SVM. To determine the value, on the NAS file server, issue the following ONTAP operating system command:

```
network interface show -vserver vserver_name -role data
```

where *vserver_name* specifies the name of the SVM. This value that you obtain is required in step 6.

6. Define an associated data mover for the IBM Spectrum Protect node by issuing the DEFINE DATAMOVER command and specifying `TYPE=NASVSERVER`. On the IBM Spectrum Protect server, issue the following command on one line:

```
define datamover data_mover_name type=nasvserver
hladdress=svm_data_interface lladdress=port
USER=user_name password=password dataformat=netappdump
```

where *svm_data_interface* is the value that you obtained in step 5 and *data_mover_name* is the name of the node that you registered in step 4.

For information about specifying the other parameters, see DEFINE DATAMOVER (Define a data mover).

7. Configure an IBM Spectrum Protect policy for managing NAS image backups. Follow the instructions in Configuring an IBM Spectrum Protect policy for NDMP operations.
8. Update the node that you registered in step 4 to the domain that you configured in step 7. On the IBM Spectrum Protect server, issue the UPDATE NODE command:

```
update node node_name domain=domain_name
```

9. Optional: Identify the volumes in the cluster and schedule backup operations. Take the following steps:
   a. On the NAS file server, identify the volumes in the cluster by issuing the following Data ONTAP command:

   ```
   volume show -vserver vserver_name
   ```

   where *vserver_name* specifies the name of the SVM.
   b. Schedule backup operations by following the instructions in Scheduling NDMP operations.

What to do next

To verify that volumes in the NetApp cluster are backed up, complete the following steps:

1. On the Operations Center menu bar, click Clients.
2. Double-click a NAS device client and click Volumes.
3. To determine when the last full volume backup was completed, review the information in the Last Full column. To determine when the most recent differential backup was completed, review the information in the Last Differential column.

REGISTER NODE (Register a node)

Reconfiguring IBM Spectrum Protect to optimize clustered backups

If you configured IBM Spectrum Protect™ to back up NetApp clusters by using node-scoped NDMP, you can reconfigure IBM Spectrum Protect to use NDMP Cluster Aware Backup (CAB). In this way, you can optimize backup operations for NetApp clusters.

Before you begin

For an overview of NDMP functionality in IBM Spectrum Protect and NetApp file servers, see technote 7046965. This technote also lists system requirements.

About this task

When you reconfigure IBM Spectrum Protect to use CAB, you can optimize backup operations in the following ways:

- You can configure IBM Spectrum Protect to back up all volumes in a NetApp cluster to a directly attached tape device or to an IBM Spectrum Protect server. In both cases, the data is owned by a single IBM Spectrum Protect node. Even if you move

volumes within the cluster, backup operations continue and no reconfiguration is required.
- You can complete a partial backup of a NetApp cluster to an IBM Spectrum Protect server. This method is useful when multiple organizations own data in the cluster. Each organization can manage backup operations for its data. You set the scope of a partial backup by specifying a NetApp storage virtual machine (SVM), which provides access to part of a cluster.

To reconfigure IBM Spectrum Protect to use CAB, you must define a new IBM Spectrum Protect node and a new data mover.

Procedure

1. Verify that NetApp Clustered Data ONTAP 8.2 or later, or 9.1 or later, is installed on the NetApp file server.
2. Enable the use of NDMP by following the instructions in the *Clustered Data ONTAP® Data Protection Tape Backup and Recovery Guide*. Take one of the following actions:

   For a full cluster backup
   Complete the following steps:
   a. Enable SVM-scoped NDMP backup operations at the cluster level. In this way, you disable node-scoped NDMP backup operations on the NAS file server. Ensure that the node-scoped-ndmp option on the NAS file server is set to OFF.
   b. Create a backup user ID for NDMP operations.
   c. Configure a network interface for NDMP control connections at the cluster level.

   For a partial cluster backup
   Complete the following steps:
   a. Enable SVM-scoped NDMP to control NDMP backup operations.
   b. Create a backup user ID for NDMP operations.
   c. Configure a network interface for NDMP control connections at the SVM level.

3. Register the IBM Spectrum Protect node that will own the backup data. On the IBM Spectrum Protect server, issue the REGISTER NODE command:

   ```
   register node node_name password domain=nas_domain type=nas
   ```

   where *node_name* specifies the node name, *password* specifies the node password, and *nas_domain* specifies the domain of the node.
4. If you plan to back up a full cluster, determine the IP address of the NetApp cluster management interface on the NAS file server. The interface provides access to the entire cluster. On the NAS file server, issue the following Data ONTAP operating system command:

   ```
   network interface show -role cluster-mgmt
   ```

   The IP address in the output is required when you specify the HLADDRESS parameter in step 6.
5. If you plan to back up a partial cluster, determine the numerical IP address or the domain name of the cluster interface that is used by the SVM. To determine the value, issue the following Data ONTAP operating system command on the NAS file server:

   ```
   network interface show -vserver vserver_name -role data
   ```

   where *vserver_name* specifies the name of the SVM. The value that you obtain is required in step 6.
6. Define a data mover for the IBM Spectrum Protect node. Take one of the following actions:

   For a full cluster backup
   Define a data mover for the IBM Spectrum Protect node that will own the backup data. On the IBM Spectrum Protect server, issue the DEFINE DATAMOVER command on one line:

   ```
   define datamover data_mover_name type=nascluster
   hladdress=cluster_management_interface lladdress=port
   USER=user_name password=password dataformat=netappdump
   ```

   where *cluster_management_interface* is the value that you obtained in step 4 and *data_mover_name* is the node name that you registered in step 3.
   Tip: After you define the data mover, additional data movers are defined automatically for each node in the cluster. The name of each data mover matches the name of the physical node in the cluster. You will use these data movers when you define paths to tape drives that are attached to the cluster.

   For a partial cluster backup
   Define a data mover for the node by issuing the DEFINE DATAMOVER command and specifying `TYPE=NASVSERVER`. On the IBM Spectrum Protect server, issue the following command on one line:

```
define datamover data_mover_name type=nasvserver
hladdress=svm_data_interface lladdress=port
USER=user_name password=password dataformat=netappdump
```

where *svm_data_interface* is the value that you obtained in step 5 and *data_mover_name* is the node name that you registered in step 3.

For information about specifying the other parameters on the DEFINE DATAMOVER command, see DEFINE DATAMOVER (Define a data mover).

7. To back up data to a directly attached tape device, for each tape drive that is attached to the cluster, identify the device name and the physical node to which the drive is attached:
   a. On the NAS file server, issue the following Data ONTAP command:

      ```
      storage tape show-tape-drive
      ```

   b. Review the output to find the serial number of the tape drive, and the node of the cluster to which the drive is attached. The same stanza includes the device name, for example, `st1`, `st2`, or `st3`.
8. To configure a full cluster backup to a directly attached tape device, follow the instructions in Configuring tape devices for full cluster backups.
9. To configure a full or partial cluster backup to an IBM Spectrum Protect server, configure a policy for managing NAS image backups. Follow the instructions in Configuring an IBM Spectrum Protect policy for NDMP operations.
10. Disable scheduled backup operations for all nodes that were previously used to back up the NetApp cluster.
11. Identify the volumes in the cluster and optionally schedule backup operations for the volumes. Take one of the following actions:

    For a full cluster backup
    a. On the NAS file server, identify the volumes in the cluster by using the following Data ONTAP command:

       ```
       volume show
       ```

    b. Run a full backup of the entire cluster.
    c. Optional: To schedule backup operations, follow the instructions in Scheduling NDMP operations.

    For a partial cluster backup
    a. On the NAS file server, identify the volumes in the cluster by using the following Data ONTAP command:

       ```
       volume show -vserver vserver_name
       ```

       where *vserver_name* specifies the name of the SVM.
    b. Run a full backup of the partial cluster.
    c. Optional: To schedule backup operations, follow the instructions in Scheduling NDMP operations.

What to do next

To verify that volumes in the NetApp cluster are backed up, complete the following steps:

1. On the Operations Center menu bar, click Clients.
2. Double-click a NAS device client and click Volumes.
3. To determine when the last full volume backup was completed, review the information in the Last Full column. To determine when the most recent differential backup was completed, review the information in the Last Differential column.

Backing up and restoring NAS file servers using NDMP

After you configure IBM Spectrum Protect™ for NDMP operations, you are ready to begin using NDMP.

Procedure

Use either a client interface or an administrative interface to perform a file system image backup. For example, to use the Windows backup-archive client interface to back up a file system that is named /vol/vol1 on a NAS file server that is named NAS1, issue the following command:

```
dsmc backup nas -nasnodename=nas1 {/vol/vol1}
```

For more information about the command, see Backup Image.
Tip: Whenever you use the client interface, you are asked to authenticate yourself as an IBM Spectrum Protect administrator before the operation can begin. The administrator ID must have at least client owner authority for the NAS node.
You can complete the same backup operation with a server interface. For example, from the administrative command-line client, back up the file system that is named /vol/vol1 on a NAS file server that is named NAS1, by issuing the following command:

```
backup node nas1 /vol/vol1
```

Restriction: The BACKUP NAS and BACKUP NODE commands do not include snapshots. To back up snapshots, see Backing up and restoring with snapshots.
You can restore the image by using either interface. Backups are identical whether they are backed up using a client interface or a server interface. For example, suppose that you want to restore the image that is backed up in the previous examples. For this example, the file system that is named /vol/vol1 is being restored to /vol/vol2. Restore the file system with the following command, issued from a Windows backup-archive client interface:

```
dsmc restore nas -nasnodename=nas1 {/vol/vol1} {/vol/vol2}
```

You can choose to restore the file system by using a server interface. For example, to restore the file system name /vol/vol1 to file system /vol/vol2, for a NAS file server that is named NAS1, enter the following command:

```
restore node nas1 /vol/vol1 /vol/vol2
```

You can restore data from one NAS vendor system to another NAS vendor system when you use the NDMPDUMP data format. However, you must either verify compatibility between systems or maintain a separate storage pool for each NAS vendor.

- NAS file servers: backups to a single IBM Spectrum Protect server
  If you have several NAS file servers in different locations, you might prefer to send the backup data to a single IBM Spectrum Protect server rather than attaching a tape library to each NAS device.
- Backing up NDMP file servers to an IBM Spectrum Protect server
  You can back up data to a single IBM Spectrum Protect server rather than attaching a tape library to each NAS device.

NAS file servers: backups to a single IBM Spectrum Protect server

If you have several NAS file servers in different locations, you might prefer to send the backup data to a single IBM Spectrum Protect™ server rather than attaching a tape library to each NAS device.

When you store NAS backup data in the IBM Spectrum Protect server's storage hierarchy, you can apply IBM Spectrum Protect back-end data management functions. In this way, you can take advantage of migration, reclamation, disaster recovery, and other features.

To back up a NAS device to an IBM Spectrum Protect native storage pool, set the destination storage pool in the copy group to point to the wanted native storage pool. The destination storage pool provides the information about the library and drives that are used for backup and restore. You must ensure that there is sufficient space in your target storage pool to contain the NAS data, which can be backed up to sequential, disk, or file type devices. Defining a separate device class is not necessary.

If you are creating a table of contents, a management class must be specified with the TOCDESTINATION parameter in the DEFINE and UPDATE COPYGROUP commands. When you back up a NAS file server to IBM Spectrum Protect native pools, the TOCDESTINATION can be the same as the destination of the data that is backed up by using NDMP.

Firewall considerations are more stringent than they are for filer-to-attached-library because communications can be initiated by either the IBM Spectrum Protect server or the NAS file server. NDMP tape servers run as threads within the IBM Spectrum Protect server and the tape server accepts connections on port of 10001. This port number can be changed through the following option in the IBM Spectrum Protect server options file: NDMPPORTRANGE port-number-low, port-number-high.

During NDMP filer-to-server backup operations, you can use the NDMPPREFDATAINTERFACE option to specify which network interface the IBM Spectrum Protect server uses to receive backup data. The value for this option is a host name or IPV4 address that is associated with one of the active network interfaces of the system on which the IBM Spectrum Protect server is running. This interface must be IPV4 enabled.

Before you use this option, verify that your NAS device supports NDMP operations that use a different network interface for NDMP control and NDMP data connections. NDMP control connections are used by IBM Spectrum Protect to authenticate with an NDMP server and monitor an NDMP operation while NDMP data connections are used to transmit and receive back up data during NDMP operations. You must still configure your NAS device to route backup and restore data to the appropriate network interface.

When enabled, the NDMPPREFDATAINTERFACE option affects all subsequent NDMP filer-to-server operations. It does not affect NDMP control connections because they use the system's default network interface. You can update this server option without stopping and restarting the server by using the SETOPT command.

NetApp file servers provide an NDMP option (ndmpd.preferred_interface) to change the interface that is used for NDMP data connections. For more information, see the documentation for your NAS device.

For instructions about completing NDMP filer-to-server backup operations, see Backing up NDMP file servers to an IBM Spectrum Protect server.

For information about server options, see Server options.

Backing up NDMP file servers to an IBM Spectrum Protect server

You can back up data to a single IBM Spectrum Protect™ server rather than attaching a tape library to each NAS device.

Procedure

To back up a server on a NAS file system, complete the following steps:

1. Select an existing storage pool or set up a storage pool for the NAS data by issuing the following command:

   ```
   define stgpool naspool disk
   ```

2. Define volumes to add to the storage pool. For example, define a volume that is named naspool_volAB:

   ```
   define volume naspool /usr/storage/naspool_volAB formatsize=100
   ```

3. Set the copy destination to the storage pool defined previously and activate the associated policy set.

   ```
   update copygroup standard standard standard destination=naspool
    tocdestination=naspool
   activate policyset standard standard
   ```

   The destination for NAS data is determined by the destination in the copy group. The storage size estimate for NAS differential backups uses the occupancy of the file space, the same value that is used for a full backup. You can use this size estimate as one of the considerations in choosing a storage pool. One of the attributes of a storage pool is the MAXSIZE value, which indicates that data is sent to the NEXT storage pool when the MAXSIZE value is exceeded by the estimated size. Because NAS differential backups to IBM Spectrum Protect native storage pools use the base file space occupancy size as a storage size estimate, differential backups end up in the same storage pool as the full backup. Depending on collocation settings, differential backups might end up on the same media as the full backup.
4. Set up a node and data mover for the NAS device. The data format signifies that the backup images created by this NAS device are a dump type of backup image in a NetApp specific format.

   ```
   register node nas1 nas1 type=nas domain=standard
   define datamover nas1 type=nas hla=nas1 user=root
   password=***** dataformat=netappdump
   ```

   The NAS device is now ready to be backed up to an IBM Spectrum Protect server storage pool. Paths can be defined to local drives, but the destination that is specified by the management class determines the target location for this backup operation.
5. Back up the NAS device to the IBM Spectrum Protect storage pool by issuing the following command:

   ```
   backup node nas1 /vol/vol0
   ```

6. Restore a NAS device from the IBM Spectrum Protect storage pool by issuing the following command:

   ```
   restore node nas1 /vol/vol0
   ```

File-level backup and restore for NDMP operations

When you back up data by using NDMP, you can specify that the IBM Spectrum Protect™ server collects and stores file-level information in a table of contents (TOC).

If you specify this option at the time of backup, you can later display the TOC of the backup image. Through the backup-archive web client, you can select individual files or directories to restore directly from the backup images generated.

Collecting file-level information requires extra processing time, network resources, storage pool space, temporary database space, and possibly additional storage device interaction. For instructions about configuring storage devices, see Configuring storage devices. You must consider dedicating more space in the IBM Spectrum Protect server database. You must set up policy so that the IBM Spectrum Protect server stores the TOC in a different storage pool from the one where the backup image is stored. The TOC is treated like any other object in that storage pool.

You can also do a backup by using NDMP without collecting file-level restore information.

To allow creation of a TOC for a backup by using NDMP, you must define the TOCDESTINATION attribute in the backup copy group for the management class to which this backup image is bound. You cannot specify a copy storage pool or an active-data pool as the destination. The storage pool that you specify for the TOC destination must have a data format of either NATIVE or NONBLOCK, so it cannot be the tape storage pool that is used for the backup image.

If you choose to collect file-level information, specify the TOC parameter in the BACKUP NODE server command. Or, if you initiate your backup by using the client, you can specify the TOC option in the client options file, client option set, or client command line. You can specify NO, PREFERRED, or YES. When you specify PREFERRED or YES, the IBM Spectrum Protect server stores file information for a single NDMP-controlled backup in a TOC. The TOC is placed into a storage pool. After that, the IBM Spectrum Protect server can access the TOC so that file and directory information can be queried by the server or client. Use of the TOC parameter allows a TOC to be generated for some images and not others, without requiring different management classes for the images.

For more information about the BACKUP NODE command, see BACKUP NODE (Back up a NAS node).

To avoid mount delays and ensure sufficient space, use random access storage pools (DISK device class) as the destination for the TOC. For sequential access storage pools, no labeling or other preparation of volumes is necessary if scratch volumes are allowed.

For more information, see Managing tables of contents.

- Interfaces for file-level restore operations
  When you restore individual files and directories, you have the choice of using one of two interfaces to initiate the restore: the backup-archive web client or the server interface.
- International characters for NetApp file servers
  All systems that create or access data on a particular NAS file server volume must do so in a manner compatible with the volume language setting.
- File-level restore operations from a directory-level backup image
  File-level restore operations are supported for directory-level backup images.

Interfaces for file-level restore operations

When you restore individual files and directories, you have the choice of using one of two interfaces to initiate the restore: the backup-archive web client or the server interface.

Restore operations by using the backup-archive web client
: The backup-archive web client requires that a TOC exists to restore files and directories. The web client must be on a Windows system. The IBM Spectrum Protect™ server accesses the TOC from the storage pool and loads TOC information into a temporary database table. Then, you can use the backup-archive web client to examine directories and files that are contained in one or more file system images, and select individual files or directories to restore directly from the backup images generated.

Restore operations by using the server interface

- If you have a TOC, use the QUERY NASBACKUP command to display information about backup images that are generated by NDMP and to see which images have a corresponding TOC. Then, use the RESTORE NODE command with the FILELIST parameter.
- If you did not create a TOC, the contents of the backup image cannot be displayed. You can restore individual files, directories, or both if you know the name of the file or directory, and in which image the backup is located. Use the RESTORE NODE command with the FILELIST parameter.

International characters for NetApp file servers

All systems that create or access data on a particular NAS file server volume must do so in a manner compatible with the volume language setting.

You must install Data ONTAP 6.4.1 or later, if it is available, on your NetApp NAS file server to garner full support of international characters in the names of files and directories.

If your level of Data ONTAP is earlier than 6.4.1, you must have one of the following two configurations to collect and restore file-level information. Results with configurations other than the two listed are unpredictable. The IBM Spectrum Protect™ server issues a warning message (ANR4946W) during backup operations. The message indicates that the character encoding of NDMP file history messages is unknown, and UTF-8 is assumed to build a table of contents. It is safe to ignore this message only for the following two configurations.

- Your data has directory and file names that contain only English (7-bit ASCII) characters.
- Your data has directory and file names that contain non-English-language characters and the volume language is set to the UTF-8 version of the proper locale (for example, `de.UTF-8` for German).

If your level of Data ONTAP is 6.4.1 or later, you must have one of the following three configurations to collect and restore file-level information. Results with configurations other than the three listed are unpredictable.

- Your data has directory and file names that contain only English (7-bit ASCII) characters and the volume language is either not set or is set to one of the following values:
  - `C (POSIX)`
  - `en`
  - `en_US`
  - `en.UTF-8`
  - `en_US.UTF-8`
- Your data has directory and file names that contain non-English-language characters, and the volume language is set to the proper locale (for example, `de.UTF-8` or `de` for German).
  Tip: Using the UTF-8 version of the volume language setting is more efficient in terms of IBM Spectrum Protect server processing and table of contents storage space.
- You use CIFS only to create and access your data.

File-level restore operations from a directory-level backup image

File-level restore operations are supported for directory-level backup images.

As with a NAS file system backup, a table of contents (TOC) is created during a directory-level backup and you are able to browse the files in the image by using the web client. The default is that the files are restored to the original location. During a file-level restore from a directory-level backup, however, you can either select a different file system or another virtual file space name as a destination.

For a TOC of a directory-level backup image, the path names for all files are relative to the directory that is specified in the virtual file space definition, not the root of the file system.

Directory-level backup and restore operations

If you have a large NAS file system, initiating a backup at a directory level reduces backup and restore times and provides more flexibility in configuring NAS backups. By defining virtual file spaces, a file system backup can be partitioned among several NDMP backup operations and multiple tape drives. You can also use different backup schedules to back up subtrees of a file system.

The virtual file space name cannot be identical to any file system on the NAS node. If a file system is created on the NAS device with the same name as a virtual file system, a name conflict occurs on the IBM Spectrum Protect™ server when the new file space is backed up. For instructions about issuing commands for mapping virtual file spaces, see DEFINE VIRTUALFSMAPPING (Define a virtual file space mapping).
Restriction: Virtual file space mappings are supported only for NAS nodes.

- Directory-level backup and restore for NDMP operations
  The DEFINE VIRTUALFSMAPPING command maps a directory path of a NAS file server to a virtual file space name on the IBM Spectrum Protect server. After a mapping is defined, you can conduct NAS operations such as BACKUP NODE and RESTORE NODE by using the virtual file space names as if they were actual NAS file spaces.
- Backing up and restoring with snapshots
  NDMP directory-level backup operations give you the ability to back up user-created snapshots of a NAS file system. Those snapshots are then stored as subdirectories. The snapshots can be taken at any time, and the backup to tape can be deferred to a more convenient time.

Directory-level backup and restore for NDMP operations

The DEFINE VIRTUALFSMAPPING command maps a directory path of a NAS file server to a virtual file space name on the IBM Spectrum Protect™ server. After a mapping is defined, you can conduct NAS operations such as BACKUP NODE and RESTORE NODE by using the virtual file space names as if they were actual NAS file spaces.

To start a backup of the directory, issue the BACKUP NODE command and specify the virtual file space name instead of a file space name. To restore the directory subtree to the original location, run the RESTORE NODE command and specify the virtual file space name.

Virtual file space definitions can also be specified as the destination in a RESTORE NODE command. In this way, you can restore backup images (either file system or directory) to a directory on any file system of the NAS device.

You can use the web client to select files for restore from a directory-level backup image because the IBM Spectrum Protect client treats the virtual file space names as NAS file spaces.

Backing up and restoring with snapshots

NDMP directory-level backup operations give you the ability to back up user-created snapshots of a NAS file system. Those snapshots are then stored as subdirectories. The snapshots can be taken at any time, and the backup to tape can be deferred to a more convenient time.

Procedure

For example, to back up a snapshot that is created for a NetApp file system, complete the following steps:

1. On the console for the NAS device, issue the command to create the snapshot. SNAP CREATE is the command for a NetApp device.

   ```
   snap create vol2 february17
   ```

   This example creates a snapshot that is named FEBRUARY 17 of the /vol/vol2 file system. The physical location for the snapshot data is in the directory /vol/vol2/.snapshot/february17. The stored location for snapshot data depends on the NAS vendor implementation. For NetApp, the SNAP LIST command can be used to display all snapshots for a file system.
2. Define a virtual file space mapping definition on the IBM Spectrum Protect™ server for the snapshot data that is created in the previous step.

   ```
   define virtualfsmapping  nas1 /feb17snapshot  /vol/vol2  /.snapshot/february17
   ```

   This example creates a virtual file space mapping definition named /feb17snapshot.
3. Back up the virtual file space mapping.

   ```
   backup node nas1 /feb17snapshot mode=full toc=yes
   ```

4. After the backup is created, you can either restore the entire snapshot image or restore an individual file. Before you restore the data, you can create a virtual file space mapping name for the target directory. You can select any file system name as a target. The target location in this example is the directory /feb17snaprestore on the file system /vol/vol1.

   ```
   define virtualfsmapping  nas1 /feb17snaprestore  /vol/vol1  /feb17snaprestore
   ```

5. Restore the snapshot backup image.

   ```
   restore node nas1 /feb17snapshot /feb17snaprestore
   ```

   This example restores a copy of the /vol/vol2 file system to the directory /vol/vol1/feb17snaprestore in the same state as when the snapshot was created in the first step.

Backup and restore operations by using the NetApp SnapMirror to Tape feature

You can back up large NetApp file systems by using the NetApp SnapMirror to Tape feature (also known as SMTape). Using a block-level copy of data for backup, the SnapMirror to Tape method is faster than a traditional NDMP full backup and can be used when NDMP full backups are impractical.

Use the NDMP SnapMirror to Tape feature as a disaster recovery option for copying large NetApp file systems to auxiliary storage. For most NetApp file systems, use the standard NDMP full or differential backup method.

By specifying a parameter on the BACKUP NODE and RESTORE NODE commands, you can back up and restore file systems by using SnapMirror to Tape. There are several limitations and restrictions on how SnapMirror images can be used. Consider the following guidelines before you use it as a backup method:

- If you installed NetApp ONTAP 8.2 or later, you must define a data mover of type NASCLUSTER or NASVSERVER for SnapMirror to Tape operations.
- You cannot initiate a SnapMirror to Tape backup or restore operation from the IBM Spectrum Protect™ Operations Center, web client, or command-line client.
- You cannot perform differential backups of SnapMirror images.
- You cannot perform a directory-level backup by using SnapMirror to Tape. Therefore, IBM Spectrum Protect does not permit SnapMirror to Tape backup operations on a server virtual file space.
- You cannot perform an NDMP file-level restore operation from SnapMirror to Tape images. Therefore, a table of contents is never created during SnapMirror to Tape image backups.
- At the start of a SnapMirror to Tape copy operation, the file server generates a snapshot of the file system. NetApp provides an NDMP environment variable to control whether this snapshot is removed at the end of the SnapMirror to Tape operation. IBM Spectrum Protect always sets this variable to remove the snapshot.
- After a SnapMirror to Tape image is retrieved and copied to a NetApp file system, the target file system remains configured as a SnapMirror partner. NetApp provides an NDMP environment variable to control whether this SnapMirror relationship should be broken. IBM Spectrum Protect always "breaks" the SnapMirror relationship during the retrieval. After the restore operation is complete, the target file system is in the same state as that of the original file system at the time of backup.

For more information about the SnapMirror to Tape feature, see BACKUP NODE (Back up a NAS node) and RESTORE NODE (Restore a NAS node).

NDMP backup operations using Celerra file server-integrated checkpoints

When the IBM Spectrum Protect™ server initiates an NDMP backup operation on a Celerra data mover, the backup of a large file system might take several hours to complete. Without Celerra integrated checkpoints, any changes that occur on the file system are written to the backup image.

As a result, the backup image includes changes that are made to the file system during the entire backup operation. The backup image is not a true point-in-time image of the file system.

If you are performing NDMP backup operations from Celerra file servers, upgrade the operating system of your data mover to Celerra file server version T5.5.25.1 or later. This version of the operating system allows enablement of integrated checkpoints for all NDMP backup operations from the Celerra Control Workstation. By enabling this feature, you ensure that the backup data represents true point-in-time images of the file system that is being backed up.

For instructions about enabling integrated checkpoints during all NDMP backup operations, see the Celerra file server documentation.

If your version of the Celerra file server operating system is earlier than version T5.5.25.1 and if you use NDMP to back up Celerra data movers, manually generate a snapshot of the file system by using Celerra's command-line checkpoint feature. Then, initiate an NDMP backup operation for the checkpoint file system rather than the original file system.

For instructions about creating and scheduling checkpoints from the Celerra control workstation, see the Celerra file server documentation.

Replicating NAS nodes

You can replicate a NAS node that uses NDMP for backup operations. Before you configure the replication operation, review the restrictions that apply.

About this task

Restrictions:

- The backup data must be in a storage pool with the NATIVE data format. You cannot replicate backup data in storage pools that have the following data formats:
  - NETAPPDUMP
  - CELERRADUMP
  - NDMPDUMP
- A differential backup can be replicated only if its full backup is replicated.

Procedure

1. Enable the NAS node for replication by issuing the UPDATE NODE command:

   ```
   update node node_name replstate=enabled
   ```

   where *node_name* specifies the name of the NAS node.
2. Replicate the node by issuing the REPLICATE NODE command:

   ```
   replicate node node_name
   ```

   where *node_name* specifies the name of the NAS node.
3. To ensure that the replicated data can be restored, define a data mover on the target server for the node by issuing the DEFINE DATAMOVER command:

   ```
   define datamover node_name type=nas hladdress=hl_address lladdress=ll_address
       userid=user_id password=user_password dataformat=netappdump
   ```

   where:

   node_name
   Specifies the name of the NAS node.
   hl_address
   Specifies either the numerical IP address or the domain name that is used to access the NAS file server.
   ll_address
   Specifies the TCP port number to access the NAS device for NDMP sessions.
   user_id
   Specifies the ID of a user who is authorized to initiate an NDMP session with the NAS file server.
   user_password
   Specifies the password of the user who is authorized to initiate an NDMP session with the NAS file server.

Results

The format of the backup data does not change during the replication process. If backup data is replicated, its associated table of contents is also replicated.

Data protection by using the NetApp SnapLock licensed feature

You can use the NetApp SnapLock licensed feature to meet strict regulatory requirements for archived data. When you enable the SnapLock feature, you can use IBM Spectrum Protect™ to set a retention date for files and to commit a file to a Write Once Read Many (WORM) state.

Data that is stored with a retention date cannot be deleted from the file system before the retention period expires. The SnapLock feature can be used by IBM Spectrum Protect servers only if the servers are enabled for data retention protection.

Data that is archived by data retention protection servers and stored to NetApp NAS file servers is stored as IBM Spectrum Protect FILE volumes. At the end of a write transaction, a retention date is set for the FILE volume, through the SnapLock interface. This date is calculated by using the RETVER and RETMIN parameters of the archive copy group that is used when you archive the data. By associating a retention date with the FILE volume, the FILE volume does not destroy or overwrite the data until the retention date passes. These FILE volumes are referred to as WORM FILE volumes. After a retention date is set, the WORM FILE volume cannot be deleted until the retention date passes. IBM Spectrum Protect for Data Retention combined with WORM FILE volume reclamation ensures protection for the life of the data.

Storage pools can be managed either by threshold or by data retention period. The RECLAMATIONTYPE storage pool parameter indicates that a storage pool is managed based on a data retention period. When a traditional storage pool is queried with the FORMAT=DETAILED parameter, this output is displayed:

```
Reclamation Type: THRESHOLD
```

If an IBM Spectrum Protect server is enabled with data retention protection through IBM Spectrum Protect for Data Retention, and the server has access to a NetApp filer with the SnapLock licensed feature, you can define a storage pool with the RECLAMATIONTYPE parameter set to SNAPLOCK. This means that data that is created on volumes in this storage pool is managed by retention date. When a SnapLock storage pool is queried with the FORMAT=DETAILED parameter, the output indicates that the storage pools are managed by data retention period:

```
Reclamation Type: SNAPLOCK
```

For more information about the SnapLock filer, see the NetApp documentation *Data ONTAP Archive and Compliance Management Guide for 7-Mode*.

Attention: Do not use this feature to protect data with a retention period of less than three months.

- Reclamation and the SnapLock feature
  To help ensure that data is always protected, set the NetApp default retention period to 30 days to match the default reclamation period of the WORM FILE volume. IBM Spectrum Protect reclaims any remaining data on a WORM FILE volume just before the retention date expiration.
- Retention periods
  IBM Spectrum Protect policies manage the retention time for the WORM FILE volume. The retention of some files might exceed the retention time for the WORM FILE volume that they are stored on. You might need to move some files to another volume to ensure that the files are stored on WORM media.
- Configuration of the SnapLock feature for event-based retention
  Data that is stored in SnapLock volumes that are managed by IBM Spectrum Protect for Data Retention and event-based retention can result in excessive reclamation, which causes performance degradation of the server.
- Continuous data protection with the SnapLock feature
  If data is stored on a volume with the SnapLock feature enabled, and the data is moved or copied to a non-SnapLock volume, the data loses the unique hardware protection that is provided by NetApp WORM volumes.
- Setting up SnapLock volumes as IBM Spectrum Protect WORM FILE volumes
  To meet strict requirements for archived data, enable the NetApp SnapLock feature.

Reclamation and the SnapLock feature

To help ensure that data is always protected, set the NetApp default retention period to 30 days to match the default reclamation period of the WORM FILE volume. IBM Spectrum Protect™ reclaims any remaining data on a WORM FILE volume just before the retention date expiration.

The reclamation of a WORM FILE volume to another WORM FILE volume before the retention date expiration helps to ensure that data is always protected by the SnapLock feature.

Because this protection is at an IBM Spectrum Protect volume level, the data on the volumes can be managed by IBM Spectrum Protect policy without consideration of where the data is stored. Data that is stored on WORM FILE volumes is protected both by data retention protection and by the retention period that is stored with the physical file on the SnapLock volume. If an IBM Spectrum Protect administrator issues a command to delete the data, the command fails. If someone attempts to delete the file by using a series of network file system calls, the SnapLock feature prevents the data from being deleted.

During reclamation processing, if the IBM Spectrum Protect server cannot move data from an expiring SnapLock volume to a new SnapLock volume, a warning message is issued.

Retention periods

IBM Spectrum Protect™ policies manage the retention time for the WORM FILE volume. The retention of some files might exceed the retention time for the WORM FILE volume that they are stored on. You might need to move some files to another volume to ensure that the files are stored on WORM media.

Some objects on the volume might need to be retained longer than other objects on the volume for the following reasons:

- The objects are bound to management classes with different retention times.
- The objects cannot be removed because of a deletion hold.
- The objects are waiting for an event to occur before expiration.
- The retention period for a copy group is increased, requiring a longer retention time than the time that is specified in the SnapLock feature when the WORM FILE volume was committed.

To manage a WORM FILE volume by retention time, you must issue the DEFINE STGPOOL command and specify RECLAMATIONTYPE=SNAPLOCK. In this way, you define a storage pool as a SnapLock storage pool. After that, you cannot update the RECLAMATIONTYPE parameter to a value of THRESHOLD. When you define a SnapLock storage pool, the system verifies that the specified directories are in the device class are SnapLock WORM volumes. When a file class is defined and storage pools are created with the reclamation type of SNAPLOCK, all volumes must be WORM volumes or the operation fails. If a device class is updated to contain extra directories and SnapLock storage pools are assigned to the device class, the same check is made to ensure that all directories are SnapLock WORM volumes.

Three retention periods are available for the NetApp SnapLock feature. The retention periods must be configured correctly so that the IBM Spectrum Protect server can properly manage WORM data that is stored in SnapLock volumes. The IBM Spectrum Protect server sets the retention period for data that is stored on NetApp SnapLock volumes based on the values in the copy group for the data that is archived. The NetApp file server must not conflict with the ability of the IBM Spectrum Protect server to set the retention period. The preferred method is to configure the following settings for retention periods in the NetApp file server:

- Minimum Retention Period. Set the higher value: either 30 days or the minimum number of days that is specified by any copy group (by using a NetApp SnapLock file server for WORM FILE storage) for the data retention period. The copy group is the one in use that stores data on NetApp SnapLock volumes.
- Maximum Retention Period. Leave the default value of 30 years. This retention period allows the IBM Spectrum Protect server to set the actual volume retention period based on the settings in the archive copy group.
- Default Retention Period. Set to 30 days. If you do not set this value and you do not set the maximum retention period, each volume's retention period is set to 30 years. If this occurs, the IBM Spectrum Protect server cannot manage expiration and reuse of NetApp SnapLock volumes. As a result, no volume can be reused for 30 years.

With the NetApp SnapLock retention periods set, IBM Spectrum Protect can manage the data in SnapLock storage pools with maximum efficiency. For each volume that is in a SNAPLOCK storage pool, an IBM Spectrum Protect reclamation period is created. The IBM Spectrum Protect reclamation period has a start date, BEGIN RECLAIM PERIOD, and an end date, END RECLAIM PERIOD. You can view these dates by issuing the QUERY VOLUME command with the FORMAT=DETAILED parameter on a SnapLock volume. The output is similar to this example:

```
Begin Reclaim Period: 09/05/2017
  End Reclaim Period: 10/06/2017
```

When IBM Spectrum Protect archives files to a SnapLock volume, the server tracks the latest expiration date of those files, and the BEGIN RECLAIM PERIOD value is set to that latest expiration date. When more files are added to the SnapLock volume, the starting date is set to that later date if you have a file with a later expiration date than the one currently on the volume. The start date is set to the latest expiration date for any file on that volume. The expectation is that all files on that volume are already either expired, or are expiring on that day. On the following day, no valid data remains on that volume.

The END RECLAIM PERIOD is set to a month later than the BEGIN RECLAIM PERIOD. The retention date set in the NetApp file server for that volume is set to the END RECLAIM PERIOD date. The NetApp file server prevents deletion of that volume until the END RECLAIM PERIOD date is reached. This date is approximately a month after the data has expired in the IBM Spectrum Protect server. When the IBM Spectrum Protect server calculates an END RECLAIM PERIOD date for a volume, and the date is later than the current END RECLAIM PERIOD, the date is reset in the NetApp file server for that volume to the later date. Resetting the data to a later date guarantees that the IBM Spectrum Protect WORM FILE volume is not deleted until all data on the volume expires, or the data is moved to another SnapLock volume.

The IBM Spectrum Protect reclamation period is the amount of time between the begin date and the end date. During the reclamation period, the IBM Spectrum Protect server deletes volumes on which all the data is expired, or moves files that are not expired on expiring SnapLock volumes to new SnapLock volumes with new dates. This month is critical to how the server safely and efficiently manages the data on WORM FILE volumes. Data on a SnapLock volume typically expires by the time the beginning date arrives, and the volume must be empty. When the end date arrives, the volume can be safely deleted from the IBM Spectrum Protect inventory and the SnapLock file server.

However, some events might cause valid data to be on a SnapLock volume:

- Expiration processing in the IBM Spectrum Protect server for that volume might be delayed or is incomplete.
- The retention parameters on the copy group or associated management classes might be altered for a file after it was archived, and that file is not going to expire for some time.
- A deletion hold might be placed on one or more of the files on the volume.
- Reclamation processing is either disabled or is encountering errors by moving data to new SnapLock volumes on a SnapLock storage pool.
- A file is waiting for an event to occur before the IBM Spectrum Protect server can begin the expiration of the file.

When the beginning date arrives and files are not expired on a SnapLock volume, the files must be moved to a new SnapLock volume with a new begin and end date. However, if expiration processing is delayed on the IBM Spectrum Protect server, and

those files expire when expiration processing on the IBM Spectrum Protect server runs, it is inefficient to move those files to a new SnapLock volume. To ensure that unnecessary data movement does not occur for files that are due to expire, movement of files on expiring SnapLock volumes will be delayed by a number of days after the BEGIN RECLAIM PERIOD date. Since the data is protected in the SnapLock file server until the END RECLAIM PERIOD date, there is no risk to the data in delaying this movement. This allows IBM Spectrum Protect expiration processing to finish. After that number of days, if valid data is on an expiring SnapLock volume, the data is moved to a new SnapLock volume, thus continuing the protection of the data.

Since the data was initially archived, there might be changes in the retention parameters for that data (for example, changes in the management class or copy pool parameters) or there might be a deletion hold on that data. However, the data on that volume is protected by SnapLock only until the END RECLAIM PERIOD date. Data that is not expired is moved to new SnapLock volumes during the IBM Spectrum Protect reclamation period. If errors occur when data is moved to a new SnapLock volume, a warning message is issued indicating that the data will soon be unprotected. If the error persists, issue a MOVE DATA command for the problem volume.

Attention: Do not disable reclamation processing on a SnapLock storage pool. After the processing is disabled, the IBM Spectrum Protect server has no way to issue warning messages that data will become unprotected. This situation can also occur if reclamation and migration are disabled for the entire server (for example, NOMIGRRECL set in the server options file). Ensure that your data is protected when you manage SnapLock storage pools.

Configuration of the SnapLock feature for event-based retention

Data that is stored in SnapLock volumes that are managed by IBM Spectrum Protect™ for Data Retention and event-based retention can result in excessive reclamation, which causes performance degradation of the server.

If data is managed by event-based retention, IBM Spectrum Protect initially sets the retention period to the greater of the RETVER and RETMIN values for the archive copy group. When the volume enters the reclamation period and data that remains on the volume is moved, the retention period for the target volume is set to the remaining retention period of the data, which is typically 0. The new volume then enters the reclamation period shortly after the volume receives the data, resulting in the reclamation of volumes that were just created.

You can avoid this situation by using the RETENTIONEXTENSION server option. This option allows the server to set or extend the retention date of a SnapLock volume. You can specify a value in the range 30 - 9999 days. The default is 365 days.

When you select volumes in a SnapLock storage pool for reclamation, the server verifies whether the volume is within the reclamation period:

- If the volume is not within the reclamation period, no action is taken. The volume is not reclaimed, and the retention date is unchanged.
- If the volume is within the reclamation period, the server verifies whether the percentage of reclaimable space on the volume is greater than the reclamation threshold of the storage pool or of the threshold percentage that is passed in on the THRESHOLD parameter of a RECLAIM STGPOOL command:
    - If the reclaimable space is greater than the threshold, the server reclaims the volume and sets the retention date of the target volume is set to the greater of these values:
        - The remaining retention time of the data plus 30 days for the reclamation period.
        - The RETENTIONEXTENSION value plus 30 days for the reclamation period.
    - If the reclaimable space is not greater than the threshold, the server resets the retention date of the volume by the amount that is specified in the RETENTIONEXTENSION option. The new retention period is calculated by adding the number of days that are specified to the current date.

In the following examples, the SnapLock volume, VolumeA, is in a storage pool whose reclamation threshold is set to 60%. The RETENTIONEXTENSION server option is set to 365 days. The retention period for VolumeA is in the reclamation period. The following situations show how retention is affected:

- The reclaimable space on VolumeA is less than 60%. The retention date of VolumeA is extended by 365 days.
- The reclaimable space on VolumeA is greater than 60%, and the remaining retention time of the data is more than 365 days. VolumeA is reclaimed, and the retention date of the target volume is set based on the remaining retention period of the data plus 30 days for the reclamation period.
- The reclaimable space on VolumeA is greater than 60%, and the retention time of the data is less than 365 days. VolumeA is reclaimed, and its retention date is set to 365 days, the RETENTIONEXTENTION value, plus 30 days for the reclamation period.

Continuous data protection with the SnapLock feature

If data is stored on a volume with the SnapLock feature enabled, and the data is moved or copied to a non-SnapLock volume, the data loses the unique hardware protection that is provided by NetApp WORM volumes.

The IBM Spectrum Protect™ server allows this type of movement. However, if data is moved from a WORM FILE volume to another type of media, the data might no longer be protected from inadvertent or malicious deletion. If this data is on WORM volumes to meet data retention and protection requirements for legal purposes and is moved to other media, the data might no longer meet those requirements. You must configure your storage pools so that this type of data is kept in storage pools that consist of SnapLock WORM volumes during the entire data retention period.

Setting up SnapLock volumes as IBM Spectrum Protect WORM FILE volumes

To meet strict requirements for archived data, enable the NetApp SnapLock feature.

About this task

When you define or update configurations that involve SnapLock storage pools, ensure that the RECLAMATIONTYPE=SNAPLOCK option is specified for the storage pools that are selected for the NEXTSTGPOOL, RECLAIMSTGPOOL, and COPYSTGPOOLS parameters.

When you configure the storage pools in this way, you help to ensure that your data is properly protected. If you define a next, reclaim, copy storage pool, or active-data pool without selecting the RECLAMATIONTYPE=SNAPLOCK option, the storage pool is not protected. The command succeeds, but a warning message is issued.

Procedure

To set up a SnapLock volume for use as an IBM Spectrum Protect™ WORM FILE volume, complete the following steps:

1. Install and set up SnapLock on the NetApp file server. Ensure that you configure the minimum, maximum, and default retention periods. For instructions, see the NetApp documentation.
2. Install and configure an IBM Spectrum Protect server.
3. Enable archive data retention protection by issuing the SET ARCHIVERETENTIONPROTECTION command:

   ```
   set archiveretentionprotection on
   ```

4. Set up policy by using the DEFINE COPYGROUP command. Select RETVER and RETMIN values in the archive copy group that meet your requirements for protecting this data in WORM storage. If the RETVER or RETMIN values are not specified, the default management classes values are used.
5. Set up storage by using the DEFINE DEVCLASS command.
   - Use the FILE device class.
   - Specify the DIRECTORY parameter to point to the directory or directories on the SnapLock volumes.
6. Define a storage pool by using the device class that is defined in step 5 by issuing the DEFINE STGPOOL command and specifying the RECLAMATIONTYPE=SNAPLOCK parameter.
7. Update the copy group to point to the storage pool by issuing the UPDATE COPYGROUP command.
8. Use the IBM Spectrum Protect API to archive your objects into the SnapLock storage pool. This feature is not available on standard IBM Spectrum Protect backup-archive clients.

Repairing and recovering data in directory-container storage pools

You can repair damaged data extents in directory-container storage pools and recover lost data after a disaster.

Data extents are part of a file that is created during the data-deduplication process. Extents are compared with other file extents to identify duplicates. If you have damaged files or directories in your directory-container storage pool, you can repair deduplicated data extents from either the target replication server, the source replication server, or from container-copy storage pool tape volumes.

- Repairing storage pools from a target replication server
  If files, directories, or storage pools on a source replication server are damaged, you can repair deduplicated data extents in a directory-container storage pool on the source replication server from a target replication server.
- Repairing storage pools from container-copy storage pool volumes
  If files, directories, or storage pools on a source server are damaged, you can repair data extents in a directory-container

storage pool on the source server by retrieving the deduplicated data extents from onsite or offsite container-copy storage pool tape volumes.

- Repairing storage pools in an environment with both a replication server and container-copy storage pool volumes
  If files, directories, or storage pools on a source server are damaged, you can repair data extents in a directory-container storage pool on the source replication server by retrieving the deduplicated data extents from either the target replication server or from container-copy storage pool tape volumes.
- Repairing storage pools on a target replication server
  If files, directories, or storage pools on a target replication server are damaged, you can repair data extents in a directory-container storage pool on the target replication server by retrieving the deduplicated data extents from the source replication server.
- Repairing storage pools after a disaster
  You can repair directory-container storage pools and recover their lost data after a disaster.
- Replacing a damaged container-copy storage pool tape volume
  If a tape volume that is storing a copy of deduplicated data extents in a container-copy storage pool becomes damaged, you can replace the volume.

Recovering from data loss or system outages

Repairing storage pools from a target replication server

If files, directories, or storage pools on a source replication server are damaged, you can repair deduplicated data extents in a directory-container storage pool on the source replication server from a target replication server.

Before you begin

Evaluate your storage environment to determine whether outages, network issues, or hardware failures are causing damage to data or causing the data to appear damaged. If issues in your environment are causing damage to data, identify and resolve the issues.

Ensure that there is enough available space in the directory-container storage pool for the recovered data. The PREVIEW=YES parameter in the REPAIR STGPOOL command specifies how much data will be repaired. If there is not enough space, use the DEFINE STGPOOLDIRECTORY command to provision space.

About this task

Use the procedure to repair the following types of damage:

- Minor damage that is caused by accidental deletion of files or directories, overwritten files, accidental changes in file permissions, or disk errors caused by hardware issues.
- Moderate damage that is caused by disk errors or disk mount errors. This type of damage results in the loss of one or more directories, but not a loss of the entire storage pool.

Damaged deduplicated extents are repaired with extents that were protected to the target replication server.
Restriction: You can issue the REPAIR STGPOOL command for a specified storage pool only if you already copied the data to another storage pool on a target replication server by using the PROTECT STGPOOL command.
When you repair a directory-container storage pool from a replication server, the REPAIR STGPOOL command fails if any of the following conditions occur:

- The target replication server is unavailable.
- The target storage pool is damaged.
- A network outage occurs.

Procedure

1. If you suspect minor damage, issue the AUDIT CONTAINER command for the container storage pool at the directory level to identify inconsistencies between the database and the directory-container storage pool. By identifying the damaged data extents in the directory-container storage pool, you can determine which data extents to repair. To conserve time and

resources, audit only containers that you suspect are damaged. If you suspect that your directory-container storage pool has more serious damage, issue the AUDIT CONTAINER command at the storage pool level.
For example, to audit a directory, n:\pooldir, in a storage pool that is named STGPOOL1, issue the following command:

```
audit container stgpool=stgpool1 stgpooldirectory=n:\pooldir
```

To audit a storage pool that is named STGPOOL1, issue the following command:

```
audit container stgpool=stgpool1
```

The audit process might run for several hours.

2. To repair a directory-container storage pool, issue the REPAIR STGPOOL command and specify the SRCLOCATION=REPLSERVER parameter. For example, to repair a storage pool that is named STGPOOL1 from a replication server, issue the following command:

   ```
   repair stgpool stgpool1 srclocation=replserver
   ```

   When you issue the REPAIR STGPOOL command, the damaged extents are deleted from the volume immediately after they are repaired. The damaged extents are not retained according to the value specified by the REUSEDELAY parameter.

3. Identify any additional damaged extents by issuing the QUERY DAMAGED command.
4. If damage is detected and deduplicated extents cannot be repaired from the replication server, it is still possible that they will be repaired. In some cases, the client node resends data during a backup operation and the damaged extents are repaired. Wait two backup cycles to allow client backup operations to occur. After two backup cycles, complete the following steps:
   a. To confirm that the damage is repaired, reissue the QUERY DAMAGED command.
   b. If an entire storage pool directory is damaged, create a new replacement storage pool directory using the DEFINE STGPOOLDIRECTORY command.
   c. To remove objects that refer to damaged data, issue the AUDIT CONTAINER command and specify the ACTION=REMOVEDAMAGED parameter.
      For example, to audit a directory-container storage pool that is named STGPOOL1 and remove damaged objects, issue the following command:

      ```
      audit container stgpool=stgpool1 action=removedamaged
      ```

   d. Optionally, issue the DELETE STGPOOLDIRECTORY command to delete the empty storage pool directory that you replaced with a new directory in step 4.b.

What to do next

If you continue to detect damaged data over time, issue the AUDIT CONTAINER command for the directory-container storage pool to determine whether there is more widespread damage. For example, to audit a storage pool that is named STGPOOL1, issue the following command:

```
audit container stgpool=stgpool1
```

Repairing storage pools from container-copy storage pool volumes

If files, directories, or storage pools on a source server are damaged, you can repair data extents in a directory-container storage pool on the source server by retrieving the deduplicated data extents from onsite or offsite container-copy storage pool tape volumes.

Before you begin

Evaluate your storage environment to determine whether outages, network issues, or hardware failures are causing damage to data or causing the data to appear damaged. If issues in your environment are causing damage to data, identify and resolve the issues.

About this task

Use the procedure to repair the following types of damage:

- Minor damage that is caused by accidental deletion of files or directories, overwritten files, accidental changes in file permissions, or disk errors caused by hardware issues.
- Moderate damage that is caused by disk errors or disk mount errors. This type of damage results in the loss of one or more directories, but not a loss of the entire storage pool.

Damaged deduplicated extents are repaired with extents that were protected to container-copy storage pools.
Restriction: You can issue the REPAIR STGPOOL command for a specified storage pool only if you already copied the data to container-copy storage pools by using the PROTECT STGPOOL command.
When you repair a directory-container storage pool from container-copy pools, the REPAIR STGPOOL command fails if any of the following conditions occur:

- The container-copy storage pool is unavailable.
- The container-copy storage pool is damaged.
- The container-copy storage pool volumes are unavailable or damaged.

Procedure

1. If you suspect minor damage, issue the AUDIT CONTAINER command for the container storage pool at the directory level to identify inconsistencies between the database and the directory-container storage pool. By identifying the damaged data extents in the directory-container storage pool, you can determine which data extents to repair. To conserve time and resources, audit only containers that you suspect are damaged. If you suspect that your container storage pool has more serious damage, issue the AUDIT CONTAINER command at the storage pool level. For example, to audit a directory, n:\pooldir, in a storage pool that is named STGPOOL1, issue the following command:

   ```
   audit container stgpool=stgpool1 stgpooldirectory=n:\pooldir
   ```

   To audit a storage pool that is named STGPOOL1, issue the following command:

   ```
   audit container stgpool=stgpool1
   ```

   The audit process might run for several hours.

   During the repair operation, the server prompts you for the volumes that it requires. In step 3, you will bring the volumes onsite and check them into the library. The required volumes must be brought onsite and checked into the library.

2. To preview the repair operation and generate the list of tape volumes that are needed for the repair operation, issue the REPAIR STGPOOL command and specify the SRCLOCATION=LOCAL and PREVIEW=YES parameters.
   For example, to preview the repair operation for a storage pool that is named STGPOOL1 from container-copy storage pools, issue the following command:

   ```
   repair stgpool stgpool1 srclocation=local preview=yes
   ```

   The preview process might take some time to finish.

3. If some of the required volumes are offsite, complete the following steps:
   a. Use the list from the preview operation to determine which volumes need to be brought onsite.
   b. When the volumes are back onsite, check them into the library by issuing the CHECKIN LIBVOLUME command and specifying the STATUS=PRIVATE parameter.
   c. Update the status of the volumes by issuing the UPDATE STGPOOL command and specifying the ACCESS=READWRITE parameter.

   For detailed instructions about the disaster recovery manager (DRM) function, see Using disaster recovery manager for tape environments (V7.1.1).
4. Based on the information that you obtained during the preview operation, ensure that the storage pool contains enough space for the recovered data. If there is not enough space, use the DEFINE STGPOOLDIRECTORY command to provision space.
5. To repair the directory-container storage pool, issue the REPAIR STGPOOL command and specify the SRCLOCATION=LOCAL parameter.

For example, to repair a storage pool that is named STGPOOL1 from a container-copy storage pool, issue the following command:

```
repair stgpool stgpool1 srclocation=local
```

When you issue the REPAIR STGPOOL command, the damaged extents are deleted from the volume immediately after they are repaired. The damaged extents are not retained according to the value specified by the REUSEDELAY parameter.

6. Identify any additional damaged extents by issuing the QUERY DAMAGED command.
7. If damage is detected and deduplicated extents cannot be repaired from the container-copy storage pools, it is still possible that they will be repaired. In some cases, the client node resends data during a backup operation and the damaged extents are repaired. Wait two backup cycles to allow client backup operations to occur. After two backup cycles, complete the following steps:
   a. To confirm that the damage is repaired, reissue the QUERY DAMAGED command.
   b. If an entire storage pool directory is damaged, create a new replacement storage pool directory using the DEFINE STGPOOLDIRECTORY command.
   c. To remove objects that refer to damaged data, issue the AUDIT CONTAINER command and specify the ACTION=REMOVEDAMAGED parameter.
   For example, to audit a directory-container storage pool that is named STGPOOL1 and remove damaged objects, issue the following command:

   ```
   audit container stgpool=stgpool1 action=removedamaged
   ```

   d. Optionally, issue the DELETE STGPOOLDIRECTORY command to delete the empty storage pool directory that you replaced with a new directory in step 7.b.
8. If you repaired an entire storage pool directory, delete the original directory, which is empty and was replaced by a new directory. Delete the original directory by issuing the DELETE STGPOOLDIRECTORY command.

What to do next

If you continue to detect damaged data over time, issue the AUDIT CONTAINER command for the directory-container storage pool to determine whether there is more widespread damage. For example, to audit a storage pool that is named STGPOOL1, issue the following command:

```
audit container stgpool=stgpool1
```

Repairing storage pools in an environment with both a replication server and container-copy storage pool volumes

If files, directories, or storage pools on a source server are damaged, you can repair data extents in a directory-container storage pool on the source replication server by retrieving the deduplicated data extents from either the target replication server or from container-copy storage pool tape volumes.

Before you begin

Evaluate your storage environment to determine whether outages, network issues, or hardware failures are causing damage to data or causing the data to appear damaged. If issues in your environment are causing damage to data, identify and resolve the issues.

Ensure that there is enough available space in the directory-container storage pool for the recovered data. The PREVIEW=YES parameter in the REPAIR STGPOOL command specifies how much data will be repaired. If there is not enough space, use the DEFINE STGPOOLDIRECTORY command to provision space.

About this task

Use the procedure to repair the following types of damage:

- Minor damage that is caused by accidental deletion of files or directories, overwritten files, accidental changes in file permissions, or disk errors caused by hardware issues.
- Moderate damage that is caused by disk errors or disk mount errors. This type of damage results in the loss of one or more directories, but not a loss of the entire storage pool.

Damaged deduplicated extents are repaired with extents that were protected to the target replication server or to container-copy storage pools on a source server.
Restriction: You can issue the REPAIR STGPOOL command for a specified storage pool only if you already copied the data to another storage pool on a target replication server or to container-copy storage pools by using the PROTECT STGPOOL command.
When you repair a directory-container storage pool from a target replication server, the REPAIR STGPOOL command fails if any of the following conditions occur:

- The target replication server is unavailable.
- The target storage pool is damaged.
- A network outage occurs.

When you repair a directory-container storage pool from container-copy pools, the REPAIR STGPOOL command fails if any of the following conditions occur:

- The container-copy storage pool is unavailable.
- The container-copy storage pool is damaged.
- The container-copy storage pool volumes are unavailable or damaged.

Procedure

1. Attempt to repair the storage pool from the target replication server by completing the steps in Repairing storage pools from a target replication server.
2. If the damaged extents cannot be repaired from the target replication server, repair the damaged extents from container-copy storage pools by completing the steps in Repairing storage pools from container-copy storage pool volumes.
3. If you repaired damaged extents from container-copy storage pools, issue the PROTECT STGPOOL command and specify the TYPE=REPLSERVER parameter for the storage pools on the source replication server.

What to do next

If you continue to detect damaged data over time, issue the AUDIT CONTAINER command for the directory-container storage pool to determine whether there is more widespread damage. For example, to audit a storage pool that is named STGPOOL1, issue the following command:

```
audit container stgpool=stgpool1
```

Related reference:
AUDIT CONTAINER (Verify the consistency of database information for a directory-container)

DEFINE STGPOOLDIRECTORY (Define a storage pool directory)
DELETE STGPOOLDIRECTORY (Deleting a storage pool directory)

Repairing storage pools on a target replication server

If files, directories, or storage pools on a target replication server are damaged, you can repair data extents in a directory-container storage pool on the target replication server by retrieving the deduplicated data extents from the source replication server.

Before you begin

Evaluate your storage environment to determine whether outages, network issues, or hardware failures are causing damage to data or causing the data to appear damaged. If issues in your environment are causing damage to data, identify and resolve the issues.

About this task

Use the procedure to repair the following types of damage:

- Minor damage that is caused by accidental deletion of files or directories, overwritten files, accidental changes in file permissions, or disk errors caused by hardware issues.
- Moderate damage that is caused by disk errors or disk mount errors. This type of damage results in the loss of one or more directories, but not a loss of the entire storage pool.

As part of the operation of the PROTECT STGPOOL command, damaged extents in the target storage pool are repaired. To be repaired, extents must already be marked as damaged on the target server. For example, an AUDIT CONTAINER command might identify damage in the target storage pool before the PROTECT STGPOOL command is issued.

Procedure

1. Protect data extents in a directory-container storage pool on a source server by issuing the PROTECT STGPOOL command. For example, to protect a directory-container storage pool that is named POOL1, issue the following command:

   ```
   protect stgpool pool1
   ```

   Wait for the protection process to finish.

2. To identify the damaged data extents in the directory-container storage pool on the target server, issue the AUDIT CONTAINER command.
   For example, to audit a storage pool that is named STGPOOL1, issue the following command:

   ```
   audit container stgpool=stgpool1
   ```

3. Repair damaged extents in the target storage pool by reissuing the PROTECT STGPOOL command on the source server. The damaged extents in the target storage pool are marked as damaged and are repaired.
4. Confirm that there are no additional damaged extents by issuing the QUERY DAMAGED command.

Repairing storage pools from container-copy storage pool volumes after a disaster

If a disaster occurs on a source server, you can repair deduplicated data extents in a directory-container storage pool from offsite container-copy storage pool tape volumes. The directory-container storage pool is repaired on a target server at a recovery site.

About this task

Use the procedure to repair the following types of major damage:

- Complete loss of all container storage pools on the source server
- Complete loss of the primary site

The following assumptions are made for this disaster recovery scenario:

- You were using the PROTECT STGPOOL command to back up data to offsite container-copy storage pools from a source server. You retrieved the offsite tape volumes and have them at your recovery site.
- You were not using the PROTECT STGPOOL command to back up data to a target replication server.
- You used the IBM Spectrum Protect™ Blueprints to configure the IBM Spectrum Protect source server, and you also used the Blueprint configuration scripts to restore the environment by setting up a new target server at a recovery site. The scripts copied backup versions of the IBM Spectrum Protect database, the server options file (dsmserv.opt), the volume history file (volhist.out), and device configuration file (devconfig.out) to their original locations on the recovery server. After the scripts run, you see the newly created, empty directories on the recovery server.

When you attempt to repair a directory-container storage pool from container-copy pools, the REPAIR STGPOOL command fails if any of the following conditions occur:

- The container-copy storage pool is unavailable.
- The container-copy storage pool is damaged.
- The container-copy storage pool volumes are unavailable or damaged.

Procedure

1. Mark all data extents in the container storage pool as damaged by issuing the AUDIT CONTAINER command for the container storage pool at the storage pool level, and specifying the ACTION=MARKDAMAGED parameter.
   For example, to audit a storage pool that is named STGPOOL1 and mark it as damaged, issue the following command:

   ```
   audit container stgpool=stgpool1 action=markdamaged
   ```

2. If you protected the directory-container storage pool by using both onsite and offsite container-copy storage pools, issue the UPDATE STGPOOL command for the onsite copy of the container-copy storage pools, and specify the ACCESS=UNAVAILABLE parameter.
3. When the offsite container-copy storage pool volumes are back onsite, check them into the library by issuing the CHECKIN LIBVOLUME command and specifying the STATUS=PRIVATE parameter.
4. Update the status of the volumes by issuing the UPDATE STGPOOL command and specifying the ACCESS=READWRITE parameter.
5. Repair the storage pool by issuing the REPAIR STGPOOL command and specifying the SRCLOCATION=LOCAL parameter.
   For example, to repair a storage pool that is named STGPOOL1 from offsite container-copy storage pools, issue the following command:

   ```
   repair stgpool stgpool1 srclocation=local
   ```

   When you issue the REPAIR STGPOOL command, the damaged extents are deleted from the volume immediately after they are repaired. The damaged extents are not retained according to the value specified by the REUSEDELAY parameter.

6. Confirm that there are no additional damaged extents by issuing the QUERY DAMAGED command.
7. Repeat this procedure to repair all of your storage pools.

Repairing storage pools from a target replication server after a disaster

If a disaster occurs on a source replication server, you can repair deduplicated data extents in a directory-container storage pool from a target replication server. The directory-container storage pool is repaired on a target server at a recovery site.

About this task

Use the procedure to repair the following types of major damage:

- Complete loss of all container storage pools on the source replication server
- Complete loss of the primary site

The following assumptions are made for this disaster recovery scenario:

- You were using the PROTECT STGPOOL command to back up data from a source replication server to a target replication server. The target replication server is running at your recovery site.
- You were not using the PROTECT STGPOOL command to back up data to offsite container-copy storage pools.
- You used the IBM Spectrum Protect™ Blueprints to configure the IBM Spectrum Protect source server, and you also used the Blueprint configuration scripts to restore the environment by setting up a new target server at a recovery site. The scripts copied backup versions of the IBM Spectrum Protect database, the server options file (dsmserv.opt), the volume history file (volhist.out), and device configuration file (devconfig.out) to their original locations on the recovery server. After the scripts run, you see the newly created, empty directories on the recovery server.

When you attempt to repair a directory-container storage pool from a target replication server, the REPAIR STGPOOL command fails if any of the following conditions occur:

- The target replication server is unavailable.
- The target storage pool is damaged.
- A network outage occurs.

Procedure

1. Mark all data extents in the container storage pool as damaged by issuing the AUDIT CONTAINER command for the container storage pool at the storage pool level, and specifying the ACTION=MARKDAMAGED parameter.
   For example, to audit a storage pool that is named STGPOOL1 and mark it as damaged, issue the following command:

   ```
   audit container stgpool=stgpool1 action=markdamaged
   ```

2. Repair the storage pool by issuing the REPAIR STGPOOL command and specifying the SRCLOCATION=REPLSERVER parameter.
   For example, to repair a storage pool that is named STGPOOL1 from a target replication server, issue the following command:

   ```
   repair stgpool stgpool1 srclocation=replserver
   ```

   When you issue the REPAIR STGPOOL command, the damaged extents are deleted from the volume immediately after they are repaired. The damaged extents are not retained according to the value specified by the REUSEDELAY parameter.

3. If you did not use Blueprint configuration scripts to set up your target replication server, the file structure on the target replication server might not match the information that is stored in the database. Optionally, remove the storage pool directories that do not exist on the target replication server by issuing the DELETE STGPOOLDIRECTORY command.
4. Confirm that there are no additional damaged extents by issuing the QUERY DAMAGED command.
5. If damage is detected and deduplicated extents cannot be repaired from the replication server, it is still possible that they will be repaired. In some cases, the client node resends data during a backup operation and the damaged extents are repaired. Wait two backup cycles to allow client backup operations to occur. After two backup cycles, complete the following steps:
   a. To confirm that the damage is repaired, reissue the QUERY DAMAGED command.
   b. To remove objects that refer to damaged data, issue the AUDIT CONTAINER command and specify the ACTION=REMOVEDAMAGED parameter.
      For example, to audit a directory-container storage pool that is named STGPOOL1 and remove damaged objects, issue the following command:

      ```
      audit container stgpool=stgpool1 action=removedamaged
      ```

6. Repeat this procedure to repair all of your storage pools.

Repairing storage pools in an environment with both a replication server and container-copy storage pool volumes after a disaster

If a disaster occurs on a source server, you can repair deduplicated data extents in a directory-container storage pool from a replication target server or from offsite container-copy storage pool tape volumes. The directory-container storage pool is repaired on a target server at a recovery site.

About this task

Use the procedure to repair the following types of major damage:

- Complete loss of all container storage pools on the source server
- Complete loss of the primary site

The following assumptions are made for this disaster recovery scenario:

- You were using the PROTECT STGPOOL command to back up data from a source replication server to a target replication server. The target replication server is running at your recovery site.
- You were using the PROTECT STGPOOL command to back up data to offsite container-copy storage pools.
- You used the IBM Spectrum Protect™ Blueprints to configure the IBM Spectrum Protect source server, and you also used the Blueprint configuration scripts to restore the environment by setting up a new target server at a recovery site. The scripts copied backup versions of the IBM Spectrum Protect database, the server options file (dsmserv.opt), the volume history file (volhist.out), and device configuration file (devconfig.out) to their original locations on the recovery server. After the scripts run, you see the newly created, empty directories on the recovery server.

When you attempt to repair a directory-container storage pool from a target replication server, the REPAIR STGPOOL command fails if any of the following conditions occur:

- The target replication server is unavailable.
- The target storage pool is damaged.
- A network outage occurs.

When you repair a directory-container storage pool from container-copy pools, the REPAIR STGPOOL command fails if any of the following conditions occur:

- The container-copy storage pool is unavailable.
- The container-copy storage pool is damaged.
- The container-copy storage pool volumes are unavailable or damaged.

Procedure

1. Mark all data extents in the container storage pool as damaged by issuing the AUDIT CONTAINER command for the container storage pool at the storage pool level, and specifying the ACTION=MARKDAMAGED parameter.
   For example, to audit a storage pool that is named STGPOOL1 and mark it as damaged, issue the following command:

   ```
   audit container stgpool=stgpool1 action=markdamaged
   ```

2. If you protected the directory-container storage pool by using both onsite and offsite container-copy storage pools, issue the UPDATE STGPOOL command for the onsite copy of the container-copy storage pools, and specify the ACCESS=UNAVAILABLE parameter.
3. When the offsite container-copy storage pool volumes are back onsite, check them into the library by issuing the CHECKIN LIBVOLUME command and specifying the STATUS=PRIVATE parameter. By moving the tape volumes onsite now, you are prepared to repair damaged extents from the container-copy tape volumes if the damaged extents cannot be repaired from the target replication server.
4. Update the status of the volumes by issuing the UPDATE STGPOOL command and specifying the ACCESS=READWRITE parameter.
5. Repair the storage pool by issuing the REPAIR STGPOOL command and specifying the SRCLOCATION=REPLSERVER parameter.
   For example, to repair a storage pool that is named STGPOOL1 from a target replication server, issue the following command:

```
repair stgpool stgpool1 srclocation=replserver
```

When you issue the REPAIR STGPOOL command, the damaged extents are deleted from the volume immediately after they are repaired. The damaged extents are not retained according to the value specified by the REUSEDELAY parameter.

6. If you did not use Blueprint configuration scripts to set up your target replication server, the file structure on the target replication server might not match the information that is stored in the database. Optionally, remove the storage pool directories that do not exist on the target replication server. Issue the DELETE STGPOOLDIRECTORY command to delete directories that are not on the target replication server.
7. Confirm that there are no additional damaged extents by issuing the QUERY DAMAGED command.
8. If the damaged extents cannot be repaired from the target replication server, you can repair the damaged extents from offsite container-copy storage pools. For instructions, see Repairing storage pools from container-copy storage pool volumes after a disaster.
9. Confirm that there are no additional damaged extents by reissuing the QUERY DAMAGED command.
10. If damage is detected and deduplicated extents cannot be repaired from the replication server, it is still possible that they will be repaired. In some cases, the client node resends data during a backup operation and the damaged extents are repaired. Wait two backup cycles to allow client backups to occur. After two backup cycles, complete the following steps:
    a. To confirm that the damage is repaired, reissue the QUERY DAMAGED command.
    b. To remove objects that refer to damaged data, issue the AUDIT CONTAINER command and specify the ACTION=REMOVEDAMAGED parameter.
    For example, to audit a directory-container storage pool that is named STGPOOL1 and remove damaged objects, issue the following command:

    ```
    audit container stgpool=stgpool1 action=removedamaged
    ```

11. Repeat this procedure to repair all of your storage pools.

Replacing a damaged container-copy storage pool tape volume

If a tape volume that is storing a copy of deduplicated data extents in a container-copy storage pool becomes damaged, you can replace the volume.

Procedure

1. Delete the damaged tape volume by issuing the DELETE VOLUME command and specifying the DISCARDDATA=YES parameter.
   For example, to delete a volume that is named VOLUME1, issue the following command:

   ```
   delete volume volume1 discarddata=yes
   ```

2. Protect data extents in the directory-container storage pool by copying the data to existing volumes in the container-copy storage pool. Issue the PROTECT STGPOOL command from the source server.
   For example, to protect a directory-container storage pool that is named POOL1, issue the following command:

   ```
   protect stgpool pool1 type=local
   ```

PROTECT STGPOOL (Protect storage pool data)
DELETE VOLUME (Delete a storage pool volume)

Server commands, options, and utilities

Use commands to administer and configure the server, options to customize the server, and utilities to perform special tasks when the server is not running.

- Managing the server from the command line
  IBM Spectrum Protect™ provides several different command-line interfaces for managing IBM Spectrum Protect servers.
- Administrative commands
  Administrative commands are available to manage and configure the server.
- Server options
  At installation, IBM Spectrum Protect provides a server options file that contains a set of default options to start the server.
- Server utilities
  Use server utilities to perform special tasks on the server while the server is not running.

- Return codes for use in IBM Spectrum Protect scripts
  You can write IBM Spectrum Protect scripts that use return codes to determine how script processing proceeds. The return codes can be one of three severities: OK, WARNING, ERROR.
- Device utilities
  You can use device utilities for tasks that are related to configuring storage devices for the IBM Spectrum Protect server.
- Server scripts and macros for automation
  You can automate common administrative tasks by creating IBM Spectrum Protect server scripts or administrative client macros. Server scripts are stored in the server database and can be scheduled to run with an administrative schedule command. Administrative client macros are stored as files on the administrative client.

Managing the server from the command line

IBM Spectrum Protect™ provides several different command-line interfaces for managing IBM Spectrum Protect servers.

About this task

The following command-line interfaces are available:

Administrative command-line client
: The administrative command-line client is a program that runs on a file server, workstation, or mainframe. It is installed as part of the IBM Spectrum Protect server installation process. The administrative client can be accessed remotely.

  From the administrative client, you can issue any server commands.

Server console
: The server console is a command-line window on the system where the server is installed. Therefore, to use the server console, you must be at the physical location of the server system.

  Compared to the administrative client, the capabilities of the server console are limited. From the server console, you cannot issue certain commands, and you cannot route commands to other servers. Also, you cannot specify that certain commands process before other commands can be issued. However, this limitation can be useful if, for example, you want to run two commands in quick succession.

Operations Center command line
: From the Operations Center, you can access the IBM Spectrum Protect command line. You might want to use this command line to issue server commands to complete certain IBM Spectrum Protect tasks that are not supported in the Operations Center.

Server scripts provide for automation of common administrative tasks. A macro is a file that contains one or more IBM Spectrum Protect administrative commands. When you issue the MACRO command, the server processes all commands in the macro file in order, including commands that are contained in any nested macros.

- Issuing commands from the administrative client
  The administrative command-line client is a program that runs on a file server, workstation, or mainframe.
- Issuing commands from the Operations Center
  From the Operations Center command-line interface, you can issue commands to manage IBM Spectrum Protect servers that are configured as hub or spoke servers.
- Issuing commands from the server console
  IBM Spectrum Protect provides a user ID named SERVER_CONSOLE that allows you to issue commands and administer the server from the server console after IBM Spectrum Protect is installed. At installation, SERVER_CONSOLE is automatically registered as an administrator and is given system authority.
- Entering administrative commands
  Commands consist of command names and usually parameters and variables. Syntax diagrams depict the rules to follow when entering commands.
- Controlling command processing
  You can run some IBM Spectrum Protect commands sequentially or concurrently with other commands. You can also route commands from one server to other servers for processing.
- Performing tasks concurrently on multiple servers
  Command routing allows you to route commands to one or more servers for processing and then collect the output from these servers.
- Privilege classes for commands
  The authority granted to an administrator through the privilege class determines which administrative commands that the administrator can issue.

Related concepts:
Server scripts
Related reference:
Administrative client macros

Issuing commands from the administrative client

The administrative command-line client is a program that runs on a file server, workstation, or mainframe.

About this task

Ensure that your administrative client and your server are running in compatible languages. See LANGUAGE for language and locale options. If your client and server are using different languages, the messages that IBM Spectrum Protect™ generates might not be understandable.

Tip: Text strings that are sent from the client to the server do not depend on the server language setting. The text is displayed properly if the administrative client runs in the same locale when sending the string and when receiving the string.

For example, assume that you update a node contact field with a value that contains national characters (`update node myNode contact=NLcontact_info`), and later query the node (`query node myNode format=detailed`). If the client is running in the same locale when you update as when you query, the *NLcontact_info* displays properly. If you update the node contact field when the client is running in one locale, and query the node when the client is running in a different locale, the *NLcontact_info* might not display properly.

- Starting and stopping the administrative client
  Use the DSMADMC command to start an administrative client session.
- Monitoring server activities from the administrative client
  To monitor IBM Spectrum Protect activities, such as server migration and client logons, run the administrative client in console mode. You cannot enter any administrative commands in console mode.
- Monitoring removable-media mounts from the administrative client
  To monitor the mounting and dismounting of removable media, run the administrative client in mount mode. When the client is running in mount mode, you cannot enter any administrative commands.
- Processing individual commands from the administrative client
  Use batch mode to enter a single administrative command. Your administrative client session automatically ends when the command is processed.
- Processing a series of commands from the administrative client
  Use the interactive mode to process a series of administrative commands.
- Formatting output from commands
  IBM Spectrum Protect formats the output processed from commands according to your screen or window width.
- Saving command output to a specified location
  The most common use for redirecting output is to save the output from query commands to a specified file or program. You can then browse the contents of the file or in some cases, print the contents.
- Administrative client options
  In all administrative client modes, you can use options to modify administrative client session responses.

Starting and stopping the administrative client

Use the DSMADMC command to start an administrative client session.

About this task

The IBM Spectrum Protect™ server must be running before an administrative client can connect.

Procedure

- To start an administrative client session in command-line mode, enter this command on your workstation:

  ```
  dsmadmc -id=admin -password=admin -dataonly=yes
  ```

  By entering the DSMADMC command with the -ID and -PASSWORD options as shown, you are not prompted for a user ID and password.

- To stop an administrative command-line client session, enter the following command:

  ```
  quit
  ```

- To interrupt a DSMADMC command before the IBM Spectrum Protect server finishes processing it, use the UNIX `kill -9` command from an available command line. Do not press `Ctrl+C` because, while it ends the session, it can lead to unexpected results.

Monitoring server activities from the administrative client

To monitor IBM Spectrum Protect™ activities, such as server migration and client logons, run the administrative client in console mode. You cannot enter any administrative commands in console mode.

Procedure

- To start an administrative client session in console mode, enter the following command:

  ```
  dsmadmc -consolemode
  ```

  You are prompted for a password if authentication is turned on for the server. If you do not want to be prompted for your user ID and password, enter the DSMADMC command with the -ID and -PASSWORD options.

- To end an administrative client session in console mode, use a keyboard break sequence.

Operating system	Break sequence
UNIX and Linux clients	Ctrl+C
Windows clients	Ctrl+C or Ctrl+Break

Monitoring removable-media mounts from the administrative client

To monitor the mounting and dismounting of removable media, run the administrative client in mount mode. When the client is running in mount mode, you cannot enter any administrative commands.

Procedure

- To start an administrative client session in mount mode, enter the following command:

  ```
  dsmadmc -mountmode
  ```

  You are prompted for a password if authentication is turned on for the server. If you do not want to be prompted for your user ID and password, enter the DSMADMC command with the -ID and -PASSWORD options.

- To end an administrative client session in mount mode, use a keyboard break sequence.

Operating system	Break sequence
UNIX and Linux clients	Ctrl+C
Windows clients	Ctrl+C or Ctrl+Break

Processing individual commands from the administrative client

Use batch mode to enter a single administrative command. Your administrative client session automatically ends when the command is processed.

Procedure

To start an administrative client session in batch mode, use the following command: `dsmadmc` *`server_command`*

If you do not want to be prompted for your user ID and password, you can enter the DSMADMC command with the -ID and -PASSWORD options.

In batch mode, you must enter the complete command on one line. If a command does not fit on one line, enter the command by using a macro or a script. If you specify a parameter with a string of text using batch mode, enclose the text in single quotation marks (' ') in the macro. Do not use double quotation marks for commands in batch mode, because your operating system might not parse the quotation marks correctly.

Windows You can bypass this batch mode double quotation mark restriction for Windows clients by using the back slash (\) escape character. For example, on the OBJECTS parameter of the DEFINE CLIENTACTION command, you could enter the string with the \ character preceding the double quotation marks in the command.

```
dsmadmc -id=admin -password=admin define clientaction test_node domain=test_dom
action=restore objects='\"C:\program files\test\*\"'
```

Processing a series of commands from the administrative client

Use the interactive mode to process a series of administrative commands.

About this task

To start an administrative client session in interactive mode, a server session must be available. To ensure the availability of server sessions for both administrative and client node sessions, the interactive mode of the administrative client is disconnected if one or more of the following conditions is true:

- The server was stopped by using the HALT command.
- Commands were not issued from the administrative client session for the length of time that is specified with the IDLETIMEOUT server option.
- The administrative client session was canceled with the CANCEL SESSION command.

Procedure

To start an administrative session in interactive mode, use the following command: `dsmadmc`

You can use continuation characters when you use interactive mode. For more information, see Using continuation characters to enter long commands.

You can automatically restart your administrative client session by entering another command each time the `tsm: servername >` prompt appears.

Do not enter a server command with the DSMADMC command. Doing so starts the administrative client in batch, not interactive, mode. For example, do not enter:

```
dsmadmc server_command
```

Formatting output from commands

IBM Spectrum Protect™ formats the output processed from commands according to your screen or window width.

Procedure

- If the width of your screen or window is not wide enough to display the output horizontally, IBM Spectrum Protect arranges and displays the information vertically.
- You can format the output of QUERY commands using the DISPLAYMODE and OUTFILE administrative client options.

Saving command output to a specified location

The most common use for redirecting output is to save the output from query commands to a specified file or program. You can then browse the contents of the file or in some cases, print the contents.

About this task

On some operating systems, you can redirect output of a command by using special characters such as >, >>, and |. Redirection characters direct the output of a command to a file or program that you specify instead of to your screen. You can save the output

from a command by entering redirection characters at the end of the command. To redirect output, leave a blank between the redirection character and the file or program name. See the following examples.

When redirecting output, follow the naming conventions of the operating system where you are running the administrative client.

Procedure

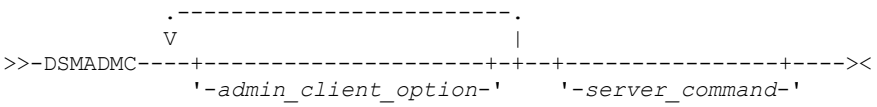
The examples in the following table show how to redirect command output.

Task	Procedure
Redirect the output of a QUERY DOMAIN command to a new file in batch or interactive mode	Use a single greater-than sign (>) to redirect the output to a new file or write over an existing file: `dsmadmc -id=xxx -pa=xxx query domain acctg > dominfo.acc`
Append the output of a QUERY DOMAIN command to the end of an existing file in batch or interactive mode	Use two consecutive greater-than signs (>>) to append the output to the end of an existing file: `dsmadmc -id=xxx -pa=xxx query domain acctg >> dominfo.acc`
Redirect all output from an administrative client session in console mode to a program called filter.exe	Use the vertical bar (|) to direct all output for a session to a program: `dsmadmc -console -id=admin -password=xxx | filter.exe` The program can be set up to monitor the output for individual messages as they occur and take appropriate action, such as sending mail to another user.
In console mode, redirect all output to a file	Specify the -OUTFILE option with a destination file name. For example, the following command redirects all output to the save.out file: `dsmadmc -id=sullivan -password=secret -consolemode -outfile=save.out`

Administrative client options

In all administrative client modes, you can use options to modify administrative client session responses.

Syntax



Example of using administrative client options

You can enter the DSMADMC command with your user ID and password by using the -ID and -PASSWORD options so that you are not prompted for that information. To have IBM Spectrum Protect™ redirect all output to a file, specify the -OUTFILE option with a destination file name. For example, to issue the QUERY NODE command in batch mode with the output redirected to the SAVE.OUT file, enter:

```
dsmadmc -id=sullivan -password=secret -outfile=save.out query node
```

Options

Administrative client options can be specified with the DSMADMC command and are valid from an administrative client session only. You can type an option in uppercase letters, lowercase letters, or any combination. Uppercase letters denote the shortest acceptable abbreviation. If an option appears entirely in uppercase letters, you cannot abbreviate it.

-ALWAYSPrompt
: Specifies that a command prompt is displayed if the input is from the keyboard or if it is redirected (for example, from a file). If this option is not specified and the input is redirected, the command prompt is not written.

  If the input is redirected, only the command output is displayed. If this option is specified, the command prompt and the command output are displayed.

-CHECKAliashalt
Allows the administrative client to recognize an alias for the HALT command as set in the ALIASHALT server option. See ALIASHALT for details.

-COMMAdelimited
Specifies that any tabular output from a server query is to be formatted as comma-separated strings rather than in readable format. This option is intended to be used primarily when you redirect the output of an SQL query (SELECT command). The comma-separated value format is a standard data format, which can be processed by many common programs, including spreadsheets, databases, and report generators.

-CONsolemode
Specifies that IBM Spectrum Protect runs in console mode. Most server console output is echoed to your screen. The exception are items such as responses to query commands that are issued from the console, trace output, or any system messages that displayed on the console.

-DATAONLY=NO or YES
Specifies whether product version information and output headers display with the output. The default is NO.

NO
Specifies that the product version information and output column headers display.

YES
Suppresses the product version information and output column headers.

-DISPLaymode=LISt or TABle
You can force the QUERY output to tabular or list format regardless of the command-line window column width.

If you are using the -DISPLAYMODE option and you want the output to go to a file, do not specify the -OUTFILE option. Use redirection to write to the file.

-ID=userid
Specifies the administrator's user ID.

-Itemcommit
Specifies that IBM Spectrum Protect commits commands inside a script or a macro as each command is processed.

-MOUNTmode
Specifies that IBM Spectrum Protect runs in mount mode. All server removable-media mount messages are echoed to your screen.

-NEWLINEAFTERPrompt
Specifies that a newline character is written after the command prompt and commands that are entered from the keyboard are displayed underneath the prompt. If this option is not specified, commands entered from the keyboard are displayed to the right side of the prompt.

-NOConfirm
Specifies that you do not want IBM Spectrum Protect to request confirmation before processing commands that affect the availability of the server or data that is managed by the server.

-OUTfile
Specifies that output from a server query is displayed in one row. If the output in a row exceeds the column width that is defined by the server, the output is displayed on multiple lines in that row. This option is available in batch mode only.

-OUTfile=filename
Specifies that output from a server query is redirected to a specified file. In batch mode, output is redirected to a specified file you specify and the format of the output matches the format of the output on your screen.

In interactive, console, or mount mode sessions, output displays on your screen.

-PAssword=password
Specifies the administrator's password.

-Quiet
Specifies that IBM Spectrum Protect does not display standard output messages to your screen. However, when you use this option, certain error messages still appear.

AIX Linux -SErveraddress
AIX Linux Specifies the server stanza in the dsm.sys file. The client uses the server stanza to determine the server it connects to. The SERVERADDRESS option is supported by administrative clients that are running on UNIX, Linux, and Macintosh operating systems only.

-TABdelimited
Specifies that any tabular output from a server query is to be formatted as tab-separated strings rather than in readable format. This option is intended to be used primarily when you redirect the output of an SQL query (SELECT command). The tab-separated value format is a standard data format, which can be processed by many common programs, including spreadsheets, databases, and report generators.

-TCPPort
: Specifies a TCP/IP port address for an IBM Spectrum Protect server. The TCPPORT option is only supported by administrative clients that are running on Windows operating systems and is valid on the Windows administrative client command line.

-TCPServeraddress
: Specifies a TCP/IP server address for an IBM Spectrum Protect server. The TCPSERVERADDRESS option is only supported by administrative clients that are running on Windows operating systems and is valid on the Windows administrative client command line.

In addition to the options that are listed here, you can also specify any option that is in the client options file. Each option must be preceded with a hyphen and delimited with a space.

Issuing commands from the Operations Center

From the Operations Center command-line interface, you can issue commands to manage IBM Spectrum Protect™ servers that are configured as hub or spoke servers.

Procedure

To open the command-line interface, hover over the globe icon in the Operations Center menu bar, and click Command Builder.

Issuing commands from the server console

IBM Spectrum Protect™ provides a user ID named SERVER_CONSOLE that allows you to issue commands and administer the server from the server console after IBM Spectrum Protect is installed. At installation, SERVER_CONSOLE is automatically registered as an administrator and is given system authority.

About this task

If you have system privilege, you can revoke or grant new privileges to the SERVER_CONSOLE user ID. You cannot take any of the following actions:

- Register or update the SERVER_CONSOLE user ID
- Lock or unlock the SERVER_CONSOLE user ID
- Rename the SERVER_CONSOLE user ID
- Remove SERVER_CONSOLE user ID
- Route commands from the SERVER_CONSOLE user ID

Not all IBM Spectrum Protect commands are supported by the server console. You cannot specify the WAIT parameter from the server console.

Entering administrative commands

Commands consist of command names and usually parameters and variables. Syntax diagrams depict the rules to follow when entering commands.

About this task

To display command-line help for server commands that have unique names, you can type `help commandName`, where *commandName* is the name of the server command for which you want information. For example, to display help for the REGISTER NODE command, type `help register node`. Command syntax and parameter descriptions are displayed in the output.

You can also type `help` followed by the topic number for the command. Topic numbers are listed in the table of contents for command-line help, for example:

```
3.0 Administrative commands
  3.46 REGISTER
     3.46.1 REGISTER ADMIN (Register an administrator)
     3.46.2 REGISTER LICENSE (Register a new license)
     3.46.3 REGISTER NODE (Register a node)
```

To display help about the REGISTER NODE command, type:

```
help 3.46.3
```

Use topic numbers to display command-line help for subcommands. DEFINE DEVCLASS is an example of a command that has subcommands. For example, you can specify the DEFINE DEVCLASS command for 3590 device classes and for 3592 device classes:

```
3.0 Administrative commands
  ...
  3.13.10 DEFINE DEVCLASS (Define a device class)
      3.13.10.1 DEFINE DEVCLASS (Define a 3590 device class)
      3.13.10.2 DEFINE DEVCLASS (Define a 3592 device class)
      ...
```

To display help for the DEFINE DEVCLASS command for 3590 device classes, type:

```
help 3.13.10.1
```

- Reading syntax diagrams
  To read a syntax diagram for entering a command, follow the path of the line. Read from left to right and from top to bottom.
- Using continuation characters to enter long commands
  Continuation characters are useful when you want to process a command that is longer than your screen or window width. You can use continuation characters in the interactive mode of the administrative client.
- Naming IBM Spectrum Protect objects
  IBM Spectrum Protect restricts the number and type of characters that you can use to name objects.
- Using wildcard characters to specify object names
  In some commands, such as the query commands, you can use wildcard characters to create a pattern-matching expression that specifies more than one object. Using wildcard characters makes it easier to tailor a command to your needs.
- Specifying descriptions in keyword parameters
  If a description (a string of text) for a parameter begins with a single or double quotation mark, or contains any embedded blanks or equal signs, you must surround the value with either single (') or double (") quotation marks.

Reading syntax diagrams

To read a syntax diagram for entering a command, follow the path of the line. Read from left to right and from top to bottom.

- The >>--- symbol indicates the beginning of a syntax diagram.
- The ---> symbol at the end of a line indicates that the syntax diagram continues onto the next line.
- The >--- symbol at the beginning of a line indicates that a syntax diagram continues from the previous line.
- The --->< symbol indicates the end of a syntax diagram.

Command names

The command name can consist of a single action word, such as HALT, or it can consist of an action word and an object for the action, such as DEFINE DOMAIN. You can enter the command in any column of the input line.

Enter the entire command name or the abbreviation that is specified in the syntax diagram for the command. Uppercase letters denote the shortest acceptable abbreviation. If a command appears entirely in uppercase letters, you cannot abbreviate it. You can enter the command in uppercase letters, lowercase letters, or any combination. In this example, you can enter CMDNA, CMDNAM, or CMDNAME in any combination of uppercase and lowercase letters.

```
>>-CMDNAme-----------------------------------------------------><
```

Note: Command names in descriptive text are always capitalized.

Required parameters

When a parameter is on the same line as the command name, the parameter is required. When two or more parameter values are in a stack and one of them is on the line, you *must* specify one value.

In this example, you must enter PARMNAME=A, PARMNAME=B, or PARMNAME=C. Do not include any blanks immediately before or after the equal sign (=).

```
>>-PARMName--=--+-A-+-----------------------------------------><
                +-B-+
                '-C-'
```

Optional parameters

When a parameter is below the line, the parameter is optional. In this example, you can enter PARMNAME=A or nothing at all. Do not include any blanks immediately before or after the equal sign (=).

```
>>-+----------------+-----------------------------------------><
   '-PARMName--=--A-'
```

When two or more parameter values are in a stack below the line, all of them are optional. In this example, you can enter PARMNAME=A, PARMNAME=B, PARMNAME=C, or nothing at all. Do not include any blanks immediately before or after the equal sign (=).

```
>>-+--------------------+-------------------------------------><
   '-PARMNAme--=--+-A-+-'
                  +-B-+
                  '-C-'
```

Defaults

Defaults are above the line. The system uses the default unless you override it. You can override the default by entering an option from the stack below the line.

In this example, PARMNAME=A is the default. You can also enter PARMNAME=A, PARMNAME=B, or PARMNAME=C. Do not include any blanks before or after the equal sign (=).

```
   .-PARMNAme--=--A-----.
>>-+--------------------+-------------------------------------><
   '-PARMName--=--+-A-+-'
                  +-B-+
                  '-C-'
```

Variables

Highlighted lowercase items (like this) denote variables. In these examples, var_name represents variables::

```
>>-CMDNAme--var_name-----------------------------------------><
```

```
>>-+----------------------+-----------------------------------><
   '-PARMname--=--var_name-'
```

Special characters

You must code these symbols exactly as they appear in the syntax diagram.

*
: Asterisk

:
: Colon

,

,
Comma

=
Equal sign

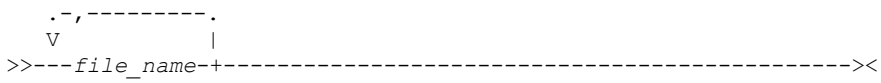
-
Hyphen

( )
Parentheses

.
Period

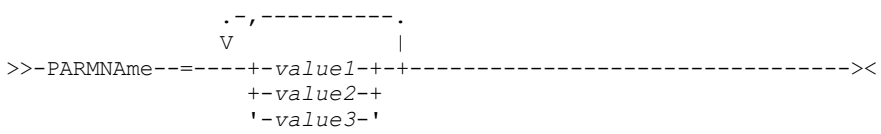
Repeating values

An arrow returning to the left means that the item can be repeated. A character within the arrow means that you must separate repeated items with that character.



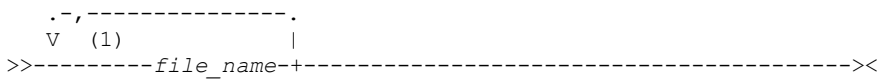
Repeatable choices

A stack of values followed by an arrow returning to the left means that you can select more than one value or, when permitted, repeat a single item. In this example, you can choose more than one value, with each name delimited with a comma. Do not include any blanks before or after the equal sign (=).



Footnotes

Footnotes are enclosed in parentheses.

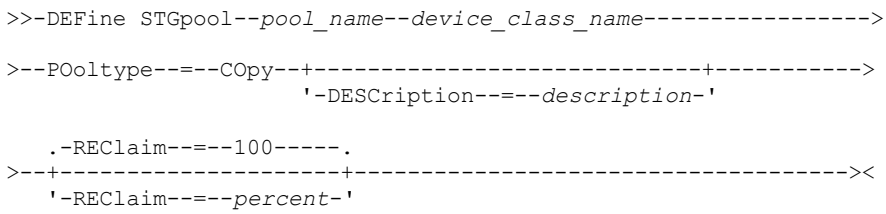


Notes:

1. You can specify up to five file names.

Entering parameters

The order in which you enter parameters can be important. The following example shows a portion of the command for defining a copy storage pool:



The first two parameters in this command (*pool_name* and *device_class_name* are required parameters. *pool_name* and *device_class_name* are also positional. That is, they must be entered in the order shown, immediately after the command name. The POOLTYPE parameter is a required keyword parameter. DESCRIPTION and RECLAIM, are optional keyword parameters.

Keyword parameters are identified by an equal sign that specifies a specific value or a variable. Keyword parameters must follow any positional parameters in a command.

The following command entries, in which the keyword parameters are ordered differently, are both acceptable:

```
define stgpool mycopypool mydeviceclass pooltype=copy description=engineering
   reclaim=50
define stgpool mycopypool mydeviceclass description=engineering pooltype=copy
   reclaim=50
```

The following example, in which one of the positional parameters follows a keyword parameter, is not acceptable:

```
define stgpool mycopypool pooltype=copy mydeviceclass description=engineering
   reclaim=50
```

Syntax fragments

Some diagrams, because of their length, must display parts of the syntax with fragments. The fragment name appears between vertical bars in the diagram.

The expanded fragment appears in the diagram after all other parameters or at the bottom of the diagram. A heading with the fragment name identifies the expanded fragment. Commands appearing directly on the line are required.

In this example, the fragment is named "Fragment".

```
>>-| Fragment |-------------------------------------------------><

Fragment

   .-A-.
|--+---+-------------------------------------------------------|
   +-B-+
   '-C-'
```

Using continuation characters to enter long commands

Continuation characters are useful when you want to process a command that is longer than your screen or window width. You can use continuation characters in the interactive mode of the administrative client.

About this task

Without continuation characters, you can enter up to 256 characters. With continuation characters, you can enter up to 1500 characters.

Note: In the MACRO command, the maximums apply after any substitution variables have been applied.
With continuation characters, you can do the following:

- Enter a dash at the end of the line you want to continue.
  For example:

  ```
  register admin pease mypasswd -
  contact="david, ext1234"
  ```

- Continue a list of values by entering a dash or a back slash, with no preceding blank spaces, after the last comma of the list that you enter on the first line. Then, enter the remaining items in the list on the next line with no preceding blank spaces.
  For example:

  ```
  stgpools=stg1,stg2,stg3,-
  stg4,stg5,stg6
  ```

- Continue a string of values that are enclosed in quotation marks by entering the first part of the string that is enclosed in quotation marks, followed by a dash or a back slash at the end of the line. Then, enter the remainder of the string on the next line, enclosed in the same type of quotation marks.
  For example:

```
contact="david pease, bldg. 100, room 2b, san jose,"-
"ext. 1234, alternate contact-norm pass,ext 2345"
```

IBM Spectrum Protect™ concatenates the two strings with no intervening blanks. You must use only this method to continue a quoted string of values across more than one line.

Naming IBM Spectrum Protect objects

IBM Spectrum Protect™ restricts the number and type of characters that you can use to name objects.

About this task

The following characters are available for defining object names.

Character	Description
A–Z	Any letter, A through Z
0–9	Any number, 0 through 9
_	Underscore
.	Period
-	Hyphen
+	Plus
&	Ampersand

The following table shows the maximum length of characters permitted for naming objects.

Type of Name	Maximum Length
Administrators, client option sets, client nodes, passwords, server groups, server, names, virtual file space names	64
Restartable export identifiers	64
High-level and low-level TCP/IP (IPv4 or IPv6) addresses	64
Device classes, drives, libraries, management classes, policy domains, profiles, schedules scripts, backup sets, storage pools	30

The following characters are available for defining password names:

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9 . ! @ # $ % ^ & * _ - + = ` ( )
| { } [ ] : ; < > , ? / ~
```

Passwords considered "LOCAL" are those passwords that authenticate with the IBM Spectrum Protect server and are not case-sensitive. Once a node or administrator is updated to use the SESSIONSECURITY=STRICT parameter, the password becomes case-sensitive the next time you change the it. Passwords considered "LDAP" are those passwords that authenticate with an LDAP directory server and are case-sensitive.

When you use DEFINE commands to define database, recovery log, and storage pool volumes, the naming convention for the volume name is dependent on the type of sequential access media or random access media that you are using. Refer to the specific VOLUME command for details.

Using wildcard characters to specify object names

In some commands, such as the query commands, you can use wildcard characters to create a pattern-matching expression that specifies more than one object. Using wildcard characters makes it easier to tailor a command to your needs.

About this task

The wildcard characters you use depend on the operating system from which you issue commands. For example, you can use wildcard characters such as an asterisk (*) to match any (0 or more) characters, or you can use a question mark (?) or a percent sign (%) to match exactly one character.

Table 1 provides references to wildcard characters for some operating systems. Use wildcard characters appropriate for your system.

Table 1. Wildcard characters by operating system

Operating system	Match any	Match exactly one
AIX®, Linux, Windows	*	?
TSO	*	%

For example, if you want to query all the management classes whose names begin with DEV in all the policy sets in DOMAIN1, and your system uses an asterisk as the *match-any* character, you can enter:

```
query mgmtclass domain1 * dev*
```

If your system uses a question mark as the *match-exactly-one* character, and you want to query the management classes in POLICYSET1 in DOMAIN1, you can enter:

```
query mgmtclass domain1 policyset1 mc?
```

IBM Spectrum Protect™ displays information about management classes with names MC.

Table 2 shows additional examples of using wildcard characters to match any characters.

Table 2. Match-any character

Pattern	Matches	Does not match
ab*	ab, abb, abxxx	a, b, aa, bb
ab*rs	abrs, abtrs, abrsrs	ars, aabrs, abrss
ab*ef*rs	abefrs, abefghrs	abefr, abers

Table 3 shows additional examples of using wildcard characters to match exactly one character. The question mark (?) can be replaced by a percent sign (%) if your platform uses that character instead of (?).

Table 3. Match-exactly-one character

Pattern	Matches	Does not match
ab?	abc	ab, abab, abzzzz
ab?rs	abfrs	abrs, abllrs
ab?ef?rs	abdefjrs	abefrs, abdefrs, abefjrs
ab??rs	abcdrs, abzzrs	abrs, abjrs, abkkkrs

Specifying descriptions in keyword parameters

If a description (a string of text) for a parameter begins with a single or double quotation mark, or contains any embedded blanks or equal signs, you must surround the value with either single (') or double (") quotation marks.

About this task

The opening and closing quotation marks must be the same type of quotation marks. For example, if the opening quotation is a single quotation mark, the closing quotation mark must also be a single quotation mark.

For example, to register a new client node named Louie, with a password of secret, and with his title included as contact information, enter:

```
register node louie secret contact="manager of dept. 61f"
```

The following table presents ways of entering a description for the CONTACT parameter. The value can contain quotation marks, embedded blanks, or equal signs.

For this description	Enter this

For this description	Enter this
manager	contact=manager
manager's	contact="manager's" *or* contact='manager"s'
"manager"	contact='"manager"' *or* contact="""manager"""
manager's report	contact="manager's report" *or* contact='manager''s report'
manager's "report"	contact='manager''s "report"'
manager=dept. 61f	contact='manager=dept. 61f'
manager reports to dept. 61f	contact='manager reports to dept. 61f' *or* contact="manager reports to dept. 61f"

Controlling command processing

You can run some IBM Spectrum Protect™ commands sequentially or concurrently with other commands. You can also route commands from one server to other servers for processing.

About this task

- Server command processing
  IBM Spectrum Protect processes administrator commands either in the foreground or in the background. Commands that process in the foreground must complete before you can issue another command. When commands are processing in the background, you can issue additional commands at any time.
- Stopping background processes
  Use the CANCEL PROCESS command to cancel commands that generate background processes.

Server command processing

IBM Spectrum Protect™ processes administrator commands either in the foreground or in the background. Commands that process in the foreground must complete before you can issue another command. When commands are processing in the background, you can issue additional commands at any time.

Most IBM Spectrum Protect commands process in the foreground. For some commands that normally process in the background (for example, BACKUP DB), you can specify the WAIT parameter (WAIT=YES) with the command so that the command processes in the foreground. You might want to process a command in the foreground rather than in the background for any of the following reasons:

- To quickly determine whether a command completed successfully. When you issue a command that processes in the foreground, IBM Spectrum Protect sends a confirmation message that indicates that the command completed successfully. If you process the command in the background, you need to open operational reporting or query the activity log to determine whether the command completed successfully.
- To monitor server activities (for example, messages) on the administrative client as a command is being processed. This might be preferable to searching a long activity log after the command has completed.
- To be able to start another process immediately after a command completed. For example, you might specify WAIT=YES for a command that takes a short time to process so that, when the processing completes, you can immediately start processing another command.
- To serialize commands in an administrative script when it is important that one command completes before another begins.

Check the individual command description to determine whether a command has a WAIT parameter.

You can cancel commands that are processed in the foreground from the server console or from another administrative client session.

Each background process is assigned a process number. Use the QUERY PROCESS command to obtain the status and process number of a background process.

Note:

- If you are defining a schedule with a command that specifies WAIT=NO (the default), and you issue QUERY EVENT to determine the status of your scheduled operation, failed operations report an event status of COMPLETED with a return of

OK. In order for the QUERY EVENT output to reflect the failed status, the WAIT parameter must be set to YES. This runs the scheduled operation in the foreground and informs you of the status when it completes.

- You cannot process commands in the foreground from the server console.

Stopping background processes

Use the CANCEL PROCESS command to cancel commands that generate background processes.

About this task

Use the QUERY PROCESS command to obtain the status and process number of a background process. If a background process is active when you cancel it, the server stops the process. Any changes that are uncommitted are rolled back. However, changes that are committed are not rolled back.

When you issue a QUERY command from the administrative client, multiple screens of output might be generated. If this occurs and additional output is not needed, you can cancel the display of output to the client workstation. Doing so does not end the processing of the command.

Performing tasks concurrently on multiple servers

Command routing allows you to route commands to one or more servers for processing and then collect the output from these servers.

About this task

To route commands to other servers, you must have the same administrator ID and password as well as the required administrative authority on each server to which the command is being routed. You cannot route commands to other servers from the server console.

After the command has completed processing on all servers, the output displays, in its entirety, for each server. For example, the output from SERVER_A displays in its entirety, followed by the output from SERVER_B. The output includes summary messages for each individual server and identifies which server processed the output. Return codes indicate whether commands processed on the servers successfully. These return codes include one of three severities: 0, ERROR, or WARNING.

Each server that is identified as the target of a routed command must first be defined using the DEFINE SERVER command. The command is automatically routed to all servers specified as members of a server group or to individual servers specified with the command.

The following examples describe how to route the QUERY STGPOOL command to one server, multiple servers, a server group, multiple server groups, or a combination of servers and server groups. Each server or server group in a list must be separated with a comma, without spaces.

Routing commands to a single server

Procedure

To route the QUERY STGPOOL command to a server named ASTRO, enter:

```
astro: query stgpool
```

The colon after the server name indicates the end of the routing information. This is also called the *server prefix*. Another way to indicate the end of routing information is to use parentheses around the server name, for example:

```
(astro) query stgpool
```

Routing commands to multiple servers

About this task

Procedure

To route the QUERY STGPOOL command to multiple servers named HD_QTR, MIDAS, SATURN, enter:

```
hd_qtr,midas,saturn: query stgpool
```

If the first server has not been defined to IBM Spectrum Protect, the command is routed to the next defined server in the list of servers.

You can also enter the command this way:

```
(hd_qtr,midas,saturn) query stgpool
```

Routing commands to a server group

About this task

In this example, the server group ADMIN has servers named SECURITY, PAYROLL, PERSONNEL defined as group members. The command is routed to each of these servers.

Procedure

To route the QUERY STGPOOL command to the server group named ADMIN, enter:

```
admin: query stgpool
```

You can also enter the command this way:

```
(admin) query stgpool
```

Routing commands to server groups

About this task

In this example, the server group ADMIN2 has servers SERVER_A, SERVER_B, and SERVER_C defined as group members, and server group ADMIN3 has servers ASTRO, GUMBY, and CRUSTY defined as group members. The command is routed to servers SERVER_A, SERVER_B, SERVER_C, ASTRO, GUMBY, and CRUSTY.

Procedure

To route the QUERY STGPOOL command to two server groups that are named ADMIN2 and ADMIN3, enter:

```
admin2,admin3: query stgpool
```

You can also enter the command this way:

```
(admin2,admin3) query stgpool
```

Routing commands to two servers and a server group

About this task

In this example, the server group DEV_GROUP has servers SALES, MARKETING, and STAFF defined as group members. The command is routed to servers SALES, MARKETING, STAFF, MERCURY, and JUPITER.

Procedure

To route the QUERY STGPOOL command to a server group named DEV_GROUP and to the servers named MERCURY and JUPITER, enter:

```
dev_group,mercury,jupiter: query stgpool
```

You can also enter the command this way:

```
(dev_group,mercury,jupiter) query stgpool
```

Routing commands inside scripts

About this task

When routing commands inside scripts, you must enclose the server or server group in parentheses and omit the colon. Otherwise, the command will not be routed when the RUN command is issued, and will only be run on the server where the RUN command is issued.

For example, to route the QUERY STGPOOL command inside a script:

Procedure

1. Define a script called QU_STG to route it to the DEV_GROUP server group.

   ```
   define script qu_stg "(dev_group) query stgpool"
   ```

2. Run the QU_STG script:

   ```
   run qu_stg
   ```

Results

In this example, the server group DEV_GROUP has servers SALES, MARKETING, and STAFF defined as group members. The QUERY STGPOOL command is routed to these servers.

Privilege classes for commands

The authority granted to an administrator through the privilege class determines which administrative commands that the administrator can issue.

There are four administrator privilege classes in IBM Spectrum Protect™:

- System
- Policy
- Storage
- Operator

After an administrator has been registered using the REGISTER ADMIN command, the administrator can issue a limited set of commands, including all query commands. When you install IBM Spectrum Protect, the server console is defined as a system administrator named SERVER_CONSOLE and is granted system privilege.

- Commands requiring system privilege
  An administrator with system privilege has the highest level of authority for the server. With system privilege, an administrator can issue any administrative command and has authority to manage all policy domains and all storage pools.
- Commands requiring policy privilege
  An administrator with policy privilege can issue commands that relate to policy management objects such as policy domains, policy sets, management classes, copy groups, and schedules. The policy privilege can be unrestricted, or can be restricted to specific policy domains.
- Commands requiring storage privilege
  An administrator with storage privilege can issue commands that allocate and control storage resources for the server. The storage privilege can be unrestricted, or can be restricted to specific storage pools.
- Commands requiring operator privilege
  An administrator with operator privilege can issue commands that control the immediate operation of the server and the availability of storage media.
- Commands any administrator can issue
  A limited number of commands can be used by any administrator, even if that administrator has not been granted any specific administrator privileges.

Commands requiring system privilege

An administrator with system privilege has the highest level of authority for the server. With system privilege, an administrator can issue any administrative command and has authority to manage all policy domains and all storage pools.

Table 1 lists the commands that administrators with system privilege can issue. In some cases administrators with lower levels of authority, for example, unrestricted storage privilege, can also issue these commands. In addition, the REQSYSAUTHOUTFILE server option can be used to specify that certain commands require system privilege if they cause the server to write to an external file. For more information about this server option, review REQSYSAUTHOUTFILE.

Table 1. System privilege commands

Command name	Command name
• AUDIT LDAPDIRECTORY • AUDIT LICENSES • ACCEPT DATE • BEGIN EVENTLOGGING • CANCEL EXPIRATION • CANCEL PROCESS • CANCEL REPLICATION • CANCEL REQUEST • CANCEL RESTORE • CLEAN DRIVE • COPY ACTIVEDATA • COPY DOMAIN • COPY POLICYSET • COPY PROFILE • COPY SCHEDULE (Review note.) • COPY SCRIPT • COPY SERVERGROUP • DEFINE BACKUPSET • DEFINE CLIENTACTION • DEFINE CLIENTOPT • DEFINE CLOPTSET • DEFINE COLLOCGROUP • DEFINE COLLOCMEMBER • DEFINE DEVCLASS • DEFINE DOMAIN • DEFINE DRIVE • DEFINE EVENTSERVER • DEFINE GRPMEMBER • DEFINE LIBRARY • DEFINE MACHINE • DEFINE MACHNODEASSOCIATION • DEFINE NODEGROUP • DEFINE NODEGROUPMEMBER • DEFINE PATH • DEFINE PROFASSOCIATION • DEFINE PROFILE • DEFINE RECMEDMACHASSOCIATION • DEFINE RECOVERYMEDIA • DEFINE SCHEDULE (Review note.) • DEFINE SCRIPT • DEFINE SERVER • DEFINE SERVERGROUP	• DEFINE SPACETRIGGER • DEFINE STGPOOL • DEFINE SUBSCRIPTION • DEFINE VIRTUALFSMAPPING • DEFINE VOLUME • DELETE BACKUPSET • DELETE CLIENTOPT • DELETE CLOPTSET • DEFINE COLLOCGROUP • DEFINE COLLOCMEMBER • DELETE DOMAIN • DELETE DRIVE • DELETE EVENTSERVER • DELETE GRPMEMBER • DELETE LIBRARY • DELETE MACHINE • DELETE MACHNODEASSOCIATION • DELETE NODEGROUP • DELETE NODEGROUPMEMBER • DELETE PROFASSOCIATION • DELETE PROFILE • DELETE RECMEDMACHASSOCIATION • DELETE RECOVERYMEDIA • DELETE SCHEDULE (Review note.) • DELETE SCRIPT • DELETE SERVER • DELETE SERVERGROUP • DELETE SPACETRIGGER • DELETE STGPOOL • DELETE SUBSCRIBER • DELETE SUBSCRIPTION • DELETE VIRTUALFSMAPPING • DISABLE EVENTS • ENABLE EVENTS • END EVENTLOGGING • EXPIRE INVENTORY • EXPORT ADMIN • EXPORT NODE • EXPORT POLICY • EXPORT SERVER • GENERATE BACKUPSET • GRANT AUTHORITY

Command name	Command name
Note: This command is restricted by the authority that is granted to an administrator. System privilege is required only for administrative command schedules. System or policy privilege is required for client operation schedules.	

Commands requiring policy privilege

An administrator with policy privilege can issue commands that relate to policy management objects such as policy domains, policy sets, management classes, copy groups, and schedules. The policy privilege can be unrestricted, or can be restricted to specific policy domains.

With unrestricted policy privilege, you can issue all of the administrator commands that require policy privilege. You can issue commands that affect all existing policy domains as well as any policy domains that are defined in the future. An unrestricted policy administrator cannot define, delete, or copy policy domains.

With restricted policy privilege, you can issue administrator commands that affect one or more policy domains for which authority is granted. For example, the DELETE MGMTCLASS command requires you to have policy privilege for the policy domain to which the management class belongs.

Table 1 lists the commands that an administrator with policy privilege can issue.

Table 1. Policy privilege commands

Command name	Command name
• ACTIVATE POLICYSET • ASSIGN DEFMGMTCLASS • CLEAN DRIVE • BACKUP NODE • COPY MGMTCLASS • COPY POLICYSET • COPY SCHEDULE (Review note 2.) • DEFINE ASSOCIATION • DEFINE BACKUPSET • DEFINE COPYGROUP • DEFINE CLIENTACTION • DEFINE CLIENTOPT • DEFINE MGMTCLASS • DEFINE NODEGROUP • DEFINE NODEGROUPMEMBER • DEFINE POLICYSET • DEFINE SCHEDULE • DELETE ASSOCIATION • DELETE BACKUPSET • DELETE COPYGROUP • DELETE EVENT (Review note 1.) • DELETE FILESPACE • DELETE MGMTCLASS • DELETE NODEGROUP • DELETE NODEGROUPMEMBER	• DELETE POLICYSET • DELETE PATH • DELETE SCHEDULE (Review note 2.) • GENERATE BACKUPSET • LOCK NODE • QUERY BACKUPSETCONTENTS • REGISTER NODE • REMOVE NODE • RENAME FILESPACE • RENAME NODE • SET SUMMARYRETENTION • RESTORE NODE • QUERY TOC • UNLOCK NODE • UPDATE BACKUPSET • UPDATE COPYGROUP • UPDATE DOMAIN • UPDATE MGMTCLASS • UPDATE NODE • UPDATE NODEGROUP • UPDATE POLICYSET • UPDATE SCHEDULE (Review note 2.) • VALIDATE POLICYSET
Notes: 1. This command can be restricted by policy domain. An administrator with unrestricted policy privilege or restricted policy privilege for a specified policy domain can issue this command. 2. This command is restricted by the authority that is granted to an administrator. System privilege is required only for administrative command schedules. System or policy privilege is required for client operation schedules.	

Commands requiring storage privilege

An administrator with storage privilege can issue commands that allocate and control storage resources for the server. The storage privilege can be unrestricted, or can be restricted to specific storage pools.

Unrestricted storage privilege permits you to issue all of the administrator commands that require storage privilege. You can issue commands that affect all existing storage pools as well as any storage pools that are defined in the future. You can also issue commands that affect the database and the recovery log. An unrestricted storage administrator cannot define or delete storage pools.

Restricted storage privilege permits you to issue administrator commands that only affect a storage pool for which you have been granted authority. For example, the DELETE VOLUME command only affects a storage pool volume that is defined to a specific storage pool.

Table 1 lists the commands an administrator with storage privilege can issue.

Table 1. Storage privilege commands

Command name	Command name
• AUDIT LIBRARY • AUDIT VOLUME (Review note.) • BACKUP DB • BACKUP DEVCONFIG • BACKUP STGPOOL • BACKUP VOLHISTORY • CHECKIN LIBVOLUME • CHECKOUT LIBVOLUME • COPY ACTIVEDATA (Review note.) • DEFINE COLLOCGROUP • DEFINE COLLOCMEMBER • DEFINE DATAMOVER • DEFINE DEVCLASS • DEFINE DRIVE • DEFINE LIBRARY • DEFINE PATH • DEFINE VIRTUALFSMAPPING • DEFINE VOLUME (Review note.) • DEFINE SPACETRIGGER • DELETE COLLOCGROUP • DELETE COLLOCMEMBER • DELETE DATAMOVER • DELETE DEVCLASS • DELETE DRIVE • DELETE LIBRARY • DELETE PATH	• DELETE SPACETRIGGER • DELETE VIRTUALFSMAPPING • DELETE VOLHISTORY • DELETE VOLUME (Review note.) • GRANT PROXYNODE • LABEL LIBVOLUME • MIGRATE STGPOOL • MOVE DATA (Review note.) • MOVE MEDIA • QUERY TAPEALERTMSG • RECLAIM STGPOOL • RESTORE STGPOOL • RESTORE VOLUME • REVOKE PROXYNODE • SET TAPEALERTMSG • UPDATE COLLOCGROUP • UPDATE DATAMOVER • UPDATE DEVCLASS • UPDATE DRIVE • UPDATE LIBRARY • UPDATE PATH • UPDATE SPACETRIGGER • UPDATE STGPOOL (Review note.) • UPDATE VIRTUALFSMAPPING
Note: This command can be restricted by storage pool. An administrator with unrestricted storage privilege or restricted storage privilege for a specified storage pool can issue this command.	

Commands requiring operator privilege

An administrator with operator privilege can issue commands that control the immediate operation of the server and the availability of storage media.

Table 1 lists the commands an administrator with operator privilege can issue.

Table 1. Operator privilege commands

Command Name	Command Name

Command Name	Command Name
• CANCEL SESSION • DISABLE SESSIONS • DISMOUNT VOLUME • ENABLE SESSIONS • HALT	• MOVE DRMEDIA • MOVE MEDIA • QUERY MEDIA • REPLY • UPDATE VOLUME • VARY

Commands any administrator can issue

A limited number of commands can be used by any administrator, even if that administrator has not been granted any specific administrator privileges.

Table 1 lists the commands any registered administrator can issue.

Table 1. Commands issued by all administrators

Command Name	Command Name
• COMMIT • HELP • ISSUE MESSAGE • MACRO • PARALLEL • QUERY ACTLOG • QUERY ADMIN • QUERY ASSOCIATION • QUERY AUDITOCCUPANCY • QUERY BACKUPSET • QUERY CLOPTSET • QUERY COLLOCGROUP • QUERY CONTENT • QUERY COPYGROUP • QUERY DATAMOVER • QUERY DB • QUERY DBSPACE • QUERY DEVCLASS • QUERY DIRSPACE • QUERY DOMAIN • QUERY DRIVE • QUERY DRMEDIA • QUERY DRMSTATUS • QUERY ENABLED • QUERY EVENT • QUERY EVENTRULES • QUERY EVENTSERVER • QUERY FILESPACE • QUERY LIBRARY • QUERY LIBVOLUME • QUERY LICENSE • QUERY LOG • QUERY MACHINE • QUERY MGMTCLASS • QUERY MOUNT • QUERY NASBACKUP	• QUERY NODE • QUERY NODEDATA • QUERY NODEGROUP • QUERY OCCUPANCY • QUERY OPTION • QUERY PATH • QUERY POLICYSET • QUERY PROCESS • QUERY PROFILE • QUERY PROXYNODE • QUERY RECOVERYMEDIA • QUERY REPLICATION • QUERY REPLNODE • QUERY REPLRULE • QUERY REQUEST • QUERY RESTORE • QUERY RPFILE • QUERY SCHEDULE • QUERY SCRIPT • QUERY SERVER • QUERY SERVERGROUP • QUERY SESSION • QUERY SPACETRIGGER • QUERY STATUS • QUERY STGPOOL • QUERY SUBSCRIBER • QUERY SUBSCRIPTION • QUERY SYSTEM • QUERY VIRTUALFSMAPPING • QUERY VOLHISTORY • QUERY VOLUME • QUIT • ROLLBACK • SELECT • SERIAL

Administrative commands

Administrative commands are available to manage and configure the server.

Information for each command includes:

- A description of the tasks a command performs
- The administrator privilege class required to use the command
- A syntax diagram that identifies the required and optional parameters for the command
- Descriptions of each parameter of the command
- Examples of using the command
- A list of related commands

- ACCEPT DATE (Accepts the current system date)
  Use this command to allow the server to begin normal processing, when the server does not start normal processing because of a discrepancy between the server date and the current date on the system.
- ACTIVATE POLICYSET (Activate a new policy set)
  Use this command to copy the contents of a policy set to the ACTIVE policy set for the domain. The server uses the rules in the ACTIVE policy set to manage client operations in the domain. You can define multiple policy sets for a policy domain, but only one policy set can be active. The current ACTIVE policy set is replaced by the one you specify when you issue this command. You can modify the ACTIVE policy set only by activating another policy set.
- ASSIGN DEFMGMTCLASS (Assign a default management class)
  Use this command to specify a management class as the default management class for a policy set. You must assign a default management class for a policy set before you can activate that policy set.
- AUDIT commands
  Use the AUDIT commands to review or examine the adequacy of the database information and the storage pool volume. The AUDIT LDAPDIRECTORY command deletes nodes or administrator IDs from an LDAP directory server, that do not authenticate their passwords with the LDAP directory server.
- BACKUP commands
  Use the BACKUP commands to create backup copies of IBM Spectrum Protect™ information or objects.
- BEGIN EVENTLOGGING (Begin logging events)
  Use this command to begin logging events to one or more receivers. A receiver for which event logging has begun is an *active receiver*.
- CANCEL commands
  Use the CANCEL commands to end a task or process before it is completed.
- CHECKIN LIBVOLUME (Check a storage volume into a library)
  Use this command to add a sequential access storage volume or a cleaning tape to the server inventory for an automated library. The server cannot use a volume that physically resides in an automated library until that volume is checked in.
- CHECKOUT LIBVOLUME (Check a storage volume out of a library)
  Use this command to remove a sequential access storage volume from the server inventory for an automated library. This command creates a background process that can be canceled with the CANCEL PROCESS command. To display information on background processes, use the QUERY PROCESS command.
- CLEAN DRIVE (Clean a drive)
  Use this command when you want IBM Spectrum Protect to immediately load a cleaner cartridge into a drive regardless of the cleaning frequency.
- COMMIT (Control committing of commands in a macro)
  Use this command to control when a command is committed in a macro and to update the database when commands complete processing. When issued from the console mode of the administrative client, this command does not generate a message.
- CONVERT STGPOOL (Convert a storage pool to a container storage pool)
  Use this command to convert a primary storage pool that uses a FILE device class, a tape device class, or a virtual tape library (VTL) to a directory-container or a cloud-container storage pool. You can use container storage pools for both inline and client-side data deduplication.
- COPY commands
  Use the COPY commands to create a copy of IBM Spectrum Protect objects or data.
- DEACTIVATE DATA (Deactivate data for a client node)
  Use this command to specify that active data that was backed up for an application client node before a specified date is no longer needed. The command marks the data as inactive so it can be deleted according to your data retention policies.
- DECOMMISSION commands
  Use the DECOMMISSION commands to remove client nodes from the production environment. Client nodes include applications, systems, and virtual machines.
- DEFINE commands
  Use the DEFINE commands to create IBM Spectrum Protect objects.
- DELETE commands
  Use the DELETE commands to delete or remove an IBM Spectrum Protect object.

- DISABLE commands
  Use DISABLE commands to prevent some types of operations by the server.
- DISMOUNT command
  Use the DISMOUNT command to dismount a volume by the real device address or by volume name.
- DISPLAY OBJNAME (Display a full object name)
  Use this command when you want IBM Spectrum Protect to display a full object name if the name displayed in a message or query output has been abbreviated due to length. Object names that are very long can be difficult to display and use through normal operating system facilities. The IBM Spectrum Protect server will abbreviate long names and assign them a token ID which might be used if the object path name exceeds 1024 bytes. The token ID is displayed in a string that includes identifiers for the node, filespace, and object name. The format is: [TSMOBJ:*nID.fsID.objID*]. When specified with the DISPLAY OBJNAME command, the token ID can be used to show the full object name.
- ENABLE commands
  Use ENABLE commands to allow some types of operations by the server.
- ENCRYPT STGPOOL (Encrypt data in a storage pool)
  Use this command to encrypt data in a directory-container or cloud-container storage pool.
- END EVENTLOGGING (Stop logging events)
  Use this command to stop logging events to an active receiver.
- EXPIRE INVENTORY (Manually start inventory expiration processing)
  Use this command to manually start inventory expiration processing. The inventory expiration process removes client backup and archive file copies from server storage. Removal is based on policy specifications in the backup and archive copy groups of the management classes to which the files are bound.
- EXPORT commands
  Use the EXPORT commands to copy information from an IBM Spectrum Protect server to sequential removable media.
- EXTEND DBSPACE (Increase space for the database)
  Use this command to increase space for the database by adding directories for the database to use.
- GENERATE commands
  Use the GENERATE commands for backup sets for a selected filespace or client node.
- GRANT commands
  Use the GRANT command to grant appropriate privileges or access.
- HALT (Shut down the server)
  Use this command to shut down the server. The HALT command forces an abrupt shutdown, which cancels all the administrative and client node sessions even if they are not completed.
- HELP (Get help on commands and error messages)
  Use this command to display administrative commands and error messages. You can issue the command from an administrative command line client.
- IDENTIFY DUPLICATES (Identify duplicate data in a storage pool)
  Use this command to start or stop processes that identify duplicate data in a storage pool. You can specify the number of duplicate-identification processes and their duration.
- IMPORT commands
  Use the IMPORT commands to import information from export media to an IBM Spectrum Protect server.
- INSERT MACHINE (Insert machine characteristics information or recovery instructions)
  Use this command to add client machine characteristics or recovery instructions to existing machine information in the database.
- ISSUE MESSAGE (Issue a message from a server script)
  Use this command with return code processing in a script to issue a message from a server script to determine where the problem is with a command in the script.
- LABEL LIBVOLUME (Label a library volume)
  Use this command to label tape volumes or, in an automated library, to label the volumes automatically as they are checked in. With this command, the server uses the full-length label with which the volumes are often prelabeled.
- LOAD DEFALERTTRIGGERS (Load the default set of alert triggers)
  Use this command to load the default set of alert triggers to the IBM Spectrum Protect server.
- LOCK commands
  Use the LOCK command to prevent users from accessing the server.
- MACRO (Invoke a macro)
  Use this command to invoke a file from the administrative command line that contains one or more IBM Spectrum Protect administrative commands to be performed.
- MIGRATE STGPOOL (Migrate storage pool to next storage pool)
  Use this command to migrate files from one storage pool to the next storage pool in the storage hierarchy.
- MOVE commands
  Use the MOVE commands to either transfer backup or archive data between storage pools, or to move disaster recovery media on and off site.

- NOTIFY SUBSCRIBERS (Notify managed servers to update profiles)
  Use this command on a configuration manager to notify one or more managed servers to request that their configuration information be immediately refreshed.
- PERFORM LIBACTION (Define or delete all drives and paths for a library)
  Use this command to define or delete all drives and their paths for a single library in one step.
- PING SERVER (Test the connection between servers)
  Use this command to test the connection between the local server and a remote server.
- PREPARE (Create a recovery plan file)
  Use this command to create a recovery plan file, which contains the information that is needed to recover an IBM Spectrum Protect server. You can store a recovery plan file on a file system that is accessible to the source server or on a target server.
- PROTECT STGPOOL (Protect data that belongs to a storage pool)
  Use this command to protect data in a directory-container storage pool by storing a copy of the data in another storage pool on a replication target server or on the same server by protecting the data to tape. When you protect the directory-container storage pool, you can later try to repair damage in the storage pool by using the REPAIR STGPOOL command.
- QUERY commands
  Use the QUERY commands to request or display information about IBM Spectrum Protect objects.
- QUIT (End the interactive mode of the administrative client)
  Use this command to end an administrative client session in interactive mode.
- RECLAIM STGPOOL (Reclaim volumes in a sequential-access storage pool)
  Use this command to reclaim volumes in a sequential-access storage pool. Reclamation does not move inactive versions of backup data from volumes in active-data pools.
- RECONCILE VOLUMES (Reconcile differences in the virtual volume definitions)
  Issue this command from the source server to reconcile differences between virtual volume definitions on the source server and archive files on the target server. IBM Spectrum Protect finds all volumes of the specified device class on the source server and all corresponding archive files on the target server. The target server inventory is also compared to the local definition for virtual volumes to see if inconsistencies exist.
- REGISTER commands
  Use the REGISTER commands to define or add objects to IBM Spectrum Protect.
- REMOVE commands
  Use the REMOVE commands to remove an object from IBM Spectrum Protect.
- RENAME commands
  Use the RENAME commands to change the name of an existing object.
- REPAIR STGPOOL (Repair a directory-container storage pool)
  Use this command to repair deduplicated extents in a directory-container storage pool. Damaged deduplicated extents are repaired with extents that are backed up to the target replication server or to container-copy storage pools on the same server.
- REPLICATE NODE (Replicate data in file spaces that belong to a client node)
  Use this command to replicate data in file spaces that belong to one or more client nodes or defined groups of client nodes.
- REPLY (Allow a request to continue processing)
  Use this command and an identification number to inform the server that you have completed a requested operation. Not all server requests require a reply. This command is required only if the request message specifically indicates that a reply is needed.
- RESET PASSEXP (Reset password expiration)
  Use the RESET PASSEXP command to reset the password expiration period to the common expiration period for administrator and client node passwords. The RESET PASSEXP command does not apply to passwords that are stored on an LDAP directory server.
- RESTART EXPORT (Restart a suspended export operation)
  Use this command to restart a suspended export operation.
- RESTORE commands
  Use the RESTORE commands to restore IBM Spectrum Protect storage pools or volumes.
- REVOKE commands
  Use the REVOKE commands to revoke privileges or access.
- ROLLBACK (Rollback uncommitted changes in a macro)
  Use this command within a macro to undo any processing changes made by commands run by the server but not yet committed to the database. A committed change is permanent and cannot be rolled back. The ROLLBACK command is useful for testing macros.
- RUN (Run an IBM Spectrum Protect script)
  Use this command to run an IBM Spectrum Protect script. To issue this command on another server, the script being run must be defined on that server.
- SELECT (Perform an SQL query of the IBM Spectrum Protect database)
  Use the SELECT command to create and format a customized query of the IBM Spectrum Protect database.

- SET commands
  Use the SET commands to specify values that affect many different IBM Spectrum Protect operations.
- SETOPT (Set a server option for dynamic update)
  You can use the SETOPT command to update most server options dynamically without stopping and restarting the server. For the DBDIAGLOGSIZE option, you must stop and start the server. A SETOPT command contained in a macro or a script cannot be rolled back.
- SHRED DATA (Shred data)
  Use this command to manually start the process of shredding deleted sensitive data. Manual shredding is possible only if automatic shredding is disabled.
- SUSPEND EXPORT (Suspend a currently running export operation)
  Use this command to suspend a currently running server-to-server export operation which has a FILEDATA value that is not NONE. The export operation that you want to suspend must be past the initialization phase to be eligible for suspension. The state of the export operation is saved. The operation can be restarted by issuing the RESTART EXPORT command.
- UNLOCK commands
  Use the UNLOCK commands to reestablish access after an object was locked.
- UPDATE commands
  Use the UPDATE command to modify one or more attributes of an existing IBM Spectrum Protect object.
- VALIDATE commands
  Use the VALIDATE command to verify that an object is complete or valid for IBM Spectrum Protect.
- VARY (Bring a random access volume online or offline)
  Use this command to make a random access storage pool volume online or offline to the server.

ACCEPT DATE (Accepts the current system date)

Use this command to allow the server to begin normal processing, when the server does not start normal processing because of a discrepancy between the server date and the current date on the system.

When the server does not start normal processing because of a discrepancy between the server date and the current date, this command forces the server to accept the current date and time as valid. If the system time is valid and the server has not been run for an extended time, this command should be run to allow the server to begin normal processing.

Attention: If the system date is invalid or the server was created or run previously with an invalid system date and this command is issued, any server processing or command that uses dates can have unexpected results. File expiration can be affected, for example. When the server is started with the correct date, files backed up with future dates will not be considered for expiration until that future date is reached. Files backed up with dates that have passed will expire faster. When the server processing encounters a future date, an error message is issued.

If the server detects an invalid date or time, server sessions become disabled (as if the DISABLE SESSIONS command had been issued). Expiration, migration, reclamation, and volume history deletion operations are not able to continue processing.

Use the ENABLE SESSIONS ALL command after you issue the ACCEPT DATE command to re-enable sessions to start.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-ACCept Date-------------------------------------------------><
```

Parameters

None.

Example: Accept the current system date

Allow the server to accept the current date as the valid date.

```
accept date
```

Related commands

Table 1. Command related to ACCEPT DATE

Command	Description
ENABLE SESSIONS	Resumes server activity following the DISABLE command or the ACCEPT DATE command.

ACTIVATE POLICYSET (Activate a new policy set)

Use this command to copy the contents of a policy set to the ACTIVE policy set for the domain. The server uses the rules in the ACTIVE policy set to manage client operations in the domain. You can define multiple policy sets for a policy domain, but only one policy set can be active. The current ACTIVE policy set is replaced by the one you specify when you issue this command. You can modify the ACTIVE policy set only by activating another policy set.

Before activating a policy set, check that the policy set is complete and valid by using the VALIDATE POLICYSET command.

The ACTIVATE POLICYSET command fails if any of the following conditions exist:

- A copy group specifies a copy storage pool as a destination.
- A management class specifies a copy storage pool as the destination for files that were migrated by an IBM Spectrum Protect™ for Space Management client.
- The policy set has no default management class.
- A TOCDESTINATION parameter is specified, and the storage pool is either a copy pool or has a data format other than NATIVE or NONBLOCK.

The ACTIVE policy set and the last activated policy set are not necessarily identical. You can modify the original policy set that you activated without affecting the ACTIVE policy set.

If the server has data retention protection enabled, the following conditions must exist:

- All management classes in the policy set to be activated must contain an archive copy group.
- If a management class exists in the active policy set, a management class with the same name must exist in the policy set to be activated.
- If an archive copy group exists in the active policy set, the corresponding copy group in the policy set to be activated must have a RETVER value at least as large as the corresponding values in the active copy group.

Attention: Retention protection only applies to archive objects.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the policy set belongs.

Syntax

```
>>-ACTivate POlicyset--domain_name--policy_set_name------------><
```

Parameters

domain_name (Required)
: Specifies the policy domain for which you want to activate a policy set.

policy_set_name (Required)
: Specifies the policy set to activate.

Example: Activate a policy set on a specific policy domain

Activate the VACATION policy set in the EMPLOYEE_RECORDS policy domain.

```
activate policyset employee_records vacation
```

Related commands

Table 1. Commands related to ACTIVATE POLICYSET

Command	Description
COPY POLICYSET	Creates a copy of a policy set.
DEFINE POLICYSET	Defines a policy set within the specified policy domain.
DELETE POLICYSET	Deletes a policy set, including its management classes and copy groups, from a policy domain.
QUERY DOMAIN	Displays information about policy domains.
QUERY POLICYSET	Displays information about policy sets.
UPDATE POLICYSET	Changes the description of a policy set.
VALIDATE POLICYSET	Verifies and reports on conditions the administrator must consider before activating the policy set.

ASSIGN DEFMGMTCLASS (Assign a default management class)

Use this command to specify a management class as the default management class for a policy set. You must assign a default management class for a policy set before you can activate that policy set.

To ensure that clients can always back up and archive files, choose a default management class that contains both an archive copy group and a backup copy group.

The server uses the default management class to manage client files when a management class is not otherwise assigned or appropriate. For example, the server uses the default management class when a user does not specify a management class in the include-exclude list.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the policy set belongs.

Syntax

```
>>-ASsign DEFMGmtclass--domain_name--policy_set_name--class_name-><
```

Parameters

domain_name (Required)
: Specifies the policy domain to which the management class belongs.

policy_set_name (Required)
: Specifies the policy set for which you want to assign a default management class. You cannot assign a default management class to the ACTIVE policy set.

class_name (Required)
: Specifies the management class that is to be the default management class for the policy set.

Example: Assign a default management class

Assign DEFAULT1 as the default management class for policy set SUMMER in the PROG1 policy domain.

```
assign defmgmtclass prog1 summer default1
```

Related commands

Table 1. Commands related to ASSIGN DEFMGMTCLASS

Command	Description

Command	Description
ACTIVATE POLICYSET	Validates and activates a policy set.
DEFINE COPYGROUP	Defines a copy group for backup or archive processing within a specified management class.
DEFINE MGMTCLASS	Defines a management class.
DEFINE POLICYSET	Defines a policy set within the specified policy domain.
DELETE MGMTCLASS	Deletes a management class and its copy groups from a policy domain and policy set.
QUERY COPYGROUP	Displays the attributes of a copy group.
QUERY MGMTCLASS	Displays information about management classes.
QUERY POLICYSET	Displays information about policy sets.
UPDATE COPYGROUP	Changes one or more attributes of a copy group.
UPDATE MGMTCLASS	Changes the attributes of a management class.
VALIDATE POLICYSET	Verifies and reports on conditions the administrator must consider before activating the policy set.

AUDIT commands

Use the AUDIT commands to review or examine the adequacy of the database information and the storage pool volume. The AUDIT LDAPDIRECTORY command deletes nodes or administrator IDs from an LDAP directory server, that do not authenticate their passwords with the LDAP directory server.

- AUDIT CONTAINER
  - AUDIT CONTAINER (Verify the consistency of database information for a cloud container)
  - AUDIT CONTAINER (Verify the consistency of database information for a directory-container)
- AUDIT LDAPDIRECTORY (Audit an LDAP directory server)
- AUDIT LIBRARY (Audit volume inventories in an automated library)
- AUDIT LIBVOLUME (Verify database information for a tape volume)
- AUDIT LICENSES (Audit server storage usage)
- AUDIT VOLUME (Verify database information for a storage pool volume)

AIX | Linux | Windows

AUDIT CONTAINER commands

Use the AUDIT CONTAINER command to scan for inconsistencies between database information and a container in either a cloud or a directory storage pool.

- AUDIT CONTAINER (Verify the consistency of database information for a cloud container)
  Use this command to scan for inconsistencies between database information and a container in a cloud-container storage pool. Cloud-container storage pools are not supported on Linux on System z®.
- AUDIT CONTAINER (Verify the consistency of database information for a directory-container)
  Use this command to scan for inconsistencies between database information and a container in a directory-container storage pool.

AUDIT CONTAINER (Verify the consistency of database information for a cloud container)

Use this command to scan for inconsistencies between database information and a container in a cloud-container storage pool. Cloud-container storage pools are not supported on Linux on System z®.

You can use this command to complete the following actions for a container in a cloud-container storage pool:

- Scan the contents of a container to validate the integrity of the data extents

- Remove data from a container that is marked as *damaged*, such as when a file has references in the server database, but has missing or corrupted data in the cloud
- Mark an entire container as damaged
- Remove data that is marked as *orphaned*, such as when an object stored in the cloud does not have a reference in the server database

Privilege class

To use this command, you must have system privilege, or unrestricted storage privilege.

Syntax

```
>>-AUDit CONTainer--+-container_name-----------------------------------------------+-->
                    +-STGpool--=--pool_name-----------------------------------+
                    '-STGpool--=--pool_name--STGPOOLDIRectory--=--directory_name-'

   .-Action--=--SCANAll-----------.
>--+------------------------------+----------------------------->
   '-Action--=--+-SCANAll-------+-'
                +-REMOVEDamaged-+
                +-MARKDamaged---+
                '-SCANDamaged---'

   .-FORCEOrphandbdel--=--No------.
>--+------------------------------+----------------------------->
   '-FORCEOrphandbdel--=--+-No--+-'
                          '-Yes-'

   .-MAXProcess--=--4------.  .-Wait--=--No------.
>--+----------------------+--+------------------+-------------->
   '-MAXProcess--=--number-'  '-Wait--=--+-No--+-'
                                         '-Yes-'

   .-BEGINDate--=--before_first_audit-.
>--+----------------------------------+------------------------->
   '-BEGINDate--=--begin_date---------'

   .-BEGINTime--=--00:00:00---.
>--+--------------------------+-------------------------------->
   '-BEGINTime--=--begin_time-'

   .-ENDDate--=--after_last_audit-.  .-ENDTime--=--23:59:59-.
>--+-------------------------------+--+----------------------+-->
   '-ENDDate--=--end_date---------'  '-ENDTime--=--end_time-'
```

Parameters

container_name
: Specifies the name of the container that you want to audit. If you do not specify this parameter, you must specify a cloud-container storage pool.

STGpool
: Specifies the name of the cloud-container storage pool that you want to audit. This parameter is optional. If you specify only this parameter, all containers that are defined to the storage pool are audited. If you do not specify this parameter, you must specify a container.

STGPOOLDIRectory
: Specifies the name of the cloud-container storage pool directory that you want to audit. This parameter is optional. Restriction: You must specify a storage pool that uses local storage.

Action
: Specifies what action the server takes when a container in a cloud-container storage pool is audited. This parameter is optional. You can specify one of the following values:

  SCANAll
  : Specifies that the server identifies database records that refer to data extents with inconsistencies. A check is done for data in the cloud-container storage pool that does not match data in the server database. This value is the default. The server marks the data extent as damaged in the database.

Tip: If you specify the ACTION=SCANALL parameter on an IBM® Cloud Object Storage storage pool that uses a vault with name indexing disabled, the audit operation scans the entire vault to identify orphaned extents in each container. In this situation, specify WAIT=YES if you want the audit operation to wait for the scan for orphaned extents to complete before it reports the audit as complete. This scan for orphaned extents occurs only if you do not specify a container name. If you specify a container that is in a vault with name indexing disabled, the audit operation does not scan for orphaned extents.

REMOVEDamaged
: Specifies that the server removes any references to damaged extents from the server database. The damaged extents are also removed from the cloud-container storage pool if found. The server also removes any orphaned extents from the cloud-container storage pool, and removes the references to these orphaned extents from the database, as specified by the FORCEORPHANDBDEL parameter.

MARKDamaged
: Specifies that the server explicitly marks all data extents in the container as damaged.

SCANDamaged
: Specifies that the server checks only the existing damaged extents in the container.

Important: If no connection to the cloud exists, the ACTION=SCANALL and ACTION=SCANDAMAGED parameters do not run. However, the ACTION=MARKDAMAGED parameter runs as expected without a cloud connection, and the ACTION=REMOVEDAMAGED parameter marks any damaged data as orphaned. As soon as the connection to the cloud returns, the server deletes the orphaned extents.

State reset condition: If the audit does not detect an error with a data extent that is marked as damaged, the state of the data extent is reset. The data extent can then be used. This condition provides a means for resetting the state of damaged data extents if errors are caused by a correctable problem. The SCANALL and SCANDAMAGED options are the only options that reset a damaged extent if it is found not to be damaged.

FORCEOrphandbdel
: Specifies that the server forces the deletion of orphaned extents from the server database, even if they are not deleted from the cloud-container storage pool. This parameter is optional. If you specify this parameter, you must also specify the ACTION=REMOVEDAMAGED parameter. The following options are available:

Yes
: Specifies that the server deletes any orphaned extents from the server database, even if they are not deleted from the cloud-container storage pool.

No
: Specifies that the server keeps the orphaned extents in the server database if they cannot be deleted from the cloud-container storage pool. This value is the default.

MAXProcess
: Specifies the maximum number of parallel processes to use for checking a container in a cloud-container storage pool. This parameter is optional. Enter a value in the range 1 - 99. The default value is 4.

Restriction: The server ignores this parameter when you use MAXPROCESS with the ACTION=REMOVEDAMAGED parameter.

Wait
: Specifies whether the audit or verification operation is completed in the foreground or background. This parameter is optional. The following options are available:

No
: Specifies that the operation is completed in the background. You can continue with other tasks when the command is processing. Messages that are related to the background process are displayed in the activity log file or the server console, depending on where the messages are logged. This value is the default.

Yes
: Specifies that the operation is completed in the foreground. It might take a long time to complete the operation. The operation must complete before you can continue with other tasks. Messages are displayed in the activity log file or the server console, or both, depending on where the messages are logged.

Restriction: You cannot specify the WAIT=YES parameter from the server console.

BEGINDate
: Specifies the date range value at which auditing should start. Containers that were last audited within the specified date range are audited. If you specify a time but do not specify a beginning date, the current date is used. If you do not specify a beginning and end date, all containers are audited. The default is the date before the first audit was completed for the container. This parameter is optional.

You can specify the date to begin the audit in one of the following ways:

Value	Description	Example

Value	Description	Example
MM/DD/YYYY	A specific date.	09/15/2016
TODAY	The current date.	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY –7 *or* –7. To audit all containers that were audited in the last week, specify BEGINDATE=TODAY-7 or BEGINDATE= -7.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include containers that were audited a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include containers that were audited on the 10th day of the current month.

BEGINTime

Specifies the time range value at which auditing should start. Containers that were last audited within the specified time range are audited. If you do not specify a beginning and end time, the time range is set from 00:00:00 to 23:59:59. The default is 00:00:00. If you did not specify a date range, the default is today's date. This parameter is optional.

You can specify the date to begin the audit in one of the following ways:

Value	Description	Example
HH:MM:SS	A specific time on the specified begin date.	10:30:08
NOW	The current time on the specified begin date.	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes on the specified begin date.	NOW+03:00 *or* +03:00. If you issue this command at 9:00 with BEGINTIME=NOW+3 or BEGINTIME=+3, containers with a last audit time of 12:00 or later on the begin date are audited.
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes on the specified begin date.	NOW-04:00 *or* -04:00. If you issue this command at 9:00 with BEGINTime=NOW-3:30 or BEGINTime= -3:30, IBM Spectrum Protect™ audits containers with a last audit time of 5:30 or later on the begin date.

ENDDate

Specifies the date range value at which auditing should stop. Containers that were last audited within the specified date range are audited. If you specify a time but do not specify a value, the current date is used. If you do not specify a beginning and end date, all containers are audited. The default is the date after the last audit was completed for the container. This parameter is optional.

You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date.	09/15/2016
TODAY	The current date.	TODAY

Value	Description	Example
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY–1 *or* –1. To include containers that were audited up to yesterday, you can specify ENDDATE=TODAY-1 or ENDDATE= -1.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include containers that were audited a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include containers that were audited on the 10th day of the current month.

ENDTime

Specifies the time range value at which auditing should stop. Containers that were last audited within the specified time range are audited. If you do not specify a beginning and end time, the time range is set to 00:00:00 to 23:59:59. The default is 23:59:59. This parameter is optional.

You can specify the time using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time on the specified end date.	10:30:08
NOW	The current time on the specified end date.	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes on the specified end date.	NOW+03:00 *or* +03:00. If you issue this command at 9:00 with ENDTIME=NOW+3:00 or ENDTIME= +3:00, containers with a last audit time of 12:00 or earlier on the end date you specify are audited.
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes on the specified end date.	NOW-03:30 *or* -03:30. If you issue this command at 9:00 with ENDTIME=NOW-3:30 or ENDTIME= -3:30, containers with a last audit time of 5:30 or earlier on the end date you specify are audited.

Example: Audit a specific container in a cloud-container storage pool

Audit the 42-00000my000example000container000 container in a cloud-container storage pool.

```
audit container 42-00000my000example000container000 action=scanall
```

Example: Audit a cloud-container storage pool within a specific time frame

Audit a cloud-container storage pool that is named POOL3 and only include containers from yesterday between 9:30 and 12:30.

```
audit container stgpool=pool3 begindate=today-1
begintime=09:30:00 endtime=12:30:00
```

Table 1. Commands related to AUDIT CONTAINER

Command	Description
CANCEL PROCESS	Cancels a background server process.
QUERY CONTAINER	Displays information about a container.

Command	Description
QUERY DAMAGED	Displays information about damaged files.

AIX Linux Windows

AUDIT CONTAINER (Verify the consistency of database information for a directory-container)

Use this command to scan for inconsistencies between database information and a container in a directory-container storage pool.

You can use this command to complete the following actions for a container in a directory-container storage pool:

- Scan the contents of a container to validate the integrity of the data extents
- Remove damaged data from a container
- Mark an entire container as damaged

Privilege class

To issue this command, you must have system privilege, or unrestricted storage privilege.

Syntax

```
>>-AUDit CONTainer--+-container_name-----------------------------------------------+-->
                    +-STGpool--=--pool_name-----------------------------------+
                    '-STGpool--=--pool_name--STGPOOLDIRectory--=--directory_name-'

>--+-------------------------------+--+----------------------+--><
   '-ENDDate--=--end_date---------'  '-ENDTime--=--end_time-'
```

Parameters

container_name
: Specifies the name of the container that you want to audit. If you do not specify this parameter, you must specify a directory-container storage pool.

STGpool
: Specifies the name of the directory-container storage pool that you want to audit. This parameter is optional. If you specify only this parameter, all containers that are defined to the storage pool are audited. If you do not specify this parameter, you must specify a container.

STGPOOLDIRectory
: Specifies the name of the container storage pool directory that you want to audit. This parameter is optional. If you specify this parameter, all containers that are defined to the container storage pool directory are audited. To specify this parameter,

you must also specify a storage pool.

Action

Specifies what action the server takes when a container in a directory-container storage pool is audited. This parameter is optional. You can specify one of the following values:

SCANAll

Specifies that the server identifies database records that refer to data extents with inconsistencies. This value is the default. The server marks the data extent as damaged in the database.

Tip: If you used the PROTECT STGPOOL command on a directory-container storage pool on the target server, you can repair the damaged data extent by using the REPAIR STGPOOL command.

REMOVEDamaged

Specifies that the server removes any files from the database that reference the damaged data extent.

MARKDamaged

Specifies that the server explicitly marks all data extents in the container as damaged.

SCANDamaged

Specifies that the server checks only the existing damaged extents in the container.

State reset condition: If the audit does not detect an error with a data extent that is marked as damaged, the state of the data extent is reset. The data extent can then be used. This condition provides a means for resetting the state of damaged data extents if errors are caused by a correctable problem. The SCANALL and SCANDAMAGED options are the only options that reset a damaged extent if it is found not to be damaged.

MAXProcess

Specifies the maximum number of parallel processes to use for checking a container in a directory-container storage pool. This parameter is optional. Enter a value in the range 1 - 99. The default value is 4.

Wait

Specifies whether the audit or verification operation is completed in the foreground or background. This parameter is optional. The following options are available:

No

Specifies that the operation is completed in the background. You can continue with other tasks when the command is processing. Messages that are related to the background process are displayed in the activity log file or the server console, depending on where the messages are logged. This is the default value.

Yes

Specifies that the operation is completed in the foreground. It might take a long time to complete the operation. The operation must complete before you can continue with other tasks. Messages are displayed in the activity log file or the server console, or both, depending on where the messages are logged.

Restriction: You cannot specify the WAIT=YES parameter from the server console.

BEGINDate

Specifies the date range value at which auditing should start. Containers that were last audited within the specified date range are audited. If you specify a time but do not specify a beginning date, the current date is used. If you do not specify a beginning and end date, all containers are audited. The default is the date before the first audit was completed for the container. This parameter is optional.

You can specify the date to begin the audit in one of the following ways:

Value	**Description**	**Example**
MM/DD/YYYY	A specific date.	09/15/2016
TODAY	The current date.	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY –7 *or* –7. To audit all containers that were audited in the last week, specify BEGINDATE=TODAY-7 or BEGINDATE= -7.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include containers that were audited a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM

Value	Description	Example
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include containers that were audited on the 10th day of the current month.

BEGINTime

Specifies the time range value at which auditing should start. Containers that were last audited within the specified time range are audited. If you do not specify a beginning and end time, the time range is set from 00:00:00 to 23:59:59. The default is 00:00:00. If you did not specify a date range, the default is today's date. This parameter is optional.

You can specify the date to begin the audit in one of the following ways:

Value	Description	Example
HH:MM:SS	A specific time on the specified begin date.	10:30:08
NOW	The current time on the specified begin date.	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes on the specified begin date.	NOW+03:00 *or* +03:00. If you issue this command at 9:00 with BEGINTIME=NOW+3 or BEGINTIME=+3, containers with a last audit time of 12:00 or later on the begin date are audited.
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes on the specified begin date.	NOW-04:00 *or* -04:00. If you issue this command at 9:00 with BEGINTime=NOW-3:30 or BEGINTime= -3:30, IBM Spectrum Protect™ audits containers with a last audit time of 5:30 or later on the begin date.

ENDDate

Specifies the date range value at which auditing should stop. Containers that were last audited within the specified date range are audited. If you specify a time but do not specify a value, the current date is used. If you do not specify a beginning and end date, all containers are audited. The default is the date after the last audit was completed for the container. This parameter is optional.

You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date.	09/15/2016
TODAY	The current date.	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY–1 *or* –1. To include containers that were audited up to yesterday, you can specify ENDDATE=TODAY-1 or ENDDATE= -1.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include containers that were audited a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include containers that were audited on the 10th day of the current month.

ENDTime

Specifies the time range value at which auditing should stop. Containers that were last audited within the specified time range are audited. If you do not specify a beginning and end time, the time range is set to 00:00:00 to 23:59:59. The

default is 23:59:59. This parameter is optional.
You can specify the time using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time on the specified end date.	10:30:08
NOW	The current time on the specified end date.	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes on the specified end date.	NOW+03:00 *or* +03:00. If you issue this command at 9:00 with ENDTIME=NOW+3:00 or ENDTIME= +3:00, containers with a last audit time of 12:00 or earlier on the end date you specify are audited.
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes on the specified end date.	NOW-03:30 *or* -03:30. If you issue this command at 9:00 with ENDTIME=NOW-3:30 or ENDTIME= -3:30, containers with a last audit time of 5:30 or earlier on the end date you specify are audited.

Example: Audit a specific storage pool container

Audit the 0000000000000721.dcf storage pool container.

```
audit container n:\ddcont2\07\0000000000000721.dcf action=scanall
```

Example: Remove damaged data from a directory-container storage pool

Audit a directory-container storage pool that is named NEWDEDUP and remove damaged files.

```
audit container stgpool=newdedup action=removedamaged
```

Example: Mark as damaged all of the data in a directory-container storage pool

Audit a directory-container storage pool that is named NEWDEDUP and mark all files as damaged.

```
audit container stgpool=newdedup maxprocess=2 action=markdamaged
```

Example: Audit a directory-container storage pool within a specific time frame

Audit a directory-container storage pool that is named POOL2 and only include containers before yesterday between 9:30 and 12:30.

```
audit container stgpool=pool2 begindate=today-1
begintime=09:30:00 endtime=12:30:00
```

Table 1. Commands related to AUDIT CONTAINER

Command	Description
CANCEL PROCESS	Cancels a background server process.
MOVE CONTAINER	Moves the contents of a storage pool container to another container.
QUERY DAMAGED	Displays information about damaged files.

AUDIT LDAPDIRECTORY (Audit an LDAP directory server)

Use this command to audit an IBM Spectrum Protect™ controlled namespace on a Lightweight Directory Access Protocol (LDAP) server. The LDAP server and namespace are specified by using one or more LDAPURL options.

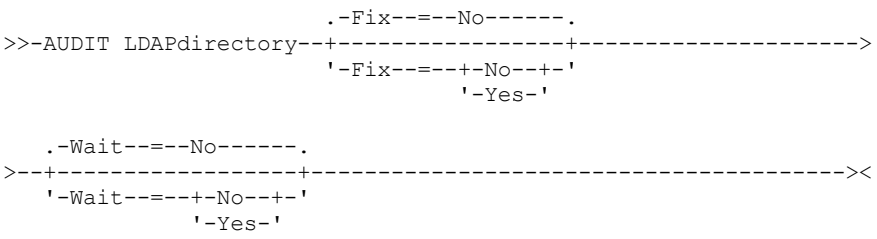
Restriction: Use this command only if you configured password authentication as described in Authenticating users by using an LDAP server. Information that is provided about the AUDIT LDAPDIRECTORY command applies only to environments in which

password authentication is configured as described in Authenticating users by using an LDAP server.
Nodes and administrator user IDs that do not authenticate their passwords with the LDAP directory server are deleted with the AUDIT LDAPDIRECTORY FIX=YES command. Nodes or administrator user IDs that no longer exist in the IBM Spectrum Protect database are also deleted.
Before you issue this command, ensure that the LDAPURL option is specified in the dsmserv.opt file. See the LDAPURL option for more information. If you specified more than one LDAPURL option in the dsmserv.opt file, each option is validated in the order in which they are placed. If the LDAPURL option is not specified, the command fails.

Privilege class

You must have system privileges to issue this command.

Syntax



Parameters

Fix
: This optional parameter specifies how the IBM Spectrum Protect server resolves inconsistencies between the database and the external directory. The default is NO. You can specify the following values:

  No
  : The server reports all inconsistencies but does not change the external directory.

  Yes
  : The server resolves any inconsistencies that it can and suggests further actions, if needed.
  Important: If there are LDAP entries that are shared with other IBM Spectrum Protect servers, choosing YES might cause those servers to become out-of-sync.

Wait
: This optional parameter specifies whether to wait for the IBM Spectrum Protect server to complete processing this command in the foreground. The default is NO. You can specify the following values:

  No
  : The server processes this command in the background and you can continue with other tasks while the command is processing. Messages related to the background process are shown either in the activity log file or the server console, depending on where the messages are logged.

  Yes
  : The server processes this command in the foreground. The operation must complete before you can continue with other tasks. Messages are shown either in the activity log file or the server console, or both, depending on where the messages are logged.
  Restriction: You cannot specify WAIT=YES from the server console.

Example: Audit an LDAP directory and repair inconsistencies

Audit the LDAP directory that you specified in the LDAPURL option. The IBM Spectrum Protect server resolves some inconsistencies.

```
audit ldapdirectory fix=yes

ANR2749W Admin ADMIN1 was located in the LDAP directory server but not
in the database.
ANR2749W Admin ADMIN2 was located in the LDAP directory server but not
in the database.
```

```
ANR2749W Admin NODE1 was located in the LDAP directory server but not
in the database.
ANR2749W Admin NODE2 was located in the LDAP directory server but not
in the database.
ANR2748W Node NODE1 was located in the LDAP directory server but not
in the database.
ANR2748W Node NODE2 was located in the LDAP directory server but not
in the database.
ANR2745I AUDIT LDAPDIRECTORY command completed: 4 administrator
entries are only in the LDAP directory server (not in the IBM Spectrum
Protect server), 0 administrator entries are only in the IBM Spectrum
Protect server (not in the LDAP directory server), 2 node entries are
only in the LDAP directory server (not in the IBM Spectrum Protect
server), 0 node entries are only in the IBM Spectrum Protect server,
(not in the LDAP directory server), 6 entries were deleted from the
LDAP server in total.
```

Related commands

Table 1. Commands related to AUDIT LDAPDIRECTORY

Command	Description
SET DEFAULTAUTHENTICATION	Specifies the default password authentication method for any REGISTER NODE or REGISTER ADMIN commands.
SET LDAPPASSWORD	Sets the password for the LDAPUSER.
SET LDAPUSER	Sets the user who oversees the passwords and administrators on the LDAP directory server.

AUDIT LIBRARY (Audit volume inventories in an automated library)

Use this command to audit and synchronize volume inventories in an automated library.

When the AUDIT LIBRARY command is issued on a library client, the client synchronizes its inventory with the inventory on the library manager. If the library client detects inconsistencies, it corrects them by changing the ownership of the volume on the library manager.

When the AUDIT LIBRARY command is issued on a server where the library is SCSI, 349X, or ACSLS (LIBTYPE=SCSI, LIBTYPE=349X, or LIBTYPE=ACSLS), the server synchronizes its inventory with the inventory of the library device. If the server detects inconsistencies, it deletes missing volumes from its inventory.

- In SCSI libraries, the server also updates the locations of volumes in its inventory that have been moved since the last audit.
- In 349X libraries, the server also ensures that scratch volumes are in the scratch category and that private volumes are in the private category.

When the AUDIT LIBRARY command is issued on a server that is a library manager for the library (SHARED=YES), the server updates ownership of its volumes if it detects inconsistencies.

Regardless the type of server or type of library, issuing the AUDIT LIBRARY command does not automatically add new volumes to a library. To add new volumes, you must use the CHECKIN LIBVOLUME command.

Attention: The following precautions apply to SCSI, 349X, and ACSLS libraries only (LIBTYPE=SCSI, LIBTYPE=349X, and LIBTYPE=ACSLS):

- Running the AUDIT LIBRARY command prevents any other library activity until the audit completes. For example, the server will not process restore or retrieve requests that involve the library when the AUDIT LIBRARY command is running.
- If other activity is occurring in the library, do not issue the AUDIT LIBRARY command. Issuing the AUDIT LIBRARY command when a library is active can produce unpredictable results (for example, a hang condition) if a process currently accessing the library attempts to acquire a new tape mount.

This command creates a background process that you can cancel with the CANCEL PROCESS command. To display information about background processes, use the QUERY PROCESS command.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-AUDIT LIBRary--library_name---------------------------------->

   .-CHECKLabel--=--Yes---------.
>--+----------------------------+------------------------------->
   '-CHECKLabel--=--+-Yes-----+-'
                    '-Barcode-'

   .-REFRESHstate--=--No------.
>--+-------------------------+-------------------------------><
   '-REFRESHstate--=--+-No--+-'
                      '-Yes-'
```

Parameters

library_name (Required)
: Specifies the name of the library to audit.

CHECKLabel
: Specifies how the storage volume label is checked during the audit. This parameter applies to SCSI libraries only. The parameter is ignored for other library types. The default is YES. Possible values are:

  Yes
  : Specifies that the server checks each volume label to verify the identity of the volume.

  Barcode
  : Specifies that the server uses the barcode reader to read the storage label. Using the barcode decreases the audit processing time. This parameter applies only to SCSI libraries.
    Attention: If the scanner cannot read the barcode label or the barcode label is missing, the server loads that tape in a drive to read the label.

REFRESHstate
: Specifies whether the server's information about a library, which is normally obtained during initialization, is refreshed, so that any changes in configuration are reflected. By setting the REFRESHSTATE parameter to Yes, this action is completed without having to restart the server or re-define the library. The default is No. Possible values are:

  No
  : Specifies that the server does not refresh the library's state when the library is audited.

  Yes
  : Specifies that the server does refresh the library's state when the AUDIT LIBRARY command is issued.

Example: Audit an automated library

Audit the EZLIFE automated library.

```
audit library ezlife
```

Related commands

Table 1. Commands related to AUDIT LIBRARY

Command	Description
CANCEL PROCESS	Cancels a background server process.
DEFINE LIBRARY	Defines an automated or manual library.
DELETE LIBRARY	Deletes a library.
DISMOUNT VOLUME	Dismounts a sequential, removable volume by the volume name.
QUERY LIBRARY	Displays information about one or more libraries.
QUERY LIBVOLUME	Displays information about a library volume.

Command	Description
QUERY PROCESS	Displays information about background processes.
UPDATE LIBRARY	Changes the attributes of a library.

AUDIT LIBVOLUME (Verify database information for a tape volume)

Use this command to determine whether a tape volume is intact and to audit data on any tape volume.

You can issue the AUDIT LIBVOLUME command from any tape volume that is checked in to a library. The command runs in the background by default. You can issue the command from the following library types that have IBM® TS1140, IBM LTO 5, or a later generation tape drive:

- SCSI tape library
- Virtual tape library (VTL)

The following table outlines the tape drives that can verify tape volumes with media types for IBM TS1140 and IBM LTO 5 and later generation LTO tape drives:

Table 1. Tape drives and the media types

Drive	Media type
TS1140	JB, JX, JA, JW, JJ, JR, JC, JY, and JK
IBM LTO 5	LTO 3, LTO 4, and LTO 5
IBM LTO 6	LTO 4, LTO 5, and LTO 6
IBM LTO 7	LTO 5, LTO 6, and LTO 7

The following table outlines the minimum device driver level that you require to run the command:

Table 2. Minimum IBM device driver level

Driver name	Device driver level
Atape driver on AIX®	12.3.5.00
lin_tape driver on Linux	1.6.7.00
IBM tape driver on Windows	6.2.2.00

Restriction: You cannot issue the CANCEL PROCESS command while the AUDIT LIBVOLUME command is in progress.

Privilege class

To issue this command, you must have system privilege, or unrestricted storage privilege for the library to which the tape volume is defined.

Syntax

```
>>-AUDit LIBVolume--library_name--volume_name------------------->

   .-Wait--=--No------.
>--+------------------+---------------------------------------><
   '-Wait--=--+-No--+-'
              '-Yes-'
```

Parameters

library_name (Required)
: Specifies the name of the library volume where the tape volume is located that you want to audit.

volume_name (Required)
: Specifies the name of the physical tape volume that you want to audit.

Wait (Optional)
: Specifies whether the audit or verification operation is completed in the foreground or background. This parameter is optional. The following options are available:

No
: Specifies that the operation is completed in the background. The NO value is the default value.

Yes
: Specifies that the operation is completed in the foreground. It might take a long time to complete the operation.

Example: Audit a tape volume

Audit the EZLIFE library that has a tape volume that is called KM0347L5.

```
audit libvolume ezlife KM0347L5
```

AUDIT LICENSES (Audit server storage usage)

Use this command to audit the server storage used by client nodes and to audit the server licenses. The audit determines whether the current configuration is in compliance with the license terms.

An audit creates a background process you can cancel with the CANCEL PROCESS command. If you halt and restart the server, an audit is run automatically as specified by the SET LICENSEAUDITPERIOD. To view audit results, use the QUERY LICENSE command.

Attention: The audit of server storage can take a lot of CPU time. You can use the AUDITSTORAGE server option to specify that storage is not to be audited.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-AUDit LICenses-----------------------------------------------><
```

Parameters

None.

Example: Audit server licenses

Issue the AUDIT LICENSES command.

```
audit licenses
```

Related commands

Table 1. Commands related to AUDIT LICENSES

Command	Description
CANCEL PROCESS	Cancels a background server process.
QUERY AUDITOCCUPANCY	Displays the server storage utilization for a client node.
QUERY LICENSE	Displays information about licenses and audits.
QUERY PROCESS	Displays information about background processes.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REGISTER LICENSE	Registers a license with the IBM Spectrum Protect server.
SET LICENSEAUDITPERIOD	Specifies the number of days between automatic license audits.

AUDIT VOLUME (Verify database information for a storage pool volume)

Use this command to check for inconsistencies between database information and a storage pool volume. Processing information generated during an audit is sent to the activity log and server console.

Restriction: You cannot use this command for volumes that are assigned to copy-container storage pools.
You can only audit volumes that belong to storage pools with DATAFORMAT=NATIVE and DATAFORMAT=NONBLOCK.

You cannot audit a volume if it is being deleted from a primary or copy storage pool.

While an audit process is active, clients cannot restore data from the specified volume or store new data to that volume.

If the server detects a file with errors, handling of the file will depend on the type of storage pool to which the volume belongs, whether the FIX option is specified on this command, and whether the file is also stored on a volume assigned to other pools.

If IBM Spectrum Protect™ does not detect errors for a file that was marked as damaged, the state of the file is reset so that it can be used.

The server will not delete archive files that are on deletion hold. If archive retention protection is enabled, the server will not delete archive files whose retention period has not expired.

To display information about the contents of a storage pool volume, use the QUERY CONTENT command.

To audit multiple volumes, you can use the FROMDATE and TODATE parameters. Use the STGPOOL parameter to audit all volumes in a storage pool. When you use the parameters FROMDATE, TODATE, or both, the server limits the audit to only the sequential media volumes that meet the date criteria, and automatically includes all online disk volumes in storage. To limit the number of volumes that may include disk volumes, use the FROMDATE, TODATE, and STGPOOL parameters.

If you are running a server with archive retention protection enabled, and you have data stored in storage pools which are defined with the parameter RECLAMATIONTYPE=SNAPLOCK, the Last Access Date on the NetApp SnapLock Filer for a volume should be equal to the End Reclaim Period date that you see when you issue a QUERY VOLUME F=D command on that volume. During AUDIT VOLUME processing, these dates are compared. If they do not match and the AUDIT VOLUME command is being run with the FIX=NO parameter, a message will be issued to you indicating that the command should be run with the FIX=YES parameter to resolve the inconsistency. If they do not match and the AUDIT VOLUME command is being run with the FIX=YES parameter, the inconsistencies will be resolved.

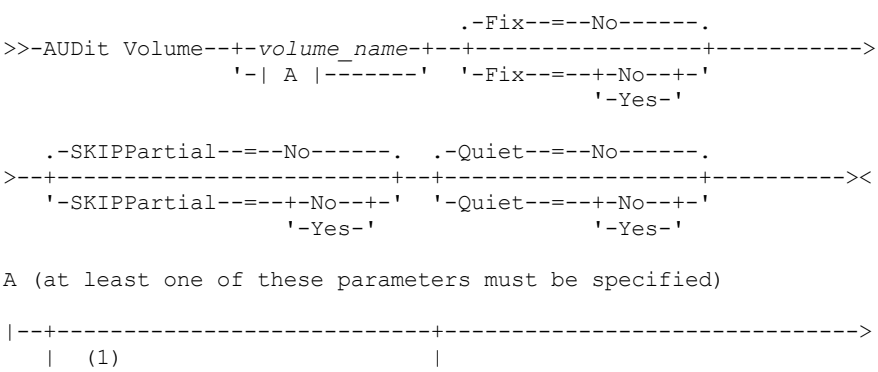
Attention: Use the FIX=Yes parameter only if your tape drive and storage area network (SAN) infrastructure is stable. Ensure that the tape heads are clean and that the tape device drivers are stable and reliable. Otherwise, you risk deleting data that is error free when you use this parameter. The server cannot determine whether a tape is physically damaged or whether a tape infrastructure is unstable.

This command creates a background process that can be canceled with the CANCEL PROCESS command. To display information on background processes, use the QUERY PROCESS command.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the storage pool to which the volume is defined.

Syntax



```
   '-------STGPool--=--poolname-'

      (1)                                          (1)
   .-------FROMDate--=--TODAY-.   .-TODate--=--TODay-----.
>--+------------------------+--+---------------------+-------|
   '-FROMDate--=-----date------'   '-TODate--=-----date----'
```

Notes:

1. You cannot specify a volume name if you specify a storage pool name, FROMDATE, or TODATE.

Parameters

volume_name
: Specifies the name of the storage pool volume you want to audit. This parameter is required if you do not specify a storage pool. You cannot specify a volume name together with the FROMDATE and TODATE parameters.

Fix
: Specifies how the server resolves inconsistencies between the database inventory and the specified storage pool volume. This parameter is optional. The default is NO.

  The actions the server performs depend on whether the volume is assigned to a primary or a copy storage pool.

  Primary Storage Pool:

  Note: If the AUDIT VOLUME command does not detect an error in a file that was previously marked as damaged, IBM Spectrum Protect resets the state of the file so that it can be used. This provides a means for resetting the state of damaged files if it is determined that the errors were caused by a correctable hardware problem such as a dirty tape head.

  Fix=No
  : IBM Spectrum Protect reports, but does not delete, database records that refer to files with inconsistencies:

    - IBM Spectrum Protect marks the file as damaged in the database. If a backup copy is stored in a copy storage pool, you can restore the file using the RESTORE VOLUME or RESTORE STGPOOL command.
    - If the file is a cached copy, you must delete references to the file on this volume by issuing the AUDIT VOLUME command and specifying FIX=YES. If the physical file is not a cached copy, and a duplicate is stored in a copy storage pool, it can be restored by using the RESTORE VOLUME or RESTORE STGPOOL command.

  Fix=Yes
  : The server fixes any inconsistencies as they are detected:

    - If the physical file is a cached copy, the server deletes the database records that refer to the cached file. The primary file is stored on another volume.
    - If the physical file is not a cached copy, and the file is also stored in one or more copy storage pools, the error will be reported and the physical file marked as damaged in the database. You can restore the physical file by using the RESTORE VOLUME or RESTORE STGPOOL command.
    - If the physical file is not a cached copy, and the physical file is not stored in a copy storage pool, each logical file for which inconsistencies are detected are deleted from the database.
    - If archive retention protection is enabled by using the SET ARCHIVERETENTIONPROTECTION command, a cached copy of data can be deleted if needed. Data in primary and copy storage pools can only be marked damaged and never deleted.

    Do not use the AUDIT VOLUME command with FIX=YES if a restore process (RESTORE STGPOOL or RESTORE VOLUME) is running. The AUDIT VOLUME command could cause the restore to be incomplete.

  Copy Storage Pool:

  Fix=No
  : The server reports the error and marks the physical file copy as damaged in the database.

  Fix=Yes
  : The server deletes any references to the physical file and any database records that point to a physical file that does not exist.

SKIPPartial
: Specifies whether IBM Spectrum Protect ignores partial files, which are files that span multiple storage pool volumes. This parameter is optional. The default value is NO. When performing an audit operation on a sequential access media volume,

this parameter prevents additional sequential access media mounts that may be necessary to audit any partial files. Possible values are:

No
: IBM Spectrum Protect audits files that span multiple volumes.
Unless you specify SKIPPARTIAL=YES, IBM Spectrum Protect attempts to process each file stored on the volume, including files that span into and out of other volumes. To audit files that span multiple volumes, the following conditions must be true:

- For sequential access volumes, the additional sequential access volumes must have an access mode of read/write or read-only.
- For random access volumes, the additional volumes must be online.

Yes
: IBM Spectrum Protect audits only files that are stored on the volume to be audited. The status of any partial files is unknown.

Quiet
: Specifies whether IBM Spectrum Protect sends detailed informational messages to the activity log and the server console about irretrievable files on the volume. This parameter is optional. The default is NO. Possible values are:

No
: Specifies that IBM Spectrum Protect sends detailed informational messages and a summary. Each message contains the node, file space, and client name for the file.

Yes
: Specifies that IBM Spectrum Protect sends only a summary report.

FROMDate
: Specifies the beginning date of the range to audit volumes. The default is the current date. All sequential media volumes meeting the time range criteria that were written to after this date are audited. The server includes all online disk volumes in storage. The server starts one audit process for each volume and runs the process serially. You cannot use this parameter if you have specified a volume. This parameter is optional. To limit the number of volumes that may include disk volumes, use the FROMDATE, TODATE, and STGPOOL parameters.
You can specify the date by using one of the following values:

Value	**Description**	**Example**
MM/DD/YYYY	A specific date	10/15/2001 If a date is entered, all candidate volumes written on that day (starting at 12:00:01 am) will be evaluated.
TODAY	The current date	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY –7 *or* –7. To display information beginning with volumes written a week ago, you can specify FROMDATE=TODAY-7 or FROMDATE= -7.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

TODate

Specifies the ending date of the range for volumes to audit. All sequential media volumes meeting the time range criteria that were written to before this date are audited. The server includes all online disk volumes in storage. If you do not specify a value, the server defaults to the current date. You cannot use this parameter if you have specified a volume. This parameter is optional. To limit the number of volumes that may include disk volumes, use the FROMDATE, TODATE, and STGPOOL parameters.

You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	10/15/2001 If a date is entered, all candidate volumes written on that day (ending at 11:59:59 pm) will be evaluated.
TODAY	The current date	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY–1 **or** –1. To display information created up to yesterday, you can specify TODATE=TODAY-1 or simply TODATE= -1.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

STGPool

This parameter specifies that the server only audits the volumes from the specified storage pool. This parameter is optional. You cannot use this parameter if you have specified a volume.

Example: Verify database information for a specific storage pool volume

Verify that the database information for storage pool volume PROG2 is consistent with the data stored on the volume. IBM Spectrum Protect fixes any inconsistencies.

```
audit volume prog2 fix=yes
```

Example: Verify database information for all volumes written to during a specific date range

Verify that the database information for all eligible volumes written to from 3/20/2002 to 3/22/2002 is consistent with data stored on the volume.

```
audit volume fromdate=03/20/2002 todate=03/22/2002
```

Example: Verify database information for all volumes in a specific storage pool

Verify that the database information for all volumes in storage pool STPOOL3 is consistent with data stored on the volume for today.

```
audit volume stgpool=STPOOL3
```

Example: Verify database information for all volumes in a specific storage pool written to in the last two days

Verify that the database information for all volumes in storage pool STPOOL3 is consistent with data stored on the volume for the last two days.

```
audit volume stgpool=STPOOL3 fromdate=-1
```

Related commands

Table 1. Commands related to AUDIT VOLUME

Command	Description
CANCEL PROCESS	Cancels a background server process.
QUERY CONTENT	Displays information about files in a storage pool volume.
QUERY PROCESS	Displays information about background processes.
QUERY VOLUME	Displays information about storage pool volumes.
SET ARCHIVERETENTIONPROTECTION	Specifies whether data retention protection is activated.

BACKUP commands

Use the BACKUP commands to create backup copies of IBM Spectrum Protect™ information or objects.

- BACKUP DB (Back up the database)
- BACKUP DEVCONFIG (Create backup copies of device configuration information)
- BACKUP NODE (Back up a NAS node)
- BACKUP STGPOOL (Back up primary storage pool data to a copy storage pool)
- BACKUP VOLHISTORY (Save sequential volume history information)

BACKUP DB (Back up the database)

Use this command to back up an IBM Spectrum Protect™ database to sequential access volumes.

Attention: To restore a database, the server must use information from the volume history file and the device configuration file. You must make and save copies of the volume history file and the device configuration file. These files cannot be recreated.

To determine how much extra storage space a backup requires, issue the QUERY DB command.

Restrictions: You cannot restore a server database if the release level of the server database backup is different from the release level of the server that is being restored. For example, an error occurs when you restore a Version 6.3 database and you are using a Version 7.1 server.
After the database backup is complete, the IBM Spectrum Protect server backs up information, depending on the options that are specified in the server options file. The following information is backed up:

- Sequential volume-history information is backed up to all files that the VOLUMEHISTORY option specifies
- Information about device configuration is backed up to all files that the DEVCONFIG option specifies
- The server's master encryption key

If there is not enough space available on the defined active log directory volume or file space, you can define the DB2® option, *overflowlogpath*, to use a directory with the required space available. For example, use the following command to use the /home/tsminst2/overflow_dir directory:

```
db2 update db cfg for TSMDB1 using overflowlogpath /home/tsminst2/overflow_dir
```

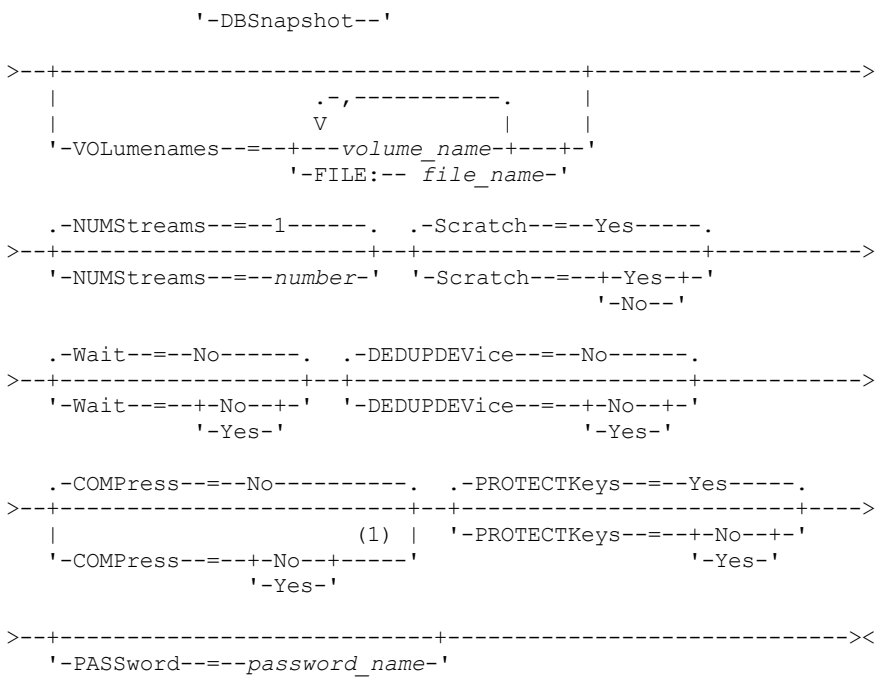
Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-BAckup DB--DEVclass--=--device_class_name--------------------->

   .-Type--=--Full------------.
>--+--------------------------+-------------------------------->
   '-Type--=--+-Incremental-+-'
              +-Full--------+
```



Notes:

1. The default value of the COMPRESS parameter is conditional. If you specify the COMPRESS parameter in the BACKUP DB command, it overrides any COMPRESS parameter value that is set in the SET DBRECOVERY command. Otherwise, the value that is set in the SET DBRECOVERY command is the default.

Parameters

DEVclass (Required)
: Specifies the name of the sequential access device class to use for the backup. If you issue the BACKUP DB command, and the device class is not the one that is specified in the SET DBRECOVERY command, a warning message is issued. However, the backup operation continues and is not affected.

  If the SET DBRECOVERY command is not issued to set a device class, the BACKUP DB command fails.

  Restriction:

  - You cannot use a device class with a device type of NAS or CENTERA.
  - A restore database operation fails if the source for the restore is a FILE library. A FILE library is created if the FILE device class specifies SHARED=YES.

  If all drives for this device class are busy when the backup runs, IBM Spectrum Protect cancels lower priority operations, such as reclamation, to make a drive available for the backup.

Type
: Specifies the type of backup to run. This parameter is optional. The default is FULL. The following values are possible:

  Full
  : Specifies that you want to run a full backup of the IBM Spectrum Protect database.

  Incremental
  : Specifies that you want to run an incremental backup of the IBM Spectrum Protect database. An incremental (or cumulative) backup image contains a copy of all database data that is changed since the last successful full backup operation.

  DBSnapshot
  : Specifies that you want to run a full snapshot database backup. The entire contents of a database are copied and a new snapshot database backup is created without interrupting the existing full and incremental backup series for the database.

VOLumenames

Specifies the volumes that are used to back up the database. This parameter is optional. However, if you specify SCRATCH=NO, you must specify a list of volumes.

volume_name
: Specifies the volumes that are used to back up the database. Specify multiple volumes by separating the names with commas and no intervening spaces.

FILE:filename
: Specifies the name of a file that contains a list of volumes that are used to back up the database. Each volume name must be on a separate line. Blank lines and comment lines, which begin with an asterisk, are ignored.
For example, to use volumes DB0001, DB0002, and DB0003, create a file that contains these lines:

```
DB0001
DB0002
DB0003
```

Name the file appropriately. For example:

- AIX Linux TAPEVOL
- Windows TAPEVOL.DATA

You can then specify the volumes for the command as follows:

AIX Linux

```
VOLUMENAMES=FILE:TAPEVOL
```

Windows

```
VOLUMENAMES=FILE:TAPEVOL.DATA
```

NUMStreams
: Specifies the number of parallel data movement streams to use when you back up the database. The minimum value is 1, and the maximum value is 32. Increasing the value causes a corresponding increase in the number of database backup sessions to be used and the number of drives to be used for the device class. If you specify a NUMSTREAMS value in the BACKUP DB command, it overrides any value that is set in the SET DBRECOVERY command. Otherwise, the value that is set in the SET DBRECOVERY command is used. The NUMSTREAMS value is used for all types of database backups.
If a value is specified that is greater than the number of drives available for the device class, only the number of available drives are used. The available drives are those defined to the device class by the MOUNTLIMIT parameter or by the number of online drives for the specified device class. The session is displayed in the QUERY SESSION output.
If you increase the number of streams, more volumes are used from the corresponding device class for this operation. Using more volumes might improve the speed of the database backups, but at the cost of more volumes that are not fully used.

Scratch
: Specifies whether scratch volumes can be used for the backup. This parameter is optional. The default is YES. The following values are possible:

  Yes
  : Specifies that scratch volumes can be used.

    If you specify SCRATCH=YES and the VOLUMENAMES parameter, IBM Spectrum Protect uses only scratch volumes if space is unavailable on the specified volumes.

    If you do not include a list of volumes by using the VOLUMENAMES parameter, you must either specify SCRATCH=YES or use the default.

  No
  : Specifies that scratch volumes cannot be used.

    If you specify volumes by using the VOLUMENAMES parameter and SCRATCH=NO, the backup fails if there is not enough space available to store the backup data on the specified volumes.

Wait
: Specifies whether to wait for the server to complete processing this command in the foreground. The default is NO. The following values are possible:

  No
  : Specifies that the server processes this command in the background. You can continue with other tasks while the command is being processed.

Messages that are created from the background process are displayed either in the activity log or the server console, depending on where messages are logged.

To cancel a background process, use the CANCEL PROCESS command. If a BACKUP DB background process is canceled, some of the database might have already been backed up before the cancellation.

Yes

Specifies that the server processes this command in the foreground. Wait for the command to complete before you continue with other tasks. The server then displays the output messages to the administrative client when the command completes.
Restriction: You cannot specify WAIT=YES from the server console.

DEDUPDEVice

Specifies that a target storage device supports data deduplication. When set to YES, the format for backup images is optimized for data deduplication devices, making backup operations more efficient. The following values are possible:

No

Specifies that a target storage device does not support data deduplication. NO is the default.
Ensure that this parameter is set to NO for the following devices:

- SCSI libraries
- All devices that are defined with a FILE device class
- Virtual tape libraries (VTL) that do not support the data deduplication function

Yes

Specifies that a target device supports data deduplication and that you want to optimize backups for this function. You can set this parameter to YES if you are using VTLs that support data deduplication.

COMPress

Specifies whether volumes that are created by the BACKUP DB command are compressed. The COMPRESS value is used for all types of database backups. This parameter is optional. The default value is conditional. If you specify the COMPRESS parameter on the BACKUP DB command, it overrides any value that is set in the SET DBRECOVERY command. Otherwise, the value that is set in the SET DBRECOVERY command is the default. You can specify one of the following values:

No

Specifies that the volumes that are created by the BACKUP DB command are not compressed.

Yes

Specifies that the volumes that are created by the BACKUP DB command are compressed.

Restrictions:

- Use caution when you specify the COMPRESS parameter. Using compression during database backups can reduce the size of the backup files. However, compression can increase the time that is required to complete database backup processing.
- Do not back up compressed data to tape. If your system environment stores database backups on tape, set the COMPRESS parameter to No in the SET DBRECOVERY and BACKUP DB commands.

AIX Linux Windows PROTECTKeys

AIX Linux Windows Specifies that database backups include a copy of the server master encryption key that is used to encrypt storage pool data. This parameter is optional. The default is the value that is specified for the PROTECTKEYS parameter on the SET DBRECOVERY command. You can specify one of the following values:

No

Specifies that database backups do not include a copy of the server master encryption key.
Attention: If you specify PROTECTKEYS=NO, you must manually back up the master encryption key for the server and make the key available when you implement disaster recovery.

Yes

Specifies that database backups include a copy of the server master encryption key.
Attention: If you specify PROTECTKEYS=YES, you must also specify the PASSWORD parameter.

AIX Linux Windows PASSword

AIX Linux Windows Specifies the password that is used to protect the database backup. The default is the value that is specified for the PASSWORD parameter on the SET DBRECOVERY command.

Important: Ensure that you remember this password. If you specify a password for database backups, you must specify the same password on the RESTORE DB command to restore the database.

Example: Run an incremental backup by using a scratch volume

Run an incremental backup of the database by using a scratch volume. Use a device class of FILE for the backup.

```
backup db devclass=file type=incremental
```

AIX | Linux | Windows

Example: Encrypt storage pool data in database backups

Encrypt storage pool data by specifying that database backups include a copy of the server master encryption key. Issue the following command:

```
backup db protectkeys=yes password=password_name
```

Related commands

Table 1. Commands related to BACKUP DB

Command	Description
BACKUP DEVCONFIG	Backs up IBM Spectrum Protect device information to a file.
BACKUP VOLHISTORY	Records volume history information in external files.
CANCEL PROCESS	Cancels a background server process.
DELETE VOLHISTORY	Removes sequential volume history information from the volume history file.
EXPIRE INVENTORY	Manually starts inventory expiration processing.
MOVE DRMEDIA	Moves DRM media onsite and offsite.
PREPARE	Creates a recovery plan file.
QUERY DB	Displays allocation information about the database.
QUERY PROCESS	Displays information about background processes.
QUERY VOLHISTORY	Displays sequential volume history information that has been collected by the server.
SET DBRECOVERY	Specifies the device class to be used for automatic backups.
SET DRMDBBACKUPEXPIREDAYS	Specifies criteria for database backup series expiration.

BACKUP DEVCONFIG (Create backup copies of device configuration information)

Use this command to back up information about device configuration for the server.

Attention: To restore a database, the server must use information from the volume history file and the device configuration file. You must make and save copies of the volume history file and the device configuration file. These files cannot be recreated. This command backs up the following information in one or more files:

- Device class definitions
- Library definitions
- Drive definitions
- Path definitions when SRCTYPE=SERVER
- Server definitions
- Server name
- Server password
- Volume location information for LIBTYPE=SCSI libraries

AIX Linux You can use the DEVCONFIG server option to specify one or more files in which to store device configuration information. IBM Spectrum Protect™ updates the files whenever a device class, library, or drive is defined, updated, or deleted.

Windows At installation, the server options file includes a DEVCONFIG option that specifies a device configuration file named devcnfg.out. IBM Spectrum Protect updates this file whenever a device class, library, or drive is defined, updated, or deleted.

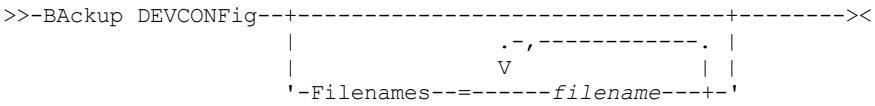
To ensure updates are complete before the server is halted:

- Do not halt the server for a few minutes after issuing the BACKUP DEVCONFIG command.
- Specify multiple DEVCONFIG options in the server options file.
- Examine the device configuration file to see if the file has been updated.

Privilege class

Any administrator can issue this command unless it includes the FILENAMES parameter. If the FILENAMES parameter is specified and the REQSYSAUTHOUTFILE server option is set to YES, the administrator must have system privilege. If the FILENAMES parameter is specified and the REQSYSAUTHOUTFILE server option is set to NO, the administrator must have operator, policy, storage or system privilege.

Syntax



Parameters

Filenames
: Specifies the files in which to store device configuration information. You can specify multiple files by separating the names with commas and no intervening spaces. This parameter is optional.

  If you do not specify a file name, IBM Spectrum Protect stores the information in all files specified with the DEVCONFIG option in the server options file.

Example: Backup device configuration information to a file

Back up device configuration information to a file named DEVICE.

```
backup devconfig filenames=device
```

Related commands

Table 1. Commands related to BACKUP DEVCONFIG

Command	Description
CHECKIN LIBVOLUME	Checks a storage volume into an automated library.
CHECKOUT LIBVOLUME	Checks a storage volume out of an automated library.
DEFINE DEVCLASS	Defines a device class.
AIX Linux DEFINE DEVCLASS (z/OS® media server)	AIX Linux Defines a device class to use storage managed by a z/OS media server.
DEFINE DRIVE	Assigns a drive to a library.
DEFINE LIBRARY	Defines an automated or manual library.
DEFINE PATH	Defines a path from a source to a destination.
DEFINE SERVER	Defines a server for server-to-server communications.
LABEL LIBVOLUME	Labels volumes in manual or automated libraries.
QUERY LIBVOLUME	Displays information about a library volume.

Command	Description
SET SERVERNAME	Specifies the name by which the server is identified.
SET SERVERPASSWORD	Specifies the server password.
UPDATE DEVCLASS	Changes the attributes of a device class.
AIX Linux UPDATE DEVCLASS (z/OS media server)	AIX Linux Changes the attributes of a device class for storage managed by a z/OS media server.
UPDATE DRIVE	Changes the attributes of a drive.
UPDATE LIBRARY	Changes the attributes of a library.
UPDATE LIBVOLUME	Changes the status of a storage volume.
UPDATE PATH	Changes the attributes associated with a path.
UPDATE SERVER	Updates information about a server.

BACKUP NODE (Back up a NAS node)

Use this command to start a backup operation for a network-attached storage (NAS) node.

Backups that are created for NAS nodes with this BACKUP NODE command are functionally equivalent to backups that are created by using the BACKUP NAS command on an IBM Spectrum Protect™ client. You can restore these backups with either the server's RESTORE NODE command or the client's RESTORE NAS command.

Privilege class

To issue this command, you must have system privilege, policy privilege for the domain to which the node is assigned, or client owner authority over the node.

Syntax

Parameters

node_name (Required)
: Specifies the node for which the backup will be performed. You cannot use wildcard characters or specify a list of names.

file_system_name
: Specifies the name of one or more file systems to back up. You can also specify names of virtual file spaces that have been defined for the NAS node. The file system name that you specify cannot contain wildcard characters. You can specify more than one file system by separating the names with commas and no intervening spaces.

If you do not specify a file system, all file systems will be backed up. Any virtual file spaces defined for the NAS node are backed up as part of the file system image, not separately.

If a file system exists on the NAS device with the same name as the virtual file space specified, IBM Spectrum Protect automatically renames the existing virtual file space in the server database, and backs up the NAS file system which matches the name specified. If the virtual file space has backup data, the file space definition associated with the virtual file space will also be renamed.

Tip: See the virtual file space name parameter in the DEFINE VIRTUALFSMAPPING command for more naming considerations.

In determining the file systems to process, the server will not use any DOMAIN.NAS, INCLUDE.FS.NAS, or EXCLUDE.FS.NAS statements in any client option file or client option set. If you back up multiple file systems, the backup of each file system is a separate server process.

MGmtclass
Specifies the name of the management class to which this backup data is bound. If you do not specify a management class, the backup data is bound to the default management class of the policy domain to which the node is assigned. In determining the management class, the server will *not* use any INCLUDE.FS.NAS statements in any client option file or client option set. The destination management class might refer to an IBM Spectrum Protect native pool, in which case Network Data Management Protocol (NDMP) data is sent into the IBM Spectrum Protect native hierarchy. After this occurs, the data stays in the IBM Spectrum Protect hierarchy. Data flowing to IBM Spectrum Protect native pools goes over the LAN and data flowing to NAS pools can be directly attached or over a SAN.

When you specify a management class with the BACKUP NODE command, all versions of the backup data that belong to the NAS node are rebound to the new management class.

TOC
Specifies whether a table of contents (TOC) is saved for each file system backup. Consider the following in determining whether you want to save a table of contents:

- If a table of contents is saved, you will be able to use the QUERY TOC command to determine the contents of a file system backup in conjunction with the RESTORE NODE command to restore individual files or directory trees. You can also use the IBM Spectrum Protect web backup-archive client to examine the entire file system tree and choose files and directories to restore. Creation of a table of contents requires that you define the TOCDESTINATION attribute in the backup copy group for the management class to which this backup image is bound. Creating a table of contents requires additional processing, network resources, storage pool space, and possibly a mount point during the backup operation.
- A table of contents for a NAS file system cannot have a directory path greater than 1024 characters.
- If a table of contents is not saved for a file system backup, you will still be able to restore individual files or directory trees using the RESTORE NODE command, provided that you know the fully qualified name of each file or directory to be restored and the image in which that object was backed up.

This parameter is optional. The default value is Preferred. Possible values are:

No
Specifies that table of contents information is not saved for file system backups.
Preferred
Specifies that table of contents information should be saved for file system backups. However, a backup does not fail just because an error occurs during creation of the table of contents. This is the default value.
Yes
Specifies that table of contents information must be saved for each file system backup. A backup fails if an error occurs during creation of the table of contents.

Attention: If MODE=DIFFERENTIAL is specified and a table of contents is requested (TOC=PREFERRED or TOC=YES), but the last full image does not have a table of contents, a full backup will be performed and a table of contents will be created for that full backup.

Wait
Specifies whether to wait for the server to complete processing this command in the foreground. The default is NO. Possible values are:

No
Specifies that the server processes this command in the background. Use the QUERY PROCESS command to monitor the background processing of this command.
Yes

Specifies that the server processes this command in the foreground. You wait for the command to complete before continuing with other tasks. The server then displays the output messages to the administrative client when the command completes. If you are backing up multiple file systems, all backup processes must complete before the command is complete.
Attention: You cannot specify WAIT=YES from the server console.

MODE

Specifies whether the file system backups are full or differential. The default is DIFFERENTIAL.

FULL
Specifies to back up the entire file system.

DIFFerential
Specifies that only the files that have changed since the most recent full backup should be backed up. If you choose a differential backup, and a full backup is not found, a full backup is performed. You cannot specify TYPE=SNAPMIRROR when the MODE parameter is set to DIFFERENTIAL.

TYPE

Specifies the backup method used to perform the NDMP backup operation. The default value for this parameter is BACKUPIMAGE and it should be used to perform a standard NDMP base or differential backup. Other image types represent backup methods that might be specific to a particular file server. Possible values are:

BACKUPImage
Specifies that the file system should be backed up using an NDMP dump operation. This is the default method for performing an NDMP backup. The BACKUPIMAGE type operation supports full and differential backups, file-level restore processing and directory-level backup.

SNAPMirror
Specifies that the file system should be copied to an IBM Spectrum Protect storage pool using the NetApp SnapMirror to Tape function. SnapMirror images are block level full backup images of a file system. Typically, a SnapMirror backup takes significantly less time to perform than a traditional NDMP full file system backup. However there are limitations and restrictions on how SnapMirror images can be used. The SnapMirror to Tape function is intended to be used as a disaster-recovery option for copying very large NetApp file systems to secondary storage.

For most NetApp file systems, use the standard NDMP full or differential backup method. Refer to the documentation that came with your NetApp file server for more information.

When setting the TYPE parameter to SNAPMirror, the following restrictions apply:

Restrictions:

- You cannot specify TOC=YES or TOC=PREFERRED.
- The file_system_name cannot be a virtual filespace name.
- The snapshot which is created automatically by the file server during the SnapMirror copy operation will be deleted at end of the operation.
- This parameter is valid for NetApp and IBM® N-Series file servers only.

Example: Perform a full backup

Perform a full backup on the /vol/vol10 file system of NAS node NAS1.

```
backup node nas1 /vol/vol10 mode=full
```

Example: Perform a backup on a directory and create a table of contents

Back up the directory /vol/vol2/mikes on the node NAS1 and create a table of contents for the image. For the following two examples, assume Table 1 contains the virtual file space definitions exist on the server for the node NAS1.

```
backup node nas1 /mikesdir
```

Table 1. Virtual file space definitions

Virtual file space name	File system	Path
/mikesdir	/vol/vol2	/mikes
/DataDirVol2	/vol/vol2	/project1/data

Virtual file space name	File system	Path
/TestDirVol1	/vol/vol1	/project1/test

Example: Perform a backup on two directories

Back up the directories /vol/vol2/project1/data and /vol/vol1/project1/test of the node NAS1. Refer to Table 1 for the virtual file space definitions that exist on the server for the node NAS1.

```
backup node nas1 /DataDirVol2,/testdirvol1  mode=full toc=yes
```

Related commands

Table 2. Commands related to BACKUP NODE

Command	Description
BACKUP NAS (client command)	Creates a backup of NAS node data.
CANCEL PROCESS	Cancels a background server process.
DEFINE COPYGROUP	Defines a copy group for backup or archive processing within a specified management class.
DEFINE VIRTUALFSMAPPING	Define a virtual file space mapping.
QUERY NASBACKUP	Displays information about NAS backup images.
QUERY TOC	Displays details about the table of contents for a specified backup image.
QUERY COPYGROUP	Displays the attributes of a copy group.
RESTORE NAS (client command)	Restores a backup of NAS node data.
RESTORE NODE	Restores a network-attached storage (NAS) node.
UPDATE COPYGROUP	Changes one or more attributes of a copy group.

Backup and restore using NetApp SnapMirror to Tape feature

BACKUP STGPOOL (Back up primary storage pool data to a copy storage pool)

Use this command to back up primary storage pool files to a copy storage pool.

You can back up data from a primary storage pool that is defined with the NATIVE, NONBLOCK, or any of the NDMP formats (NETAPPDUMP, CELERRADUMP, or NDMPDUMP). The copy storage pool to which data is to be backed up must have the same data format as the primary storage pool. IBM Spectrum Protect™ supports back-end data movement for NDMP images.

If a file exists in the copy storage pool, the file is not backed up unless the copy of the file in the copy storage pool is marked as damaged. However, a new copy is not created if the file in the primary storage pool is also marked as damaged. In a random-access storage pool, cached copies of migrated files and damaged primary files are not backed up.

Tip: Issuing this command for a primary storage pool that is set up for data deduplication removes duplicate data, if the copy storage pool is also set up for data deduplication.

If migration for a storage pool starts during a storage pool backup, some files might be migrated before they are backed up. You might want to back up storage pools that are higher in the migration hierarchy before you back up storage pools that are lower.

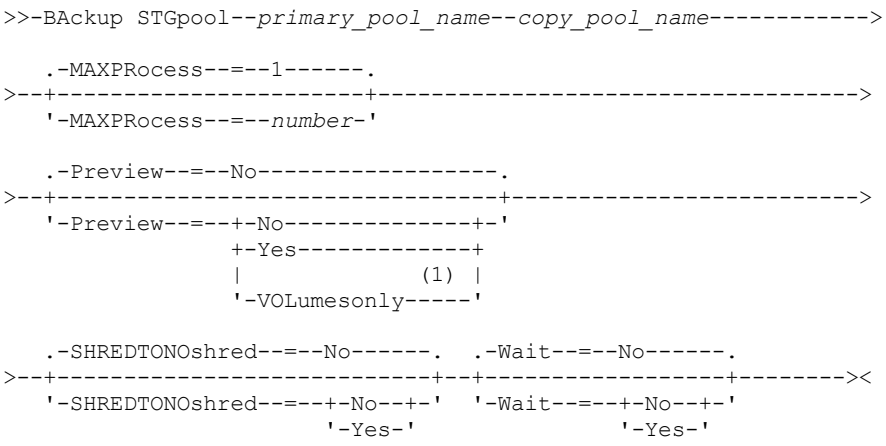
Restrictions:

- Do not run the MOVE DRMEDIA and BACKUP STGPOOL commands concurrently. Ensure that the storage pool backup processes are complete before you issue the MOVE DRMEDIA command.
- You cannot back up data from or to storage pools defined with a CENTERA device class.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the copy storage pool in which backup copies are to be produced.

Syntax



Notes:

1. Valid only for storage pools that are associated with a sequential-access device class.

Parameters

primary_pool (Required)
: Specifies the primary storage pool.

copy_pool (Required)
: Specifies the copy storage pool.

MAXPRocess
: Specifies the maximum number of parallel processes to use for backing up files. This parameter is optional. Enter a value 1 - 999. The default is 1.

  Using multiple, parallel processes can improve throughput for the backup. The expectation is that the time needed to complete the storage pool backup is decreased by using multiple processes. However, when multiple processes are running, in some cases one or more of the processes needs to wait to use a volume that is already in use by a different backup process.

  When you determine this value, consider the number of logical and physical drives that can be dedicated to this operation. To access a sequential access volume, IBM Spectrum Protect uses a mount point and, if the device type is not FILE, a physical drive. The number of available mount points and drives depends on other IBM Spectrum Protect and system activity and on the mount limits of the device classes for the sequential access storage pools that are involved in the backup.

  Each process needs a mount point for copy storage pool volumes, and, if the device type is not FILE, each process also needs a drive. If you are backing up a sequential storage pool, each process needs an extra mount point for primary storage pool volumes and, if the device type is not FILE, an extra drive. For example, suppose that you specify a maximum of three processes to back up a primary sequential storage pool to a copy storage pool of the same device class. Each process requires two mount points and two drives. To run all three processes, the device class must have a mount limit of at least 6, and at least six mount points and six drives must be available.

  To preview a backup, only one process is used and no mount points or drives are needed.

Preview
: Specifies whether you want to preview but not run the backup. The preview displays the number of files and bytes to be backed up and a list of the primary storage pool volumes that you must mount. This parameter is optional. The default is NO. You can specify the following values:

  No
  : Specifies that the backup is done.

  Yes

Specifies that you want to preview the backup but not do the backup.

VOLumesonly
: Specifies that you want to preview the backup only as a list of the volumes that must be mounted. This choice requires the least processing time. The VOLUMESONLY option is valid only for storage pools that are associated with a sequential-access device class.
The VOLUMESONLY option can be used to obtain a list of volumes that are needed by the storage pool backup process. For example:

```
backup stgpool primary_pool copystg preview=volumesonly
```

The list of volumes are logged in the server activity log with the ANR1228I message. Query the server activity log to get the list of volumes required. For example:

```
query actlog msg=1228
```

SHREDTONOshred
: Specifies whether data is backed up to a copy storage pool from a primary storage pool that enforces shredding. This parameter is optional. The default value is NO. You can specify the following values:

No
: Specifies that the server does not allow data to be backed up to a copy storage pool from a primary storage pool that enforces shredding. If the primary storage pool enforces shredding, the operation fails.

Yes
: Specifies that the server does allow data to be backed up to a copy storage pool from a primary storage pool that enforces shredding. The data in the copy storage pool is not shredded when it is deleted.

Wait
: Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default is NO. You can specify the following values:

No
: Specifies that the server processes this command in the background.

You can continue with other tasks while the command is being processed. Messages that are created from the background process are displayed either in the activity log or the server console, depending on where messages are logged.

To cancel a background process, use the CANCEL PROCESS command. If you cancel this process, some files might already have been backed up before the cancellation.

Yes
: Specifies that the server processes this operation in the foreground. You must wait for the operation to complete before you continue with other tasks. The server displays the output messages to the administrative client when the operation completes.
Note: You cannot specify WAIT=YES from the server console.

Example: Back up the primary storage pool

Back up the primary storage pool that is named PRIMARY_POOL to the copy storage pool named COPYSTG.

```
backup stgpool primary_pool copystg
```

Related commands

Table 1. Commands related to BACKUP STGPOOL

Command	Description
CANCEL PROCESS	Cancels a background server process.
MOVE DRMEDIA	Moves DRM media onsite and offsite.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY PROCESS	Displays information about background processes.
QUERY SHREDSTATUS	Displays information about data waiting to be shredded.

Command	Description
QUERY STGPOOL	Displays information about storage pools.
RESTORE STGPOOL	Restores files to a primary storage pool from copy storage pools.
RESTORE VOLUME	Restores files stored on specified volumes in a primary storage pool from copy storage pools.
SHRED DATA	Manually starts the process of shredding deleted data.

BACKUP VOLHISTORY (Save sequential volume history information)

Use this command to back up sequential volume history information to one or more files.

Tip: You must use volume history information when you reload the database and audit affected storage pool volumes. If you cannot start the server, you can use the volume history file to query the database about these volumes.
The volume history includes information about the following types of volumes:

- Archive log volumes
- Database backup volumes
- Export volumes
- Backup set volumes
- Database snapshot volumes
- Database recovery plan file volumes
- Recovery plan file volumes
- Recovery plan file snapshot volumes
- The following sequential access storage pool volumes:
  - Volumes added to storage pools
  - Volumes reused through reclamation or MOVE DATA operations
  - Volumes removed by using the DELETE VOLUME command or during reclamation of scratch volumes

Attention: To restore a database, the server must use information from the volume history file and the device configuration file. You must make and save copies of the volume history file and the device configuration file. These files cannot be recreated.

AIX Linux You must use the VOLUMEHISTORY server option to specify one or more volume history files. IBM Spectrum Protect™ updates volume history files whenever server sequential volume history information is changed.

Windows At installation, the server options file includes a VOLUMEHISTORY option that specifies a default volume history file named volhist.out. IBM Spectrum Protect updates volume history files whenever server sequential volume history information is changed.

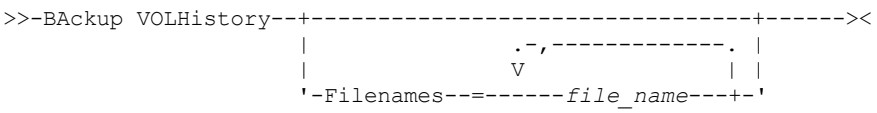
To ensure that updates are complete before the server is halted, follow these steps:

- Do not halt the server for a few minutes after you issue the BACKUP VOLHISTORY command.
- Specify multiple VOLUMEHISTORY options in the server options file.
- Examine the volume history file to see if the file has been updated.

Privilege class

Any administrator can issue this command unless it includes the FILENAMES parameter. If the FILENAMES parameter is specified and the REQSYSAUTHOUTFILE server option is set to YES, the administrator must have system privilege. If the FILENAMES parameter is specified and the REQSYSAUTHOUTFILE server option is set to NO, the administrator must have operator, policy, storage or system privilege.

Syntax



Parameters

Filenames

Specifies the names of one or more files in which to store a backup copy of volume history information. Separate multiple file names with commas and no intervening spaces. This parameter is optional.

If you do not specify a file name, IBM Spectrum Protect stores the information in all files specified with the VOLUMEHISTORY option in the server options file.

Example: Back up the volume history information to a file

Back up the volume history information to a file called VOLHIST.

```
backup volhistory filenames=volhist
```

Related commands

Table 1. Commands related to BACKUP VOLHISTORY

Command	Description
DELETE VOLHISTORY	Removes sequential volume history information from the volume history file.
DELETE VOLUME	Deletes a volume from a storage pool.
QUERY VOLHISTORY	Displays sequential volume history information that has been collected by the server.
UPDATE VOLHISTORY	Adds or changes location information for a volume in the volume history file.

BEGIN EVENTLOGGING (Begin logging events)

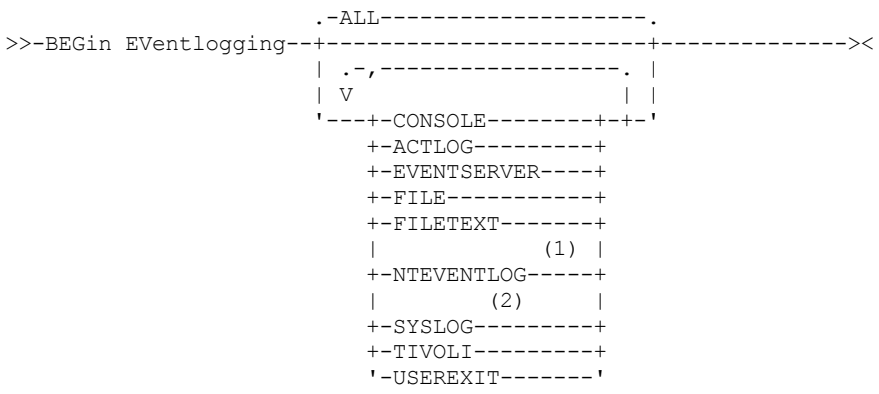
Use this command to begin logging events to one or more receivers. A receiver for which event logging has begun is an *active receiver*.

When the server is started, event logging automatically begins for the console and activity log and for any receivers that are started automatically based on entries in the server options file. You can use this command to begin logging events to receivers for which event logging is *not* automatically started at server startup. You can also use this command after you have disabled event logging to one or more receivers.

Privilege class

To issue this command, you must have system privilege.

Syntax



Notes:

1. This parameter is only available for the Windows operating system.
2. This parameter is only available for the Linux operating system.

Parameters

Specify one or more receivers. You can specify multiple receivers by separating them with commas and no intervening spaces. If you specify ALL, logging begins for all receivers that are configured. The default is ALL.

ALL
: Specifies all receivers that are configured for event logging.

CONSOLE
: Specifies the server console as a receiver.

ACTLOG
: Specifies the IBM Spectrum Protect™ activity log as a receiver.

EVENTSERVER
: Specifies the event server as a receiver.

FILE
: Specifies a user file as a receiver. Each logged event is a record in the file and a person cannot read each logged event easily.

FILETEXT
: Specifies a user file as a receiver. Each logged event is a fixed-size, readable line.

Windows NTEVENTLOG
: Windows Specifies the Windows application log as a receiver.

Linux SYSLOG
: Linux Specifies the Linux system log as a receiver.

TIVOLI
: Specifies the Tivoli Management Environment (TME) as a receiver.

USEREXIT
: Specifies a user-written routine to which IBM Spectrum Protect writes information as a receiver.

Example: Begin logging events

Begin logging events to the IBM Spectrum Protect activity log.

```
begin eventlogging actlog
```

Related commands

Table 1. Commands related to BEGIN EVENTLOGGING

Command	Description
DISABLE EVENTS	Disables specific events for receivers.
ENABLE EVENTS	Enables specific events for receivers.
END EVENTLOGGING	Ends event logging to a specified receiver.
QUERY ENABLED	Displays enabled or disabled events for a specific receiver.
QUERY EVENTRULES	Displays information about rules for server and client events.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

CANCEL commands

Use the CANCEL commands to end a task or process before it is completed.

- CANCEL EXPIRATION (Cancel an expiration process)
- CANCEL EXPORT (Delete a suspended export operation)
- CANCEL PROCESS (Cancel an administrative process)
- CANCEL REPLICATION (Cancel node replication processes)
- CANCEL REQUEST (Cancel one or more mount requests)
- CANCEL RESTORE (Cancel a restartable restore session)

- CANCEL SESSION (Cancel one or more client sessions)

CANCEL EXPIRATION (Cancel an expiration process)

Use this command to cancel a process with an unknown process number that is running as a result of an inventory expiration operation.

Use the CANCEL EXPIRATION command if the expiration process number is not known, otherwise use the CANCEL PROCESS and specify the process number of the expiration process. Both commands call the same code to end the expiration process.

You can use the CANCEL EXPIRATION command to automate the cancellation of an expiration process. For example, if you start inventory expiration at midnight and, due to the maintenance workload on the server, the process must finish at 03:00, you can schedule a CANCEL EXPIRATION command to run at 03:00 without knowing the process number.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-CANcel EXPIration-------------------------------------------><
```

Example: Cancel an inventory expiration process

Cancel the process that was generated by an inventory expiration operation.

```
cancel expiration
```

Related commands

Table 1. Command related to CANCEL EXPIRATION

Command	Description
QUERY PROCESS	Displays information about background processes.
EXPIRE INVENTORY	Manually starts inventory expiration processing.

CANCEL EXPORT (Delete a suspended export operation)

Use this command to delete a suspended server-to server export operation. After issuing the CANCEL EXPORT command, you cannot restart the export operation. Issue the CANCEL PROCESS command to delete a currently running export operation.

Privilege class

You must have system privilege to issue this command.

Syntax

```
                  .-*--------------------.
>>-CANcel EXPort -+------------------------+--------------------><
                  '---export_identifier---'
```

Parameters

export_identifier
: The unique identifier of the suspended export operation that you wish to delete. You can also enter wildcard characters for the identifier. Issue the QUERY EXPORT command to list the currently suspended export operations.

Example: Delete a specific suspended export operation

Cancel the suspended server-to-server export operation EXPORTALLACCTNODES.

```
cancel export exportallacctnodes
```

Example: Delete all suspended server-to-server export operations

Cancel all suspended server-to-server export processes.

```
cancel export *
```

Related commands

Table 1. Commands related to CANCEL EXPORT

Command	Description
CANCEL PROCESS	Cancels a background server process.
EXPORT NODE	Copies client node information to external media or directly to another server.
EXPORT SERVER	Copies all or part of the server to external media or directly to another server.
QUERY EXPORT	Displays the export operations that are currently running or suspended.
RESTART EXPORT	Restarts a suspended export operation.
SUSPEND EXPORT	Suspends a running export operation.

CANCEL PROCESS (Cancel an administrative process)

Use this command to cancel a background process started by an administrative command or by a process, such as storage pool migration.

The following commands generate background processes:

- AUDIT CONTAINER
- AUDIT LIBRARY
- AUDIT LICENSES
- AUDIT VOLUME
- BACKUP DB
- BACKUP NODE
- BACKUP STGPOOL
- CHECKIN LIBVOLUME
- CHECKOUT LIBVOLUME
- AIX Linux Windows CONVERT STGPOOL
- DELETE FILESPACE
- DELETE VOLUME
- EXPIRE INVENTORY
- EXPORT ADMIN
- EXPORT NODE
- EXPORT POLICY
- EXPORT SERVER
- GENERATE BACKUPSET
- IMPORT ADMIN
- IMPORT NODE
- IMPORT POLICY
- IMPORT SERVER
- MIGRATE STGPOOL
- MOVE DATA
- MOVE DRMEDIA

- MOVE MEDIA
- PREPARE
- PROTECT STGPOOL
- RECLAIM STGPOOL
- REPLICATE NODE
- RESTORE NODE
- RESTORE STGPOOL
- RESTORE VOLUME
- VARY

The following internal server operations generate background processes:

- Inventory expiration
- Migration
- Reclamation

To cancel a process, you must have the process number, which you can obtain by issuing the QUERY PROCESS command.

Some processes, such as reclamation, generate mount requests to complete processing. If a process has a pending mount request, the process might not respond to a CANCEL PROCESS command until the mount request is answered or canceled by using the REPLY or CANCEL REQUEST command, or by timing out.

Issue the QUERY REQUEST command to list open requests, or query the activity log to determine whether a process has a pending mount request. A mount request indicates that a volume is needed for the current process, but the volume is not available in the library. The volume might not be available if the administrator issues the MOVE MEDIA or CHECKOUT LIBVOLUME command, or manually removes the volume from the library.

After you issue a CANCEL PROCESS command for an export operation, the process cannot be restarted. To stop a server-to-server export operation but allow it to be restarted later, issue the SUSPEND EXPORT command.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-CANcel PRocess--process_number------------------------------><
```

Parameters

process_number (Required)
Specifies the number of the background process you want to cancel.

Example: Cancel a background process by using its process number

Cancel background process number 3.

```
cancel process 3
```

Related commands

Table 1. Commands related to CANCEL PROCESS

Command	Description
CANCEL EXPORT	Deletes a suspended export operation.
CANCEL REQUEST	Cancels pending volume mount requests.
AIX Linux Windows CONVERT STGPOOL	AIX Linux Windows Convert a storage pool to a directory-container storage pool.
AIX Linux Windows PROTECT STGPOOL	AIX Linux Windows Protects a directory-container storage pool.

Command	Description
QUERY EXPORT	Displays the export operations that are currently running or suspended.
QUERY PROCESS	Displays information about background processes.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
REPLY	Allows a request to continue processing.
RESTART EXPORT	Restarts a suspended export operation.
SUSPEND EXPORT	Suspends a running export operation.

CANCEL REPLICATION (Cancel node replication processes)

Use this command to cancel all node replication processes.

Issue this command on the server that acts as a source for replicated data.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-CANcel REPLication-----------------------------------------><
```

Parameters

None.

Example: Cancel node replication processes

Cancel all node replication processes.

```
cancel replication
```

Related commands

Table 1. Commands related to CANCEL REPLICATION

Command	Description
QUERY PROCESS	Displays information about background processes.
QUERY REPLICATION	Displays information about node replication processes.

CANCEL REQUEST (Cancel one or more mount requests)

Use this command to cancel one or more pending media mount requests. To cancel a mount request, you need to know the request number assigned to the request. This number is included in the mount request message and can also be shown by using the QUERY REQUEST command.

Privilege class

To issue this command, you must have system privilege or operator privilege.

Syntax

```
>>-CANcel REQuest--+-request_number-+--+-----------+-----------><
```

```
                    '-ALl------------'  '-PERManent-'
```

Parameters

request_number
: Specifies the request number of the mount request to cancel.

ALl
: Specifies to cancel all pending mount requests.

PERManent
: Specifies that you want the server to flag the volumes for which you are canceling a mount request as unavailable. This parameter is optional.

Example: Cancel a mount request

Cancel request number 2.

```
cancel request 2
```

Related commands

Table 1. Commands related to CANCEL REQUEST

Command	Description
QUERY REQUEST	Displays information about all pending mount requests.
UPDATE VOLUME	Updates the attributes of storage pool volumes.

CANCEL RESTORE (Cancel a restartable restore session)

Use this command to cancel a restartable restore session. You can cancel restore sessions in the active or restartable state. Any outstanding mount requests related to this session are automatically canceled.

To display restartable restore sessions, use the QUERY RESTORE command.

Privilege class

To issue this command, you must have system or operator privilege.

Syntax

```
>>-CANcel--RESTore--+-session_number-+------------------------><
                    '-ALl------------'
```

Parameters

session_number
: Specifies the number for the restartable restore session. An active session is a positive number, and a restartable session is a negative number.

ALl
: Specifies that all the restartable restore sessions are to be canceled.

Example: Cancel restore operations

Cancel all restore operations.

```
cancel restore all
```

Related commands

Table 1. Commands related to CANCEL RESTORE

Command	Description
QUERY RESTORE	Displays information about restartable restore sessions.

CANCEL SESSION (Cancel one or more client sessions)

Use this command to cancel existing administrative or client node sessions, and to force an administrative or client node session off the server. Any outstanding mount requests related to this session are automatically canceled. The client node must start a new session to resume activities.

If you cancel a session that is in the idle wait (IdleW) state, the client session is automatically reconnected to the server when it starts to send data again.

If this command interrupts a process, such as backup or archive, the results of any processing active at the time of interruption are rolled back and not committed to the database.

Privilege class

To issue this command, you must have system or operator privilege.

Syntax

```
>>-CANcel SEssion--+-session_number-+-------------------------><
                   '-ALl------------'
```

Parameters

session_number
: Specifies the number of the administrative, server, or client node sessions that you want to cancel.

ALl
: Specifies that all client node sessions are canceled. You cannot use this parameter to cancel administrative client or server sessions.

Example: Cancel a specific client node session

Cancel the client node session with NODEP (session 3).

```
cancel session 3
```

Related commands

Table 1. Commands related to CANCEL SESSION

Command	Description
DISABLE SESSIONS	Prevents new sessions from accessing IBM Spectrum Protect but permits existing sessions to continue.
LOCK ADMIN	Prevents an administrator from accessing IBM Spectrum Protect.
LOCK NODE	Prevents a client from accessing the server.
QUERY SESSION	Displays information about all active administrator and client sessions with IBM Spectrum Protect.

CHECKIN LIBVOLUME (Check a storage volume into a library)

Use this command to add a sequential access storage volume or a cleaning tape to the server inventory for an automated library. The server cannot use a volume that physically resides in an automated library until that volume is checked in.

Important:

1. The CHECKIN LIBVOLUME command processing does not wait for a drive to become available, even if the drive is only in the IDLE state. If necessary, you can make a library drive available issuing the DISMOUNT VOLUME command to dismount the volume. After a library drive is available, reissue the CHECKIN LIBVOLUME command.
2. You do not define the drives, check in media, or label the volumes in an external library. The server provides an interface that external media management systems use to operate with the server.
3. When you check in WORM tapes other than 3592, you must use CHECKLABEL=YES or they are checked in as normal read/write tapes.

This command creates a background process that you can cancel with the CANCEL PROCESS command. To display information about background processes, use the QUERY PROCESS command.

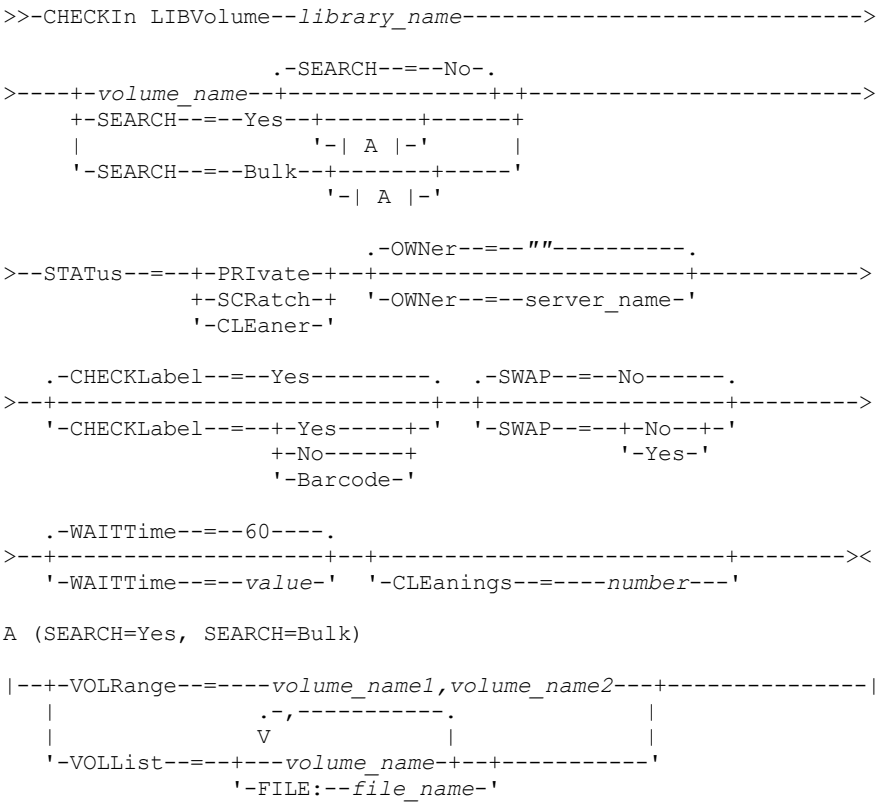
For detailed and current drive and library support information, see the Supported Devices website for your operating system:

- AIX Windows Supported devices for AIX and Windows
- Linux Supported devices for Linux

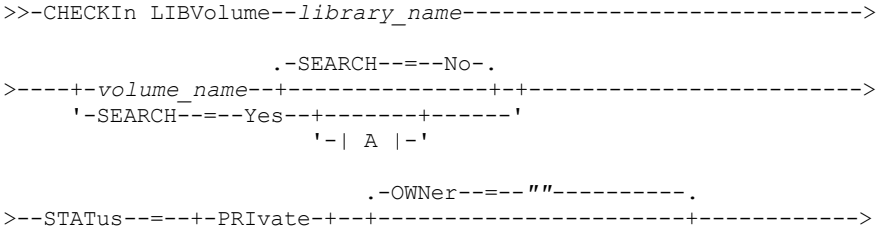
Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax for SCSI libraries



Syntax for 349X libraries



```

   '-VOLList--=--+---volume_name-+--+-----------'
                 '-FILE:--file_name-'
```

Parameters

library_name (Required)
: Specifies the name of the library.

volume_name
: Specifies the volume name of the storage volume that is being checked in. This parameter is required if SEARCH equals NO. Do not enter this parameter if the SEARCH parameter equals YES or BULK. If you are checking a volume into a SCSI library with multiple entry/exit ports, the volume in the lowest numbered slot is checked in.

STATus (Required)
: Specifies the volume status. Possible values are:

  PRIvate
  : Specifies that the volume is a private volume that is mounted only when it is requested by name.

  SCRatch
  : Specifies that the volume is a new scratch volume. This volume can be mounted to satisfy scratch mount requests during either data storage operations or export operations.

If a volume has an entry in volume history, you cannot check it in as a scratch volume.

CLEaner
Specifies that the volume is a cleaner cartridge and not a data cartridge. The CLEANINGS parameter is required for a cleaner cartridge and must be set to the number of cleaner uses.

CHECKLABEL=YES is not valid for checking in a cleaner cartridge. Use STATUS=CLEANER to check in a cleaner cartridge separately from a data cartridge.

OWNer
Specifies which library client owns a private volume in a library that is shared across a SAN. The volume for which you specify ownership must be a private volume. You cannot specify ownership for a scratch volume. Furthermore, you cannot specify an owner when you use SEARCH=YES or SEARCH=BULK.

When you issue the CHECKIN LIBVOLUME command, the server validates the owner. If you did not specify this parameter, then the server uses the default and delegates volume ownership to the owning library client, as recorded in the volume history file on the library manager. If the volume is not owned by any library client, then the server delegates ownership to the library manager.

SEARCH
Specifies whether the server searches the library to find volumes that were not checked in. This parameter is optional. The default is NO.

Possible values are:

No
Specifies that only the named volume is checked into the library.

For SCSI libraries: The server issues a request to have the volume inserted into a cartridge slot in the library or, if available, into an entry port. The cartridge slot or entry port is identified by its element address. **For 349X libraries:** The volume might already be in the library, or you can put it into the I/O station when prompted.

Yes
Specifies that the server searches the library for volumes to be checked in. You can use the VOLRANGE or VOLLIST parameter to limit the search. When you use this parameter, consider the following restrictions:

- If the library is shared between applications, the server might examine a volume that is required by another application. For 349X libraries, the server queries the library manager to determine all volumes that are assigned to the SCRATCH or PRIVATE category and to the INSERT category.
- For SCSI libraries, do not specify both SEARCH=YES and CHECKLABEL=NO in the same command.

Bulk
Specifies that the server searches the library's entry/exit ports for volumes that can be checked in automatically. This option applies to only SCSI libraries.
Important:

1. Do not specify both CHECKLABEL=NO and SEARCH=BULK.
2. You can use the VOLRANGE or VOLLIST parameter to limit the search.

VOLRange
Specifies a range of volume names that are separated by commas. You can use this parameter to limit the search for volumes to be checked in when you specify SEARCH=YES (349X, ACSLS, and SCSI libraries) or SEARCH=BULK (SCSI libraries only). If there are no volumes in the library that are within the specified range, the command completes without errors.

Specify only volume names that can be numerically incremented. In addition to the incremental area, a volume name can include an alphanumeric prefix and an alphanumeric suffix, for example:

Parameter	**Description**
`volrange=bar110,bar130`	The 21 volumes are checked in: bar110, bar111, bar112,...bar129, bar130.
`volrange=bar11a,bar13a`	The 3 volumes are checked in: bar11a, bar12a, bar13a.

Parameter	Description
`volrange=123400,123410`	The 11 volumes are checked in: 123400, 123401, ...123409, 123410.

VOLList

Specifies a list of volumes. You can use this parameter to limit the search for volumes to be checked in when you specify SEARCH=YES (349X, ACSLS, and SCSI libraries) or SEARCH=BULK (SCSI libraries only). If there are no volumes in the library that are in the list, the command completes without errors.
Possible values are:

volume_name
: Specifies one or more volumes names that are separated by commas and no intervening spaces. For example: VOLLIST=TAPE01,TAPE02.

FILE: file_name
: Specifies the name of a file that contains a list of volumes for the command. In the file, each volume name must be on a separate line. Blank lines and comment lines that begin with an asterisk are ignored. For example, to use volumes TAPE01, TAPE02 and TAPE03, create a file, TAPEVOL, that contains these lines:

```
TAPE01
TAPE02
TAPE03
```

You can specify the volumes for the command as follows: VOLLIST=FILE:TAPEVOL.

Attention: The file name is case-sensitive.

CHECKLabel

Specifies how or whether the server should read sequential media labels of volumes. This parameter is optional. The default is YES.
Possible values are:

Yes
: Specifies that an attempt is made to read the media label during check-in.
Attention:

1. For SCSI libraries, do not specify both SEARCH=YES and CHECKLABEL=NO in the same command.
2. For WORM media other than 3592, you must specify YES.

No
: Specifies that the media label is not read during check-in. However, suppressing label checking can result in future errors (for example, either a wrong label or an improperly labeled volume can cause an error). For 349X and ACSLS libraries, specify NO to avoid loading cartridges into a drive to read the media label. These libraries always return the external label information about cartridges, and IBM Spectrum Protect™ uses that information.

Barcode
: Specifies that the server reads the bar code label if the library has a bar code reader and the volumes have external bar code labels. You can decrease the check-in time by using the bar code. This parameter applies only to SCSI libraries.

If the bar code reader cannot read the bar code label, or if the tape does not have a bar code label, the server mounts the tape and reads the internal label.

DEVType

Specifies the device type for the volume that is being checked in. This parameter is required if none of the drives in this library have defined paths.

3590
: Specifies that the device type for the volume that is being checked in is 3590.

3592
: Specifies that the device type for the volume that is being checked in is 3592.

SWAP

Specifies whether the server swaps volumes if an empty library slot is not available. The volume that is selected for the swap operation (target swap volume) is ejected from the library and replaced with the volume that is being checked in. The server identifies a target swap volume by checking for an available scratch volume. If none exists, the server identifies the least frequently mounted volume.

This parameter is optional. The default is NO. This parameter applies only if there is a volume name that is specified in the command. Possible values are:

No
: Specifies that the server checks in the volume only if an empty slot is available.

Yes
: Specifies that if an empty slot is not available, the server swaps cartridges to check in the volume.

WAITTime
: Specifies the number of minutes that the server waits for you to reply or respond to a request. Specify a value in the range 0-9999. If you want to be prompted by the server, specify a wait time greater than zero. The default value is 60 minutes. For example, suppose the server prompts you to insert a tape into the entry/exit port of a library. If you specified a wait time of 60 minutes, the server issues a request and waits 60 minutes for you to reply. Suppose, on the other hand, you specify a wait time of 0. If you already inserted a tape, a wait time of zero causes the operation to continue without prompting. If you have *not* inserted a tape, a wait time of zero will cause the operation to fail.

CLEanings
: Enter the recommended value for the individual cleaner cartridge (usually indicated on the cartridge). Cleanings apply only to SCSI libraries. This parameter is required if STATUS=CLEANER.

  If more than one cleaner is checked into the library, only one is used until its CLEANINGS value decreases to zero. Another cleaner is then selected, and the first cleaner can be checked out and discarded.

Example: Check a volume into a SCSI library

Check in a volume named `WPDV00` into the SCSI library named AUTO.

```
checkin libvolume auto wpdv00 status=scratch
```

Example: Use a bar code reader to scan a library for a cleaner cartridge

Scan a SCSI library named `AUTOLIB1` and, using the bar code reader, look for cleaner cartridge `CLNV`. Use SEARCH=YES, but limit the search by using the VOLLIST parameter.

```
checkin libvolume autolib1 search=yes vollist=cleanv status=cleaner
  cleanings=10 checklabel=barcode
```

Example: Scan a library to put unused volumes in a specific range in scratch status

Scan a 349X library named ABC, and limit the search to a range of unused volumes `BAR110` to `BAR130` and put them in scratch status.

```
checkin libvolume abc search=yes volrange=bar110,bar130
 status=scratch
```

Example: Scan a library to put a specific volume in scratch status

Use the barcode reader to scan a SCSI library named `MYLIB` for `VOL1`, and put it in scratch status.

```
checkin libvolume mylib search=yes vollist=vol1 status=scratch
 checklabel=barcode
```

Related commands

Table 1. Commands related to CHECKIN LIBVOLUME

Command	Description
AUDIT LIBRARY	Ensures that an automated library is in a consistent state.
CANCEL PROCESS	Cancels a background server process.
CHECKOUT LIBVOLUME	Checks a storage volume out of an automated library.

Command	Description
DEFINE LIBRARY	Defines an automated or manual library.
DEFINE VOLUME	Assigns a volume to be used for storage within a specified storage pool.
DISMOUNT VOLUME	Dismounts a sequential, removable volume by the volume name.
LABEL LIBVOLUME	Labels volumes in manual or automated libraries.
QUERY LIBRARY	Displays information about one or more libraries.
QUERY LIBVOLUME	Displays information about a library volume.
QUERY PROCESS	Displays information about background processes.
REPLY	Allows a request to continue processing.
UPDATE LIBVOLUME	Changes the status of a storage volume.

CHECKOUT LIBVOLUME (Check a storage volume out of a library)

Use this command to remove a sequential access storage volume from the server inventory for an automated library. This command creates a background process that can be canceled with the CANCEL PROCESS command. To display information on background processes, use the QUERY PROCESS command.

Restrictions:

1. Check out processing does not wait for a drive to become available, even if the drive is in the IDLE state. If necessary, you can make a library drive available by dismounting the volume with the DISMOUNT VOLUME command. After a drive is available, the CHECKOUT LIBVOLUME command can be reissued.
2. Before checking out volumes from a 349X library, ensure that the 349x Cartridge Input and Output facility has enough empty slots for the volumes to be checked out. The 3494 Library Manager does not inform an application that the Cartridge Input and Output facility is full. It accepts requests to eject a cartridge and waits until the Cartridge Input and Output facility is emptied before returning to the server. IBM Spectrum Protect™ might appear to be hung when it is not. Check the library and clear any intervention requests.
3. Before checking volumes out of an ACSLS library, ensure that the CAP priority in ACSLS is greater than zero. If the CAP priority is zero, then you must specify a value for the CAP parameter on the CHECKOUT LIBVOLUME command.

For detailed and current drive and library support information, see the Supported Devices website for your operating system:

- AIX Windows Supported devices for AIX and Windows
- Linux Supported devices for Linux

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax for SCSI library

```
>>-CHECKOut LIBVolume--library_name----+-volume_name-+---------->
                                       '-| A |-------'

   '-VOLList--=--+---volume_name-+--+-----------'
                 '-FILE:--file_name-'
```

Parameters

library_name (Required)
: Specifies the name of the library.

volume_name
: Specifies the volume name.

VOLRange
: Specifies two volume names separated by a comma. This parameter is a range of volumes to be checked out. If there are no volumes in the library that are within the specified range, the command completes without errors.

Specify only volume names that can be numerically incremented. In addition to the incremental area, a volume name can include an alphanumeric prefix and an alphanumeric suffix, for example:

Parameter	Description
`volrange=bar110,bar130`	The 21 volumes are checked out: bar110, bar111, bar112,...bar129, bar130.
`volrange=bar11a,bar13a`	The 3 volumes are checked out: bar11a, bar12a, bar13a.
`volrange=123400,123410`	The 11 volumes are checked out: 123400, 123401, ...123409, 123410.

VOLList

Specifies a list of volumes to check out. If there are no volumes in the library that are in the list, the command completes without errors.

Possible values are:

volume_name

Specifies the names of one or more values that are used for the command. Example: VOLLIST=TAPE01,TAPE02.

FILE:file_name

Specifies the name of a file that contains a list of volumes for the command. In the file, each volume name must be on a separate line. Blank lines and comment lines that begin with an asterisk are ignored. For example, to use volumes TAPE01, TAPE02 and TAPE03, create a file, TAPEVOL, that contains these lines:

```
TAPE01
TAPE02
TAPE03
```

You can specify the volumes for the command as follows: VOLLIST=FILE:TAPEVOL.

Attention: The file name is case-sensitive.

REMove

Specifies that the server tries to move the volume out of the library and into the convenience I/O station or entry/exit ports. This parameter is optional. Possible values, depending on the type of library, are YES, BULK, and NO. The response of the server to each of those options and the default values are described in the following sections.

349X libraries: The default is BULK. The following table shows how the server responds for 349X libraries.

Table 1. How the server responds for 349X libraries

REMOVE=YES	REMOVE=BULK	REMOVE=NO
The 3494 Library Manager ejects the cartridge to the convenience I/O station.	The 3494 Library Manager ejects the cartridge to the high-capacity output facility.	The 3494 Library Manager does not eject the volume. The server leaves the cartridge in the library in the INSERT category for use by other applications.

SCSI libraries: The default is BULK. The following table shows how the server responds for a SCSI libraries.

Table 2. How the server responds for SCSI libraries

If a library . . .	And REMOVE=YES, then...	And REMOVE=BULK, then...	And REMOVE=NO, then...
Does not have entry/exit ports	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server then prompts you to remove the cartridge from the slot and to issue a REPLY command.	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server does not prompt you to remove the cartridge and does not require a REPLY command.	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server does not prompt you to remove the cartridge and does not require a REPLY command.

If a library . . .	And REMOVE=YES, then...	And REMOVE=BULK, then...	And REMOVE=NO, then...
Has entry/exit ports and an entry/exit *port is available*	The server moves the cartridge to the available entry/exit port and specifies the port address in a message. The server then prompts you to remove the cartridge from the slot and to issue a REPLY command.	The server moves the cartridge to the available entry/exit port and specifies the port address in a message. The server does not prompt you to remove the cartridge and does not request a REPLY command.	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server does not prompt you to remove the cartridge and does not require a REPLY command.
Has entry/exit ports, but *no ports are available*	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server then prompts you to remove the cartridge from the slot and to issue a REPLY command.	The server waits for an entry/exit port to be made available.	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server does not prompt you to remove the cartridge and does not require a REPLY command.

ACSLS libraries: The default is YES. If the parameter is set to YES, and the cartridge access port (CAP) has an automatic selection priority value of 0, you must specify a CAP ID. The following table shows how the server responds for ACSLS libraries.

Table 3. How the server responds for ACSLS libraries

REMOVE=YES or REMOVE=BULK	REMOVE=NO
The server ejects the cartridge to the convenience I/O station, and deletes the volume entry from the server library inventory.	The server does not eject the cartridge. The server deletes the volume entry from the server library inventory and leaves the volume in the library.

CHECKLabel

Specifies how or whether the server reads sequential media labels of volumes.
Attention: This parameter does not apply to IBM® 349X or ACSLS libraries.
This parameter is optional. The default is YES. Possible values are:

Yes
: Specifies that the server attempts to read the media label to verify that the correct volume is being checked out.

No
: Specifies that during checkout the media label is not read. This improves performance because the read process does not occur.

FORCE

Specifies whether the server checks out a volume if an input/output (I/O) error occurs when reading the label.
Attention: This parameter does not apply to IBM 349X or ACSLS libraries.
This parameter is optional. The default is NO. Possible values are:

No
: The server does not check out a storage volume if an I/O error occurs when reading the label.

Yes
: The server checks out the storage volume even if an I/O error occurs.

CAP

Specifies which cartridge access port (CAP) to use for ejecting volumes if you specify REMOVE=YES. This parameter applies to volumes in ACSLS libraries only. If the CAP priority value is set to 0 in the library, this parameter is required. If a CAP priority value greater than 0 is set in the library, this parameter is optional. By default, all CAPs initially have a priority value of 0, which means that ACSLS does not automatically select the CAP.
To display valid CAP identifiers (*x,y,z*), issue the QUERY CAP command with ALL specified from the Automated Cartridge System System Administrator (ACSSA) console on the ACSLS server host. The identifiers are as follows:

x
The Automated Cartridge System (ACS) ID. This identifier can be a number in the range 0 - 126.

y
The Library Storage Module (LSM) ID. This identifier can be a number in the range 0 - 23.

z
The CAP ID. This identifier can be a number in the range 0 - 11.

For more information, see the StorageTek documentation.

Example: Check out a volume and check the label

Check out the volume that is named EXB004 from the library named FOREST. Read the label to verify the volume name, but do not move the volume out of the library.

```
checkout libvolume forest exb004 checklabel=yes remove=no
```

Related commands

Table 4. Commands related to CHECKOUT LIBVOLUME

Command	Description
AUDIT LIBRARY	Ensures that an automated library is in a consistent state.
CANCEL PROCESS	Cancels a background server process.
CHECKIN LIBVOLUME	Checks a storage volume into an automated library.
DEFINE LIBRARY	Defines an automated or manual library.
DEFINE VOLUME	Assigns a volume to be used for storage within a specified storage pool.
LABEL LIBVOLUME	Labels volumes in manual or automated libraries.
QUERY LIBRARY	Displays information about one or more libraries.
QUERY LIBVOLUME	Displays information about a library volume.
QUERY PROCESS	Displays information about background processes.
REPLY	Allows a request to continue processing.
UPDATE LIBVOLUME	Changes the status of a storage volume.

CLEAN DRIVE (Clean a drive)

Use this command when you want IBM Spectrum Protect™ to immediately load a cleaner cartridge into a drive regardless of the cleaning frequency.

There are special considerations if you plan to use this command with a SCSI library that provides automatic drive cleaning through its device hardware.

Restriction: You cannot run the CLEAN DRIVE command for a drive whose only path source is a NAS file server.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-CLEAN DRIVE--library_name--drive_name----------------------><
```

Parameters

library_name (Required)

Specifies the name of the library to which the drive is assigned.

drive_name (Required)

Specifies the name of the drive.

Example: Clean a specific tape drive

You have already defined a library named AUTOLIB by using the DEFINE LIBRARY command, and you have already checked a cleaner cartridge into the library using the CHECKIN LIBVOL command. Inform the server that TAPEDRIVE3 in this library requires cleaning.

```
clean drive autolib tapedrive3
```

Related commands

Table 1. Commands related to CLEAN DRIVE

Command	Description
CHECKIN LIBVOLUME	Checks a storage volume into an automated library.
CHECKOUT LIBVOLUME	Checks a storage volume out of an automated library.
DEFINE DRIVE	Assigns a drive to a library.
DEFINE LIBRARY	Defines an automated or manual library.
DELETE DRIVE	Deletes a drive from a library.
QUERY DRIVE	Displays information about drives.
UPDATE DRIVE	Changes the attributes of a drive.

COMMIT (Control committing of commands in a macro)

Use this command to control when a command is committed in a macro and to update the database when commands complete processing. When issued from the console mode of the administrative client, this command does not generate a message.

If an error occurs while processing the commands in a macro, the server stops processing the macro and rolls back any changes (since the last COMMIT). After a command is committed, it cannot be rolled back.

Ensure that your administrative client session is not running with the ITEMCOMMIT option if you want to control command processing. The ITEMCOMMIT option commits commands inside a script or a macro as *each* command is processed.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-COMMIT-----------------------------------------------------><
```

Parameters

None.

Example: Control committing of commands in a macro

From the interactive mode of the administrative client, register and grant authority to new administrators using a macro named REG.ADM. Changes are committed after each administrator is registered and is granted authority.

Macro Contents:

```
/* REG.ADM-register policy admin & grant authority*/
REGister Admin sara hobby
GRant AUTHority sara CLasses=Policy
```

```
COMMIT  /* Commits changes */
REGister Admin ken plane
GRant AUTHority ken CLasses=Policy
COMMIT  /* Commits changes */
```

Command

```
macro reg.adm
```

Related commands

Table 1. Commands related to COMMIT

Command	Description
MACRO	Runs a specified macro file.
ROLLBACK	Discards any uncommitted changes to the database since the last COMMIT was executed.

CONVERT STGPOOL (Convert a storage pool to a container storage pool)

Use this command to convert a primary storage pool that uses a FILE device class, a tape device class, or a virtual tape library (VTL) to a directory-container or a cloud-container storage pool. You can use container storage pools for both inline and client-side data deduplication.

Restrictions: The following restrictions apply to storage pool conversion:

- You can convert a storage pool only once.
- You cannot update the storage pool during conversion processing. Migration and data movement processes are unavailable.
- You must update all policies to ensure that the destination specifies a storage pool that is not converted or undergoing conversion.

During conversion processing, all data from the source storage pool is moved to the target storage pool. When the process is completed, the source storage pool becomes unavailable. When a storage pool is unavailable, you are unable to write any data to it. The source storage pool is eligible for deletion but is not automatically deleted. You can restore data from the source storage pool if necessary.
Attention: During storage pool conversion, data is deleted from copy storage pools and active-data storage pools. This action occurs even if you specified the number of days that must elapse after all files are deleted from a volume before the volume can be rewritten or returned to the scratch pool.

Privilege class

To issue this command, you must have restricted storage privilege.

Syntax

```
>>-CONvert STGpool--source_stgpool--target_stgpool-------------->

   .-MAXPRocess--=--8----------.
>--+---------------------------+--+----------------------+----><
   '-MAXPRocess--=----number---'  '-DUration--=--minutes-'
```

Parameters

source_stgpool (Required)
: Specify a primary storage pool that uses a FILE device class, a tape device class, or a virtual tape library (VTL) for backup and archive processing. This parameter is required.

target_stgpool (Required)
: Specify the name of an existing directory-container or cloud-container storage pool that the storage pool is converted to. This parameter is required the first time that you issue this command.

Tip: If you restart storage pool conversion and the target storage pool is different than the value that is specified the first time that you issued the CONVERT STGPOOL command, the command fails.

MAXPRocess

Specifies the maximum number of parallel processes that can be used to convert data in the storage pool. This parameter is optional. You can specify a number in the range 1 - 99. The default value is 8.

Tip: Changes to the default value are automatically saved. If you restart storage pool conversion and the parameter value is different than the value that is specified the first time that you issued the CONVERT STGPOOL command, the most recently specified value is used.

DUration

Specifies the maximum number of minutes that a conversion should take before it is canceled. When the specified number of minutes elapses, the server cancels all conversion processes for the storage pool. You can specify a number in the range 1 - 9999. This parameter is optional. If you do not specify this parameter, the conversion runs until it is completed.

Tip: Storage pool conversion for large storage pools can take days to complete. Use this parameter to limit the amount of time for storage pool conversion daily. As a best practice, schedule conversion for at least 2 hours for a storage pool that uses a FILE type device class and at least 4 hours for VTL.

Example: Convert a storage pool and specify a maximum number of processes

Convert a storage pool that is named DEDUPPOOL1, move the data to a container storage pool that is named DIRPOOL1, and specify 25 maximum processes.

```
convert stgpool deduppool1 dirpool1 maxprocess=25
```

Table 1. Commands related to CONVERT STGPOOL

Command	Description
CANCEL PROCESS	Cancels a background server process.
QUERY CLEANUP	Query the cleanup status of a source storage pool.
QUERY CONVERSION	Query conversion status of a storage pool.
PROTECT STGPOOL	Protects a directory-container storage pool.
REMOVE DAMAGED	Removes damaged data from a source storage pool.

COPY commands

Use the COPY commands to create a copy of IBM Spectrum Protect™ objects or data.

- COPY ACTIVEDATA (Copy active backup data from a primary storage pool to an active-data pool)
- COPY CLOPTSET (Copy a client option set)
- COPY DOMAIN (Copy a policy domain)
- COPY MGMTCLASS (Copy a management class)
- COPY POLICYSET (Copy a policy set)
- COPY PROFILE (Copy a profile)
- COPY SCHEDULE (Copy a client or an administrative command schedule)
- COPY SCRIPT (Copy an IBM Spectrum Protect script)
- COPY SERVERGROUP (Copy a server group)

COPY ACTIVEDATA (Copy active backup data from a primary storage pool to an active-data pool)

Use this command to copy active versions of backup data from a primary storage pool to an active-data pool. The primary benefit of active-data pools is fast client restores. Copy your active data regularly to ensure that the data is protected in case of a disaster.

If a file already exists in the active-data pool, the file is not copied unless the copy of the file in the active-data pool is marked damaged. However, a new copy is not created if the file in the primary storage pool is also marked damaged. In a random-access storage pool, neither cached copies of migrated files nor damaged primary files are copied.

If migration for a storage pool starts while active data is being copied, some files might be migrated before they are copied. For this reason, you should copy active data from storage pools that are higher in the migration hierarchy before copying active data from storage pools that are lower. Be sure a copy process is complete before beginning another.

Remember:

- You can only copy active data from storage pools that have a data format of NATIVE or NONBLOCK.
- Issuing this command for a primary storage pool that is set up for data deduplication removes duplicate data, if the active-data pool is also set up for data deduplication.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the active-data pool from which active versions of backup data are being copied.

Syntax

```
>>-COPY ACTIVEdata--primary_pool_name--active-data_pool_name---->

   .-MAXProcess--=--1----------.
>--+---------------------------+-------------------------------->
   '-MAXProcess--=----number---'

   .-Preview--=--No-----------------.  .-Wait--=--No------.
>--+--------------------------------+--+------------------+---->
   '-Preview--=--+-No--------------+-'  '-Wait--=--+-No--+-'
                 +-Yes-------------+               '-Yes-'
                 |             (1) |
                 '-VOLumesonly-----'

   .-SHREDTONOshred--=--No------.
>--+---------------------------+------------------------------><
   '-SHREDTONOshred--=--+-No--+-'
                        '-Yes-'
```

Notes:

1. The VOLUMESONLY parameter applies to sequential-access storage pools only.

Parameters

primary_pool_name (Required)
: Specifies the primary storage pool.

active_data_pool_name (Required)
: Specifies the active-data pool.

MAXProcess
: Specifies the maximum number of parallel processes to use for copying files. This parameter is optional. Enter a value from 1 to 999. The default is 1.

  Using multiple, parallel processes may improve throughput for the COPY ACTIVEDATA command. The expectation is that the time needed to copy active data will be decreased by using multiple processes. However, when multiple processes are running, in some cases one or more of the processes might need to wait to use a volume that is already in use by a different COPY ACTIVEDATA process.

  When determining this value, consider the number of logical and physical drives that can be dedicated to this operation. To access a sequential-access volume, the server uses a mount point and, if the device type is not FILE, a physical drive. The number of available mount points and drives depends on other server and system activity, and also on the mount limits of the device classes for the sequential-access storage pools that are involved when copying active data.

  Each process needs a mount point for active-data pool volumes, and, if the device type is not FILE, each process also needs a drive. If you are copying active data from a sequential-access storage pool, each process needs an additional mount point for primary storage pool volumes and, if the device type is not FILE, an additional drive. For example, suppose you specify a maximum of 3 processes to copy a primary sequential storage pool to an active-data pool of the same device class. Each process requires two mount points and two drives. To run all three processes, the device class must have a mount limit of at least six, and at least six mount points and six drives must be available.

  To use the PREVIEW parameter, only one process is used, and no mount points or drives are needed.

Preview

Specifies whether you want to preview but not actually copy any active data. The preview displays the number of files and bytes to be copied and a list of the primary storage pool volumes that you must mount. This parameter is optional. The default is NO. Possible values are:

No
: Specifies that active data will be copied.

Yes
: Specifies that you want to preview the process but not copy any data.

VOLumesonly
: Specifies that you want to preview the process only as a list of the volumes that must be mounted. This choice requires the least processing time.

Wait
: Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default is NO. Possible values are:

No
: Specifies that the server processes this command in the background.

  You can continue with other tasks while the command is being processed. Messages created from the background process are displayed either in the activity log or the server console, depending on where messages are logged.

  To cancel a background process, use the CANCEL PROCESS command. If you cancel this process, some files may have already been copied prior to the cancellation.

Yes
: Specifies that the server performs this operation in the foreground. You must wait for the operation to complete before continuing with other tasks. The server displays the output messages to the administrative client when the operation completes.

  You cannot specify WAIT=YES from the server console.

SHREDTONOshred
: Specifies whether data should be copied from a primary storage pool that enforces shredding to an active-data pool that does not enforce shredding. This parameter is optional. The default value is NO. Possible values are:

No
: Specifies that the server does not allow data to be copied from a primary storage pool that enforces shredding to an active-data pool that does not enforce shredding. If the primary storage pool enforces shredding and the active-data pool does not, the operation will fail.

Yes
: Specifies that the server does allow data to be copied from a primary storage pool that enforces shredding to an active-data pool that does not enforce shredding. The data in the active-data pool will not be shredded when it is deleted.

Example: Copy primary storage pool data to active-data pool

Copy the active data from a primary storage pool named PRIMARY_POOL to the active-data pool named ACTIVEPOOL. Issue the command:

```
copy activedata primary_pool activepool
```

Related commands

Table 1. Commands related to COPY ACTIVEDATA

Command	Description
DEFINE DOMAIN	Defines a policy domain that clients can be assigned to.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
EXPORT NODE	Copies client node information to external media or directly to another server.

Command	Description
EXPORT SERVER	Copies all or part of the server to external media or directly to another server.
IMPORT NODE	Restores client node information from external media.
IMPORT SERVER	Restores all or part of the server from external media.
MOVE NODEDATA	Moves data for one or more nodes, or a single node with selected file spaces.
QUERY CONTENT	Displays information about files in a storage pool volume.
QUERY DOMAIN	Displays information about policy domains.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY NODEDATA	Displays information about the location and size of data for a client node.
QUERY STGPOOL	Displays information about storage pools.
RESTORE STGPOOL	Restores files to a primary storage pool from copy storage pools.
RESTORE VOLUME	Restores files stored on specified volumes in a primary storage pool from copy storage pools.
UPDATE DOMAIN	Changes the attributes of a policy domain.
UPDATE STGPOOL	Changes the attributes of a storage pool.

COPY CLOPTSET (Copy a client option set)

Use this command to copy a client option set.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the client node is assigned.

Syntax

```
>>-COPy CLOptset--current_option_set_name--new_option_set_name->><
```

Parameters

current_option_set_name (Required)
: Specifies the name of the client option set to be copied.

new_option_set_name (Required)
: Specifies the name of the new client option set. The maximum length of the name is 64 characters.

Example: Copy a client option set

Copy a client option set named ENG to a new client option set named ENG2.

```
copy cloptset eng eng2
```

Related commands

Table 1. Commands related to COPY CLOPTSET

Command	Description

Command	Description
DEFINE CLIENTOPT	Adds a client option to a client option set.
DEFINE CLOPTSET	Defines a client option set.
DELETE CLIENTOPT	Deletes a client option from a client option set.
DELETE CLOPTSET	Deletes a client option set.
QUERY CLOPTSET	Displays information about a client option set.
UPDATE CLIENTOPT	Updates the sequence number of a client option in a client option set.
UPDATE CLOPTSET	Updates the description of a client option set.

COPY DOMAIN (Copy a policy domain)

Use this command to create a copy of a policy domain.

The server copies the following information to the new domain:

- Policy domain description
- Policy sets in the policy domain (including the ACTIVE policy set, if a policy set is activated)
- Management classes in each policy set (including the default management class, if assigned)
- Copy groups in each management class

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-COPy DOmain--current_domain_name--new_domain_name----------><
```

Parameters

current_domain_name (Required)
: Specifies the policy domain to copy.

new_domain_name (Required)
: Specifies the name of the new policy domain. The maximum length of this name is 30 characters.

Example: Copy a policy domain to a new policy domain

Copy the STANDARD policy domain to a new policy domain, ENGPOLDOM, by entering the following command:

```
copy domain standard engpoldom
```

ENGPOLDOM now contains the standard policy set, management class, backup copy group, and archive copy group.

Related commands

Table 1. Commands related to COPY DOMAIN

Command	Description
ACTIVATE POLICYSET	Validates and activates a policy set.
COPY MGMTCLASS	Creates a copy of a management class.
DEFINE COPYGROUP	Defines a copy group for backup or archive processing within a specified management class.
DEFINE DOMAIN	Defines a policy domain that clients can be assigned to.

Command	Description
DEFINE MGMTCLASS	Defines a management class.
DEFINE POLICYSET	Defines a policy set within the specified policy domain.
DELETE COPYGROUP	Deletes a backup or archive copy group from a policy domain and policy set.
DELETE DOMAIN	Deletes a policy domain along with any policy objects in the policy domain.
DELETE MGMTCLASS	Deletes a management class and its copy groups from a policy domain and policy set.
QUERY COPYGROUP	Displays the attributes of a copy group.
QUERY DOMAIN	Displays information about policy domains.
QUERY MGMTCLASS	Displays information about management classes.
QUERY POLICYSET	Displays information about policy sets.
REGISTER NODE	Defines a client node to the server and sets options for that user.
UPDATE COPYGROUP	Changes one or more attributes of a copy group.
UPDATE DOMAIN	Changes the attributes of a policy domain.
UPDATE MGMTCLASS	Changes the attributes of a management class.
UPDATE POLICYSET	Changes the description of a policy set.
VALIDATE POLICYSET	Verifies and reports on conditions the administrator must consider before activating the policy set.

COPY MGMTCLASS (Copy a management class)

Use this command to create a copy of a management class within the same policy set.

The server copies the following information to the new management class:

- Management class description
- Copy groups defined to the management class
- Any attributes for managing files for IBM Spectrum Protect™ for Space Management clients

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the new management class belongs.

Syntax

```
>>-COPy MGmtclass--domain_name--policy_set_name----------------->

>--current_class_name--new_class_name-------------------------><
```

Parameters

domain_name (Required)
: Specifies the policy domain to which the management class belongs.

policy_set_name (Required)
: Specifies the policy set to which the management class belongs.

current_class_name (Required)
: Specifies the management class to copy.

new_class_name (Required)

Specifies the name of the new management class. The maximum length of this name is 30 characters.

Example: Copy a management class to a new management class

Copy the management class ACTIVEFILES to a new management class, FILEHISTORY. The management class is in policy set VACATION in the EMPLOYEE_RECORDS policy domain.

```
copy mgmtclass employee_records vacation
activefiles filehistory
```

Related commands

Table 1. Commands related to COPY MGMTCLASS

Command	Description
DEFINE COPYGROUP	Defines a copy group for backup or archive processing within a specified management class.
DELETE MGMTCLASS	Deletes a management class and its copy groups from a policy domain and policy set.
QUERY COPYGROUP	Displays the attributes of a copy group.
QUERY MGMTCLASS	Displays information about management classes.
QUERY POLICYSET	Displays information about policy sets.
UPDATE COPYGROUP	Changes one or more attributes of a copy group.
UPDATE MGMTCLASS	Changes the attributes of a management class.

COPY POLICYSET (Copy a policy set)

Use this command to copy a policy set (including the ACTIVE policy set) within the same policy domain.

The server copies the following information to the new policy set:

- Policy set description
- Management classes in the policy set (including the default management class, if assigned)
- Copy groups in each management class

The policies in the new policy set do not take effect unless you make the new set the ACTIVE policy set.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the new policy set belongs.

Syntax

```
>>-COPy POlicyset--domain_name--current_set_name--new_set_name-><
```

Parameters

domain_name (Required)
: Specifies the policy domain to which the policy set belongs.

current_set_name (Required)
: Specifies the policy set to copy.

new_set_name (Required)
: Specifies the name of the new policy set. The maximum length of this name is 30 characters.

Example: Copy a policy set to a new policy set

Copy the policy set VACATION to the new policy set HOLIDAY in the EMPLOYEE_RECORDS policy domain.

```
copy policyset employee_records vacation holiday
```

Related commands

Table 1. Commands related to COPY POLICYSET

Command	Description
ACTIVATE POLICYSET	Validates and activates a policy set.
COPY MGMTCLASS	Creates a copy of a management class.
DEFINE MGMTCLASS	Defines a management class.
DELETE POLICYSET	Deletes a policy set, including its management classes and copy groups, from a policy domain.
QUERY POLICYSET	Displays information about policy sets.
UPDATE POLICYSET	Changes the description of a policy set.
VALIDATE POLICYSET	Verifies and reports on conditions the administrator must consider before activating the policy set.

COPY PROFILE (Copy a profile)

Use this command on a configuration manager to copy a profile and all its associated object names to a new profile.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-COPy PROFIle--current_profile_name--new_profile_name-------><
```

Parameters

current_profile_name (Required)
: Specifies the profile to copy.

new_profile_name (Required)
: Specifies the name of the new profile. The maximum length of the profile name is 30 characters.

Example: Make a copy of a profile

Copy a profile named VAL to a new profile named VAL2.

```
copy profile val val2
```

Related commands

Table 1. Commands related to COPY PROFILE

Command	Description
DEFINE PROFASSOCIATION	Associates objects with a profile.
DEFINE PROFILE	Defines a profile for distributing information to managed servers.
DEFINE SUBSCRIPTION	Subscribes a managed server to a profile.
DELETE PROFASSOCIATION	Deletes the association of an object with a profile.

Command	Description
DELETE PROFILE	Deletes a profile from a configuration manager.
DELETE SUBSCRIBER	Deletes obsolete managed server subscriptions.
DELETE SUBSCRIPTION	Deletes a specified profile subscription.
LOCK PROFILE	Prevents distribution of a configuration profile.
NOTIFY SUBSCRIBERS	Notifies servers to refresh their configuration information.
QUERY PROFILE	Displays information about configuration profiles.
QUERY SUBSCRIBER	Displays information about subscribers and their subscriptions to profiles.
QUERY SUBSCRIPTION	Displays information about profile subscriptions.
SET CONFIGMANAGER	Specifies whether a server is a configuration manager.
UNLOCK PROFILE	Enables a locked profile to be distributed to managed servers.
UPDATE PROFILE	Changes the description of a profile.

COPY SCHEDULE (Copy a client or an administrative command schedule)

Use this command to create a copy of a schedule.

The COPY SCHEDULE command takes two forms, depending on whether the schedule applies to client operations or administrative commands. The syntax and parameters for each form are defined separately.

Table 1. Commands related to COPY SCHEDULE

Command	Description
DEFINE ASSOCIATION	Associates clients with a schedule.
DEFINE SCHEDULE	Defines a schedule for a client operation or an administrative command.
DELETE SCHEDULE	Deletes a schedule from the database.
QUERY SCHEDULE	Displays information about schedules.
UPDATE SCHEDULE	Changes the attributes of a schedule.

- COPY SCHEDULE (Create a copy of a schedule for client operations)
  Use the COPY SCHEDULE command to create a copy of a schedule for client operations. You can copy a schedule within a policy domain or from one policy domain to another policy domain. Use the DEFINE ASSOCIATION command to associate the new schedule with the client nodes.
- COPY SCHEDULE (Create a copy of a schedule for administrative operations)
  Use the COPY SCHEDULE command to create a copy of an administrative command schedule.

COPY SCHEDULE (Create a copy of a schedule for client operations)

Use the COPY SCHEDULE command to create a copy of a schedule for client operations. You can copy a schedule within a policy domain or from one policy domain to another policy domain. Use the DEFINE ASSOCIATION command to associate the new schedule with the client nodes.

Privilege class

To copy a client schedule, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which you are copying the schedule.

Syntax

```
>>-COPy SCHedule--current_domain_name--current_sched_name------->
```

```
                    .-current_sched_name-.
>--new_domain_name--+--------------------+---------------------->
                    '-new_sched_name-----'

   .-REPlace--=--No------.
>--+---------------------+------------------------------------><
   '-REPlace--=--+-No--+-'
                 '-Yes-'
```

Parameters

current_domain_name (Required)
: Specifies the name of the policy domain that contains the schedule you want to copy.

current_sched_name (Required)
: Specifies the name of the schedule you want to copy.

new_domain_name (Required)
: Specifies the name of a policy domain to which you want to copy the new schedule.

new_sched_name
: Specifies the name of the new schedule. You can specify up to 30 characters for the name.

  If you do not specify this name, the name of the original schedule is used.

  If the schedule name is already defined in the policy domain, you must specify REPLACE=YES, or the command fails.

REPlace
: Specifies whether to replace a client schedule. The default is NO. The values are:

  No
  : Specifies that a client schedule is not replaced.

  Yes
  : Specifies that a client schedule is replaced.

Example: Copy a schedule from one policy domain to another

Copy the WEEKLY_BACKUP schedule that belongs to policy domain EMPLOYEE_RECORDS to the PROG1 policy domain and name the new schedule WEEKLY_BACK2. If there is already a schedule with this name defined in the PROG1 policy domain, do not replace it.

```
copy schedule employee_records weekly_backup
prog1 weekly_back2
```

COPY SCHEDULE (Create a copy of a schedule for administrative operations)

Use the COPY SCHEDULE command to create a copy of an administrative command schedule.

Privilege class

To copy an administrative command schedule, you must have system privilege.

Syntax

```
>>-COPy SCHedule--current_sched_name--new_sched_name------------>

                            .-REPlace--=--No------.
>--Type--=--Administrative--+---------------------+------------><
                            '-REPlace--=--+-No--+-'
                                          '-Yes-'
```

Parameters

current_schedule_name (Required)
Specifies the name of the schedule you want to copy.
new_schedule_name (Required)
Specifies the name of the new schedule. You can specify up to 30 characters for the name.

If the schedule name is already defined, you must specify REPLACE=YES, or the command fails.

Type=Administrative
Specifies that an administrative command schedule is to be copied.
REPlace
Specifies whether to replace an administrative command schedule. The default is NO. The values are:

No
Specifies that an administrative command schedule is not replaced.
Yes
Specifies that an administrative command schedule is replaced.

Example: Copy an administrative command schedule to another schedule

Copy the administrative command schedule, DATA_BACKUP and name the schedule DATA_ENG. If there is already a schedule with this name, replace it.

```
copy schedule data_backup data_eng
type=administrative replace=yes
```

COPY SCRIPT (Copy an IBM Spectrum Protect script)

Use this command to copy an existing IBM Spectrum Protect™ script to a new script with a different name.

Privilege class

To issue this command, you must have operator, policy, storage, or system privilege.

Syntax

```
>>-COPy SCRipt--current_script_name--new_script_name ---------><
```

Parameters

current_script_name (Required)
Specifies the name of the script you want to copy.
new_script_name (Required)
Specifies the name of the new script. You can specify up to 30 characters for the name.

Example: Make a copy of a script

Copy script TESTDEV to a new script and name it ENGDEV.

```
copy script testdev engdev
```

Related commands

Table 1. Commands related to COPY SCRIPT

Command	Description
DEFINE SCRIPT	Defines a script to the IBM Spectrum Protect server.
DELETE SCRIPT	Deletes the script or individual lines from the script.
QUERY SCRIPT	Displays information about scripts.
RENAME SCRIPT	Renames a script to a new name.

Command	Description
RUN	Runs a script.
UPDATE SCRIPT	Changes or adds lines to a script.

COPY SERVERGROUP (Copy a server group)

Use this command to create a copy of a server group.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-COPy SERVERGroup--current_group_name--new_group_name--------><
```

Parameters

current_group_name (Required)
: Specifies the server group to copy.

new_group_name (Required)
: Specifies the name of the new server group. The maximum length of this name is 64 characters.

Example: Make a copy of a server group

Copy the server group GRP_PAYROLL to the new group HQ_PAYROLL.

```
copy servergroup grp_payroll hq_payroll
```

Related commands

Table 1. Commands related to COPY SERVERGROUP

Command	Description
DEFINE GRPMEMBER	Defines a server as a member of a server group.
DEFINE SERVER	Defines a server for server-to-server communications.
DEFINE SERVERGROUP	Defines a new server group.
DELETE GRPMEMBER	Deletes a server from a server group.
DELETE SERVER	Deletes the definition of a server.
DELETE SERVERGROUP	Deletes a server group.
MOVE GRPMEMBER	Moves a server group member.
QUERY SERVER	Displays information about servers.
QUERY SERVERGROUP	Displays information about server groups.
RENAME SERVERGROUP	Renames a server group.
UPDATE SERVER	Updates information about a server.
UPDATE SERVERGROUP	Updates a server group.

DEACTIVATE DATA (Deactivate data for a client node)

Use this command to specify that active data that was backed up for an application client node before a specified date is no longer needed. The command marks the data as inactive so it can be deleted according to your data retention policies.

Restriction: The DEACTIVATE DATA command applies only to application clients that protect Oracle databases.

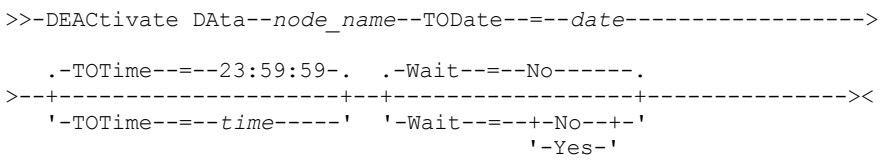
When you issue the DEACTIVATE DATA command, all active backup data that was stored before the specified date becomes inactive. The data can no longer be retrieved, and is deleted when it expires.

The DEACTIVATE DATA command affects only the files that were copied to the server before the specified date and time. Files that were copied after the specified date are still accessible, and the client can still access the server.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

node_name (Required)
: Specifies the name of an application client node whose data is to be deactivated.

TODate (Required)
: Specifies the date to use to select the backup files to deactivate. IBM Spectrum Protect™ deactivates only those files with a date on or before the date you specify. You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	01/23/2014
TODAY	The current date	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY–30 **or** –30. To deactivate files that are 30 or more days old, you can specify TODAY-30 or -30.
EOLM	End of last month. The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To deactivate files that were active a day before the last day of the previous month.
BOTM	Beginning of this month. The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To deactivate files that were active on the 10th day of the current month.

TOTime
: Specifies that you want to deactivate files that were created on the server before this time on the specified date. This parameter is optional. The default is the end of the day (23:59:59). Specify the time by using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time on the specified date	12:30:22
NOW	The current time on the specified date	NOW

Value	Description	Example
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes on the specified date	NOW+03:00 **or** +03:00. If you issue the DEACTIVATE DATA command at 9:00 with TOTIME=NOW+03:00 or TOTIME=+03:00, IBM Spectrum Protect deactivates files that were put on the server at 12:00 or earlier on the specified date.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes on the specified date	NOW-03:30 **or** -03:30. If you issue the DEACTIVATE DATA command at 9:00 with TOTIME=NOW-3:30 or TOTIME=-3:30, IBM Spectrum Protect deactivates files that were put on the server at 5:30 or earlier on the specified date.

Wait

Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default value is NO. Specify the following values:

No

The server processes this command in the background and you can continue with other tasks while the command is processing. Messages that are related to the background process are shown either in the activity log file or the server console, depending on where the messages are logged.

Yes

The server processes this command in the foreground. The operation must complete before you can continue with other tasks. Messages are shown either in the activity log file or the server console, or both, depending on where the messages are logged.

Restriction: You cannot specify WAIT=YES from the server console.

Example: Deactivate data for a data protection client node

The client node BANDIT is an IBM Spectrum Protect for Databases: Data Protection for Oracle application client. All of the backup data is active, and so all of the backup data is retained. The following command deactivates data that was backed up before January 3, 2014, so it can be deleted when it expires.

```
deactivate data bandit todate=01/23/2014
```

To periodically deactivate data so it can be deleted when it expires, you might run the following command from within a client schedule.

```
deactivate data bandit todate=today
```

Related commands

Table 1. Commands related to DEACTIVATE DATA

Command	Description
DECOMMISSION NODE	Decommissions an application or system.
DECOMMISSION VM	Decommissions a virtual machine.

DECOMMISSION commands

Use the DECOMMISSION commands to remove client nodes from the production environment. Client nodes include applications, systems, and virtual machines.

- DECOMMISSION NODE (Decommission an application or system)
- DECOMMISSION VM (Decommission a virtual machine)

DECOMMISSION NODE (Decommission an application or system)

Use this command to remove an application or system client node from the production environment. Any backup data that is stored for the client node expires according to policy settings unless you explicitly delete the data.

Attention: This action cannot be reversed and causes deletion of data. Although this command does not delete the client node definition until after its data expires, you cannot recommission the client node. After you issue this command, the client node cannot access the server and its data is not backed up. The client node is locked, and can be unlocked only to restore files. File spaces that belong to the client node, and the client node itself, are eventually removed.
By using this command, you can decommission the following types of client nodes:

Application client nodes
: Application client nodes include email servers, databases, and other applications. For example, any of the following applications can be an application client node:

  - IBM Spectrum Protect™ Snapshot
  - IBM Spectrum Protect for Databases
  - IBM Spectrum Protect for Enterprise Resource Planning
  - IBM Spectrum Protect for Mail
  - IBM Spectrum Protect for Virtual Environments

System client nodes
: System client nodes include workstations, network-attached storage (NAS) file servers, and API clients.

When a client node is no longer needed in the production environment, you can issue this command to initiate a gradual, controlled decommission operation. The command completes the following actions:

- Deletes all schedule associations for the client node. Schedules are no longer run on the client node. This action is equivalent to issuing the DELETE ASSOCIATION command for every schedule with which the client node is associated.
- Prevents the client from accessing the server. This action is equivalent to issuing the LOCK NODE command.

After the command finishes, client node data is no longer backed up to the server. Data that was backed up before the client node was decommissioned is not immediately deleted from the server. However, all backup file versions, including the most recent backup, are now inactive copies. The client files are retained on the server according to your storage management policies.

After all data retention periods expire, and all client backup and archive file copies are removed from server storage, IBM Spectrum Protect deletes the file spaces that belong to the decommissioned node. This action is equivalent to issuing the DELETE FILESPACE command.

After the file spaces for the decommissioned node are deleted, the node definition is deleted from the server. This action is equivalent to issuing the REMOVE NODE command.

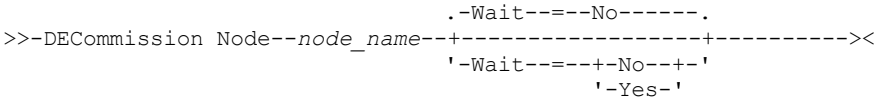
After you decommission a client node, but before it is removed from the server, you can use the QUERY NODE command to verify that the client node is decommissioned.

Restriction: You cannot decommission a client node that is configured for replication. You can determine a client node's replication state by using the QUERY NODE command. If a client node is configured for replication, you can remove the client node from replication by using the REMOVE REPLNODE command.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

node_name (Required)
: Specifies the name of the client node to be decommissioned.

Wait

Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default value is NO. You can specify the following values:

No
: The server processes this command in the background and you can continue with other tasks while the command is processing. Messages that are related to the background process are shown either in the activity log file or the server console, depending on where the messages are logged.

Yes
: The server processes this command in the foreground. The operation must complete before you can continue with other tasks. Messages are shown either in the activity log file or the server console, or both, depending on where the messages are logged.

Restriction: You cannot specify WAIT=YES from the server console.

Example: Decommission a client node

Decommission the client node CODY.

```
decommission node cody
```

Related commands

Table 1. Commands related to DECOMMISSION NODE

Command	Description
DECOMMISSION VM	Decommissions a virtual machine.
DEACTIVATE DATA	Deactivates data for a client node.

DECOMMISSION VM (Decommission a virtual machine)

Use this command to remove an individual virtual machine within a data center node. The file space that represents the virtual machine is deleted from the server only after its backup data expires.

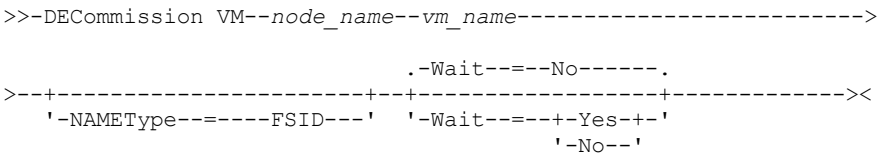
Attention: This command cannot be reversed and causes deletion of data. Although this command does not delete the virtual machine file space until after its data expires, you cannot recommission the virtual machine.

When a virtual machine is no longer needed in your production environment, you can issue this command to initiate a staged removal of the virtual machine file space from the server. The DECOMMISSION VM command marks all data that was backed up for the virtual machine as inactive, so it can be deleted according to your data retention policies. After all data that was backed up for the virtual machine expires, the file space that represents the virtual machine is deleted. The DECOMMISSION VM command affects only the virtual machine that you identify. The data center node, and the other virtual machines that are hosted by the data center node are not affected.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

node_name (Required)
: Specifies the name of the data center node that hosts the virtual machine to be decommissioned.

vm_name (Required)

Identifies the file space that represents the virtual machine to be decommissioned. Each virtual machine that is hosted by a data center node is represented as a file space.

If the name includes one or more spaces, you must enclose the name in double quotation marks when you issue the command.

By default, the server interprets the file space name that you enter by using the server code page and also attempts to convert the file space name from the server code page to the UTF-8 code page. Conversion might fail if the string includes characters that are not available in the server code page, or if the server cannot access system conversion routines.

If the name of the virtual machine is a non-English-language name, this parameter must specify the file space ID (FSID). By specifying the NAMEType parameter, you can instruct the server to interpret the file space name by its file space ID (FSID) instead.

NAMEType
Specify how you want the server to interpret the file space name that you enter to identify the virtual machine. This parameter is useful when the server has clients with Unicode support. You can specify the following value:

FSID
The server interprets the file space name by its file space ID (FSID).

Wait
Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default value is No. You can specify the following values:

No
The server processes this command in the background and you can continue with other tasks while the command is processing. Messages that are related to the background process are shown either in the activity log file or the server console, depending on where the messages are logged.

Yes
The server processes this command in the foreground. The operation must complete before you can continue with other tasks. Messages are shown either in the activity log file or the server console, or both, depending on where the messages are logged.

Restriction: You cannot specify WAIT=YES from the server console.

Examples: Decommission a virtual machine

Decommission the virtual machine CODY.

```
decommission vm dept06node cody
```

Decommission the virtual machine CODY 2.

```
decommission vm dept06node "cody 2"
```

Decommission a virtual machine by specifying its file space ID.

```
decommission vm dept06node 7 nametype=fsid
```

Related commands

Table 1. Commands related to DECOMMISSION VM

Command	Description
DECOMMISSION NODE	Decommissions an application or system.
DEACTIVATE DATA	Deactivates data for a client node.

DEFINE commands

Use the DEFINE commands to create IBM Spectrum Protect™ objects.

- DEFINE ALERTTRIGGER (Define an alert trigger)
- DEFINE ASSOCIATION (Associate client nodes with a schedule)

- DEFINE BACKUPSET (Define a backup set)
- DEFINE CLIENTACTION (Define a one-time client action)
- DEFINE CLIENTOPT (Define an option to an option set)
- DEFINE CLOPTSET (Define a client option set name)
- DEFINE COLLOCGROUP (Define a collocation group)
- DEFINE COLLOCMEMBER (Define collocation group member)
- DEFINE COPYGROUP (Define a copy group)
- DEFINE DATAMOVER (Define a data mover)
- DEFINE DEVCLASS (Define a device class)
- DEFINE DOMAIN (Define a new policy domain)
- DEFINE DRIVE (Define a drive to a library)
- DEFINE EVENTSERVER (Define a server as the event server)
- DEFINE GRPMEMBER (Add a server to a server group)
- DEFINE LIBRARY (Define a library)
- DEFINE MACHINE (Define machine information for disaster recovery)
- DEFINE MACHNODEASSOCIATION (Associate a node with a machine)
- DEFINE MGMTCLASS (Define a management class)
- DEFINE NODEGROUP (Define a node group)
- DEFINE NODEGROUPMEMBER (Define node group member)
- DEFINE PATH (Define a path)
- DEFINE POLICYSET (Define a policy set)
- DEFINE PROFASSOCIATION (Define a profile association)
- DEFINE PROFILE (Define a profile)
- DEFINE RECMEDMACHASSOCIATION (Associate recovery media with a machine)
- DEFINE RECOVERYMEDIA (Define recovery media)
- DEFINE SCHEDULE (Define a client or an administrative command schedule)
- DEFINE SCRIPT (Define an IBM Spectrum Protect script)
- DEFINE SERVER (Define a server for server-to-server communications)
- DEFINE SERVERGROUP (Define a server group)
- DEFINE SPACETRIGGER (Define the space trigger)
- DEFINE STATUSTHRESHOLD (Define a status monitoring threshold)
- DEFINE STGPOOL (Define a storage pool)
- DEFINE STGPOOLDIRECTORY (Define a storage pool directory)
- DEFINE SUBSCRIPTION (Define a profile subscription)
- DEFINE VIRTUALFSMAPPING (Define a virtual file space mapping)
- DEFINE VOLUME (Define a volume in a storage pool)

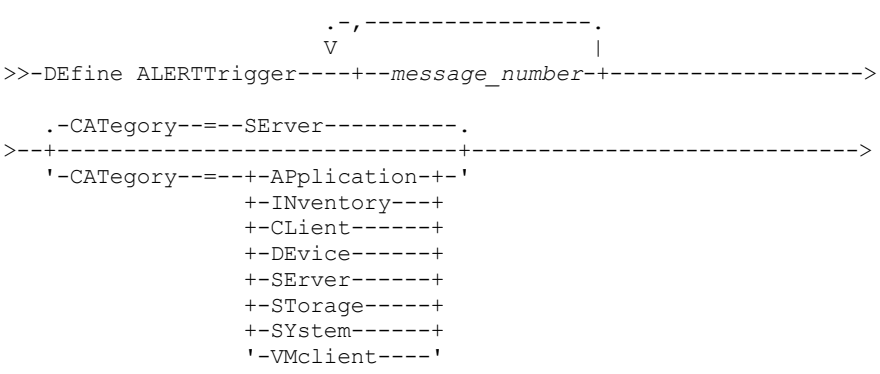
DEFINE ALERTTRIGGER (Define an alert trigger)

Use this command to trigger an alert whenever a server issues a specific error message. You can define a message number to be an alert trigger, assign it to a category, or specify administrators who can be notified of the alert by email.

Privilege class

To issue this command, you must have system privilege.

Syntax



```
>--+-------------------------+--------------------------------><
   |           .-,----------. |
   |           V            | |
   '-ADmin--=----admin_name-+-'
```

Parameters

message_number (Required)
: Specifies the message number that you want to associate with the alert trigger. Specify multiple message numbers, which are separated by commas, and no intervening spaces. Message numbers are a maximum of eight characters in length.

CATegory
: Specifies the category type for the alert, which is determined by the message types. The default value is SERVER.
Note: Changing the category of an alert trigger does not change the category of existing alerts on the server. New alerts are categorized with the new category.
Specify one of the following values:

  APplication
  : Alert is classified as application category. For example, you can specify this category for messages that are associated with application (TDP) clients.

  INventory
  : Alert is classified as inventory category. For example, you can specify this category for messages that are associated with the database, active log file, or archive log file.

  CLient
  : Alert is classified as client category. For example, you can specify this category for messages that are associated with general client activities.

  DEvice
  : Alert is classified as device category. For example, you can specify this category for messages that are associated with device classes, libraries, drives, or paths.

  SErver
  : Alert is classified as general server category. For example, you can specify this category for messages that are associated with general server activities or events.

  STorage
  : Alert is classified as storage category. For example, you can specify this category for messages that are associated with storage pools.

  SYstems
  : Alert is classified under system clients category. For example, you can specify this category for messages that are associated with system backup and archive or hierarchical storage management (HSM) backup-archive clients.

  VMclient
  : Alert is classified under VMclient category. For example, you can specify this category for messages that are associated with virtual machine clients.

ADmin
: This optional parameter specifies the name of the administrator who receives email notification of this alert. The alert trigger is defined successfully even if no administrator names are specified.

Assign two message numbers to an alert

Issue the following command to specify that you want two message numbers to trigger an alert:

```
define alerttrigger ANR1067E,ANR1073E
```

Assign a message number to an alert and email two administrators

Issue the following command to specify the message numbers that you want to trigger an alert and have them sent by email to two administrators:

```
define alerttrigger ANR1067E,ANR1073E ADmin=BILL,DJADMIN
```

Related commands

Table 1. Commands related to DEFINE ALERTTRIGGER

Command	Description
DELETE ALERTTRIGGER (Remove a message from an alert trigger)	Removes a message number that can trigger an alert.
QUERY ALERTSTATUS (Query the status of an alert)	Displays information about alerts that have been issued on the server.
QUERY ALERTTRIGGER (Query the list of defined alert triggers)	Displays message numbers that trigger an alert.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
UPDATE ALERTTRIGGER (Update a defined alert trigger)	Updates the attributes of one or more alert triggers.
UPDATE ALERTSTATUS (Update the status of an alert)	Updates the status of a reported alert.

DEFINE ASSOCIATION (Associate client nodes with a schedule)

Use this command to associate one or more clients with a schedule. You must assign a client node to the policy domain to which a schedule belongs. Client nodes process operations according to the schedules associated with the nodes.

Note:

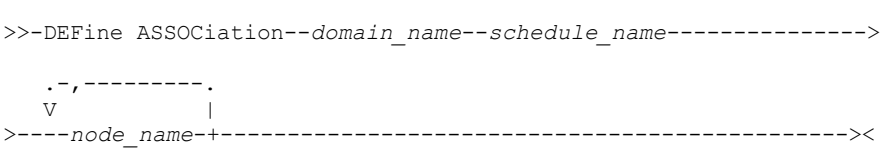
1. IBM Spectrum Protect™ cannot run multiple schedules concurrently for the same client node.
2. In a macro, the server may stall if some commands (such as REGISTER NODE and DEFINE ASSOCIATION) are not committed as soon as you issue them. You could follow each command in a macro with a COMMIT command. However, a simpler solution is to include the -ITEMCOMMIT option with the DSMADMC command.

Privilege class

To issue this command, you must have one of the following privilege classes:

- System privilege
- Unrestricted policy privilege
- Restricted policy privilege for the policy domain to which the schedule belongs

Syntax



Parameters

domain_name (Required)
: Specifies the name of the policy domain to which the schedule belongs.

schedule_name (Required)
: Specifies the name of the schedule that you want to associate with one or more clients.

node_name (Required)
: Specifies the name of a client node or a list of client nodes to associate with the specified schedule. Use commas to separate the items in the list. Do not leave spaces between the items and commas. You can use a wildcard character to specify a name. The command will not associate a listed client to the schedule if:

  - The client is already associated with the specified schedule.
  - The client is not assigned to the policy domain to which the schedule belongs.
  - The client is a NAS node name. All NAS nodes are ignored.

Example: Associate client nodes with a schedule

Associate the client nodes SMITH or JOHN with the WEEKLY_BACKUP schedule. The associated clients are assigned to the EMPLOYEE_RECORDS policy domain.

```
define association employee_records
weekly_backup smith*,john*
```

Example: Associate client nodes with a schedule

Associate the client nodes JOE, TOM, and LARRY with the WINTER schedule. The associated clients are assigned to the EMPLOYEE_RECORDS policy domain; however, the client JOE is already associated with the WINTER schedule.

```
define association employee_records
winter joe,tom,larry
```

Related commands

Table 1. Commands related to DEFINE ASSOCIATION

Command	Description
DEFINE SCHEDULE	Defines a schedule for a client operation or an administrative command.
DELETE ASSOCIATION	Deletes the association between clients and a schedule.
DELETE SCHEDULE	Deletes a schedule from the database.
QUERY ASSOCIATION	Displays the clients associated with one or more schedules.
REGISTER NODE	Defines a client node to the server and sets options for that user.

DEFINE BACKUPSET (Define a backup set)

Use this command to define a client backup set that was previously generated on one server and make it available to the server that is running this command. The client node has the option of restoring the backup set from the server that is running this command rather than the one on which the backup set was generated.

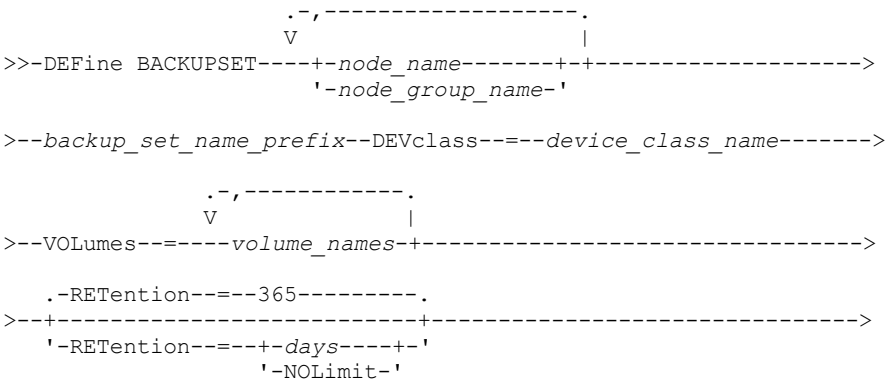
Any backup set generated on one server can be defined to another server when the servers share a common device type. The level of the server to which the backup set is being defined must be equal to or greater than the level of the server that generated the backup set.

You can also use the DEFINE BACKUPSET command to redefine a backup set that was deleted on a server.

Privilege class

If the REQSYSAUTHOUTFILE server option is set to YES (the default), the administrator must have system privilege. If the REQSYSAUTHOUTFILE server option is set to NO, the administrator must have system privilege or policy privilege for the domain to which the client node is assigned.

Syntax



```
>--+-----------------------------+-----------------------------><
   '-DESCription--=--description-'

   .-WHEREDATAType--=--ALL-----------.
>--+-----------------------------------+-------------------------->
   |                    .-,---------. |
   |                    V           | |
   '-WHEREDATAType--=-----+-FILE--+-+-'
                          '-IMAGE-'

>--+-----------------------+--+-----------------------------+--><
   '-TOC--=--+-PREFERRED-+-'  '-TOCMGmtclass--=--class_name-'
             +-YES-------+
             '-NO--------'
```

Parameters

node_name or node_group_name (Required)
: Specifies the name of the client nodes or node groups whose data is contained in the specified backup set volumes. To specify multiple node and node group names, separate the names with commas and no intervening spaces. Node names can contain wildcard characters, but node group names cannot. If the backup set volumes contain backup sets from multiple nodes, every backup set whose node name matches one of the specified node names is defined. If the volumes contain a backup set for a node that is not currently registered, the DEFINE BACKUPSET command does not define the backup set for that node.

backup_set_name_prefix (Required)
: Specifies the name of the backup set to define to this server. The maximum length of the name is 30 characters.

  When you select a name, IBM Spectrum Protect™ adds a suffix to construct the backup set name. For example, if you name your backup set *mybackupset*, IBM Spectrum Protect adds a unique number such as 3099 to the name. Your backup set name is then identified as *mybackupset.3099*. To later display information about this backup set, you can include a wildcard with the name, such as *mybackupset** or you can specify the fully qualified name, such as *mybackupset.3099*.

  If the backup set volumes contain backup sets for multiple nodes, then backup sets are defined for each of the nodes by using the same backup set name prefix and suffix.

DEVclass (Required)
: Specifies the device class name for the volumes from which the backup set is read.
  Note: The device type that is associated with the device class you specify must match the device class with which the backup set was originally generated.

VOLumes (Required)
: Specifies the names of the volumes that are used to store the backup set. You can specify multiple volumes by separating the names with commas and no intervening spaces. The volumes that you specify must be available to the server that is defining the backup set.
  Note: The volumes that you specify must be listed in the order they were created, or the DEFINE BACKUPSET command fails.
  The server does not verify that every volume specified for a multiple-volume backup set contains part of the backup set. The first volume is always checked, and in some cases extra volumes are also checked. If these volumes are correct, the backup set is defined and all of the volumes that are listed in the command are protected from being overwritten. If a volume that contains part of the backup set is not listed in the command, the volume is not protected and can potentially be overwritten during normal server operations.
  Note: By default, the server attempts to create a table of contents when a backup set is defined. If an incorrect volume is specified, or if volumes are not listed in the correct order, the table of contents creation fails. If this failure occurs, check the volume list in the command and consider using the QUERY BACKUPSETCONTENTS command to verify the contents of the backup set.

RETention
: Specifies the number of days that the backup set is retained on the server. You can specify an integer 0 - 30000. The default is 365 days. The values are:

  days
  : Specifies the number of days to retain the backup set on the server.

  NOLimit
  : Specifies that the backup set must be retained on the server indefinitely.

If you specify NOLIMIT, IBM Spectrum Protect retains the volumes that contain the backup set forever, unless a user or administrator deletes the volumes from server storage.

DESCription
Specifies the description to associate with the backup set that belongs to the client node. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters.

WHEREDATAType
Specifies the backup sets containing the specified types of data are to be defined. This parameter is optional. The default is that backup sets for all types of data (file level, image, and application) are to be defined. To specify multiple data types, separate the data types with commas and no intervening spaces. Possible values are:

ALL
Specifies that backup sets for all types of data (file level, image, and application) are to be defined. ALL is the default value.

FILE
Specifies that a file level backup set is to be defined. File level backup sets contain files and directories that are backed up by the backup client.

IMAGE
Specifies that an image backup set is to be defined. Image backup sets contain images that are created by the backup-archive client BACKUP IMAGE command.

TOC
Specifies whether a table of contents (TOC) must be created for the file level backup set when it is defined. The TOC parameter is ignored when you define image and application data backup sets because a table of contents is always created for these backup sets.
Consider the following in determining whether you want to create a table of contents:

- If a table of contents is created, you can use the IBM Spectrum Protect web backup-archive client to examine the entire file system tree and choose files and directories to restore. Creation of a table of contents requires that you define the TOCDESTINATION attribute in the backup copy group for the management class that is specified by the TOCMGMTCLASS parameter. To create a table of contents extra processing, storage pool space, and possibly a mount point during the backup set operation is required.
- If a table of contents is not saved for a backup set, you can still restore individual files or directory trees by using the backup-archive client RESTORE BACKUPSET command if you know the fully qualified name of each file or directory to be restored.

This parameter is optional. The default value is Preferred. Possible values are:

No
Specifies that table of contents information is not saved for file level backup sets.

Preferred
Specifies that table of contents information must be saved for file level backup sets. However, a backup set does not fail just because an error occurs during creation of the table of contents.

Yes
Specifies that table of contents information must be saved for each file level backup set. A backup set fails if an error occurs during creation of the table of contents.

TOCMGmtclass
Specifies the name of the management class to which the table of contents must be bound. If you do not specify a management class, the table of contents is bound to the default management class for the policy domain to which the node is assigned. In this case, creation of a table of contents requires that you define the TOCDESTINATION attribute in the backup copy group for the specified management class.

Example: Define a backup set

Define the PERS_DATA backup set that belongs to client node JANE to the server that is running this command. Retain the backup set on the server for 50 days. Specify that volumes VOL001 and VOL002 contain the data for the backup set. The volumes are to be read by a device that is assigned to the AGADM device class. Include a description.

```
define backupset jane pers_data devclass=agadm
volumes=vol1,vol2 retention=50
description="sector 7 base image"
```

Related commands

Table 1. Commands related to DEFINE BACKUPSET

Command	Description
DEFINE NODEGROUP	Defines a group of nodes.
DEFINE NODEGROUPMEMBER	Adds a client node to a node group.
DELETE NODEGROUP	Deletes a node group.
DELETE BACKUPSET	Deletes a backup set.
DELETE NODEGROUPMEMBER	Deletes a client node from a node group.
GENERATE BACKUPSET	Generates a backup set of a client's data.
GENERATE BACKUPSETTOC	Generates a table of contents for a backup set.
QUERY BACKUPSET	Displays backup sets.
QUERY BACKUPSETCONTENTS	Displays contents contained in backup sets.
QUERY NODEGROUP	Displays information about node groups.
UPDATE BACKUPSET	Updates a retention value associated with a backup set.
UPDATE NODEGROUP	Updates the description of a node group.

DEFINE CLIENTACTION (Define a one-time client action)

Use this command to schedule one or more clients to process a command for a one-time action.

The server automatically defines a schedule and associates the client node to the schedule. The server assigns the schedule priority 1, sets the PERUNITS to ONETIME, and determines the number of days to keep the schedule active. The number of days is based on the value set with the SET CLIENTACTDURATION command.

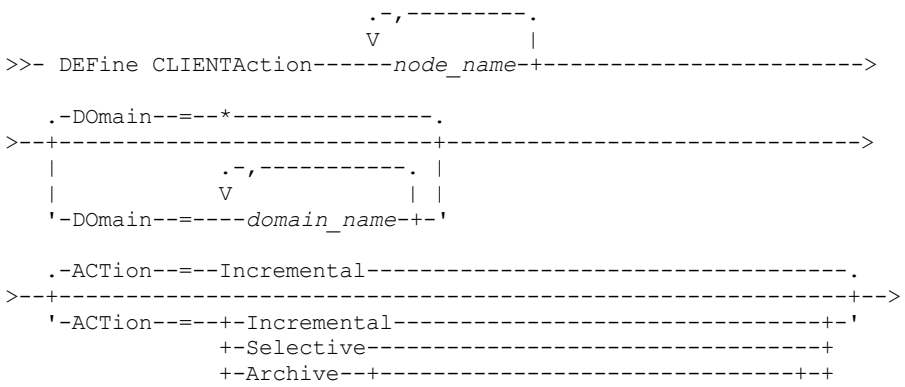
How quickly the client processes this command depends on whether the scheduling mode for the client is set to server-prompted or client-polling. The client scheduler must be started on the client workstation in order for the server to process the schedule.

Remember: The start of the IBM Spectrum Protect™ scheduler depends on the processing of other threads in the server and other processes on the IBM Spectrum Protect server host system. The amount of time it takes to start the scheduler also depends on network traffic and how long it takes to open a socket, to connect with the IBM Spectrum Protect client, and to receive a response from the client. In general, the greater the processing and connectivity requirements on the IBM Spectrum Protect server and client, the longer it can take to start the scheduler.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy for the policy domain to which the schedule belongs.

Syntax



Parameters

node_name (Required)
: Specifies the name of the client node that will process the schedule associated with the action. If you specify multiple node names, separate the names with commas; do not use intervening spaces. You can use the asterisk wildcard character to specify multiple names.

DOmain
: Specifies the list of policy domains used to limit the list of client nodes. Only client nodes that are assigned to one of the specified policy domains will be scheduled. All clients assigned to a matching domain will be scheduled. Separate multiple domain names with commas and no intervening spaces. If you do not specify a value, all policy domains will be included in the list.

ACTion
: Specifies the action that occurs when this schedule is processed. Possible values are:

  Incremental
  : Specifies that the schedule backs up all files that are new or that have changed since the last incremental backup. Incremental also backs up any file for which all existing backups might have expired.

  Selective
  : Specifies that the schedule backs up only files that are specified with the OBJECTS parameter.

  Archive
  : Specifies that the schedule archives files that are specified with the OBJECTS parameter.

  Backup
  : Specifies that the schedule backs up files that are specified with the OBJECTS parameter.

  REStore
  : Specifies that the schedule restores files that are specified with the OBJECTS parameter.

    When you specify ACTION=RESTORE for a scheduled operation, and the REPLACE option is set to PROMPT, no prompting occurs. If you set the option to PROMPT, the files are skipped.

    If you specify a second file specification, this second file specification acts as the restore destination. If you need to restore multiple groups of files, schedule one for each file specification that you need to restore.

  RETrieve
  : Indicates that the schedule retrieves files that are specified with the OBJECTS parameter.
    Remember: A second file that is specified acts as the retrieve destination. If you need to retrieve multiple groups of files, create a separate schedule for each group of files.

  IMAGEBACkup
  : Specifies that the schedule backs up logical volumes that are specified with the OBJECTS parameter.

  IMAGEREStore
  : Specifies that the schedule restores logical volumes that are specified with the OBJECTS parameter.

Command
: Specifies that the schedule processes a client operating system command or script that is specified with the OBJECTS parameter.

Macro
: Specifies that a client processes a macro whose file name is specified with the OBJECTS parameter.

SUBACTion
: You can specify one of the following values:

  ""
  : When a null string (two double quotes) is specified with ACTION=BACKUP the backup is an incremental.

  FASTBAck
  : Specifies that a FastBack client operation that is identified by the ACTION parameter is to be scheduled for processing. The ACTION parameter must be either ARCHIVE or BACKUP.

  SYSTEMSTate
  : Specifies that a client Systemstate backup is scheduled.

  VApp
  : Specifies that a client vApp backup is scheduled. A vApp is a collection of pre-deployed virtual machines.

  VM
  : Specifies that a client VMware backup operation is scheduled.

OPTions
: Specifies the client options that you specify to the scheduled command at the time the schedule is processed. This parameter is optional.
Only those options that are valid on the scheduled command can be specified for this parameter. Refer to the appropriate client manual for information about options that are valid from the command line. All options described there as valid only on the initial command line result in an error or are ignored when running the schedule from the server. For example, do not include the following options because they have no effect when the client processes the scheduled command:

- MAXCMDRETRIES
- OPTFILE
- QUERYSCHEDPERIOD
- RETRYPERIOD
- SCHEDLOGNAME
- SCHEDMODE
- SERVERNAME
- TCPCLIENTADDRESS
- TCPCLIENTPORT

Windows When you define a scheduler service by using the DSMCUTIL command or the backup-archive client GUI wizard, you specify an options file. You cannot override the options in that options file by issuing the scheduled command. You must modify the options in your scheduler service.

If the option string contains multiple options or options with embedded spaces, surround the entire option string with one pair of apostrophes. Enclose individual options that contain spaces in quotation marks. A leading minus sign is required in front of the option. Errors can occur if the option string contains spaces that are not quoted correctly.

The following examples show how to specify some client options:

- To specify `subdir=yes` and `domain all-local -systemobject`, enter:
  - `options='-subdir=yes -domain="all-local -c: -systemobject"'`
- To specify `domain all-local -c: -d:`, enter:
  - `options='-domain="all-local -c: -d:"'`

Windows Tip:

For Windows clients running in batch mode, if the use of quotation marks is necessary, use interactive mode or operating system escape characters. For additional information, see the following topics:

- Processing a series of commands from the administrative client
- Processing individual commands from the administrative client

OBJects
: Specifies the objects for which the specified action is performed. Use a single space between each object. This parameter is required except when ACTION=INCREMENTAL. If the action is a backup, archive, retrieve, or restore operation, the

objects are file spaces, directories, or logical volumes. If the action is to run a command or macro, the object is the name of the command or macro to run.

When you specify ACTION=INCREMENTAL without specifying a value for this parameter, the scheduled command is invoked without specified objects and attempts to process the objects as defined in the client option file. To select all file spaces or directories for an action, explicitly list them in the object string. Entering only an asterisk in the object string causes the backup to occur only for the directory where the scheduler was started.

Important:

- If you specify a second file specification, and it is not a valid destination, you receive this error:

  ```
  ANS1082E Invalid destination file specification <filespec> entered.
  ```

- If you specify more than two file specifications, you receive this error:

  ```
  ANS1102E Excessive number of command line arguments passed to the
  program!
  ```

When you specify ACTION=ARCHIVE, INCREMENTAL, or SELECTIVE for this parameter, you can list a maximum of twenty (20) file specifications.

Enclose the object string in double quotes if it contains blank characters (spaces), and then surround the double quotes with single quotes. If the object string contains multiple file names, enclose each file name with its own pair of double quotes, then surround the entire string with one pair of single quotes. Errors can occur if file names contain a space that is not quoted correctly.

Windows If you are using characters that have a special meaning for Windows users, such as commas, surround the entire argument in two pairs of double quotes, then surround the entire string with single quotes. The following examples show you how to specify some file names:

- To specify C:\FILE 2, D:\GIF FILES, and E:\MY TEST FILE, enter:
  - `OBJECTS='"C:\FILE 2" "D:\GIF FILES" "E:\MY TEST FILE"'`
- To specify D:\TEST FILE, enter:
  - `OBJECTS='"D:\TEST FILE"'`
- To specify D:TEST,FILE:
  - `OBJECTS='""D:\TEST,FILE""'`

AIX Linux The following examples show how to specify some file names:

- To specify /home/file 2, /home/gif files, and /home/my test file, enter:
  - `OBJECTS='"/home/file 2" "/home/gif files" "/home/my test file"'`
- To specify /home/test file, enter:
  - `OBJECTS='"/home/test file"'`

Windows Tip:

For Windows clients running in batch mode, if the use of double quotes is necessary, use interactive mode or operating system escape characters. For additional information, see the following topics:

- Processing a series of commands from the administrative client
- Processing individual commands from the administrative client

Wait

Specifies whether to wait for a scheduled client operation to complete. This parameter is useful when defining client actions from a command script or macro. This parameter is optional. The default is No. Possible values are:

No
: Specifies that you do not wait for the scheduled client operation to complete. If you specify this value and the value of the ACTION parameter is COMMAND, the return code indicates whether the client action was defined.

Yes
: Specifies that you wait for the scheduled client operation to complete. If you specify this value and the value of the ACTION parameter is COMMAND, the return code indicates the status of the client operation.

You cannot issue the DEFINE CLIENTACTION command with WAIT=YES from the server console. However, from the server console, you can:

- Specify WAIT=YES with DEFINE CLIENTACTION as the command line of a DEFINE SCRIPT command.
- Specify WAIT=YES with DEFINE CLIENTACTION as the command line of a file whose contents will be read into the script that is defined by a DEFINE SCRIPT command.

Restriction: If you specify the DEFINE CLIENTACTION command with WAIT=YES in a macro, the immediate schedules defined by the command will not roll back if the macro does not complete successfully.

Example: Perform a one-time incremental backup

Issue an incremental backup command for client node TOM assigned to policy domain EMPLOYEE_RECORDS. IBM Spectrum Protect defines a schedule and associates the schedule to client node TOM (assuming that the client scheduler is running).

```
define clientaction tom domain=employee_records
action=incremental
```

Related commands

Table 1. Commands related to DEFINE CLIENTACTION

Command	Description
DELETE SCHEDULE	Deletes a schedule from the database.
QUERY ASSOCIATION	Displays the clients associated with one or more schedules.
QUERY EVENT	Displays information about scheduled and completed events for selected clients.
QUERY SCHEDULE	Displays information about schedules.
SET CLIENTACTDURATION	Specifies the duration of a schedule defined using the DEFINE CLIENTACTION command.

DEFINE CLIENTOPT (Define an option to an option set)

Use this command to add a client option to an option set.

Privilege class

To issue this command, you must have system privilege or unrestricted policy privilege.

Syntax

```
>>-DEFine CLIENTOpt--option_set_name--option_name--option_value-->

   .-Force--=--No------.
>--+-------------------+--+----------------------+-------------><
   '-Force--=--+-No--+-'  '-SEQnumber--=--number-'
               '-Yes-'
```

Parameters

option_set_name (Required)
: Specifies the name of the option set.

option_name (Required)
: Specifies a client option to add to the option set.

  See Client options that can be set by the server for a list of valid options.

  Note: To define include-exclude values, specify the include or exclude option with *option-name*, and use *option_value* to specify any valid include or exclude statement, as you would in the client options file. For example:

```
define clientopt option_set_name inclexcl "include c:\proj\text\devel.*"
```

option_value (Required)
: Specifies the value for the option. If the option includes more than one value, enclose the value in quotation marks.
Note:

1. The QUIET and VERBOSE options do not have an option value in the client option's file. To specify these values in a server client option set, specify a value of YES or NO.
2. To add an INCLUDE or EXCLUDE option for a file name that contains one or more spaces, put single quotation marks around the file specification, and double quotation marks around the entire option. See Example: Add an option to a client option set for more information.
3. The *option_value* is limited to 1024 characters.

Force
: Specifies whether the server forces the client to use the option set value. The value is ignored for additive options, such as INCLEXCL and DOMAIN. The default is NO. This parameter is optional. The values are:

  Yes
  : Specifies that the server forces the client to use the value. (The client cannot override the value.)

  No
  : Specifies that the server does not force the client to use the value. (The client can override the value.)

SEQnumber
: Specifies a sequence number when an option name is specified more than once. This parameter is optional.

Example: Add an option to a client option set

Add a client option (MAXCMDRETRIES 5) to a client option set named ENG.

```
define clientopt eng maxcmdretries 5
```

Example: Add an option to exclude a file from backup

Add a client option to the option set ENGBACKUP to exclude the c:\admin\file.txt from backup services.

```
define clientopt engbackup inclexcl "exclude c:\admin\file.txt"
```

Example: Add an option to exclude a directory from backup

Add a client option to the option set WINSPEC to exclude a temporary internet directory from backup services. When you use the EXCLUDE or INCLUDE option with file names that contain spaces, put single quotation marks around the file specification, then double quotation marks around the entire option.

```
define clientopt winspec inclexcl "exclude.dir '*:\...\Temporary Internet Files'"
```

Example: Add an option to bind files in specified directories

Add client options to the option set WINSPEC to bind all files in directories C:\Data and C:\Program Files\My Apps to a management class named PRODCLASS.

```
define clientopt winspec inclexcl "include C:\Data\...\* prodclass"
define clientopt winspec inclexcl "include 'C:\Program
   Files\My Apps\...\*' prodclass"
```

Related commands

Table 1. Commands related to DEFINE CLIENTOPT

Command	Description
COPY CLOPTSET	Copies a client option set.
DEFINE CLOPTSET	Defines a client option set.
DELETE CLIENTOPT	Deletes a client option from a client option set.
DELETE CLOPTSET	Deletes a client option set.

Command	Description
REGISTER NODE	Defines a client node to the server and sets options for that user.
QUERY CLOPTSET	Displays information about a client option set.
UPDATE CLIENTOPT	Updates the sequence number of a client option in a client option set.
UPDATE CLOPTSET	Updates the description of a client option set.
UPDATE NODE	Changes the attributes that are associated with a client node.

DEFINE CLOPTSET (Define a client option set name)

Use this command to define a name for a set of options you can assign to clients for archive, backup, restore, and retrieve operations.

To add options to the new set, issue the DEFINE CLIENTOPT command.

Privilege class

To issue this command, you must have system privilege or unrestricted policy privilege.

Syntax

```
>>-DEFine CLOptset--option_set_name----------------------------->

>--+-----------------------------+----------------------------><
   '-DESCription--=--description-'
```

Parameters

option_set_name (Required)
: Specifies the name of the client option set. The maximum length of the name is 64 characters.

DESCription
: Specifies a description of the client option set. The maximum length of the description is 255 characters. The description must be enclosed in quotation marks if it contains any blank characters. This parameter is optional.

Example: Define a client option set

To define a client option set named ENG issue the following command.

```
define cloptset eng
```

Related commands

Table 1. Commands related to DEFINE CLOPTSET

Command	Description
COPY CLOPTSET	Copies a client option set.
DEFINE CLIENTOPT	Adds a client option to a client option set.
DELETE CLIENTOPT	Deletes a client option from a client option set.
DELETE CLOPTSET	Deletes a client option set.
QUERY CLOPTSET	Displays information about a client option set.
UPDATE CLIENTOPT	Updates the sequence number of a client option in a client option set.
UPDATE CLOPTSET	Updates the description of a client option set.

DEFINE COLLOCGROUP (Define a collocation group)

Use this command to define a collocation group. A *collocation group* is a group of nodes or file spaces on a node whose data is collocated on a minimal number of sequential access volumes. Their data is collocated only if the storage pool definition is set to collocate by group (COLLOCATE=GROUP).

Privilege class

To issue this command, you must have system or unrestricted storage privilege.

Syntax

```
>>-DEFine COLLOCGroup--group_name------------------------------>

>--+-----------------------------+----------------------------><
   '-DESCription--=--description-'
```

Parameters

group_name
: Specifies the name of the collocation group name that you want to create. The maximum length of the name is 30 characters.

DESCription
: Specifies a description of the collocation group. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters.

Define a collocation group

To define a node or file space collocation group named GROUP1, issue the following command:

```
define collocgroup group1
```

Related commands

Table 1. Commands related to DEFINE COLLOCGROUP

Command	Description
DEFINE COLLOCMEMBER	Adds a client node or file space to a collocation group.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DELETE COLLOCGROUP	Deletes a collocation group.
DELETE COLLOCMEMBER	Deletes a client node or file space from a collocation group.
MOVE NODEDATA	Moves data for one or more nodes, or a single node with selected file spaces.
QUERY COLLOCGROUP	Displays information about collocation groups.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY NODEDATA	Displays information about the location and size of data for a client node.
QUERY STGPOOL	Displays information about storage pools.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.
UPDATE COLLOCGROUP	Updates the description of a collocation group.
UPDATE STGPOOL	Changes the attributes of a storage pool.

DEFINE COLLOCMEMBER (Define collocation group member)

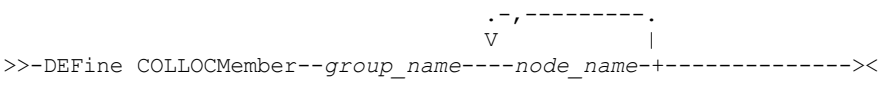
Issue this command to add a client node to a collocation group or to add a file space from a node to a collocation group. A collocation group is a group of nodes or file spaces on a node whose data is collocated on a minimal number of sequential access volumes.

Privilege class

To issue this command, you must have system or unrestricted storage privilege.

Syntax

Add a node to a collocation group

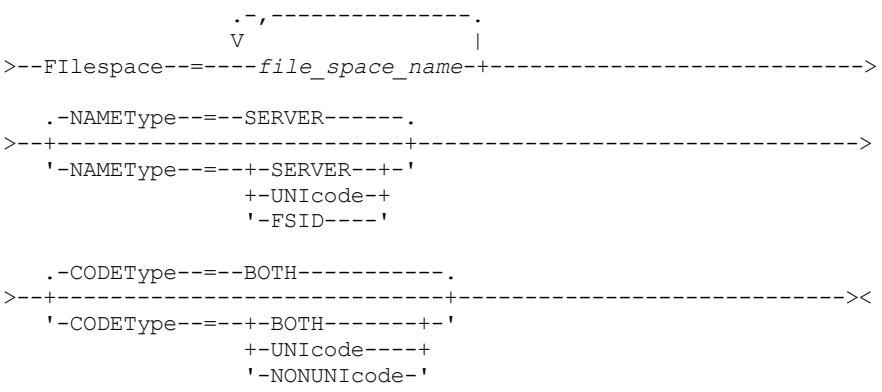


Parameters

group_name
: Specifies the name of the collocation group to which you want to add a client node.

node_name
: Specifies the name of the client node that you want to add to the collocation group. You can specify one or more names. Separate multiple names with commas; do not use intervening spaces. You can also use wildcard characters to specify multiple names.

Add a file space from a node to a collocation group



Parameters

group_name
: Specifies the name of the collocation group to which you want to add a file space.

node_name
: Specifies the client node where the file space is located.

FIlespace
: Specifies the *file_space_name* on the client node that you want to add to the collocation group. You can specify one or more file space names that are on a specific client node. If you specify multiple file space names, separate the names with commas with no intervening spaces. You can also use wildcard characters to specify multiple file space names. For example:

```
define collocmember manufacturing linux237 filespace=*_linux_fs
```

This command places all file spaces on the linux237 node with a name that ends with _linux_fs into the manufacturing collocation group.
See the following list for tips about working with collocation groups:

- When you add members to a new collocation group, the type of the first collocation group member determines the type of the collocation group. The group can either be a node collocation group or a file space collocation group. Restriction: After the collocation group type is set, it cannot be changed.
- You cannot mix collocation group member types when you add members to a collocation group (either a node group or a file space group).
- For a file space collocation group, you can add file spaces to the group. The file spaces must use the same value as the *node_name* parameter that is specified when the collocation group is established.
- A client node can be included in multiple file space groups. However, if a node is a member of a node collocation group, it cannot be a member of a file space collocation group.
- A file space can be a member of only one file space group.

NAMEType
Specify how you want the server to interpret the file space names that you enter. Specify this parameter when the server communicates with clients that have Unicode support. A backup-archive client with Unicode support is available only for Windows, Macintosh OS 9, Macintosh OS X, and NetWare systems. The filespace name cannot be a wildcard character when NAMETYPE is specified for a filespace collocation group. The default value is SERVER. You can specify one of the following values:

SERVER
The server uses the server code page to interpret the file space names.

UNIcode
The server converts the file space names from the server code page to the UTF-8 code page. Whether the name can be converted depends on the characters in the names and the server code page. Conversion might fail if the string includes characters that are not available in the server code page, or if the server cannot access system conversion routines.

FSID
The server interprets the file space names by their file space IDs (FSIDs).

CODEType
Specify how you want the server to interpret the file space names that you enter. Use this parameter when you use a wildcard character for the file space name. For example:

```
define collocmember production Win_3419 filespace=* codetype=unicode
```

This example command adds all file spaces from the Win_3419 node to the production collocation group. The default is BOTH, so the file spaces are included, regardless of code page type. You can specify one of the following values:

BOTH
Include the file spaces, regardless of code page type.

UNIcode
Include file spaces that are only in Unicode.

NONUNIcode
Include file spaces that are not in Unicode.

Define two collocation group members

Define two members, NODE1 and NODE2, to a collocation group, GROUP1.

```
define collocmember group1 node1,node2
```

Define one file space group member CNTR90524, on node clifton to collocation group TSM_alpha_1

```
define collocmember TSM_alpha_1 clifton filespace=CNTR90524
```

Related commands

Table 1. Commands related to DEFINE COLLOCMEMBER

Command	Description
DEFINE COLLOCGROUP	Defines a collocation group.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DELETE COLLOCGROUP	Deletes a collocation group.
DELETE COLLOCMEMBER	Deletes a client node or file space from a collocation group.
DELETE FILESPACE	Deletes data associated with client file spaces. If a file space is part of a collocation group and you remove the file space from a node, the file space is removed from the collocation group.
MOVE NODEDATA	Moves data for one or more nodes, or a single node with selected file spaces.
QUERY COLLOCGROUP	Displays information about collocation groups.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY NODEDATA	Displays information about the location and size of data for a client node.
QUERY STGPOOL	Displays information about storage pools.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.
UPDATE COLLOCGROUP	Updates the description of a collocation group.
UPDATE STGPOOL	Changes the attributes of a storage pool.

DEFINE COPYGROUP (Define a copy group)

Use this command to define a new backup or archive copy group within a specific management class, policy set, and policy domain. The server uses the backup and archive copy groups to control how clients back up and archive files, and to manage the backed-up and archived files.

To enable clients to use the new copy group, you must activate the policy set that contains the new copy group.

You can define one backup and one archive copy group for each management class. To ensure that client nodes can back up files, include a backup copy group in the default management class for a policy set.

Attention: The DEFINE COPYGROUP command fails if you specify a copy storage pool as a destination.

The DEFINE COPYGROUP command has two forms, one for defining a backup copy group and one for defining an archive copy group. The syntax and parameters for each form are defined separately.

Table 1. Commands related to DEFINE COPYGROUP

Command	Description
ASSIGN DEFMGMTCLASS	Assigns a management class as the default for a specified policy set.
BACKUP NODE	Backs up a network-attached storage (NAS) node.
COPY MGMTCLASS	Creates a copy of a management class.
DEFINE MGMTCLASS	Defines a management class.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DELETE COPYGROUP	Deletes a backup or archive copy group from a policy domain and policy set.

Command	Description
DELETE MGMTCLASS	Deletes a management class and its copy groups from a policy domain and policy set.
EXPIRE INVENTORY	Manually starts inventory expiration processing.
QUERY COPYGROUP	Displays the attributes of a copy group.
QUERY MGMTCLASS	Displays information about management classes.
SET ARCHIVERETENTIONPROTECTION	Specifies whether data retention protection is activated.
UPDATE COPYGROUP	Changes one or more attributes of a copy group.

- DEFINE COPYGROUP (Define a backup copy group)
  Use this command to define a new backup copy group within a specific management class, policy set, and policy domain.
- DEFINE COPYGROUP (Define an archive copy group)
  Use this command to define a new archive copy group within a specific management class, policy set, and policy domain.

DEFINE COPYGROUP (Define a backup copy group)

Use this command to define a new backup copy group within a specific management class, policy set, and policy domain.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the copy group belongs.

Syntax

```
>>-DEFine COpygroup--domain_name--policy_set_name--class_name--->

   .-STANDARD-.  .-Type--=--Backup-.

                       +-STatic-----+
                       +-SHRDYnamic-+
                       '-DYnamic----'

>--+--------------------------------+------------------------><
```

```
'-TOCDestination--=----pool_name---'
```

Parameters

domain_name (Required)
: Specifies the policy domain for which you are defining the copy group.

policy_set_name (Required)
: Specifies the policy set for which you are defining the copy group.

  You cannot define a copy group for a management class that belongs to the ACTIVE policy set.

class_name (Required)
: Specifies the management class for which you are defining the copy group.

STANDARD
: Specifies the name of the copy group, which must be STANDARD. This parameter is optional. The default value is STANDARD.

Type=Backup
: Specifies that you want to define a backup copy group. The default parameter is BACKUP. This parameter is optional.

DESTination (Required)
: Specifies the primary storage pool where the server initially stores backup data. You cannot specify a copy storage pool as the destination.

FREQuency
: Specifies how frequently IBM Spectrum Protect™ can back up a file. This parameter is optional. IBM Spectrum Protect backs up a file only when the specified number of days has elapsed since the last backup. The FREQUENCY value is used only during a full incremental backup operation. This value is ignored during selective backup or partial incremental backup. You can specify an integer from 0 to 9999. The default value is 0, meaning that IBM Spectrum Protect can back up a file regardless of when the file was last backed up.

VERExists
: Specifies the maximum number of backup versions to retain for files that are currently on the client file system. This parameter is optional. The default value is 2.
  If an incremental backup operation causes the limit to be exceeded, the server expires the oldest backup version that exists in server storage. Possible values are:

  number
  : Specifies the number of backup versions to retain for files that are currently on the client file system. You can specify an integer from 1 to 9999.

  NOLimit
  : Specifies that you want the server to retain all backup versions.

  The number of backup versions to retain is controlled by this parameter until versions exceed the retention time specified by the RETEXTRA parameter.

VERDeleted
: Specifies the maximum number of backup versions to retain for files that have been deleted from the client file system after being backed up using IBM Spectrum Protect. This parameter is optional. The default value is 1.
  If a user deletes a file from the client file system, the next incremental backup causes the server to expire the oldest versions of the file in excess of this number. The expiration date for the remaining versions is determined by the retention time specified by the RETEXTRA or RETONLY parameter. Possible values are:

  number
  : Specifies the number of backup versions to retain for files that are deleted from the client file system after being backed up. You can specify an integer from 0 to 9999.

  NOLimit
  : Specifies that you want the server to retain all backup versions for files that are deleted from the client file system after being backed up.

RETExtra
: Specifies the number of days to retain a backup version after that version becomes inactive. A version of a file becomes inactive when the client stores a more recent backup version, or when the client deletes the file from the workstation and then runs a full incremental backup. The server deletes inactive versions based on retention time even if the number of inactive versions does not exceed the number allowed by the VEREXISTS or VERDELETED parameters. This parameter is optional. The default value is 30 days. Possible values are:

days
Specifies the number of days to retain inactive backup versions. You can specify an integer from 0 to 9999.

NOLimit
Specifies that you want to retain inactive backup versions indefinitely.

If you specify NOLIMIT, the server deletes inactive backup versions based on the VEREXISTS parameter (when the file still exists on the client file system) VERDELETED parameter (when the file no longer exists on the client file system).

RETOnly
Specifies the number of days to retain the last backup version of a file that has been deleted from the client file system. This parameter is optional. The default value is 60. Possible values are:

days
Specifies the number of days to retain the last remaining inactive version of a file. You can specify an integer from 0 to 9999.

NOLimit
Specifies that you want to keep the last remaining inactive version of a file indefinitely.

If you specify NOLIMIT, the server retains the last remaining backup version forever, unless a user or administrator deletes the file from server storage.

MODE
Specifies whether IBM Spectrum Protect backs up a file only if the file has changed since the last backup, or whenever a client requests a backup. This parameter is optional. The default value is MODIFIED. Possible values are:

MODified
Specifies that IBM Spectrum Protect backs up the file only if it has changed since the last backup. IBM Spectrum Protect considers a file changed if any of the following is true:

- The date last modified is different
- The file size is different
- The file owner is different
- The file permissions are different

ABSolute
Specifies that IBM Spectrum Protect backs up the file regardless of whether it has been modified.

The MODE value is used only for full incremental backup. This value is ignored during partial incremental backup or selective backup.

SERialization
Specifies how IBM Spectrum Protect processes files or directories when they are modified during backup processing. This parameter is optional. The default value is SHRSTATIC. Possible values are:

SHRSTatic
Specifies that IBM Spectrum Protect backs up a file or directory only if it is not being modified during backup. IBM Spectrum Protect attempts to perform a backup as many as four times, depending on the value specified for the CHANGINGRETRIES client option. If the file or directory is modified during each backup attempt, IBM Spectrum Protect does not back it up.

STatic
Specifies that IBM Spectrum Protect backs up a file or directory only if it is not being modified during backup. IBM Spectrum Protect attempts to perform the backup only once.

Platforms that do not support the STATIC option default to SHRSTATIC.

SHRDYnamic
Specifies that if the file or directory is being modified during a backup attempt, IBM Spectrum Protect backs up the file or directory during the last attempt even though the file or directory is being modified. IBM Spectrum Protect attempts to perform a backup as many as four times, depending on the value specified for the CHANGINGRETRIES client option.

DYnamic
Specifies that IBM Spectrum Protect backs up a file or directory on the first attempt, regardless of whether the file or directory is being modified during backup processing.

Attention: Be careful about using the SHRDYNAMIC and DYNAMIC values. IBM Spectrum Protect uses these values to determine if it backs up a file or directory while modifications are occurring. As a result, the backup version might be a fuzzy backup. A fuzzy backup does not accurately reflect what is currently in the file or directory because it contains some, but not all, modifications. If a file that contains a fuzzy backup is restored, the file may or may not be usable, depending on the application that uses the file. If a fuzzy backup is not acceptable, set SERIALIZATION to SHRSTATIC or STATIC so that IBM Spectrum Protect creates a backup version only if the file or directory is not being modified.

TOCDestination

Specifies the primary storage pool in which a table of contents (TOC) will initially be stored for any Network Data Management Protocol (NDMP) backup or backup set operation for which a TOC is generated. This parameter is optional. You cannot specify a copy storage pool as the destination. The storage pool specified for the destination must have NATIVE or NONBLOCK data format. To avoid mount delays, it is recommended that the storage pool have a device class of DISK or DEVTYPE=FILE. TOC generation is an option for NDMP backup operations, but is not supported for other image-backup operations.

If TOC creation is requested for a backup operation that uses NDMP and the image is bound to a management class whose backup copy group does not specify a TOC destination, the outcome will depend on the TOC parameter for the backup operation.

- If TOC=PREFERRED (the default), the backup proceeds without creation of a TOC.
- If TOC=YES, the entire backup fails because no TOC can be created.

Example: Create a backup copy group

Create a backup copy group named STANDARD for management class ACTIVEFILES in policy set VACATION in the EMPLOYEE_RECORDS policy domain. Set the backup destination to BACKUPPOOL. Set the minimum interval between backups to three days, regardless of whether the files have been modified. Retain up to five backup versions of a file while the file exists on the client file system.

```
define copygroup employee_records
vacation activefiles standard type=backup
destination=backuppool frequency=3
verexists=5 mode=absolute
```

DEFINE COPYGROUP (Define an archive copy group)

Use this command to define a new archive copy group within a specific management class, policy set, and policy domain.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the copy group belongs.

Syntax

```
>>-DEFine COpygroup--domain_name--policy_set_name--class_name--->

   .-STANDARD-.
>--+----------+--Type--=--Archive--DESTination--=--pool_name---->
   '-STANDARD-'

   .-FREQuency--=--Cmd-.  .-RETVer--=--365---------.
>--+-------------------+--+-----------------------+------------>
   '-FREQuency--=--Cmd-'  '-RETVer--=--+-days----+-'
                                       '-NOLimit-'

   .-RETInit--=--CREATion--.  .-RETMin--=--365------.
>--+----------------------+--+--------------------+----------->
   '-RETInit--=-----EVent---'  '-RETMin--=----days---'

   .-MODE--=--ABSolute-.
>--+-------------------+---------------------------------------->
   '-MODE--=--ABSolute-'
```

```
   .-SERialization--=--SHRSTatic------.
>--+---------------------------------+-----------------------><
   '-SERialization--=--+-SHRSTatic--+-'
                       +-STatic-----+
                       +-SHRDYnamic-+
                       '-DYnamic----'
```

Parameters

domain_name (Required)
: Specifies the name of the policy domain for which you are defining the copy group.

policy_set_name (Required)
: Specifies the name of the policy set for which you are defining the copy group.

  You cannot define a copy group for a management class that belongs to the ACTIVE policy set.

class_name (Required)
: Specifies the name of the management class for which you are defining the copy group.

STANDARD
: Specifies the name of the copy group, which must be STANDARD. This parameter is optional. The default value is STANDARD.

Type=Archive (Required)
: Specifies that you want to define an archive copy group.

DESTination (Required)
: Specifies the primary storage pool where the server initially stores the archive copy. You cannot specify a copy storage pool as the destination.

FREQuency=Cmd
: Specifies the copy frequency, which must be CMD. This parameter is optional. The default value is CMD.

RETVer
: Specifies the number of days to keep an archive copy. This parameter is optional. The default value is 365. Possible values are:

  days
  : Specifies the length of time to keep an archive copy. You can specify an integer in the range 0 - 30000.
    The RETENTIONEXTENSION server option can affect the volume retention if the following conditions are true:

    - You specify zero for the number of days
    - The destination storage pool for the archive copy group is a SnapLock storage pool (RECLAMATIONTYPE=SNAPLOCK)

    If the two conditions are met, retention of the volumes is defined by the value of the RETENTIONEXTENSION server option. The RETENTIONEXTENSION server option value also applies if data is copied or moved into the SnapLock storage pool by a server process such as migration, or by using the MOVE DATA or MOVE NODEDATA commands.

  NOLimit
  : Specifies that you want to keep an archive copy indefinitely.

    If you specify NOLIMIT, the server retains archive copies forever, unless a user or administrator deletes the file from server storage. If you specify NOLIMIT, you cannot also specify EVENT for the RETINIT parameter.

  The value of the RETVER parameter can affect the management class to which the server binds an archived directory. If the client does not use the ARCHMC option, the server binds directories that are archived to the default management class. If the default management class has no archive copy group, the server binds directories that are archived to the management class with the shortest retention period.

  The RETVER parameter of the archive copy group of the management class to which an object is bound determines the retention criterion for each object. See the SET ARCHIVERETENTIONPROTECTION command for a description of data protection.

  If the primary storage pool specified in the DESTINATION parameter belongs to a Centera device class and data protection is enabled, then the RETVER value is sent to Centera for retention management purposes. See the SET ARCHIVERETENTIONPROTECTION command for a description of data protection.

RETInit

Specifies when the retention time specified by the RETVER attribute is initiated. This parameter is optional. If you define the RETINIT value during copy group creation, you cannot modify it later. The default value is CREATION. Possible values are:

CREATion
: Specifies that the retention time specified by the RETVER attribute is initiated at the time an archive copy is stored on the IBM Spectrum Protect™ server.

EVent
: Specifies that the retention time specified in the RETVER parameter is initiated at the time a client application notifies the server of a retention-initiating event for the archive copy. If you specify RETINIT=EVENT, you cannot also specify RETVER=NOLIMIT.

Tip: You can place a deletion hold on an object that was stored with RETINIT=EVENT for which the event has not been signaled. If the event is signaled while the deletion hold is in effect, the retention period is initiated, but the object is not deleted while the hold is in effect.

RETMin
: Specifies the minimum number of days to keep an archive copy after it is archived. This parameter is optional. The default value is 365. If you specify RETINIT=CREATION, this parameter is ignored.

MODE=ABSolute
: Specifies that a file is always archived when the client requests it. The MODE must be ABSOLUTE. This parameter is optional. The default value is ABSOLUTE.

SERialization
: Specifies how IBM Spectrum Protect processes files that are modified during archive. This parameter is optional. The default value is SHRSTATIC. Possible values are:

SHRSTatic
: Specifies that IBM Spectrum Protect archives a file only if it is not being modified. IBM Spectrum Protect attempts to perform an archive operation as many as four times, depending on the value that is specified for the CHANGINGRETRIES client option. If the file is modified during the archive attempt, IBM Spectrum Protect does not archive the file.

STatic
: Specifies that IBM Spectrum Protect archives a file only if it is not being modified. IBM Spectrum Protect attempts to perform the archive operation only once.

  Platforms that do not support the STATIC option default to SHRSTATIC.

SHRDYnamic
: Specifies that if the file is being modified during an archive attempt, IBM Spectrum Protect archives the file during its last attempt even though the file is being modified. IBM Spectrum Protect attempts to archive the file as many as four times, depending on the value that is specified for the CHANGINGRETRIES client option.

DYnamic
: Specifies that IBM Spectrum Protect archives a file on the first attempt, regardless of whether the file is being modified during archive processing.
  Attention: Be careful about using the SHRDYNAMIC and DYNAMIC values. IBM Spectrum Protect uses them to determine if it archives a file while modifications are occurring. As a result, the archive copy might be a fuzzy backup. A fuzzy backup does not accurately reflect what is in the file because it contains some, but not all, modifications. If a file that contains a fuzzy backup is retrieved, the file might or might not be usable, depending on the application that uses the file. If a fuzzy backup is not acceptable, set SERIALIZATION to SHRSTATIC or STATIC so that IBM Spectrum Protect creates an archive copy only if the file is not being modified.

Example: Define an archive copy group for event-based retention

Create an archive copy group named STANDARD for management class EVENTMC in policy set SUMMER in the PROG1 policy domain. Set the archive destination to ARCHIVEPOOL, where the archive copy is kept until the server is notified of an event to initiate the retention time, after which the archive copy is kept for 30 days. The archive copy will be kept for a minimum of 90 days after being stored on the server, regardless of when the server is notified of an event to initiate the retention time.

```
define copygroup prog1 summer eventmc standard type=archive
destination=archivepool retinit=event retver=30 retmin=90
```

DEFINE DATAMOVER (Define a data mover)

Use this command to define a data mover. A data mover is a named device that accepts a request from IBM Spectrum Protect™ to transfer data. A data mover can be used to complete outboard copy operations.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine DATAMover--data_mover_name---------------------------->

   .-Type--=--NAS--------------------.
>--+-----------------------------------+--HLAddress--=--address--->
   |                          (1) (2) |
   '-Type--=--+-NASCLUSTER-+---------'
              '-NASVSERVER-'

   .-LLAddress--=--10000----.
>--+------------------------+--USERid--=--userid----------------->
   '-LLAddress--=--tcp_port-'

                           .-ONLine--=--Yes-----.
>--PASsword--=--password--+--------------------+---------------->
                           '-ONLine--=--+-Yes-+-'
                                        '-No--'

>--DATAFormat--=--+-NETAPPDump--+----------------------------><
                  +-CELERRADump-+
                  '-NDMPDump----'
```

Notes:

1. You can specify `TYPE=NASCLUSTER` and `TYPE=NASVSERVER` only on an AIX®, Linux, or Windows operating system.
2. You can specify `TYPE=NASCLUSTER` and `TYPE=NASVSERVER` only if `DATAFORMAT=NETAPPDUMP`.

Parameters

data_mover_name (Required)
: Specifies the name of the data mover. This name must be the same as a node name that you previously registered by using the `REGISTER NODE TYPE=NAS` command. The data that is backed up from this NAS data mover will be assigned to this node name in the server database. A maximum of 64 characters can be used to specify the name.

Type
: Specifies the type of data mover. This parameter is optional. The default value is NAS.

  NAS
  : Specifies that the data mover is a NAS file server.

  NASCLUSTER
  : Specifies that the data mover is a clustered NAS file server.
    Restriction: You can specify the NASCLUSTER value only if `DATAFORMAT=NETAPPDUMP`.

  NASVSERVER
  : Specifies that the data mover is a virtual storage device within a cluster.
    Restriction: You can specify the NASVSERVER value only if `DATAFORMAT=NETAPPDUMP`.

HLAddress (Required)
: Specifies either the numerical IP address or the domain name that is used to access the NAS file server.
  Tip: To determine the numerical IP address, access the NAS file server. Then, follow the instructions in the file server documentation for obtaining the address.

LLAddress
: Specifies the TCP port number to access the NAS device for Network Data Management Protocol (NDMP) sessions. This parameter is optional. The default value is 10000.

USERid (Required)
: Specifies the user ID for a user that is authorized to initiate an NDMP session with the NAS file server. For example, enter the user ID that is configured on the NetApp file server for NDMP connections.

Tip: To determine the user ID, access the NAS file server. Then, follow the instructions in the file server documentation for obtaining the user ID.

PASsword (Required)

Specifies the password for the user ID to log on to the NAS file server.

Tip: To determine the password, access the NAS file server. Then, follow the instructions in the file server documentation for obtaining the password.

ONLine

Specifies whether the data mover is available for use. This parameter is optional. The default is YES.

Yes

The default value. Specifies that the data mover is available for use.

No

Specifies that the data mover is not available for use. When the hardware is being maintained, you can use the UPDATE DATAMOVER command to set the data mover offline.

If a library is controlled by using a path from a NAS data mover to the library, and the NAS data mover is offline, the server is not able to access the library. If the server is halted and restarted while the NAS data mover is offline, the library is not initialized.

DATAFormat (Required)

Specifies the data format that is used by this data mover.

NETAPPDump

Must be used for NetApp NAS file servers and the IBM® System Storage® N Series.

CELERRADump

Must be used for EMC Celerra NAS file servers.

NDMPDump

Must be used for NAS file servers other than NetApp or EMC file servers.

Example: Define a data mover by domain name

Define a data mover for the node named NAS1. The domain name for the data mover is NETAPP2.EXAMPLE.COM at port 10000.

```
define datamover nas1 type=nas hladdress=netapp2.example.com lladdress=10000
    userid=root password=admin dataformat=netappdump
```

Example: Define a data mover by IP address

Define a data mover for the node named NAS2. The numerical IP address for the data mover is 203.0.113.0, at port 10000. The NAS file server is not a NetApp or EMC file server.

```
define datamover nas2 type=nas hladdress=203.0.113.0 lladdress=10000
    userid=root password=admin dataformat=ndmpdump
```

Example: Define a data mover for a clustered file server by IP address

Define a data mover for the clustered file server named NAS3. The NAS file server is a NetApp device. The numerical IP address for the data mover is 198.51.100.0, at port 10000.

```
define datamover nas3 type=nascluster hladdress=198.51.100.0
    lladdress=10000 userid=root password=admin dataformat=netappdump
```

Related commands

Table 1. Commands related to DEFINE DATAMOVER

Command	Description
DEFINE PATH	Defines a path from a source to a destination.
DELETE DATAMOVER	Deletes a data mover.
QUERY DATAMOVER	Displays data mover definitions.
REGISTER NODE	Defines a client node to the server and sets options for that user.

Command	Description
UPDATE DATAMOVER	Changes the definition for a data mover.

DEFINE DEVCLASS (Define a device class)

Use this command to define a device class for a type of storage device. The server requires that a device class be defined to allow the use of a device.

For the most up-to-date list of supported devices and valid device class formats, see the IBM Spectrum Protect™ Supported Devices website: AIX Windows

- Supported devices for AIX and Windows

Linux

- Supported devices for Linux

Note: The DISK device class is defined by IBM Spectrum Protect and cannot be modified with the DEFINE DEVCLASS command.

AIX Linux If you are defining a device class for devices that are to be accessed through a z/OS® media server, see DEFINE DEVCLASS - z/OS media server (Define device class for z/OS media server).

The following IBM Spectrum Protect device classes are ordered by device type.

- DEFINE DEVCLASS (Define a 3590 device class)
- DEFINE DEVCLASS (Define a 3592 device class)
- DEFINE DEVCLASS (Define a 4MM device class)
- DEFINE DEVCLASS (Define an 8MM device class)
- DEFINE DEVCLASS (Define a CENTERA device class)
- DEFINE DEVCLASS (Define a DLT device class)
- DEFINE DEVCLASS (Define an ECARTRIDGE device class)
- DEFINE DEVCLASS (Define a FILE device class)
- AIX Windows DEFINE DEVCLASS (Define a GENERICTAPE device class)
- DEFINE DEVCLASS (Define an LTO device class)
- DEFINE DEVCLASS (Define a NAS device class)
- DEFINE DEVCLASS (Define a REMOVABLEFILE device class)
- DEFINE DEVCLASS (Define a SERVER device class)
- DEFINE DEVCLASS (Define a VOLSAFE device class)

Table 1. Commands related to DEFINE DEVCLASS

Command	Description
BACKUP DEVCONFIG	Backs up IBM Spectrum Protect device information to a file.
DEFINE LIBRARY	Defines an automated or manual library.
DELETE DEVCLASS	Deletes a device class.
QUERY DEVCLASS	Displays information about device classes.
QUERY DIRSPACE	Displays information about FILE directories.
UPDATE DEVCLASS	Changes the attributes of a device class.

DEFINE DEVCLASS (Define a 3590 device class)

Use the 3590 device class when you are using 3590 tape devices.

AIX Linux If you are defining a device class for devices that are to be accessed through a z/OS® media server, see DEFINE DEVCLASS (Define a 3590 device class for z/OS media server).

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine DEVclass--device_class_name--------------------------->

>--LIBRary---=--library_name--DEVType--=--3590------------------->

   '-MOUNTLimit--=--+-DRIVES-+-'
                    +-number-+
                    '-0------'
```

Parameters

device_class_name (Required)
: Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

LIBRary (Required)

: Specifies the name of the defined library object that contains the tape drives that can be used by this device class.

: For information about defining a library object, see the DEFINE LIBRARY command.

DEVType=3590 (Required)
: Specifies the 3590 device type is assigned to the device class. 3590 indicates that IBM® 3590 cartridge tape devices are assigned to this device class.

FORMAT
: Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. The default value is DRIVE.

: If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use.

: The following tables list the recording formats, estimated capacities, and recording format options for 3590 devices:

Table 1. Recording formats and default estimated capacities for 3590

Format	Estimated Capacity	Description
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
3590B	10.0 GB	Uncompressed (basic) format

Format	Estimated Capacity	Description
3590C	See note 20.0 GB	Compressed format
3590E-B	10.0 GB	Uncompressed (basic) format, similar to the 3590B format
3590E-C	See note 20.0 GB	Compressed format, similar to the 3590C format
3590H-B	30.0 GB (J cartridge – standard— length) 60.0 GB (K cartridge - extended length)	Uncompressed (basic) format, similar to the 3590B format
3590H-C	See note 60.0 GB (J cartridge - standard length) 120.0 GB (K cartridge - extended length)	Compressed format, similar to the 3590C format
Note: If this format uses the tape drive hardware compression feature, depending on the effectiveness of compression, the actual capacity might be greater than the listed value.		

Table 2. 3590 device recording format selections

Device	Format					
	3590B	3590C	3590E-B	3590E-C	3590H-B	3590H-C
3590	Read/Write	Read/Write	–	–	–	–
Ultra SCSI	Read/Write	Read/Write	–	–	–	–
3590E	Read	Read	Read/Write	Read/Write	–	–
3590H	Read	Read	Read	Read	Read/Write	Read/Write

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

PREFIX

Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The default value is ADSM. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention
Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. The default value is 60 minutes. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types, setting this parameter to a low value (for example, two minutes) enhances device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait
Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. The default value is 60 minutes. You can specify a number 0 - 9999.
Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. The default is DRIVES. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES
Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number
Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)
Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

DEFINE DEVCLASS (Define a 3592 device class)

Use the 3592 device class when you are using 3592 tape devices.

AIX | Linux If you are defining a device class for devices that are to be accessed through a z/OS® media server, see DEFINE DEVCLASS (Define a 3592 device class for z/OS media server).

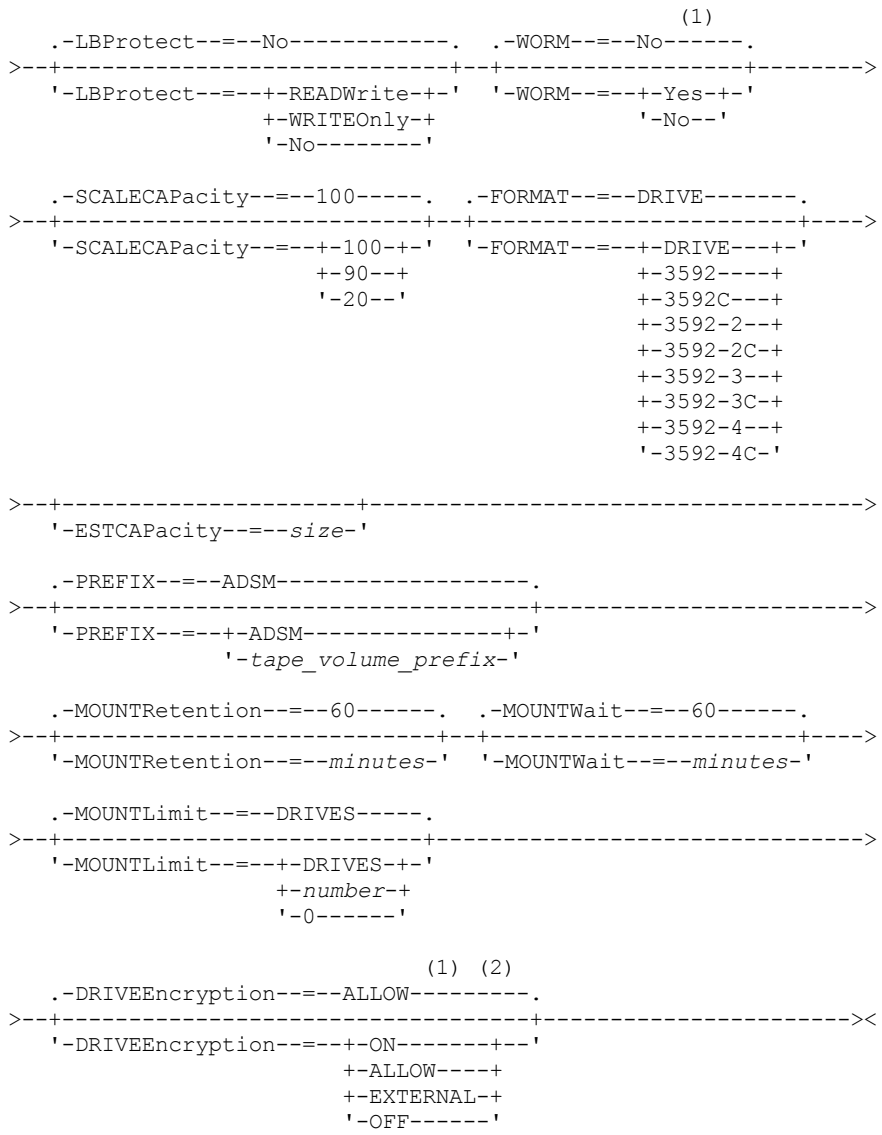
Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine DEVclass--device_class_name--------------------------->

>--LIBRary--=--library_name--DEVType--=--3592------------------->
```



Notes:

1. You cannot specify both WORM=Yes and DRIVEENCRYPTION=ON.
2. Drive encryption is supported only for 3592 Generation 2 or later drives.

Parameters

device_class_name (Required)
Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

LIBRary (Required)

Specifies the name of the defined library object that contains the tape drives that can be used by this device class.

For information about defining a library object, see the DEFINE LIBRARY command.

DEVType=3592 (Required)
Specifies that the 3592 device type is assigned to the device class.

LBProtect

Specifies whether logical block protection is used to ensure the integrity of data stored on tape. When LBPROTECT is set to READWRITE or to WRITEONLY, the server uses this feature of the tape drive for logical block protection and generates cyclic redundancy check (CRC) protection information for each data block written on tape. The server also validates the CRC protection information when data is read from the tape.

The default is NO.

The following values are possible:

READWrite
: Specifies that logical block protection is enabled in the server and the tape drive for both read and write operations. Data is stored with CRC information in each block. This mode affects performance because additional processor usage is required for IBM Spectrum Protect™ and the tape drive to calculate and compare CRC values. The READWRITE value does not affect backup sets and data that is generated by the BACKUP DB command.

  When the LBPROTECT parameter is set to READWRITE, you do not have to specify the CRCDATA parameter in a storage pool definition because logical block protection provides better protection against data corruption.

WRITEOnly
: Specifies that logical block protection is enabled in the server and the tape drive for write operations only. Data is stored containing CRC information in each block. For read operations, the server and the tape drive do not validate the CRC. This mode affects performance because additional processor usage is required for IBM Spectrum Protect to generate the CRC and for the tape drive to calculate and compare CRC values for write operations. The WRITEONLY value does not affect backup sets and data that are generated by the BACKUP DB command.

No
: Specifies that logical block protection is not enabled in the server and the tape drive for read and write operations. However, the server enables logical block protection on write operations for a filling volume that already has data with logical block protection.

Restriction: Logical block protection is supported only on IBM® 3592 Generation 3 drives and later with 3592 Generation 2 media and later.

See Technote 1634851, Additional information on the IBM Spectrum Protect LBProtect option, for an explanation about when to use the LBProtect parameter.

WORM
: Specifies whether the drives use WORM (write once, read many) media. This parameter is optional. The default is No. The field can contain one of the following values:

  Yes
  : Specifies that the drives use WORM media.

  No
  : Specifies that the drives do not use WORM media.

  Remember:

  1. To use 3592 WORM support in 3584 libraries, you must specify the WORM parameter. The server distinguishes between WORM and non-WORM scratch volumes. However, to use 3592 WORM support in 349X libraries, you also must set the WORMSCRATCHCATEGORY on the DEFINE LIBRARY command. For details, see DEFINE LIBRARY (Define a library).
  2. When WORM=Yes, the only valid value for the SCALECAPACITY parameter is 100.
  3. Verify with your hardware vendors that your hardware is at the appropriate level of support.

SCALECAPacity
: Specifies the percentage of the media capacity that can be used to store data. This parameter is optional. The default is 100. Possible values are 20, 90, or 100.

  Setting the scale capacity percentage to 100 provides maximum storage capacity. Setting it to 20 provides fastest access time.

  Note: The scale capacity value takes effect only when data is first written to a volume. Any updates to the device class for scale capacity do not affect volumes that already have data that is written to them until the volume is returned to scratch status.

FORMAT
: Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. The default value is DRIVE.

  If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use.

  The following table lists the recording formats, estimated capacities, and recording format options for 3592 devices:

Table 1. Recording formats and default estimated capacities for 3592

Format	Estimated Capacity	Description
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
3592	300 GB	Uncompressed (basic) format
3592C	See note 900 GB	Compressed format
3592-2	500 GB 700 GB	Uncompressed (basic) format JA tapes Uncompressed (basic) format JB tapes
3592-2C	1.5 TB 2.1 TB	Compressed format JA tapes Compressed format JB tapes
3592–3	640 GB 1 TB	Uncompressed (basic) format JA tapes Uncompressed (basic) format JB tapes
3592–3C	1.9 TB 3 TB	Compressed format JA tapes Compressed format JB tapes
3592-4	400 GB 1.5 TB 3.1 TB	Uncompressed (basic) format JK tapes Uncompressed (basic) format JB tapes Uncompressed (basic) format JC tape
3592-4C	1.2 TB 4.4 TB 9.4 TB	Compressed format JK tapes Compressed format JB tapes Compressed format JC tapes
Note: If this format uses the tape drive hardware compression feature, depending on the effectiveness of compression, the actual capacity might be different from the listed value.		

Important: For optimal performance, avoid mixing different generations of drives in a single SCSI library. If you must mix drive generations in a SCSI library, use one of the special configurations that are described in the topic about mixing generations of 3592 media.

Special configurations are also required for mixing different generations of 3592 drives in 349x and ACSLS libraries.

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

PREFIX

Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The default value is ADSM. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention
: Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. The default value is 60 minutes. You can specify a number 0 - 9999.

  This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

  However, for EXTERNAL library types, setting this parameter to a low value (for example, two minutes) enhances device sharing between applications.

  Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait
: Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. The default value is 60 minutes. You can specify a number 0 - 9999.
  Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
: Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. The default is DRIVES. You can specify a number 0 - 4096.

  If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

  The following are possible values:

  DRIVES
  : Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
    Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

  number
  : Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

  0 (zero)
  : Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

DRIVEEncryption
: Specifies whether drive encryption is allowed. This parameter is optional. The default is ALLOW.

  ON
  : Specifies that IBM Spectrum Protect is the key manager for drive encryption and allows drive encryption for empty storage pool volumes only if the application method is enabled. (Other types of volumes-for example, back up sets, export volumes, and database backup volumes-will not be encrypted.) If you specify ON and you enable either the library or system method of encryption, drive encryption is not allowed and backup operations fail.

  ALLOW

Specifies that IBM Spectrum Protect does not manage the keys for drive encryption. However, drive encryption for empty volumes is allowed if either the library or system method of encryption is enabled.

EXTERNAL
Specifies that IBM Spectrum Protect does not manage the keys for drive encryption. Use this setting with an encryption methodology that is provided by another vendor and that is used with Application Method Encryption (AME) enabled on the drive.
When you specify EXTERNAL and IBM Spectrum Protect detects that AME encryption is enabled, IBM Spectrum Protect does not turn off encryption.
By contrast, when you specify ALLOW and IBM Spectrum Protect detects that AME encryption is enabled, IBM Spectrum Protect turns off encryption.

OFF
Specifies that drive encryption is not allowed. If you enable either the library or system method of encryption, backups fail. If you enable the application method, IBM Spectrum Protect disables encryption and backups are attempted.

DEFINE DEVCLASS (Define a 4MM device class)

Use the 4MM device class when you are using 4 mm tape devices.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine DEVclass--device_class_name---------------------------->

>--LIBRary--=--library_name--DEVType--=--4MM-------------------->

   .-FORMAT--=--DRIVE-----.
>--+----------------------+--+----------------------+----------->
   '-FORMAT--=--+-DRIVE-+-'  '-ESTCAPacity--=--size-'
                +-DDS1---+
                +-DDS1C--+
                +-DDS2---+
                +-DDS2C--+
                +-DDS3---+
                +-DDS3C--+
                +-DDS4---+
                +-DDS4C--+
                +-DDS5---+
                +-DDS5C--+
                +-DDS6---+
                '-DDS6C--'

   .-PREFIX--=--ADSM-------------------.
>--+---------------------------------+------------------------->
   '-PREFIX--=--+-ADSM---------------+-'
                '-tape_volume_prefix-'

   .-MOUNTWait--=--60------.  .-MOUNTRetention--=--60------.
>--+----------------------+--+---------------------------+---->
   '-MOUNTWait--=--minutes-'  '-MOUNTRetention--=--minutes-'

   .-MOUNTLimit--=--DRIVES-----.
>--+---------------------------+------------------------------><
   '-MOUNTLimit--=--+-DRIVES-+-'
                    +-number-+
                    '-0------'
```

Parameters

device_class_name (Required)
Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

LIBRary (Required)

Specifies the name of the defined library object that contains the 4 mm tape drives used by this device class. For information about defining a library object, see the DEFINE LIBRARY command.

DEVType=4MM (Required)

Specifies that the 4MM device type is assigned to the device class. The 4MM indicates that 4 mm tape devices are assigned to this device class.

FORMAT

Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. The default value is DRIVE.

If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use.

The following table lists the recording formats and estimated capacities for 4 mm devices:

Table 1. Recording formats and default estimated capacities for 4 mm tapes

Format	Estimated Capacity	Description
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
DDS1	2.6 GB (60 meter) 4.0 GB (90 meter)	Uncompressed format, applies only to 60-meter and 90-meter tapes
DDS1C	See note 1.3 GB (60 meter) 2.0 GB (90 meter)	Compressed format, applies only to 60-meter and 90-meter tapes
DDS2	4.0 GB	Uncompressed format, applies only to 120-meter tapes
DDS2C	See note 8.0 GB	Compressed format, applies only to 120-meter tapes
DDS3	12.0 GB	Uncompressed format, applies only to 125-meter tapes
DDS3C	See note 24.0 GB	Compressed format, applies only to 125-meter tapes
DDS4	20.0 GB	Uncompressed format, applies only to 150-meter tapes
DDS4C	See note 40.0 GB	Compressed format, applies only to 150-meter tapes
DDS5	36 GB	Uncompressed format, when using DAT 72 media
DDS5C	See note 72 GB	Compressed format, when using DAT 72 media
DDS6	80 GB	Uncompressed format, when using DAT 160 media
DDS6C	See note 160 GB	Compressed format, when using DAT 160 media
Note: If this format uses the tape drive hardware compression feature, depending on the effectiveness of compression, the actual capacity might be greater than the listed value.		

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

For more information about the default estimated capacity for 4 mm tapes, see Table 1

PREFIX

Specifies the high-level qualifier of the file name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The default is ADSM. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention

Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. The default value is 60 minutes. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types (that is, a library that is managed by an external media management system), set this parameter to a low value (for example, two minutes) to enhance device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait

Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. The default value is 60 minutes. You can specify a number 0 - 9999.
Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit

Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. The default is DRIVES. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES

Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number

Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)
Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

DEFINE DEVCLASS (Define an 8MM device class)

Use the 8MM device class when you are using 8 mm tape devices.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine DEVclass--device_class_name--------------------------->

```

Parameters

device_class_name (Required)
Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

LIBRary (Required)
Specifies the name of the defined library object that contains the 8 mm tape drives used by this device class. For information about defining a library object, see the DEFINE LIBRARY command.

DEVType=8MM (Required)

Specifies that the 8MM device type is assigned to the device class. 8MM indicates that 8 mm tape devices are assigned to this device class.

WORM

Specifies whether the drives use WORM (write once, read many) media. This parameter is optional. The default is No. The field can contain one of the following values:

Yes
: Specifies that the drives use WORM media.

No
: Specifies that the drives do not use WORM media.

Note: If you select Yes, the only options available for the FORMAT parameter are:

- DRIVE
- AIT
- AITC

FORMAT

Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. The default value is DRIVE.

If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use.

The following table lists the recording formats and estimated capacities for 8 mm devices:

Table 1. Recording format and default estimated capacity for 8 mm tape

Format **Medium Type**	**Estimated Capacity**	**Description**
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
8200	2.3 GB	Uncompressed (standard) format, using standard 112-meter tape cartridges

SAITC	See note	Drive (Read Write)
	1300 GB (1.3 TB)	Sony SAIT1–500(RW)

Format Medium Type	 Estimated Capacity	Description
VXA2 V6 (62m) V10 (124m) V17 (170m)	See note 20 GB 40 GB 60 GB	Drive (Read Write) VXA–2
VXA2C V6 (62m) V10 (124m) V17 (170m)	See note 40 GB 80 GB 120 GB	Drive (Read Write) VXA–2
VXA3 X6 (62m) X10 (124m) X23 (230m)	See note 40 GB 86 GB 160 GB	Drive (Read Write) VXA–3
VXA3C X6 (62m) X10 (124m) X23 (230m)	See note 80 GB 172 GB 320 GB	Drive (Read Write) VXA–3
Note: The actual capacities might vary depending on which cartridges and drives are used. • For the M2C format, the normal compression ratio is 2.5:1. • For the AITC and SAITC formats, the normal compression ratio is 2.6:1.		

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

For more information about the default estimated capacity for 8 mm tapes, see Table 1.

PREFIX

Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The default value is ADSM. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention

Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. The default value is 60 minutes. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types (that is, a library that is managed by an external media management system), set this parameter to a low value (for example, two minutes) to enhance device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait

Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. The default value is 60 minutes. You can specify a number 0 - 9999.
Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit

Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. The default is DRIVES. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES

Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number

Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)

Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

Example: Define an 8 mm device class

Define a device class that is named 8MMTAPE for an 8 mm device in a library named AUTO. The format is DRIVE, mount limit is 2, mount retention is 10, tape volume prefix is named ADSMVOL, and the estimated capacity is 6 GB.

```
define devclass 8mmtape devtype=8mm library=auto
format=drive mountlimit=2 mountretention=10
prefix=adsmvol estcapacity=6G
```

DEFINE DEVCLASS (Define a CENTERA device class)

Use the CENTERA device class when you are using EMC Centera storage devices. The CENTERA device type uses files as volumes to store data sequentially. It is similar to the FILE device class.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine DEVclass--device_class_name--DEVType--=--CENTERA------>

                      .-,----------.
             (1)      V            |
>--HLAddress------=----ip_address-+-?PEA_file------------------>

   .-MINCAPacity--=--100M-.  .-MOUNTLimit--=--1------.
>--+----------------------+--+----------------------+---------><
   '-MINCAPacity--=--size-'  '-MOUNTLimit--=--number-'
```

Notes:

1. For each Centera device class, you must specify one or more IP addresses. However, a Pool Entry Authorization (PEA) file name and path are optional, and up to one PEA file specification can follow the IP addresses. Use the "?" character to separate the PEA file name and path from the IP addresses.

Parameters

device_class_name (Required)
: Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

DEVType=CENTERA (Required)
: Specifies that the Centera device type is assigned to this device class. All volumes that belong to a storage pool that is defined to this device class are logical volumes that are a form of sequential access media.

HLAddress
: Specifies one ore more IP addresses for the Centera storage device and, optionally, the name and path of one Pool Entry Authorization (PEA) file. Specify the IP addresses with the dotted decimal format (for example, 9.10.111.222). A Centera device might have multiple IP addresses. If multiple IP addresses are specified, then the store or retrieve operation attempts a connection by using each IP address that is specified until a valid address is found.

  AIX The PEA file name and path name are case-sensitive.

  If you append the name and path of a PEA file, ensure that the file is stored in a directory on the system that runs the server. Separate the PEA file name and path from the IP address with the "?" character, for example: Windows

  ```
  HLADDRESS=9.10.111.222,9.10.111.223?c:\controlFiles\TSM.PEA
  ```

  AIX

  ```
  HLADDRESS=9.10.111.222,9.10.111.223?/user/ControlFiles/TSM.PEA
  ```

  Specify only one PEA file name and path for each device class definition. If you specify two different Centera device classes that point to the same Centera storage device and if the device class definitions contain different PEA file names and paths, the server uses the PEA file that is specified in the device class HLADDRESS parameter that was first used to open the Centera storage device.
  Tips:

  1. The server does not include a PEA file during installation. If you do not create a PEA file, the server uses the Centera default profile, which can allow applications to read, write, delete, purge, and query data on a Centera storage device. To provide tighter control, create a PEA file with the command-line interface that is provided by EMC Centera. For details about Centera authentication and authorization, refer to the EMC Centera *Programmer's Guide*.
  2. You can also specify the PEA file name and path in an environment variable with the syntax CENTERA_PEA_LOCATION=filePath_ fileName. The PEA file name and path that is specified with this environment variable apply to all Centera clusters. If you use this variable, you do not have to specify the PEA file name and path with the HLADDRESS parameter.

MINCAPacity
: Specifies the minimum size for Centera volumes that are assigned to a storage pool in this device class. This value represents the minimum amount of data that is stored on a Centera volume before the server marks it full. Centera volumes continue to accept data until the minimum amount of data is stored. This parameter is optional.

  Specify this value as an integer followed by `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The default value is 100 MB (MINCAPACITY=100M). The minimum value that is allowed is 1 MB (MINCAPACITY=1M). The maximum value that is allowed is 128 GB (MINCAPACITY=128G).

MOUNTLimit

Specifies the maximum number of files that can be simultaneously open for input and output. The default value is 1. This parameter is optional. You can specify any number from 0 or greater; however, the sum of all mount limit values for all device classes that are assigned to the same Centera device must not exceed the maximum number of sessions that are allowed by Centera.

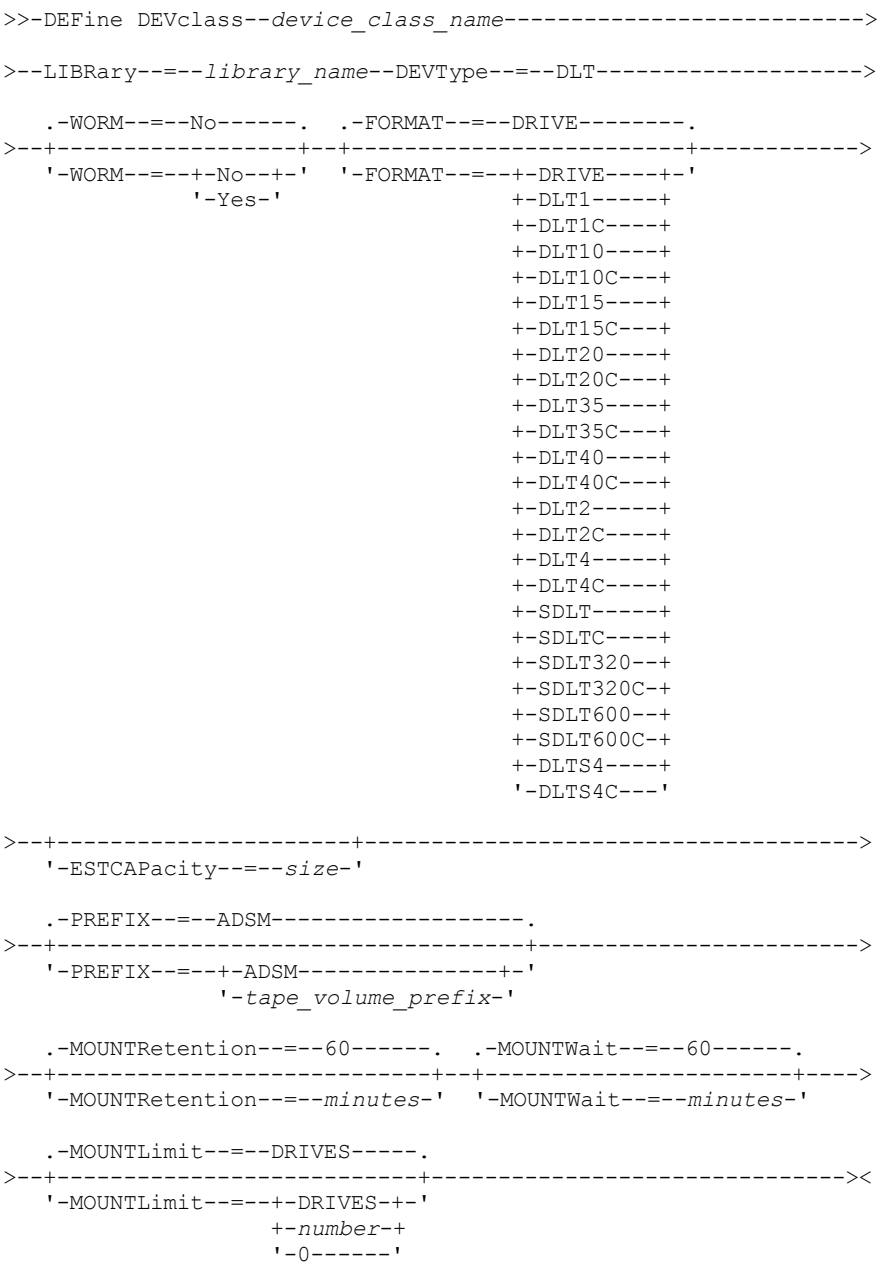
DEFINE DEVCLASS (Define a DLT device class)

Use the DLT device class when you are using DLT tape devices.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax



Parameters

device_class_name (Required)
Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

LIBRary (Required)
Specifies the name of the defined library object that contains the DLT tape drives used by this device class. For information about defining a library object, see the DEFINE LIBRARY command.

DEVType=DLT (Required)
Specifies that the DLT device type is assigned to the device class. DLT indicates that DLT tape devices are assigned to this device class.

WORM
Specifies whether the drives use WORM (write once, read many) media. This parameter is optional. The default is No. The field can contain one of the following values:

Yes
Specifies that the drives use WORM media.

No
Specifies that the drives do not use WORM media.

Note: Support for DLT WORM media is available only for SDLT-600, Quantum DLT-V4, and Quantum DLT-S4 drives in manual, SCSI, and ACSLS libraries.

FORMAT
Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. The default value is DRIVE.

If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use.

The following table lists the recording formats and estimated capacities for DLT devices:

Table 1. Recording format and default estimated capacity for DLT

Format	Estimated Capacity	Description
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
DLT1	40.0 GB	Uncompressed format, using only CompacTape III cartridges Valid with DLT4000, DLT7000, and DLT8000 drives
DLT1C	See note 1. 80.0 GB	Compressed format, using only CompacTape III cartridges Valid with DLT4000, DLT7000, and DLT8000 drives
DLT10	10.0 GB	Uncompressed format, using only CompacTape III cartridges Valid with DLT4000, DLT7000, and DLT8000 drives
DLT10C	See note 1. 20.0 GB	Compressed format, using only CompacTape III cartridges Valid with DLT4000, DLT7000, and DLT8000 drives
DLT15	15.0 GB	Uncompressed format, using only CompacTape IIIxt cartridges Valid with DLT4000, DLT7000, and DLT8000 drives
DLT15C	See note 1. 30.0 GB	Compressed format, using only CompacTape IIIxt cartridges Valid with DLT4000, DLT7000, and DLT8000 drives
DLT20	20.0 GB	Uncompressed format, using only CompacTape IV cartridges Valid with DLT4000, DLT7000, and DLT8000 drives
DLT20C	See note 1. 40.0 GB	Compressed format, using only CompacTape IV cartridges Valid with DLT4000, DLT7000, and DLT8000 drives

Format	Estimated Capacity	Description
DLT35	35.0 GB	Uncompressed format, using only CompacTape IV cartridges Valid with DLT7000 and DLT8000 drives
DLT35C	See note 1. 70.0 GB	Compressed format, using only CompacTape IV cartridges Valid with DLT7000 and DLT8000 drives
DLT40	40.0 GB	Uncompressed format, using CompacTape IV cartridges Valid with a DLT8000 drive
DLT40C	See note 1. 80.0 GB	Compressed format, using CompacTape IV cartridges Valid with a DLT8000 drive
DLT2	80.0 GB	Uncompressed format, using Quantum DLT tape VS1 media
DLT2C	See note 1. 160.0 GB	Compressed format, using Quantum DLT tape VS1 media
DLT4	160.0 GB	Uncompressed format, using Quantum DLTtape VS1 cartridges. Valid with Quantum DLT-V4 drive
DLT4C	See note 1. 320.0 GB	Compressed format, using Quantum DLTtape VS1 cartridges. Valid with Quantum DLT-V4 drive
SDLT See note 2.	100.0 GB	Uncompressed format, using Super DLT Tape 1 cartridges Valid with a Super DLT drive
SDLTC See note 2.	See note 1. 200.0 GB	Compressed format, using Super DLT Tape 1 cartridges Valid with a Super DLT drive
SDLT320 See note 2.	160.0 GB	Uncompressed format, using Quantum SDLT I media Valid with a Super DLT drive
SDLT320C See note 2.	See note 1. 320.0 GB	Compressed format, using Quantum SDLT I media Valid with a Super DLT drive
SDLT600	300.0 GB	Uncompressed format, using SuperDLTtape-II media Valid with a Super DLT drive
SDLT600C	See note 1. 600.0 GB	Compressed format, using SuperDLTtape-II media Valid with a Super DLT drive
DLTS4	800 GB	Uncompressed format, using Quantum DLT S4 media. Valid with a DLT-S4 drive
DLTS4C	See note 1. 1.6 TB	Compressed format, using Quantum DLT S4 media. Valid with a DLT-S4 drive

Note:

1. Depending on the effectiveness of compression, the actual capacity might be greater than the listed value.
2. IBM Spectrum Protect™ does not support a library that contains both Backward Read Compatible (BRC) SDLT and Non-Backward Read Compatible (NBRC) SDLT drives.

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

For more information about estimated capacities, see Table 1.

PREFIX
Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The default value is ADSM. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention
Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. The default value is 60 minutes. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types (that is, a library that is managed by an external media management system), set this parameter to a low value (for example, two minutes) to enhance device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait
Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. The default value is 60 minutes. You can specify a number 0 - 9999.
Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. The default is DRIVES. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES
Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number

Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)
Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

DEFINE DEVCLASS (Define an ECARTRIDGE device class)

Use the ECARTRIDGE device class when you are using StorageTek drives such as the StorageTek T9840 or T10000.

AIX Linux If you are defining a device class for devices that are to be accessed through a z/OS® media server, see DEFINE DEVCLASS (Define an ECARTRIDGE device class for z/OS media server).

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine DEVclass--device_class_name--------------------------->

>--LIBRary--=--library_name--DEVType--=--ECARTridge------------->

                                                      (1)
   .-LBProtect--=--No-----------.  .-WORM--=--No------.

                         '-OFF------'
```

Notes:

1. You cannot specify both WORM=Yes and DRIVEENCRYPTION=ON.
2. You can use drive encryption only for Oracle StorageTek T10000B drives with a format value of DRIVE, T10000B, or T10000B-C, for Oracle StorageTek T10000C drives with a format value of DRIVE, T10000C or T10000C-C, and for Oracle StorageTek T10000D drives with a format value of DRIVE, T10000D and T10000D-C.

Parameters

device_class_name (Required)
Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

LIBRary (Required)
Specifies the name of the defined library object that contains the ECARTRIDGE tape drives that can be used by this device class. For information about defining a library object, see the DEFINE LIBRARY command.

DEVType=ECARTridge (Required)
Specifies that the ECARTRIDGE device type is assigned to the device class. ECARTRIDGE indicates that a specific type of cartridge tape device (StorageTek) is assigned to this device class.

LBProtect

Specifies whether logical block protection is used to ensure the integrity of data stored on tape. When LBPROTECT is set to READWRITE or to WRITEONLY, the server uses this feature of the tape drive for logical block protection and generates cyclic redundancy check (CRC) protection information for each data block written on tape. The server also validates the CRC protection information when data is read from the tape.

The default is NO.

The following values are possible:

READWrite
Specifies that logical block protection is enabled in the server and the tape drive for both read and write operations. Data is stored with CRC information in each block. This mode affects performance because additional processor usage is required for IBM Spectrum Protect™ and the tape drive to calculate and compare CRC values. The READWRITE value does not affect backup sets and data that is generated by the BACKUP DB command.

When the LBPROTECT parameter is set to READWRITE, you do not have to specify the CRCDATA parameter in a storage pool definition because logical block protection provides better protection against data corruption.

WRITEOnly
Specifies that logical block protection is enabled in the server and the tape drive for write operations only. Data is stored containing CRC information in each block. For read operations, the server and the tape drive do not validate the CRC. This mode affects performance because additional processor usage is required for IBM Spectrum Protect to generate the CRC and for the tape drive to calculate and compare CRC values for write operations. The WRITEONLY value does not affect backup sets and data that are generated by the BACKUP DB command.

No
Specifies that logical block protection is not enabled in the server and the tape drive for read and write operations. However, the server enables logical block protection on write operations for a filling volume that already has data with logical block protection.

Restriction: Logical block protection is supported only on Oracle StorageTek T10000C and Oracle StorageTek T10000D drives.

WORM
Specifies whether the drives use WORM (write once, read many) media. This parameter is optional. The default is No. The field can contain one of the following values:

Yes
Specifies that the drives use WORM media.

No
Specifies that the drives do not use WORM media.

Restriction: If you select Yes, the only options that are available for the FORMAT parameter are:

- DRIVE
- T9840C
- T9840C-C

- T9840D
- T9840D-C
- T10000A
- T10000A-C
- T10000B
- T10000B-C
- T10000C
- T10000C-C
- T10000D
- T10000D-C

FORMAT

Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. The default value is DRIVE.

If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use.

Important: If you specify DRIVE for a device class that has non-compatible sequential access devices, then you must mount volumes on devices that are capable of reading or writing the format that is established when the volume was first mounted. This can cause delays if the only sequential access device that can access the volume is already in use.
The following table lists the recording formats and estimated capacities for ECARTRIDGE devices:

Table 1. Recording formats and default estimated capacities for ECARTRIDGE tapes

Format	Estimated capacity	Description
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
T9840C	40 GB	Uncompressed T9840C format, using a StorageTek 9840 cartridge
T9840C-C	80 GB	Compressed T9840C format, using a StorageTek 9840 cartridge
T9840D	75 GB	Uncompressed T9840D format, using a StorageTek 9840 cartridge
T9840D-C	150 GB	Compressed T9840D format, using a StorageTek 9840 cartridge
T10000A	500 GB	Uncompressed T10000A format, using a StorageTek T10000 cartridge
T10000A-C	1 TB	Compressed T10000A format, using a StorageTek T10000 cartridge
T10000B	1 TB	Uncompressed T10000B format, using an Oracle StorageTek T10000 cartridge
T10000B-C	2 TB	Compressed T10000B format, using an Oracle StorageTek T10000 cartridge
T10000C	5 TB	Uncompressed T10000C format, using an Oracle StorageTek T10000 T2 cartridge
T10000C-C	10 TB	Compressed T10000C format, using an Oracle StorageTek T10000 T2 cartridge
T10000D	8 TB	Uncompressed T10000D format, using an Oracle StorageTek T10000 T2 cartridge
T10000D-C	15 TB	Compressed T10000D format, using an Oracle StorageTek T10000 T2 cartridge

Format	Estimated capacity	Description
Notes: • Some formats use a tape drive hardware compression feature. Depending on the effectiveness of compression, the actual capacity might be double or more than the listed value. • T10000A drives can read and write the T10000A format only. T10000B drives can read, but cannot write, the T10000A format. T10000C drives can read, but cannot write, the T10000A and T10000B formats. T10000D drives can read, but cannot write, the T10000A, T10000B, and T10000C formats.		

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

PREFIX

Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The default value is ADSM. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention

Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. The default value is 60 minutes. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types (that is, a library that is managed by an external media management system), set this parameter to a low value (for example, two minutes) to enhance device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait

Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. The default value is 60 minutes. You can specify a number 0 - 9999.
Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit

Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. The default is DRIVES. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES
: Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number
: Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)
: Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

DRIVEEncryption
: Specifies whether drive encryption is allowed. This parameter is optional. The default is ALLOW.
Restrictions:

1. You can use drive encryption only for the following drives:
   - Oracle StorageTek T10000B drives that have a format value of DRIVE, T10000B, or T10000B-C
   - Oracle StorageTek T10000C drives that have a format value of DRIVE, T10000C, or T10000C-C
   - Oracle StorageTek T10000D drives that have a format value of DRIVE, T10000D, or T10000D-C
2. You cannot specify IBM Spectrum Protect as the key manager for drive encryption of write once, read many (WORM) media. You cannot specify both WORM=Yes and DRIVEENCRYPTION=ON.
3. If encryption is enabled for a device class, and the device class is associated with a storage pool, the storage pool should not share a scratch pool with other device classes that cannot be encrypted. If a tape is encrypted, and you plan to use it on a drive that cannot be encrypted, you must manually relabel the tape before it can be used on that drive.

ON
: Specifies that IBM Spectrum Protect is the key manager for drive encryption and allows drive encryption for empty storage pool volumes only if the application method is enabled. (Other types of volumes are not encrypted. For example, back up sets, export volumes, and database backup volumes are not encrypted.) If you specify ON and you enable another method of encryption, drive encryption is not allowed and backup operations fail.

ALLOW
: Specifies that IBM Spectrum Protect does not manage the keys for drive encryption. However, drive encryption for empty volumes is allowed if another method of encryption is enabled.

EXTernal
: Specifies that IBM Spectrum Protect does not manage the keys for drive encryption. Use this setting with an encryption methodology that is provided by another vendor and that is used with Application Method Encryption (AME) enabled on the drive. When you specify EXTERNAL and IBM Spectrum Protect detects that AME encryption is enabled, IBM Spectrum Protect does not turn off encryption. By contrast, when you specify ALLOW and IBM Spectrum Protect detects that AME encryption is enabled, IBM Spectrum Protect turns off encryption.

OFF
: Specifies that drive encryption is not allowed. If you enable another method of encryption, backups fail. If you enable the application method, IBM Spectrum Protect disables encryption and backups are attempted.

DEFINE DEVCLASS (Define a FILE device class)

Use the FILE device class when you are using files on magnetic disk storage as volumes that store data sequentially (as on tape).

AIX Linux The FILE device class does not support EXTERNAL libraries.

Windows The FILE device class does not support EXTERNAL or Remote Storage Manager libraries.

AIX Linux If you are defining a device class for devices that are to be accessed through a z/OS® media server, see DEFINE DEVCLASS (Define a FILE device class for z/OS media server).

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine DEVclass--device_class_name--DEVType--=--FILE--------->

   .-MOUNTLimit--=--20-----.  .-MAXCAPacity--=--10G--.
>--+----------------------+--+---------------------+---------->
   '-MOUNTLimit--=--number-'  '-MAXCAPacity--=--size-'

   .-DIRectory--=--current_directory_name-.
>--+--------------------------------------+-------------------->
   |               .-,--------------.     |
   |               V                |     |
   '-DIRectory--=-----directory_name-+-----'

   .-SHAREd--=--No------.
>--+--------------------+-------------------------------------><
   '-SHAREd--=--+-No--+-'
                '-Yes-'
```

Parameters

device_class_name (Required)
: Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

DEVType=FILE (Required)
: Specifies that the FILE device type is assigned to the device class. FILE indicates that a file is assigned to this device class. When the server must access a volume that belongs to this device class, it opens a file and reads or writes file data.

  A file is a form of sequential-access media.

MOUNTLimit
: Specifies the maximum number of files that can be simultaneously open for input and output. This parameter is optional. The default value is 20. You can specify a number from 0 to 4096.

  Windows If the device class is shared with a storage agent (by specifying the SHARED=YES parameter), drives are defined or deleted to match the mount limit value.

  If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

MAXCAPacity
: Specifies the maximum size of any data storage files that are defined to a storage pool in this device class.

  The value of the MAXCAPACITY parameter is also used as the unit of allocation when storage pool space triggers create volumes. The default value is 10 GB (MAXCAPACITY=10G). The value that is specified must be less than or equal to the maximum supported size of a file on the target file system.

  Specify this value as an integer followed by `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The minimum size is 1 MB (MAXCAPACITY=1M). If you are defining a FILE device class for database-backup volumes, specify a value for MAXCAPACITY that is appropriate for the size of the database and that minimizes the number of database volumes.

  AIX Linux Do not define a MAXCAPACITY value greater than 640M when this file is for REMOVABLEFILE CD support. A value less than a CD's usable space (650 MB) enables a one-to-one match between files from the FILE device class and copies that are on CD.

DIRectory
: Specifies the directory location or locations of the files that are used in this device class. Enclose the entire list of directories within quotation marks, and use commas to separate individual directory names. Special characters (for

example, blank spaces) are allowed within directory names. For example, the directory list "abc def,xyz" contains two directories: abc def and xyz.

This parameter is optional.

AIX Linux The default is the current working directory of the server at the time the command is issued.

Windows The default is the current working directory of the server at the time the command is issued. Windows registry information is used to determine the default directory.

By specifying a directory name or names, you identify the location where the server places the files that represent storage volumes for this device class.

For NetApp SnapLock support (storage pools with RECLAMATIONTYPE=SNAPLOCK, which are going to use this device class), the directory, or directories that are specified with DIRECTORY parameter must point to the directory or directories on the NetApp SnapLock volumes.

AIX Linux While the command is processed, the server expands the specified directory name or names into their fully qualified forms, starting from the root directory.

If the server must allocate a scratch volume, it creates a new file in one of these directories. (The server can choose any of the directories in which to create new scratch volumes.) For scratch volumes used to store client data, the file that is created by the server has a file name extension of .bfs. For scratch volumes used to store export data, a file name extension of .exp is used.

AIX Linux For example, if you define a device class with a directory of tsmstor and the server needs a scratch volume in this device class to store export data, the file that the server creates might be named /tsmstor/00566497.exp.

Windows For example, if you define a device class with a directory of c:\server and the server needs a scratch volume in this device class to store export data, the file that the server creates might be named c:\server\00566497.exp.

Important: You must ensure that storage agents can access newly created FILE volumes. Failure of the storage agent to access a FILE volume can cause operations to be retried on a LAN-only path or to fail. For more information, see the description of the DIRECTORY parameter in DEFINE PATH (Define a path).
Tip: If you specify multiple directories for a device class, ensure that the directories are associated with separate file systems. Space trigger functions and storage pool space calculations take into account the space that remains in each directory. If you specify multiple directories for a device class and the directories are in the same file system, the server calculates space by adding values that represent the space that remains in each directory. These space calculations are inaccurate. Rather than choosing a storage pool with sufficient space for an operation, the server might choose the wrong storage pool and run out of space prematurely. For space triggers, an inaccurate calculation might result in a failure to expand the space available in a storage pool. Failure to expand space in a storage pool is one of the conditions that can cause a trigger to become disabled. If a trigger is disabled because the space in a storage pool could not be expanded, you can re-enable the trigger by issuing the following command: `update spacetrigger stg`. No further changes are required to the space trigger.

SHAREd

Specifies that this FILE device class is shared between the server and one or more storage agents. To prepare for sharing, a library is automatically defined along with a number of drives corresponding to the MOUNTLIMIT parameter value. The drive names are the name of the library plus a number from 1 to the mount limit number. For example, if the library name is FILE and the mount limit is set to 4, the drives are named FILE11, FILE12, FILE13, FILE14.

For information about prerequisites when storage is shared by the server and storage agent, see IBM® Support Portal for IBM Spectrum Protect™.

Example: Define a FILE device class with multiple directories

Define a device class that specifies multiple directories.

AIX

```
define devclass multidir devtype=file
   directory=/usr/xyz,/usr/abc,/usr/uvw
```

Linux

```
define devclass multidir devtype=file
   directory=/opt/xyz,/opt/abc,/opt/uvw
```

Windows

```
define devclass multidir devtype=file
   directory=e:\xyz,f:\abc,g:\uvw
```

Example: Define a FILE device class with a 50 MB capacity

Define a device class named PLAINFILES with a FILE device type and a maximum capacity of 50 MB.

```
define devclass plainfiles devtype=file
maxcapacity=50m
```

AIX | Windows

DEFINE DEVCLASS (Define a GENERICTAPE device class)

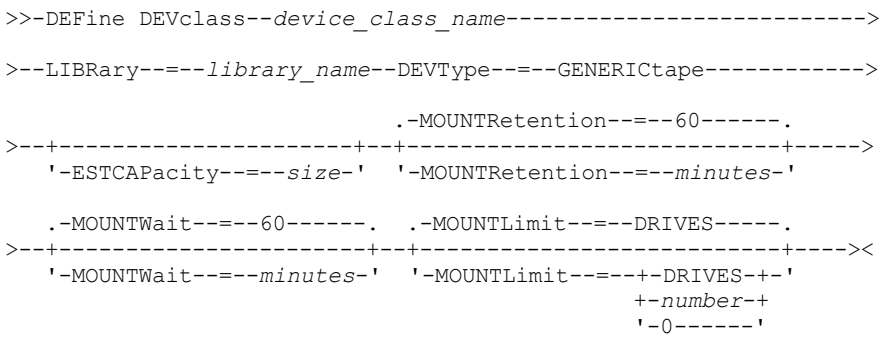
Use the GENERICTAPE device class for tape drives that are supported by operating system device drivers.

When you use this device type, the server does not recognize either the type of device or the cartridge recording format. Because the server does not recognize the type of device, if an I/O error occurs, error information is less detailed compared to error information for a specific device type (for example, 8MM). When you define devices to the server, do not mix various types of devices within the same device type.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax



Parameters

device_class_name (Required)
: Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

LIBRary (Required)

: Specifies the name of the defined library object that contains the tape drives that can be used by this device class.

: For information about defining a library object, see the DEFINE LIBRARY command.

DEVType=GENERICtape (Required)
: Specifies that the GENERICTAPE device type is assigned to the device class. GENERICTAPE indicates that the volumes for this device class are used in tape drives that are supported by the operating system's tape device driver.

: The server recognizes that the media can be removed and that more media can be inserted, subject to limits set with the MOUNTLIMIT parameter for the device class and the MAXSCRATCH parameter for the storage pool.

: Volumes in a device class with device type GENERICTAPE are sequential access volumes.

ESTCAPacity
: Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

Specify a capacity appropriate to the particular tape drive that is being used.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

MOUNTRetention
Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. The default value is 60 minutes. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types, setting this parameter to a low value (for example, two minutes) enhances device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait
Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. The default value is 60 minutes. You can specify a number 0 - 9999.
Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. The default is DRIVES. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES
Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number
Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)
Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

DEFINE DEVCLASS (Define an LTO device class)

Use the LTO device class when you are using LTO tape devices.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

Notes:

1. You cannot specify both WORM=Yes and DRIVEENCRYPTION=ON.
2. Drive encryption is supported only for Ultrium 4, Ultrium 5, and Ultrium 6 drives and media.

Parameters

device_class_name (Required)
: Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

LIBRary (Required)
: Specifies the name of the defined library object that contains the LTO tape drives used by this device class. For information about defining a library object, see the DEFINE LIBRARY command.

DEVType=LTO (Required)
: Specifies that the linear tape open (LTO) device type is assigned to the device class.

LBProtect
: Specifies whether logical block protection is used to ensure the integrity of data stored on tape. When LBPROTECT is set to READWRITE or to WRITEONLY, the server uses this feature of the tape drive for logical block protection and generates

cyclic redundancy check (CRC) protection information for each data block written on tape. The server also validates the CRC protection information when data is read from the tape.

The default is NO.

The following values are possible:

READWrite
: Specifies that logical block protection is enabled in the server and the tape drive for both read and write operations. Data is stored with CRC information in each block. This mode affects performance because additional processor usage is required for IBM Spectrum Protect™ and the tape drive to calculate and compare CRC values. The READWRITE value does not affect backup sets and data that is generated by the BACKUP DB command.

  When the LBPROTECT parameter is set to READWRITE, you do not have to specify the CRCDATA parameter in a storage pool definition because logical block protection provides better protection against data corruption.

WRITEOnly
: Specifies that logical block protection is enabled in the server and the tape drive for write operations only. Data is stored containing CRC information in each block. For read operations, the server and the tape drive do not validate the CRC. This mode affects performance because additional processor usage is required for IBM Spectrum Protect to generate the CRC and for the tape drive to calculate and compare CRC values for write operations. The WRITEONLY value does not affect backup sets and data that are generated by the BACKUP DB command.

No
: Specifies that logical block protection is not enabled in the server and the tape drive for read and write operations. However, the server enables logical block protection on write operations for a filling volume that already has data with logical block protection.

Restriction: Logical block protection is supported only on IBM® LTO5 and supported LTO6 drives.

WORM
: Specifies whether the drives use WORM (write once, read many) media. This parameter is optional. The default is No. The field can contain one of the following values:

  Yes
  : Specifies that the drives use WORM media.

  No
  : Specifies that the drives do not use WORM media.

  Note:

  1. To use WORM media in a library, all the drives in the library must be WORM capable.
  2. You cannot specify IBM Spectrum Protect as the key manager for drive encryption of WORM (write once, read many) media. (Specifying both WORM=Yes and DRIVEENCRYPTION=ON is not supported.)

FORMAT
: Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. The default value is DRIVE.

  If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use.

  When migrating all drives from Ultrium to Ultrium 2 devices:

  - Delete all existing Ultrium drive definitions and the paths that are associated with them.
  - Define the new Ultrium 2 drives and paths.

  If you are considering mixing different generations of LTO media and drives, be aware of the following restrictions.

Table 1. Read - write capabilities for different generations of LTO drives

Drives	Generation 1 media	Generation 2 media	Generation 3 media	Generation 4 media	Generation 5 media	Generation 6 media
Generation 1	Read and write	n/a	n/a	n/a	n/a	n/a
Generation 2	Read and write	Read and write	n/a	n/a	n/a	n/a
Generation 3 [1]	Read only	Read and write	Read and write	n/a	n/a	n/a

Drives	Generation 1 media	Generation 2 media	Generation 3 media	Generation 4 media	Generation 5 media	Generation 6 media
Generation 4 [2]	n/a	Read only	Read and write	Read and write	n/a	n/a
Generation 5 [3]	n/a	n/a	Read only	Read and write	Read and write	n/a
Generation 6 [4]	n/a	n/a	n/a	Read only	Read and write	Read and write

[1] In a library with a Generation 3 drive, all Generation 1 scratch volumes must be checked out, and all Generation 1 storage pool volumes must be updated to read-only.

[2] In a library with a Generation 4 drive, all Generation 2 scratch volumes must be checked out, and all Generation 2 storage pool volumes must be updated to read-only.

[3] In a library with a Generation 5 drive, all Generation 3 scratch volumes must be checked out, and all Generation 3 storage pool volumes must be updated to read-only.

[4] In a library with a Generation 6 drive, all Generation 4 scratch volumes must be checked out, and all Generation 4 storage pool volumes must be updated to read-only.

The following table lists the recording formats and estimated capacities for LTO devices:

Table 2. Recording format and default estimated capacity for LTO

Format	Estimated capacity	Description
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
ULTRIUM	100 GB	Uncompressed format, using Ultrium cartridges
ULTRIUMC	See note 200 GB	Compressed format, using Ultrium cartridges
ULTRIUM2	200 GB	Uncompressed (standard) format, using Ultrium 2 cartridges
ULTRIUM2C	See note 400 GB	Compressed format, using Ultrium 2 cartridges
ULTRIUM3	400 GB	Uncompressed (standard) format, using Ultrium 3 cartridges
ULTRIUM3C	See note 800 GB	Compressed format, using Ultrium 3 cartridges
ULTRIUM4	800 GB	Uncompressed (standard) format, using Ultrium 4 cartridges
ULTRIUM4C	See note 1.6 TB	Compressed format, using Ultrium 4 cartridges
ULTRIUM5	1.5 TB	Uncompressed (standard) format, using Ultrium 5 cartridges
ULTRIUM5C	See note 3.0 TB	Compressed format, using Ultrium 5 cartridges
ULTRIUM6	2.5 TB	Uncompressed (standard) format, using Ultrium 6 cartridges
ULTRIUM6C	See note 6.25 TB	Compressed format, using Ultrium 6 cartridges
Note: If this format uses the tape-drive hardware-compression feature, depending on the effectiveness of compression, the actual capacity might be greater than the listed value.		

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

For more information about estimated capacities, see Table 2.

PREFIX

Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The default value is ADSM. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention

Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. The default value is 60 minutes. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types, setting this parameter to a low value (for example, two minutes) enhances device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait

Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. The default value is 60 minutes. You can specify a number 0 - 9999.
Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit

Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. The default is DRIVES. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES

Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.

Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number
Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)
Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

DRIVEEncryption
Specifies whether drive encryption is allowed. This parameter is optional. The default is ALLOW. Drive encryption is supported only for Ultrium 4, Ultrium 5, and Ultrium 6 drives and media.
Restriction: If encryption is enabled for a device class, and the device class is associated with a storage pool, the storage pool should not share a scratch pool with other device classes that cannot be encrypted. If a tape is encrypted, and you plan to use it on a drive that cannot be encrypted, you must manually relabel the tape before it can be used on that drive.

ON
Specifies that IBM Spectrum Protect is the key manager for drive encryption and allows drive encryption for empty storage pool volumes only if the application method is enabled. (Other types of volumes are not encrypted. For example, back up sets, export volumes, and database backup volumes are not encrypted.) If you specify ON and you enable another method of encryption, drive encryption is not allowed and backup operations fail.
Note: You cannot specify IBM Spectrum Protect as the key manager for drive encryption of WORM (write once, read many) media. (Specifying both WORM=Yes and DRIVEENCRYPTION=ON is not supported.)

ALLOW
Specifies that IBM Spectrum Protect does not manage the keys for drive encryption. However, drive encryption for empty volumes is allowed if another method of encryption is enabled.

EXTERNAL
Specifies that IBM Spectrum Protect does not manage the keys for drive encryption. Use this setting with an encryption methodology that is provided by another vendor and that is used with Application Method Encryption (AME) enabled on the drive. When you specify EXTERNAL and IBM Spectrum Protect detects that AME encryption is enabled, IBM Spectrum Protect does not turn off encryption. By contrast, when you specify ALLOW and IBM Spectrum Protect detects that AME encryption is enabled, IBM Spectrum Protect turns off encryption.

OFF
Specifies that drive encryption is not allowed. If you enable another method of encryption, backups fail. If you enable the application method, IBM Spectrum Protect disables encryption and backups are attempted.

Example: Define an LTO device class

Define a device class that is named LTOTAPE for an LTO drive in a library named LTOLIB. The format is ULTRIUM, mount limit is 12, mount retention is 5, tape volume prefix is named SMVOL, and the estimated capacity is 100 GB.

```
define devclass ltotape devtype=lto library=ltolib
format=ultrium mountlimit=12 mountretention=5
prefix=smvol estcapacity=100G
```

DEFINE DEVCLASS (Define a NAS device class)

Use the NAS device class when you are using NDMP (Network Data Management Protocol) operations to back up network-attached storage (NAS) file servers. The device class is for drives that are supported by the NAS file server for backups.

AIX | Linux The NAS device class does not support EXTERNAL libraries.

Windows The NAS device class does not support EXTERNAL or Remote Storage Manager libraries.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine DEVclass--device_class_name--DEVType---=--NAS----------><
```

```
>--LIBRary--=--library_name--MOUNTRetention--=--0--------------->

   .-MOUNTWait--=--60------.  .-MOUNTLimit--=--DRIVES-----.
>--+---------------------+--+-------------------------+----->
   '-MOUNTWait--=--minutes-'  '-MOUNTLimit--=--+-DRIVES-+-'
                                               +-number-+
                                               '-0------'

>--ESTCAPacity--=--size-------------------------------------------->

   .-PREFIX--=--ADSM-----------------.
>--+-----------------------------------+----------------------><
   '-PREFIX--=--+-ADSM--------------+-'
                '-tape_volume_prefix-'
```

Parameters

device_class_name (Required)
: Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

DEVType=NAS (Required)
: Specifies that the network-attached storage (NAS) device type is assigned to the device class. The NAS device type is for drives that are attached to and used by a NAS file server for backup of NAS file systems.

LIBRary (Required)
: Specifies the name of the defined library object that contains the SCSI tape drives used by this device class. For information about defining a library object, see the DEFINE LIBRARY command.

MOUNTRetention=0 (Required)
: Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. Zero (0) is the only supported value for device classes with DEVType=NAS.

MOUNTWait
: Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. The default value is 60 minutes. You can specify a number 0 - 9999.
  Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
: Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. The default is DRIVES. You can specify a number 0 - 4096.

  If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

  The following are possible values:

  DRIVES
  : Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
    Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

  number
  : Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

  0 (zero)
  : Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

ESTCAPacity (Required)
: Specifies the estimated capacity for the volumes that are assigned to this device class.

  You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

  For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

PREFIX
Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The default value is ADSM. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

Example: Define a NAS device class

Define a device class that is named NASTAPE for a NAS drive in a library named NASLIB. The mount limit is DRIVES, mount retention is 0, tape volume prefix is named SMVOL, and the estimated capacity is 200 GB.

```
define devclass nastape devtype=nas library=naslib
mountretention=0 mountlimit=drives
prefix=smvol estcapacity=200G
```

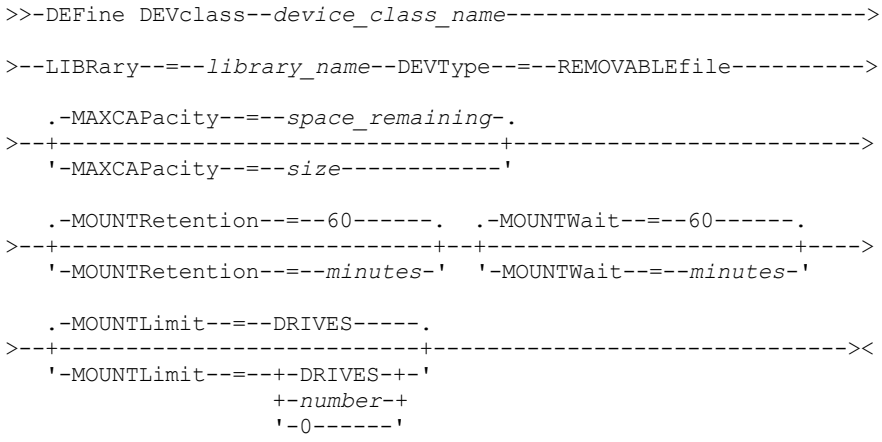
DEFINE DEVCLASS (Define a REMOVABLEFILE device class)

Use the REMOVABLEFILE device class for removable media devices that are attached as local, removable file systems.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax



Parameters

device_class_name (Required)
Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.
LIBRary (Required)

Specifies the name of the defined library object that contains the removable media drives used by this device class. For information about defining a library object, see the DEFINE LIBRARY command.

DEVType=REMOVABLEfile (Required)

Specifies that the REMOVABLEFILE device type is assigned to the device class. REMOVABLEFILE indicates that the volumes for this device class are files on local, removable media.

Volumes in a device class with device type REMOVABLEFILE are sequential access volumes.

Use the device manufacturer's utilities to format (if necessary) and label the media. The label on the media must meet the following restrictions:

- The label can have no more than 11 characters.
- The volume label and the name of the file on the volume must match exactly.
- AIX Windows The MAXCAPACITY parameter value must be specified at less than the capacity of the media.

MAXCAPacity

Specifies the maximum size of any volumes that are defined to a storage pool categorized by this device class. This parameter is optional.

The MAXCAPACITY parameter must be set at less value than the capacity of the media. For CD media, the maximum capacity can be no greater than 650 MB.

AIX Windows Because the server opens only one file per physical removable medium, specify a capacity that enables one file to make full use of your media capacity.

space_remaining

The default maximum capacity is the space that remains on the media after it is first used.

size

You must specify this value as an integer followed by `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes).

For example, MAXCAPACITY=5M specifies that the maximum capacity for a volume in this device class is 5 MB. The smallest value that is allowed is 1 MB (that is, MAXCAPACITY=1M).

MOUNTRetention

Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. The default value is 60 minutes. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

MOUNTWait

Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. The default value is 60 minutes. You can specify a number 0 - 9999.
Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit

Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. The default is DRIVES. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES

Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.

Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number
: Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)
: Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

DEFINE DEVCLASS (Define a SERVER device class)

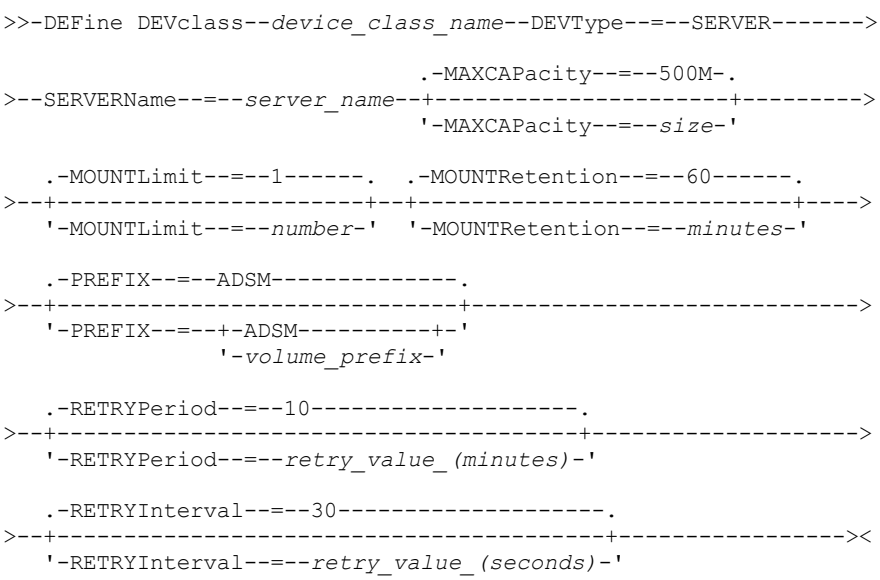
Use the SERVER device class to use storage volumes or files that are archived in another IBM Spectrum Protect™ server.

If data retention protection is activated with the SET ARCHIVERETENTIONPROTECTION command, you cannot define a server device class.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax



Parameters

device_class_name (Required)
: Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

DEVType=SERVER (Required)
: Specifies a remote connection that supports virtual volumes.

SERVERName (Required)
: Specifies the name of the server. The SERVERNAME parameter must match a defined server.

MAXCAPacity
: Specifies the maximum size for objects that are created on the target server; the default for this value is 500M. This parameter is optional.

  500M
  : Specifies that the maximum capacity is 500M (500 MB).

  size
  : Specify this value as an integer followed by `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The minimum value that is allowed is 1 MB (MAXCAPACITY=1M).

MOUNTLimit
Specifies the maximum number of simultaneous sessions between the source server and the target server. Any attempts to access more sessions than indicated by the mount limit cause the requester to wait. This parameter is optional. The default value is 1. You can specify a number 1 - 4096.
The following are possible values:

1
Specifies that only one session between the source server and the target server is allowed.
number
Specifies the number of simultaneous sessions between the source server and the target server.

MOUNTRetention
Specifies the number of minutes to retain an idle connection with the target server before the connection closes. This parameter is optional. The default value is 60. You can specify a number 0 - 9999.
Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.
PREFIX
Specifies the beginning portion of the high-level archive file name on the target server. This parameter is optional. The default is ADSM. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a high-level archive file name that uses the default prefix is ADSM.volume1.

RETRYPeriod
Specifies the retry period in minutes. The retry period is the interval during which the server attempts to contact a target server if there is a suspected communications failure. This parameter is optional. You can specify a number 0 - 9999. The default value is 10 minutes.
RETRYInterval
Specifies the retry interval in seconds. The retry interval is how often retries are done within a specific time period. This parameter is optional. You can specify a number 1 - 9999. The default value is 30 seconds.

DEFINE DEVCLASS (Define a VOLSAFE device class)

Use the VOLSAFE device type to work with StorageTek VolSafe brand media and drives. This technology uses media that cannot be overwritten. Therefore, do not use these media for short-term backups of client files, the server database, or export tapes.

Restrictions:

1. NAS-attached libraries are not supported.
2. VolSafe media and read/write media must be in separate storage pools.
3. Check in cartridges with CHECKLABEL=YES on the CHECKIN LIBVOLUME command.
4. Label cartridges with OVERWRITE=NO on the LABEL LIBVOLUME command. If VolSafe cartridges are labeled more than one time, no additional data can be written to them.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine DEVclass--device_class_name---------------------------->

>--LIBRary--=--library_name--DEVType--=--VOLSAFE---------------->

                 .-FORMAT--=--DRIVE---------.
>--WORM--=--Yes--+--------------------------+------------------->
                 '-FORMAT--=--+-DRIVE------+-'
                              +-9840-------+
                              +-9840-C-----+
                              +-T9840C-----+
                              +-T9840C-C---+
                              +-T9840D-----+
                              +-T9840D-C---+
                              +-T10000A----+
                              +-T10000A-C--+
                              +-T10000B----+
                              +-T10000B-C--+
                              +-T10000C----+
                              +-T10000C-C--+
                              +-T10000D----+
                              '-T10000D-C--'

                             .-MOUNTRetention--=--60------.
>--+----------------------+--+---------------------------+----->
   '-ESTCAPacity--=--size-'  '-MOUNTRetention--=--minutes-'

   .-PREFIX--=--ADSM--------------.
>--+-----------------------------+----------------------------->
   '-PREFIX--=--+-ADSM-----------+-'
                '-volume_prefix-'

   .-MOUNTWait--=--60------.  .-MOUNTLimit--=--DRIVES-----.
>--+----------------------+--+--------------------------+---><
   '-MOUNTWait--=--minutes-'  '-MOUNTLimit--=--+-DRIVES-+-'
                                               +-number-+
                                               '-0------'
```

Parameters

device_class_name (Required)
: Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

LIBRary (Required)
: Specifies the name of the defined library object that contains the VolSafe drives that can be used by this device class. If any drives in a library are VolSafe-enabled, all drives in the library must be VolSafe-enabled. Consult your hardware documentation to enable VolSafe on the 9840 and T10000 drives.

  For information about defining a library object, see DEFINE LIBRARY (Define a library).

DEVType=VOLSAFE (Required)
: Specifies that the VOLSAFE device type is assigned to the device class. The label on this type of cartridge can be overwritten one time, which IBM Spectrum Protect™ does when it writes the first block of data. Therefore, it is important to limit the use of the LABEL LIBVOLUME command to one time per volume by using the OVERWRITE=NO parameter.

WORM
: Specifies whether the drives use WORM (write once, read many) media. The parameter is required. The value must be Yes.

  Yes
  : Specifies that the drives use WORM media.

FORMAT
: Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. The default value is DRIVE.
  Important: If you specify DRIVE for a device class that has non-compatible sequential access devices, then you must mount volumes on devices that are capable of reading or writing the format that is established when the volume was first mounted. This can cause delays if the only sequential access device that can access the volume is already in use.
  The following table lists the recording formats and estimated capacities for VolSafe devices:

Table 1. Recording formats and default estimated capacities for Volsafe media

Format	Estimated Capacity	Description
DRIVE	–	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library that contains some drives that support recording formats superior to other drives.
9840	20 GB	Uncompressed (standard) format, using a 20 GB cartridge with 270 meters (885 feet) of tape
9840-C	See note 80 GB	LZ-1 Enhanced (4:1) compressed format, using an 80 GB cartridge with 270 meters (885 feet) of tape
T9840C	40 GB	Uncompressed T9840C format, using a StorageTek 9840 cartridge
T9840C-C	80 GB	Compressed T9840C format, using a StorageTek 9840 cartridge
T9840D	75 GB	Uncompressed T9840D format, using a StorageTek 9840 cartridge
T9840D-C	150 GB	Compressed T9840D format, using a StorageTek 9840 cartridge
T10000A	500 GB	Uncompressed T10000A format, using a StorageTek T10000 cartridge
T10000A-C	1 TB	Compressed T10000A format, using a StorageTek T10000 cartridge
T10000B	1 TB	Uncompressed T10000B format, using an Oracle StorageTek T10000 cartridge
T10000B-C	2 TB	Compressed T10000B format, using an Oracle StorageTek T10000 cartridge
T10000C	5 TB	Uncompressed T10000C format, using an Oracle StorageTek T10000 T2 cartridge
T10000C-C	10 TB	Compressed T10000C format, using an Oracle StorageTek T10000 T2 cartridge
T10000D	8 TB	Uncompressed T10000D format, using an Oracle StorageTek T10000 T2 cartridge
T10000D-C	15 TB	Compressed T10000D format, using an Oracle StorageTek T10000 T2 cartridge

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate due to compression of data.

You must specify this value as an integer followed by one of the following unit indicators: `K` (kilobytes), `M` (megabytes), `G` (gigabytes), or `T` (terabytes). The smallest value that is accepted is 1 MB (ESTCAPACITY=1M).

For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G.

For more information about the default estimated capacity for cartridge tapes, see Table 1.

MOUNTRetention

Specifies the number of minutes that an idle sequential access volume is retained before it is dismounted. This parameter is optional. The default value is 60 minutes. You can specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

However, for EXTERNAL library types (that is, a library that is managed by an external media management system), set this parameter to a low value (for example, two minutes) to enhance device sharing between applications.

Note: For environments in which devices are shared across storage applications, the MOUNTRETENTION setting must be carefully considered. This parameter determines how long an idle volume remains in a drive. Some media managers do not dismount an allocated drive to satisfy pending requests. You might need to tune this parameter to satisfy competing mount

requests while maintaining optimal system performance. Typically, problems arise more frequently when the MOUNTRETENTION parameter is set to a value that is too small, for example, zero.

PREFIX
Specifies the beginning portion of the high-level archive file name on the target server. This parameter is optional. The default is ADSM. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a high-level archive file name that uses the default prefix is ADSM.volume1.

MOUNTWait
Specifies the maximum number of minutes the server waits for an operator to respond to a request to either mount a volume in a drive in a manual library or check in a volume to be mounted in an automated library. This parameter is optional. If the mount request is not satisfied within the specified amount of time, the mount request is canceled. The default value is 60 minutes. You can specify a number 0 - 9999.
Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. The default is DRIVES. You can specify a number 0 - 4096.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

The following are possible values:

DRIVES
Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.
Note: For EXTERNAL library types, do not specify DRIVES for the MOUNTLIMIT value. Specify the number of drives for the library as the MOUNTLIMIT value.

number
Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class.

0 (zero)
Specifies that no new transactions can gain access to the storage pool. Any current transactions continue and complete, but new transactions are terminated.

AIX | Linux

DEFINE DEVCLASS - z/OS media server (Define device class for z/OS media server)

Use the DEFINE DEVCLASS command to define a device class for a type of storage device. The server requires that a device class be defined to allow the use of a device. A limited set of device class types is available for devices that are accessed through a z/OS® media server.

- DEFINE DEVCLASS (Define a 3590 device class for z/OS media server)
- DEFINE DEVCLASS (Define a 3592 device class for z/OS media server)
- DEFINE DEVCLASS (Define an ECARTRIDGE device class for z/OS media server)
- DEFINE DEVCLASS (Define a FILE device class for z/OS media server)

Table 1. Commands related to DEFINE DEVCLASS

Command	Description
BACKUP DEVCONFIG	Backs up IBM Spectrum Protect device information to a file.
DEFINE LIBRARY	Defines an automated or manual library.
DELETE DEVCLASS	Deletes a device class.
QUERY DEVCLASS	Displays information about device classes.
UPDATE DEVCLASS (z/OS media server)	Changes the attributes of a device class for storage managed by a z/OS media server.

AIX Linux

DEFINE DEVCLASS (Define a 3590 device class for z/OS media server)

To use a z/OS® media server to access 3590 devices, you must define a 3590 device class. In the device class definition, specify a library that was defined with the LIBTYPE=ZOSMEDIA parameter.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine DEVclass--device_class_name--------------------------->

>--LIBRary--=--zos_media_library--DEVType--=--3590-------------->

                              .-ESTCAPacity--=--9G-------.
>--+-------------------------+--+--------------------------+----->
   '-FORMAT--=--+-DRIVE---+-'  '-ESTCAPacity--=----size---'
                +-3590B---+
                +-3590C---+
                +-3590E-B-+
                +-3590E-C-+
                +-3590H-B-+
                '-3590H-C-'

   .-PREFIX--=--ADSM-------------------.
>--+-----------------------------------+------------------------>
   '-PREFIX--=--+-ADSM---------------+-'
                '-tape_volume_prefix-'

   .-MOUNTRetention--=--60------.  .-MOUNTWait--=--60------.
>--+----------------------------+--+-----------------------+---->
   '-MOUNTRetention--=--minutes-'  '-MOUNTWait--=--minutes-'

   .-MOUNTLimit--=--2----------.  .-COMPression--=--Yes-----.
>--+---------------------------+--+-------------------------+--->
   '-MOUNTLimit--=--+-DRIVES-+-'  '-COMPression--=--+-Yes-+-'
                    +-number-+                     '-No--'
                    '-0------'

>--+------------------------+----------------------------------->
   +-EXPiration--=--yyyyddd-+
   '-RETention--=--days-----'

   .-PROtection--=--No------------.  .-UNIT--=--3590------.
>--+---------------------------+--+--------------------+---->><
   '-PROtection--=--+-No--------+-'  '-UNIT--=--unit_name-'
                    +-Yes-------+
                    '-Automatic-'
```

Parameters

device_class_name (Required)
Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

LIBRary (Required)

Specifies the name of a library that was defined with the LIBTYPE=ZOSMEDIA parameter. The library and the tape drives that can be used by this device class are controlled by the z/OS media server.

For information about defining a library, see the DEFINE LIBRARY command.

DEVtype=3590 (Required)
Specifies the 3590 device type is assigned to the device class. 3590 indicates that 3590 cartridge tape devices are assigned to the device class.
Restriction: The z/OS media server supports 256 KB data blocks when writing to 3590 tape drives. Verify that your hardware supports this capability.

FORMAT
Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. See the following table for the recording formats.

Table 1. Recording formats for 3590

Format	Description
3590B	Uncompressed (basic) format
3590C	Compressed format
3590E-B	Uncompressed (basic) format, similar to the 3590B format
3590E-C	Compressed format, similar to the 3590C format
3590H-B	Uncompressed (basic) format, similar to the 3590B format
3590H-C	Compressed format, similar to the 3590C format
Note: If the format uses the tape drive hardware compression feature the actual capacity can increase, depending on the effectiveness of compression.	

ESTCAPacity
Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional. The default estimated capacity for 3590 tapes is 9 GB.

You can specify this parameter if the default estimated capacity for the device class is inaccurate because of compression of data. The value does not determine the amount of data stored on the volume. The server uses the value to estimate the usage before a volume is filled. After a volume is full, the actual amount of data stored on the tape is used for the usage calculation.

Specify the value as an integer with one of the following unit indicators: `K` (KB), `M` (MB), `G` (GB), or `T` (TB). For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G. The smallest value that is accepted is 100 KB (ESTCAPACITY=100K).

PREFIX
Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The default value is ADSM. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention
Specifies the number of minutes that an idle tape volume is retained before it is dismounted. The time span for mount retention begins after the idle timeout period has expired. This parameter is optional. The default value is 60 minutes. Specify a number 0 - 9999.

This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

MOUNTWait
Specifies the maximum number of minutes that the z/OS media server waits for a volume mount. If the mount request is not satisfied within the specified time, the mount request fails. If a device is successfully allocated and the device-open request does not complete within the specified time, the device-open request ends and the mount request fails.

This parameter is optional. The default value is 60. Specify a number, 1 - 9999.

Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. The default is 2.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

You can specify one of the following values:

DRIVES
Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.

number
Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class. You can specify a number, 0 - 4096.

0 (zero)
Specifies that no new transactions can gain access to the storage pool.

COMPression
Specifies whether file compression is used for this device class. This parameter is optional. The default value is YES. You can specify one of the following values:

Yes
Specifies that the data for each tape volume is compressed.

No
Specifies that the data for each tape volume is not compressed.

EXPiration
Specifies the expiration date that is placed on the tape labels for this device class. This parameter is optional. There is no default value.

Specify the date when the server no longer requires the tape. The server does not use this information, but this information is passed to the z/OS media server for use by z/OS or tape management systems.

Specify the expiration date using the format, *yyyyddd* (four digits for the year and three digits for the day). For example, January 7, 2014 is specified as `2014007` (the seventh day of year 2014).

If you specify the EXPIRATION parameter, you cannot specify the RETENTION parameter.

RETention
Specifies the number of days to retain the tape. This parameter is optional.

Specify the number of days (1 - 9999) that the server is expected to use the tape. The server does not use this information, but this information is passed to the z/OS media server for use by z/OS or tape management systems.

If you specify the RETENTION parameter, you cannot specify the EXPIRATION parameter.

PROtection

Specifies whether the RACF® program, if installed, protects volumes that are assigned to this device class. If protection is provided, RACF profiles are created when volumes are first used. This parameter is optional. The default value is NO. You can specify one of the following values:

No

Specifies that the RACF program does not protect volumes that are assigned to this device class.

Yes

Specifies that the RACF program protects volumes that are assigned to this device class. RACF profiles are created for volumes when the server first uses the volumes, but the profiles are not deleted when volumes are deleted from the server. Profiles must be manually deleted.
Tip: If sensitive data is stored on volumes that are assigned to this device class, use PROTECTION=YES and manually delete RACF profiles only after tape volumes have been erased.

The profiles that are created for volumes depend on the system RACF settings. The protection that is provided is the same as using PROTECT=YES in JCL. If the RACF program is active and both TAPEVOL and TAPEDSN are inactive, allocation of tapes fails.

Automatic

Specifies that the RACF program protects volumes that are assigned to this device class. RACF profiles are created for volumes when the server first uses the volumes. RACF profiles are deleted when volumes are deleted from the server.

The profiles that are created for volumes depend on the system RACF settings. The protection that is provided is the same as using PROTECT=YES in JCL. If the RACF program is active and both TAPEVOL and TAPEDSN are inactive, allocation of tapes fails.

Important: If you specify PROTECTION=AUTOMATIC, when a volume is deleted, its RACF profile is deleted. The volume therefore is no longer protected by the RACF program. The data on these volumes can be accessed by other users.

If you specify PROTECTION=AUTOMATIC, the z/OS media server issues RACROUTE commands to delete profiles when a volume is deleted from the server. The deletion commands that are issued depend on the current system settings for TAPEVOL and TAPEDSN. If the system settings are changed, the z/OS media server might not delete existing profiles.

Do not change the setting to PROTECTION=AUTOMATIC for a device class that was set to PROTECTION=NO. Volumes without profiles might exist and error messages are generated when such volumes are deleted. If a different value for PROTECTION is required, define a new device class.

Profile creation and deletion occur based on the protection setting when the volume is first used and when it is deleted. The server does not attempt to create profiles for volumes that it has already used. If protection is set to AUTOMATIC, the server attempts to delete profiles when volumes are deleted.

See the documentation for the RACF program for details about the TAPEVOL and TAPEDSN settings and the profiles that are created when these settings are active.

UNIT

Specifies an esoteric unit name to specify a group of tape devices that support 3590 tape. This parameter is optional. The default unit name is 3590. The unit name can be up to 8 characters.

AIX | Linux

DEFINE DEVCLASS (Define a 3592 device class for z/OS media server)

To use a z/OS® media server to access 3592 devices, you must define a 3592 device class. In the device class definition, specify a library that was defined with the LIBTYPE=ZOSMEDIA parameter.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine DEVclass--device_class_name-------------------------->

>--LIBRary--=--zos_media_library--DEVType--=--3592-------------->

   .-FORMAT--=--Drive-------.  .-WORM--=--No------.
>--+-----------------------+--+------------------+------------->

>--+-----------------------------+--+--------------------+---><
   '-PROtection--=--+-No--------+-'  '-UNIT--=--unit_name-'
                    +-Yes-------+
                    '-Automatic-'
```

Parameters

device_class_name (Required)
: Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

LIBRary (Required)

: Specifies the name of a library that was defined with the LIBTYPE=ZOSMEDIA parameter. The library and the tape drives that can be used by this device class are controlled by the z/OS media server.

: For information about defining a library, see the DEFINE LIBRARY command.

DEVType=3592 (Required)
: Specifies the 3592 device type is assigned to the device class.

FORMAT
: Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. The default value is DRIVE.
: See the following table for the recording formats.

Table 1. Recording formats for 3592

Format	Description
3592	Uncompressed (basic) format
3592C	Compressed format

Format	Description
3592-2	Uncompressed (basic) format, similar to the 3592 format
3592-C	Compressed format, similar to the 3592C format
3592-3	Uncompressed (basic) format, similar to the 3592 format
3592-3C	Compressed format, similar to the 3592C format
3592-4	Uncompressed (basic) format, similar to the 3592 format
3592-4C	Compressed format, similar to the 3592C format
DRIVE	The server selects the highest format that is supported by the drive on which a volume is mounted. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library containing some drives that support recording formats superior to other drives.
Note: If this format uses the tape drive hardware compression feature, depending on the effectiveness of compression, the actual capacity might be different from the listed value.	

If the drives are in a library that includes drives of different tape technology, do not use the DRIVE value. Use the specific format that the drives use. For optimal results, do not mix generations of drives in the same library. If a library contains mixed generations, media problems can result. For example, generation 1 and generation 2 drives cannot read generation 3 media. If possible, upgrade all drives to 3592 generation 3. If you cannot upgrade all drives to 3592 generation 3, you must use a special configuration.

WORM
Specifies whether the drives use WORM (write once, read many) media. This parameter is optional. The default is No. You can specify one of the following values:

Yes
Specifies that the drives use WORM media.

No
Specifies that the drives do not use WORM media.

Tip: The IBM Spectrum Protect™ server does not automatically delete scratch volumes in WORM storage pools after the volumes are emptied by expiration or other processes. To delete these volumes and remove them from WORM storage pools, you must use the DELETE VOLUME command. IBM Spectrum Protect cannot reuse WORM volumes that were written to by the server and then deleted from a storage pool.

ESTCAPacity
Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional.

You can specify this parameter if the default estimated capacity for the device class is inaccurate because of compression of data. The value does not determine the amount of data stored on the volume. The server uses the value to estimate the usage before a volume is filled. After a volume is full, the actual amount of data stored on the tape is used for the usage calculation.

Specify the value as an integer with one of the following unit indicators: `K` (KB), `M` (MB), `G` (GB), or `T` (TB). For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G. The smallest value that is accepted is 100 KB (ESTCAPACITY=100K).

PREFIX
Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The default value is ADSM. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

```
AB.CD2.E
```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention
: Specifies the number of minutes that an idle tape volume is retained before it is dismounted. The time span for mount retention begins after the idle timeout period has expired. This parameter is optional. The default value is 60 minutes. Specify a number 0 - 9999.

  This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

MOUNTWait
: Specifies the maximum number of minutes that the z/OS media server waits for a volume mount. If the mount request is not satisfied within the specified time, the mount request fails. If a device is successfully allocated and the device-open request does not complete within the specified time, the device-open request ends and the mount request fails.

  This parameter is optional. The default value is 60. Specify a number, 1 - 9999.

  Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
: Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. The default is 2.

  If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

  You can specify one of the following values:

  DRIVES
  : Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.

  number
  : Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class. You can specify a number, 0 - 4096.

  0 (zero)
  : Specifies that no new transactions can gain access to the storage pool.

COMPression
: Specifies whether file compression is used for this device class. This parameter is optional. The default value is YES. You can specify one of the following values:

  Yes
  : Specifies that the data for each tape volume is compressed.

  No
  : Specifies that the data for each tape volume is not compressed.

EXPiration
: Specifies the expiration date that is placed on the tape labels for this device class. This parameter is optional. There is no default value.

  Specify the date when the server no longer requires the tape. The server does not use this information, but this information is passed to the z/OS media server for use by z/OS or tape management systems.

  Specify the expiration date using the format, *yyyyddd* (four digits for the year and three digits for the day). For example, January 7, 2014 is specified as `2014007` (the seventh day of year 2014).

  If you specify the EXPIRATION parameter, you cannot specify the RETENTION parameter.

RETention
: Specifies the number of days to retain the tape. This parameter is optional.

Specify the number of days (1 - 9999) that the server is expected to use the tape. The server does not use this information, but this information is passed to the z/OS media server for use by z/OS or tape management systems.

If you specify the RETENTION parameter, you cannot specify the EXPIRATION parameter.

PROtection
Specifies whether the RACF® program, if installed, protects volumes that are assigned to this device class. If protection is provided, RACF profiles are created when volumes are first used. This parameter is optional. The default value is NO. You can specify one of the following values:

No
Specifies that the RACF program does not protect volumes that are assigned to this device class.

Yes
Specifies that the RACF program protects volumes that are assigned to this device class. RACF profiles are created for volumes when the server first uses the volumes, but the profiles are not deleted when volumes are deleted from the server. Profiles must be manually deleted.
Tip: If sensitive data is stored on volumes that are assigned to this device class, use PROTECTION=YES and manually delete RACF profiles only after tape volumes have been erased.

The profiles that are created for volumes depend on the system RACF settings. The protection that is provided is the same as using PROTECT=YES in JCL. If the RACF program is active and both TAPEVOL and TAPEDSN are inactive, allocation of tapes fails.

Automatic
Specifies that the RACF program protects volumes that are assigned to this device class. RACF profiles are created for volumes when the server first uses the volumes. RACF profiles are deleted when volumes are deleted from the server.

The profiles that are created for volumes depend on the system RACF settings. The protection that is provided is the same as using PROTECT=YES in JCL. If the RACF program is active and both TAPEVOL and TAPEDSN are inactive, allocation of tapes fails.

Important: If you specify PROTECTION=AUTOMATIC, when a volume is deleted, its RACF profile is deleted. The volume therefore is no longer protected by the RACF program. The data on these volumes can be accessed by other users.

If you specify PROTECTION=AUTOMATIC, the z/OS media server issues RACROUTE commands to delete profiles when a volume is deleted from the server. The deletion commands that are issued depend on the current system settings for TAPEVOL and TAPEDSN. If the system settings are changed, the z/OS media server might not delete existing profiles.

Do not change the setting to PROTECTION=AUTOMATIC for a device class that was set to PROTECTION=NO. Volumes without profiles might exist and error messages are generated when such volumes are deleted. If a different value for PROTECTION is required, define a new device class.

Profile creation and deletion occur based on the protection setting when the volume is first used and when it is deleted. The server does not attempt to create profiles for volumes that it has already used. If protection is set to AUTOMATIC, the server attempts to delete profiles when volumes are deleted.

See the documentation for the RACF program for details about the TAPEVOL and TAPEDSN settings and the profiles that are created when these settings are active.

UNIT
Specifies an esoteric unit name to specify a group of tape devices that support 3592 tape. This parameter is optional. The default value is 3592. The unit name can be up to 8 characters.

AIX Linux

DEFINE DEVCLASS (Define an ECARTRIDGE device class for z/OS media server)

To use a z/OS® media server to access StorageTek drives such as the StorageTek T9840 or T10000, you must define an ECARTRIDGE device class. In the device class definition, specify a library that was defined with the LIBTYPE=ZOSMEDIA parameter.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```

```

Parameters

device_class_name (Required)
: Specifies the name of the device class to be defined. The maximum length of the device class name is 30 characters.

LIBRary (Required)

: Specifies the name of a library that was defined with the LIBTYPE=ZOSMEDIA parameter. The library and the tape drives that can be used by this device class are controlled by the z/OS media server.

: For information about defining a library, see the DEFINE LIBRARY command.

DEVType=ECARTridge (Required)
: Specifies that the ECARTRIDGE device type is assigned to the device class. The ECARTRIDGE device type is for StorageTek drives such as the StorageTek T9840 or T10000.

FORMAT
: Specifies the recording format to be used when data is written to sequential access media. This parameter is optional. See the following table for the recording formats.

Table 1. Recording formats for ECARTRIDGE tapes

Format	Estimated Capacity	Description
DRIVE	-	The server selects the highest format that is supported by the drive on which a volume is mounted. DRIVE is the default value. Attention: Avoid specifying DRIVE when a mixture of drives is used within the same library. For example, do not use this option for a library containing some drives that support recording formats superior to other drives.
T9840C	40 GB	Uncompressed T9840C format, using a StorageTek 9840 cartridge
T9840C-C	80 GB	Compressed T9840C format, using a StorageTek 9840 cartridge
T9840D	75 GB	Uncompressed T9840D format, using a StorageTek 9840 cartridge
T9840D-C	150 GB	Compressed T9840D format, using a StorageTek 9840 cartridge
T10000A	500 GB	Uncompressed T10000A format, using a StorageTek T10000 cartridge
T10000A-C	1 TB	Compressed T10000A format, using a StorageTek T10000 cartridge
T10000B	1 TB	Uncompressed T10000B format, using an Oracle StorageTek T10000 cartridge
T10000B-C	2 TB	Compressed T10000B format, using an Oracle StorageTek T10000 cartridge
T10000C	5 TB	Uncompressed T10000C format, using an Oracle StorageTek T10000 T2 cartridge
T10000C-C	10 TB	Compressed T10000C format, using an Oracle StorageTek T10000 T2 cartridge
T10000D	8 TB	Uncompressed T10000D format, using an Oracle StorageTek T10000 T2 cartridge
T10000D-C	15 TB	Compressed T10000D format, using an Oracle StorageTek T10000 T2 cartridge

Note:

- Some formats use a compression feature of the tape drive hardware. Depending on the effectiveness of compression, the actual capacity might be double or more than the listed value.
- T10000A drives can read and write the T10000A format only. T10000B drives can read, but cannot write, the T10000A format. T10000C drives can read, but cannot write, the T10000A and T10000B formats. T10000D drives can read, but cannot write, the T10000A, T10000B, and T10000C formats.

ESTCAPacity

Specifies the estimated capacity for the volumes that are assigned to this device class. This parameter is optional. The default estimated capacity is 9 GB.

You can specify this parameter if the default estimated capacity for the device class is inaccurate because of compression of data. The value does not determine the amount of data stored on the volume. The server uses the value to estimate the usage before a volume is filled. After a volume is full, the actual amount of data stored on the tape is used for the usage calculation.

Specify the value as an integer with one of the following unit indicators: `K` (KB), `M` (MB), `G` (GB), or `T` (TB). For example, specify that the estimated capacity is 9 GB with the parameter ESTCAPACITY=9G. The smallest value that is accepted is 100 KB (ESTCAPACITY=100K).

PREFIX

Specifies the high-level qualifier of the data set name that the server writes into the sequential access media labels. For each sequential access volume assigned to this device class, the server uses this prefix to create the data set name. This parameter is optional. The default value is ADSM. The maximum length of this prefix is 8 characters.

If you have a naming convention for media labels to support your current management system, use a volume prefix that conforms to your naming conventions.

Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

```
AB.CD2.E
```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a tape volume data set name using the default prefix is ADSM.BFS.

MOUNTRetention
: Specifies the number of minutes that an idle tape volume is retained before it is dismounted. The time span for mount retention begins after the idle timeout period has expired. This parameter is optional. The default value is 60 minutes. Specify a number 0 - 9999.

  This parameter can improve response time for sequential access media mounts by leaving previously mounted volumes online.

MOUNTWait
: Specifies the maximum number of minutes that the z/OS media server waits for a volume mount. If the mount request is not satisfied within the specified time, the mount request fails. If a device is successfully allocated and the device-open request does not complete within the specified time, the device-open request ends and the mount request fails.

  This parameter is optional. The default value is 60. Specify a number, 1 - 9999.

  Restriction: If the library that is associated with this device class is external (LIBTYPE=EXTERNAL), do not specify the MOUNTWAIT parameter.

MOUNTLimit
: Specifies the maximum number of sequential access volumes that can be simultaneously mounted for the device class. This parameter is optional. The default is 2.

  If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

  You can specify one of the following values:

  DRIVES
  : Specifies that every time a mount point is allocated, the number of drives that are defined and online in the library is used to calculate the true value.

  number
  : Specifies the maximum number of drives in this device class that are used concurrently by the server. This value must never exceed the number of drives that are defined and online in the library that services this device class. You can specify a number, 0 - 4096.

  0 (zero)
  : Specifies that no new transactions can gain access to the storage pool.

COMPression
: Specifies whether file compression is used for this device class. This parameter is optional. The default value is YES. You can specify one of the following values:

  Yes
  : Specifies that the data for each tape volume is compressed.

  No
  : Specifies that the data for each tape volume is not compressed.

EXPiration
: Specifies the expiration date that is placed on the tape labels for this device class. This parameter is optional. There is no default value.

  Specify the date when the server no longer requires the tape. The server does not use this information, but this information is passed to the z/OS media server for use by z/OS or tape management systems.

  Specify the expiration date using the format, *yyyyddd* (four digits for the year and three digits for the day). For example, January 7, 2014 is specified as `2014007` (the seventh day of year 2014).

  If you specify the EXPIRATION parameter, you cannot specify the RETENTION parameter.

RETention
: Specifies the number of days to retain the tape. This parameter is optional.

Specify the number of days (1 - 9999) that the server is expected to use the tape. The server does not use this information, but this information is passed to the z/OS media server for use by z/OS or tape management systems.

If you specify the RETENTION parameter, you cannot specify the EXPIRATION parameter.

PROtection
Specifies whether the RACF® program, if installed, protects volumes that are assigned to this device class. If protection is provided, RACF profiles are created when volumes are first used. This parameter is optional. The default value is NO. You can specify one of the following values:

No
Specifies that the RACF program does not protect volumes that are assigned to this device class.

Yes
Specifies that the RACF program protects volumes that are assigned to this device class. RACF profiles are created for volumes when the server first uses the volumes, but the profiles are not deleted when volumes are deleted from the server. Profiles must be manually deleted.
Tip: If sensitive data is stored on volumes that are assigned to this device class, use PROTECTION=YES and manually delete RACF profiles only after tape volumes have been erased.

The profiles that are created for volumes depend on the system RACF settings. The protection that is provided is the same as using PROTECT=YES in JCL. If the RACF program is active and both TAPEVOL and TAPEDSN are inactive, allocation of tapes fails.

Automatic
Specifies that the RACF program protects volumes that are assigned to this device class. RACF profiles are created for volumes when the server first uses the volumes. RACF profiles are deleted when volumes are deleted from the server.

The profiles that are created for volumes depend on the system RACF settings. The protection that is provided is the same as using PROTECT=YES in JCL. If the RACF program is active and both TAPEVOL and TAPEDSN are inactive, allocation of tapes fails.

Important: If you specify PROTECTION=AUTOMATIC, when a volume is deleted, its RACF profile is deleted. The volume therefore is no longer protected by the RACF program. The data on these volumes can be accessed by other users.

If you specify PROTECTION=AUTOMATIC, the z/OS media server issues RACROUTE commands to delete profiles when a volume is deleted from the server. The deletion commands that are issued depend on the current system settings for TAPEVOL and TAPEDSN. If the system settings are changed, the z/OS media server might not delete existing profiles.

Do not change the setting to PROTECTION=AUTOMATIC for a device class that was set to PROTECTION=NO. Volumes without profiles might exist and error messages are generated when such volumes are deleted. If a different value for PROTECTION is required, define a new device class.

Profile creation and deletion occur based on the protection setting when the volume is first used and when it is deleted. The server does not attempt to create profiles for volumes that it has already used. If protection is set to AUTOMATIC, the server attempts to delete profiles when volumes are deleted.

See the documentation for the RACF program for details about the TAPEVOL and TAPEDSN settings and the profiles that are created when these settings are active.

UNIT
Specifies an esoteric unit name to specify a group of tape devices that support ECARTRIDGE tapes. Use the unit name that represents the subset of drives in the library that are attached to the z/OS system. This parameter is optional. The default value is 9840. The unit name can be up to 8 characters.

Example: Define a device class with the ECARTRIDGE device type

Define a device class named E1 with the ECARTRIDGE device type and with RACF protection active for all tape volumes that are assigned to this device class. All data is compressed for this device class. The device class is for a z/OS media server library named ZOSELIB.

```
define devclass e1 devtype=ecartridge library=zoselib compression=yes
   protection=yes
```

AIX | Linux

DEFINE DEVCLASS (Define a FILE device class for z/OS media server)

To use a z/OS® media server to access storage volumes on magnetic disk devices, you must define a FILE device class. In the device class definition, specify a library that was defined with the LIBTYPE=ZOSMEDIA parameter.

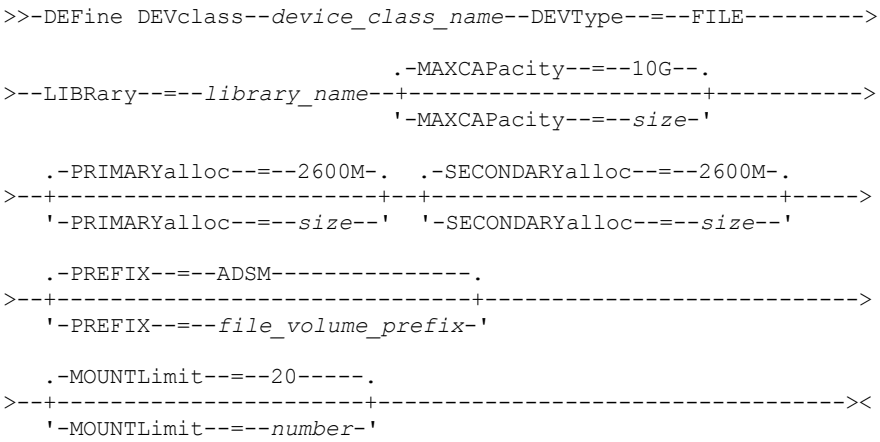
A volume in this device class is a Virtual Storage Access Method (VSAM) linear data set that is accessed by the z/OS media server. SCRATCH volumes can be used with device class and the z/OS media server can dynamically allocate the VSAM LDS. It is not necessary to define volumes for the server to use the device class. If you define volumes, set the high-level qualifier (HLQ) so that SMS recognizes the allocation request by the z/OS media server. If you are using defined volumes, the format volume function is not supported for the server when this device class is used. The z/OS media server uses a FormatWrite feature of DFSMS Media Manager when filling FILE volumes.

You can define volumes for the FILE device class by using the DEFINE VOLUME command. However, the z/OS media server does not allocate space for a defined volume until the volume is opened for its first use.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax



Parameters

DEVType=FILE (Required)
: Specifies that the FILE device type is assigned to the device class.

LIBRary (Required)
: Specifies the name of a library that was defined with the LIBTYPE=ZOSMEDIA parameter. The disk storage that is used by this device class is accessed by the z/OS media server and managed by SMS.

  For information about defining a library, see the DEFINE LIBRARY command.

MAXCAPacity
: Specifies the maximum size of file volumes that are defined to a storage pool in this device class. This parameter is optional. The default value is 10 GB (MAXCAPACITY=10G).

  Specify this value as an integer followed by `K` (KB), `M` (MB), `G` (GB), or `T` (TB). The minimum size is 1 MB (MAXCAPACITY=1M). The maximum size is 16384 GB (MAXCAPACITY=16384G).

PRIMARYalloc
: Specifies the initial amount of space that is dynamically allocated when a new volume is opened. Enough space must be available to satisfy the primary allocation amount. Storage Management Subsystem (SMS) policy determines whether multiple physical volumes can be used to satisfy the primary allocation request.

This parameter is optional. Specify this value as an integer followed by K (KB), M (MB), G (GB), or T (TB). The minimum size is 100 KB (PRIMARYALLOC=100K). The maximum size is 16384 GB (MAXCAPACITY=16384G). The default size is 2600 MB (PRIMARYALLOC=2600M). All values are rounded to the next higher multiple of 256 KB.

To avoid wasted space, the dynamic allocation operation uses the smaller of the values that are specified in the two parameters, PRIMARYALLOC and MAXCAPACITY.

SMS automatic class selection (ACS) routines can affect whether the PRIMARYALLOC and SECONDARYALLOC parameter values are used.

SECONDARYalloc

Specifies the amount of space by which a file volume is extended when space that is already allocated to the file volume is used up. The data set for a file volume is extended up to the size set by the MAXCAPACITY parameter, then the volume is marked full.

Because secondary allocation of a linear data set cannot span a physical volume, consider the size of the physical volume when you select a secondary allocation size. For example, physical volumes for a 3390 Model 3 are approximately 2.8 GB. To ensure that each extend request occupies nearly an entire physical volume but not more, use a secondary allocation size that is just less than 2.8 GB. A secondary allocation amount of 2600 MB allots enough space for the VSAM volume data set (VVDS), the volume label, and the volume table of contents (VTOC).

This parameter is optional. Specify this value as an integer followed by K (KB), M (MB), G (GB), or T (TB). The minimum value is 0 KB (SECONDARYALLOC=0K). The default value is 2600 MB. The maximum value is 16384 GB. Except for 0, all values are rounded to the next higher multiple of 256 KB.

If you specify 0 (SECONDARYALLOC=0), the file volume cannot be extended beyond the primary allocation amount.

SMS automatic class selection (ACS) routines can affect whether the PRIMARYALLOC and SECONDARYALLOC parameter values are used.

If you specify a value for the SECONDARYALLOCATION parameter that is not 0, or if you allow the value to default to 2600M, the SMS DATACLAS associated with the PREFIX identifier (for example, High Level Qualifier) must have the Extended Addressability (EA) attribute specified. Without the EA attribute, the SMS DATACLAS limits the allocation of the VSAM LDS FILE volume to the primary extent. (See the description of the PRIMARYALLOCATION parameter). With the data set limited to primary allocation size, the data set cannot be extended by the z/OS media server, and the volume is marked FULL before the maximum capacity is reached.

Restriction: Ensure that the values that you specify for the PRIMARYALLOC and SECONDARYALLOC parameters are within practical limits for the storage device. The server cannot check whether the values exceed practical device limits, and does not check whether the two values together exceed the current MAXCAPACITY setting.
Tip: To fill volumes when you specify a large value for the MAXCAPACITY parameter, specify large values for the PRIMARYALLOC and SECONDARYALLOC parameters. Use larger MVS™ volume sizes to reduce the chance of extend failure.

PREFIX

Specifies the high-level qualifier of the data set name that is used to allocate scratch volume data sets. For all scratch file volumes created in this device class, the server uses this prefix to create the data set name. This parameter is optional. The default is ADSM. The maximum length of the prefix, including periods, is 32 characters.
Values that are specified for this parameter must meet the following conditions:

- The value is to be made up of qualifiers, which can be a maximum of eight characters including periods. For example, the following value is acceptable:

  ```
  AB.CD2.E
  ```

- The qualifiers must be separated by a single period.
- The first letter of each qualifier must be alphabetic or national (@,#,$), followed by alphabetic, national, hyphen, or numeric characters.

An example of a file volume data set name using the default prefix is `ADSM.B0000021.BFS`.

If you have a data set naming convention, use a prefix that conforms to your naming conventions. For example, the following value is acceptable: `TSM.SERVER2.VSAMFILE`.

If you are running multiple server instances for either IBM Spectrum Protect™ or Tivoli® Storage Manager for z/OS Media you must use a unique value for the PREFIX parameter for each device class that you define.

MOUNTLimit

Specifies the maximum number of FILE volumes that can be open concurrently for this device class. This parameter is optional. The default value is 20.
If you are using IBM® 3995 devices that emulate 3390 devices, set the value no higher than the number of concurrent input or output streams that are possible on the physical media.

The value that you specify in this parameter is important if there is a significant penalty switching from one volume to another. For example, switching can take place when using IBM 3995 devices to emulate 3390 devices. The value that you specify must be no higher than the number of physical drives available on the device.

If you plan to use the simultaneous-write function, ensure that sufficient drives are available for the write operation. If the number of drives needed for a simultaneous-write operation is greater than the value of the MOUNTLIMIT parameter for a device class, the transaction fails.

DEFINE DOMAIN (Define a new policy domain)

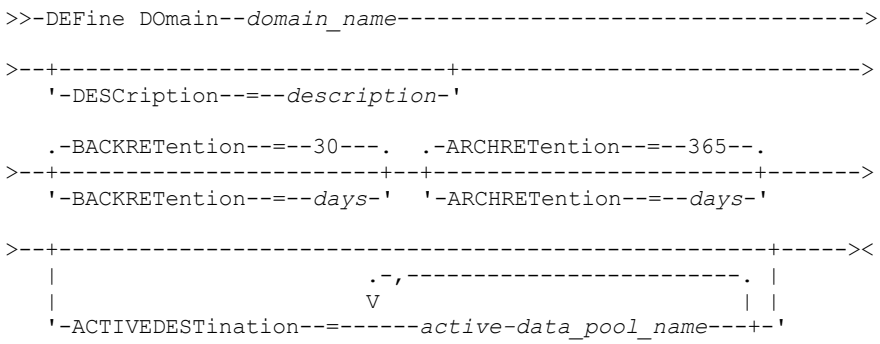
Use this command to define a new policy domain. A policy domain contains policy sets, management classes, and copy groups. A client is assigned to one policy domain. The ACTIVE policy set in the policy domain determines the rules for clients that are assigned to the domain. The rules control the archive, backup, and space management services that are provided for the clients.

You must activate a policy set in the domain before clients assigned to the policy domain can back up, archive, or migrate files.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

domain_name (Required)
Specifies the name of the policy domain to be defined. The maximum length of this name is 30 characters.

DESCription
Specifies a description of the policy domain. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters.

BACKRETention
Specifies the number of days (from the date the backup versions became inactive) to retain backup versions of files that are no longer on the client file system. This parameter is optional. You can specify an integer from 0 to 9999. The default value is 30. The server uses the backup retention value to manage inactive versions of files when any of the following conditions occur:

- A file is rebound to a new management class, but the new management class and the default management class do not contain a backup copy group.
- The management class to which a file is bound no longer exists. The default management class does not contain a backup copy group.
- The backup copy group is deleted from the management class to which a file is bound. The default management class does not contain a backup copy group.

ARCHRETention

Specifies the number of days (from the date of archive) to retain archive copies. This parameter is optional. You can specify an integer from 0 to 30000. The default value is 365. The server uses the archive retention value to manage archive copies of files when either of the following conditions occur:

- The management class to which a file is bound no longer exists. The default management class does not contain an archive copy group.
- The archive copy group is deleted from the management class to which a file is bound. The default management class does not contain an archive copy group.

ACTIVEDESTination

This optional parameter specifies the names of active-data pools that store active versions of backup data for nodes that are assigned to the domain. You can specify up to 10 active-data pools for a domain, which is separated by commas. Spaces are not permitted between the names.

Before the IBM Spectrum Protect™ server writes data to an active-data pool, it verifies that the node owning the data is assigned to a domain that has the active-data pool that is listed in the ACTIVEDESTINATION list. If the server verifies that the node meets this criteria, the data is stored in the active-data pool. If the node does not meet the criteria, then the data is not stored in the active-data pool. If the simultaneous-write function is used to write data to an active-data pool, the server verifies that the node meets the criteria during backup operations by IBM Spectrum Protect backup-archive clients or by application clients by using the IBM Spectrum Protect API. The verification is also performed when active-data is being copied by using the COPY ACTIVEDATA command.

Example: Define a policy domain

Define a policy domain with a name of PROG1 and the description, Programming Group Domain. Specify that archive copies are retained for 90 days when management classes or archive copy groups are deleted and the default management class does not contain an archive copy group. Also, specify that backup versions are retained for 60 days when management classes or copy groups are deleted and the default management class does not contain a backup copy group.

```
define domain prog1
description="Programming Group Domain"
backretention=60 archretention=90
```

Related commands

Table 1. Commands related to DEFINE DOMAIN

Command	Description
ACTIVATE POLICYSET	Validates and activates a policy set.
COPY DOMAIN	Creates a copy of a policy domain.
DEFINE POLICYSET	Defines a policy set within the specified policy domain.
DELETE DOMAIN	Deletes a policy domain along with any policy objects in the policy domain.
QUERY DOMAIN	Displays information about policy domains.
UPDATE DOMAIN	Changes the attributes of a policy domain.

DEFINE DRIVE (Define a drive to a library)

Use this command to define a drive. Each drive is assigned to a library, and so the library must be defined before you issue this command.

A path must be defined after you issue the DEFINE DRIVE command to make the drive usable by IBM Spectrum Protect™. For more information, see DEFINE PATH (Define a path). If you are using a SCSI or VTL library type, see PERFORM LIBACTION (Define or delete all drives and paths for a library).

You can define more than one drive for a library by issuing the DEFINE DRIVE command for each drive. Stand-alone drives always require a manual library.

Windows Restriction: Before you issue the DEFINE DRIVE command, for a removable media device such as a Jaz, Zip, or CD drive, you must load the drive with properly formatted and labeled media.

For detailed and current drive support information, see the Supported Devices website for your operating system:

- AIX Windows Supported devices for AIX and Windows
- Linux Supported devices for Linux

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine DRive--library_name--drive_name----------------------->

   .-SERial--=--AUTODetect--------.  .-ONLine--=--Yes-----.
>--+-------------------------------+--+--------------------+----->
   '-SERial--=--+-AUTODetect----+-'  '-ONLine--=--+-Yes-+-'
                '-serial_number-'                 '-No--'

                              (1)
   .-ELEMent--=--AUTODetect-----.
>--+----------------------------+------------------------------->
   '-ELEMent--=--+-AUTODetect-+-'
                 '-address----'

>--+--------------------------+-------------------------------->
   |                       (2) |
   '-ACSDRVID--=--drive_id-----'

>--+-----------------------------------------+----------------><
   |                      (3)                |
   '-CLEANFREQuency--=------+-NONE----------+-'
                            |          (4) |
                            +-ASNEEDED-----+
                            '-gigabytes----'
```

Notes:

1. The ELEMENT parameter is only necessary for drives in SCSI libraries when the drive type is a network attached SCSI (NAS) drive.
2. ACSDRVID is required for drives in ACSLS libraries. This parameter is not valid for non-ACSLS libraries.
3. The CLEANFREQUENCY parameter is valid only for drives in SCSI libraries.
4. The CLEANFREQUENCY=ASNEEDED parameter value does not work for all tape drives. For more information, see the parameter description.

Parameters

library_name (Required)
: Specifies the name of the library to which the drive is assigned. This parameter is required for all drives, including stand-alone drives. The specified library must have been previously defined by using the DEFINE LIBRARY command.

drive_name (Required)
: Specifies the name that is assigned to the drive. The maximum length of this name is 30 characters.

SERial
: Specifies the serial number for the drive that is being defined. This parameter is optional. The default is AUTODETECT.

  If SERIAL=AUTODETECT, then the serial number reported by the drive when you define the path is used as the serial number.

  If SERIAL=*serial_number*, then the serial number that is entered is used to verify that the path to the drive is correct when you define the path.

  Note: Depending on the capabilities of the device, SERIAL=AUTODETECT might not be supported. In this case, the serial number is reported as blank.

ONLine
: Specifies whether the drive is available for use. This parameter is optional. The default is YES.

Yes
: Specifies that the drive is available for use.

No
: Specifies that the drive is not available for use.

ELEMent
: Specifies the element address of a drive within a SCSI or virtual tape library (VTL). The server uses the element address to connect the physical location of the drive to the SCSI or VTL address of the drive. The default is AUTODETECT.

  If ELEMENT=AUTODETECT, then the element number is automatically detected by the server when the path to the drive is defined.

  To find the element address for your library configuration, consult the information from the manufacturer.

  Restriction:

  - The ELEMENT parameter is valid only for drives in SCSI libraries or VTLs when the drive type is not a network attached SCSI (NAS) drive.
  - This parameter is not effective when the command is issued from a library client server (that is, when the library type is SHARED).
  - Depending on the capabilities of the library, ELEMENT=AUTODETECT might not be supported. In this case, you must supply the element address.

ACSDRVID
: Specifies the ID of the drive that is being accessed in an ACSLS library. The drive ID is a set of numbers that indicates the physical location of a drive within an ACSLS library. This drive ID must be specified as *a,l,p,d,* where *a* is the ACSID, *l* is the LSM (library storage module), *p* is the panel number, and *d* is the drive ID. The server needs the drive ID to connect the physical location of the drive to the drive's SCSI address. See the StorageTek documentation for details.
  Windows Restriction: To use ACSLS functions, the installation of StorageTek Library Attach software is required.

CLEANFREQuency
: Specifies how often the server activates drive cleaning. This parameter is optional. For the most complete automation of cleaning for an automated library, you must have a cleaner cartridge that is checked into the library's volume inventory.

  If you are using library-based cleaning, NONE is advised when your library type supports this function.

  This parameter is not valid for externally managed libraries, such as 3494 libraries or StorageTek libraries that are managed under ACSLS.

  Important: There are special considerations if you plan to use server-activated drive cleaning with a SCSI library that provides automatic drive cleaning support in its device hardware.

  NONE
  : Specifies that the server does not track cleaning for this drive. This value can be used for libraries that have their own automatic cleaning.

  ASNEEDED
  : Specifies that the server loads the drive with a checked-in cleaner cartridge only when a drive reports to the device driver that it needs cleaning.

    The CLEANFREQUENCY=ASNEEDED parameter value does not work for all tape drives. See the Supported Devices website for your operating system to view detailed drive information. If ASNEEDED is not supported, you can use the gigabytes value for automatic cleaning.

    For IBM 3592 and LTO drives, library-based cleaning is advised. If library-based cleaning is not supported, then ASNEEDED must be used. Gigabytes is not recommended.

    Restriction: IBM Spectrum Protect does not control the drives that are connected to the NAS file server. If a drive is attached only to a NAS file server (no connection to a storage agent or server), do not specify ASNEEDED for the cleaning frequency.

  gigabytes
  : Specifies, in gigabytes, how much data is processed on the drive before the server loads the drive with a cleaner cartridge. The server resets the gigabytes-processed counter each time it loads a cleaner cartridge in the drive. Important: When CLEANFREQUENCY=gigabyte, drive cleaning can occur before the gigabyte setting is reached, if the drive notifies the device driver that a cleaning is necessary.

Consult the information from the drive manufacturer for cleaning recommendations. If the information gives recommendations for cleaning frequency in terms of hours of use, convert to a gigabytes value by doing the following:

1. Use the bytes-per-second rating for the drive to determine a gigabytes-per-hour value.
2. Multiply the gigabytes-per-hour value by the recommended hours of use between cleanings.
3. Use the result as the cleaning frequency value.

Using the cleaning frequency that is recommended by IBM® for IBM drives ensures that the drives are not overcleaned.

For IBM 3590 drives, specify a gigabyte value for the cleaning frequency to ensure that the drives receive adequate cleaning.

Example: Define a drive to library

Define a drive in a manual library with a library name of LIB01 and a drive name of DRIVE01.

```
define drive lib01 drive01
```

AIX

```
define path server01 drive01 srctype=server desttype=drive
library=lib01 device=/dev/rmt0
```

Linux

```
define path server01 drive01 srctype=server desttype=drive
library=lib01 device=/dev/tsmscsi/mt0
```

Windows

```
define path server01 drive01 srctype=server desttype=drive
library=lib01 device=mt3.0.0.0
```

Example: Define a drive in an ACSLS library

Define a drive in an ACSLS library with a library name of ACSLIB and a drive name of ACSDRV1.

```
define drive acslib acsdrv1 acsdrvid=1,2,3,4
```

AIX

```
define path server01 acsdrv1 srctype=server desttype=drive
library=acslib device=/dev/rmt0
```

Linux

```
define path server01 acsdrv1 srctype=server desttype=drive
library=acslib device=/dev/tsmscsi/mt0
```

Windows

```
define path server01 acsdrv1 srctype=server desttype=drive
library=acslib device=mt3.0.0.0
```

Example: Define a drive in an automated library

Define a drive in an automated library with a library name of AUTO8MMLIB and a drive name of DRIVE01.

```
define drive auto8mmlib drive01 element=82
```

AIX

```
define path server01 drive01 srctype=server desttype=drive
library=auto8mmlib device=/dev/rmt0
```

Linux

```
define path server01 drive01 srctype=server desttype=drive
library=auto8mmlib device=/dev/tsmscsi/mt0
```

Windows

```
define path server01 drive01 srctype=server desttype=drive
library=auto8mmlib device=mt3.0.0.0
```

Related commands

Table 1. Commands related to DEFINE DRIVE

Command	Description
DEFINE LIBRARY	Defines an automated or manual library.
DEFINE PATH	Defines a path from a source to a destination.
DELETE DRIVE	Deletes a drive from a library.
DELETE LIBRARY	Deletes a library.
PERFORM LIBACTION	Defines all drives and paths for a library.
QUERY DRIVE	Displays information about drives.
QUERY LIBRARY	Displays information about one or more libraries.
QUERY PATH	Displays information about the path from a source to a destination.
UPDATE DRIVE	Changes the attributes of a drive.
UPDATE PATH	Changes the attributes associated with a path.

DEFINE EVENTSERVER (Define a server as the event server)

Use this command to identify a server as the event server.

If you define an event server, one IBM Spectrum Protect™ server can send events to another IBM Spectrum Protect server that will log those events.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DEFine EVENTSERVer--server_name-----------------------------><
```

Parameters

server_name (Required)
Specifies the name of the event server. The server you specify must have already been defined with the DEFINE SERVER command.

Example: Designate the event server

Designate ASTRO to be the event server.

```
define eventserver astro
```

Related commands

Table 1. Commands related to DEFINE EVENTSERVER

Command	Description
DEFINE SERVER	Defines a server for server-to-server communications.
DELETE EVENTSERVER	Deletes reference to the event server.

Command	Description
DISABLE EVENTS	Disables specific events for receivers.
ENABLE EVENTS	Enables specific events for receivers.
PING SERVER	Tests the connections between servers..
QUERY EVENTSERVER	Displays the name of the event server.
QUERY SERVER	Displays information about servers.

Related information:

Enterprise event logging: logging events to another server

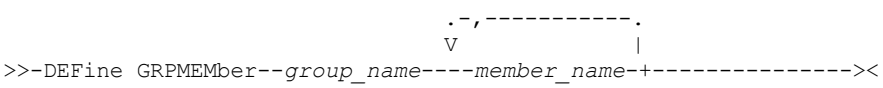
DEFINE GRPMEMBER (Add a server to a server group)

Use this command to add a server as a member of a server group. You can also add one server group to another server group. A server group lets you route commands to multiple servers by specifying only the server group name.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

group_name (Required)
: Specifies the name of the server group to which the member will be added.

member_name (Required)
: Specifies the names of the servers or groups to be added to the group. To specify multiple servers and groups, separate the names with commas and no intervening spaces. The servers or server groups must already be defined to the server.

Example: Define a server to a server group

Define the server SANJOSE to server group CALIFORNIA.

```
define grpmember california sanjose
```

Example: Define a server and a server group to a server group

Define the server TUCSON and the server group CALIFORNIA to server group WEST_COMPLEX.

```
define grpmember west_complex tucson,california
```

Related commands

Table 1. Commands related to DEFINE GRPMEMBER

Command	Description
DEFINE SERVER	Defines a server for server-to-server communications.
DEFINE SERVERGROUP	Defines a new server group.
DELETE GRPMEMBER	Deletes a server from a server group.
DELETE SERVERGROUP	Deletes a server group.
MOVE GRPMEMBER	Moves a server group member.

Command	Description
QUERY SERVER	Displays information about servers.
RENAME SERVERGROUP	Renames a server group.
UPDATE SERVERGROUP	Updates a server group.

DEFINE LIBRARY (Define a library)

Use this command to define a library. A library is a collection of one or more drives, and possibly robotic devices (depending on the library type), which can be used to access storage volumes.

A library can be accessed by only one source: an IBM Spectrum Protect™ server or a data mover. However, the drives in a library can be accessed by multiple sources.

The following library types can be defined to the server. Syntax and parameter descriptions are available for each type.

- DEFINE LIBRARY (Define a 349X library)
- DEFINE LIBRARY (Define an ACSLS library)
- DEFINE LIBRARY (Define an External library)
- DEFINE LIBRARY (Define a FILE library)
- DEFINE LIBRARY (Define a manual library)
- DEFINE LIBRARY (Define a SCSI library)
- DEFINE LIBRARY (Define a shared library)
- DEFINE LIBRARY (Define a VTL library)
- AIX Linux DEFINE LIBRARY (Define a ZOSMEDIA library type)

For detailed and current library support information, see the Supported Devices website for your operating system:

- AIX Windows Supported devices for AIX and Windows
- Linux Supported devices for Linux

Windows

To automatically label tape volumes in SCSI-type libraries, use the AUTOLABEL parameter on the DEFINE LIBRARY and UPDATE LIBRARY commands. Using this parameter eliminates the need to pre-label a set of tapes. It is also more efficient than using the LABEL LIBVOLUME command, which requires you to mount volumes separately. If you use the AUTOLABEL parameter, you must check in tapes by specifying CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

A label cannot include embedded blanks or periods and must be valid when used as a file name on the media.

You must label CD-ROM, Zip, or Jaz volumes with the device utilities from the manufacturer or the Windows utilities because IBM Spectrum Protect does not provide utilities to format or label these media types. The operating system utilities include the Disk Administrator program (a graphical user interface) and the label command.

Related commands

Table 1. Commands related to DEFINE LIBRARY

Command	Description
AUDIT LIBRARY	Ensures that an automated library is in a consistent state.
CHECKIN LIBVOLUME	Checks a storage volume into an automated library.
CHECKOUT LIBVOLUME	Checks a storage volume out of an automated library.
DEFINE DRIVE	Assigns a drive to a library.
DEFINE PATH	Defines a path from a source to a destination.
DEFINE SERVER	Defines a server for server-to-server communications.
DELETE DRIVE	Deletes a drive from a library.
DELETE LIBRARY	Deletes a library.
DELETE PATH	Deletes a path from a source to a destination.

Command	Description
LABEL LIBVOLUME	Labels volumes in manual or automated libraries.
PERFORM LIBACTION	Defines all drives and paths for a library.
QUERY DRIVE	Displays information about drives.
QUERY LIBRARY	Displays information about one or more libraries.
QUERY LIBVOLUME	Displays information about a library volume.
QUERY PATH	Displays information about the path from a source to a destination.
UPDATE DRIVE	Changes the attributes of a drive.
UPDATE LIBRARY	Changes the attributes of a library.
UPDATE LIBVOLUME	Changes the status of a storage volume.
UPDATE PATH	Changes the attributes associated with a path.

DEFINE LIBRARY (Define a 349X library)

Use this syntax to define a 349X library.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

Notes:

1. The default value of the RESETDRIVES parameter is conditional. If the SHARED parameter is set to NO, the value of the RESETDRIVES parameter is NO. If the SHARED parameter is set to YES, the value of the RESETDRIVES parameter is YES.

Parameters

library_name (Required)
Specifies the name of the library to be defined. The maximum length of this name is 30 characters.
LIBType=349X (Required)

AIX | Linux Specifies that the library is an IBM 3494 or 3495 Tape Library Dataserver.

Windows Specifies that the library is an IBM 3494 Tape Library Dataserver or an IBM Tape System Library Manager emulating a 3494 Tape Library Dataserver.

Restriction: IBM 3494 libraries support only one unique device type at a time.

SHAREd
Specifies whether this library is shared with other servers in a storage area network (SAN). This parameter is required when you define a library to the library manager.

YES
Specifies that this library can be shared with other servers. When you specify YES, the library manager server mounts volumes as requested by other servers and tracks drive and volume allocation to other servers.

NO
Specifies that this library cannot be shared with other servers. SHARED=NO is required if the library is controlled by passing commands through a NAS file server.

AUTOLabel
Specifies whether the server attempts to automatically label tape volumes. This parameter is optional. The default is YES.

To use this option, you must check in the tapes with CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

Restriction: If you are defining a library that has drives that are attached to a network-attached storage (NAS) device, you must use the LABEL LIBVOLUME command to label the volumes for this library.

No
Specifies that the server does not attempt to label any volumes.

Yes
Specifies that the server labels only unlabeled volumes.

OVERWRITE
Specifies that the server attempts to overwrite an existing label. The server overwrites existing labels only if both the existing label and the bar code label are not already defined in any server storage pool or volume history list.

SCRATCHCATegory
Specifies the category number to be used for scratch volumes in the library. This parameter is optional. The default value is 301 (becomes X'12D' on the IBM 3494 since it uses hexadecimal values). You can specify a number from 1 to 65279. This number must be unique. It cannot be shared with other applications or defined libraries, and it must be different from the other category numbers in this library.

PRIVATECATegory
Specifies the category number for private volumes that must be mounted by name. This parameter is optional. The default value is 300 (this value becomes X'12C' on the IBM 3494 because it uses hexadecimal values). You can specify a number from 1 to 65279. This number must be unique. It cannot be shared with other applications or defined libraries, and it must be different from the other category numbers in this library.

WORMSCRatchcategory
Specifies the category number to be used for WORM scratch volumes in the library. This parameter is required if you use WORM volumes. You can specify a number from 1 to 65279. This number must be unique. It cannot be shared with other applications or defined libraries, and it must be different from the other category numbers in this library. This parameter is only valid when 3592 WORM volumes are used.
Restriction: If the WORMSCRATCHCATEGORY is not defined and the WORM parameter is set to YES for the device class, the mount operation fails with an error message.

RESETDrives
Specifies whether the server preempts a drive reservation with persistent reserve when the server is restarted or when a library client or storage agent reconnection is established. If, for example, a storage agent becomes unavailable but is still holding the path to a drive, persistent reserve allows the server to break the storage agent's reservation and access the drive.

AIX | Windows If persistent reserve is not supported, the server completes a reset of the path to the target device.

Linux If persistent reserve is not supported, the server is not able to reset the path to the target device.

Support for persistent reservation has the following limitations:

- If you are using the IBM Spectrum Protect™ device driver, persistent reserve is only supported on some tape drives. See Technote 1470319 for details.

- If you are using the IBM® device driver, persistent reserve must be enabled at the device driver level. See the *IBM Tape Device Drivers Installation and User's Guide* for information about driver configuration.
- If you are using a virtual tape library that is emulating a supported drive, it might not support persistent reserve.

The following table describes the three possible configurations for drives that are attached to NAS devices.

Table 1. Configurations for drives that are attached to NAS devices.

Library device configuration	The behavior for persistent reserve
The library device is attached to the IBM Spectrum Protect server, and the tape drives are shared by the server and the NAS device.	Drive reservation preemption is supported when the NAS device supports persistent reserve and it is enabled. For more information about setting persistent reserve, see the documentation for your NAS device.
The library device is attached to the IBM Spectrum Protect server and the tape drives are accessed only from the NAS device.	Drive reservation preemption is not supported. If you enable persistent reserve on the NAS device for these drives and a reservation is set by the NAS device but never cleared, you must use another method to clear the reservation.

AIX Windows

Yes
: Specifies that drive preemption through persistent reserve or target reset are used. YES is the default for a library that is defined with SHARED=YES.

No
: Specifies that drive preemption through persistent reserve or target reset are not used. NO is the default for a library that is defined with SHARED=NO. The RESETDRIVES parameter must be set to YES in a clustered environment when SHARED=NO.

Linux

Yes
: Specifies that drive preemption through persistent reserve is used. YES is the default for a library that is defined with SHARED=YES.

No
: Specifies that drive preemption through persistent reserve is not used. NO is the default for a library that is defined with SHARED=NO.

Note: A library manager will not be able to break a drive reservation if the system that has the drive reservation is not configured to use persistent reservation.

Example: Define a 3494 library

Define a library named `my3494` with a scratch category number of 550, a private category number of 600, and a WORM scratch category number of 400®

```
define library my3494 libtype=349x scratchcategory=550
privatecategory=600 wormscratchcategory=400
```

DEFINE LIBRARY (Define an ACSLS library)

Use this syntax to define an ACSLS library.

Privilege class

Windows To use ACSLS functions, the installation of StorageTek Library Attach software is required.

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine LIBRary--library_name--LIBType--=--ACSLS-------------->

   .-SHAREd--=--No------.   .-RESETDrives--=--No----------.
```

```
>--+--------------------+--+---------------------------+------>
   '-SHAREd--=--+-Yes-+-'  |                           (1) |
                '-No--'    '-RESETDrives--=--+-Yes-+-----'
                                             '-No--'

   .-AUTOLabel--=--Yes-----------.
>--+-----------------------------+--ACSID--=--number-----------><
   '-AUTOLabel--=--+-No--------+-'
                   +-Yes-------+
                   '-OVERWRITE-'
```

Notes:

1. The default value of the RESETDRIVES parameter is conditional. If the SHARED parameter is set to NO, the value of the RESETDRIVES parameter is NO. If the SHARED parameter is set to YES, the value of the RESETDRIVES parameter is YES.

Parameters

library_name (Required)
: Specifies the name of the library to be defined. The maximum length of this name is 30 characters.

LIBType=ACSLS (Required)
: Specifies that the library is a StorageTek library that is controlled by StorageTek Automated Cartridge System Library Software (ACSLS).

SHAREd
: Specifies whether this library is shared with other servers in a storage area network (SAN). This parameter is required when you define a library to the library manager.

  YES
  : Specifies that this library can be shared with other servers. When you specify YES, the library manager server mounts volumes as requested by other servers and tracks drive and volume allocation to other servers.

  NO
  : Specifies that this library cannot be shared with other servers. SHARED=NO is required if the library is controlled by passing commands through a NAS file server.

RESETDrives
: Specifies whether the server preempts a drive reservation with persistent reserve when the server is restarted or when a library client or storage agent reconnection is established. If, for example, a storage agent becomes unavailable but is still holding the path to a drive, persistent reserve allows the server to break the storage agent's reservation and access the drive.

  AIX Windows If persistent reserve is not supported, the server completes a reset of the path to the target device.

  Linux If persistent reserve is not supported, the server is not able to reset the path to the target device.

  Support for persistent reservation has the following limitations:

  - If you are using the IBM Spectrum Protect™ device driver, persistent reserve is only supported on some tape drives. See Technote 1470319 for details.
  - If you are using the IBM® device driver, persistent reserve must be enabled at the device driver level. See the *IBM Tape Device Drivers Installation and User's Guide* for information about driver configuration.
  - If you are using a virtual tape library that is emulating a supported drive, it might not support persistent reserve.

  The following table describes the three possible configurations for drives that are attached to NAS devices.

Table 1. Configurations for drives that are attached to NAS devices.

Library device configuration	The behavior for persistent reserve
The library device is attached to the IBM Spectrum Protect server, and the tape drives are shared by the server and the NAS device.	Drive reservation preemption is supported when the NAS device supports persistent reserve and it is enabled. For more information about setting persistent reserve, see the documentation for your NAS device.

Library device configuration	The behavior for persistent reserve
The library device is attached to the IBM Spectrum Protect server and the tape drives are accessed only from the NAS device.	Drive reservation preemption is not supported. If you enable persistent reserve on the NAS device for these drives and a reservation is set by the NAS device but never cleared, you must use another method to clear the reservation.

AIX Windows

Yes
: Specifies that drive preemption through persistent reserve or target reset are used. YES is the default for a library that is defined with SHARED=YES.

No
: Specifies that drive preemption through persistent reserve or target reset are not used. NO is the default for a library that is defined with SHARED=NO. The RESETDRIVES parameter must be set to YES in a clustered environment when SHARED=NO.

Linux

Yes
: Specifies that drive preemption through persistent reserve is used. YES is the default for a library that is defined with SHARED=YES.

No
: Specifies that drive preemption through persistent reserve is not used. NO is the default for a library that is defined with SHARED=NO.

Note: A library manager will not be able to break a drive reservation if the system that has the drive reservation is not configured to use persistent reservation.

AUTOLabel
: Specifies whether the server attempts to automatically label tape volumes. This parameter is optional. The default is YES.

To use this option, you must check in the tapes with CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

Restriction: If you are defining a library that has drives that are attached to a network-attached storage (NAS) device, you must use the LABEL LIBVOLUME command to label the volumes for this library.

No
: Specifies that the server does not attempt to label any volumes.

Yes
: Specifies that the server labels only unlabeled volumes.

OVERWRITE
: Specifies that the server attempts to overwrite an existing label. The server overwrites existing labels *only* if both the existing label and the bar code label are not already defined in any server storage pool or volume history list.

ACSID (Required)
: Specifies the number of this StorageTek library that is assigned by the ACSSA (Automatic Cartridge System System Administrator). This number can be from 0 to 126. Issue QUERY ACS on your system to get the number for your library ID. This parameter is required.

For more information, see your StorageTek documentation.

Example: Define a shared ACSLS library

Define a library named ACSLIB with the library type of ACSLS and an ACSID of 1.

```
define library acslib libtype=acsls acsid=1 shared=yes
```

DEFINE LIBRARY (Define an External library)

Use this syntax to define an External library.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine LIBRary--library_name--LIBType--=--EXTernal----------->

   .-AUTOLabel--=--Yes-----------.
>--+-----------------------------+----------------------------><
   '-AUTOLabel--=--+-No--------+-'
                   +-Yes-------+
                   '-OVERWRITE-'
```

Parameters

library_name (Required)
: Specifies the name of the library to be defined. The maximum length of this name is 30 characters.

LIBType=EXTernal (Required)
: Specifies that the library is managed by an external media management system. This library type does not support drive definitions with the DEFINE DRIVE command. Rather, the external media management system identifies the appropriate drive for media access operations.

  AIX Windows In an IBM Spectrum Protect™ for Storage Area Networks environment, this parameter specifies that StorageTek Automated Cartridge System Library Software (ACSLS) or Library Station software controls the library. Software, such as Gresham EDT-DistribuTAPE, allows multiple servers to share the library. The drives in this library are not defined to IBM Spectrum Protect. ACSLS identifies the drive for media operations.

AUTOLabel
: Specifies whether the server attempts to automatically label tape volumes. This parameter is optional. The default is YES.

  To use this option, you must check in the tapes with CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

  No
  : Specifies that the server does not attempt to label any volumes.

  Yes
  : Specifies that the server labels only unlabeled volumes.

  OVERWRITE
  : Specifies that the server attempts to overwrite an existing label. The server overwrites existing labels *only* if both the existing label and the bar code label are not already defined in any server storage pool or volume history list.

Example: Define an external library for a SAN configuration

For an IBM Spectrum Protect for Storage Area Networks configuration, define a library named EXTLIB with the library type of EXTERNAL. If you are using Gresham Enterprise DistribuTAPE, the external library manager executable file is in the following directory:

- AIX /usr/lpp/dtelm/bin/elm
- Linux /opt/OMIdtelm/bin/elm
- Windows c:\program files\GES\EDT\bin\elm.exe

If you are using the IBM® Tape System Library Manager, the external library manager executable file can be found in the following directory:

- AIX Linux /opt/IBM/TSLM/client/tsm/elm
- Windows ...\IBM\rmm\client\tsm\elm.exe

For more information, see the *IBM Tape System Library Manager User's Guide* at *http://www.ibm.com/support/docview.wss?uid=ssg1S7004001*.

1. Define the library:

   ```
   define library extlib libtype=external
   ```

2. Define the path:

   AIX

```
define path server1 extlib srctype=server desttype=library
  externalmanager="/usr/lpp/dtelm/bin/elm"
```

Linux

```
define path server1 extlib srctype=server desttype=library
  externalmanager="/opt/OMIdtelm/bin/elm"
```

Windows

```
define path server1 extlib srctype=server desttype=library
  externalmanager="c:\program files\GES\EDT\bin\elm.exe"
```

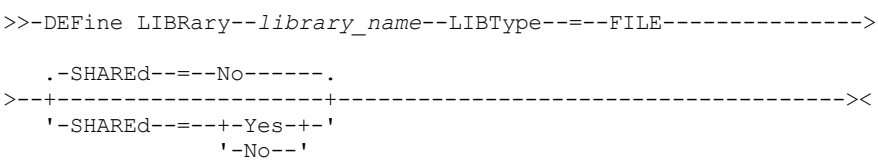
DEFINE LIBRARY (Define a FILE library)

Use this syntax to define a FILE library.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax



Parameters

library_name (Required)
: Specifies the name of the library to be defined. The maximum length of this name is 30 characters.

LIBType=FILE (Required)
: Specifies that a pseudo-library is created for sequential file volumes. When you issue the DEFINE DEVCLASS command with DEVTYPE=FILE and SHARED=YES parameters, this occurs automatically. FILE libraries are necessary only when sharing sequential file volumes between the server and one or more storage agents. The use of FILE libraries requires library sharing. Shared FILE libraries are supported for use in LAN-free backup configurations only. You cannot use a shared FILE library in an environment in which a library manager is used to manage library clients.

SHAREd
: Specifies whether this library is shared with other IBM Spectrum Protect™ servers in a storage area network (SAN). This parameter is required when you define a library to the library manager.

  YES
  : Specifies that this library can be shared with other servers. When you specify YES, the library manager server mounts volumes as requested by other servers and tracks drive and volume allocation to other servers.

  NO
  : Specifies that this library cannot be shared with other servers. SHARED=NO is required if the library is controlled by passing commands through a NAS file server.

Example: Define a shared FILE library

Define a file library with shared=yes.

```
define library file1 libtype=file shared=yes
```

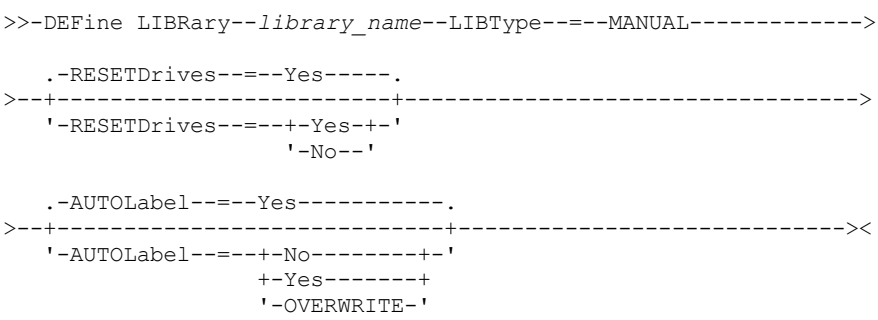
DEFINE LIBRARY (Define a manual library)

Use this syntax to define a manual library.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax



Parameters

library_name (Required)
: Specifies the name of the library to be defined. The maximum length of this name is 30 characters.

LIBType=MANUAL (Required)
: Specifies that the library is not automated. When volumes must be mounted on drives in this type of library, messages are sent to operators. This type of library is used with stand-alone drives.

AUTOLabel
: Specifies whether the server attempts to automatically label tape volumes. This parameter is optional. The default is YES.

  To use this option, you need to check in the tapes with CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

  No
  : Specifies that the server does not attempt to label any volumes.

  Yes
  : Specifies that the server only labels unlabeled volumes.

  OVERWRITE
  : Specifies that the server attempts to overwrite an existing label. The server overwrites existing labels *only* if both the existing label and the bar code label are not already defined in any server storage pool or volume history list.

RESETDrives
: Specifies whether the server preempts a drive reservation with persistent reserve when the server is restarted or when a library client or storage agent reconnection is established. If, for example, a storage agent becomes unavailable but is still holding the path to a drive, persistent reserve allows the server to break the storage agent's reservation and access the drive.

  AIX Windows If persistent reserve is not supported, the server completes a reset of the path to the target device.

  Linux If persistent reserve is not supported, the server is not able to reset the path to the target device.

  Support for persistent reservation has the following limitations:

  - If you are using the IBM Spectrum Protect™ device driver, persistent reserve is only supported on some tape drives. See Technote 1470319 for details.
  - If you are using the IBM® device driver, persistent reserve must be enabled at the device driver level. See the *IBM Tape Device Drivers Installation and User's Guide* for information about driver configuration.
  - If you are using a virtual tape library that is emulating a supported drive, it might not support persistent reserve.

  AIX Windows

  Yes
  : Specifies that drive preemption through persistent reserve or target reset are used. YES is the default for a library that is defined with SHARED=YES.

  No
  : Specifies that drive preemption through persistent reserve or target reset are not used. NO is the default for a library that is defined with SHARED=NO. The RESETDRIVES parameter must be set to YES in a clustered environment when SHARED=NO.

Linux

Yes
: Specifies that drive preemption through persistent reserve is used. YES is the default for a library that is defined with SHARED=YES.

No
: Specifies that drive preemption through persistent reserve is not used. NO is the default for a library that is defined with SHARED=NO.

Note: A library manager will not be able to break a drive reservation if the system that has the drive reservation is not configured to use persistent reservation.

Example: Define a manual library

Define a library named `MANUALMOUNT` with the library type of MANUAL.

```
define library manualmount libtype=manual
```

DEFINE LIBRARY (Define a SCSI library)

Use this syntax to define a SCSI library.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine LIBRary--library_name--LIBType--=--SCSI---------------->

   .-SHAREd--=--No------.  .-RESETDrives--=--No----------.
>--+--------------------+--+----------------------------+------>
   '-SHAREd--=--+-Yes-+-'  |                          (1) |
                '-No--'    '-RESETDrives--=--+-Yes-+-----'
                                             '-No--'

   .-AUTOLabel--=--No------------.
>--+-----------------------------+----------------------------->
   '-AUTOLabel--=--+-No--------+-'
                   +-Yes-------+
                   '-OVERWRITE-'

   .-RELABELSCRatch--=--No------.
>--+----------------------------+------------------------------>
   '-RELABELSCRatch--=--+-No--+-'
                        '-Yes-'

   .-SERial--=--AUTODetect--------.
>--+-----------------------------+--------------------------><
   '-SERial--=--+-AUTODetect----+-'
                '-serial_number-'
```

Notes:

1. The default value of the RESETDRIVES parameter is conditional. If the SHARED parameter is set to NO, the value of the RESETDRIVES parameter is NO. If the SHARED parameter is set to YES, the value of the RESETDRIVES parameter is YES.

Parameters

library_name (Required)
: Specifies the name of the library to be defined. The maximum length of this name is 30 characters.

LIBType=SCSI (Required)
: Specifies that the library has a SCSI-controlled media changer device. To mount volumes on drives in this type of library, the server uses the media changer device.

SHAREd
Specifies whether this library is shared with other servers in a storage area network (SAN). This parameter is required when you define a library to the library manager.

YES
Specifies that this library can be shared with other servers. When you specify YES, the library manager server mounts volumes as requested by other servers and tracks drive and volume allocation to other servers.
NO
Specifies that this library cannot be shared with other servers. SHARED=NO is required if the library is controlled by passing commands through a NAS file server.

AUTOLabel
Specifies whether the server attempts to automatically label tape volumes. This parameter is optional. The default is NO.

To use this option, you must check in the tapes with CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

Restriction: If you are defining a library that has drives that are attached to a network-attached storage (NAS) device, you must use the LABEL LIBVOLUME command to label the volumes for this library.

No
Specifies that the server does not attempt to label any volumes.
Yes
Specifies that the server labels only unlabeled volumes.
OVERWRITE
Specifies that the server attempts to overwrite an existing label. The server overwrites existing labels *only* if both the existing label and the bar code label are not already defined in any server storage pool or volume history list.

RELABELSCRatch
Specifies whether the server relabels volumes that were deleted and returned to scratch. When this parameter is set to YES, a LABEL LIBVOLUME operation is started and the existing volume label is overwritten. This parameter is optional and intended for use with a Virtual Tape Library (VTL).

If you have both virtual and real volumes in your VTL, both types are relabeled when this parameter is enabled. If the VTL includes real volumes, specifying this option might impact performance.

Restriction: If you are defining a library that has drives that are attached to a network-attached storage (NAS) device, you must use the LABEL LIBVOLUME command to label the volumes for this library.

No
Specifies that the server does not relabel volumes that are deleted and returned to scratch.
Yes
Specifies that the server relabels volumes that are deleted and returned to scratch.

RESETDrives
Specifies whether the server preempts a drive reservation with persistent reserve when the server is restarted or when a library client or storage agent reconnection is established. If, for example, a storage agent becomes unavailable but is still holding the path to a drive, persistent reserve allows the server to break the storage agent's reservation and access the drive.

AIX Windows If persistent reserve is not supported, the server completes a reset of the path to the target device.

Linux If persistent reserve is not supported, the server is not able to reset the path to the target device.

Support for persistent reservation has the following limitations:

- If you are using the IBM Spectrum Protect™ device driver, persistent reserve is only supported on some tape drives. See Technote 1470319 for details.
- If you are using the IBM® device driver, persistent reserve must be enabled at the device driver level. See the *IBM Tape Device Drivers Installation and User's Guide* for information about driver configuration.
- If you are using a virtual tape library that is emulating a supported drive, it might not support persistent reserve.

The following table describes the three possible configurations for drives that are attached to NAS devices.

Table 1. Configurations for drives that are attached to NAS devices

Library device configuration	The behavior for persistent reserve

Library device configuration	The behavior for persistent reserve
The library device is attached to the IBM Spectrum Protect server, and the tape drives are shared by the server and the NAS device.	Drive reservation preemption is supported when the NAS device supports persistent reserve and it is enabled. For more information about setting persistent reserve, see the documentation for your NAS device.
The library device is attached to the IBM Spectrum Protect server and the tape drives are accessed only from the NAS device.	Drive reservation preemption is not supported. If you enable persistent reserve on the NAS device for these drives and a reservation is set by the NAS device but never cleared, you must use another method to clear the reservation.
The library device is attached to the NAS device and accessed indirectly by NDMP (network data management protocol), and the tape drives are accessed only from the NAS device.	Drive reservation preemption is not supported. If you enable persistent reserve on the NAS device for these drives and a reservation is set by the NAS device but never cleared, you must use another method to clear the reservation.

AIX Windows

Yes
: Specifies that drive preemption through persistent reserve or target reset are used. YES is the default for a library that is defined with SHARED=YES.

No
: Specifies that drive preemption through persistent reserve or target reset are not used. NO is the default for a library that is defined with SHARED=NO. The RESETDRIVES parameter must be set to YES in a clustered environment when SHARED=NO.

Linux

Yes
: Specifies that drive preemption through persistent reserve is used. YES is the default for a library that is defined with SHARED=YES.

No
: Specifies that drive preemption through persistent reserve is not used. NO is the default for a library that is defined with SHARED=NO.

Note: A library manager will not be able to break a drive reservation if the system that has the drive reservation is not configured to use persistent reservation.

SERial
: Specifies the serial number for the library that is being defined. This parameter is optional. The default is AUTODETECT.

If SERIAL=AUTODETECT, then when you define the path to the library, the serial number reported by the library is used as the serial number.

If SERIAL=*serial_number*, then the number you entered is compared to the number detected by the server.

Attention: Depending on the capabilities of the device, SERIAL=AUTODETECT might not be supported. In this case, the serial number is reported as blank.

Example: Define a SCSI library

Define a library that is named SCSILIB with a library type of SCSI.

```
define library scsilib libtype=scsi
```

The library requires a path. The device name for the library is:

- AIX `/dev/lb0`
- Linux `/dev/tsmscsi/lb0`
- Windows `lb3.0.0.0`

Define the path:

AIX

```
define path server1 scsilib srctype=server desttype=library
   device=/dev/lb0
```

Linux

```
define path server1 scsilib srctype=server desttype=library
   device=/dev/tsmscsi/lb0
```

Windows

```
define path server1 scsilib srctype=server desttype=library
   device=lb3.0.0.0
```

DEFINE LIBRARY (Define a shared library)

Use this syntax to define a shared library.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine LIBRary--library_name--LIBType--=--SHAREd------------>

>--PRIMarylibmanager--=--server_name--------------------------><
```

Parameters

library_name (Required)
: Specifies the name of the library to be defined. The maximum length of this name is 30 characters.

LIBType=SHAREd (Required)
: Specifies that the library is shared with another IBM Spectrum Protect™ server over a storage area network (SAN) or a dual SCSI connection to library drives.
: Important: Specify this library type when you define the library on a library client.

PRIMarylibmanager
: Specifies the name of the IBM Spectrum Protect server that is responsible for controlling access to library resources. You must define this server with the DEFINE SERVER command before you can use it as a library manager. This parameter is required and valid only if LIBTYPE=SHARED.

Example: Define a shared library

In a SAN, define a library named `SHAREDTSM` to a library client server named LIBMGR1

```
define library sharedtsm libtype=shared primarylibmanager=libmgr1
```

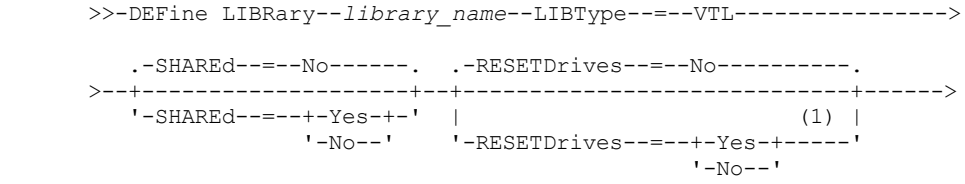
DEFINE LIBRARY (Define a VTL library)

Use this syntax to define a library that has a SCSI-controlled media changer device that is represented by a virtual tape library (VTL).

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax



```
   .-AUTOLabel--=--No------------.
>--+-----------------------------+----------------------------->
   '-AUTOLabel--=--+-No--------+-'
                   +-Yes-------+
                   '-OVERWRITE-'

   .-RELABELSCRatch--=--Yes-----.
>--+-----------------------------+----------------------------->
   '-RELABELSCRatch--=--+-No--+-'
                        '-Yes-'

   .-SERial--=--AUTODetect--------.
>--+-----------------------------+---------------------------><
   '-SERial--=--+-AUTODetect----+-'
                '-serial_number-'
```

Notes:

1. The default value of the RESETDRIVES parameter is conditional. If the SHARED parameter is set to NO, the value of the RESETDRIVES parameter is NO. If the SHARED parameter is set to YES, the value of the RESETDRIVES parameter is YES.

Parameters

library_name (Required)
: Specifies the name of the library to be defined. The maximum length of this name is 30 characters.

LIBType=VTL (Required)
: Specifies that the library has a SCSI-controlled media changer device that is represented by a virtual tape library. To mount volumes in drives in this type of library, the server uses the media changer device.

  If you are defining a VTL library, your environment must not include any mixed-media and paths must be defined between all drives in the library and all defined servers, including storage agents, that use the library. If either of these characteristics are not true, the overall performance can degrade to the same levels as the SCSI library type; especially during times of high stress.

SHAREd
: Specifies whether this library is shared with other servers in a storage area network (SAN). This parameter is required when you define a library to the library manager.

  YES
  : Specifies that this library can be shared with other servers. When you specify YES, the library manager server mounts volumes as requested by other servers and tracks drive and volume allocation to other servers.

  NO
  : Specifies that this library cannot be shared with other servers. SHARED=NO is required if the library is controlled by passing commands through a NAS file server.

RESETDrives
: Specifies whether the server preempts a drive reservation with persistent reserve when the server is restarted or when a library client or storage agent reconnection is established. If, for example, a storage agent becomes unavailable but is still holding the path to a drive, persistent reserve allows the server to break the storage agent's reservation and access the drive.

  AIX | Windows If persistent reserve is not supported, the server completes a reset of the path to the target device.

  Linux If persistent reserve is not supported, the server is not able to reset the path to the target device.

  Support for persistent reservation has the following limitations:

  - If you are using the IBM Spectrum Protect™ device driver, persistent reserve is only supported on some tape drives. See Technote 1470319 for details.
  - If you are using the IBM® device driver, persistent reserve must be enabled at the device driver level. See the *IBM Tape Device Drivers Installation and User's Guide* for information about driver configuration.
  - If you are using a virtual tape library that is emulating a supported drive, it might not support persistent reserve.

  AIX | Windows

  Yes

Specifies that drive preemption through persistent reserve or target reset are used. YES is the default for a library that is defined with SHARED=YES.

No
Specifies that drive preemption through persistent reserve or target reset are not used. NO is the default for a library that is defined with SHARED=NO. The RESETDRIVES parameter must be set to YES in a clustered environment when SHARED=NO.

Linux

Yes
Specifies that drive preemption through persistent reserve is used. YES is the default for a library that is defined with SHARED=YES.

No
Specifies that drive preemption through persistent reserve is not used. NO is the default for a library that is defined with SHARED=NO.

Note: A library manager will not be able to break a drive reservation if the system that has the drive reservation is not configured to use persistent reservation.

AUTOLabel
Specifies whether the server attempts to automatically label tape volumes. This parameter is optional. The default is NO.

To use this option, you must check in the tapes with CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

Restriction: If you are defining a library that has drives that are attached to a network-attached storage (NAS) device, you must use the LABEL LIBVOLUME command to label the volumes for this library.

No
Specifies that the server does not attempt to label any volumes.

Yes
Specifies that the server labels only unlabeled volumes.

OVERWRITE
Specifies that the server attempts to overwrite an existing label. The server overwrites existing labels *only* if both the existing label and the bar code label are not already defined in any server storage pool or volume history list.

RELABELSCRatch
Specifies whether the server relabels volumes that were deleted and returned to scratch. When this parameter is set to YES, a LABEL LIBVOLUME operation is started and the existing volume label is overwritten.

If you have both virtual and real volumes in your VTL, both types are relabeled when this parameter is enabled. If the VTL includes real volumes, specifying this option might impact performance.

Restriction: If you are defining a library that has drives that are attached to a network-attached storage (NAS) device, you must use the LABEL LIBVOLUME command to label the volumes for this library.

Yes
Specifies that the server relabels volumes that are deleted and returned to scratch. YES is the default.

No
Specifies that the server does not relabel volumes that are deleted and returned to scratch.

SERial
Specifies the serial number for the library that is being defined. This parameter is optional. The default is AUTODETECT.

If SERIAL=AUTODETECT, then when you define the path to the library, the serial number reported by the library is used as the serial number.

If SERIAL=*serial_number*, then the number you entered is compared to the number detected by the server.

Attention: Depending on the capabilities of the device, SERIAL=AUTODETECT might not be supported. In this case, the serial number is reported as blank.

Example: Define a VTL library

Define a library named VTLLIB with a library type of VTL.

```
define library vtllib libtype=vtl
```

The library requires a path. The device name for the library is:

- AIX /dev/lb0
- Linux /dev/tsmscsi/lb0
- Windows lb3.0.0.0

Define the path:

AIX

```
define path server1 vtllib srctype=server desttype=library
   device=/dev/lb0
```

Linux

```
define path server1 vtllib srctype=server desttype=library
   device=/dev/tsmscsi/lb0
```

Windows

```
define path server1 vtllib srctype=server desttype=library
   device=lb3.0.0.0
```

AIX | Linux

DEFINE LIBRARY (Define a ZOSMEDIA library type)

Use this syntax to define a library that represents a TAPE or FILE storage resource that is maintained by Tivoli® Storage Manager for z/OS® Media.

Define a library of type ZOSMEDIA when you want the library to be exclusively managed by Tivoli Storage Manager for z/OS Media. The library appears to the IBM Spectrum Protect™ server as a logical storage device that does not require DRIVE definitions. A PATH definition is required for the server and any storage agents that need access to the ZOSMEDIA library resource.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine LIBRary--library_name--LIBType--=--ZOSMEDIA----------><
```

Parameters

library_name (Required)
: Specifies the name of the library to be defined.

LIBType=ZOSMEDIA (Required)
: Specifies that the library type is the ZOSMEDIA which represents a TAPE or FILE storage resource that is maintained by Tivoli Storage Manager for z/OS Media.

Example: Configure a ZOSMEDIA library

The following example shows the steps needed to define and configure a zosmedia library. The configuration includes these components:

- A server named sahara
- A library defined as type zosmedia named zebra
- A z/OS media server named oasis
- A storage agent named mirage

Define a library named ZEBRA with a library type of ZOSMEDIA:

```
define library zebra libtype=zosmedia
```

Define the z/OS media server:

```
define server oasis serverpassword=sanddune
hladdress=9.289.19.67 lladdress=1777
```

The server requires a path to the library resource managed by Tivoli Storage Manager for z/OS Media:

```
define path sahara zebra srctype=server
desttype=library zosmediaserver=oasis
```

The storage agent requires a path to the library resource managed by Tivoli Storage Manager for z/OS Media:

```
define path mirage zebra srctype=server
desttype=library zosmediaserver=oasis
```

DEFINE MACHINE (Define machine information for disaster recovery)

Use this command to save disaster recovery information for a server or client node machine. This information will be included in the plan file to help you recover your machines.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DEFine MACHine--machine_name---------------------------------->

>--+-----------------------------+--+-----------------------+--->
   '-DESCription--=--description-'  '-BUilding--=--building-'

>--+-----------------+--+--------------+----------------------->
   '-FLoor--=--floor-'  '-ROom--=--room-'

   .-PRIority--=--50---------.  .-ADSMServer--=--No------.
>--+-------------------------+--+-----------------------+-----><
   '-PRIority--=----number---'  '-ADSMServer--=--+-No--+-'
                                                 '-Yes-'
```

Parameters

machine_name (Required)
: Specifies the machine name. The name can be up to 64 characters.

DESCription
: Specifies a machine description. This parameter is optional. The text can be up to 255 characters. Enclose the text in quotation marks if it contains any blank characters.

BUilding
: Specifies the building that this machine is in. This parameter is optional. The text can be up to 16 characters. Enclose the text in quotation marks if it contains any blank characters.

FLoor
: Specifies the floor that this machine is on. This parameter is optional. The text can be up to 16 characters. Enclose the text in quotation marks if it contains any blank characters.

ROom
: Specifies the room that this machine is in. This parameter is optional. The text can be up to 16 characters. Enclose the text in quotation marks if it contains any blank characters.

PRIority
: Specifies the restore priority for the machine an integer from 1 to 99. The highest priority is 1. This parameter is optional. The default is 50.

ADSMServer
: Specifies whether the machine is an IBM Spectrum Protect™ server. Only one machine can be defined as an IBM Spectrum Protect server. This parameter is optional. The default is NO. Possible values are:

  No
  : This machine is not an IBM Spectrum Protect server.

  Yes

This machine is an IBM Spectrum Protect server.

Example: Define a machine's disaster recovery information

Define a machine named DISTRICT5, and specify a location, a floor, and a room name. This machine contains critical data and has the highest priority.

```
define machine district5 building=101 floor=27
room=datafacilities priority=1
```

Related commands

Table 1. Commands related to DEFINE MACHINE

Command	Description
DEFINE MACHNODEASSOCIATION	Associates an IBM Spectrum Protect node with a machine.
DEFINE RECMEDMACHASSOCIATION	Associates recovery media with a machine.
DELETE MACHINE	Deletes a machine.
INSERT MACHINE	Inserts machine characteristics or recovery instructions into the IBM Spectrum Protect database.
QUERY MACHINE	Displays information about machines.
UPDATE MACHINE	Changes the information for a machine.

DEFINE MACHNODEASSOCIATION (Associate a node with a machine)

Use this command to associate client nodes with a machine. During disaster recovery, you can use this information to identify the client nodes that resided on destroyed machines.

The machine must be defined and the nodes registered to IBM Spectrum Protect™.

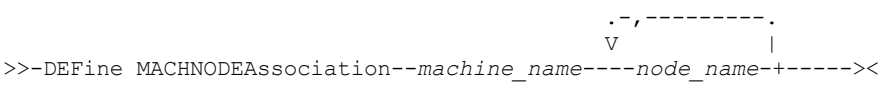
To retrieve the information, issue the QUERY MACHINE command. This information will be included in the plan file to help you recover the client machines.

A node remains associated with a machine unless the node, the machine, or the association itself is deleted.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

machine_name (Required)
: Specifies the machine name.

node_name (Required)
: Specifies the node names. A node can only be associated with one machine. To specify multiple nodes, separate the names with commas and no intervening spaces. You can use wildcard characters to specify a name.

Example: Associate a node with a machine

Associate the node named ACCOUNTSPAYABLE with the machine named DISTRICT5.

```
define machnodeassociation district5 accountspayable
```

Related commands

Table 1. Commands related to DEFINE MACHNODEASSOCIATION

Command	Description
DEFINE MACHINE	Defines a machine for DRM.
DELETE MACHINE	Deletes a machine.
DELETE MACHNODEASSOCIATION	Deletes association between a machine and node.
QUERY MACHINE	Displays information about machines.
REGISTER NODE	Defines a client node to the server and sets options for that user.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.

DEFINE MGMTCLASS (Define a management class)

Use this command to define a new management class in a policy set. To allow clients to use the new management class, you must activate the policy set that contains the new class.

You can define one or more management classes for each policy set in a policy domain. A management class can contain a backup copy group, an archive copy group, or both. The user of a client node can select any management class in the active policy set or use the default management class.

Attention: The DEFINE MGMTCLASS command fails if a copy storage pool is specified as the destination for files that were migrated by an IBM Spectrum Protect™ for Space Management client.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the management class belongs.

Syntax

```
>>-DEFine MGmtclass--domain_name--policy_set_name--class_name--->

   .-SPACEMGTECHnique--=--NONE----------.
>--+-----------------------------------+---------------------->
   '-SPACEMGTECHnique--=--+-AUTOmatic-+-'
                          +-SELective-+
                          '-NONE------'

   .-AUTOMIGNOnuse--=--0----.
>--+------------------------+---------------------------------->
   '-AUTOMIGNOnuse--=--days-'

   .-MIGREQUIRESBkup--=--Yes-----.
>--+-----------------------------+------------------------------>
   '-MIGREQUIRESBkup--=--+-Yes-+-'
                         '-No--'

   .-MIGDESTination--=--SPACEMGPOOL-.
>--+--------------------------------+--------------------------->
   '-MIGDESTination--=--pool_name---'

>--+-----------------------------+----------------------------><
   '-DESCription--=--description-'
```

Parameters

domain_name (Required)

Specifies the policy domain to which the management class belongs.

policy_set_name (Required)
Specifies the policy set to which the management class belongs. You cannot define a management class to the ACTIVE policy set.

class_name (Required)
Specifies the name of the new management class. The maximum length of this name is 30 characters. You cannot use either *default* or *grace_period* as a class name.

SPACEMGTECHnique
Specifies whether a file that is using this management class is eligible for migration. This parameter is optional. The default is NONE. This parameter is effective only for IBM Spectrum Protect for Space Management clients, not for backup-archive clients or application clients. Possible values are:

AUTOmatic
Specifies that the file is eligible for both automatic migration and selective migration.

SELective
Specifies that the file is eligible for selective migration only.

NONE
Specifies that the file is not eligible for migration.

AUTOMIGNOnuse
Specifies the number of days that must elapse since a file was last accessed before it is eligible for automatic migration. This parameter is optional. The default value is 0. If SPACEMGTECHNIQUE is not AUTOMATIC, the server ignores this attribute. You can specify an integer in the range 0 - 9999.

This parameter is effective only for IBM Spectrum Protect for Space Management clients, not for backup-archive clients or application clients.

MIGREQUIRESBkup
Specifies whether a backup version of a file must exist before a file can be migrated. This parameter is optional. The default is YES. This parameter is effective only for IBM Spectrum Protect for Space Management clients, not for backup-archive clients or application clients. Possible values are:

Yes
Specifies that a backup version must exist.

No
Specifies that a backup version is optional.

MIGDESTination
Specifies the primary storage pool where the server initially stores files that are migrated by IBM Spectrum Protect for Space Management clients. This parameter is effective only for IBM Spectrum Protect for Space Management clients, and is not effective for backup-archive clients or application clients. The default is SPACEMGPOOL.
Your choice for the destination might depend on factors such as the following:

- The number of client nodes that are migrated to the storage pool. When many user files are stored in the same storage pool, volume contention can occur as users try to migrate files to or recall files from the storage pool.
- How quickly the files must be recalled. If you need immediate access to migrated versions, you can specify a disk storage pool as the destination.

The command fails if you specify a copy storage pool or an active-data pool as the destination.

DESCription
Specifies a description of the management class. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters.

Example: Define a management class for a specific policy set and policy domain

Define a management class that is called MCLASS1 for policy set SUMMER in the PROG1 policy domain. For IBM Spectrum Protect for Space Management clients, allow both automatic and selective migration, and store migrated files in the SMPOOL storage pool. Add the description, "Technical Support Mgmt Class."

```
define mgmtclass prog1 summer mclass1
spacemgtechnique=automatic migdestination=smpool
description="technical support mgmt class"
```

Related commands

Table 1. Commands related to DEFINE MGMTCLASS

Command	Description
ASSIGN DEFMGMTCLASS	Assigns a management class as the default for a specified policy set.
COPY MGMTCLASS	Creates a copy of a management class.
DEFINE COPYGROUP	Defines a copy group for backup or archive processing within a specified management class.
DEFINE POLICYSET	Defines a policy set within the specified policy domain.
DELETE MGMTCLASS	Deletes a management class and its copy groups from a policy domain and policy set.
QUERY COPYGROUP	Displays the attributes of a copy group.
QUERY MGMTCLASS	Displays information about management classes.
QUERY POLICYSET	Displays information about policy sets.
UPDATE COPYGROUP	Changes one or more attributes of a copy group.
UPDATE MGMTCLASS	Changes the attributes of a management class.

DEFINE NODEGROUP (Define a node group)

Use this command to define a node group. A *node group* is a group of client nodes that are acted upon as if they were a single entity. A node can be a member of one or more node groups.

Privilege class

To issue this command, you must have system or unrestricted policy privilege.

Syntax

```
>>-DEFine NODEGroup--group_name---------------------------------->

>--+-----------------------------+----------------------------><
   '-DESCription--=--description-'
```

Parameters

group_name
: Specifies the name of the node group that you want to create. The maximum length of the name is 64 characters. The specified name may not be the same as any existing client node name.

DESCription
: Specifies a description of the node group. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters.

Example: Define a node group

Define a node group named `group1`.

```
define nodegroup group1
```

Related commands

Table 1. Commands related to DEFINE NODEGROUP

Command	Description
DEFINE BACKUPSET	Defines a previously generated backup set to a server.

Command	Description
DEFINE NODEGROUPMEMBER	Adds a client node to a node group.
DELETE BACKUPSET	Deletes a backup set.
DELETE NODEGROUP	Deletes a node group.
DELETE NODEGROUPMEMBER	Deletes a client node from a node group.
GENERATE BACKUPSET	Generates a backup set of a client's data.
QUERY BACKUPSET	Displays backup sets.
QUERY NODEGROUP	Displays information about node groups.
UPDATE BACKUPSET	Updates a retention value associated with a backup set.
UPDATE NODEGROUP	Updates the description of a node group.

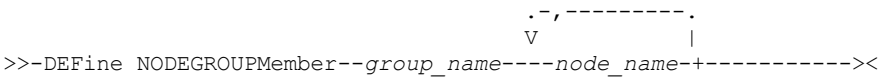
DEFINE NODEGROUPMEMBER (Define node group member)

Use this command to add a client node to a node group. A *node group* is a group of client nodes that are acted upon as if they were a single entity.

Privilege class

To issue this command you must have system or unrestricted policy privilege.

Syntax



Parameters

group_name
: Specifies the name of the node group to which you want to add a client node.

node_name
: Specifies the name of the client node that you want to add to the node group. You can specify one or more names. Separate multiple names with commas; do not use intervening spaces. You can also use wildcard characters when specifying multiple names.

Example: Define node group members

Define two members, `node1` and `node2`, to a node group, `group1`.

```
define nodegroupmember group1 node1,node2
```

Related commands

Table 1. Commands related to DEFINE NODEGROUPMEMBER

Command	Description
DEFINE BACKUPSET	Defines a previously generated backup set to a server.
DEFINE NODEGROUP	Defines a group of nodes.
DELETE BACKUPSET	Deletes a backup set.
DELETE NODEGROUP	Deletes a node group.
DELETE NODEGROUPMEMBER	Deletes a client node from a node group.
GENERATE BACKUPSET	Generates a backup set of a client's data.

Command	Description
QUERY BACKUPSET	Displays backup sets.
QUERY NODEGROUP	Displays information about node groups.
UPDATE BACKUPSET	Updates a retention value associated with a backup set.
UPDATE NODEGROUP	Updates the description of a node group.

DEFINE PATH (Define a path)

Use this command to define a path for a source to access a destination. Both the source and destination must be defined before you can define a path. For example, if a path is required between a server and a drive, you must first issue the DEFINE DRIVE command and then issue the DEFINE PATH command. A path must be defined after you issue the DEFINE DRIVE command in order to make the drive usable by the server.

Syntax and parameter descriptions are available for the following path types.

- DEFINE PATH (Define a path when the destination is a drive)
- DEFINE PATH (Define a path when the destination is a library)
- AIX Linux DEFINE PATH (Define a path when the destination is a ZOSMEDIA library)

For detailed and current device support information, see the Supported Devices website for your operating system:

- AIX Windows Supported devices for AIX and Windows
- Linux Supported devices for Linux

Related commands

Table 1. Commands related to DEFINE PATH

Command	Description
DEFINE DATAMOVER	Defines a data mover to the IBM Spectrum Protect server.
DEFINE DRIVE	Assigns a drive to a library.
DEFINE LIBRARY	Defines an automated or manual library.
DELETE PATH	Deletes a path from a source to a destination.
PERFORM LIBACTION	Defines all drives and paths for a library.
QUERY PATH	Displays information about the path from a source to a destination.
UPDATE DATAMOVER	Changes the definition for a data mover.
UPDATE PATH	Changes the attributes associated with a path.

DEFINE PATH (Define a path when the destination is a drive)

Use this syntax when you define a path to a drive.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine PATH--source_name--destination_name------------------->

>--SRCType--=--+-DATAMover-+--+-----------------------+-------->
               '-SERVer----'  '-AUTODetect--=--+-No--+-'
                                               '-Yes-'
```

```
>--DESTType--=--DRive--LIBRary--=--library_name----------------->

>----DEVIce--=--+-device_name-+--------------------------------->
                '-FILE--------'

   .-GENERICTAPE--=--No------.  .-ONLine--=--Yes-----.
>--+-------------------------+--+--------------------+---------->
   '-GENERICTAPE--=--+-Yes-+-'  '-ONLine--=--+-Yes-+-'
                     '-No--'                 '-No--'

   .-DIRectory--=--current_directory_name-.
>--+--------------------------------------+--------------------><
   |               .-,--------------.     |
   |               V                |     |
   '-DIRectory--=----directory_name-+-----'
```

Parameters

source_name (Required)
: Specifies the name of source for the path. This parameter is required.

destination_name (Required)
: Specifies the name of the destination. This parameter is required.

SRCType (Required)
: Specifies the type of the source. This parameter is required. Possible values are:

  DATAMover
  : Specifies that a data mover is the source.

  SERVer
  : Specifies that a storage agent is the source.

AUTODetect
: Specifies whether the serial number for a drive is automatically updated in the database at the time that the path is defined. This parameter is optional. This parameter is only valid for paths that are defined from the local server to a drive. Possible values are:

  No
  : Specifies that the serial number is not automatically updated. The serial number is still compared with what is already in the database for the device. The server issues a message if there is a mismatch.

  Yes
  : Specifies that the serial number is not automatically updated to reflect the same serial number that the drive reports to the server.
    Important:

    1. If you did not set the serial number when you defined the drive, the server always tries to detect the serial number, and AUTODETECT defaults to YES. If you previously entered a serial number, then AUTODETECT defaults to NO.
    2. The use of AUTODETECT=YES in this command means that the serial number set in the drive definition is updated with the detected serial number.
    3. If you set DESTTYPE=DRIVE and AUTODETECT=YES, then the drive element number in the database is automatically changed to reflect the same element number that corresponds to the serial number of that drive. This is true for drives in a SCSI library. For more information about the element number, see DEFINE DRIVE.
    4. Depending on the capabilities of the device, the AUTODETECT parameter might not be supported.

DESTType=DRive (Required)
: Specifies that a drive is the destination. When the destination is a drive, you must specify a library name.

LIBRary
: Specifies the name of the library to which the drive is assigned. The library and its drives must already be defined to the server. If the path is from a NAS data mover to a library, the library must have LIBTYPE of SCSI, 349X, or ACSLS.

DEVIce
: Specifies the name of the device as known to the source, or FILE if the device is a logical drive in a FILE library.
  AIX Windows The source uses the device name to access the drive. See Table 1 for examples.

Table 1. Examples of device names

Source to destination	Example

Source to destination	Example
Server to a drive (not a FILE drive)	AIX `/dev/mt3` Windows `mt3`
Storage agent (on a Windows system) to a drive (not a FILE drive)	`mt3`
Storage agent to a drive when the drive is a logical drive in a FILE library	`FILE`
NAS data mover to a drive	NetApp NAS file server: `rst01` EMC Celerra NAS file server: `c436t0l1` IBM® System Storage® N Series: `rst01`

Linux The source uses the device name to access the drive. See Table 2 for examples.

Table 2. Examples of device names

Source to destination	Example
Server to a drive (not a FILE drive)	`/dev/tsmscsi/mt3`
Storage agent to a drive (not a FILE drive)	`/dev/tsmscsi/mt3`
Storage agent to a drive when the drive is a logical drive in a FILE library	`FILE`
NAS data mover to a drive	NetApp NAS file server: `rst01` EMC Celerra NAS file server: `c436t0l1` IBM System Storage N Series: `rst01`

Important:

- AIX | Linux For 349X libraries, the alias name is a symbolic name that is specified in the /etc/ibmatl.conf file. Windows For 349X libraries, the alias name is a symbolic name that is specified in the c:\winnt\ibmatl.conf file. For more information, see *IBM Tape Device Drivers Installation and User's Guide*, which can be downloaded from the IBM Systems support site at http://www.ibm.com/support/docview.wss?uid=ssg1S7002972.
- For information about how to obtain names for devices that are connected to a NAS file server, consult the product information for the file server. For example, for a NetApp file server, connect to the file server using Telnet and issue the SYSCONFIG command. Use this command to determine device names for drives:

  ```
  sysconfig -t
  ```

Windows GENERICTAPE

Windows Specifies whether the tape drive to be used is a GENERICTAPE device class type. If the device is a tape drive and is not supported by IBM Spectrum Protect™ but is supported for the Windows operating system, you can use it with the generic tape format. To use the drive, specify GENERICTAPE=Yes when you define a path to the drive. The default is No. Possible values are:

Yes
: Specifies that the tape drive to be used is a GENERICTAPE device class type.

No
: Specifies that the tape drive to be used is not a GENERICTAPE device class type.

ONLine

Specifies whether the path is available for use. This parameter is optional. The default is YES. Possible values are:

Yes
: Specifies that the path is available for use.

No
: Specifies that the path is not available for use.

The source and the destination must both be available to use the path.

For example, if the path from a data mover to a drive is online, but either the data mover or the drive is offline, you cannot use the path.

DIRectory

Specifies the directory location or locations where the storage agent reads and writes the files that represent storage volumes for the FILE device class that is associated with the FILE library. The DIRECTORY parameter is also used for devices of type REMOVABLEFILE. For REMOVABLEFILE devices, the DIRECTORY parameter provides information for the server (not a storage agent) along with the DRIVE parameter to describe access to the device. This parameter is optional. For a path from a storage agent to a FILE device, this parameter is only valid when *all* of the following conditions are true:

- The source type is SERVER (meaning a storage agent that has been defined as a server to this server).
- The source name is the name of a storage agent, *not* the server.
- The destination is a logical drive that is part of a FILE library that is created when the device class was defined.

If you specified multiple directories for the device class associated with the FILE library, you must specify the same number of directories for each path to the FILE library. Do not change or move existing directories on the server that the storage agent is using so that the device class and the path remain synchronized. Adding directories is permitted. Specifying a mismatched number of directories can cause a runtime failure.

The default value for DIRECTORY is the directory of the server at the time the command is issued. The Windows registry is used to locate the default value.

Use a naming convention that you can use to associate the directory with a particular physical drive. This can help ensure that your configuration is valid for sharing the FILE library between the server and storage agent. If the storage agent is on a Windows system, use a universal naming convention (UNC) name. When the storage agent lacks permission to access remote storage, it experiences mount failures.

Windows The account that is associated with the storage agent service must either be an account within the local administrator's group or an account within the domain administrator's group. If the account is in the local administrator's group, the user ID and password must match that of an account with permissions to access storage as provided by the system that administers the remote share. For example, if a SAMBA server is providing access to remote storage, the user ID and password in the SAMBA configuration must match that of the local administrator user ID and password associated with the storage agent service.

```
define devclass file devtype=file shared=yes mountlimit=1
directory=d:\filedir\dir1
define path sta1 file1 srctype=server desttype=drive
library=file1 device=file
directory=\\192.168.1.10\filedir\dir1
```

In the previous example, the DEFINE DEVCLASS command establishes the shared file system in the directory that is accessed by the server as D:\FILEDIR\DIR1. The storage agent, however, is using UNC name \\192.168.1.10\FILEDIR\DIR1. This means that the system with TCP/IP address 192.168.1.10 is sharing the same directory using FILEDIR as the shared name. Also, the storage agent service has an account that can access this storage. It can access it either because it is associated with a local account with the same user ID and password as 192.168.1.10 or it is associated with a domain account that is available on both the storage agent and on 192.168.1.10. If appropriate to the installation, you can replace the 192.168.1.10 with a symbolic name such as:

```
example.yourcompany.com
```

Attention:

1. Storage agents access FILE volumes by replacing a directory name in a volume name with a directory name from a directory in the list provided with the DEFINE PATH command. Directories that are specified with this parameter are not validated on the server.
2. IBM Spectrum Protect does not create shares or permissions, or mount the target file system. You must complete these actions before you start the storage agent.

Example: Define a path from a server to a drive

Define a path from a server to a drive. In this case, the server name is *NET1*, the drive name is *TAPEDRV6*, the library is *NETLIB*, and the device name is *mt4*. Set AUTODETECT to NO.

```
define path net1 tapedrv6 srctype=server autodetect=no desttype=drive
    library=netlib device=mt4
```

Example: Define a path from a data mover server to a drive for backup and restore

Define a path from the data mover that is a NAS file server to the drive that the NAS file server will use for backup and restore operations. In this example, the NAS data mover is *NAS1*, the drive name is *TAPEDRV3*, the library is NASLIB, and the device name for the drive is *rst0l*.

```
define path nas1 tapedrv3 srctype=datamover desttype=drive library=naslib
    device=rst0l
```

Linux

Example: Define a path from a storage agent to a drive for backup and restore

Define a path from storage agent *SA1* to the drive that the storage agent uses for backup and restore operations. In this example, the library is *TSMLIB*, the drive is *TAPEDRV4*, and the device name for the drive is /dev/tsmscsi/mt3.

```
define path sa1 tapedrv4 srctype=server desttype=drive library=tsmlib
    device=/dev/tsmscsi/mt3
```

AIX | Windows

Example: Define a path from a storage agent to a drive for backup and restore

Define a path from storage agent *SA1* to the drive that the storage agent uses for backup and restore operations. In this example, the library is *TSMLIB*, the drive is *TAPEDRV4*, and the device name for the drive is /dev/mt3.

```
define path sa1 tapedrv4 srctype=server desttype=drive library=tsmlib
    device=/dev/mt3
```

AIX | Windows

Example: Define a path to give a storage agent access to shared disk storage

Define a path that gives the storage agent access to files on disk storage that is shared with the server. Drive *FILE9* is defined to library *FILE1* on the server. The storage agent *SA1* accesses *FILE9*. On the storage agent, this data is on directory \\192.168.1.10\filedata.

AIX The data for *FILE9* resides on the server at /tsmdata/filedata.

Windows The data for *FILE9* resides on the server at d:\tsmdata\filedata.

```
define path sa1 file9 srctype=server desttype=drive library=file1 device=file
    directory="\\192.168.1.10\filedata"
```

Example: Configure a storage agent to use a FILE library

The following example illustrates the importance of matching device classes and paths to ensure that storage agents can access newly created FILE volumes.

Suppose you want to use these three directories for a FILE library: Windows

- c:\server
- d:\server
- e:\server

AIX | Linux

- /opt/tivoli1
- /opt/tivoli2
- /opt/tivoli3

1. Use the following command to set up a FILE library named CLASSA with one drive named CLASSA1 on SERVER1: Windows

   ```
   define devclass classa devtype=file
   directory="c:\server,d:\server,e:\server"
   shared=yes mountlimit=1
   ```

   AIX | Linux

   ```
   define devclass classa devtype=file
   directory="/opt/tivoli1,/opt/tivoli2,/opt/tivoli3"
   ```

```
shared=yes mountlimit=1
```

2. You want the storage agent STA1 to be able to use the FILE library, so you define the following path for storage agent STA1:

   Windows

   ```
   define path sta1 classa1 srctype=server desttype=drive device=file
   directory="\\192.168.1.10\c\server,\\192.168.1.10\d\server,
   \\192.168.1.10\e\server" library=classa
   ```

   AIX | Linux

   ```
   define path sta1 classa1 srctype=server desttype=drive device=file
   directory="/opt/ibm1,/opt/ibm2,/opt/ibm3" library=classa
   ```

   Windows In this scenario, the storage agent, STA1, replaces the directory name c:\server with the directory name \\192.168.1.10\c\server to access FILE volumes that are in the c:\server directory on the server.

   AIX | Linux In this scenario, the storage agent, STA1, replaces the directory name /opt/tivoli1 with the directory name /opt/ibm1/ to access FILE volumes that are in the /opt/tivoli1 directory on the server.

3. Windows File volume c:\server\file1.dsm is created by SERVER1. If you later change the first directory for the device class with the following command:

   ```
   update devclass classa directory="c:\otherdir,d:\server,e:\server"
   ```

   SERVER1 is still able to access file volume c:\server\file1.dsm, but the storage agent STA1 is not able to access it because a matching directory name in the PATH directory list no longer exists. If a directory name is not available in the directory list that is associated with the device class, the storage agent can lose access to a FILE volume in that directory. Although the volume is still accessible from the server for reading, failure of the storage agent to access the FILE volume can cause operations to be retried on a LAN-only path or to fail.

4. If file volume /opt/tivoli1/file1.dsm is created on SERVER1, and if the following command is issued,

   ```
   update devclass classa directory="/opt/otherdir,/opt/tivoli2,
   /opt/tivoli3"
   ```

   SERVER1 is still able to access file volume /opt/tivoli1/file1.dsm, but the storage agent STA1 is not able to access it because a matching directory name in the PATH directory list no longer exists. If a directory name is not available in the directory list that is associated with the device class, the storage agent can lose access to a FILE volume in that directory. Although the volume is still accessible from the server for reading, failure of the storage agent to access the FILE volume can cause operations to be retried on a LAN-only path or to fail.

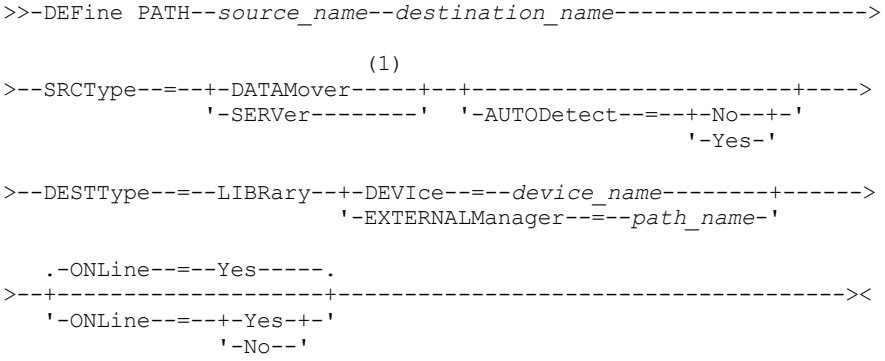
DEFINE PATH (Define a path when the destination is a library)

Use this syntax when defining a path to a library.

Privilege class

To issue this command you must have system privilege or unrestricted storage privilege.

Syntax



Notes:

1. DATAMOVER only applies to NAS devices.

Parameters

source_name (Required)
Specifies the name of source for the path. This parameter is required.

destination_name (Required)
Specifies the name of the destination. This parameter is required.
Attention: To define a path from a NAS data mover to a library, the library must have LIBTYPE of SCSI, 349x, or ACSLS.

SRCType (Required)
Specifies the type of the source. This parameter is required. Possible values are:

DATAMover
Specifies that a data mover is the source.

SERVer
Specifies that a storage agent is the source.

AUTODetect
Specifies whether the serial number for a drive or library will be automatically updated in the database at the time that the path is defined. This parameter is optional. This parameter is only valid for paths defined from the local server to a drive or a library. Possible values are:

No
Specifies that the serial number will not be automatically updated. The serial number is still compared with what is already in the database for the device. The server issues a message if there is a mismatch.

Yes
Specifies that the serial number will be automatically updated to reflect the same serial number that the drive reports to IBM Spectrum Protect™.
Important:

1. If you did not set the serial number when you defined the drive or the library, the server always tries to detect the serial number, and AUTODETECT defaults to YES. If you have previously entered a serial number, then AUTODETECT defaults to NO.
2. The use of AUTODETECT=YES in this command means that the serial number set in the drive or library definition is updated with the detected serial number.
3. Depending on the capabilities of the device, the AUTODETECT parameter may not be supported.

DESTType=LIBRary (Required)
Specifies that a library is the destination. This parameter is required.

DEVIce
Specifies the name of the device as known to the source, or FILE if the device is a logical drive in a FILE library.
AIX Windows The source uses the device name to access the library. See Table 1 for examples.

Table 1. Examples of device names

Source to destination	Example
Server to a library	AIX /dev/lb4 Linux /dev/tsmscsi/lb4 Windows lb4.1
Storage agent to a drive when the drive is a logical drive in a FILE library	FILE
NAS data mover to a library	mc0

Linux The source uses the device name to access the library. See Table 2 for examples.

Table 2. Examples of device names

Source to destination	Example
Server to a library	/dev/tsmscsi/lb4
NAS data mover to a library	mc0

Important:

- AIX | Linux For 349X libraries, the alias name is a symbolic name that is specified in the /etc/ibmatl.conf file. Windows For 349X libraries, the alias name is a symbolic name that is specified in the c:\winnt\ibmatl.conf file. For more information, see *IBM Tape Device Drivers Installation and User's Guide*, which can be downloaded from the IBM® Systems support site at http://www.ibm.com/support/docview.wss?uid=ssg1S7002972.
- For information about how to obtain names for devices that are connected to a NAS file server, consult the product information for the file server. For example, for a NetApp file server, connect to the file server using Telnet and issue the SYSCONFIG command. Use this command to determine device names for drives:

  ```
  sysconfig -t
  ```

  Use this command to determine the device name for a library:

  ```
  sysconfig -m
  ```

EXTERNALManager
: Specifies the location of the external library manager where IBM Spectrum Protect can send media access requests. Use single quotation marks around the value of this parameter. For example, enter: AIX

  ```
  /usr/lpp/GESedt-acsls/bin/elmdt
  ```

  Linux

  ```
  /opt/GESedt-acsls/bin/elmdt
  ```

  Windows

  ```
  C:\Program Files\GES\EDT-ACSLS\bin\elmdt.exe
  ```

  This parameter is required when the library name is an external library.

ONLine
: Specifies whether the path is available for use. This parameter is optional. The default is YES. Possible values are:

  Yes
  : Specifies that the path is available for use.

  No
  : Specifies that the path is not available for use.

  The source and the destination must both be available to use the path.

  Attention: If the path to a library is offline, the server will not be able to access the library. If the server is halted and restarted while the path to the library is offline, the library will not be initialized.

Example: Define a path from a server to a library

Define a path from the server SATURN to the SCSI type library SCSILIB: AIX

```
define path saturn scsilib srctype=server
desttype=library device=/dev/lb3
```

Linux

```
define path saturn scsilib srctype=server
desttype=library device=/dev/tsmscsi/lb3
```

Windows

```
define path saturn scsilib srctype=server
desttype=library device=lb3.0.0.0
```

AIX | Linux

DEFINE PATH (Define a path when the destination is a ZOSMEDIA library)

Use this syntax when defining a path to a ZOSMEDIA library. You must first define the z/OS® media server in your configuration with the DEFINE SERVER command.

Privilege class

To issue this command you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DEFine PATH--source_name--destination_name------------------>

>--SRCType--=--SERVer--DESTType--=--LIBRary--------------------->

                                  .-ONLine--=--Yes-----.
>--ZOSMEDIASERVER--=--server_name--+--------------------+------><
                                  '-ONLine--=--+-Yes-+-'
                                               '-No--'
```

Parameters

source_name (Required)
: Specifies the name of source for the path.

destination_name (Required)
: Specifies the name of the ZOSMEDIA library.

SRCType=SERVer (Required)
: Specifies that a storage agent or server is the source.

DESTType=LIBRary (Required)
: Specifies that a library is the destination.

ZOSMEDIAServer (Required)
: Specifies the name of the server that represents a Tivoli® Storage Manager for z/OS Media server.

ONLine
: Specifies whether the path is available for use. This parameter is optional. The default is YES. Possible values are:

  Yes
  : Specifies that the path is available for use.

  No
  : Specifies that the path is not available for use.

  The source and the destination must both be available to use the path.

  Attention: If the path to a library is offline, the server will not be able to access the library. If the server is halted and restarted while the path to the library is offline, the library will not be initialized.

  If the z/OS media server cannot be accessed during initialization of the IBM Spectrum Protect™ server, the library path will be set offline. Use the UPDATE PATH command and specify ONLINE=YES to vary the ZOSMEDIA library back online.

DEFINE POLICYSET (Define a policy set)

Use this command to define a policy set in a policy domain. A policy set contains management classes, which contain copy groups. You can define one or more policy sets for each policy domain.

To put a policy set into effect, you must activate the policy set by using the ACTIVATE POLICYSET command. Only one policy set can be active in a policy domain. The copy groups and management classes within the active policy set determine the rules by which client nodes perform backup, archive, and space management operations, and how the client files stored are managed.

Use the VALIDATE POLICYSET command to verify that a policy set is complete and valid before activating it with the ACTIVATE POLICYSET command.

Privilege class

To issue this command you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the policy set belongs.

Syntax

```
>>-DEFine POlicyset--domain_name--policy_set_name--------------->

>--+---------------------------+--------------------------><
   '-DESCription--=--description-'
```

Parameters

domain_name (Required)
: Specifies the name of the policy domain to which the policy set belongs.

policy_set_name (Required)
: Specifies the name of the policy set. The maximum length of this name is 30 characters. You cannot define a policy set named ACTIVE.

DESCription
: Specifies a description for the new policy set. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters.

Example: Define a policy set

Define a policy set called `SUMMER` for the `PROG1` policy domain and include the description, "Programming Group Policies."

```
define policyset prog1 summer
description="Programming Group Policies"
```

Related commands

Table 1. Commands related to DEFINE POLICYSET

Command	Description
ACTIVATE POLICYSET	Validates and activates a policy set.
COPY MGMTCLASS	Creates a copy of a management class.
COPY POLICYSET	Creates a copy of a policy set.
DEFINE DOMAIN	Defines a policy domain that clients can be assigned to.
DEFINE MGMTCLASS	Defines a management class.
DELETE POLICYSET	Deletes a policy set, including its management classes and copy groups, from a policy domain.
QUERY POLICYSET	Displays information about policy sets.
UPDATE POLICYSET	Changes the description of a policy set.
VALIDATE POLICYSET	Verifies and reports on conditions the administrator must consider before activating the policy set.

DEFINE PROFASSOCIATION (Define a profile association)

Use this command on a configuration manager to associate one or more objects with a configuration profile for distribution to subscribing managed servers. After a managed server subscribes to a profile, the configuration manager sends object definitions associated with the profile to the managed server where they are stored in the database. Objects created this way in the database of a managed server become managed objects. An object can be associated with more than one profile.

You can use this command to define an initial set of profile associations and to add to existing associations.

You can associate the following types of objects with a profile:

- Administrator registrations and authorities
- Policy domains, which include the domains' policy sets, management classes, copy groups, and client schedules
- Administrative schedules
- Server command scripts
- Client option sets
- Server definitions

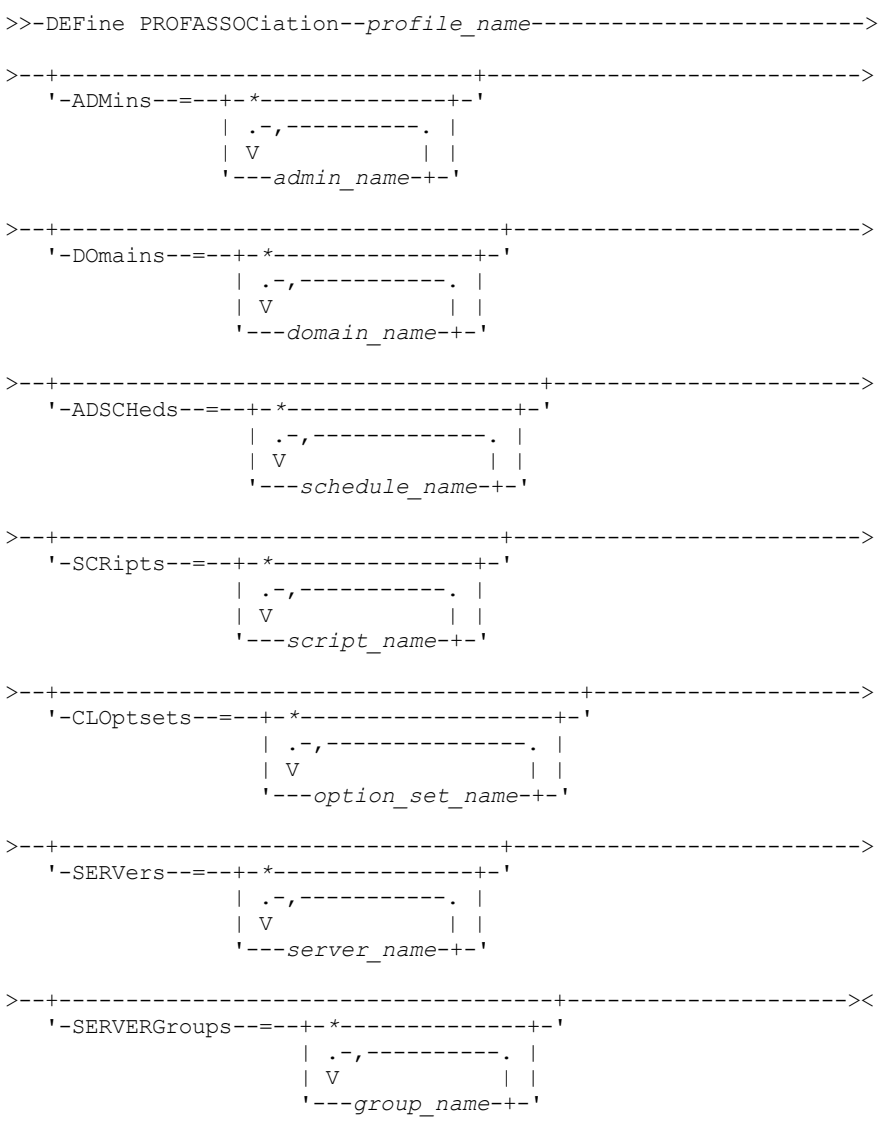
- Server group definitions

Tip: The configuration manager does not distribute status information for an object to managed servers. For example, information such as the number of days since an administrator last accessed the server is not distributed to managed servers. This type of information is maintained in the databases of the individual managed servers.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

profile_name (Required)
: Specifies the name of the configuration profile.

ADMins
: Specifies administrators to associate with the profile. You can use wildcard characters in the names. You can specify more than one name by separating the names with commas and no intervening spaces. Use the match-all definition, an asterisk (*) by itself, to specify all administrators that are registered with the configuration manager. If you specify the match-all definition and later add more administrators, they are automatically distributed through the profile.
The configuration manager distributes the administrator name, password, contact information, and authorities of administrators associated with the profile. The configuration manager does not distribute the following:

- The administrator named SERVER_CONSOLE, even if you use a match-all definition
- The locked or unlocked status of an administrator

When the profile already has administrators associated with it, the following apply:

- If you specify a list of administrators and a list already exists, IBM Spectrum Protect™ combines the new list with the existing list.
- If you specify a match-all definition and a list of administrators already exists, IBM Spectrum Protect replaces the list with the match-all definition.
- If you specify a list of administrators, and a match-all definition had previously been specified, IBM Spectrum Protect ignores the list. To remove the match-all definition, issue the DELETE PROFASSOCIATION command with the ADMINS=* parameter.

DOmains

Specifies policy domains to associate with the profile. You can use wildcard characters in the names. You can specify more than one name by separating the names with commas and no intervening spaces. Use the match-all definition, an asterisk (*) by itself, to specify all domains that are defined on the configuration manager. If you specify the match-all definition and later add more domains, they are automatically distributed through the profile.

The configuration manager distributes domain information that includes definitions of policy domains, policy sets, management classes, copy groups, and client schedules. The configuration manager does not distribute the ACTIVE policy set. Administrators on a managed server can activate any policy set within a managed domain on a managed server.

When the profile already has domains associated with it, the following apply:

- If you specify a list of domains and a list already exists, IBM Spectrum Protect combines the new list with the existing list.
- If you use a match-all definition and a list of domains already exists, IBM Spectrum Protect replaces the list with the match-all definition.
- If you specify a list of domains, and a match-all definition had previously been specified, IBM Spectrum Protect ignores the list. To remove the match-all definition, issue the DELETE PROFASSOCIATION command with the DOMAINS=* parameter.

Important: Client operations such as backup and archive fail if destination pools do not exist. Therefore, managed servers that subscribe to this profile must have definitions for any storage pools specified as destinations in the associated domains. Use the RENAME STGPOOL command to rename existing storage pools to match the destination names distributed.

ADSCHeds

Specifies administrative schedules to associate with the profile. You can use wildcard characters in the names. You can specify more than one name by separating the names with commas and no intervening spaces. Use the match-all definition, an asterisk (*) by itself, to specify all administrative schedules that are defined on the configuration manager. If you specify the match-all definition and later add more administrative schedules, they are automatically distributed through the profile.
Tip: Administrative schedules are not active when they are distributed by a configuration manager. An administrator on a managed server must activate any schedule to have it run on that server.
When the profile already has administrative schedules associated with it, the following apply:

- If you specify a list of administrative schedules and a list already exists, IBM Spectrum Protect combines the new list with the existing list.
- If you use a match-all definition and a list of administrative schedules already exists, IBM Spectrum Protect replaces the list with the match-all definition.
- If you specify a list of administrative schedules, and a match-all definition had previously been specified, IBM Spectrum Protect ignores the list. To remove the match-all definition, issue the DELETE PROFASSOCIATION command with the ADSCHEDS=* parameter.

SCRipts

Specifies server command scripts to associate with the profile. You can use wildcard characters in the names. You can specify more than one name by separating the names with commas and no intervening spaces. Use the match-all definition, an asterisk (*) by itself, to specify all scripts that are defined on the configuration manager. If you specify the match-all definition and later add more scripts, they are automatically distributed through the profile.
When the profile already has scripts associated with it, the following apply:

- If you specify a list of scripts and a list already exists, IBM Spectrum Protect combines the new list with the existing list.

- If you use a match-all definition and a list of scripts already exists, IBM Spectrum Protect replaces the list with the match-all definition.
- If you specify a list of scripts, and a match-all definition had previously been specified, IBM Spectrum Protect ignores the list. To remove the match-all definition, issue the DELETE PROFASSOCIATION command with the SCRIPTS=* parameter.

CLOptsets

Specifies client option sets to associate with the profile. You can use wildcard characters in the names. You can specify more than one name by separating the names with commas and no intervening spaces. Use the match-all definition, an asterisk (*) by itself, to specify all client option sets that are defined on the configuration manager. If you specify the match-all definition and later add more client option sets, they are automatically distributed through the profile.
When the profile already has client option sets associated with it, the following apply:

- If you specify a list of client option sets and a list already exists, IBM Spectrum Protect combines the new list with the existing list.
- If you use a match-all definition and a list of client option sets already exists, IBM Spectrum Protect replaces the list with the match-all definition.
- If you specify a list of client option sets, and a match-all definition had previously been specified, IBM Spectrum Protect ignores the list. To remove the match-all definition, issue the DELETE PROFASSOCIATION command with the CLOPSETS=* parameter.

SERVers

Specifies server definitions to associate with the profile. The definitions are distributed to managed servers that subscribe to this profile. You can use wildcard characters in the names. You can specify more than one name by separating the names with commas and no intervening spaces. Use the match-all definition, an asterisk (*) by itself, to specify all servers that are defined on the configuration manager. If you specify the match-all definition and later add more servers, they are automatically distributed through the profile.

The configuration manager distributes the following server attributes: communication method, IP address, port address, server password, URL, and the description. Distributed server definitions always have the ALLOWREPLACE attribute set to YES on the managed server, regardless of this parameter's value on the configuration manager. On the managed server, you can use the UPDATE SERVER command to set all other attributes.

When the profile already has servers associated with it, the following apply:

- If you specify a list of servers and a list already exists, IBM Spectrum Protect combines the new list with the existing list.
- If you use a match-all definition and a list of servers already exists, IBM Spectrum Protect replaces the list with the match-all definition.
- If you specify a list of servers, and a match-all definition had previously been specified, IBM Spectrum Protect ignores the list. To remove the match-all definition, issue the DELETE PROFASSOCIATION command with the SERVERS=* parameter.

Important:

1. A server definition on a managed server is not replaced by a definition from the configuration manager unless you have allowed replacement of the definition on the managed server. To allow replacement, on the managed server update the server definition by using the UPDATE SERVER command with ALLOWREPLACE=YES.
2. If a configuration manager distributes a server definition to a managed server, and a server group of the same name exists on the managed server, the distributed server definition replaces the server group definition.

SERVERGroups

Specifies server groups to associate with the profile. You can use wildcard characters in the names. You can specify more than one name by separating the names with commas and no intervening spaces. Use the match-all definition, an asterisk (*) by itself, to specify all server groups that are defined on the configuration manager. If you specify the match-all definition and later add more server groups, they are automatically distributed through the profile.
Tip: A configuration manager does not distribute a server group definition to a managed server if the managed server has a server defined with the same name as that of the server group.
When the profile already has server groups associated with it, the following apply:

- If you specify a list of server groups and a list already exists, IBM Spectrum Protect combines the new list with the existing list.
- If you use a match-all definition and a list of server groups already exists, IBM Spectrum Protect replaces the list with the match-all definition.

- If you specify a list of server groups, and a match-all definition had previously been specified, IBM Spectrum Protect ignores the list. To remove the match-all definition, issue the DELETE PROFASSOCIATION command with the SERVERGROUPS=* parameter.

Example: Associate a specific domain with a specific profile

Associate a domain named MARKETING with a profile named DELTA.

```
define profassociation delta domains=marketing
```

Example: Associate all domains with a specific profile

You have already associated a list of domains with a profile named GAMMA. Now associate all domains defined on the configuration manager with the profile.

```
define profassociation gamma domains=*
```

Related commands

Table 1. Commands related to DEFINE PROFASSOCIATION

Command	Description
COPY PROFILE	Creates a copy of a profile.
DEFINE PROFILE	Defines a profile for distributing information to managed servers.
DELETE PROFASSOCIATION	Deletes the association of an object with a profile.
DELETE PROFILE	Deletes a profile from a configuration manager.
LOCK PROFILE	Prevents distribution of a configuration profile.
NOTIFY SUBSCRIBERS	Notifies servers to refresh their configuration information.
QUERY PROFILE	Displays information about configuration profiles.
SET CONFIGMANAGER	Specifies whether a server is a configuration manager.
UNLOCK PROFILE	Enables a locked profile to be distributed to managed servers.
UPDATE PROFILE	Changes the description of a profile.

DEFINE PROFILE (Define a profile)

Use this command on a configuration manager to define a profile (a set of configuration information) that can be distributed to managed servers.

After defining a profile, you can use the DEFINE PROFASSOCIATION command to specify objects to be distributed to managed servers subscribing to the profile.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DEFine PROFIle--profile_name--------------------------------->

>--+-----------------------------+----------------------------><
   '-DESCription--=--description-'
```

Parameters

profile_name (Required)

Specifies the name of the profile. The maximum length of the name is 30 characters.

DESCription
: Specifies a description of the profile. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters. This parameter is optional.

Example: Define a new profile

Define a profile named ALPHA with a description of "Programming Center."

```
define profile alpha
description="Programming Center"
```

Related commands

Command	Description
COPY PROFILE	Creates a copy of a profile.
DEFINE PROFASSOCIATION	Associates objects with a profile.
DEFINE SUBSCRIPTION	Subscribes a managed server to a profile.
DELETE PROFASSOCIATION	Deletes the association of an object with a profile.
DELETE PROFILE	Deletes a profile from a configuration manager.
LOCK PROFILE	Prevents distribution of a configuration profile.
QUERY PROFILE	Displays information about configuration profiles.
SET CONFIGMANAGER	Specifies whether a server is a configuration manager.
UNLOCK PROFILE	Enables a locked profile to be distributed to managed servers.
UPDATE PROFILE	Changes the description of a profile.

DEFINE RECMEDMACHASSOCIATION (Associate recovery media with a machine)

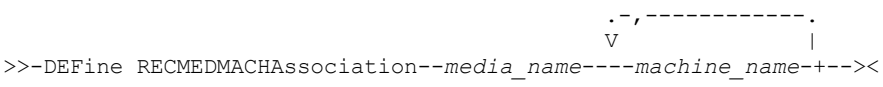
Use this command to associate recovery media with one or more machines. A machine is associated with recovery media so that the location of the boot media and its list of volume names are available to recover the machine. To retrieve the information, issue the QUERY MACHINE command. This information will be included in the plan file to help you recover the client machines.

To associate a machine with recovery media, both the machine and media must be defined to IBM Spectrum Protect™. A machine remains associated with the media until the association, the media, or the machine is deleted.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

media_name (Required)
: Specifies the name of the recovery media with which one or more machines will be associated.

machine_name (Required)
: Specifies the name of the machines to be associated with the recovery media. A machine can be associated with multiple recovery media. To specify a list of machines, separate the names with commas and no intervening spaces. You can use

wildcard characters to specify a name.

Example: Associate machines to recovery media

Associate machines DISTRICT1 and DISTRICT5 to the DIST5RM recovery media.

```
define recmedmachassociation dist5rm
district1,district5
```

Related commands

Table 1. Commands related to DEFINE RECMEDMACHASSOCIATION

Command	Description
DEFINE MACHINE	Defines a machine for DRM.
DEFINE RECOVERYMEDIA	Defines the media required to recover a machine.
DELETE MACHINE	Deletes a machine.
DELETE RECMEDMACHASSOCIATION	Deletes association between recovery media and a machine.
DELETE RECOVERYMEDIA	Deletes recovery media.
QUERY MACHINE	Displays information about machines.
QUERY RECOVERYMEDIA	Displays media available for machine recovery.

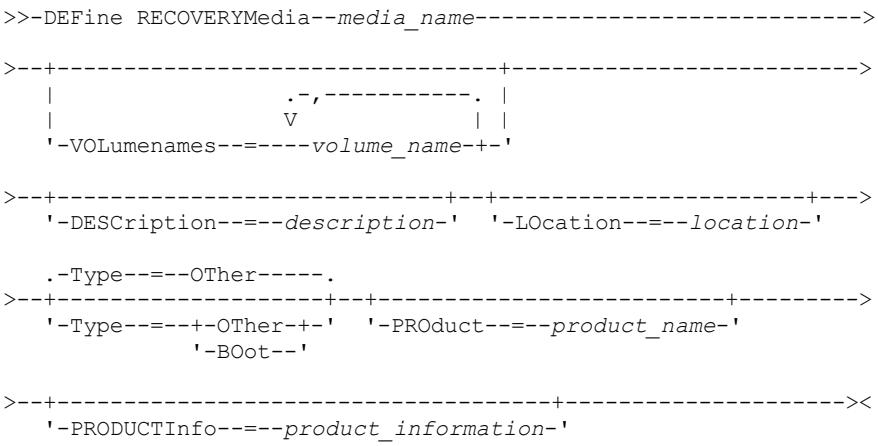
DEFINE RECOVERYMEDIA (Define recovery media)

Use this command to define the media needed to recover a machine. The same media can be associated with multiple machines. To display the information, use the QUERY MACHINE command. This information will be included in the plan file to help you to recover the client machines.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

media_name (Required)
: Specifies the name of the recovery media to be defined. The name can be up to 30 characters.

VOLumenames
: Specifies the names of volumes that contain the recoverable data (for example, operating system image copies). This parameter is required if you specify a media type of BOOT. Specify boot media volume names in the order in which they are

to be inserted into the machine at recovery time. The maximum length of the volume names list is 255 characters. Enclose the list in quotation marks if it contains any blank characters.

DESCription
: Specifies the description of the recovery media. This parameter is optional. The maximum length is 255 characters. Enclose the text in quotation marks if it contains any blank characters.

LOcation
: Specifies the location of the recovery media. This parameter is optional. The maximum length is 255 characters. Enclose the text in quotation marks if it contains any blank characters.

Type
: Specifies the type of recovery media. This parameter is optional. The default is OTHER.

  BOot
  : Specifies that this is boot media. You must specify volume names if the type is BOOT.

  OTher
  : Specifies that this is not boot media. For example, a CD that contains operating system manuals.

PROduct
: Specifies the name of the product that wrote to this media. This parameter is optional. The maximum length is 16 characters. Enclose the text in quotation marks if it contains any blank characters.

PRODUCTInfo
: Specifies information about the product that wrote to the media. This would be information that you may need to restore the machine. This parameter is optional. The maximum length is 255 characters. Enclose the text in quotation marks if it contains any blank characters.

Example: Define the media needed to recover a machine

Define the recovery media named DIST5RM. Include a description and the location.

```
define recoverymedia dist5rm
description="district 5 base system image"
location="district 1 vault"
```

Related commands

Table 1. Commands related to DEFINE RECOVERYMEDIA

Command	Description
DEFINE RECMEDMACHASSOCIATION	Associates recovery media with a machine.
DELETE RECOVERYMEDIA	Deletes recovery media.
QUERY RECOVERYMEDIA	Displays media available for machine recovery.
UPDATE RECOVERYMEDIA	Changes the attributes of recovery media.

DEFINE SCHEDULE (Define a client or an administrative command schedule)

Use this command to create a client or administrative command schedule.

The DEFINE SCHEDULE command takes two forms: one if the schedule applies to client operations, one if the schedule applies to administrative commands. Within these two forms, you can select either classic or enhanced style schedules. The syntax and parameters for each form are defined separately.

For each schedule, a startup window is specified. The startup window is the time period during which the schedule must be initiated. The schedule will not necessarily complete processing within this window. If the server is not running when this window starts, but is started before the end of the defined window is reached, the schedule will run when the server is restarted. Options associated with each schedule style (classic and enhanced) determine when the startup windows should begin.

Table 1. Commands related to DEFINE SCHEDULE

Command	Description

Command	Description
COPY SCHEDULE	Creates a copy of a schedule.
DEFINE ASSOCIATION	Associates clients with a schedule.
DELETE SCHEDULE	Deletes a schedule from the database.
QUERY EVENT	Displays information about scheduled and completed events for selected clients.
QUERY SCHEDULE	Displays information about schedules.
SET MAXCMDRETRIES	Specifies the maximum number of retries after a failed attempt to execute a scheduled command.
SET MAXSCHEDSESSIONS	Specifies the maximum number of client/server sessions available for processing scheduled work.
SET RETRYPERIOD	Specifies the time between retry attempts by the client scheduler.
UPDATE SCHEDULE	Changes the attributes of a schedule.

- DEFINE SCHEDULE (Define a client schedule)
  Use the DEFINE SCHEDULE command to define a client schedule. IBM Spectrum Protect uses this schedule to automatically perform a variety of client operations for your client workstation at specified intervals or days. After you define a schedule, use the DEFINE ASSOCIATION command to associate the client with the schedule.
- DEFINE SCHEDULE (Define a schedule for an administrative command)
  Use the DEFINE SCHEDULE command to create a new schedule for processing an administrative command.

DEFINE SCHEDULE (Define a client schedule)

Use the DEFINE SCHEDULE command to define a client schedule. IBM Spectrum Protect™ uses this schedule to automatically perform a variety of client operations for your client workstation at specified intervals or days. After you define a schedule, use the DEFINE ASSOCIATION command to associate the client with the schedule.

You must start the client scheduler on the client workstation for IBM Spectrum Protect to process the schedule.

Not all clients can run all scheduled operations, even though you can define the schedule on the server and associate it with the client. For example, a Macintosh client cannot run a schedule when the action is to restore or retrieve files, or run an executable script. An executable script is also known as a command file, a batch file, or a script on different client operating systems.

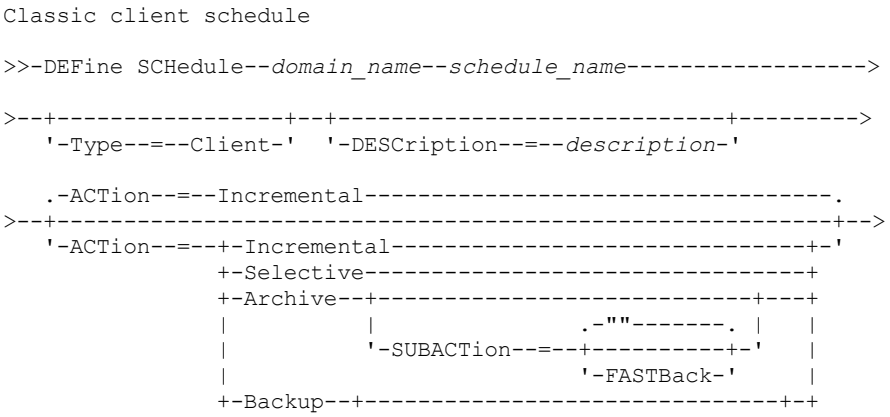
IBM Spectrum Protect cannot run multiple schedules concurrently for the same client node.

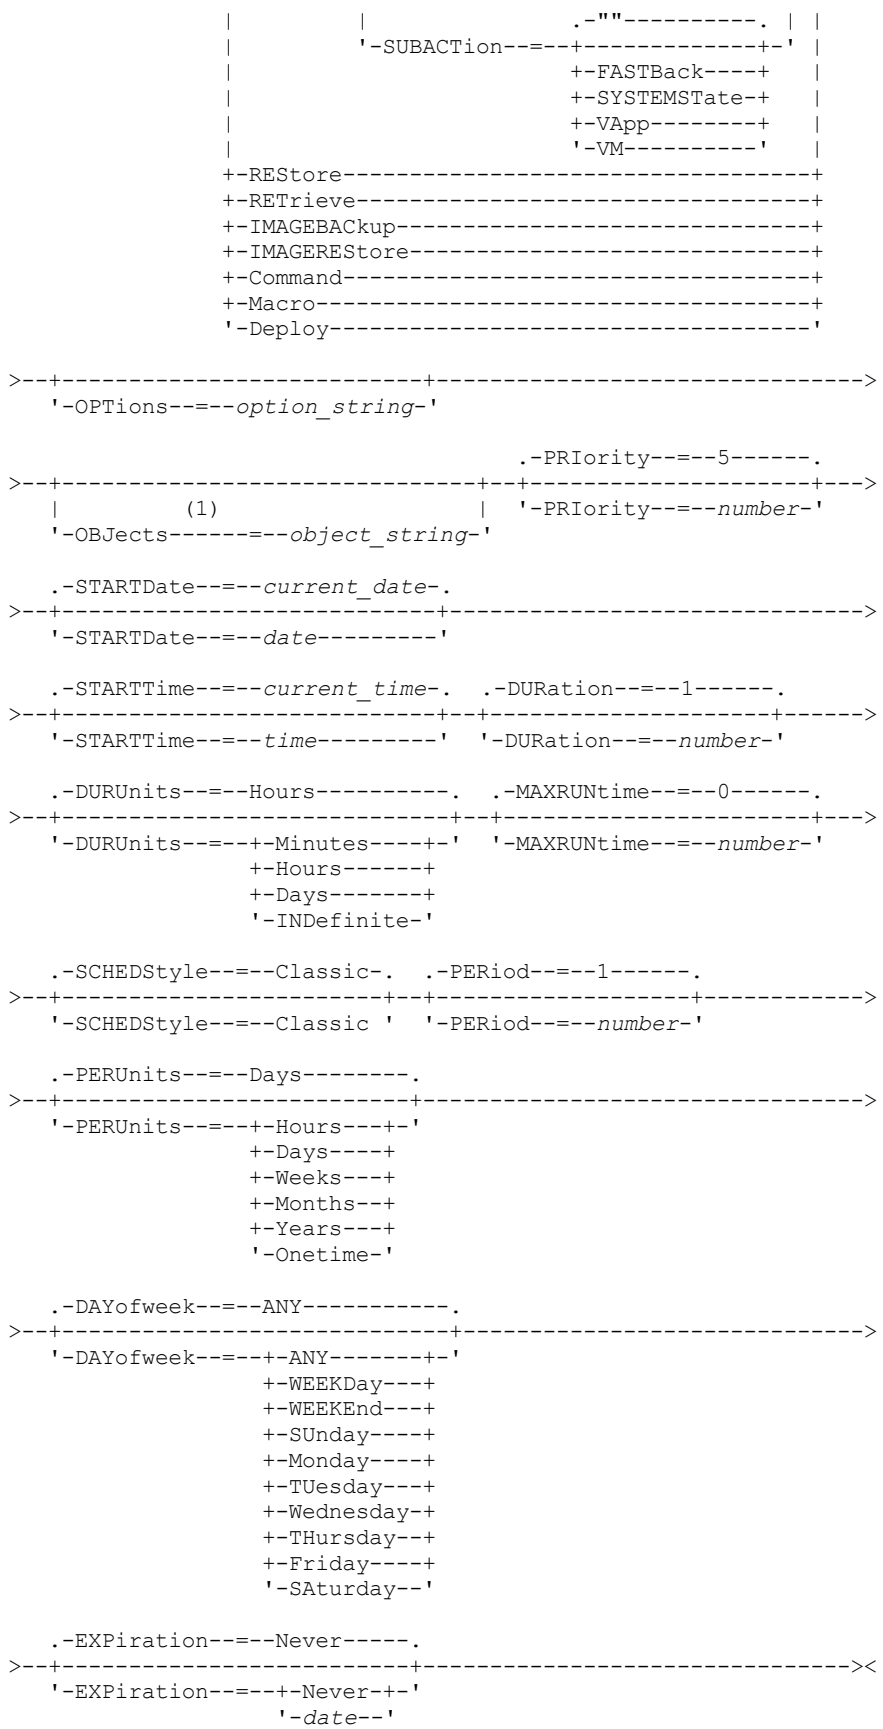
Privilege class

To define a client schedule, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the schedule belongs.

Syntax

Classic client schedule





Notes:

1. The OBJECTS parameter is optional when `ACTION=INCREMENTAL`, but is required for other actions.

Syntax

Enhanced client schedule

```

Notes:

1. The OBJECTS parameter is optional when `ACTION=INCREMENTAL`, but is required for other actions.

Parameters

domain_name (Required)
: Specifies the name of the policy domain to which this schedule belongs.

schedule_name (Required)
: Specifies the name of the schedule to be defined. You can specify up to 30 characters for the name.

Type=Client
: Specifies that a schedule for a client is defined. This parameter is optional.

DESCription
: Specifies a description of the schedule. This parameter is optional. You can specify up to 255 characters for the description. Enclose the description in quotation marks if it contains any blank characters.

ACTion
: Specifies the action that occurs when this schedule is processed. Possible values are:

  Incremental
  : Specifies that the schedule backs up all files that are new or that have changed since the last incremental backup. Incremental also backs up any file for which all existing backups might have expired.

  Selective
  : Specifies that the schedule backs up only files that are specified with the OBJECTS parameter.

  Archive
  : Specifies that the schedule archives files that are specified with the OBJECTS parameter.

  Backup
  : Specifies that the schedule backs up files that are specified with the OBJECTS parameter.

  REStore
  : Specifies that the schedule restores files that are specified with the OBJECTS parameter.

    When you specify ACTION=RESTORE for a scheduled operation, and the REPLACE option is set to PROMPT, no prompting occurs. If you set the option to PROMPT, the files are skipped.

    If you specify a second file specification, this second file specification acts as the restore destination. If you need to restore multiple groups of files, schedule one for each file specification that you need to restore.

  RETrieve
  : Indicates that the schedule retrieves files that are specified with the OBJECTS parameter.
    Remember: A second file that is specified acts as the retrieve destination. If you need to retrieve multiple groups of files, create a separate schedule for each group of files.

  IMAGEBACkup
  : Specifies that the schedule backs up logical volumes that are specified with the OBJECTS parameter.

  IMAGEREStore
  : Specifies that the schedule restores logical volumes that are specified with the OBJECTS parameter.

Command
: Specifies that the schedule processes a client operating system command or script that is specified with the OBJECTS parameter.

Macro
: Specifies that a client processes a macro whose file name is specified with the OBJECTS parameter.

SUBACTion
: You can specify one of the following values:

  ""
  : When a null string (two double quotes) is specified with ACTION=BACKUP the backup is an incremental.

  FASTBAck
  : Specifies that a FastBack client operation that is identified by the ACTION parameter is to be scheduled for processing. The ACTION parameter must be either ARCHIVE or BACKUP.

  SYSTEMSTate
  : Specifies that a client Systemstate backup is scheduled.

  VApp
  : Specifies that a client vApp backup is scheduled. A vApp is a collection of pre-deployed virtual machines.

  VM
  : Specifies that a client VMware backup operation is scheduled.

Deploy
: Specifies whether to update client workstations with deployment packages that are specified with the OBJECTS parameter. The OBJECTS parameter must contain two specifications, the package files to retrieve and the location from which to retrieve them. Ensure that the objects are in the order *files location*. For example:

  ```
  define schedule standard deploy_1 action=DEPLOY objects=
  "\\IBM_ANR_WIN\c$\tsm\maintenance\client\v6r2\Windows\X32\v620\v6200\*
  ..\IBM_ANR_WIN\"
  ```

  Values for the following options are restricted when you specify ACTION=DEPLOY:

  PERUNITS
  : Specify `PERUNITS=ONETIME`. If you specify `PERUNITS=PERIOD`, the parameter is ignored.

  DURUNITS
  : Specify `MINUTES`, `HOURS`, or `DAYS` for the DURUNITS parameter. Do not specify INDEFINITE.

  SCHEDSTYLE
  : Specify the default style, CLASSIC.

  The SCHEDULE command fails if the parameters do not conform to the required parameter values, such as the V.R.M.F.

OPTions
: Specifies the client options that you specify to the scheduled command at the time the schedule is processed. This parameter is optional.
  Only those options that are valid on the scheduled command can be specified for this parameter. Refer to the appropriate client manual for information about options that are valid from the command line. All options described there as valid only on the initial command line result in an error or are ignored when running the schedule from the server. For example, do not include the following options because they have no effect when the client processes the scheduled command:

  - MAXCMDRETRIES
  - OPTFILE
  - QUERYSCHEDPERIOD
  - RETRYPERIOD
  - SCHEDLOGNAME
  - SCHEDMODE
  - SERVERNAME
  - TCPCLIENTADDRESS
  - TCPCLIENTPORT

  Windows When you define a scheduler service by using the DSMCUTIL command or the backup-archive client GUI wizard, you specify an options file. You cannot override the options in that options file by issuing the scheduled command. You must modify the options in your scheduler service.

  If the option string contains multiple options or options with embedded spaces, surround the entire option string with one pair of apostrophes. Enclose individual options that contain spaces in quotation marks. A leading minus sign is required in

front of the option. Errors can occur if the option string contains spaces that are not quoted correctly.

The following examples show how to specify some client options:

- To specify `subdir=yes` and `domain all-local -systemobject`, enter:
  - `options='-subdir=yes -domain="all-local -c: -systemobject"'`
- To specify `domain all-local -c: -d:`, enter:
  - `options='-domain="all-local -c: -d:"'`

Windows Tip:

For Windows clients running in batch mode, if the use of quotation marks is necessary, use interactive mode or operating system escape characters. For additional information, see the following topics:

- Processing a series of commands from the administrative client
- Processing individual commands from the administrative client

OBJects

Specifies the objects for which the specified action is performed. Use a single space between each object. This parameter is required except when ACTION=INCREMENTAL. If the action is a backup, archive, retrieve, or restore operation, the objects are file spaces, directories, or logical volumes. If the action is to run a command or macro, the object is the name of the command or macro to run.

When you specify ACTION=INCREMENTAL without specifying a value for this parameter, the scheduled command is invoked without specified objects and attempts to process the objects as defined in the client option file. To select all file spaces or directories for an action, explicitly list them in the object string. Entering only an asterisk in the object string causes the backup to occur only for the directory where the scheduler was started.

Important:

- If you specify a second file specification, and it is not a valid destination, you receive this error:

  ```
  ANS1082E Invalid destination file specification <filespec> entered.
  ```

- If you specify more than two file specifications, you receive this error:

  ```
  ANS1102E Excessive number of command line arguments passed to the
  program!
  ```

When you specify ACTION=ARCHIVE, INCREMENTAL, or SELECTIVE for this parameter, you can list a maximum of twenty (20) file specifications.

Enclose the object string in double quotes if it contains blank characters (spaces), and then surround the double quotes with single quotes. If the object string contains multiple file names, enclose each file name with its own pair of double quotes, then surround the entire string with one pair of single quotes. Errors can occur if file names contain a space that is not quoted correctly.

Windows If you are using characters that have a special meaning for Windows users, such as commas, surround the entire argument in two pairs of double quotes, then surround the entire string with single quotes. The following examples show you how to specify some file names:

- To specify C:\FILE 2, D:\GIF FILES, and E:\MY TEST FILE, enter:
  - `OBJECTS='"C:\FILE 2" "D:\GIF FILES" "E:\MY TEST FILE"'`
- To specify D:\TEST FILE, enter:
  - `OBJECTS='"D:\TEST FILE"'`
- To specify D:TEST,FILE:
  - `OBJECTS='""D:\TEST,FILE""'`

AIX Linux The following examples show how to specify some file names:

- To specify /home/file 2, /home/gif files, and /home/my test file, enter:
  - `OBJECTS='"/home/file 2" "/home/gif files" "/home/my test file"'`
- To specify /home/test file, enter:
  - `OBJECTS='"/home/test file"'`

Windows Tip:

For Windows clients running in batch mode, if the use of double quotes is necessary, use interactive mode or operating system escape characters. For additional information, see the following topics:

- Processing a series of commands from the administrative client
- Processing individual commands from the administrative client

PRIority

Specifies the priority value for a schedule. This parameter is optional. You can specify an integer from 1 to 10, with 1 being the highest priority and 10 being the lowest. The default is 5.

If two or more schedules have the same window start time, the value you specify determines when IBM Spectrum Protect processes the schedule. The schedule with the highest priority starts first. For example, a schedule with PRIORITY=3 starts before a schedule with PRIORITY=5.

STARTDate

Specifies the date for the beginning of the window in which the schedule is first processed. This parameter is optional. The default is the current date. Use this parameter with the STARTTIME parameter to specify when the initial startup window of the schedule starts.

You can specify the date using one of the values below:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY+days **or** +days	The current date plus days specified. The maximum number of days you can specify is 9999.	TODAY +3 **or** +3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

STARTTime

Specifies the time for the beginning of the window in which the schedule is first processed. This parameter is optional. The default is the current time. This parameter is used in conjunction with the STARTDATE parameter to specify when the initial startup window begins.

You can specify the time using one of the values below:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes specified	NOW+02:00 **or** +02:00. If you issue this command at 5:00 with STARTTIME=NOW+02:00 or STARTTIME=+02:00, the beginning of the startup window is at 7:00.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes specified	NOW-02:00 **or** -02:00. If you issue this command at 5:00 with STARTTIME=NOW-02:00 or STARTTIME=-02:00, the beginning of the startup window is at 3:00.

DURation

Specifies the number of units that define the length of the startup window of the scheduled operation. This parameter is optional. This value must be from 1 to 999. The default is 1.

Use this parameter with the DURUNITS parameter to specify the length of the startup window. For example, if you specify DURATION=20 and DURUNITS=MINUTES, the schedule must be started within 20 minutes of the start date and start time. The default length of the startup window is 1 hour. The duration of the window must be shorter than the period between windows.

This value is ignored if you specify DURUNITS=INDEFINITE.

Tip: Define schedules with durations longer than 10 minutes. Doing this will give the IBM Spectrum Protect scheduler enough time to process the schedule and prompt the client.

DURUnits

Specifies the time units used to determine the duration of the window in which the schedule can start. This parameter is optional. The default is HOURS.

Use this parameter with the DURATION parameter to specify how long the startup window remains open to process the schedule. For example, if DURATION=20 and DURUNITS=MINUTES, the schedule must be started within 20 minutes of the start date and start time. The schedule may not necessarily complete processing within this window. If the schedule needs to be retried for any reason, the retry attempts must begin before the startup window elapses, or the operation does not restart.

The default value for the length of the startup window is 1 hour. You can specify one of the following values:

Minutes
: Specifies that the duration of the window is defined in minutes.

Hours
: Specifies that the duration of the window is defined in hours.

Days
: Specifies that the duration of the window is defined in days.

INDefinite
: Specifies that the startup window of the scheduled operation has an indefinite duration. The schedule can run any time after the scheduled start time, until the schedule expires. You cannot specify DURUNITS=INDEFINITE, unless you specify PERUNITS=ONETIME. The INDEFINITE value is not allowed with enhanced schedules.

MAXRUNtime

Specifies the maximum run time, which is the number of minutes during which all client sessions that are started by the scheduled operation should be completed. If sessions are still running after the maximum run time, the server issues a warning message, but the sessions continue to run.

Tip: The maximum run time is calculated from the beginning of the startup window and not from the time that sessions start within the startup window.

Restrictions:

- The value of the parameter is not distributed to servers that are managed by an enterprise configuration manager.
- The value of the parameter is not exported by the EXPORT command.

The parameter is optional. You can specify a number in the range 0-1440. The default value is 0. A value of 0 means that the maximum run time is indefinite, and no warning message is issued. The maximum run time must be greater than the startup window duration, which is defined by the DURATION and DURUNITS parameters.

For example, if the start time of a scheduled operation is 9:00 PM, and the duration of the startup window is 2 hours, the startup window is 9:00 PM - 11:00 PM. If the maximum run time is 240 minutes, that is, 4 hours, all client sessions for this operation should be completed by 1:00 AM. If one or more sessions are still running after 1:00 AM, the server issues a warning message.

Tip: Alternatively, you can specify a *Run time alert* value of 1:00 AM in the IBM Spectrum Protect Operations Center.

SCHEDStyle

This parameter is optional. SCHEDSTYLE defines either the interval between times when a schedule can run, or the days on which it runs. The default is the classic syntax.

Possible values are:

Classic
: The parameters for the Classic syntax are: PERIOD, PERUNITS, and DAYOFWEEK. You cannot use these parameters: MONTH, DAYOFMONTH, and WEEKOFMONTH.

Enhanced

The parameters for the Enhanced syntax are: MONTH, DAYOFMONTH, WEEKOFMONTH, and DAYOFWEEK. You cannot use these parameters: PERIOD and PERUNITS.

PERiod
Specifies the length of time between startup windows for this schedule. This parameter is optional. This parameter is used only with classic schedules. You can specify an integer from 1 to 999. The default is 1.

Use this parameter with the PERUNITS parameter to specify the period between startup windows. For example, if you specify PERIOD=5 and PERUNITS=DAYS (assuming that DAYOFWEEK=ANY), the operation is scheduled every five days after the initial start date and start time. The period between startup windows must exceed the duration of each window. The default is 1 day.

This value is ignored if you specify PERUNITS=ONETIME.

PERUnits
Specifies the time units used to determine the period between startup windows for this schedule. This parameter is optional. This parameter is used only with classic schedules. The default is DAYS.
Use this parameter with the PERIOD parameter to specify the period between startup windows. For example, if you specify PERIOD=5 and PERUNITS=DAYS (assuming that DAYOFWEEK=ANY), the operation is scheduled every 5 days after the initial start date and start time. The default is 1 day. You can specify one of the following values:

Hours
Specifies that the time between startup windows is in hours.
Days
Specifies that the time between startup windows is in days.
Weeks
Specifies that the time between startup windows is in weeks.
Months
Specifies that the time between startup windows is in months.

When you specify PERUNITS=MONTHS, the scheduled operation will be processed each month on the same date. For example, if the start date for the scheduled operation is 02/04/1998, the schedule will process on the 4th of every month thereafter. However, if the date is not valid for the next month, then the scheduled operation will be processed on the last valid date in the month. Thereafter, subsequent operations are based on this new date. For example, if the start date is 03/31/1998, the next month's operation will be scheduled for 04/30/1998. Thereafter, all subsequent operations will be on the 30th of the month until February. Because February has only 28 days, the operation will be scheduled for 02/28/1999. Subsequent operations will be processed on the 28th of the month.

Years
Specifies that the time between startup windows for the schedule is in years.

When you specify PERUNITS=YEARS, the scheduled operation will be processed on the same month and date of each year. For example, if the start date for the scheduled operation is 02/29/2004, the next year's scheduled operation will be 02/28/2005 because February only has 28 days. Thereafter, subsequent operations will be scheduled for February 28th.

Onetime
Specifies that the schedule processes once. This value overrides the value you specified for the PERIOD parameter.

DAYofweek
Specifies the day of the week on which the startup window for the schedule begins. This parameter is optional. You can specify different options for the DAYofweek parameter, depending on whether the schedule style was defined as Classic or Enhanced:

Classic Schedule
Specifies the day of the week on which the startup window for the schedule begins. This parameter is optional. You can either specify one day of the week, or WEEKDAY, WEEKEND, or ANY. If the start date and start time fall on a day that does not correspond to a day you specify, the start date and start time will be shifted forward in 24-hour increments until the DAYOFWEEK parameter is satisfied.

If you select a value for DAYOFWEEK other than ANY, and depending on the values for PERIOD and PERUNITS, schedules may not be processed when you would expect. The default is ANY.

Enhanced Schedule

Specifies the days of the week on which to run the schedule. You can either specify multiple days separated by commas and no intervening blanks, or WEEKDAY, WEEKEND, or ANY. If you specify multiple days, the schedule will run on each of the specified days. If you specify WEEKDAY or WEEKEND, you must also specify either WEEKOFMONTH=FIRST or WEEKOFMONTH=LAST, and the schedule will run just once per month.

The default value is ANY, meaning the schedule will run every day of the week or on the day or days determined by other enhanced schedule parameters. DAYOFWEEK must have a value of ANY (either by default or specified with the command) when used with the DAYOFMONTH parameter.

Possible values for the DAYofweek parameter are:

ANY
: Specifies that the startup window can begin on any day of the week.

WEEKDay
: Specifies that the startup window can begin on Monday, Tuesday, Wednesday, Thursday, or Friday.

WEEKEnd
: Specifies that the startup window can begin on Saturday or Sunday.

SUnday
: Specifies that the startup window begins on Sunday.

Monday
: Specifies that the startup window begins on Monday.

TUesday
: Specifies that the startup window begins on Tuesday.

Wednesday
: Specifies that the startup window begins on Wednesday.

THursday
: Specifies that the startup window begins on Thursday.

Friday
: Specifies that the startup window begins on Friday.

SAturday
: Specifies that the startup window begins on Saturday.

MONth
: Specifies the months of the year during which to run the schedule. This parameter is used only with enhanced schedules. Specify multiple values by using commas and no intervening blanks. The default value is ANY, which means that the schedule runs during every month of the year.

DAYOFMonth
: Specifies the day of the month to run the schedule. This parameter is used only with enhanced schedules. You can either specify ANY or a number from -31 through 31, excluding zero. Negative values are a day from the end of the month, counting backwards. For example, the last day of the month is -1, the next-to-the-last day of the month is -2, and so on. You can specify multiple values separated by commas and no intervening blanks. If you specify multiple values, the schedule runs on each of the specified days of the month. If multiple values resolve to the same day, the schedule runs only once that day.

  The default value is ANY. ANY means that the schedule runs on every day of the month or on the days determined by other enhanced schedule parameters. DAYOFMONTH must have a value of ANY (either by default or specified with the command) when used with the DAYOFWEEK or WEEKOFMONTH parameters.

WEEKofmonth
: Specifies the week of the month in which to run the schedule. This parameter is used only with enhanced schedules. A week is considered any seven-day period which does not start on a particular day of the week. You can specify FIRST, SECOND, THIRD, FOURTH, LAST, or ANY. You can specify multiple values separated by commas and no intervening blanks. If you specify multiple values, the schedule runs during each of the specified weeks of the month. If multiple values resolve to the same week, the schedule runs only once during that week.

  The default value is ANY. ANY means that the schedule runs during every week of the month or on the day or days determined by other enhanced schedule parameters. WEEKOFMONTH must have a value of ANY (either by default or specified with the command) when used with the DAYOFMONTH parameter.

EXPiration
: Specifies the date after which this schedule is no longer used. This parameter is optional. The default is NEVER. You can specify one of the following values:

  Never

Specifies that the schedule never expires.

expiration_date
Specifies the date on which this schedule expires, in MM/DD/YYYY format. If you specify an expiration date, the schedule expires at 23:59:59 on the date you specify.

Example: Define a schedule for a monthly incremental backup

Define a schedule named MONTHLY_BACKUP that initiates an incremental backup of all associated nodes. Specify the start date as Tuesday, May 1, 2001. This date does not match the specified day of the week (Sunday), so the initial startup window begins on the first Sunday after May 1, 2001 (05/01/2001). The startup windows for this schedule extend from 01:00 through 03:00. This monthly schedule initiates backup of c: and d: file spaces for all associated nodes.

```
define schedule standard monthly_backup
description="Monthly Backup of c: and d: drives"
objects="c:\* d:\*"
startdate=05/01/2001 starttime=01:00
duration=2 durunits=hours period=1
perunits=months dayofweek=sunday
```

Example: Define a schedule for a weekly incremental backup

Define a schedule named WEEKLY_BACKUP that initiates an incremental backup of all associated nodes. The initial startup window for this schedule extends from 23:00 on Saturday, June 7, 1997 (06/07/1997), to 03:00 on Sunday, June 8, 1997 (06/08/1997). Subsequent windows begin at 23:00, every Saturday. No messages are returned to the client node when this schedule is run.

```
define schedule employee_records weekly_backup
startdate=06/07/1997 starttime=23:00 duration=4
durunits=hours perunits=weeks
dayofweek=saturday options=-quiet
```

Example: Define a schedule that archives a specific directory every quarter

Define a schedule that archives specific files quarterly on the last Friday of the month.

```
define schedule employee_records quarterly_archive
starttime=20:00 action=archive
object=/home/employee/records/*
duration=1 durunits=hour schedstyle=enhanced
month=mar,jun,sep,dec weekofmonth=last dayofweek=fri
```

DEFINE SCHEDULE (Define a schedule for an administrative command)

Use the DEFINE SCHEDULE command to create a new schedule for processing an administrative command.

You can include scripts in an administrative command schedule so the commands are processed automatically.
Note:

1. You cannot schedule the MACRO command or the QUERY ACTLOG command.
2. If you are scheduling a command that specifies the WAIT parameter, the parameter must be set to YES in order for the process to provide a return code to the session that started it. For more information about the WAIT parameter, see Server command processing.

Privilege class

To define an administrative command schedule, you must have system privilege.

Syntax

```
Classic administrative schedule

Parameters

schedule_name (Required)
: Specifies the name of the schedule to be defined. You can specify up to 30 characters for the name.

Type=Administrative
: Specifies that a schedule for an administrative command is defined. This parameter is optional. An administrative command is assumed if the CMD parameter is specified.

CMD (Required)
: Specifies the administrative command to schedule for processing. The maximum length of the command is 512 characters. Enclose the administrative command in quotation marks if it contains any blank characters.
Restriction: You cannot specify redirection characters with this parameter.

ACTIVE
: Specifies whether IBM Spectrum Protect processes an administrative command schedule when the startup window occurs. This parameter is optional. The default is NO. The administrative command schedule must be set to the active state with the UPDATE SCHEDULE command so that IBM Spectrum Protect can process the schedule. Possible values are:

  YES

Specifies that IBM Spectrum Protect processes an administrative command schedule when the startup window begins.

NO

Specifies that IBM Spectrum Protect does not process an administrative command schedule when the startup window begins.

DESCription

Specifies a description of the schedule. This parameter is optional. You can specify up to 255 characters for the description. Enclose the description in quotation marks if it contains any blank characters.

PRIority

Specifies the priority value for a schedule. This parameter is optional. You can specify an integer from 1 to 10, with 1 being the highest priority and 10 being the lowest. The default is 5.

If two or more schedules have the same window start time, the value you specify determines when IBM Spectrum Protect processes the schedule. The schedule with the highest priority starts first. For example, a schedule with PRIORITY=3 starts before a schedule with PRIORITY=5.

STARTDate

Specifies the date for the beginning of the window in which the schedule is first processed. This parameter is optional. The default is the current date. Use this parameter with the STARTTIME parameter to specify when the initial startup window of the schedule starts.

You can specify the date using one of the values below:

Value	**Description**	**Example**
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY+days **or** +days	The current date plus days specified. The maximum number of days you can specify is 9999.	TODAY +3 **or** +3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

STARTTime

Specifies the time for the beginning of the window in which the schedule is first processed. This parameter is optional. The default is the current time. This parameter is used in conjunction with the STARTDATE parameter to specify when the initial startup window begins.

You can specify the time using one of the values below:

Value	**Description**	**Example**
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes specified	NOW+02:00 **or** +02:00. If you issue this command at 5:00 with STARTTIME=NOW+02:00 or STARTTIME=+02:00, the beginning of the startup window is at 7:00.

Value	Description	Example
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes specified	NOW-02:00 **or** -02:00. If you issue this command at 5:00 with STARTTIME=NOW-02:00 or STARTTIME=-02:00, the beginning of the startup window is at 3:00.

DURation
: Specifies the number of units that define the length of the startup window of the scheduled operation. This parameter is optional. This value must be from 1 to 999. The default is 1.

  Use this parameter with the DURUNITS parameter to specify the length of the startup window. For example, if you specify DURATION=20 and DURUNITS=MINUTES, the schedule must be started within 20 minutes of the start date and start time. The default length of the startup window is 1 hour. The duration of the window must be shorter than the period between windows.

  This value is ignored if you specify DURUNITS=INDEFINITE.

DURUnits
: Specifies the time units used to determine the duration of the window in which the schedule can start. This parameter is optional. The default is HOURS.

  Use this parameter with the DURATION parameter to specify how long the startup window remains open to process the schedule. For example, if DURATION=20 and DURUNITS=MINUTES, the schedule must be started within 20 minutes of the start date and start time. The schedule may not necessarily complete processing within this window. If the schedule needs to be retried for any reason, the retry attempts must begin before the startup window elapses, or the operation does not restart.

  The default value for the length of the startup window is 1 hour. You can specify one of the following values:

  Minutes
  : Specifies that the duration of the window is defined in minutes.

  Hours
  : Specifies that the duration of the window is defined in hours.

  Days
  : Specifies that the duration of the window is defined in days.

  INDefinite
  : Specifies that the startup window of the scheduled operation has an indefinite duration. The schedule can run any time after the scheduled start time, until the schedule expires. You cannot specify DURUNITS=INDEFINITE, unless you specify PERUNITS=ONETIME. The INDEFINITE value is not allowed with enhanced schedules.

MAXRUNtime
: Specifies the maximum run time, which is the number of minutes during which server processes that are started by the scheduled commands must be completed. If processes are still running after the maximum run time, the central scheduler cancels the processes.
  Tips:

  - The processes might not end immediately when the central scheduler cancels them; they end when they register the cancellation notification from the central scheduler.
  - The maximum run time is calculated beginning from when the server process starts. If the schedule command starts more than one process, each process maximum run time is calculated from when the process starts.
  - This parameter does not apply to some processes, such as duplicate-identification processes, which can continue to run after the maximum run time.
  - This parameter does not apply if the scheduled command does not start a server process.
  - Another cancel time might be associated with some commands. For example, the MIGRATE STGPOOL command can include a parameter that specifies the length of time that the storage pool migration runs before the migration is automatically canceled. If you schedule a command for which a cancel time is defined, and you also define a maximum run time for the schedule, the processes are canceled at whichever cancel time is reached first.

  Restrictions:

  - The value of the parameter is not distributed to servers that are managed by an enterprise configuration manager.
  - The value of the parameter is not exported by the EXPORT command.

The parameter is optional. You can specify a number in the range 0-1440. The default value is 0. A value of 0 means that the maximum run time is indefinite, and the central scheduler does not cancel processes. The maximum run time must be greater than the startup window duration, which is defined by the DURATION and DURUNITS parameters.

For example, if the start time of a scheduled command is 9:00 PM, and the duration of the startup window is 2 hours, the startup window is 9:00 PM - 11:00 PM. If the maximum run time is 240 minutes, that is, 4 hours, all applicable server processes that are started by the command must be completed by 1:00 AM. If one or more applicable processes are still running after 1:00 AM, the central scheduler cancels the processes.
Tip: Alternatively, you can specify an *end time* of 1:00 AM in the IBM Spectrum Protect Operations Center.

SCHEDStyle
: This parameter is optional. SCHEDSTYLE defines either the interval between times when a schedule should run, or the days on which it should run. The style can be either classic or enhanced. The default is the classic syntax.

  For classic schedules, these parameters are allowed: PERIOD, PERUNITS, and DAYOFWEEK. Not allowed for classic schedules are: MONTH, DAYOFMONTH, and WEEKOFMONTH.

  For enhanced schedules, these parameters are allowed: MONTH, DAYOFMONTH, WEEKOFMONTH, and DAYOFWEEK. These parameters are not allowed: PERIOD and PERUNITS.

PERiod
: Specifies the length of time between startup windows for this schedule. This parameter is optional. This parameter is used only with classic schedules. You can specify an integer from 1 to 999. The default is 1.

  Use this parameter with the PERUNITS parameter to specify the period between startup windows. For example, if you specify PERIOD=5 and PERUNITS=DAYS (assuming that DAYOFWEEK=ANY), the operation is scheduled every five days after the initial start date and start time. The period between startup windows must exceed the duration of each window. The default is 1 day.

  This value is ignored if you specify PERUNITS=ONETIME.

PERUnits
: Specifies the time units used to determine the period between startup windows for this schedule. This parameter is optional. This parameter is used only with classic schedules. The default is DAYS.
  Use this parameter with the PERIOD parameter to specify the period between startup windows. For example, if you specify PERIOD=5 and PERUNITS=DAYS (assuming that DAYOFWEEK=ANY), the operation is scheduled every 5 days after the initial start date and start time. The default is 1 day. You can specify one of the following values:

  Hours
  : Specifies that the time between startup windows is in hours.

  Days
  : Specifies that the time between startup windows is in days.

  Weeks
  : Specifies that the time between startup windows is in weeks.

  Months
  : Specifies that the time between startup windows is in months.

    When you specify PERUNITS=MONTHS, the scheduled operation will be processed each month on the same date. For example, if the start date for the scheduled operation is 02/04/1998, the schedule will process on the 4th of every month thereafter. However, if the date is not valid for the next month, then the scheduled operation will be processed on the last valid date in the month. Thereafter, subsequent operations are based on this new date. For example, if the start date is 03/31/1998, the next month's operation will be scheduled for 04/30/1998. Thereafter, all subsequent operations will be on the 30th of the month until February. Because February has only 28 days, the operation will be scheduled for 02/28/1999. Subsequent operations will be processed on the 28th of the month.

  Years
  : Specifies that the time between startup windows for the schedule is in years.

    When you specify PERUNITS=YEARS, the scheduled operation will be processed on the same month and date of each year. For example, if the start date for the scheduled operation is 02/29/2004, the next year's scheduled operation will be 02/28/2005 because February only has 28 days. Thereafter, subsequent operations will be scheduled for February 28th.

  Onetime
  : Specifies that the schedule processes once. This value overrides the value you specified for the PERIOD parameter.

DAYofweek

Specifies the day of the week on which the startup window for the schedule begins. This parameter is optional. You can specify different options for the DAYofweek parameter, depending on whether the schedule style was defined as Classic or Enhanced:

Classic Schedule

Specifies the day of the week on which the startup window for the schedule begins. This parameter is optional. You can either specify one day of the week, or WEEKDAY, WEEKEND, or ANY. If the start date and start time fall on a day that does not correspond to a day you specify, the start date and start time will be shifted forward in 24-hour increments until the DAYOFWEEK parameter is satisfied.

If you select a value for DAYOFWEEK other than ANY, and depending on the values for PERIOD and PERUNITS, schedules may not be processed when you would expect. The default is ANY.

Enhanced Schedule

Specifies the days of the week on which to run the schedule. You can either specify multiple days separated by commas and no intervening blanks, or WEEKDAY, WEEKEND, or ANY. If you specify multiple days, the schedule will run on each of the specified days. If you specify WEEKDAY or WEEKEND, you must also specify either WEEKOFMONTH=FIRST or WEEKOFMONTH=LAST, and the schedule will run just once per month.

The default value is ANY, meaning the schedule will run every day of the week or on the day or days determined by other enhanced schedule parameters. DAYOFWEEK must have a value of ANY (either by default or specified with the command) when used with the DAYOFMONTH parameter.

Possible values for the DAYofweek parameter are:

ANY

Specifies that the startup window can begin on any day of the week.

WEEKDay

Specifies that the startup window can begin on Monday, Tuesday, Wednesday, Thursday, or Friday.

WEEKEnd

Specifies that the startup window can begin on Saturday or Sunday.

SUnday

Specifies that the startup window begins on Sunday.

Monday

Specifies that the startup window begins on Monday.

TUesday

Specifies that the startup window begins on Tuesday.

Wednesday

Specifies that the startup window begins on Wednesday.

THursday

Specifies that the startup window begins on Thursday.

Friday

Specifies that the startup window begins on Friday.

SAturday

Specifies that the startup window begins on Saturday.

MONth

Specifies the months of the year during which to run the schedule. This parameter is used only with enhanced schedules. Specify multiple values by using commas and no intervening blanks. The default value is ANY. This means the schedule will run during every month of the year.

DAYOFMonth

Specifies the day of the month to run the schedule. This parameter is used only with enhanced schedules. You can either specify ANY or a number from -31 through 31, excluding zero. Negative values are a day from the end of the month, counting backwards. For example, the last day of the month is -1, the next-to-the-last day of the month is -2, etc. You can specify multiple values separated by commas and no intervening blanks. If you specify multiple values, the schedule will run on each of the specified days of the month. If multiple values resolve to the same day, the schedule will run only once that day.

The default value is ANY This means the schedule will run on every day of the month or on the days determined by other enhanced schedule parameters. DAYOFMONTH must have a value of ANY (either by default or specified with the command) when used with the DAYOFWEEK or WEEKOFMONTH parameters.

WEEKofmonth

Specifies the week of the month in which to run the schedule. This parameter is used only with enhanced schedules. A week is considered any seven-day period which does not start on a particular day of the week. You can specify FIRST, SECOND, THIRD, FOURTH, LAST, or ANY. You can specify multiple values separated by commas and no intervening blanks. If you specify multiple values, the schedule will run during each of the specified weeks of the month. If multiple values resolve to the same week, the schedule will run only once during that week.

The default value is ANY, meaning the schedule will run during every week of the month or on the day or days determined by other enhanced schedule parameters. WEEKOFMONTH must have a value of ANY (either by default or specified with the command) when used with the DAYOFMONTH parameter.

EXPiration
Specifies the date after which this schedule is no longer used. This parameter is optional. The default is NEVER. You can specify one of the following values:

Never
Specifies that the schedule never expires.

expiration_date
Specifies the date on which this schedule expires, in MM/DD/YYYY format. If you specify an expiration date, the schedule expires at 23:59:59 on the date you specify.

Example: Define a schedule to back up the primary storage pool every two days

Define a schedule named BACKUP_ARCHIVEPOOL that backs up the primary storage pool ARCHIVEPOOL to the copy storage pool RECOVERYPOOL. The backup runs at 8 p.m. every two days.

```
define schedule backup_archivepool type=administrative
cmd="backup stgpool archivepool recoverypool"
active=yes starttime=20:00 period=2
```

Example: Define a schedule to back up the primary storage pool twice a month

Define a schedule named BACKUP_ARCHIVEPOOL that backs up the primary storage pool ARCHIVEPOOL to the copy storage pool RECOVERYPOOL. Select an enhanced schedule and run on the first and fifteenth day of the month.

```
define schedule backup_archivepool type=administrative
cmd="backup stgpool archivepool recoverypool"
schedstyle=enhanced dayofmonth=1,15
```

DEFINE SCRATCHPADENTRY (Define a scratch pad entry)

Use this command to enter data on a new line in the scratch pad. The scratch pad is a database table that the server hosts. You can use the scratch pad to store diverse information in table format.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DEFine SCRATCHPadentry--major_category--minor_category------->

>--subject--Line--=--number--Data--=--data--------------------><
```

Parameters

major_category (Required)
Specifies the major category in which data is to be stored. Enter a text string of up to 100 alphanumeric characters. This parameter is case sensitive.

minor_category (Required)
Specifies the minor category in which data is to be stored. Minor categories are sections within major categories. Enter a text string of up to 100 alphanumeric characters. This parameter is case sensitive.

subject (Required)

Specifies the subject under which data is to be stored. Subjects are sections within minor categories. Enter a text string of up to 100 alphanumeric characters. This parameter is case sensitive.

Line (Required)

Specifies the number of the line on which data is to be stored. Lines are sections within subjects. Specify an integer in the range 1 - 1000.

Data (Required)

Specifies the data to be stored on the line. You can enter up to 1000 characters. Enclose the data in quotation marks if the data contains one or more blanks. The data is case sensitive.

Example: Define a scratch pad entry

Enter the vacation dates of an administrator, Jane, in a table that stores information about the location of all administrators.

```
define scratchpadentry admin_info location jane line=2 data=
"Out of the office from 1-15 Nov."
```

Related commands

Table 1. Commands related to DEFINE SCRATCHPADENTRY

Command	Description
DELETE SCRATCHPADENTRY	Deletes a line of data from the scratch pad.
QUERY SCRATCHPADENTRY	Displays information that is contained in the scratch pad.
SET SCRATCHPADRETENTION	Specifies the amount of time for which scratch pad entries are retained.
UPDATE SCRATCHPADENTRY	Updates data on a line in the scratch pad.

DEFINE SCRIPT (Define an IBM Spectrum Protect script)

Use this command to define an IBM Spectrum Protect™ script or to create a new IBM Spectrum Protect script by using the contents from another script.

The first line for the script can be defined with this command. To add subsequent lines to the script, use the UPDATE SCRIPT command.

Tips:

- When routing commands inside scripts, enclose the server or server group in parentheses and omit the colon. Otherwise, if the syntax includes a colon, the command is not routed when the RUN command is issued. Instead, the command runs only on the server from which the RUN command is issued.
- You cannot redirect the output of a command within an IBM Spectrum Protect script. Instead, run the script and then specify command redirection. For example, to direct the output of script1 to the c:\temp\test.out directory, run the script and specify command redirection as in the following example:

  ```
  run script1 > c:\temp\test.out
  ```

Privilege class

To issue this command, you must have operator, policy, storage, or system privilege.

Syntax

```
>>-DEFine SCRipt--script_name----------------------------------->

                  .-Line--=--001----.
>--+-command_line--+-----------------+-+----------------------->
   |               '-Line -=--number-' |
   '-File--=--file_name----------------'

>--+-----------------------------+----------------------------><
   '-DESCription--=--description-'
```

Parameters

script_name (Required)
: Specifies the name of the script to be defined. You can specify up to 30 characters for the name.

command_line
: Specifies the first command to be processed in a script. You must specify either this parameter (and optionally, the LINE parameter) or the FILE parameter.

  The command that you specify can include substitution variables and can be continued across multiple lines if you specify a continuation character (-) as the last character in the command. Substitution variables are specified with a '$' character, followed by a number that indicates the value of the parameter when the script is processed. You can specify up to 1200 characters for the command line. Enclose the command in quotation marks if it contains blanks.

  You can run commands serially, in parallel, or serially and in parallel by specifying the SERIAL or PARALLEL script commands for the COMMAND_LINE parameter. You can run multiple commands in parallel and wait for them to complete before you proceed to the next command. Commands run serially until the parallel command is encountered.

  Conditional logic flow statements can be used. These statements include IF, EXIT, and GOTO.

  Line
  : Specifies the line number for the command line. Because commands are specified in multiple lines, line numbers are used to determine the order for processing when the script is run. The first line, or line 001 is the default. This parameter is optional.

File
: Specifies the name of the file whose contents are read into the script to be defined. The file must reside on the server where this command is running. If you specify the FILE parameter, you cannot specify a command line or line number.

  You can create a script by querying another script and specifying the FORMAT=RAW and OUTPUTFILE parameters. The output from querying the script is directed to a file you specify with the OUTPUTFILE parameter. To create the new script, the contents of the script to be defined are read in from the file you specified with the OUTPUTFILE parameter.

DESCription
: Specifies a description for the script. You can specify up to 255 characters for the description. Enclose the description in quotation marks if it contains blank characters. This parameter is optional.

Example: Write a script to display AIX clients

Define a script that displays all AIX® clients.

```
define script qaixc "select node_name from nodes where platform_name='AIX'"
  desc='Display aix clients'
```

Example: Write and run a script to route a command to a server group

Define and run a script that routes the QUERY STGPOOL command to a server group named DEV_GROUP.

```
define script qu_stg "(dev_group) query stgpool"
```

```
run qu_stg
```

Example: Create a script from an existing script

Define a script whose command lines are read in from a file that is named MY.SCRIPT and name the new script AGADM. The file must be on the server, and be read by the server.

```
define script agadm file=my.script
```

Related commands

Table 1. Commands related to DEFINE SCRIPT

Command	Description
COPY SCRIPT	Creates a copy of a script.

Command	Description
DELETE SCRIPT	Deletes the script or individual lines from the script.
QUERY SCRIPT	Displays information about scripts.
RENAME SCRIPT	Renames a script to a new name.
RUN	Runs a script.
UPDATE SCRIPT	Changes or adds lines to a script.

DEFINE SERVER (Define a server for server-to-server communications)

Use this command to define a server to use functions such as virtual volumes, node replication, command routing, and LAN-free data movement, among others.

Use this command to define a server for the following functions:

- Enterprise configuration
- Enterprise event logging
- Command routing
- Virtual volumes
- LAN-free data movement
- Node replication
- AIX Linux Data movement by using z/OS® media server
- Status monitoring of remote servers
- Alert monitoring of remote servers
- Server-to-server export

If you use an LDAP directory server to authenticate passwords, any target servers must be configured for LDAP-authenticated passwords. Data that is replicated from a node that authenticates with an LDAP directory server is inaccessible if the target replication server is not properly configured. If your target replication server is not configured, replicated data from an LDAP node can make it to the target server. But the target replication server must be configured to use LDAP if you want to access the data.

The use of virtual volumes is not supported when the source server and the target server are on the same IBM Spectrum Protect™ server.

This command also is used to define an IBM Spectrum Protect storage agent as if it were a server.

Privilege class

To issue this command, you must have system privilege.

Syntax

For:

- Command routing
- Status monitoring of remote servers
- Alert monitoring of remote servers
- Server-to-server export

Tip: Command routing uses the ID and the password of the administrator who is issuing the command.

```
>>-DEFine--SERver--server_name--HLAddress--=--ip_address-------->
```

```
>--LLAddress--=--tcp_port--+---------------------+------------>
                           '-COMMmethod--=--TCPIP-'

>--+-------------+--+----------------------------+------------>
   '-URL--=--url-'  '-DESCription--=--description-'

   .-SSL--=--No------.
>--+-----------------+-------------------------------------------->
   '-SSL--=--+-No--+-'
             '-Yes-'

   .-SESSIONSECurity--=--TRANSitional-----.
>--+--------------------------------------+--------------------><
   '-SESSIONSECurity--=--+-STRict-------+-'
                         '-TRANSitional-'
```

Syntax

For:

- Enterprise configuration
- Enterprise event logging
- Storage agent
- Node replication source and target servers
- AIX Linux z/OS media server

```
>>-DEFine--SERver--server_name--SERVERPAssword--=--password----->

>--HLAddress--=--ip_address--LLAddress--=--tcp_port------------>

>--+----------------------+--+-------------+-------------------->
   '-COMMmethod--=--TCPIP-'  '-URL--=--url-'

>--+----------------------------+----------------------------->
   '-DESCription--=--description-'

                          (1)
   .-CROSSDEFine--=--No-------. (2)
>--+--------------------------+-------------------------------->
   '-CROSSDEFine--=--+-No--+--'
                     '-Yes-'

   .-VALIdateprotocol--=--No------.  .-SSL--=--No------.
>--+-----------------------------+--+-----------------+-------->
   '-VALIdateprotocol--=--+-No--+-'  '-SSL--=--+-No--+-'
                          '-All-'              '-Yes-'

   .-SESSIONSECurity--=--TRANSitional-----.
>--+--------------------------------------+--------------------->
   '-SESSIONSECurity--=--+-STRict-------+-'
                         '-TRANSitional-'

   .-TRANSFERMethod--=--Tcpip--------.
>--+-------------------------------+------------------------><
   '-TRANSFERMethod--=--+-Tcpip----+-'
                        |      (3) |
                        '-Fasp-----'
```

Notes:

1. The CROSSDEFINE parameter does not apply to storage agent definitions.
2. The VALIDATEPROTOCOL parameter is deprecated and applies only to storage agent definitions.
3. Linux The TRANSFERMETHOD parameter is available only on Linux x86_64 operating systems.

Syntax for virtual volumes

```
>>-DEFine--SERver--server_name--PAssword--=--password----------->

>--HLAddress--=--ip_address--LLAddress--=--tcp_port------------->

>--+---------------------+--+-------------+-------------------->
   '-COMMmethod--=--TCPIP-'  '-URL--=--url-'

>--+-------------------------+--+------------------------+------>
   '-DELgraceperiod--=--days-'  '-NODEName--=--node_name-'

                                    .-SSL--=--No------.
>--+-----------------------------+--+-----------------+--------->
   '-DESCription--=--description-'  '-SSL--=--+-No--+-'
                                              '-Yes-'

   .-SESSIONSECurity--=--TRANSitional-----.
>--+--------------------------------------+-------------------><
   '-SESSIONSECurity--=--+-STRict-------+-'
                         '-TRANSitional-'
```

Parameters

server_name (Required)
: Specifies the name of the server. This name must be unique on the server. The maximum length of this name is 64 characters.

  For server-to-server event logging, library sharing, and node replication, you must specify a server name that matches the name that was set by issuing the SET SERVERNAME command at the target server.

PAssword
: Specifies the password that is used to sign on to the target server for virtual volumes. If you specify the NODENAME parameter, you must specify the PASSWORD parameter. If you specify the PASSWORD parameter but not the NODENAME parameter, the node name defaults to the server name that is specified with the SET SERVERNAME command.

SERVERPAssword
: Specifies the password of the server you are defining. This password must match the password that is set by the SET SERVERPASSWORD command. This parameter is required for enterprise configuration and server-to-server event logging functions.

HLAddress (Required)
: Specifies the IP address (in dotted decimal format) of the server.

  Do not use the loopback address as the value of this parameter. Virtual volumes are not supported when the source server and the target server are the same IBM Spectrum Protect server.

LLAddress (Required)
: Specifies the low-level address of the server. This address is usually the same as the address in the TCPPORT server option of the target server. When SSL=YES, the port must already be designated for SSL communications on the target server.

COMMmethod
: Specifies the communication method that is used to connect to the server. This parameter is optional.

URL
: Specifies the URL address of this server. The parameter is optional.

DELgraceperiod
: Specifies a number of days that an object remains on the target server after it was marked for deletion. You can specify a value 0 - 9999. The default is 5. This parameter is optional.

NODEName
: Specifies a node name to be used by the server to connect to the target server. This parameter is optional. If you specify the NODENAME parameter, you must also specify the PASSWORD parameter. If you specify the PASSWORD parameter but not the NODENAME parameter, the node name defaults to the server name specified with the SET SERVERNAME command.

DESCription
: Specifies a description of the server. The parameter is optional. The description can be up to 255 characters. Enclose the description in quotation marks if it contains blank characters.

CROSSDEFine
: Specifies whether the server that is running this command defines itself to the server that is being specified by this command. This parameter is optional.
  AIX Linux Windows Important: This parameter does not apply to storage agent definitions.

If this parameter is included, you must also issue the SET SERVERNAME, SET SERVERPASSWORD, SET SERVERHLADDRESS, SET CROSSDEFINE, and SET SERVERLLADDRESS commands. The default is NO.
Remember:

- For replication operations, the names of the source and target replication servers must match the names that you specify in this command.
- CROSSDEFINE can be used with SSL=YES if all of the conditions that are specified for the SSL=YES parameter are in place on the source and target server.

You can specify one of the following values:

No
: Cross definition is not completed.

Yes
: Cross definition is completed.

VALIdateprotocol (deprecated)

Specifies whether a cyclic redundancy check validates the data that is sent between the storage agent and IBM Spectrum Protect server. The parameter is optional. The default is NO.

Important: Beginning with IBM Spectrum Protect Version 8.1.2, validation that was enabled by this parameter is replaced by the TLS 1.2 protocol, which is enforced by the SESSIONSECURITY parameter. The VALIDATEPROTOCOL parameter is ignored. Update your configuration to use the SESSIONSECURITY parameter.

SSL
: Specifies the communication mode of the server. The default is NO.
Important: Beginning in V8.1.2, the SSL parameter uses SSL to encrypt some communication with the specified server even if SSL=NO.
The following conditions and considerations apply when you specify the SSL parameter:

- Before you start the servers, self-signed certificates of the partner servers must be in the key database file (cert.kdb) of each of the servers.
- You can define multiple server names with different parameters for the same target server.
- Storage agents can issue the DSMSTA SETSTORAGESERVER command and include the SSL parameter to create the key database.

You can specify one of the following values:

No
: Specifies an SSL session for all communication with the specified server, except when the server is sending or receiving object data. Object data is sent and received by using TCP/IP. By choosing not to encrypt the object data, server performance is similar to communication over a TCP/IP session and the session is secure.

Yes
: Specifies an SSL session for all communication with the specified server, even when the server is sending and receiving object data.

SESSIONSECurity
: Specifies whether the server that you are defining must use the most secure settings to communicate with an IBM Spectrum Protect server. This parameter is optional.

You can specify one of the following values:

STRict
: Specifies that the strictest security settings are enforced for the server that you are defining. The STRICT value uses the most secure communication protocol available, which is currently TLS 1.2. The TLS 1.2 protocol is used for SSL sessions between the specified server and an IBM Spectrum Protect server.
To use the STRICT value, the following requirements must be met to ensure that the specified server can authenticate with the IBM Spectrum Protect server:

- Both the server that you are defining and the IBM Spectrum Protect server must be using IBM Spectrum Protect software that supports the SESSIONSECURITY parameter.
- The server that you are defining must be configured to use the TLS 1.2 protocol for SSL sessions between itself and the IBM Spectrum Protect server.

Servers set to STRICT that do not meet these requirements are unable to authenticate with the IBM Spectrum Protect server.

TRANSitional
: Specifies that the existing security settings are enforced for the server. This is the default value. This value is intended to be used temporarily while you update your security settings to meet the requirements for the STRICT value.

  If SESSIONSECURITY=TRANSITIONAL and the server has never met the requirements for the STRICT value, the server will continue to authenticate by using the TRANSITIONAL value. However, after a server meets the requirements for the STRICT value, the SESSIONSECURITY parameter value automatically updates from TRANSITIONAL to STRICT. Then, the server can no longer authenticate by using a version of the client or an SSL/TLS protocol that does not meet the requirements for STRICT. In addition, after a server successfully authenticates by using a more secure communication protocol, the server can no longer authenticate by using a less secure protocol. For example, if a server that is not using SSL is updated and successfully authenticates by using TLS 1.2, the server can no longer authenticate by using no SSL protocol or TLS 1.1. This restriction also applies when you use functions such as virtual volumes, command routing, or server-to-server export, when a node or administrator authenticates to the IBM Spectrum Protect server as a node or administrator from another server.

Linux TRANSFERMethod
: Linux Specifies the method that is used for server-to-server data transfer. This parameter is optional. You can specify one of the following values:

  Tcpip
  : Specifies that TCP/IP is used to transfer data. This is the default.

  Fasp
  : Specifies that Aspera® Fast Adaptive Secure Protocol (FASP®) technology is used to transfer data. Aspera FASP technology can help you optimize data transfer in a wide area network (WAN).
    Restrictions:

    - Before you enable Aspera FASP technology, determine whether the technology is appropriate for your system environment and install the appropriate licenses. For instructions, see Determining whether Aspera FASP technology can optimize data transfer in your system environment. If the licenses are missing or expired, data transfer operations fail.
    - If WAN performance meets your business needs, do not enable Aspera FASP technology.
    - If you specify TRANSFERMETHOD=FASP on the PROTECT STGPOOL or REPLICATE NODE command, that value overrides the TRANSFERMETHOD parameter on the DEFINE SERVER and UPDATE SERVER commands.

Example: Set up two servers to use SSL to communicate (manual configuration)

Tip: If both servers are using V8.1.2 or later software, SSL is automatically configured between the servers and manual configuration is not required.
If both servers are not using V8.1.2 software, you must manually configure the two servers to use SSL to communicate.
The server addresses are as follows:

- ServerA is at `bfa.tucson.ibm.com`
- ServerB is at `bfb.tucson.ibm.com`

Complete the following steps to set up the two servers for SSL:

1. Specify option TCPPORT 1500 for both servers in the dsmserv.opt option file.
2. Start both servers.
3. Shut down both servers to import the cert256 partner certificate. For ServerA, the certificate is in the /tsma instance directory. For ServerB, the certificate is in the /tsmb instance directory.
4. Start both servers. The /tsma/cert256.arm file is copied to /tsmb/cert256.bfa.arm on the bfb.tucson.ibm.com address. The /tsmb/cert256.arm file is copied to /tsmb/cert256.bfb.arm on the bfa.tucson.ibm.com address.
5. Issue the following command:
   - From ServerA:

     ```
     gsk8capicmd_64 -cert -add -db cert.kdb -stashed -format ascii
     -label "bfb" -file /tsma/cert256.bfb.arm
     ```

   - From ServerB:

     ```
     gsk8capicmd_64 -cert -add -db cert.kdb -stashed -format ascii
     -label "bfa" -file /tsmb/cert256.bfa.arm
     ```

From each server, you can view the certificates in the key database by issuing the following command:

```
gsk8capicmd_64 -cert -list -db cert.kdb -stashed
```

6. Restart the servers.
7. Issue the appropriate DEFINE SERVER command. For ServerA, issue the following example command:

```
DEFINE SERVER BFB hla=bfb.tucson.ibm.com lla=1542
serverpa=passwordforbfb SSL=YES
```

For ServerB, issue the following example command:

```
DEFINE SERVER BFA hla=bfa.tucson.ibm.com lla=1542
serverpa=passwordforbfa SSL=YES
```

If you do not use SSL, issue the following example DEFINE SERVER command on ServerA:

```
DEFINE SERVER BFBTCP hla=bfb.tucson.ibm.com lla=1500
serverpa=passwordforbfb SSL=NO
```

If you do not use SSL, issue the following example DEFINE SERVER command on ServerB:

```
DEFINE SERVER BFATCP hla=bfa.tucson.ibm.com lla=1500
serverpa=passwordforbfa SSL=NO
```

Example: Define a server to communicate with another server by using strict session security

Define a server name of SERVER1 to use the strictest security settings to authenticate with the IBM Spectrum Protect server.

```
define server server1 sessionsecurity=strict
```

Example: Define a target server

A target server has a high-level address of 9.116.2.67 and a low-level address of 1570. Define that target server to the source server, name it SERVER2, and set the password to SECRET. Specify that objects remain on the target server for seven days after they are marked for deletion.

```
define server server2 password=secret
  hladdress=9.115.3.45 lladdress=1570 delgraceperiod=7
```

Example: Define a server to receive commands from other servers

Define a server that can receive commands that are routed from other servers. Name the server WEST_COMPLEX. Set the high-level address to 9.172.12.35, the low-level address to 1500, and the URL address to http://west_complex:1580/.

```
define server west_complex
hladdress=9.172.12.35 lladdress=1500
url=http://west_complex:1580/
```

Example: Cross-define two servers

Use cross definition to define SERVER_A and SERVER_B.

1. On SERVER_B, specify the server name, password, and high- and low-level addresses of SERVER_B. Specify that cross defining is allowed.

```
set servername server_b
set serverpassword mylife
set serverhladdress 9.115.20.80
set serverlladdress 1860
set crossdefine on
```

2. On SERVER_A, specify the server name, password, and high- and low-level addresses of SERVER_A.

```
set servername server_a
set serverpassword yourlife
set serverhladdress 9.115.20.97
set serverlladdress 1500
```

3. On SERVER_A, define SERVER_B:

```
define server server_b hladdress=9.115.20.80 lladdress=1860
serverpassword=mylife crossdefine=yes
```

Related commands

Table 1. Commands related to DEFINE SERVER

Command	Description
DEFINE DEVCLASS	Defines a device class.
AIX Linux DEFINE PATH	AIX Linux Define a path when the destination is a z/OS media server.
DELETE DEVCLASS	Deletes a device class.
DELETE FILESPACE	Deletes data associated with client file spaces. If a file space is part of a collocation group and you remove the file space from a node, the file space is removed from the collocation group.
DELETE SERVER	Deletes the definition of a server.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY SERVER	Displays information about servers.
RECONCILE VOLUMES	Reconciles source server virtual volume definitions and target server archive objects.
REGISTER NODE	Defines a client node to the server and sets options for that user.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.
SET CROSSDEFINE	Specifies whether to cross define servers.
SET SERVERNAME	Specifies the name by which the server is identified.
SET SERVERHLADDRESS	Specifies the high-level address of a server.
SET SERVERLLADDRESS	Specifies the low-level address of a server.
SET SERVERPASSWORD	Specifies the server password.
SET REPLSERVER	Specifies a target replication server.
UPDATE DEVCLASS	Changes the attributes of a device class.
UPDATE NODE	Changes the attributes that are associated with a client node.
AIX Linux UPDATE PATH	AIX Linux Define a path when the destination is a z/OS media server.
UPDATE SERVER	Updates information about a server.

DEFINE SERVERGROUP (Define a server group)

Use this command to define a server group. With a server group, you can route commands to multiple servers by specifying only the group name. After you define the server group, add servers to the group by using the DEFINE GRPMEMBER command.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DEFine SERVERGroup--group_name------------------------------>

>--+-----------------------------+----------------------------><
```

```
'-DESCription--=--description-'
```

Parameters

group_name (Required)
: Specifies the name of the server group. The maximum length of the name is 64 characters.

DESCription
: Specifies a description of the server group. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters.

Example: Define a server group

Define a server group named WEST_COMPLEX.

```
define servergroup west_complex
```

Related commands

Table 1. Commands related to DEFINE SERVERGROUP

Command	Description
COPY SERVERGROUP	Creates a copy of a server group.
DEFINE GRPMEMBER	Defines a server as a member of a server group.
DELETE GRPMEMBER	Deletes a server from a server group.
DELETE SERVERGROUP	Deletes a server group.
MOVE GRPMEMBER	Moves a server group member.
QUERY SERVERGROUP	Displays information about server groups.
RENAME SERVERGROUP	Renames a server group.
UPDATE SERVERGROUP	Updates a server group.

DEFINE SPACETRIGGER (Define the space trigger)

Use this command to define settings for triggers that determine when and how the server prepares extra space when predetermined thresholds are exceeded in storage pools that use FILE and DISK device classes. Space triggers are not enabled for storage pools with a parameter RECLAMATIONTYPE=SNAPLOCK.

The IBM Spectrum Protect™ server allocates more space when space utilization reaches a specified value. After allocating more space, the server either adds the space to the specified pool (random-access or sequential-access disk).

Important: Space trigger functions and storage pool space calculations take into account the space remaining in each directory. An inaccurate calculation can result in a failure to expand the space available in a storage pool. Failure to expand space in a storage pool is one of the conditions that can cause a trigger to become disabled.

For example, if you specify multiple directories for a device class and the directories reside in the same file system, the server calculates space by adding values representing the space remaining in each directory. These space calculations are inaccurate. Rather than choosing a storage pool with sufficient space for an operation, the server might choose the directory that is specified for the device class and run out of space prematurely.

To prevent possible problems and ensure an accurate calculation, you associate each directory with a separate file system. If a trigger becomes disabled because the space in a storage pool could not be expanded, you can re-enable the trigger by specifying the following command: `update spacetrigger stg`. No further changes are required to the space trigger.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
                                .-Fullpct--=--80------.
>>-DEFine SPACETrigger----STG----+---------------------+-------->
                                '-Fullpct--=--percent-'

   .-SPACEexpansion--=--20------.
>--+----------------------------+------------------------------->
   '-SPACEexpansion--=--percent-'

>--+----------------------------+------------------------------->
   '-EXPansionprefix--=--prefix-'

>--+-------------------------------+---------------------------><
   '-STGPOOL--=--storage_pool_name-'
```

Parameters

STG
: Specifies a storage pool space trigger.

Fullpct
: This parameter specifies the utilization percentage of the storage pool. This parameter is optional. Specify an integer value 0 - 99. The default is 80. A value of zero (0) disables the space trigger. When this value is exceeded, the space trigger creates new volumes. Exceeding the threshold might not cause new volumes to be created until the next space request is made.

  You can determine storage pool utilization by issuing the QUERY STGPOOL command with FORMAT=DETAILED. The percentage of storage pool utilization is displayed in the field "Space Trigger Util." The calculation for this percentage does not include potential scratch volumes. The calculation for the percentage utilization that is used for migration and reclamation, however, does include potential scratch volumes.

SPACEexpansion
: For sequential-access FILE-type storage pools, this parameter is used in determining the number of additional volumes that are created in the storage pool. This parameter is optional. The default is 20. Volumes are created using the MAXCAPACITY value from the storage pool's device class. For random-access DISK storage pools, the space trigger creates a single volume using the EXPANSIONPREFIX.

EXPansionprefix
: For random-access DISK storage-pools, this parameter specifies the prefix that the server uses to create new storage pool files. This parameter is optional and applies only to random-access DISK device classes. The default prefix is the server installation path.
  The prefix can include one or more directory separator characters, for example: AIX Linux

  ```
  /opt/tivoli/tsm/server/bin/
  ```

  Windows

  ```
  c:\program files\tivoli\tsm\
  ```

  AIX Linux You can specify up to 250 characters. If you specify an invalid prefix, automatic expansion can fail.

  Windows You can specify up to 200 characters. If you specify an invalid prefix, automatic expansion can fail. If the server is running as a Windows service, the default prefix is the c:\wnnt\system32 directory.

  This parameter is not valid for space triggers for sequential-access FILE storage pools. Prefixes are obtained from the directories that are specified with the associated device class.

STGPOOL
: Specifies the storage pool that is associated with this space trigger. This parameter is optional for storage pool space triggers. If you specify the STG parameter but not the STGPOOL parameter, one space trigger is created that applies to all random-access DISK and sequential-access FILE storage pools that do not have a specific space trigger.

  This parameter does not apply to storage pools with the parameter RECLAMATIONTYPE=SNAPLOCK.

Example: Define a space trigger to increase storage pool space 25 percent

Set up a storage pool space trigger for increasing the amount of space in a storage pool by 25 percent when it is filled to 80 percent utilization of existing volumes. Space is created in the directories associated with the device class.

```
define spacetrigger stg spaceexpansion=25 stgpool=file
```

Example: Define a space trigger to increase storage pool space 40 percent

Set up a space trigger for the WINPOOL1 storage pool to increase the amount of space in the storage pool by 40 percent when it is filled to 80 percent utilization of existing volumes.

```
define spacetrigger stg spaceexpansion=40 stgpool=winpool1
```

Related commands

Table 1. Commands related to DEFINE SPACETRIGGER

Command	Description
DEFINE VOLUME	Assigns a volume to be used for storage within a specified storage pool.
DELETE SPACETRIGGER	Deletes the storage pool space trigger.
QUERY SPACETRIGGER	Displays information about a storage pool space trigger.
UPDATE SPACETRIGGER	Changes attributes of storage pool space trigger.

DEFINE STATUSTHRESHOLD (Define a status monitoring threshold)

Use this command to define a new status monitoring threshold.

Status monitoring thresholds compare the defined conditions to the status monitoring server queries and inserts the results in the status monitoring table.

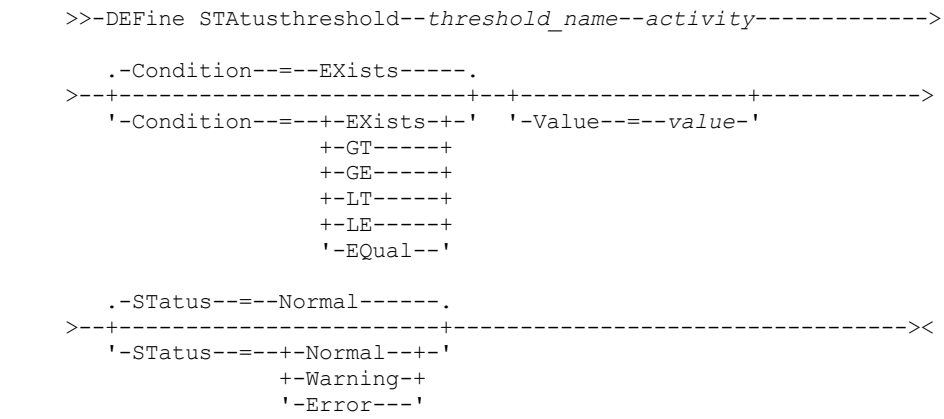
Multiple thresholds can be defined for an activity. For example, you can create a threshold that provides a warning status if storage pool capacity utilization is greater than 80%. You can then create another threshold that provides error status if storage pool capacity utilization is greater than 90%.

Note: If a threshold is already defined for an EXISTS condition, you cannot define another threshold with one of the other condition types.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

threshold_name (Required)

Specifies the threshold name. The name cannot exceed 48 characters in length.

activity (Required)

Specifies the activity for which you want to create status indicators. Specify one of the following values:

PROCESSSUMMARY

Specifies the number of processes that are currently active.

SESSIONSUMMARY

Specifies the number of sessions that are currently active.

CLIENTSESSIONSUMMARY

Specifies the number of client sessions that are currently active.

SCHEDCLIENTSESSIONSUMMARY

Specifies the number of scheduled client sessions.

DBUTIL

Specifies the database utilization percentage. The default warning threshold value is 80%, and the default error threshold value is 90%.

DBFREESPACE

Specifies the free space available in the database in gigabytes.

DBUSEDSPACE

Specifies the amount of database space that is used, in gigabytes.

ARCHIVELOGFREESPACE

Specifies the free space that is available in the archive log, in gigabytes.

STGPOOLUTIL

Specifies the storage pool utilization percentage. The default warning threshold value is 80%, and the default error threshold value is 90%.

STGPOOLCAPACITY

Specifies the storage pool capacity in gigabytes.

AVGSTGPOOLUTIL

Specifies the average storage pool utilization percentage across all storage pools. The default warning threshold value is 80%, and the default error threshold value is 90%.

TOTSTGPOOLCAPACITY

Specifies the total storage pool capacity in gigabytes for all available storage pools.

TOTSTGPOOLS

Specifies the number of defined storage pools.

TOTRWSTGPOOLS

Specifies the number of defined storage pools that are readable or writeable.

TOTNOTRWSTGPOOLS

Specifies the number of defined storage pools that are not readable or writeable.

STGPOOLINUSEANDDEFINED

Specifies the total number of defined volumes that are in use.

ACTIVELOGUTIL

Specifies the current percent utilization of the active log. The default warning threshold value is 80%, and the default error threshold value is 90%.

ARCHLOGUTIL

Specifies the current utilization of the archive log. The default warning threshold value is 80%, and the default error threshold value is 90%.

CPYSTGPOOLUTIL

Specifies the percent utilization for a copy storage pool. The default warning threshold value is 80%, and the default error threshold value is 90%.

PMRYSTGPOOLUTIL

Specifies the percent utilization for a primary storage pool. The default warning threshold value is 80%, and the default error threshold value is 90%.

DEVCLASSPCTDRVOFFLINE

Specifies the percent utilization of drives that are offline, by device class. The default warning threshold value is 25%, and the default error threshold value is 50%.

DEVCLASSPCTDRVPOLLING

Specifies the drives polling, by device class. The default warning threshold value is 25%, and the default error threshold value is 50%.

DEVCLASSPCTLIBPATHSOFFLINE

Specifies the library paths that are offline, by device class. The default warning threshold value is 25%, and the default error threshold value is 50%.

DEVCLASSPCTPATHSOFFLINE

Specifies the percentage of device class paths that are offline, by device class. The default warning threshold value is 25%, and the default error threshold value is 50%.

DEVCLASSPCTDISKSNOTRW
: Specifies the percentage of disks that are not writable for the disk device class. The default warning threshold value is 25%, and the default error threshold value is 50%.

DEVCLASSPCTDISKSUNAVAILABLE
: Specifies the percentage of the disk volumes that are unavailable, by device class. The default warning threshold value is 25%, and the default error threshold value is 50%.

FILEDEVCLASSPCTSCRUNALLOCATABLE
: Specifies the percentage of scratch volumes that the server cannot allocate for a given non-shared file device class. The default warning threshold value is 25%, and the default error threshold value is 50%.

Condition
: Specifies the condition that is used to compare the activity output to the specified value. The default value is EXISTS. Specify one of the following values:

EXists
: Creates a status monitoring indicator if the activity exists.

GT
: Creates a status monitoring indicator if the activity outcome is greater than the specified value.

GE
: Creates a status monitoring indicator if the activity outcome is greater than or equal to the specified value.

LT
: Creates a status monitoring indicator if the activity outcome is less than the specified value.

LE
: Creates a status monitoring indicator if the activity outcome is less than or equal to the specified value.

EQual
: Creates a status monitoring indicator if the activity outcome is equal to the specified value.

Value (Required)
: Specifies the value that is compared with the activity output for the specified condition. You must specify this parameter, unless CONDITION is set to EXISTS. You can specify an integer in the range 0 - 999999999999999.

STatus
: Specifies that the status indicator created in status monitoring if the condition that is being evaluated passes. This optional parameter has a default value of NORMAL. Specify one of the following values:

Normal
: Specifies that the status indicator has a normal status value.

Warning
: Specifies that the status indicator has a warning status value.

Error
: Specifies that the status indicator has an error status value.

Define status threshold

Define a status threshold for average storage pool utilization percentage by issuing the following command:

```
define statusthreshold avgstgpl "AVGSTGPOOLUTIL" value=85
  condition=gt status=warning
```

Related commands

Table 1. Commands related to DEFINE STATUSTHRESHOLD

Command	Description
DELETE STATUSTHRESHOLD (Delete a status monitoring threshold)	Deletes a status monitoring threshold.
QUERY MONITORSTATUS (Query the monitoring status)	Displays information about monitoring alerts and server status settings.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.

Command	Description
QUERY STATUSTHRESHOLD (Query status monitoring thresholds)	Displays information about a status monitoring thresholds.
SET STATUSMONITOR (Specifies whether to enable status monitoring)	Specifies whether to enable status monitoring.
SET STATUSATRISKINTERVAL (Specifies whether to enable client at-risk activity interval evaluation)	Specifies whether to enable client at-risk activity interval evaluation
SET STATUSREFRESHINTERVAL (Set refresh interval for status monitoring)	Specifies the refresh interval for status monitoring.
SET STATUSSKIPASFAILURE (Specifies whether to use client at-risk skipped files as failure evaluation)	Specifies whether to use client at-risk skipped files as failure evaluation
UPDATE STATUSTHRESHOLD (Update a status monitoring threshold)	Changes the attributes of an existing status monitoring threshold.

DEFINE STGPOOL (Define a storage pool)

Use this command to define a primary storage pool, copy storage pool, an active-data pool, a directory container storage pool, a container-copy storage pool, or a container storage pool in a cloud environment.

A primary storage pool provides a destination for backup files, archive files, or files that are migrated from client nodes. A copy storage pool provides a destination for copies of files that are in primary storage pools. An active-data pool provides a destination for active versions of backup data that are in primary storage pools. A container storage pool provides a destination for deduplicated files. A cloud storage pool provides storage in a cloud environment. A container-copy storage pool provides a tape copy of a directory-container storage pool. The maximum number of storage pools that you can define for a server is 999.

All volumes in a storage pool belong to the same device class. Random access storage pools use the DISK device type. After you define a random access storage pool, you must define volumes for the pool to create storage space.

Sequential access storage pools use device classes that you define for tape devices, files on disk (FILE device type), and storage on another server (SERVER device type). To create storage space in a sequential access storage pool, you must allow scratch volumes for the pool when you define or update it, or define volumes for the pool after you define the pool. You can also do both.

Restriction: If a client is using the simultaneous-write function and data deduplication, the data deduplication feature is disabled during backups to a storage pool.

The DEFINE STGPOOL command takes seven forms. The syntax and parameters for each form are defined separately.

Table 1. Commands related to DEFINE STGPOOL

Command	Description
BACKUP DB	Backs up the IBM Spectrum Protect database to sequential access volumes.
BACKUP STGPOOL	Backs up a primary storage pool to a copy storage pool.
COPY ACTIVEDATA	Copies active backup data.
DEFINE COLLOCGROUP	Defines a collocation group.
DEFINE COLLOCMEMBER	Adds a client node or file space to a collocation group.
DEFINE DEVCLASS	Defines a device class.
DEFINE STGPOOLDIRECTORY	Defines a storage pool directory to a directory-container or cloud-container storage pool.
DEFINE VOLUME	Assigns a volume to be used for storage within a specified storage pool.
DELETE COLLOCGROUP	Deletes a collocation group.
DELETE COLLOCMEMBER	Deletes a client node or file space from a collocation group.
DELETE STGPOOL	Deletes a storage pool from server storage.

Command	Description
MOVE DATA	Moves data from a specified storage pool volume to another storage pool volume.
MOVE MEDIA	Moves storage pool volumes that are managed by an automated library.
QUERY COLLOCGROUP	Displays information about collocation groups.
QUERY DEVCLASS	Displays information about device classes.
QUERY NODEDATA	Displays information about the location and size of data for a client node.
QUERY SHREDSTATUS	Displays information about data waiting to be shredded.
QUERY STGPOOL	Displays information about storage pools.
RENAME STGPOOL	Renames a storage pool.
REPAIR STGPOOL	Repairs a directory-container storage pool.
PROTECT STGPOOL	Protects a directory-container storage pool.
RESTORE STGPOOL	Restores files to a primary storage pool from copy storage pools.
RESTORE VOLUME	Restores files stored on specified volumes in a primary storage pool from copy storage pools.
SET DRMPRIMSTGPOOL	Specifies that primary storage pools are managed by DRM.
SHRED DATA	Manually starts the process of shredding deleted data.
UPDATE COLLOCGROUP	Updates the description of a collocation group.
UPDATE STGPOOL	Changes the attributes of a storage pool.

- DEFINE STGPOOL (Define a cloud-container storage pool)
  Use this command to define a container storage pool in a cloud environment. This type of storage pool is used for data deduplication. Cloud-container storage pools are not supported on Linux on System z®.
- DEFINE STGPOOL (Define a directory-container storage pool)
  Use this command to define a directory-container storage pool that is used for data deduplication.
- DEFINE STGPOOL (Define a container-copy storage pool)
  Use this command to define a container-copy storage pool to hold a copy of data from a directory-container storage pool.
- DEFINE STGPOOL (Define a primary storage pool assigned to random access devices)
  Use this command to define a primary storage pool that is assigned to random access devices.
- DEFINE STGPOOL (Define a primary storage pool assigned to sequential access devices)
  Use this command to define a primary storage pool that is assigned to sequential access devices.
- DEFINE STGPOOL (Define a copy storage pool assigned to sequential access devices)
  Use this command to define a copy storage pool that is assigned to sequential access devices.
- DEFINE STGPOOL (Define an active-data pool assigned to sequential-access devices)
  Use this command to define an active-data pool assigned to sequential-access devices.

DEFINE STGPOOL (Define a cloud-container storage pool)

Use this command to define a container storage pool in a cloud environment. This type of storage pool is used for data deduplication. Cloud-container storage pools are not supported on Linux on System z®.

Tip: To optimize backup and archive performance, set up one or more local storage directories to temporarily hold data that IBM Spectrum Protect™ is transferring to the cloud. After you use the DEFINE STGPOOL command to define a cloud-container storage pool, use the DEFINE STGPOOLDIRECTORY command to assign local storage directories to the cloud-container storage pool. For more information, see Optimizing performance for cloud object storage.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DEFine STGpool--pool_name--STGType--=--CLoud----------------->

                                          '-No--'

   .-COMPRession--=--Yes-----.
>--+-------------------------+-------------------------------><
   '-COMPRession--=--+-Yes-+-'
                     '-No--'
```

Notes:

1. If you specified CLOUDTYPE=AZURE, do not specify the IDENTITY parameter.
2. This parameter is valid only if you specify CLOUDTYPE=S3.
3. The default value of the ENCRYPT parameter is conditional. The server encrypts data by default if the CLOUDLOCATION parameter is set to OFFPREMISE. If the CLOUDLOCATION parameter is set to ONPREMISE, the default is No.

Parameters

pool_name (Required)
: Specifies the cloud storage pool to define. This parameter is required. The maximum length of the name is 30 characters.

STGType=CLoud (Required)
: Specifies the type of storage that you want to define for a cloud storage pool. To ensure that the storage pool can be used in a cloud environment, you must specify STGTYPE=CLOUD.
  Tip: To optimize performance, set up one or more local storage directories to temporarily hold data that is moving to the cloud. After you define a cloud-container storage pool, use the DEFINE STGPOOLDIRECTORY command to assign local directories to the cloud-container storage pool.

POoltype=PRimary

Specifies that you want to define a primary storage pool. This parameter is optional.

DESCription
: Specifies a description of the cloud storage pool. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains blank characters.

CLOUDType
: Specifies the type of cloud environment where you are configuring the storage pool.
You can specify one of the following values:

  AZure
  : Specifies that the storage pool uses a Microsoft Azure cloud computing system.

  S3
  : Specifies that the storage pool uses a cloud computing system with the Simple Storage Service (S3) protocol, such as IBM® Cloud Object Storage or Amazon Web Services (AWS) S3. If you define a storage pool as using S3 with this parameter, you cannot later change the storage pool type by using the UPDATE STGPOOL command.

  SOftlayer
  : Specifies that the storage pool uses an IBM SoftLayer® (IBM Bluemix) cloud computing system with an OpenStack Swift cloud computing system.

  SWift
  : Specifies that the storage pool uses an OpenStack Swift cloud computing system. This value also specifies that the storage pool uses Version 2 of the protocol for authentication to the cloud. The URL of the cloud usually contains the version number of the protocol it is using.

  V1Swift
  : Specifies that the storage pool uses an OpenStack Swift cloud computing system. This value also specifies that the storage pool uses Version 1 of the protocol for authentication to the cloud. The URL of the cloud usually contains the version number of the protocol it is using.

  This parameter is optional. If you do not specify the parameter, the default value, SWIFT, is used.

CLOUDUrl
: Specifies the URL of the cloud environment where you are configuring the storage pool. Based on your cloud provider, you can use a blob service endpoint, region endpoint URL, an accesser IP address, a public authentication endpoint, or a similar value for this parameter. Be sure to include the protocol, such as `https://` or `http://`, at the beginning of the URL. The maximum length of the web address is 870 characters. The CLOUDURL parameter is not validated until the first backup begins.
For more information about how to locate these values, select your cloud service provider from the list on the Configuring a cloud-container storage pool for data storage page.
Tip: To use more than one IBM Cloud Object Storage accesser, list the accesser IP addresses separated by a vertical bar (|), with no spaces, such as in the following example:

  ```
  CLOUDURL=<accesser_URL1>|<accesser_URL2>|<accesser_URL3>
  ```

  If you are using the Operations Center, type an accesser IP address in the URL field of the Add Storage pool wizard, and then press Enter to add additional IP addresses. Use multiple accessers to improve performance.
  This parameter is required if you specify the CLOUDTYPE parameter.

  - AZure
  - S3 (Simple Storage Service)
  - SOftlayer
  - SWift
  - V1Swift

IDentity
: Specifies the user ID for the cloud that is specified in the STGTYPE=CLOUD parameter. This parameter is required for all supported cloud computing systems except Azure. If you specified CLOUDTYPE=AZURE, do not specify the IDENTITY parameter. Based on your cloud provider, you can use an access key ID, a user name, a tenant name and user name, or a similar value for this parameter. The maximum length of the user ID is 255 characters.

PAssword (Required)
: Specifies the password for the cloud that is specified in the STGTYPE=CLOUD parameter. Based on your cloud provider, you can use a shared access signature (SAS) token, secret access key, an API key, a password, or a similar value for this parameter. This parameter is required. The maximum length of the password is 255 characters. The IDENTITY and PASSWORD parameters are not validated until the first backup begins.

CLOUDLocation
: Specifies the physical location of the cloud that is specified in the CLOUD parameter. This parameter is optional. The default value is OFFPREMISE. You can specify one of the following values:

- OFfpremise
- ONpremise

BUCKETName
: Specifies the name for an AWS S3 bucket or a IBM Cloud Object Storage vault to use with this storage pool, instead of using the default bucket name or vault name. This parameter is optional, and is valid only if you specify CLOUDTYPE=S3. If the name that you specify does not exist, the server creates a bucket or vault with the specified name before using the bucket or vault. Follow the naming restrictions for your cloud provider when specifying this parameter. Review the permissions for the bucket or vault and make sure that the credentials for this storage pool have permission to read, write, list, and delete objects in this bucket or vault. If you do not have the ability to change or view the permissions, and you have not already written data to this storage pool, use the UPDATE STGPOOL command with the BUCKETNAME parameter to use a different bucket or vault.

ACCess
: Specifies how client nodes and server processes access the cloud storage pool. This parameter is optional. The default value is READWRITE. You can specify one of the following values:

  READWrite
  : Specifies that client nodes and server processes can read and write to the cloud storage pool. This value is the default.

  READOnly
  : Specifies that client nodes and server processes can read only from the cloud storage pool.

  UNAVailable
  : Specifies that client nodes and server processes cannot access the cloud storage pool.

MAXWriters
: Specifies the maximum number of writing sessions that can run concurrently on the cloud storage pool. Specify a maximum number of writing sessions to control the performance of the cloud storage pool from negatively impacting other system resources. This parameter is optional. The default value is NOLIMIT. You can specify one of the following values:

  NOLimit
  : Specifies that no maximum size limit exists for the number of writers that you can use. This value is the default.

  maximum_writers
  : Limits the maximum number of writers that you can use. Specify an integer in the range 1 - 99999.

REUsedelay
: Specifies the number of days that must elapse after all deduplicated extents are removed from a cloud storage pool. This parameter controls the duration that deduplicated extents are associated with a cloud storage pool. When the value that is specified for the parameter expires, the deduplicated extents are deleted from the cloud storage pool. The default is 1. You can specify one of the following values:

  1
  : Specifies that deduplicated extents are deleted from a cloud storage pool after one day. This value is the default.

  days
  : You can specify an integer in the range 0 - 9999.

  Tip: Set this parameter to a value that is greater than the number specified for the SET DRMDBBACKUPEXPIREDAYS command. If you set this parameter to a higher value, you can ensure that when you restore the database to an earlier level, the references to files in the cloud storage pool are still valid.

ENCRypt
: Specifies whether the server encrypts client data before it writes it to the storage pool. You can specify the following values:

  Yes
  : Specifies that client data is encrypted by the server.

  No
  : Specifies that client data is not encrypted by the server.

  This parameter is optional. The default depends on the physical location of the cloud, which is specified by the CLOUDLOCATION parameter. If the cloud is off premise, the server encrypts data by default. If the cloud is on premises, the server does not encrypt data by default.

COMPRession
: Specifies whether data is compressed in the storage pool. This parameter is optional. You can specify one of the following values:

No
: Specifies that data is not compressed in the storage pool.

Yes
: Specifies that data is compressed in the storage pool. This is the default.

Example 1: Define an OpenStack Swift cloud-container storage pool

Define an OpenStack Swift cloud-container storage pool that is named STGPOOL1.

```
define stgpool stgpool1 stgtype=cloud
cloudtype=swift cloudurl=http://123.234.123.234:5000/v2.0
identity=admin:admin password=password description="OpenStack Swift cloud"
```

Example 2: Define a cloud-container primary storage pool

Define a cloud-container primary storage pool that is named STGPOOL1.

```
define stgpool stgpool1 stgtype=cloud
cloudtype=swift cloudurl=http://123.234.123.234:5000/v2.0
identity=admin:admin password=protect8991 pooltype=primary
```

Example 3: Define a cloud-container storage pool with read only access

Define a cloud-container storage pool that is named STGPOOL1 with read only access.

```
define stgpool stgpool1 stgtype=cloud
cloudtype=swift cloudurl=http://123.234.123.234:5000/v2.0
identity=admin:admin password=protect8991 access=readonly
```

Example 4: Define a cloud-container storage pool with 99 writing sessions

Define a cloud-container storage pool that is named STGPOOL1 with 99 writing sessions.

```
define stgpool stgpool1 stgtype=cloud
cloudtype=swift cloudurl=http://123.234.123.234:5000/v2.0
identity=admin:admin password=protect8991 maxwr=99
```

Example 5: Define a cloud-container storage pool in which deduplicated extents are deleted after two days

Define a cloud-container storage pool that is named STGPOOL1 and deduplicated extents are deleted after two days.

```
define stgpool stgpool1 stgtype=cloud
cloudtype=swift cloudurl=http://123.234.123.234:5000/v2.0
identity=admin:admin password=protect8991 reusedelay=2
```

```

Parameters

pool_name (Required)
: Specifies the storage pool to define. This parameter is required. The maximum length of the name is 30 characters.

STGType=DIrectory (Required)
: Specifies the type of storage that you want to define for a storage pool. This parameter specifies that a directory-container type of storage pool is assigned to the storage pool. You must define a storage pool directory for this type of storage pool by using the DEFINE STGPOOLDIRECTORY command.
  Requirements:

  - Ensure that enough space is available on the file system for the directory-container storage pool.
  - You must store the directory-container storage pool and the DB2® database on separate mount points on the file system. The directory-container storage pool might grow to occupy all the space on the directory it is stored on.
  - You must use a file system other than the file system where the IBM Spectrum Protect™ server is located.

POoltype=PRimary
: Specifies that you want the storage pool to be used as a primary storage pool. This parameter is optional.

DESCription
: Specifies a description of the storage pool. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains blank characters.

ACCess
: Specifies how client nodes and server processes can access the storage pool. This parameter is optional. You can specify one of the following values:

  READWrite
  : Specifies that client nodes and server processes can read and write to the storage pool.

  READOnly

Specifies that client nodes and server processes can read only from the storage pool.

UNAVailable
Specifies that client nodes and server processes cannot access the storage pool.

MAXSIze
Specifies the maximum size for a physical file that the server can store in the storage pool. This parameter is optional. The default value is NOLIMIT. You can specify one of the following values:

NOLimit
Specifies that there is no maximum size limit for physical files that are stored in the storage pool.

maximum_file_size
Limits the maximum physical file size. Specify an integer in the range 1 - 999999, followed by a scale factor. For example, MAXSIZE=5G specifies that the maximum file size for this storage pool is 5 GB. You can use one of the following scale factors:

Table 1. Scale factor for the maximum file size

Scale factor	Meaning
K	kilobyte
M	megabyte
G	gigabyte
T	terabyte

Tip: If you do not specify a unit of measurement for the maximum file size, the value is specified in bytes.

When the physical size of the storage pool exceeds the MAXSIZE parameter, the following table shows where files are typically stored.

Table 2. The location of a file according to the file size and the pool that is specified

Pool that is specified	Result
No pool is specified as the next storage pool in the hierarchy.	The server does not store the file.
A pool is specified as the next storage pool in the hierarchy.	The server stores the file in the storage pool that you specified.

Tip: If you also specify the NEXTstgpool parameter, define one storage pool in your hierarchy to have no limit on the maximum file size by specifying the MAXSIze=NOLimit parameter. When you have at least one pool with no size limit, you ensure that no matter what its size, the server can store the file.

For multiple files that are sent during data deduplication processing, the server considers the size of the data deduplication process to be the file size. If the total size of all files in the process is larger than the maximum size limit, the server does not store the files in the storage pool.

MAXWriters
Specifies the maximum number of I/O threads for the following processes:

- The number of I/O threads that can run concurrently on the directory-container storage pool.
- The number of I/O threads that are written simultaneously to the directory-container storage pool.

This parameter is optional. As a best practice, use the default value of NOLIMIT. You can specify the following values:

NOLimit
Specifies that no maximum number of I/O threads are written to the storage pool.

maximum_writers
Limits the maximum number of I/O threads that you can use. Specify an integer in the range 1 - 99999.

Tip: The IBM Spectrum Protect server manages the number of I/O threads automatically based on the resources that are available and the server load.

NEXTstgpool
Specifies the name of a random-access or primary sequential storage pool to which files are stored when the directory-container storage pool is full. This parameter is optional.
Restrictions:

- To ensure that you do not create a chain of storage pools that leads to an endless loop, specify at least one storage pool in the hierarchy with no value.
- If you specify a sequential-access pool as the next storage pool, the pool must be in either NATIVE or NONBLOCK data format.
- Do not specify a directory-container or cloud-container storage pool.
- Do not use this parameter to specify a storage pool for data migration.

PROTECTstgpool
: Specifies the name of the directory-container storage pool on the target replication server where the data is backed up when you use the PROTECT STGPOOL command for this storage pool. This parameter is optional.

PROTECTLOCalstgpools
: Specifies the name of the container-copy storage pool on a local device where the data is backed up. This container-copy storage pool will be a local target storage pool when you use the PROTECT STGPOOL command. You can specify a maximum of two container-copy storage pool names. Separate multiple names with commas and no intervening spaces. The maximum length of each name is 30 characters. This parameter is optional.

REUsedelay
: Specifies the number of days that must elapse before all deduplicated extents are removed from a directory-container storage pool. This parameter controls the duration that deduplicated extents are associated with a directory-container storage pool after they are no longer referenced. When the value that is specified for the parameter expires, the deduplicated extents are deleted from the directory-container storage pool. Specify an integer in the range 0 - 9999. The default value for directory-container storage pools is 1, which means that deduplicated extents that are no longer referenced are deleted from a directory-container storage pool after 1 day.

  Set this parameter to a value greater than the number that is specified as your database backup period to ensure that data extents are still valid when you restore the database to another level.

ENCRypt
: Specifies whether the server encrypts client data before the server writes the data to the storage pool. You can specify the following values:

  Yes
  : Specifies that client data is encrypted by the server.

  No
  : Specifies that client data is not encrypted by the server.

COMPRession
: Specifies whether data is compressed in the storage pool. This parameter is optional. You can specify one of the following values:

  No
  : Specifies that data is not compressed in the storage pool.

  Yes
  : Specifies that data is compressed in the storage pool. This is the default.

Example: Define a directory-container storage pool that is configured for overflow storage when the storage pool is full

Define a directory-container storage pool that is named STGPOOL1. The storage pool is configured for overflow storage to a tape storage pool when the storage pool is full.

```
define stgpool stgpool1 stgtype=directory nextstgpool=overflow_tape_pool
```

Example: Define a directory-container storage pool that specifies the maximum file size

Define a directory-container storage pool that is named STGPOOL2. The storage pool specifies the maximum file size that the server can store in the storage pool as 100 megabytes.

```
define stgpool stgpool2 stgtype=directory maxsize=100M
```

Example: Define a directory-container storage pool on the source replication server with a directory-container storage pool on the target replication server to back up data

Define a directory-container storage pool that is named STGPOOL3. The data for storage pool STGPOOL3 is backed up to a directory-container storage pool, TARGET_STGPOOL3 on the target replication server.

```
define stgpool stgpool3 stgtype=directory protectstgpool=target_stgpool3
```

Example: Define a directory-container storage pool on the source replication server with a container-copy storage pool to back up data locally

Define a directory-container storage pool that is named STGPOOL3. The data for storage pool STGPOOL3 is backed up to a local container-copy storage pool, TARGET_LOCALSTGPOOL.

```
define stgpool stgpool3 stgtype=directory protectlocalstgpools=target_localstgpool
```

Example: Define a directory-container storage pool and disable compression

Define a directory-container storage pool that is named STGPOOL1 and disable compression.

```
define stgpool stgpool1 stgtype=directory compression=no
```

Table 3. Commands related to DEFINE STGPOOL (Define a directory-container storage pool)

Command	Description
DEFINE STGPOOLDIRECTORY	Defines a storage pool directory to a directory-container or cloud-container storage pool.
PROTECT STGPOOL	Protects a directory-container storage pool.
QUERY CONTAINER	Displays information about a container.
QUERY STGPOOL	Displays information about storage pools.
REPAIR STGPOOL	Repairs a directory-container storage pool.
UPDATE STGPOOL (directory-container)	Update a directory-container storage pool.

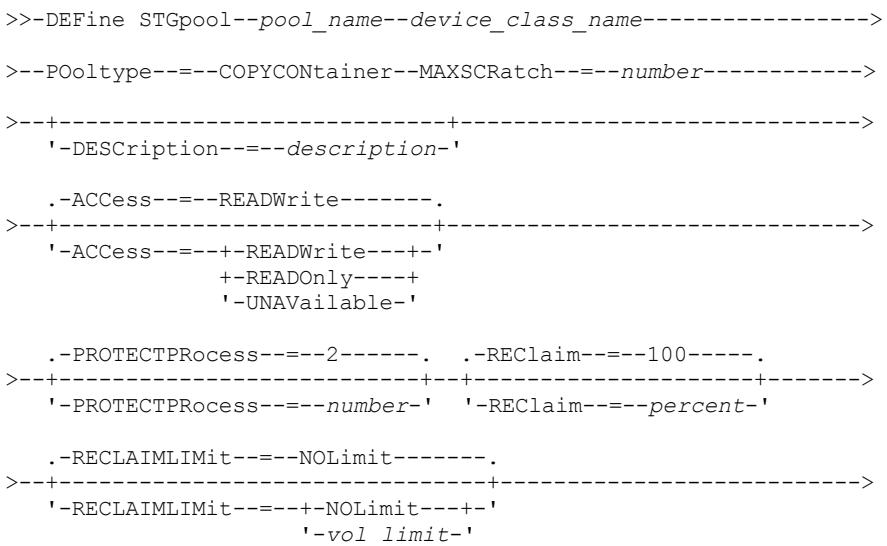
DEFINE STGPOOL (Define a container-copy storage pool)

Use this command to define a container-copy storage pool to hold a copy of data from a directory-container storage pool.

Privilege class

To issue this command, you must have system privilege.

Syntax



```
   .-REUsedelay--=--0----.
>--+---------------------+-------------------------------------><
   '-REUsedelay--=--days-'
```

Parameters

pool_name (Required)
: Specifies the name of the container-copy storage pool. The name must be unique, and the maximum length is 30 characters.

device_class_name (Required)
: Specifies the name of the sequential access device class to which this storage pool is assigned.
Restriction: You cannot specify the following device class types:

- DISK
- FILE
- CENTERA
- NAS
- REMOVABLEFILE
- SERVER

Restriction: Virtual tape libraries are not supported, regardless of which library type is defined. Only physical tape is supported.

POoltype=COPYCONtainer (Required)
: Specifies that you want to define a container-copy storage pool. A container-copy storage pool is used only to store a copy of data from a directory-container storage pool.

MAXSCRatch (Required)
: Specifies the maximum number of scratch volumes that the server can request for this storage pool. You can specify an integer in the range 0 - 100000000. If the server can request scratch volumes as needed, you do not have to define each volume to be used.

The value of this parameter is used to estimate the total number of volumes that are available in the storage pool and the corresponding estimated capacity for the storage pool.

Scratch volumes are automatically deleted from the storage pool when they become empty. However, if the access mode for a scratch volume is OFFSITE, the volume is not deleted from the storage pool until the access mode is changed. An administrator can then query the server for empty, offsite scratch volumes and return them to the onsite location.

DESCription
: Specifies a description of the storage pool. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters.

ACCess
: Specifies how server processes such as storage-pool protection and repair can access data in the storage pool. This parameter is optional. The default value is READWRITE. You can specify one of the following values:

READWrite
: Specifies that the server can read and write to volumes in the storage pool.

READOnly
: Specifies that the server can only read volumes in the storage pool. The server can use data in the storage pool to restore extents to directory-container storage pools. No operations that write to the container-copy storage pool are allowed.

UNAVailable
: Specifies that the server cannot access data that is stored on volumes in the storage pool.

PROTECTPRocess
: Specifies the maximum number of parallel processes that are used when you issue the PROTECT STGPOOL command to copy data to this pool from a directory-container storage pool. This parameter is optional. Enter a value in the range 1 - 20. The default value is 2.

The time that is required to complete the copy operation might be decreased by using multiple, parallel processes. However, in some cases when multiple processes are running, one or more of the processes must wait to use a volume that is already in use by a different process.

When you specify this value, consider the number of logical and physical drives that can be dedicated to the copy operation. To access a tape volume, the server uses a mount point and a drive. The number of available mount points and

drives depends on the mount limit of the device class for the storage pool, and on other server and system activity.

This parameter is ignored if you use the PREVIEW=YES option on the PROTECT STGPOOL command. In that case, only one process is used and no mount points or drives are needed.

RECLaim
: Specifies when a volume becomes eligible for reclamation and reuse. Specify eligibility as the percentage of a volume's space that is occupied by extents that are no longer stored in the associated directory-container storage pool. Reclamation moves any extents that are still stored in the associated directory-container storage pool from eligible volumes to other volumes. Reclamation occurs only when a PROTECT STGPOOL command stores data into this storage pool.

  This parameter is optional. You can specify an integer in the range 1 - 100. The default value is 100, which means that volumes in this storage pool are not reclaimed.

  The server determines that the volume is a candidate for reclamation if the percentage of reclaimable space on a volume is greater than the reclamation threshold of the storage pool.

  By setting the reclaim value to 50 percent or greater, data that is moved from two reclaimed volumes uses no more than the equivalent of one new volume.

  Use caution when you use reclamation with container-copy storage pools that have offsite volumes. When an offsite volume becomes eligible for reclamation, in effect the server moves the extents on the volume back to the onsite location. If a disaster occurs onsite, the server can obtain extents from the offsite volume if the restored database refers to extents on the offsite volume. Therefore, for disaster recovery purposes, ensure that you schedule database backups to run after storage pool protection schedules and DRM move schedules have run, and ensure that all database backup volumes are taken offsite along with the DRM volumes.

  Tip: Set different reclamation values for offsite container-copy storage pools and onsite container-copy storage pools. Because container-copy storage pools store deduplicated data, the data extents are spread across multiple tape volumes. When you choose a reclamation threshold for an offsite copy, carefully consider the number of available mount points and the number of tape volumes that you must retrieve if a disaster occurs. Setting a higher threshold means that you must retrieve more volumes than you would if your reclamation value was lower. Using a lower threshold reduces the number of mount points that are required in a disaster. The preferred method is to set the reclamation value for offsite copies to 60, and for onsite copies, in the range 90 - 100.

RECLAIMLIMit
: Specifies the maximum number of volumes that the server reclaims when you issue the PROTECT STGPOOL command and specify the RECLAIM=YESLIMITED or RECLAIM=ONLYLIMITED option. This parameter is valid only for container-copy storage pools. This parameter is optional. The default value is NOLIMIT. You can specify one of the following values:

  NOLimit
  : Specifies that all volumes in the container-copy storage pool are processed for reclamation.

  vol_limit
  : Specifies the maximum number of volumes in the container-copy storage pool that are reclaimed. The value that you specify determines how many new scratch tapes are available after reclamation processing completes. You can specify a number in the range 1 - 100000.

REUsedelay
: Specifies the number of days that must elapse after all extents are deleted from a volume before the volume can be rewritten or returned to scratch status. This parameter is optional. You can specify an integer in the range 0 - 9999. The default value is 0, which means that a volume can be rewritten or returned to scratch status as soon as all the extents are deleted from the volume.
  Tip: Use this parameter to ensure that when you restore the database to an earlier level, database references to extents in the storage pool are still valid. You must set this parameter to a value greater than the number of days you plan to retain the oldest database backup. If you use disaster recovery manager, the number of days that are specified for this parameter must be the same as the number specified for the SET DRMDBBACKUPEXPIREDAYS command.

Example: Define a container-copy storage pool with an LTO7A device class

Define a container-copy storage pool, CONTAINER1_COPY2, to the LTO7A device class. Allow up to 50 scratch volumes for this pool. Delay the reuse of volumes for 45 days.

```
define stgpool container1_copy2 lto7a pooltype=copycontainer
 maxscratch=50 reusedelay=45
```

Table 1. Commands related to DEFINE STGPOOL (Define a container-copy storage pool)

Command	Description
DEFINE STGPOOL (directory-container)	Define a directory-container storage pool.
PROTECT STGPOOL	Protects a directory-container storage pool.
QUERY STGPOOL	Displays information about storage pools.
REPAIR STGPOOL	Repairs a directory-container storage pool.
UPDATE STGPOOL (container-copy)	Update a container-copy storage pool that stores copies of data from a directory-container storage pool.
UPDATE STGPOOL (directory-container)	Update a directory-container storage pool.

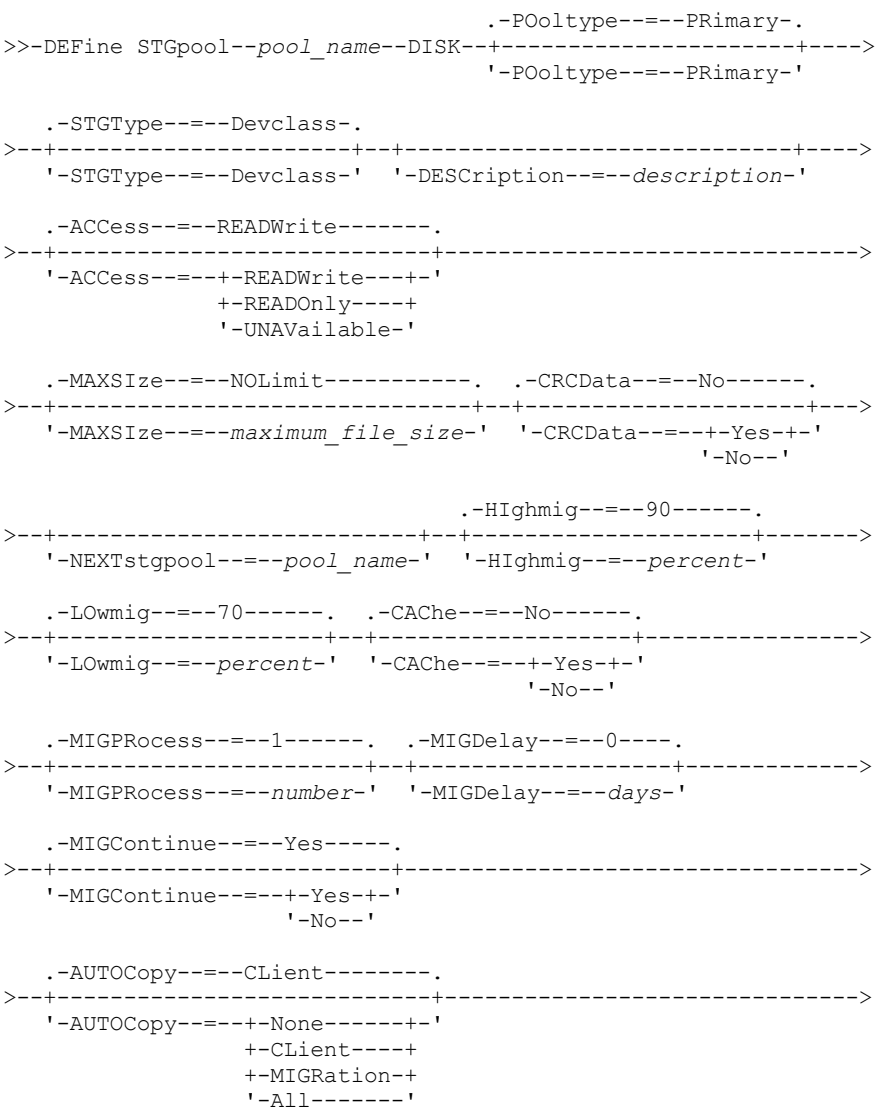
DEFINE STGPOOL (Define a primary storage pool assigned to random access devices)

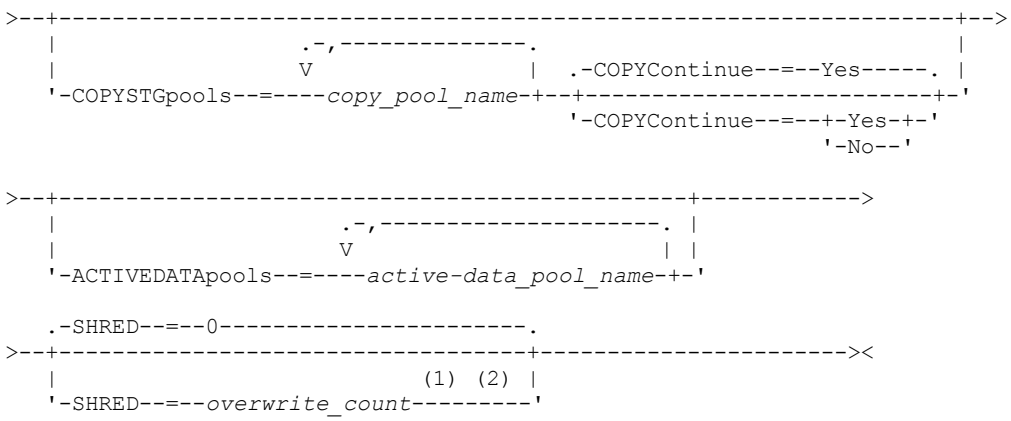
Use this command to define a primary storage pool that is assigned to random access devices.

Privilege class

To issue this command, you must have system privilege.

Syntax





Notes:

1. This parameter is not available for CENTERA or SnapLock storage pools.
2. Linux This parameter is not available for SnapLock storage pools.

Parameters

pool_name (Required)
Specifies the name of the storage pool to be defined. The name must be unique, and the maximum length is 30 characters.

DISK (Required)
Specifies that you want to define a storage pool to the DISK device class (the DISK device class is predefined during installation).

POoltype=PRimary
Specifies that you want to define a primary storage pool. This parameter is optional. The default value is PRIMARY.

STGType
Specifies the type of storage that you want to define for a storage pool. This parameter is optional. The default value is DEVCLASS.

Devclass
Specifies that a device class type of storage pool is assigned to the storage pool.

DESCription
Specifies a description of the storage pool. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters.

ACCess
Specifies how client nodes and server processes (such as migration and reclamation) can access files in the storage pool. This parameter is optional. The default value is READWRITE. You can specify the following values:

READWrite
Specifies that client nodes and server processes can read and write to files stored on volumes in the storage pool.

READOnly
Specifies that client nodes can only read files from the volumes in the storage pool.

Server processes can move files within the volumes in the storage pool. However, no new writes are permitted to volumes in the storage pool from volumes outside the storage pool.

If this storage pool was specified as a subordinate storage pool (with the NEXTSTGPOOL parameter) and is defined as *readonly*, the storage pool is skipped when server processes attempt to write files to the storage pool.

UNAVailable
Specifies that client nodes cannot access files stored on volumes in the storage pool.

Server processes can move files within the volumes in the storage pool and can also move or copy files from this storage pool to another storage pool. However, no new writes are permitted to volumes in the storage pool from volumes outside the storage pool.

If this storage pool was specified as a subordinate storage pool (with the NEXTSTGPOOL parameter) and is defined as *unavailable*, the storage pool is skipped when server processes attempt to write files to the storage pool.

MAXSIze

Specifies the maximum size for a physical file that the server can store in the storage pool. This parameter is optional. The default value is NOLIMIT. You can specify the following values:

NOLimit

Specifies that there is no maximum size limit for physical files that are stored in the storage pool.

maximum_file_size

Limits the maximum physical file size. Specify an integer 1 - 999999 terabytes, followed by a scale factor. For example, MAXSIZE=5G specifies that the maximum file size for this storage pool is 5 GB. You can use one of the following scale factors:

Scale factor	Meaning
K	kilobyte
M	megabyte
G	gigabyte
T	terabyte

The client estimates the size of files that are sent to the server. The client estimate is used rather than the actual amount of data that is sent to the server. Client options, such as deduplication, compression, and encryption, can cause the actual amount of data that is sent to the server to be larger or smaller than the size estimate. For example, the compression of a file might be smaller in size than the estimate, thus sending less data than the estimate. Furthermore, a binary file might be larger in size after the compression processing, thus sending more data than the estimate.

When the physical size of the storage pool exceeds the MAXSIZE parameter, the following table shows where files are typically stored.

Table 1. The location of a file according to the file size and the pool that is specified

File size	Pool specified	Result
Exceeds the maximum size	No pool is specified as the next storage pool in the hierarchy	The server does not store the file
	A pool is specified as the next storage pool in the hierarchy	The server stores the file in the next storage pool that can accept the file size

Tip: If you also specify the NEXTstgpool parameter, define one storage pool in your hierarchy to have no limit on the maximum file size by specifying the MAXSIze=NOLimit parameter. When you have at least one pool with no size limit, you ensure that no matter what its size, the server can store the file.

For multiple files that are sent in a single transaction, the server considers the size of the transaction to be the file size. If the total size of all files in the transaction is larger than the maximum size limit, the server does not store the files in the storage pool.

CRCData

Specifies whether a cyclic redundancy check (CRC) validates storage pool data when audit volume processing occurs on the server. This parameter is optional. The default value is NO. By setting CRCDATA to YES and scheduling an AUDIT VOLUME command, you can continually ensure the integrity of data that is stored in your storage hierarchy. You can specify the following values:

Yes

Specifies that data is stored containing CRC information, allowing for audit volume processing to validate storage pool data. This mode impacts performance because more expenditure is required to calculate and compare CRC values between the storage pool and the server.

No

Specifies that data is stored without CRC information.

NEXTstgpool

Specifies a primary storage pool to which files are migrated. This parameter is optional.
If you do not specify a next storage pool, the following actions occur:

- The server cannot migrate files from this storage pool
- The server cannot store files that exceed the maximum size for this storage pool in another storage pool

Restrictions:

- To ensure that you do not create a chain of storage pools that leads to an endless loop, specify at least one storage pool in the hierarchy with no value.
- If you specify a sequential-access pool as the next storage pool, the pool must be in either NATIVE or NONBLOCK data format.
- Do not specify a directory-container or cloud-container storage pool.
- Do not use this parameter to specify a storage pool for data migration.

HIghmig
: Specifies that the server starts migration for this storage pool when the amount of data in the pool reaches this percentage of the pool's estimated capacity. This parameter is optional. You can specify an integer 0 - 100. The default value is 90.

  When the storage pool exceeds the high migration threshold, the server can start migration of files by node, to the next storage pool. The NEXTSTGPOOL parameter defines this setting. You can specify HIGHMIG=100 to prevent migration for this storage pool.

LOwmig
: Specifies that the server stops migration for this storage pool when the amount of data in the pool reaches this percentage of the pool's estimated capacity. This parameter is optional. You can specify an integer 0 - 99. The default value is 70.

  When migration is by node or file space, depending upon collocation, the level of the storage pool can fall below the value that you specified for this parameter. To empty the storage pool, set LOWMIG=0.

CAChe
: Specifies whether the migration process leaves a cached copy of a file in this storage pool after you migrate the file to the next storage pool. This parameter is optional. The default value is NO. You can specify the following values:

  Yes
  : Specifies that caching is enabled.

  No
  : Specifies that caching is disabled.

  Using cache might improve the ability to retrieve files, but might affect the performance of other processes.

MIGPRocess
: Specifies the number of processes that the server uses for migrating files from this storage pool. This parameter is optional. You can specify an integer 1 - 999. The default value is 1.

  During migration, these processes are run in parallel to provide the potential for improved migration rates.

  Tips:

  - The number of migration processes is dependent upon the following settings:
    - The MIGPROCESS parameter
    - The collocation setting of the next pool
    - The number of nodes or the number of collocation groups with data in the storage pool that is being migrated

    For example, suppose that `MIGPROCESS =6`, the next pool COLLOCATE parameter is set to NODE, but there are only two nodes with data on the storage pool. Migration processing consists of only two processes, not six. If the COLLOCATE parameter is set to GROUP and both nodes are in the same group, migration processing consists of only one process. If the COLLOCATE parameter is set to NO or FILESPACE, and each node has two file spaces with backup data, then migration processing consists of four processes.
  - When you specify this parameter, consider whether the simultaneous-write function is enabled for server data migration. Each migration process requires a mount point and a drive for each copy storage pool and active-data pool that is defined to the target storage pool.

MIGDelay
: Specifies the minimum number of days a file must remain in a storage pool before it becomes eligible for migration. To calculate a value to compare to the specified MIGDELAY value, the server counts the following items:

  - The number of days that the file was in the storage pool
  - The number of days, if any, since the file was retrieved by a client

  The lesser of the two values are compared to the specified MIGDELAY value. For example, if all the following conditions are true, a file is not migrated:

  - A file was in a storage pool for five days.
  - The file was accessed by a client within the past three days.

- The value that is specified for the MIGDELAY parameter is four days.

This parameter is optional. You can specify an integer 0 - 9999. The default is 0, which means that you do not want to delay migration.

If you want the server to count the number of days that are based on when a file was stored and not when it was retrieved, use the NORETRIEVEDATE server option.

MIGContinue
Specifies whether you allow the server to migrate files that do not satisfy the migration delay time. This parameter is optional. The default is YES.

Because you can require that files remain in the storage pool for a minimum number of days, the server may migrate all eligible files to the next storage pool yet not meet the low migration threshold. This parameter allows you to specify whether the server is allowed to continue the migration process by migrating files that do not satisfy the migration delay time.

You can specify one of the following values:

Yes
Specifies that, when necessary to meet the low migration threshold, the server continues to migrate files that do not satisfy the migration delay time.

If you allow more than one migration process for the storage pool, some files that do not satisfy the migration delay time may be migrated unnecessarily. As one process migrates files that satisfy the migration delay time, a second process could begin migrating files that do not satisfy the migration delay time to meet the low migration threshold. The first process that is still migrating files that satisfy the migration delay time might have, by itself, caused the low migration threshold to be met.

No
Specifies that the server stops migration when no eligible files remain to be migrated, even before reaching the low migration threshold. The server does not migrate files unless the files satisfy the migration delay time.

AUTOCopy
Specifies when IBM Spectrum Protect™ runs simultaneous-write operations. The default value is CLIENT. This parameter is optional and affects the following operations:

- Client store sessions
- Server import processes
- Server data-migration processes

If an error occurs while data is being simultaneously written to a copy storage pool or active-data pool during a migration process, the server stops writing to the failing storage pools for the remainder of the process. However, the server continues to store files into the primary storage pool and any remaining copy storage pools or active-data pools. These pools remain active for the duration of the migration process. Copy storage pools are specified using the COPYSTGPOOLS parameter. Active-data pools are specified using the ACTIVEDATAPOOLS parameter.

You can specify one of the following values:

None
Specifies that the simultaneous-write function is disabled.

CLient
Specifies that data is written simultaneously to copy storage pools and active-data pools during client store sessions or server import processes. During server import processes, data is written simultaneously to only copy storage pools. Data is not written to active-data pools during server import processes.

MIGRation
Specifies that data is written simultaneously to copy storage pools and active-data pools only during migration to this storage pool. During server data-migration processes, data is written simultaneously to copy storage pools and active-data pools only if the data does not exist in those pools. Nodes whose data is being migrated must be in a domain associated with an active-data pool. If the nodes are not in a domain associated with an active pool, the data cannot be written to the pool.

All
Specifies that data is written simultaneously to copy storage pools and active-data pools during client store sessions, server import processes, or server data-migration processes. Specifying this value ensures that data is written simultaneously whenever this pool is a target for any of the eligible operations.

COPYSTGpools

Specifies the names of copy storage pools where the server simultaneously writes data. The COPYSTGPOOLS parameter is optional. You can specify a maximum of three copy pool names that are separated by commas. Spaces between the names of the copy pools are not allowed. When you specify a value for the COPYSTGPOOLS parameter, you can also specify a value for the COPYCONTINUE parameter.

The combined total number of storage pools that are specified in the COPYSGTPOOLS and ACTIVEDATAPOOLS parameters cannot exceed three.

When a data storage operation switches from a primary storage pool to a next storage pool, the next storage pool inherits the list of copy storage pools and the COPYCONTINUE value from the primary storage pool. The primary storage pool is specified by the copy group of the management class that is bound to the data.

The server can write data simultaneously to copy storage pools during the following operations:

- Back up and archive operations by IBM Spectrum Protect backup-archive clients or application clients that are using the IBM Spectrum Protect API
- Migration operations by IBM Spectrum Protect for Space Management clients
- Import operations that involve copying exported file data from external media to a primary storage pool associated with a copy storage pool list

Restriction: The simultaneous-write function is not supported for the following store operations:

- When the operation is using LAN-free data movement. Simultaneous-write operations take precedence over LAN-free data movement, causing the operations to go over the LAN. However, the simultaneous-write configuration is followed.
- NAS backup operations. If the primary storage pool specified in the DESTINATION or TOCDESTINATION in the copy group of the management class has copy storage pools that are defined:
  - The copy storage pools are ignored
  - The data is stored into the primary storage pool only

Attention: The function that is provided by the COPYSTGPOOLS parameter is not intended to replace the BACKUP STGPOOL command. If you use the COPYSTGPOOLS parameter, continue to use the BACKUP STGPOOL command to ensure that the copy storage pools are complete copies of the primary storage pool. There are cases when a copy might not be created. For more information, see the COPYCONTINUE parameter description.

COPYContinue

Specifies how the server usually reacts to a copy storage pool write failure for any of the copy storage pools that are listed in the COPYSTGPOOLS parameter. This parameter is optional. The default value is YES. When you specify the COPYCONTINUE parameter, you must also specify the COPYSTGPOOLS parameter.
You can specify the following values:

Yes

If the COPYCONTINUE parameter is set to YES, the server will stop writing to the failing copy pools for the remainder of the session, but continue storing files into the primary pool and any remaining copy pools. The copy storage pool list is active only for the life of the client session and applies to all the primary storage pools in a particular storage pool hierarchy.

No

If the COPYCONTINUE parameter is set to NO, the server will fail the current transaction and discontinue the store operation.

Restrictions:

- The setting of the COPYCONTINUE parameter does not affect active-data pools. If a write failure occurs for any of the active-data pools, the server stops writing to the failing active-data pool for the remainder of the session, but continues storing files into the primary pool and any remaining active-data pools and copy storage pools. The active-data pool list is active only for the life of the session and applies to all the primary storage pools in a particular storage pool hierarchy.
- The setting of the COPYCONTINUE parameter does not affect the simultaneous-write function during server import. If data is being written simultaneously and a write failure occurs to the primary storage pool or any copy storage pool, the server import process fails.
- The setting of the COPYCONTINUE parameter does not affect the simultaneous-write function during server data migration. If data is being written simultaneously and a write failure occurs to any copy storage pool or active-data pool, the failing storage pool is removed and the data migration process continues. Write failures to the primary storage pool cause the migration process to fail.

ACTIVEDATApools

Specifies the names of active-data pools where the server simultaneously writes data during a client backup operation. The ACTIVEDATAPOOLS parameter is optional. Spaces between the names of the active-data pools are not allowed.

The combined total number of storage pools that are specified in the COPYSGTPOOLS and ACTIVEDATAPOOLS parameters cannot exceed three.

When a data storage operation switches from a primary storage pool to a next storage pool, the next storage pool inherits the list of active-data pools from the destination storage pool that is specified in the copy group. The primary storage pool is specified by the copy group of the management class that is bound to the data.

The server can write data simultaneously to active-data pools only during backup operations by IBM Spectrum Protect backup-archive clients or application clients that use the IBM Spectrum Protect API.
Restrictions:

1. This parameter is available only to primary storage pools that use "NATIVE" or "NONBLOCK" data format. This parameter is not available for storage pools that use the following data formats:
   - NETAPPDUMP
   - CELERRADUMP
   - NDMPDUMP
2. Writing data simultaneously to active-data pools is not supported when you use LAN-free data movement. Simultaneous-write operations take precedence over LAN-free data movement, causing the operations to go over the LAN. However, the simultaneous-write configuration is followed.
3. The simultaneous-write function is not supported when a NAS backup operation is writing a TOC file. If the primary storage pool specified in the TOCDESTINATION in the copy group of the management class has active-data pools that are defined:
   - The active-data pools are ignored
   - The data is stored into the primary storage pool only
4. You cannot use the simultaneous-write function with CENTERA storage devices.
5. Data that is being imported is not stored in active-data pools. After an import operation, use the COPY ACTIVEDATA command to store the imported data in an active-data pool.

Attention: The function that is provided by the ACTIVEDATAPOOLS parameter is not intended to replace the COPY ACTIVEDATA command. If you use the ACTIVEDATAPOOLS parameter, use the COPY ACTIVEDATA command to ensure that the active-data pools contain all active data of the primary storage pool.

SHRED

Specifies whether data is physically overwritten when it is deleted. This parameter is optional. You can specify an integer 0 - 10. The default value is 0.

If you specify a value of zero, the server deletes the data from the database. However, the storage that is used to contain the data is not overwritten, and the data exists in storage until that storage is reused for other data. It might be possible to discover and reconstruct the data after it is deleted.

If you specify a value greater than zero, the server deletes the data both logically and physically. The server overwrites the storage that is used to contain the data the specified number of times. This overwriting increases the difficulty of discovering and reconstructing the data after it is deleted.

To ensure that all copies of the data are shredded, specify a SHRED value greater than zero for the storage pool that is specified in the NEXTSTGPOOL parameter. Do not specify either the COPYSTGPOOLS or ACTIVEDATAPOOLS. Specifying relatively high values for the overwrite count generally improves the level of security, but might affect performance adversely.

Overwriting of deleted data is done asynchronously after the delete operation is complete. Therefore, the space that is occupied by the deleted data remains occupied for some time. The space is not available as free space for new data.

A SHRED value greater than zero cannot be used if the value of the CACHE parameter is YES.

Important: After an export operation finishes and identifies files for export, any change to the storage pool SHRED value is ignored. An export operation that is suspended retains the original SHRED value throughout the operation. You might want to consider canceling your export operation if changes to the storage pool SHRED value jeopardize the operation. You can reissue the export command after any needed cleanup.

Example: Define a primary storage pool for a DISK device class

Define a primary storage pool, POOL1, to use the DISK device class, with caching enabled. Limit the maximum file size to 5 MB. Store any files larger than 5 MB in subordinate storage pools that begin with the PROG2 storage pool. Set the high migration threshold to 70 percent, and the low migration threshold to 30 percent.

```
define stgpool pool1 disk
 description="main disk storage pool" maxsize=5m
 highmig=70 lowmig=30 cache=yes
 nextstgpool=prog2
```

DEFINE STGPOOL (Define a primary storage pool assigned to sequential access devices)

Use this command to define a primary storage pool that is assigned to sequential access devices.

Privilege class

To issue this command, you must have system privilege.

Notes:

1. This parameter is not available for storage pools that use the data formats NETAPPDUMP, CELERRADUMP, or NDMPDUMP.
2. This parameter is not available or is ignored for CENTERA storage pools.
3. The RECLAMATIONTYPE=SNAPLOCK setting is valid only for storage pools that are defined to servers that are enabled for IBM Spectrum Protect™ for Data Retention. The storage pool must be assigned to a FILE device class, and the directories that are specified in the device class must be NetApp SnapLock volumes.
4. The values NETAPPDUMP, CELERRADUMP, and NDMPDUMP are not valid for storage pools that are defined with a FILE-type device class.
5. This parameter is valid only for storage pools that are defined with a FILE-type device class.
6. This parameter is available only when the value of the DEDUPLICATE parameter is YES.

Parameters

pool_name (Required)
: Specifies the name of the storage pool to be defined. The name must be unique, and the maximum length is 30 characters.

device_class_name (Required)
: Specifies the name of the device class to which this storage pool is assigned. You can specify any device class except for the DISK device class.

POoltype=PRimary
: Specifies that you want to define a primary storage pool. This parameter is optional. The default value is PRIMARY.

STGType
: Specifies the type of storage that you want to define for a storage pool. This parameter is optional. The default value is DEVCLASS.

  Devclass
  : Specifies that a device class type of storage pool is assigned to the storage pool.

DESCription
: Specifies a description of the storage pool. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters.

ACCess
: Specifies how client nodes and server processes (such as migration and reclamation) can access files in the storage pool. This parameter is optional. The default value is READWRITE. You can specify the following values:

  READWrite
  : Specifies that client nodes and server processes can read and write to files stored on volumes in the storage pool.

  READOnly
  : Specifies that client nodes can only read files from the volumes in the storage pool.

    Server processes can move files within the volumes in the storage pool. However, no new writes are permitted to volumes in the storage pool from volumes outside the storage pool.

    If this storage pool was specified as a subordinate storage pool (with the NEXTSTGPOOL parameter) and is defined as *readonly*, the storage pool is skipped when server processes attempt to write files to the storage pool.

  UNAVailable
  : Specifies that client nodes cannot access files stored on volumes in the storage pool.

    Server processes can move files within the volumes in the storage pool and can also move or copy files from this storage pool to another storage pool. However, no new writes are permitted to volumes in the storage pool from

volumes outside the storage pool.

If this storage pool was specified as a subordinate storage pool (with the NEXTSTGPOOL parameter) and is defined as *unavailable*, the storage pool is skipped when server processes attempt to write files to the storage pool.

MAXSIze
Specifies the maximum size for a physical file that the server can store in the storage pool. This parameter is optional. The default value is NOLIMIT. You can specify one of the following values:

NOLimit
Specifies that there is no maximum size limit for physical files stored in the storage pool.

maximum_file_size
Limits the maximum physical file size. Specify an integer from 1 to 999999 terabytes, followed by a scale factor. For example, MAXSIZE=5G specifies that the maximum file size for this storage pool is 5 gigabytes. Scale factors are:

Scale factor	Meaning
K	kilobyte
M	megabyte
G	gigabyte
T	terabyte

The client estimates the size of files that are sent to the server. The client estimate is used rather than the actual amount of data that is sent to the server. Client options, such as deduplication, compression, and encryption, can cause the actual amount of data that is sent to the server to be larger or smaller than the size estimate. For example, the compression of a file might be smaller in size than the estimate, thus sending less data than the estimate. Furthermore, a binary file might be larger in size after the compression processing, thus sending more data than the estimate.

When the physical size of the storage pool exceeds the MAXSIZE parameter, the following table shows where files are typically stored.

Table 1. The location of a file according to the file size and the pool that is specified

File size	Pool specified	Result
Exceeds the maximum size	No pool is specified as the next storage pool in the hierarchy	The server does not store the file
	A pool is specified as the next storage pool in the hierarchy	The server stores the file in the next storage pool that can accept the file size

Tip: If you also specify the NEXTstgpool parameter, define one storage pool in your hierarchy to have no limit on the maximum file size by specifying the MAXSIze=NOLimit parameter. When you have at least one pool with no size limit, you ensure that no matter what its size, the server can store the file.

For multiple files that are sent in a single transaction, the server considers the size of the transaction to be the file size. If the total size of all files in the transaction is larger than the maximum size limit, the server does not store the files in the storage pool.

Restriction:

This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

CRCData
Specifies whether a cyclic redundancy check (CRC) validates storage pool data when audit volume processing occurs on the server. This parameter is only valid for NATIVE data format storage pools. This parameter is optional. The default value is NO. By setting CRCDATA to YES and scheduling an AUDIT VOLUME command, you can continually ensure the integrity of data that is stored in your storage hierarchy. You can specify the following values:

Yes
Specifies that data is stored containing CRC information, allowing for audit volume processing to validate storage pool data. This mode impacts performance because more processing is required to calculate and compare CRC values between the storage pool and the server.

No
Specifies that data is stored without CRC information.

Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

Tip:

For storage pools that are associated with the 3592, LTO, or ECARTRIDGE device type, logical block protection provides better protection against data corruption than CRC validation for a storage pool. If you specify CRC validation for a storage pool, data is validated only during volume auditing operations. Errors are identified after data is written to tape.

To enable logical block protection, specify a value of READWRITE for the LBPROTECT parameter on the DEFINE DEVCLASS and UPDATE DEVCLASS commands for the 3592, LTO, or ECARTRIDGE device types. Logical block protection is supported only on the following types of drives and media:

- IBM® LTO5 and later.
- IBM 3592 Generation 3 drives and later with 3592 Generation 2 media and later.
- Oracle StorageTek T10000C and T10000D drives.

NEXTstgpool
Specifies a primary storage pool to which files are migrated. You cannot migrate data from a sequential access storage pool to a random access storage pool. This parameter is optional.

If this storage pool does not have a next storage pool, the server cannot migrate files from this storage pool and cannot store files that exceed the maximum size for this storage pool in another storage pool.

When there is insufficient space available in the current storage pool, the NEXTSTGPOOL parameter for sequential access storage pools does not allow data to be stored into the next pool. In this case, the server issues a message and the transaction fails.

For next storage pools with a device type of FILE, the server completes a preliminary check to determine whether sufficient space is available. If space is not available, the server skips to the next storage pool in the hierarchy. If space is available, the server attempts to store data in that pool. However, it is possible that the storage operation might fail because, at the time the actual storage operation is attempted, the space is no longer available.

Restrictions:

- To ensure that you do not create a chain of storage pools that leads to an endless loop, specify at least one storage pool in the hierarchy with no value.
- If you specify a sequential-access pool as the next storage pool, the pool must be in either NATIVE or NONBLOCK data format.
- Do not specify a directory-container or cloud-container storage pool.
- Do not use this parameter to specify a storage pool for data migration.
- This parameter is not available for storage pools that use the following data formats:
  - NETAPPDUMP
  - CELERRADUMP
  - NDMPDUMP

HIghmig
Specifies that the server starts migration when storage pool utilization reaches this percentage. For sequential-access disk (FILE) storage pools, utilization is the ratio of data in a storage pool to the pool's total estimated data capacity, including the capacity of all scratch volumes specified for the pool. For storage pools that use tape media, utilization is the ratio of volumes that contain data to the total number of volumes in the storage pool. The total number of volumes includes the maximum number of scratch volumes. This parameter is optional. You can specify an integer 0 - 100. The default value is 90.

When the storage pool exceeds the high migration threshold, the server can start migration of files by volume to the next storage pool defined for the pool. You can set the high migration threshold to 100 to prevent migration for the storage pool.

Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP

- CELERRADUMP
- NDMPDUMP

LOwmig
: Specifies that the server stops migration when storage pool utilization is at or below this percentage. For sequential-access disk (FILE) storage pools, utilization is the ratio of data in a storage pool to the pool's total estimated data capacity, including the capacity of all scratch volumes specified for the pool. For storage pools that use tape media, utilization is the ratio of volumes that contain data to the total number of volumes in the storage pool. The total number of volumes includes the maximum number of scratch volumes. This parameter is optional. You can specify an integer 0 - 99. The default value is 70.

  When the storage pool reaches the low migration threshold, the server does not start migration of files from another volume. You can set the low migration threshold to 0 to allow migration to empty the storage pool.

  Restriction: This parameter is not available for storage pools that use the following data formats:

  - NETAPPDUMP
  - CELERRADUMP
  - NDMPDUMP

RECLaim
: Specifies when the server reclaims a volume, which is based on the percentage of reclaimable space on a volume. Reclaimable space is the amount of space that is occupied by files that are expired or deleted from the database.

  Reclamation makes the fragmented space on volumes usable again by moving any remaining unexpired files from one volume to another volume, thus making the original volume available for reuse. This parameter is optional. You can specify an integer 1 - 100. The default value is 60, except for storage pools that use WORM devices.

  AIX | Windows For storage pools that use a WORM device class, you can lower the value from the default of 100. Lowering the value allows the server to consolidate data onto fewer volumes when needed. Volumes that are emptied by reclamation can be checked out of the library, freeing slots for new volumes. Because the volumes are write-once, the volumes cannot be reused.

  The server determines that the volume is a candidate for reclamation if the percentage of reclaimable space on a volume is greater than the reclamation threshold of the storage pool.

  Specify a value of 50 percent or greater for this parameter so that files stored on two volumes can be combined onto a single output volume.

  Restriction: This parameter is not available for storage pools that use the following data formats:

  - NETAPPDUMP
  - CELERRADUMP
  - NDMPDUMP

RECLAIMPRocess
: Specifies the number of parallel processes to use for reclaiming the volumes in this storage pool. This parameter is optional. Enter a value 1 - 999. The default value is 1. You can specify one or more reclamation processes for each primary sequential-access storage pool.
  When you calculate the value for this parameter, consider the following resources that are required for reclamation processing:

  - The number of sequential storage pools.
  - The number of logical and physical drives that can be dedicated to the operation.

  To access sequential volumes, IBM Spectrum Protect uses a mount point and, if the device type is not FILE, a physical drive.

  For example, suppose that you want to reclaim the volumes from two sequential storage pools simultaneously and that you want to specify four processes for each of the storage pools. The storage pools have the same device class. Assuming that the RECLAIMSTGPOOL parameter is not specified or that the reclaim storage pool has the same device class as the storage pool that is being reclaimed, each process requires two mount points and, if the device type is not FILE, two drives. (One of the drives is for the input volume, and the other drive is for the output volume.) To run eight reclamation processes simultaneously, you need a total of at least 16 mount points and 16 drives. The device class for the storage pools must have a mount limit of at least 16.

Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

RECLAIMSTGpool
Specifies another primary storage pool as a target for reclaimed data from this storage pool. This parameter is optional. When the server reclaims volumes for the storage pool, the server moves unexpired data from the volumes that are being reclaimed to the storage pool named with this parameter.

A reclaim storage pool is most useful for a storage pool that has only one drive in its library. When you specify this parameter, the server moves all data from reclaimed volumes to the reclaim storage pool regardless of the number of drives in the library.

To move data from the reclaim storage pool back to the original storage pool, use the storage pool hierarchy. Specify the original storage pool as the next storage pool for the reclaim storage pool.

Restriction:

- This parameter is not available for storage pools that use the following data formats:
- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

RECLAMATIONType
Specifies the method by which volumes are reclaimed and managed. This parameter is optional. The default value is THRESHOLD. The following are possible values:

THRESHold
Specifies that volumes that belong to this storage pool are reclaimed based on the threshold value in the RECLAIM attribute for this storage pool.
SNAPlock
Specifies that FILE volumes that belong to this storage pool are managed for retention using NetApp Data ONTAP software and NetApp SnapLock volumes. This parameter is only valid for storage pools that are defined to a server that has data retention protection enabled and that is assigned to a FILE device class. Volumes in this storage pool are not reclaimed based on threshold; the RECLAIM value for the storage pool is ignored.

All volumes in this storage pool are created as FILE volumes. A retention date, which is derived from the retention attributes in the archive copy group for the storage pool, is set in the metadata for the FILE volume by using the SnapLock feature of the NetApp Data ONTAP operating system. Until the retention date expires, the FILE volume and any data on it cannot be deleted from the physical SnapLock volume on which it is stored.

The RECLAMATIONTYPE parameter for all storage pools that are being defined must be the same when defined to the same device class name. The DEFINE command can fail if the RECLAMATIONTYPE parameter specified is different from what is defined for storage pools that are already defined to the device class name.

Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

COLlocate
Specifies whether the server attempts to keep data, which is stored on as few volumes as possible, that belong to one of the following candidates:

- A single client node
- A group of file spaces
- A group of client nodes
- A client file space

This parameter is optional. The default value is GROUP.

Collocation reduces the number of sequential access media mounts for restore, retrieve, and recall operations. However, collocation increases both the amount of server time that is needed to collocate files for storing and the number of volumes

required. Collocation can also impact the number of processes migrating disks to sequential pool.

You can specify one of the following options:

No
: Specifies that collocation is disabled. During migration from disk, processes are created at a file space level.

GRoup
: Specifies that collocation is enabled at the group level for client nodes or file spaces. For collocation groups, the server attempts to put data for nodes or file spaces that belong to the same collocation group on as few volumes as possible.

  If you specify COLLOCATE=GROUP but do not define any collocation groups, or if you do not add nodes or file spaces to a collocation group, data is collocated by node. Consider tape usage when you organize client nodes or file spaces into collocation groups.

  For example, if a tape-based storage pool consists of data from nodes and you specify COLLOCATE=GROUP, the server completes the following actions:

  - Collocates the data by group for grouped nodes. Whenever possible, the server collocates data that belongs to a group of nodes on a single tape or on as few tapes as possible. Data for a single node can also be spread across several tapes that are associated with a group.
  - Collocates the data by node for ungrouped nodes. Whenever possible, the server stores the data for a single node on a single tape. All available tapes that already have data for the node are used before available space on any other tape is used.
  - During migration from disk, the server creates migration processes at the collocation group level for grouped nodes, and at the node level for ungrouped nodes.

  If a tape-based storage pool consists of data from grouped file spaces and you specify COLLOCATE=GROUP, the server completes the following actions:

  - Collocates by group, the data for grouped file spaces only. Whenever possible, the server collocates data that belongs to a group of file spaces on a single tape or on as few tapes as possible. Data for a single file space can also be spread across several tapes that are associated with a group.
  - Collocates the data by node (for file spaces that are not explicitly defined to a file space collocation group). For example, node1 has file spaces that are named A, B, C, D, and E. File spaces A and B belong to a file space collocation group but C, D, and E do not. File spaces A and B are collocated by file space collocation group, while C, D, and E are collocated by node.
  - During migration from disk, the server creates migration processes at the collocation group level for grouped file spaces.

  Data is collocated on the least number of sequential access volumes.

NODe
: Specifies that collocation is enabled at the client node level. For collocation groups, the server attempts to put data for one node on as few volumes as possible. If the node has multiple file spaces, the server does not try to collocate those file spaces. For compatibility with an earlier version, COLLOCATE=YES is still accepted by the server to specify collocation at the client node level.

  If a storage pool contains data for a node that is a member of a collocation group and you specify COLLOCATE=NODE, the data is collocated by node.

  For COLLOCATE=NODE, the server creates processes at the node level when you migrate data from disk.

FIlespace
: Specifies that collocation is enabled at the file space level for client nodes. The server attempts to place data for one node and file space on as few volumes as possible. If a node has multiple file spaces, the server attempts to place data for different file spaces on different volumes.

  For COLLOCATE=FILESPACE, the server creates processes at the file space level when you migrate data from disk.

MAXSCRatch (Required)
: Specifies the maximum number of scratch volumes that the server can request for this storage pool. You can specify an integer 0 - 100000000. By allowing the server to request scratch volumes, you avoid having to define each volume to be used.

The value that is specified for this parameter is used to estimate the total number of volumes available in the storage pool and the corresponding estimated capacity for the storage pool.

Scratch volumes are automatically deleted from the storage pool when they become empty. When scratch volumes with the device type of FILE are deleted, the space that the volumes occupied is freed by the server and returned to the file system.

Tip: For server-to-server operations that use virtual volumes and that store a small amount of data, consider specifying a value for the MAXSCRATCH parameter that is higher than the value you typically specify for write operations to other types of volumes. After a write operation to a virtual volume, IBM Spectrum Protect marks the volume as FULL, even if the value of the MAXCAPACITY parameter on the device-class definition is not reached. The server does not keep virtual volumes in FILLING status and does not append to them. If the value of the MAXSCRATCH parameter is too low, server-to-server operations can fail.

REUsedelay

Specifies the number of days that must elapse after all files are deleted from a volume before the volume can be rewritten or returned to the scratch pool. This parameter is optional. You can specify an integer 0 - 9999. The default value is 0, which means that a volume can be rewritten or returned to the scratch pool as soon as all the files are deleted from the volume.

Tip: Use this parameter to ensure that when you restore the database to an earlier level, database references to files in the storage pool are still valid. You must set this parameter to a value greater than the number of days you plan to retain the oldest database backup. The number of days that are specified for this parameter must be the same as the number specified for the SET DRMDBBACKUPEXPIREDAYS command.

OVFLOcation

Specifies the overflow location for the storage pool. The server assigns this location name to a volume that is ejected from the library by the command. This parameter is optional. The location name can be a maximum length of 255 characters. Enclose the location name in quotation marks if the location name contains any blank characters.

Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

MIGDelay

Specifies the minimum number of days a file must remain in a storage pool before it becomes eligible for migration. All files on a volume must be eligible for migration before the server selects the volume for migration. To calculate a value to compare to the specified MIGDELAY, the server counts the number of days that the file has been in the storage pool.

This parameter is optional. You can specify an integer 0 - 9999. The default is 0, which means that you do not want to delay migration. If you want the server to count the number of days that are based only on when a file was stored and not when it was retrieved, use the NORETRIEVEDATE server option.

Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

MIGContinue

Specifies whether you allow the server to migrate files that do not satisfy the migration delay time. This parameter is optional. The default is YES.

Because you can require that files remain in the storage pool for a minimum number of days, the server may migrate all eligible files to the next storage pool yet not meet the low migration threshold. This parameter allows you to specify whether the server is allowed to continue the migration process by migrating files that do not satisfy the migration delay time.

You can specify one of the following values:

Yes

Specifies that, when necessary to meet the low migration threshold, the server continues to migrate files that do not satisfy the migration delay time.

If you allow more than one migration process for the storage pool, some files that do not satisfy the migration delay time may be migrated unnecessarily. As one process migrates files that satisfy the migration delay time, a second process could begin migrating files that do not satisfy the migration delay time to meet the low migration threshold.

The first process that is still migrating files that satisfy the migration delay time might have, by itself, caused the low migration threshold to be met.

No
: Specifies that the server stops migration when no eligible files remain to be migrated, even before reaching the low migration threshold. The server does not migrate files unless the files satisfy the migration delay time.

MIGPRocess
: Specifies the number of parallel processes to use for migrating the files from the volumes in this storage pool. This parameter is optional. Enter a value 1 - 999. The default value is 1.

When calculating the value for this parameter, consider the number of sequential storage pools that will be involved with the migration, and the number of logical and physical drives that can be dedicated to the operation. To access a sequential-access volume, IBM Spectrum Protect uses a mount point and, if the device type is not FILE, a physical drive. The number of available mount points and drives depends on other IBM Spectrum Protect and system activity and on the mount limits of the device classes for the sequential access storage pools that are involved in the migration.

For example, suppose you want to simultaneously migrate the files from volumes in two primary sequential storage pools and that you want to specify three processes for each of the storage pools. The storage pools have the same device class. Assuming that the storage pool to which files are being migrated has the same device class as the storage pool from which files are being migrated, each process requires two mount points and, if the device type is not FILE, two drives. (One drive is for the input volume, and the other drive is for the output volume.) To run six migration processes simultaneously, you need a total of at least 12 mount points and 12 drives. The device class for the storage pools must have a mount limit of at least 12.

If the number of migration processes you specify is more than the number of available mount points or drives, the processes that do not obtain mount points or drives will wait for mount points or drives to become available. If mount points or drives do not become available within the MOUNTWAIT time, the migration processes will end. For information about specifying the MOUNTWAIT time, see DEFINE DEVCLASS (Define a device class).

The IBM Spectrum Protect server will start the specified number of migration processes regardless of the number of volumes that are eligible for migration. For example, if you specify ten migration processes and only six volumes are eligible for migration, the server will start ten processes and four of them will complete without processing a volume.

Tip: When you specify this parameter, consider whether the simultaneous-write function is enabled for server data migration. Each migration process requires a mount point and a drive for each copy storage pool and active-data pool that is defined to the target storage pool.
Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

DATAFormat
: Specifies the data format to use to back up files to this storage pool and restore files from this storage pool. The default format is the NATIVE server format. You can specify the following values:

NATive
: Specifies the data format is the native IBM Spectrum Protect server format and includes block headers.

NONblock
: Specifies the data format is the native IBM Spectrum Protect server format and does not include block headers. The default minimum block size on a volume that is associated with a FILE device class is 256 KB, regardless how much data is written to the volume. For certain tasks, you can minimize wasted space on storage volumes by specifying the NONBLOCK data format. For example, you can specify the NONBLOCK data format for the following tasks:

  - Using content-management products
  - Using the DIRMC client option to store directory information
  - Migrating very small files by using IBM Spectrum Protect for Space Management or IBM Spectrum Protect HSM for Windows

  In most situations, however, the NATIVE format is preferred.

NETAPPDump
: Specifies the data is in a NetApp dump format. This data format must be specified for file system images that are in a dump format and that were backed up from a NetApp or an IBM System Storage® N Series file server that uses

NDMP. The server does not complete migration, reclamation, or AUDIT VOLUME for a storage pool with DATAFORMAT=NETAPPDUMP. You can use the MOVE DATA command to move data from one primary storage pool to another, or out of a volume if the volume must be reused.

CELERRADump
: Specifies that the data is in an EMC Celerra dump format. This data format must be specified for file system images that are in a dump format and that were backed up from an EMC Celerra file server that uses NDMP. The server does not complete migration, reclamation, or AUDIT VOLUME for a storage pool with DATAFORMAT=CELERRADUMP. You can use the MOVE DATA command to move data from one primary storage pool to another, or out of a volume if the volume must be reused.

NDMPDump
: Specifies that the data is in NAS vendor-specific backup format. Use this data format for file system images that were backed up from a NAS file server other than a NetApp or EMC Celerra file server. The server does not complete migration, reclamation, or AUDIT VOLUME for a storage pool with DATAFORMAT=NDMPDUMP. You can use the MOVE DATA command to move data from one primary storage pool to another, or out of a volume if the volume must be reused.

AUTOCopy
: Specifies when IBM Spectrum Protect completes simultaneous-write operations. The default value is CLIENT. This parameter is optional and affects the following operations:

- Client store sessions
- Server import processes
- Server data-migration processes

If the AUTOCOPY option is set to `ALL` or `CLIENT`, and there is at least one storage pool that is listed in the COPYSTGPOOLS or ACTIVEDATAPOOLS options, any client-side deduplication is disabled.

If an error occurs while data is being simultaneously written to a copy storage pool or active-data pool during a migration process, the server stops writing to the failing storage pools for the remainder of the process. However, the server continues to store files into the primary storage pool and any remaining copy storage pools or active-data pools. These pools remain active for the duration of the migration process. Copy storage pools are specified using the COPYSTGPOOLS parameter. Active-data pools are specified using the ACTIVEDATAPOOLS parameter.

You can specify one of the following values:

None
: Specifies that the simultaneous-write function is disabled.

CLient
: Specifies that data is written simultaneously to copy storage pools and active-data pools during client store sessions or server import processes. During server import processes, data is written simultaneously to only copy storage pools. Data is not written to active-data pools during server import processes.

MIGRation
: Specifies that data is written simultaneously to copy storage pools and active-data pools only during migration to this storage pool. During server data-migration processes, data is written simultaneously to copy storage pools and active-data pools only if the data does not exist in those pools. Nodes whose data is being migrated must be in a domain associated with an active-data pool. If the nodes are not in a domain associated with an active pool, the data cannot be written to the pool.

All
: Specifies that data is written simultaneously to copy storage pools and active-data pools during client store sessions, server import processes, or server data-migration processes. Specifying this value ensures that data is written simultaneously whenever this pool is a target for any of the eligible operations.

COPYSTGpools
: Specifies the names of copy storage pools where the server simultaneously writes data. The COPYSTGPOOLS parameter is optional. You can specify a maximum of three copy pool names that are separated by commas. Spaces between the names of the copy pools are not allowed. When you specify a value for the COPYSTGPOOLS parameter, you can also specify a value for the COPYCONTINUE parameter.

The combined total number of storage pools that are specified in the COPYSTGPOOLS and ACTIVEDATAPOOLS parameters cannot exceed three.

When a data storage operation switches from a primary storage pool to a next storage pool, the next storage pool inherits the list of copy storage pools and the COPYCONTINUE value from the primary storage pool. The primary storage pool is specified by the copy group of the management class that is bound to the data.

The server can write data simultaneously to copy storage pools during the following operations:

- Back up and archive operations by IBM Spectrum Protect backup-archive clients or application clients that use the IBM Spectrum Protect API
- Migration operations by IBM Spectrum Protect for Space Management clients
- Import operations that involve copying exported file data from external media to a storage pool defined with a copy storage pool list

Restrictions:

1. This parameter is available only to primary storage pools that use NATIVE or NONBLOCK data format. This parameter is not available for storage pools that use the following data formats:
   - NETAPPDUMP
   - CELERRADUMP
   - NDMPDUMP
2. Writing data simultaneously to copy storage pools is not supported when LAN-free data movement is used. Simultaneous-write operations take precedence over LAN-free data movement, causing the operations to go over the LAN. However, the simultaneous-write configuration is accepted.
3. The simultaneous-write function is not supported for NAS backup operations. If the primary storage pool specified in the DESTINATION or TOCDESTINATION in the copy group of the management class has copy storage pools defined, the copy storage pools are ignored and the data is stored into the primary storage pool only.
4. You cannot use the simultaneous-write function with CENTERA storage devices.

Attention: The function that is provided by the COPYSTGPOOLS parameter is not intended to replace the BACKUP STGPOOL command. If you use the COPYSTGPOOLS parameter, continue to use the BACKUP STGPOOL command to ensure that the copy storage pools are complete copies of the primary storage pool. There are cases when a copy might not be created. For more information, see the COPYCONTINUE parameter description.

COPYContinue

Specifies how the server reacts to a copy storage pool write failure for any of the copy storage pools that are listed in the COPYSTGPOOLS parameter. This parameter is optional. The default value is YES. When you specify the COPYCONTINUE parameter, you must also specify the COPYSTGPOOLS parameter.

The COPYCONTINUE parameter has no effect on the simultaneous-write function during migration.

You can specify the following values:

Yes

If the COPYCONTINUE parameter is set to YES, the server will stop writing to the failing copy pools for the remainder of the session, but continue storing files into the primary pool and any remaining copy pools. The copy storage pool list is active only for the life of the client session and applies to all the primary storage pools in a particular storage pool hierarchy.

No

If the COPYCONTINUE parameter is set to NO, the server will fail the current transaction and discontinue the store operation.

Restrictions:

- The setting of the COPYCONTINUE parameter does not affect active-data pools. If a write failure occurs for any of the active-data pools, the server stops writing to the failing active-data pool for the remainder of the session, but continues storing files into the primary pool and any remaining active-data pools and copy storage pools. The active-data pool list is active only for the life of the session and applies to all the primary storage pools in a particular storage pool hierarchy.
- The setting of the COPYCONTINUE parameter does not affect the simultaneous-write function during server import. If data is being written simultaneously and a write failure occurs to the primary storage pool or any copy storage pool, the server import process fails.
- The setting of the COPYCONTINUE parameter does not affect the simultaneous-write function during server data migration. If data is being written simultaneously and a write failure occurs to any copy storage pool or active-data pool, the failing storage pool is removed and the data migration process continues. Write failures to the primary storage pool cause the migration process to fail.

Restriction: This parameter is not available for storage pools that use the following data formats:

- NETAPPDUMP
- CELERRADUMP
- NDMPDUMP

ACTIVEDATApools
Specifies the names of active-data pools where the server simultaneously writes data during a client backup operation. The ACTIVEDATAPOOLS parameter is optional. Spaces between the names of the active-data pools are not allowed.

The combined total number of storage pools that are specified in the COPYSGTPOOLS and ACTIVEDATAPOOLS parameters cannot exceed three.

When a data storage operation switches from a primary storage pool to a next storage pool, the next storage pool inherits the list of active-data pools from the destination storage pool specified in the copy group. The primary storage pool is specified by the copy group of the management class that is bound to the data.

The server can write data simultaneously to active-data pools only during backup operations by IBM Spectrum Protect backup-archive clients or application clients that use the IBM Spectrum Protect API.
Restrictions:

1. This parameter is available only to primary storage pools that use NATIVE or NONBLOCK data format. This parameter is not available for storage pools that use the following data formats:
   - NETAPPDUMP
   - CELERRADUMP
   - NDMPDUMP
2. Write data simultaneously to active-data pools is not supported when LAN-free data movement is used. Simultaneous-write operations take precedence over LAN-free data movement, causing the operations to go over the LAN. However, the simultaneous-write configuration is accepted.
3. The simultaneous-write function is not supported when a NAS backup operation is writing a TOC file. If the primary storage pool specified in the TOCDESTINATION in the copy group of the management class has active-data pools defined, the active-data pools are ignored, and the data is stored into the primary storage pool only.
4. You cannot use the simultaneous-write function with CENTERA storage devices.
5. Data being imported is not stored in active-data pools. After an import operation, use the COPY ACTIVEDATA command to store the imported data in an active-data pool.

Attention: The function that is provided by the ACTIVEDATAPOOLS parameter is not intended to replace the COPY ACTIVEDATA command. If you use the ACTIVEDATAPOOLS parameter, use the COPY ACTIVEDATA command to ensure that the active-data pools contain all active data of the primary storage pool.

DEDUPlicate
Specifies whether the data that is stored in this storage pool is deduplicated. This parameter is optional and is valid only for storage pools that are defined with a FILE-type device class. The default value is NO.

IDENTIFYPRocess
Specifies the number of parallel processes to use for server-side data deduplication. This parameter is optional and is valid only for storage pools that are defined with a FILE device class. Enter a value 0 - 50. The default value is 1. If the value of the DEDUPLICATE parameter is NO, the default setting for IDENTIFYPROCESS has no effect.
Remember: Data deduplication processes can be either active or idle. Processes that are working on files are active. Processes that are waiting for files to work on are idle. Processes remain idle until volumes with data to be deduplicated become available. The output of the QUERY PROCESS command for data deduplication includes the total number of bytes and files that have been processed since the process first started. For example, if a data deduplication process processes four files, becomes idle, and then processes five more files, then the total number of files processed is nine. Processes end only when canceled or when the number of data-deduplication processes for the storage pool is changed to a value less than the number currently specified.

Example: Define a primary storage pool with an 8MMTAPE device class

Define a primary storage pool that is named 8MMPOOL to the 8MMTAPE device class (with a device type of 8MM) with a maximum file size of 5 MB. Store any files larger than 5 MB in subordinate pools, beginning with POOL1. Enable collocation of files for client nodes. Allow as many as 5 scratch volumes for this storage pool.

```
define stgpool 8mmpool 8mmtape maxsize=5m
 nextstgpool=pool1 collocate=node
 maxscratch=5
```

SET DRMDBBACKUPEXPIREDAYS (Specify DB backup series expiration)

DEFINE STGPOOL (Define a copy storage pool assigned to sequential access devices)

Use this command to define a copy storage pool that is assigned to sequential access devices.

Privilege class

To issue this command, you must have system privilege.

Syntax

Notes:

1. The RECLAMATIONTYPE=SNAPLOCK setting is valid only for storage pools that are defined to servers that are enabled for IBM Spectrum Protect™ for Data Retention. The storage pool must be assigned to a FILE device class, and the directories that are specified in the device class must be NetApp SnapLock volumes.
2. The values NETAPPDUMP, CELERRADUMP, and NDMPDUMP are not valid for storage pools that are defined with a FILE device class.
3. This parameter is valid only for storage pools that are defined with a FILE device class.
4. This parameter is available only when the value of the DEDUPLICATE parameter is YES.

Parameters

pool_name (Required)
: Specifies the name of the storage pool to be defined. The name must be unique, and the maximum length is 30 characters.

device_class_name (Required)
: Specifies the name of the sequential access device class to which this copy storage pool is assigned. You can specify any device class except DISK.

POoltype=COpy (Required)
: Specifies that you want to define a copy storage pool.

DESCription
: Specifies a description of the copy storage pool. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters.

ACCess
: Specifies how client nodes and server processes (such as reclamation) can access files in the copy storage pool. This parameter is optional. The default value is READWRITE. You can specify the following values:

  READWrite
  : Specifies that files can be read from and written to the volumes in the copy storage pool.

  READOnly
  : Specifies that client nodes can read files that are stored only on the volumes in the copy storage pool.

    Server processes can move files within the volumes in the storage pool. The server can use files in the copy storage pool to restore files to primary storage pools. However, no new writes are allowed to volumes in the copy storage pool from volumes outside the storage pool. A storage pool cannot be backed up to the copy storage pool.

  UNAVailable
  : Specifies that client nodes cannot access files that are stored on volumes in the copy storage pool.

    Server processes can move files within the volumes in the storage pool. The server can use files in the copy storage pool to restore files to primary storage pools. However, no new writes are allowed to volumes in the copy storage pool from volumes outside the storage pool. A storage pool cannot be backed up to the copy storage pool.

COLlocate
: Specifies whether the server attempts to keep data, which is stored on as few volumes as possible, that belong to one of the following candidates:

  - A single client node
  - A group of file spaces
  - A group of client nodes
  - A client file space

  This parameter is optional. The default value is NO.

  Collocation reduces the number of sequential access media mounts for restore, retrieve, and recall operations. However, collocation increases both the amount of server time that is needed to collocate files for storing and the number of volumes required.

  You can specify one of the following options:

  No
  : Specifies that collocation is disabled.

  GRoup
  : Specifies that collocation is enabled at the group level for client nodes or file spaces. For collocation groups, the server attempts to put data for nodes or file spaces that belong to the same collocation group on as few volumes as possible.

If you specify COLLOCATE=GROUP but do not define any collocation groups, or if you do not add nodes or file spaces to a collocation group, data is collocated by node. Consider tape usage when you organize client nodes or file spaces into collocation groups.

For example, if a tape-based storage pool consists of data from nodes and you specify COLLOCATE=GROUP, the server completes the following actions:

- Collocates the data by group for grouped nodes. Whenever possible, the server collocates data that belongs to a group of nodes on a single tape or on as few tapes as possible. Data for a single node can also be spread across several tapes that are associated with a group.
- Collocates the data by node for ungrouped nodes. Whenever possible, the server stores the data for a single node on a single tape. All available tapes that already have data for the node are used before available space on any other tape is used.

If a tape-based storage pool consists of data from grouped file spaces and you specify COLLOCATE=GROUP, the server completes the following actions:

- Collocates by group, the data for grouped file spaces only. Whenever possible, the server collocates data that belongs to a group of file spaces on a single tape or on as few tapes as possible. Data for a single file space can also be spread across several tapes that are associated with a group.
- Collocates the data by node (for file spaces that are not explicitly defined to a file space collocation group). For example, node1 has file spaces named A, B, C, D, and E. File spaces A and B belong to a filespace collocation group but C, D, and E do not. File spaces A and B are collocated by filespace collocation group, while C, D, and E are collocated by node.

Data is collocated on the least amount of sequential access volumes.

NODe
: Specifies that collocation is enabled at the client node level. For collocation groups, the server attempts to put data for one node on as few volumes as possible. If the node has multiple file spaces, the server does not try to collocate those file spaces. For compatibility with an earlier version, COLLOCATE=YES is still accepted by the server to specify collocation at the client node level.

  If a storage pool contains data for a node that is a member of a collocation group and you specify COLLOCATE=NODE, the data is collocated by node.

FIlespace
: Specifies that collocation is enabled at the file space level for client nodes. The server attempts to place data for one node and file space on as few volumes as possible. If a node has multiple file spaces, the server attempts to place data for different file spaces on different volumes.

RECLaim
: Specifies when the server reclaims a volume, which is based on the percentage of reclaimable space on a volume. Reclaimable space is the amount of space that is occupied by files that are expired or deleted from the IBM Spectrum Protect database.

  Reclamation makes the fragmented space on volumes usable again by moving any remaining unexpired files from one volume to another volume, thus making the original volume available for reuse. This parameter is optional. You can specify an integer 1 - 100. The default value is 100, which means that reclamation is not completed.

  The server determines that the volume is a candidate for reclamation if the percentage of reclaimable space on a volume is greater than the reclamation threshold of the storage pool.

  If you change the value from the default, specify a value of 50 percent or greater so that files stored on two volumes can be combined onto a single output volume.

  When a copy pool volume that is offsite becomes eligible for reclamation, the reclamation process attempts to obtain the unexpired files on the reclaimable volume from a primary or copy storage pool that is onsite. The process then writes these files to an available volume in the original copy storage pool. Effectively, these files are moved back to the onsite location. However, the files can be obtained from the offsite volume after a disaster if a database backup is used that references the files on the offsite volume. Because of the way reclamation works with offsite volumes, use it carefully with copy storage pools.

RECLAIMPRocess

Specifies the number of parallel processes to use for reclaiming the volumes in this storage pool. This parameter is optional. Enter a value 1 - 999. The default value is 1.
When you calculate the value for this parameter, consider the following resources that are required for reclamation processing:

- The number of sequential storage pools.
- The number of logical and physical drives that can be dedicated to the operation.

To access sequential volumes, IBM Spectrum Protect uses a mount point and, if the device type is not FILE, a physical drive.

For example, suppose that you want to reclaim the volumes from two sequential storage pools simultaneously and that you want to specify four processes for each of the storage pools. The storage pools have the same device class. Each process requires two mount points and, if the device type is not FILE, two drives. (One of the drives is for the input volume, and the other drive is for the output volume.) To run eight reclamation processes simultaneously, you need a total of at least 16 mount points and 16 drives. The device class for the storage pools must have a mount limit of at least 16.

You can specify one or more reclamation processes for each copy storage pool. You can specify multiple concurrent reclamation processes for a single copy storage pool, which makes better use of your available tape drives or FILE volumes. If multiple concurrent processing is not necessary, specify a value of 1 for the RECLAIMPROCESS parameter.

RECLAMATIONType
Specifies the method by which volumes are reclaimed and managed. This parameter is optional. The default value is THRESHOLD. The following are possible values:

THREShold
Specifies that volumes that belong to this storage pool are reclaimed based on the threshold value in the RECLAIM attribute for this storage pool.
SNAPlock
Specifies that FILE volumes that belong to this storage pool are managed for retention by using NetApp Data ONTAP software and NetApp SnapLock volumes. This parameter is only valid for storage pools that being defined to a server that has data retention protection that is enabled and that is assigned to a FILE device class. Volumes in this storage pool are not reclaimed based on threshold; the RECLAIM value for the storage pool is ignored.

All volumes in this storage pool are created as FILE volumes. A retention date, which is derived from the retention attributes in the archive copy group for the storage pool, is set in the metadata for the FILE volume by using the SnapLock feature of the NetApp Data ONTAP operating system. Until the retention date expires, the FILE volume and any data on it cannot be deleted from the physical SnapLock volume on which it is stored.

The RECLAMATIONTYPE parameter for all storage pools that are being defined must be the same when defined to the same device class name. The DEFINE command fails if the RECLAMATIONTYPE parameter specified is different from what is defined for storage pools that are already defined to the device class name.

OFFSITERECLAIMLimit
Specifies the number of offsite volumes that space is reclaimed from during reclamation for this storage pool. This parameter is optional. The default value is NOLIMIT. You can specify the following values:

NOLimit
Specifies that you want to reclaim the space in all of your offsite volumes.
number
Specifies the number of offsite volumes to reclaim space from. You can specify an integer 0 - 99999. A value of zero means that none of the offsite volumes are reclaimed.
Tip:

To determine the value for the OFFSITERECLAIMLIMIT, use the statistical information in the message that is issued at the end of the offsite volume reclamation operation. The statistical information includes the following items:

- The number of offsite volumes that were processed
- The number of parallel processes that were used
- The total amount of time required for the processing

The order in which offsite volumes are reclaimed is based on the amount of unused space in a volume. (Unused space includes both space that has never been used on the volume and space that has become empty because of file deletion.) Volumes with the largest amount of unused space are reclaimed first.

For example, suppose a copy storage pool contains three volumes: VOL1, VOL2, and VOL3. VOL1 has the largest amount of unused space, and VOL3 has the least amount of unused space. Suppose further that the percentage of unused space in each of the three volumes is greater than the value of the RECLAIM parameter. If you do not specify a value for the OFFSITERECLAIMLIMIT parameter, all three volumes will be reclaimed when the reclamation runs. If you specify a value of 2, only VOL1 and VOL2 will be reclaimed when the reclamation runs. If you specify a value of 1, only VOL1 will be reclaimed.

MAXSCRatch (Required)
Specifies the maximum number of scratch volumes that the server can request for this storage pool. You can specify an integer 0 - 100000000. By allowing the server to request scratch volumes as needed, you avoid having to define each volume to be used.

The value that is specified for this parameter is used to estimate the total number of volumes available in the copy storage pool and the corresponding estimated capacity for the copy storage pool.

Scratch volumes are automatically deleted from the storage pool when they become empty. However, if the access mode for a scratch volume is OFFSITE, the volume is not deleted from the copy storage pool until the access mode is changed. An administrator can then query the server for empty, offsite scratch volumes and return them to the onsite location.

When scratch volumes with the device type of FILE become empty and are deleted, the space that the volumes occupied is freed by the server and returned to the file system.

Tip: For server-to-server operations that use virtual volumes and that store a small amount of data, consider specifying a value for the MAXSCRATCH parameter that is higher than the value you typically specify for write operations to other types of volumes. After a write operation to a virtual volume, IBM Spectrum Protect marks the volume as FULL, even if the value of the MAXCAPACITY parameter on the device-class definition is not reached. The server does not keep virtual volumes in FILLING status and does not append to them. If the value of the MAXSCRATCH parameter is too low, server-to-server operations can fail.

REUsedelay
Specifies the number of days that must elapse after all files are deleted from a volume before the volume can be rewritten or returned to the scratch pool. This parameter is optional. You can specify an integer 0 - 9999. The default value is 0, which means that a volume can be rewritten or returned to the scratch pool as soon as all the files are deleted from the volume.
Tip: Use this parameter to ensure that when you restore the database to an earlier level, database references to files in the copy storage pool are still valid. You must set this parameter to a value greater than the number of days you plan to retain the oldest database backup. The number of days that are specified for this parameter must be the same as the number specified for the SET DRMDBBACKUPEXPIREDAYS command.

OVFLOcation
Specifies the overflow location for the storage pool. The server assigns this location name to a volume that is ejected from the library by the command. This parameter is optional. The location name can be a maximum length of 255 characters. Enclose the location name in quotation marks if the location name contains any blank characters.

DATAFormat
Specifies the data format to use to back up files to this storage pool and restore files from this storage pool. The default format is the NATIVE server format. You can specify the following values:

NATive
Specifies the data format is the native IBM Spectrum Protect server format and includes block headers.

NONblock
Specifies the data format is the native IBM Spectrum Protect server format and does not include block headers. The default minimum block size on a volume that is associated with a FILE device class is 256 KB, regardless how much data is written to the volume. For certain tasks, you can minimize wasted space on storage volumes by specifying the NONBLOCK data format. For example, you can specify the NONBLOCK data format for the following tasks:

- Using content-management products
- Using the DIRMC client option to store directory information
- Migrating very small files by using IBM Spectrum Protect for Space Management or IBM Spectrum Protect HSM for Windows

In most situations, however, the NATIVE format is preferred.

NETAPPDump
Specifies that the data is in a NetApp dump format. Do not specify this data format for file system images that are in a dump format and that were backed up from a NetApp file server by using NDMP. The server does not complete

storage pool reclamation or AUDIT VOLUME for a storage pool with DATAFORMAT=NETAPPDUMP. You can use the MOVE DATA command to move NDMP-generated data out of a volume if the volume must be reused.

CELERRADump
: Specifies that the data is in an EMC Celerra dump format. Do not specify this data format for file system images that are in a dump format and that were backed up from an EMC Celerra file server by using NDMP. The server does not complete storage pool reclamation or AUDIT VOLUME for a storage pool with DATAFORMAT=CELERRADUMP. You can use the MOVE DATA command to move NDMP-generated data out of a volume if the volume must be reused.

NDMPDump
: Specifies that the data is in a NAS vendor-specific backup format. Do not specify this data format for file system images that are in a backup format and that were backed up from a NAS file server other than a NetApp or EMC Celerra file server. The server does not complete storage pool reclamation or AUDIT VOLUME for a storage pool with DATAFORMAT=NDMPDUMP. You can use the MOVE DATA command to move NDMP-generated data out of a volume if the volume must be reused.

CRCData
: Specifies whether a cyclic redundancy check (CRC) validates storage pool data when audit volume processing occurs on the server. This parameter is only valid for NATIVE data format storage pools. This parameter is optional. The default value is NO. By setting CRCDATA to YES and scheduling an AUDIT VOLUME command, you can continually ensure the integrity of data that is stored in your storage hierarchy. You can specify the following values:

  Yes
  : Specifies that data is stored containing CRC information, allowing for audit volume processing to validate storage pool data. This mode impacts performance because more processing is required to calculate and compare CRC values between the storage pool and the server.

  No
  : Specifies that data is stored without CRC information.

  Tip:

  For storage pools that are associated with the 3592, LTO, or ECARTRIDGE device type, logical block protection provides better protection against data corruption than CRC validation for a storage pool. If you specify CRC validation for a storage pool, data is validated only during volume auditing operations. Errors are identified after data is written to tape.

  To enable logical block protection, specify a value of READWRITE for the LBPROTECT parameter on the DEFINE DEVCLASS and UPDATE DEVCLASS commands for the 3592, LTO, or ECARTRIDGE device types. Logical block protection is supported only on the following types of drives and media:

  - IBM® LTO5 and later.
  - IBM 3592 Generation 3 drives and later with 3592 Generation 2 media and later.
  - Oracle StorageTek T10000C and T10000D drives.

DEDUPlicate
: Specifies whether the data that is stored in this storage pool is deduplicated. This parameter is optional and is valid only for storage pools that are defined with a FILE-type device class. The default value is NO.

IDENTIFYPRocess
: Specifies the number of parallel processes to use for server-side data deduplication. This parameter is optional and is valid only for storage pools that are defined with a FILE device class. Enter a value 0 - 50.

  The default value for this parameter is 0. Data-deduplication processes for a copy storage pool are not necessary if you specify data-deduplication processes for the primary storage pool. When IBM Spectrum Protect analyzes a file in a storage pool, IBM Spectrum Protect also analyzes the file in all other storage pools.

  Remember: Data deduplication processes can be either active or idle. Processes that are working on files are active. Processes that are waiting for files to work on are idle. Processes remain idle until volumes with data to be deduplicated become available. The output of the QUERY PROCESS command for data deduplication includes the total number of bytes and files that have been processed since the process first started. For example, if a data deduplication process processes four files, becomes idle, and then processes five more files, then the total number of files processed is nine. Processes end only when canceled or when the number of data-deduplication processes for the storage pool is changed to a value less than the number currently specified.

Example: Define a copy storage pool with a DC480 device class.

Define a copy storage pool, TAPEPOOL2, to the DC480 device class. Allow up to 50 scratch volumes for this pool. Delay the reuse of volumes for 45 days.

```
define stgpool tapepool2 dc480 pooltype=copy
 maxscratch=50 reusedelay=45
```

Related reference:
SET DRMDBBACKUPEXPIREDAYS (Specify DB backup series expiration)

DEFINE STGPOOL (Define an active-data pool assigned to sequential-access devices)

Use this command to define an active-data pool assigned to sequential-access devices.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
'-IDENTIFYPRocess--=--number-----'
```

Notes:

1. The RECLAMATIONTYPE=SNAPLOCK setting is valid only for storage pools that are defined to servers that are enabled for IBM Spectrum Protect™ for Data Retention. The storage pool must be assigned to a FILE device class, and the directories that are specified in the device class must be NetApp SnapLock volumes.
2. This parameter is valid only for storage pools that are defined with a FILE device class.
3. This parameter is available only when the value of the DEDUPLICATE parameter is YES.

Parameters

pool_name (Required)
: Specifies the name of the storage pool to be defined. The name must be unique, and the maximum length is 30 characters.

device_class_name (Required)
: Specifies the name of the sequential access device class to which this active-data pool is assigned. You can specify any device class except DISK.

POoltype=ACTIVEdata (Required)
: Specifies that you want to define an active-data pool.

DESCription
: Specifies a description of the active-data pool. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters.

ACCess
: Specifies how client nodes and server processes (such as reclamation) can access files in the active-data pool. This parameter is optional. The default value is READWRITE. You can specify the following values:

  READWrite
  : Specifies that files can be read from and written to the volumes in the active-data pool.

  READOnly
  : Specifies that client nodes can read only files that are stored on the volumes in the active-data pool.

    Server processes can move files within the volumes in the storage pool. The server can use files in the active-data pool to restore files to primary storage pools. However, no new writes are allowed to volumes in the active-data pool from volumes outside the storage pool. A storage pool cannot be copied to the active-data pool.

  UNAVailable
  : Specifies that client nodes cannot access files that are stored on volumes in the active-data pool.

    Server processes can move files within the volumes in the storage pool. The server can use files in the active-data pool to restore files to primary storage pools. However, no new writes are allowed to volumes in the active-data pool from volumes outside the storage pool. A storage pool cannot be copied to the active-data pool.

COLlocate
: Specifies whether the server attempts to keep data, which is stored on as few volumes as possible, that belong to one of the following candidates:

  - A single client node
  - A group of file spaces
  - A group of client nodes
  - A client file space

  This parameter is optional. The default value is NO.

  Collocation reduces the number of sequential access media mounts for restore, retrieve, and recall operations. However, collocation increases both the amount of server time that is needed to collocate files for storing and the number of volumes required.

  You can specify one of the following options:

  No
  : Specifies that collocation is disabled.

  GRoup
  : Specifies that collocation is enabled at the group level for client nodes or file spaces. For collocation groups, the server attempts to put data for nodes or file spaces that belong to the same collocation group on as few volumes as

possible.

If you specify COLLOCATE=GROUP but do not define any collocation groups, or if you do not add nodes or file spaces to a collocation group, data is collocated by node. Consider tape usage when you organize client nodes or file spaces into collocation groups.

For example, if a tape-based storage pool consists of data from nodes and you specify COLLOCATE=GROUP, the server completes the following actions:

- Collocates the data by group for grouped nodes. Whenever possible, the server collocates data that belongs to a group of nodes on a single tape or on as few tapes as possible. Data for a single node can also be spread across several tapes that are associated with a group.
- Collocates the data by node for ungrouped nodes. Whenever possible, the server stores the data for a single node on a single tape. All available tapes that already have data for the node are used before available space on any other tape is used.

If a tape-based storage pool consists of data from grouped file spaces and you specify COLLOCATE=GROUP, the server completes the following actions:

- Collocates by group, the data for grouped file spaces only. Whenever possible, the server collocates data that belongs to a group of file spaces on a single tape or on as few tapes as possible. Data for a single file space can also be spread across several tapes that are associated with a group.
- Collocates the data by node (for file spaces that are not explicitly defined to a file space collocation group). For example, node1 has file spaces named A, B, C, D, and E. File spaces A and B belong to a filespace collocation group but C, D, and E do not. File spaces A and B are collocated by filespace collocation group, while C, D, and E are collocated by node.

Data is collocated on the least amount of sequential access volumes.

NODe
: Specifies that collocation is enabled at the client node level. For collocation groups, the server attempts to put data for one node on as few volumes as possible. If the node has multiple file spaces, the server does not try to collocate those file spaces. For compatibility with an earlier version, COLLOCATE=YES is still accepted by the server to specify collocation at the client node level.

  If a storage pool contains data for a node that is a member of a collocation group and you specify COLLOCATE=NODE, the data is collocated by node.

FIlespace
: Specifies that collocation is enabled at the file space level for client nodes. The server attempts to place data for one node and file space on as few volumes as possible. If a node has multiple file spaces, the server attempts to place data for different file spaces on different volumes.

RECLaim
: Specifies when the server reclaims a volume, which is based on the percentage of reclaimable space on a volume. Reclaimable space is the amount of space that is occupied by files that are expired or deleted from the IBM Spectrum Protect database.

  Reclamation makes the fragmented space and space occupied by inactive backup files on volumes usable again by moving any remaining unexpired files and active backup files from one volume to another volume. This action makes the original volume available for reuse. This parameter is optional. You can specify an integer 1 - 100. The default value is 60.

  The server determines that the volume is a candidate for reclamation if the percentage of reclaimable space on a volume is greater than the reclamation threshold of the storage pool.

  If you change the value from the default, specify a value of 50 percent or greater so that files stored on two volumes can be combined onto a single output volume.

  When an active-data pool volume that is offsite becomes eligible for reclamation, the reclamation process attempts to obtain the unexpired files on the reclaimable volume from a primary or active-data pool that is onsite. The process then writes these files to an available volume in the original active-data pool. Effectively, these files are moved back to the onsite location. However, the files can be obtained from the offsite volume after a disaster if a database backup is used that references the files on the offsite volume. Because of the way reclamation works with offsite volumes, use it carefully with active-data pools.

RECLAIMPRocess

Specifies the number of parallel processes to use for reclaiming the volumes in this storage pool. This parameter is optional. Enter a value 1 - 999. The default value is 1.
When you calculate the value for this parameter, consider the following resources that are required for reclamation processing:

- The number of sequential storage pools.
- The number of logical and physical drives that can be dedicated to the operation.

To access sequential volumes, IBM Spectrum Protect uses a mount point and, if the device type is not FILE, a physical drive.

For example, suppose that you want to reclaim the volumes from two sequential storage pools simultaneously and that you want to specify four processes for each of the storage pools. The storage pools have the same device class. Each process requires two mount points and, if the device type is not FILE, two drives. (One of the drives is for the input volume, and the other drive is for the output volume.) To run eight reclamation processes simultaneously, you need a total of at least 16 mount points and 16 drives. The device class for the storage pools must have a mount limit of at least 16.

You can specify one or more reclamation processes for each active-data pool. You can specify multiple concurrent reclamation processes for a single active-data pool, which makes better use of your available tape drives or FILE volumes. If multiple concurrent processing is not necessary, specify a value of 1 for the RECLAIMPROCESS parameter.

RECLAMATIONType
Specifies the method by which volumes are reclaimed and managed. This parameter is optional. The default value is THRESHOLD. The following are possible values:

THREShold
Specifies that volumes that belong to this storage pool are reclaimed based on the threshold value in the RECLAIM attribute for this storage pool.
SNAPlock
Specifies that FILE volumes that belong to this storage pool are managed for retention by using NetApp Data ONTAP software and NetApp SnapLock volumes. This parameter is only valid for storage pools that are being defined to a server that has data retention protection that is enabled and that is assigned to a FILE device class. Volumes in this storage pool are not reclaimed based on threshold; the RECLAIM value for the storage pool is ignored.

All volumes in this storage pool are created as FILE volumes. A retention date, which is derived from the retention attributes in the archive copy group for the storage pool, is set in the metadata for the FILE volume by using the SnapLock feature of the NetApp Data ONTAP operating system. Until the retention date expires, the FILE volume and any data on it cannot be deleted from the physical SnapLock volume on which it is stored.

The RECLAMATIONTYPE parameter for all storage pools that are being defined must be the same when defined to the same device class name. The DEFINE command fails if the RECLAMATIONTYPE parameter specified is different from what is defined for storage pools that are already defined to the device class name.

OFFSITERECLAIMLimit
Specifies the number of offsite volumes that space is reclaimed from during reclamation for this storage pool. This parameter is optional. The default value is NOLIMIT. You can specify the following values:

NOLimit
Specifies that you want to reclaim the space in all of your offsite volumes.
number
Specifies the number of offsite volumes to reclaim space from. You can specify an integer 0 - 99999. A value of zero means that none of the offsite volumes are reclaimed.
Tip:

To determine the value for the OFFSITERECLAIMLIMIT, use the statistical information in the message that is issued at the end of the offsite volume reclamation operation. The statistical information includes the following items:

- The number of offsite volumes that were processed
- The number of parallel processes that were used
- The total amount of time required for the processing

The order in which offsite volumes are reclaimed is based on the amount of unused space in a volume. (Unused space includes both space that has never been used on the volume and space that has become empty because of file deletion.) Volumes with the largest amount of unused space are reclaimed first.

For example, suppose an active-data pool contains three volumes: VOL1, VOL2, and VOL3. VOL1 has the largest amount of unused space, and VOL3 has the least amount of unused space. Suppose further that the percentage of unused space in each of the three volumes is greater than the value of the RECLAIM parameter. If you do not specify a value for the OFFSITERECLAIMLIMIT parameter, all three volumes are reclaimed when the reclamation runs. If you specify a value of 2, only VOL1 and VOL2 are reclaimed when the reclamation runs. If you specify a value of 1, only VOL1 is reclaimed.

MAXSCRatch (Required)
Specifies the maximum number of scratch volumes that the server can request for this storage pool. You can specify an integer 0 - 100000000. By allowing the server to request scratch volumes as needed, you avoid having to define each volume to be used.

The value that is specified for this parameter is used to estimate the total number of volumes available in the active-data pool and the corresponding estimated capacity for the active-data pool.

Scratch volumes are automatically deleted from the storage pool when they become empty. However, if the access mode for a scratch volume is OFFSITE, the volume is not deleted from the active-data pool until the access mode is changed. An administrator can then query the server for empty, offsite scratch volumes and return them to the onsite location.

When scratch volumes with the device type of FILE become empty and are deleted, the space that the volumes occupied is freed by the server and returned to the file system.

Tip: For server-to-server operations that use virtual volumes and that store a small amount of data, consider specifying a value for the MAXSCRATCH parameter that is higher than the value you typically specify for write operations to other types of volumes. After a write operation to a virtual volume, IBM Spectrum Protect marks the volume as FULL, even if the value of the MAXCAPACITY parameter on the device-class definition is not reached. The server does not keep virtual volumes in FILLING status and does not append to them. If the value of the MAXSCRATCH parameter is too low, server-to-server operations can fail.

REUsedelay
Specifies the number of days that must elapse after all files are deleted from a volume before the volume can be rewritten or returned to the scratch pool. This parameter is optional. You can specify an integer 0 - 9999. The default value is 0, which means that a volume can be rewritten or returned to the scratch pool as soon as all the files are deleted from the volume.
Tip: Use this parameter to ensure that when you restore the database to an earlier level, database references to files in the active-data pool are still valid. You must set this parameter to a value greater than the number of days you plan to retain the oldest database backup. The number of days that are specified for this parameter must be the same as the number specified for the SET DRMDBBACKUPEXPIREDAYS command.

OVFLOcation
Specifies the overflow location for the storage pool. The server assigns this location name to a volume that is ejected from the library by the command. This parameter is optional. The location name can be a maximum length of 255 characters. Enclose the location name in quotation marks if the location name contains any blank characters.

DATAFormat
Specifies the data format to use to copy files to this storage pool and restore files from this storage pool. The default format is the NATIVE server format. You can specify the following values:

NATive
Specifies the data format is the native IBM Spectrum Protect server format and includes block headers.

NONblock
Specifies the data format is the native IBM Spectrum Protect server format and does not include block headers. The default minimum block size on a volume that is associated with a FILE device class is 256 KB, regardless how much data is written to the volume. For certain tasks, you can minimize wasted space on storage volumes by specifying the NONBLOCK data format. For example, you can specify the NONBLOCK data format for the following tasks:

- Using content-management products
- Using the DIRMC client option to store directory information
- Migrating very small files by using IBM Spectrum Protect for Space Management or IBM Spectrum Protect HSM for Windows

In most situations, however, the NATIVE format is preferred.

CRCData
Specifies whether a cyclic redundancy check (CRC) validates storage pool data when audit volume processing occurs on the server. This parameter is only valid for NATIVE data format storage pools. This parameter is optional. The default value is

NO. By setting CRCDATA to YES and scheduling an AUDIT VOLUME command, you can continually ensure the integrity of data that is stored in your storage hierarchy. You can specify the following values:

Yes
: Specifies that data is stored containing CRC information, allowing for audit volume processing to validate storage pool data. This mode impacts performance because more processing is required to calculate and compare CRC values between the storage pool and the server.

No
: Specifies that data is stored without CRC information.

Tip:

For storage pools that are associated with the 3592, LTO, or ECARTRIDGE device type, logical block protection provides better protection against data corruption than CRC validation for a storage pool. If you specify CRC validation for a storage pool, data is validated only during volume auditing operations. Errors are identified after data is written to tape.

To enable logical block protection, specify a value of READWRITE for the LBPROTECT parameter on the DEFINE DEVCLASS and UPDATE DEVCLASS commands for the 3592, LTO, or ECARTRIDGE device types. Logical block protection is supported only on the following types of drives and media:

- IBM® LTO5 and later.
- IBM 3592 Generation 3 drives and later with 3592 Generation 2 media and later.
- Oracle StorageTek T10000C and T10000D drives.

DEDUPlicate
: Specifies whether the data that is stored in this storage pool is deduplicated. This parameter is optional and is valid only for storage pools that are defined with a FILE device class. The default value is NO.

IDENTIFYPRocess
: Specifies the number of parallel processes to use for server-side data deduplication. This parameter is optional and is valid only for storage pools that are defined with a FILE device class. Enter a value 0 - 50.

The default value for this parameter is 0. Data-deduplication processes for a copy storage pool are not necessary if you specify data-deduplication processes for the primary storage pool. When IBM Spectrum Protect analyzes a file in a storage pool, IBM Spectrum Protect also analyzes the file in all other storage pools.

Remember: Data deduplication processes can be either active or idle. Processes that are working on files are active. Processes that are waiting for files to work on are idle. Processes remain idle until volumes with data to be deduplicated become available. The output of the QUERY PROCESS command for data deduplication includes the total number of bytes and files that have been processed since the process first started. For example, if a data deduplication process processes four files, becomes idle, and then processes five more files, then the total number of files processed is nine. Processes end only when canceled or when the number of data-deduplication processes for the storage pool is changed to a value less than the number currently specified.

Example: Define an active-data pool with a DC500 device class

Define an active-data pool, TAPEPOOL2, to the DC500 device class. Allow up to 50 scratch volumes for this pool. Delay the reuse of volumes for 45 days.

```
define stgpool tapepool3 dc500 pooltype=activedata
 maxscratch=50 reusedelay=45
```

Related reference:
SET DRMDBBACKUPEXPIREDAYS (Specify DB backup series expiration)

DEFINE STGPOOLDIRECTORY (Define a storage pool directory)

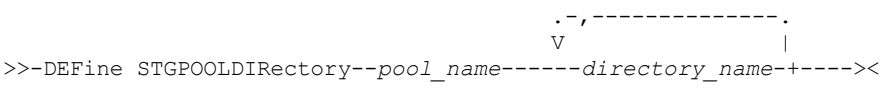
Use this command to define one or more directories in a directory-container or cloud-container storage pool.

Tip: After you define a cloud-container storage pool, create one or more directories that are used for local storage. You can temporarily store data in local storage during the data ingestion, before the data is moved to the cloud. In this way, you can improve backup and archive performance. For more information, see Optimizing performance for cloud object storage.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

pool_name (Required)
: Specifies the name of a directory-container or cloud-container storage pool. This parameter is required.

directory_name (Required)
: Specifies the directory to be defined in the storage pool. This parameter is required. You can specify more than one directory name by separating each name with a comma, with no intervening spaces.

  If you use the administrative client and the directory name contains a comma or a backslash ("\"), enclose the name in quotation marks.

Example: Define a storage pool directory

Define a storage pool directory that is named DIR1 by using a directory-container storage pool that is named POOL1.

AIX Linux

```
define stgpooldirectory pool1 /storage/dir1
```

Windows

```
define stgpooldirectory pool1 c:\storage\dir1
```

Example: Define multiple storage pool directories

Define storage pool directories that are named DIR1 and DIR2 by using a directory-container storage pool that is named POOL1.

AIX Linux

```
define stgpooldirectory pool1 /storage/dir1,/storage/dir2
```

Windows

```
define stgpooldirectory pool1 e:\storage\dir1,f:\storage\dir2
```

Example: Define local storage for a cloud-container storage pool

Create a storage pool directory that is named DIR3 in a cloud-container storage pool that is named CLOUDLOCALDISK1.

AIX Linux

```
define stgpooldirectory cloudlocaldisk1 /storage/dir3
```

Windows

```
define stgpooldirectory cloudlocaldisk1 c:\storage\dir3
```

Table 1. Commands related to DEFINE STGPOOLDIRECTORY

Command	Description
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DELETE STGPOOLDIRECTORY	Deletes a storage pool directory from a directory-container or cloud-container storage pool.
QUERY STGPOOLDIRECTORY	Displays information about storage pool directories.
UPDATE STGPOOLDIRECTORY	Changes the attributes of a storage pool directory.

DEFINE SUBSCRIPTION (Define a profile subscription)

Use this command on a managed server to subscribe that managed server to a profile.

When a server subscribes to its first profile, a subscription is also created to the default profile (if one exists) of the configuration manager. The server then contacts the configuration manager periodically for configuration updates.

Restrictions:

1. A server cannot subscribe to profiles from more than one configuration manager.
2. If a server subscribes to a profile with an associated object that is already defined on the server, the local definition is replaced by the definition from the configuration manager. For example, if a server has an administrative schedule named WEEKLY_ BACKUP, then subscribes to a profile that also has an administrative schedule named WEEKLY_BACKUP, the local definition is replaced.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DEFine SUBSCRIPtion--profile_name---------------------------->

>--+-----------------------+---------------------------------><
   '-SERVer--=--server_name-'
```

Parameters

profile_name (Required)
: Specifies the name of the profile to which the server subscribes.

SERVer
: Specifies the name of the configuration manager from which the configuration information is obtained. This parameter is required, if the managed server does not have at least one subscription. If the managed server has a subscription, you can omit this parameter and it defaults to the configuration manager for that subscription.

Example: Define a profile subscription

Subscribe a profile named BETA that resides on a configuration manager named TOM.

```
define subscription beta server=tom
```

Related commands

Table 1. Commands related to DEFINE SUBSCRIPTION

Command	Description
COPY PROFILE	Creates a copy of a profile.
DEFINE PROFILE	Defines a profile for distributing information to managed servers.
DELETE PROFILE	Deletes a profile from a configuration manager.
DELETE SUBSCRIBER	Deletes obsolete managed server subscriptions.
DELETE SUBSCRIPTION	Deletes a specified profile subscription.
LOCK PROFILE	Prevents distribution of a configuration profile.
NOTIFY SUBSCRIBERS	Notifies servers to refresh their configuration information.
QUERY PROFILE	Displays information about configuration profiles.
QUERY SUBSCRIBER	Displays information about subscribers and their subscriptions to profiles.
QUERY SUBSCRIPTION	Displays information about profile subscriptions.

Command	Description
SET CONFIGREFRESH	Specifies a time interval for managed servers to contact configuration managers.
UNLOCK PROFILE	Enables a locked profile to be distributed to managed servers.
UPDATE PROFILE	Changes the description of a profile.

DEFINE VIRTUALFSMAPPING (Define a virtual file space mapping)

Use this command to define a virtual file space mapping.

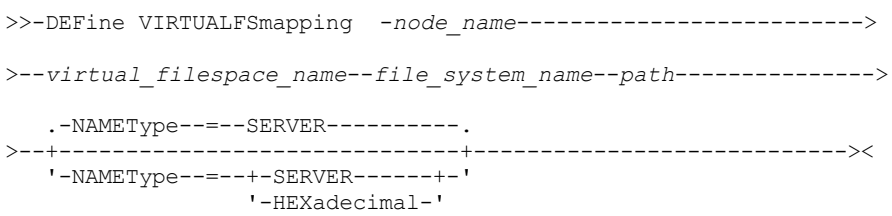
Virtual file space names can be used in the NAS data operations BACKUP NODE and RESTORE NODE similar to a file system name. Refer to the documentation about your NAS device for guidance on specifying the parameters for this command.
Note: The NAS node must have an associated data mover definition because when the IBM Spectrum Protect™ server updates a virtual file space mapping, the server attempts to contact the NAS device to validate the virtual file system and file system name.

Privilege class

To issue this command, you must have one of the following privilege classes:

- System privilege
- Unrestricted policy privilege
- Restricted policy privilege for the domain to which the NAS node is assigned.

Syntax



Parameters

node_name (Required)

Specifies the NAS node on which the file system and path reside. You cannot use wildcard characters or specify a list of names.

virtual_filespace_name (Required)

Specifies the name which refers to this virtual file space definition. The virtual file space name is case sensitive and the first character must be a forward slash /. The length of the name cannot be more than 64 characters, including the required forward slash. Virtual file space names are restricted to the same character set as all other objects in the server except that the forward slash / character is also allowed.

The virtual file space name cannot be identical to any file system on the NAS node. When selecting a virtual file space name, consider the following restrictions:

- If a file system is created on the NAS device with the same name as a virtual file system, a name conflict will occur on the server when the new file space is backed up. Use a string for the virtual file space name that is unlikely to be used as a real file system name on your NAS device in the future.

  For example: A user follows a naming convention for creating file spaces on a NAS device with names of the form /vol1, /vol2, /vol3. The user defines a virtual file space to the server with the name /vol9. If the user continues to use the same naming convention, the virtual file space name is likely to conflict with a real file space name at some point in the future.

- During backup and restore operations, the server verifies that a name conflict does not occur prior to starting the operation.
- The virtual file space name appears as a file space in the output of the QUERY FILESPACE command, and also in the backup and restore panels of the IBM Spectrum Protect web client. Therefore, consider selecting a name that unambiguously identifies this object as a directory path on the NAS device.

file_system_name (Required)

Specifies the name of the file system in which the path is located. The file system name must exist on the specified NAS node. The file system name cannot contain wildcard characters.

path (Required)

Specifies the path from the root of the file system to the directory. The path can only reference a directory. The maximum length of the path is 1024 characters. The path name is case sensitive.

NAMEType

Specifies how the server should interpret the path name specified. This parameter is useful when a path contains characters that are not part of the code page in which the server is running. The default value is SERVER.

Possible values are:

SERVER

The server uses the server code page to interpret the path name.

HEXadecimal

The server interprets the path that you enter as the hexadecimal representation of the path. This option should be used when a path contains characters that cannot be entered. This could occur if the NAS file system is set to a language different from the one in which the server is running.

Example: Define a virtual file space mapping

Define the virtual file space mapping name /mikeshomedir for the path /home/mike on the file system /vol/vol1 on the NAS node named NAS1.

```
define virtualfsmapping nas1 /mikeshomedir /vol/vol1 /home/mike
```

Related commands

Table 1. Commands related to DEFINE VIRTUALFSMAPPING

Command	Description
DELETE VIRTUALFSMAPPING	Delete a virtual file space mapping.
QUERY VIRTUALFSMAPPING	Query a virtual file space mapping.
UPDATE VIRTUALFSMAPPING	Update a virtual file space mapping.

DEFINE VOLUME (Define a volume in a storage pool)

Use this command to assign a random or sequential access volume to a storage pool.

When you define a random-access (DISK) storage-pool volume or a sequential access storage pool volume that is associated with a FILE device class, you can have the server create the volume before it is assigned. Alternatively, you can use space triggers to create preassigned volumes when predetermined space-utilization thresholds are exceeded. For details about space triggers, see DEFINE SPACETRIGGER (Define the space trigger). For volumes associated with device classes other than DISK or device types other than FILE, you can use the DEFINE VOLUME command to assign an already-created volume to a storage pool.

AIX Linux When you use a FILE device class for storage that is managed by a z/OS® media server, it is not necessary to format or define volumes. If you define a volume for such a FILE device class by using the DEFINE VOLUME command, the z/OS media server does not allocate space for the volume until the volume is opened for its first use.

Attention: Volumes for the z/OS media server that are created using the DEFINE VOLUME command remain physically full or allocated after the server empties the volume, for example, after expiration or reclamation. For FILE volumes, the DASD space is not relinquished to the system when the volume is emptied. If a storage pool requires an empty or filling volume, the FILE volume can be used. In contrast, tape volumes that are logically empty are the same as physically empty. FILE and tape volumes remain

defined in the server. In contrast, SCRATCH volumes, including the physical storage that is allocated for SCRATCH FILE volumes, are returned to the system when emptied.

To create space in sequential access storage pools, you can define volumes or allow the server to request scratch volumes as needed, as specified by the MAXSCRATCH parameter for the storage pool. For storage pools associated with the FILE device class, the server can create private volumes as needed using storage-pool space triggers. For DISK storage pools, the scratch mechanism is not available. However, you can create space by creating volumes and then defining them to the server. Alternatively, you can have the server create volumes that use storage-pool space triggers.

The server does not validate the existence of a volume name when defining a volume in a storage pool that is associated with a library. The defined volume has "0" EST capacity until data is written to the volume.

Attention: The size of a storage pool volume cannot be changed after it is defined to the server.

AIX If you change the size of IBM Spectrum Protect™ volumes by extending raw logical volumes through SMIT or otherwise altering the file sizes of the volumes with operating system commands or utilities, the server might not initialize correctly and data can be lost.

Windows If you change the size of volumes by altering the file sizes of the volumes with operating system commands or utilities, the server might not initialize correctly and data can be lost.

Restrictions:

- You cannot use this command to define volumes in storage pools with the parameter setting `RECLAMATIONTYPE=SNAPLOCK`. Volumes in this type of storage pool are allocated by using the MAXSCRATCH parameter on the storage pool definition.
- You cannot define volumes in a storage pool that is defined with the CENTERA device class.
- Linux You cannot use raw logical volumes for storage pool volumes.

Physical files that are allocated with DEFINE VOLUME command are not removed from a file space if you issue the DELETE VOLUME command.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the storage pool to which the volume is assigned.

Syntax

```
>>-DEFine Volume--pool_name--volume_name------------------------>

   .-ACCess--=--READWrite-------.
>--+----------------------------+------------------------------->
   '-ACCess--=--+-READWrite---+-'
                +-READOnly----+
                +-UNAVailable-+
                |         (1) |
                '-OFfsite-----'

>--+-------------------------------------------------+----------->
   |                           .-Wait--=--No------. |
   '-Formatsize--=--megabytes--+------------------+-'
                               '-Wait--=--+-No--+-'
                                          '-Yes-'

   .-Numberofvolumes--=--1----------.
>--+--------------------------------+--------------------------->
   |                  (2)           |
   '-Numberofvolumes------=--number-'

>--+---------------------------+------------------------------><
   |          (3)              |
   '-LOcation------=--location-'
```

Notes:

1. This value is valid only for volumes that are assigned to copy storage pools.
2. This parameter is valid only for DISK or FILE volumes.
3. This parameter is valid only for sequential access volumes.

Parameters

pool_name (Required)
Specifies the name of the storage pool to which the volume is assigned.

volume_name (Required)
Specifies the name of the storage pool volume to be defined. If you specify a number greater than 1 for the NUMBEROFVOLUMES parameter, the volume name is used as a prefix to generate multiple volume names. The volume name that you specify depends on the type of device that the storage pool uses.

Each volume that is used by a server for any purpose must have a unique name. This requirement applies to all volumes, whether the volumes are used for storage pools, or used for operations such as database backup or export. The requirement also applies to volumes that reside in different libraries but that are used by the same server.

AIX | Linux Remember: Volume names cannot contain embedded blanks or equal signs.
Windows Remember: Volume names cannot contain embedded blanks or equal signs, except for DISK or FILE volumes.
See the following tables for volume name requirements:

- Table 1: DISK
- Table 2: FILE
- AIX | Linux Table 3: FILE for the z/OS media server
- Table 4: Tape
- AIX | Linux Table 5: Tape for z/OS media server
- Table 6: REMOVABLEFILE

Table 1. Volume name requirements for DISK

Volume Name Requirements	Example
The name of the file to contain the volume data, with either the fully qualified path name or a path name relative to the current working directory. Windows If a name contains embedded blanks, equal signs, or other special characters, enclose the list in quotation marks.	AIX | Linux `/usr/storage/sbkup01.dsm` AIX If you are using an AIX® logical volume, enter the path name as: `/dev/rxxx` where xxx is the logical volume name. Windows `"c:\program files\tivoli\tsm\server\data3.dsm"`

Table 2. Volume name requirements for FILE

Volume Name Requirements	Example
The name of the file to contain the volume data, with either the fully qualified path name or the path name relative to a directory identified in the DIRECTORY parameter for the device class. Windows If a name contains embedded blanks, equal signs, or other special characters, enclose the list in quotation marks. Place FILE volumes in one of the directories that are specified with the DIRECTORY parameter of the DEFINE DEVCLASS command. Otherwise, storage agents might not have access to the volumes. For details, see DEFINE PATH (Define a path).	AIX | Linux `/data/fpool01.dsm` Windows `"f:\data storage\fpool01.dsm"`

AIX | Linux

Table 3. z/OS media server: Volume name requirements for FILE

Volume Name Requirements	Example

Volume Name Requirements	Example
For FILE volumes used with the z/OS media server server, specify a data set name. The data set name can consist of one or more qualifiers that are delimited by a period. The qualifiers can contain up to 8 characters. The maximum length of the data set name is 44 characters. The first letter of each qualifier must be alphabetic or national (@#$), followed by alphabetic, national, hyphen, or numeric characters. To allocate the associated VSAM Linear Dataset when the volume is tendered on the z/OS system, the High Level Qualifier (HLQ) is typically filtered by specific ACS routines within the SMS policy constraints on the system where the z/OS media server is running. The behavior of the HLQ is similar to the behavior of the PREFIX name on a scratch request. The HLQ is typically used by DFSMS to affect allocation attributes, such as Extended Addressability for data sets that are expected to extend when space that is already allocated to the file volume is used up. If the data set does not exist, the server creates it when the volume is used for a specific IBM Spectrum Protect storage operation. The data set is not created when the volume is defined. Data loss can result when defining volumes because the z/OS media server reuses the volume or VSAM LDS if it exists at the time of allocation time. Important: To allow the server to generate volume names, consider using SCRATCH volumes.	AIX Linux SERVER1.BFS.POOL3.VOLA

Table 4. Volume name requirements for tape

Volume Name Requirements	Example
Use 1 - 32 alphanumeric characters. The volume name cannot contain any embedded blanks or equal signs.	DSMT01

AIX Linux

Table 5. z/OS media server: Volume name requirements for tape

Volume Name Requirements	Example
For tape cartridges, specify a tape volume name with 1 - 6 alphanumeric characters. The server converts tape volume names to uppercase. The volume name cannot contain any embedded blanks or equal signs. Each volume that is used by a server for any purpose must have a unique name. This requirement applies to all volumes, whether the volumes are used for storage pools, or used for operations such as database backup or export. The requirement also applies to volumes that reside in different z/OS media libraries but that are used by the same server.	DSMT01

Table 6. Volume name requirements for REMOVABLEFILE

Volume Name Requirements	Example

Volume Name Requirements	Example
1–6 alphanumeric characters The server converts volume names to uppercase.	`DSM01`

ACCess
Specifies how client nodes and server processes (such as migration) can access files in the storage pool volume. This parameter is optional. The default value is READWRITE. Possible values are:

READWrite
Specifies that client nodes and server processes can read from and write to files stored on the volume.
READOnly
Specifies that client nodes and server processes can only read files that are stored on the volume.
UNAVailable
Specifies that client nodes or server processes cannot access files that are stored on the volume.

If you define a random access volume as UNAVAILABLE, you cannot vary the volume online.

If you define a sequential access volume as UNAVAILABLE, the server does not attempt to access the volume.

OFfsite
Specifies that the volume is at an offsite location from which it cannot be mounted. You can specify this value only for volumes in copy or active-data storage pools.
Use this value to help you track volumes at offsite locations. The server treats volumes that are designated as offsite differently:

- The server does not generate mount requests for volumes designated offsite.
- The server reclaims or moves data from offsite volumes by retrieving files from other storage pools.
- The server does not automatically delete empty, offsite scratch volumes from a copy or active-data storage pool.

LOcation
Specifies the location of the volume. This parameter is optional. It can be specified only for volumes in sequential access storage pools. The location information can be a maximum length of 255 characters. Enclose the location in quotation marks if it contains any blank characters.
Formatsize
Specifies the size of the random access volume or FILE volume that is created and formatted in one step. The value is specified in megabytes. The maximum size is 8 000 000 MB (8 terabytes). This parameter is required if any of the following conditions are true:

- A single FILE or DISK volume is specified, which is to be created and formatted in one step.
- The value for the NUMBEROFVOLUMES parameter is greater than 1, and DISK volumes are being created.
- The value of the NUMBEROFVOLUMES parameter is greater than 1, and the value of the FORMATSIZE parameter is less than or equal to the MAXCAPACITY parameter of the DEFINE DEVCLASS command.

If you are allocating volumes on a z/OS media server, this parameter is not valid.

For a FILE volume, you must specify a value less than or equal to the value of the MAXCAPACITY parameter of the device class associated with the storage pool.

You cannot use this parameter for multiple, predefined volumes. Unless you specify `WAIT=YES` is specified, the operation is completed as a background process.

Numberofvolumes
Specifies the number of volumes that are created and formatted in one step. This parameter applies only to storage pools with DISK or FILE device classes. This parameter is optional. The default is 1. If you specify a value greater than 1, you must also specify a value for the FORMATSIZE parameter. Specify a number from 1 to 256.

If you are allocating volumes on a z/OS media server, the only value that this parameter supports is the default value of 1.

If the value for the NUMBEROFVOLUMES parameter is greater than 1, the volume name you specified will have a numeric suffix appended to create each name, for example, tivolivol001 and tivolivol002. Be sure to chose a volume name so that a valid file name for the target file system is created when the suffix is appended.

Important: You must ensure that storage agents can access newly created FILE volumes. For more information, see DEFINE PATH (Define a path).

Wait

Specifies whether volume creation and formatting operation is completed in the foreground or background. This parameter is optional. It is ignored unless you also specify the FORMATSIZE parameter.

No

Specifies that a volume creation and formatting operation is completed in the background. The NO value is the default when you also specify a format size.

Yes

Specifies that a volume creation and formatting operation is completed in the foreground.
Remember: You cannot specify `WAIT=YES` from the server console.

Example: Use a background process to define a new 100 MB volume for a disk storage pool

Create a volume of 100 MB in the disk storage pool named BACKUPPOOL. AIX Linux The volume name is /var/storage/bf.dsm. Windows The volume name is j:\storage\bf.dsm. Let the volume be created as a background process. AIX Linux

```
define volume backuppool
/var/storage/bf.dsm formatsize=100
```

Windows

```
define volume backuppool j:\storage\bf.dsm formatsize=100
```

Example: Define a volume to a disk storage pool with read and write access

A storage pool named POOL1 is assigned to a tape device class. Define a volume named TAPE01 to this storage pool, with READWRITE access.

```
define volume pool1 tape01 access=readwrite
```

Example: Define a volume to a file storage pool

A storage pool that is named FILEPOOL is assigned to a device class with a device type of FILE. AIX Linux Define a volume that is named filepool_vol01 to this storage pool. Windows Define a volume that is named fp_vol01.dsm to this storage pool. AIX Linux

```
define volume filepool /usr/storage/filepool_vol01
```

Windows

```
define volume filepool j:\storage\fp_vol01.dsm
```

Example: Example: Use a background process to define 10 volumes for a file storage pool with a device class 5 GB maximum capacity

Define 10 volumes in a sequential storage pool that uses a FILE device class. The storage pool is named FILEPOOL. The value of the MAXCAPACITY parameter for the device class that is associated with this storage pool is 5 GB. Creation must occur in the background.

```
define volume filepool filevol numberofvolumes=10 formatsize=5000
```

The server creates volume names filevol001 through filevol010.

Volumes are created in the directory or directories that are specified with the DIRECTORY parameter of the device class that is associated with storage pool filepool. If you specified multiple directories for the device class, individual volumes can be created in any of the directories in the list.

Related commands

Table 7. Commands related to DEFINE VOLUME

Command	Description
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.

Command	Description
QUERY VOLUME	Displays information about storage pool volumes.
UPDATE DEVCLASS	Changes the attributes of a device class.
UPDATE LIBVOLUME	Changes the status of a storage volume.
UPDATE VOLUME	Updates the attributes of storage pool volumes.

DELETE commands

Use the DELETE commands to delete or remove an IBM Spectrum Protect™ object.

- DELETE ASSOCIATION (Delete the node association to a schedule)
- DELETE ALERTTRIGGER (Remove a message from an alert trigger)
- DELETE BACKUPSET (Delete a backup set)
- DELETE CLIENTOPT (Delete an option in an option set)
- DELETE CLOPTSET (Delete a client option set)
- DELETE COLLOCGROUP (Delete a collocation group)
- DELETE COLLOCMEMBER (Delete collocation group member)
- DELETE COPYGROUP (Delete a backup or archive copy group)
- DELETE DATAMOVER (Delete a data mover)
- DELETE DEDUPSTATS (Delete data deduplication statistics)
- DELETE DEVCLASS (Delete a device class)
- DELETE DOMAIN (Delete a policy domain)
- DELETE DRIVE (Delete a drive from a library)
- DELETE EVENT (Delete event records)
- DELETE EVENTSERVER (Delete the definition of the event server)
- DELETE FILESPACE (Delete client node data from the server)
- DELETE GRPMEMBER (Delete a server from a server group)
- DELETE LIBRARY (Delete a library)
- DELETE MACHINE (Delete machine information)
- DELETE MACHNODEASSOCIATION (Delete association between a machine and a node)
- DELETE MGMTCLASS (Delete a management class)
- DELETE NODEGROUP (Delete a node group)
- DELETE NODEGROUPMEMBER (Delete node group member)
- DELETE PATH (Delete a path)
- DELETE POLICYSET (Delete a policy set)
- DELETE PROFASSOCIATION (Delete a profile association)
- DELETE PROFILE (Delete a profile)
- DELETE RECMEDMACHASSOCIATION (Delete recovery media and machine association)
- DELETE RECOVERYMEDIA (Delete recovery media)
- DELETE SCHEDULE (Delete a client or an administrative command schedule)
- DELETE SCRIPT (Delete command lines from a script or delete the entire script)
- DELETE SERVER (Delete a server definition)
- DELETE SERVERGROUP (Delete a server group)
- DELETE SPACETRIGGER (Delete the storage pool space triggers)
- DELETE STATUSTHRESHOLD (Delete a status monitoring threshold)
- DELETE STGPOOL (Delete a storage pool)
- DELETE STGPOOLDIRECTORY (Deleting a storage pool directory)
- DELETE SUBSCRIBER (Delete subscriptions from a configuration manager database)
- DELETE SUBSCRIPTION (Delete a profile subscription)
- DELETE VIRTUALFSMAPPING (Delete a virtual file space mapping)
- DELETE VOLHISTORY (Delete sequential volume history information)
- DELETE VOLUME (Delete a storage pool volume)

DELETE ALERTTRIGGER (Remove a message from an alert trigger)

Use this command to remove a message from the list of alert triggers.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                        .-,-----------------.
                        V                   |
>>-DELete ALERTTrigger----+--message_number-+------------------><
```

Parameters

message_number (Required)
: Specifies the message number that you want to remove from the list of alert triggers. Specify multiple message numbers, which are separated by commas, and no intervening spaces. Message numbers are a maximum of eight characters in length. Wildcard characters can be used to specify message numbers.

Delete alert trigger

Delete two message numbers that are designated as alerts, by issuing the following command:

```
delete alerttrigger ANR1067E,ANR1073E
```

Related commands

Table 1. Commands related to DELETE ALERTTRIGGER

Command	Description
DEFINE ALERTTRIGGER (Define an alert trigger)	Associates specified messages to an alert trigger.
QUERY ALERTSTATUS (Query the status of an alert)	Displays information about alerts that have been issued on the server.
QUERY ALERTTRIGGER (Query the list of defined alert triggers)	Displays message numbers that trigger an alert.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
UPDATE ALERTTRIGGER (Update a defined alert trigger)	Updates the attributes of one or more alert triggers.
UPDATE ALERTSTATUS (Update the status of an alert)	Updates the status of a reported alert.

DELETE ASSOCIATION (Delete the node association to a schedule)

Use this command to delete the association of a client node to a client schedule. IBM Spectrum Protect™ no longer runs the schedule on the client node.

If you try to disassociate a client from a schedule to which it is not associated, this command has no effect for that client.

Privilege class

To issue this command, you must have one of the following privilege classes:

- System privilege
- Unrestricted policy privilege
- Restricted policy privilege for the domain to which the schedule belongs

Syntax

```
>>-DELete ASSOCiation--domain_name--schedule_name--------------->

   .-,---------.
   V           |
>----node_name-+-----------------------------------------------><
```

Parameters

domain_name (Required)
: Specifies the name of the policy domain to which the schedule belongs.

schedule_name (Required)
: Specifies the name of the schedule from which clients are to be disassociated.

node_name (Required)
: Specifies the name of the client node that is no longer associated with the client schedule. You can specify a list of clients which are to be no longer associated with the specified schedule. Commas, with no intervening spaces, separate the items in the list. You can also use a wildcard character to specify a name. All matching clients are disassociated from the specified schedule.

Example: Delete a node association to a schedule

To delete the association of the node JEFF, assigned to the DOMAIN1 policy domain, to the WEEKLY_BACKUP schedule issue the following command:

```
delete association domain1 weekly_backup jeff
```

Example: Delete a node association to a schedule using a wildcard for node selection

Delete the association of selected clients, assigned to the DOMAIN1 policy domain, to the WEEKLY_BACKUP schedule so that this schedule is no longer run by these clients. The nodes that are disassociated from the schedule contain ABC or XYZ in the node name. Issue the command:

```
delete association domain1 weekly_backup *abc*,*xyz*
```

Related commands

Table 1. Commands related to DELETE ASSOCIATION

Command	Description
DEFINE ASSOCIATION	Associates clients with a schedule.
QUERY ASSOCIATION	Displays the clients associated with one or more schedules.

DELETE BACKUPSET (Delete a backup set)

Use this command to manually delete a backup set before its retention period expires.

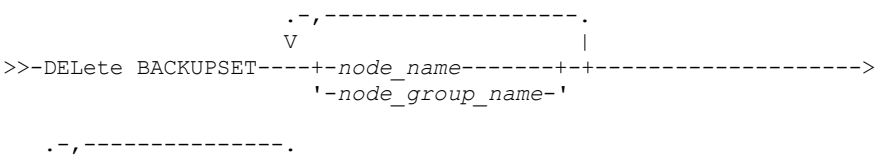
When the server creates a backup set, the retention period assigned to the backup set determines how long the backup set remains in the database. When that date passes, the server automatically deletes the backup set when expiration processing runs. However, you can also manually delete the client's backup set from the server before it is scheduled to expire by using the DELETE BACKUPSET command.

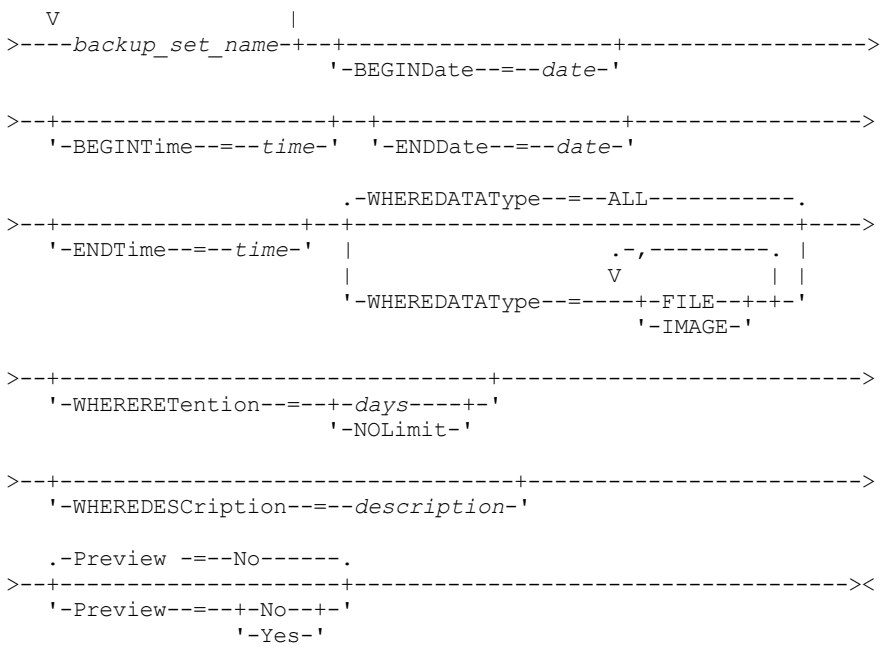
Attention: If the volumes contain multiple backup sets, they are not returned to scratch status until all the backup sets are expired or are deleted.

Privilege class

If the REQSYSAUTHOUTFILE server option is set to YES (the default), the administrator must have system privilege. If the REQSYSAUTHOUTFILE server option is set to NO, the administrator must have system privilege or policy privilege for the domain to which the client node is assigned.

Syntax





Parameters

node_name or node_group_name (Required)

Specifies the name of the client nodes or node groups whose data is contained in the specified backup set volumes. To specify multiple node and node group names, separate the names with commas and no intervening spaces. Any node name you specify may contain wildcard characters, but node group names cannot contain wildcard characters. If backup set volumes contain backup sets from multiple nodes then every backup set whose node name matches one of the specified node names will be deleted.

backup_set_name (Required)

Specifies the name of the backup set to delete. The backup set name you specify can contain wildcard characters. You can specify more than one backup set name by separating the names with commas and no intervening spaces.

BEGINDate

Specifies the beginning date in which the backup set to delete was created. This parameter is optional. You can use this parameter with the BEGINTIME parameter to specify a range for the date and time. If you specify a begin date without a begin time, the time will be at 12:00 a.m. (midnight) on the date you specify.

You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1999
TODAY	The current date	TODAY
TODAY+days *or* +days	The current date plus days specified.	TODAY +3 *or* +3.
TODAY-days *or* -days	The current date minus days specified.	TODAY -3 *or* -3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

BEGINTime

Specifies the beginning time in which the backup set to delete was created. This parameter is optional. You can use this parameter in conjunction with the BEGINDATE parameter to specify a range for the date and time. If you specify a begin time without a begin date, the date will be the current date at the time you specify.
You can specify the time by using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes specified	NOW+02:00 *or* +02:00.
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes specified	NOW-02:00 *or* –02:00.

ENDDate

Specifies the ending date in which the backup set to delete was created. This parameter is optional. You can use this parameter in conjunction with the ENDTIME parameter to specify a range for the date and time. If you specify an end date without an end time, the time will be at 11:59:59 p.m. on the specified end date.
You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1999
TODAY	The current date	TODAY
TODAY+days *or* +days	The current date plus days specified.	TODAY +3 *or* +3.
TODAY-days *or* -days	The current date minus days specified.	TODAY -3 *or* -3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

ENDTime

Specifies the ending time of the range in which the backup set to delete was created. This parameter is optional. You can use this parameter in conjunction with the ENDDATE parameter to specify a range for the date and time. If you specify an end time without an end date, the date will be the current date at the time you specify.
You can specify the time by using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes on the specified end date	NOW+02:00 *or* +02:00.
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes on the specified end date	NOW-02:00 *or* -02:00.

WHEREDATAType

Specifies the backup sets containing the specified types of data are to be deleted. This parameter is optional. The default is that backup sets for all types of data (file level, image, and application) are to be deleted. To specify multiple data types, separate the data types with commas and no intervening spaces. Possible values are:

ALL

Specifies that backup sets for all types of data (file level, image, and application) are to be deleted. This is the default.

FILE
Specifies that a file level backup set is to be deleted. File level backup sets contain files and directories backup up by the backup-archive client.
IMAGE
Specifies that an image backup set is to be deleted. Image backup sets contain images created by the backup-archive client BACKUP IMAGE command.

WHERERETention
Specifies the retention value, specified in days, that is associated with the backup sets to delete. You can specify an integer from 0 to 30000. The values are:

days
Specifies that backup sets that are retained this number of days are deleted.
NOLimit
Specifies that the backup sets that are retained indefinitely are deleted.

WHEREDESCription
Specifies the description that is associated with the backup set to delete. The description you specify can contain a wildcard character. This parameter is optional. Enclose the description in quotation marks if it contains any blank characters.

Preview
Specifies whether to preview the list of backup sets to delete, without actually deleting the backup sets. This parameter is optional. The default value is NO. The values are:

No
Specifies that the backup sets are deleted.
Yes
Specifies that the server displays the list of backup sets to delete, without actually deleting the backup sets.

Example: Delete a backup set

Delete backup set named PERS_DATA.3099 that belongs to client node JANE. The backup set was generated on 11/19/1998 at 10:30:05 and the description is "Documentation Shop".

```
delete backupset pers_data.3099
begindate=11/19/1998 begintime=10:30:05
wheredescription="documentation shop"
```

Related commands

Table 1. Commands related to DELETE BACKUPSET

Command	Description
DEFINE BACKUPSET	Defines a previously generated backup set to a server.
DEFINE NODEGROUP	Defines a group of nodes.
DEFINE NODEGROUPMEMBER	Adds a client node to a node group.
DELETE NODEGROUP	Deletes a node group.
DELETE NODEGROUPMEMBER	Deletes a client node from a node group.
GENERATE BACKUPSET	Generates a backup set of a client's data.
GENERATE BACKUPSETTOC	Generates a table of contents for a backup set.
QUERY BACKUPSET	Displays backup sets.
QUERY NODEGROUP	Displays information about node groups.
QUERY BACKUPSETCONTENTS	Displays contents contained in backup sets.
UPDATE BACKUPSET	Updates a retention value associated with a backup set.
UPDATE NODEGROUP	Updates the description of a node group.

DELETE CLIENTOPT (Delete an option in an option set)

Use this command to delete a client option in an option set.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege.

Syntax

```
>>-DELete CLIENTOpt--option_set_name--option_name--------------->

>--+-------------------------+-------------------------------><
   '-SEQnumber--=--+-number-+-'
                   '-ALL----'
```

Parameters

option_set_name (Required)
: Specifies the name of the client option set.

option_name (Required)
: Specifies a valid client option.

SEQnumber
: Specifies a sequence number when an option name is specified more than once. This parameter is optional. Valid values are:

  n
  : Specifies an integer of 0 or greater.

  ALL
  : Specifies all sequence numbers.

Example: Delete the date format option

Delete the date format option in an option set named *ENG*.

```
delete clientopt eng dateformat
```

Related commands

Table 1. Commands related to DELETE CLIENTOPT

Command	Description
COPY CLOPTSET	Copies a client option set.
DEFINE CLIENTOPT	Adds a client option to a client option set.
DEFINE CLOPTSET	Defines a client option set.
DELETE CLOPTSET	Deletes a client option set.
QUERY CLOPTSET	Displays information about a client option set.
UPDATE CLIENTOPT	Updates the sequence number of a client option in a client option set.
UPDATE CLOPTSET	Updates the description of a client option set.

DELETE CLOPTSET (Delete a client option set)

Use this command to delete a client option set.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege.

Syntax

```
>>-DELete CLOptset--option_set_name---------------------------><
```

Parameters

option_set_name (Required)
Specifies the name of the client option set to delete.

Example: Delete a client option set

Delete the client option set named ENG.

```
delete cloptset eng
```

Related commands

Table 1. Commands related to DELETE CLOPTSET

Command	Description
COPY CLOPTSET	Copies a client option set.
DEFINE CLIENTOPT	Adds a client option to a client option set.
DEFINE CLOPTSET	Defines a client option set.
DELETE CLIENTOPT	Deletes a client option from a client option set.
QUERY CLOPTSET	Displays information about a client option set.
UPDATE CLIENTOPT	Updates the sequence number of a client option in a client option set.
UPDATE CLOPTSET	Updates the description of a client option set.

DELETE COLLOCGROUP (Delete a collocation group)

Use this command to delete a collocation group. You cannot delete a collocation group if it has any members in it.

You can remove all the members in the collocation group by issuing the DELETE COLLOCMEMBER command with a wildcard in the node_name parameter.

Privilege class

To issue this command, you must have system or unrestricted storage privilege.

Syntax

```
>>-DELete COLLOCGroup--group_name-----------------------------><
```

Parameters

group_name
Specifies the name of the collocation group that you want to delete.

Example: Delete a collocation group

Delete a collocation group named group1.

```
delete collocgroup group1
```

Related commands

Table 1. Commands related to DELETE COLLOCGROUP

Command	Description
DEFINE COLLOCGROUP	Defines a collocation group.
DEFINE COLLOCMEMBER	Adds a client node or file space to a collocation group.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DELETE COLLOCMEMBER	Deletes a client node or file space from a collocation group.
MOVE NODEDATA	Moves data for one or more nodes, or a single node with selected file spaces.
QUERY COLLOCGROUP	Displays information about collocation groups.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY NODEDATA	Displays information about the location and size of data for a client node.
QUERY STGPOOL	Displays information about storage pools.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.
UPDATE COLLOCGROUP	Updates the description of a collocation group.
UPDATE STGPOOL	Changes the attributes of a storage pool.

DELETE COLLOCMEMBER (Delete collocation group member)

Use this command to delete a client node or file space from a collocation group.

Privilege class

To issue this command, you must have system or unrestricted storage privilege.

Syntax

Delete a node from a collocation group

```
                                    .-,---------.
                                    V           |
>>-DELete COLLOCMember--group_name----node_name-+--------------><
```

Parameters

group_name
: Specifies the name of the collocation group from which you want to delete a client node.

node_name
: Specifies the name of the client node that you want to delete from the collocation group. You can specify one or more names. When you specify multiple names, separate the names with commas; do not use intervening spaces. You can also use wildcard characters to specify multiple nodes.

Delete a file space from a file space collocation group

```
>>-DELete COLLOCMember--group_name--node_name------------------->

                .-,---------------.
                V                 |
>--FIlespace--=----file_space_name-+--------------------------->
```

```
   .-NAMEType--=--SERVER------.
>--+--------------------------+--------------------------------->
   '-NAMEType--=--+-SERVER--+-'
                  +-UNIcode-+
                  '-FSID----'

   .-CODEType--=--BOTH-----------.
>--+-----------------------------+---------------------------><
   '-CODEType--=--+-BOTH-------+-'
                  +-UNIcode----+
                  '-NONUNIcode-'
```

Parameters

group_name
: Specifies the name of the collocation group from which you want to delete a file space.

node_name
: Specifies the client node where the file space is located.

FIlespace
: Specifies the *file_space_name* on the client node that you want to delete from the collocation group. You can specify one or more file space names that are on a specific client node. If you specify multiple file space names, separate the names with commas, and do not use intervening spaces. You can also use wildcard characters when you specify multiple file space names.

NAMEType
: Specify how you want the server to interpret the file space names that you enter. This parameter is useful when the server has clients with Unicode support. A backup-archive client with Unicode support is available only for Windows, Macintosh OS 9, Macintosh OS X, and NetWare. Use this parameter when you specify a file space name that is not a single wildcard. You can specify a fully qualified file space name, which does not have a wildcard. Or you can specify a partly qualified file space name, which can have a wildcard but must contain other characters. The default value is SERVER. Possible values are

  SERVER
  : The server uses the server code page to interpret the file space names.

  UNIcode
  : The server converts the file space names from the server code page to the UTF-8 code page. The success of the conversion depends on the actual characters in the names and the server code page. Conversion might fail if the string includes characters that are not available in the server code page, or if the server cannot access system conversion routines.

  FSID
  : The server interprets the file space names by their file space IDs (FSIDs).

CODEType
: Specify how you want the server to interpret the file space names that you enter. Use this parameter only when you use a single wildcard character for the file space name. The default is BOTH, so the file spaces are included, regardless of code page type. The following values are available:

  BOTH
  : Include the file spaces, regardless of code page type.

  UNIcode
  : Include file spaces that are in Unicode only.

  NONUNIcode
  : Include file spaces that are not in Unicode.

Delete collocation group members

Delete two nodes, NODE1 and NODE2, from a collocation group, GROUP1.

```
delete collocmember group1 node1,node2
```

Delete a file space from a file space collocation group

Issue the following command to delete files space *cap_27400* from collocation group *collgrp_2* on node *hp_4483*:

```
delete collocmember collgrp_2 hp_4483 filespace=cap_27400
```

Delete a file space collocation group member from a node that uses Unicode

If the file space is on a node that uses Unicode, you can specify that in the command. Issue the following command to delete file space *cap_257* from collocation group *collgrp_3* from the *win_4687* node:

```
delete collocmember collgrp_3 win_4687 filespace=cap_257 codetype=unicode
```

Delete a file space with a partial name designated

If the file space has a partial name, you can use a wildcard to delete it. Issue the following command to delete file space *cap_* from collocation group *collgrp_4* from *win_4687* node:

```
delete collocmember collgrp_4 win_4687 filespace=cap_* codetype=unicode
```

If there is more than one file space whose name begins with cap_, those file spaces are also deleted.

Related commands

Table 1. Commands related to DELETE COLLOCMEMBER

Command	Description
DEFINE COLLOCGROUP	Defines a collocation group.
DEFINE COLLOCMEMBER	Adds a client node or file space to a collocation group.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DELETE COLLOCGROUP	Deletes a collocation group.
DELETE FILESPACE	Deletes data associated with client file spaces. If a file space is part of a collocation group and you remove the file space from a node, the file space is removed from the collocation group.
MOVE NODEDATA	Moves data for one or more nodes, or a single node with selected file spaces.
QUERY COLLOCGROUP	Displays information about collocation groups.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY NODEDATA	Displays information about the location and size of data for a client node.
QUERY STGPOOL	Displays information about storage pools.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.
UPDATE COLLOCGROUP	Updates the description of a collocation group.
UPDATE STGPOOL	Changes the attributes of a storage pool.

DELETE COPYGROUP (Delete a backup or archive copy group)

Use this command to delete a backup or archive copy group from a management class. You cannot delete a copy group in the ACTIVE policy set.

When you activate the changed policy set, any files that are bound to a deleted copy group are managed by the default management class.

You can delete the predefined STANDARD copy group in the STANDARD policy domain (STANDARD policy set, STANDARD management class). However, if you later reinstall the IBM Spectrum Protect™ server, the process restores all STANDARD policy objects.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the copy group belongs.

Syntax

```
>>-DELete COpygroup--domain_name--policy_set_name--class_name--->

   .-STANDARD-.  .-Type--=--Backup------.
>--+----------+--+---------------------+---------------------><
   '-STANDARD-'  '-Type--=--+-Backup--+-'
                            '-Archive-'
```

Parameters

domain_name (Required)
: Specifies the policy domain to which the copy group belongs.

policy_set_name (Required)
: Specifies the policy set to which the copy group belongs.

class_name (Required)
: Specifies the management class to which the copy group belongs.

STANDARD
: Specifies the copy group, which is always STANDARD. This parameter is optional. The default value is STANDARD.

Type
: Specifies the type of copy group to delete. This parameter is optional. The default value is BACKUP. Possible values are:

  Backup
  : Specifies that the backup copy group is deleted.

  Archive
  : Specifies that the archive copy group is deleted.

Example: Delete a backup copy group

Delete the backup copy group from the ACTIVEFILES management class that is in the VACATION policy set of the EMPLOYEE_RECORDS policy domain.

```
delete copygroup employee_records
vacation activefiles
```

Example: Delete an archive copy group

Delete the archive copy group from the MCLASS1 management class that is in the SUMMER policy set of the PROG1 policy domain.

```
delete copygroup prog1 summer mclass1 type=archive
```

Related commands

Table 1. Commands related to DELETE COPYGROUP

Command	Description
DEFINE COPYGROUP	Defines a copy group for backup or archive processing within a specified management class.
QUERY COPYGROUP	Displays the attributes of a copy group.
UPDATE COPYGROUP	Changes one or more attributes of a copy group.

DELETE DATAMOVER (Delete a data mover)

Use this command to delete a data mover. You cannot delete the data mover if any paths are defined for this data mover.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DELete DATAMover--data_mover_name--------------------------><
```

Parameters

data_mover_name (Required)
Specifies the name of the data mover.
Note: This command deletes the data mover even if there is data for the corresponding NAS node.

Example: Delete a data mover

Delete the data mover for the node named NAS1.

```
delete datamover nas1
```

Related commands

Table 1. Commands related to DELETE DATAMOVER

Command	Description
DEFINE DATAMOVER	Defines a data mover to the IBM Spectrum Protect server.
DEFINE PATH	Defines a path from a source to a destination.
DELETE PATH	Deletes a path from a source to a destination.
QUERY DATAMOVER	Displays data mover definitions.
QUERY PATH	Displays information about the path from a source to a destination.
UPDATE DATAMOVER	Changes the definition for a data mover.

AIX | Linux | Windows

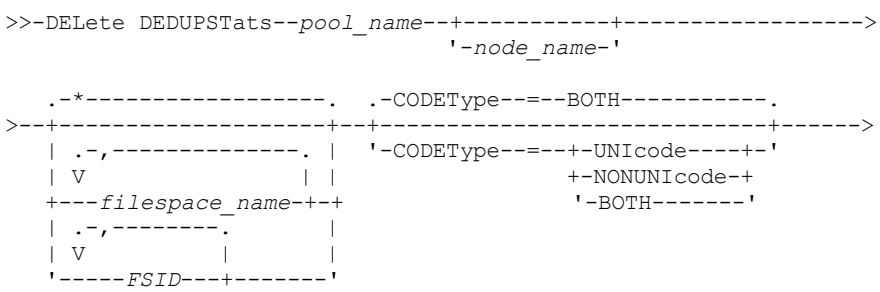
DELETE DEDUPSTATS (Delete data deduplication statistics)

Use this command to delete data deduplication statistics for a directory-container storage pool or a cloud storage pool. You cannot delete the most recent data deduplication statistics for a client node and a file space.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the storage pool.

Syntax



```
   .-NAMEType--=--SERVER------.
>--+--------------------------+--+-----------------+------------>
   '-NAMEType--=--+-SERVER--+-'  '-TODate--=--date-'
                  +-UNIcode-+
                  '-FSID----'

>--+-----------------+-----------------------------------------><
   '-TOTime--=--time-'
```

Parameters

pool_name (Required)
: Specifies the name of the directory-container storage pool that is reported in the data deduplication statistics. You can specify up to 30 characters for the storage pool name. If you specify more than 30 characters the command fails.
Restriction: You can only specify directory-container storage pools or cloud storage pools.

node_name
: Specifies the name of the client node that is reported in the data deduplication statistics. This parameter is optional. If you do not specify a value for this parameter, all nodes are displayed. You can specify up to 64 characters for the node name. If you specify more than 64 characters the command fails.

filespace_name or FSID
: Specifies the name or file space ID (FSID) of one or more file spaces that is reported in the data deduplication statistics. This parameter is optional. You can use wildcard characters to specify this name. An asterisk is the default. Specify one of the following values:

  *
  : Specify an asterisk (*) to show all file spaces or IDs.

  filespace_name
  : Specifies the name of the file space. Specify more than one file space by separating the names with commas and no intervening spaces. FSID Specifies the file space identifier. This parameter is valid for clients with file spaces that are in Unicode format. Specify more than one file space by separating the names with commas and no intervening spaces.

  For clients with file spaces that are in Unicode format, you can enter either a file space name or a FSID. If you enter a file space name, the server might have to convert the file space name that you enter. For example, the server might have to convert the name that you enter from the server's code page to Unicode.
  Restrictions: The following restrictions apply to file space names and file space identifiers (FSID):

  - You must specify a node name if you specify a file space name.
  - Do not specify both file space names and FSIDs on the same command.

CODEType
: Specifies what type of file spaces to include in the report. The default value is BOTH, which specifies that file spaces are included regardless of code page type. Use this parameter only when you enter an asterisk to display information about all file spaces. This parameter is optional. Specify one of the following values:

  UNIcode
  : Include file spaces that are in Unicode format.

  NONUNIcode
  : Include file spaces that are not in Unicode format.

  BOTH
  : Include file spaces regardless of code page type. This is the default.

NAMEType
: Specifies how you want the server to interpret the file space names that you enter. Use this parameter when IBM Spectrum Protect™ clients have file spaces that are in Unicode format, and are on Windows, NetWare, or Macintosh OS X operating systems. This parameter is optional.
This parameter is required if you specify a node name and a file space name or FSID.
Restriction: When you specify this parameter, the file space name cannot contain an asterisk.

  Specify one of the following values:

  SERVER
  : The server uses the server's code page to interpret the file space names. This is the default.

UNIcode
: The server converts the file space name that is entered from the server code page to the UTF-8 code page. The success of the conversion depends on the actual characters in the name and the server's code page. Conversion can fail if the string includes characters that are not available in the server code page, or if the server cannot access system conversion routines.

FSID
: The server interprets the file space names as their file space IDs (FSIDs).

TODate
: Specifies the latest date for statistics to be deleted. IBM Spectrum Protect deletes only those statistics with a date on or before the date you specify. This parameter is optional.
Specify one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date.	10/15/2015 If you specify a date, all candidate records that are written on that day (ending at 11:59:59 pm) will be evaluated.
TODAY	The current date.	TODAY
TODAY-days or -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY–1 or –1. To display information that is created until yesterday, you can specify TODATE=TODAY-1 or TODATE= -1.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include records that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include records that were active on the 10th day of the current month.

TOTime
: Specifies that you want to delete data deduplication statistics that are created on or before this time on the specified date. This parameter is optional. The default is the end of the day (23:59:59). Specify one of the following values:

Value	Description	Example
HH:MM:SS	A specific time on the specified date.	12:30:22
NOW	The current time on the specified date.	NOW
NOW+HH:MM or +HH:MM	The current time plus hours and minutes on the specified date.	NOW+03:00 or +03:00. If you issue the DELETE DEDUPSTATS command at 9:00 with TOTIME=NOW+03:00 or TOTIME=+03:00, IBM Spectrum Protect deletes records with a time of 12:00 or earlier on the specified date.
NOW-HH:MM or -HH:MM	The current time minus hours and minutes on the specified date.	NOW-03:30 or -03:30. If you issue the DELETE DEDUPSTATS command at 9:00 with TOTIME=NOW-3:30 or TOTIME=-3:30, IBM Spectrum Protect deletes records with a time of 5:30 or earlier on the specified date.

Example: Delete data deduplication statistics for a file space

Delete data deduplication statistics of a file space that is called /srvr that belongs to a directory-container storage pool, POOL1, that is stored on client node NODE1.

```
delete dedupstats pool1 node1 /srvr
```

Related commands

Table 1. Commands related to DELETE DEDUPSTATS

Command	Description
GENERATE DEDUPSTATS	Generates data deduplication statistics.
AIX Linux Windows QUERY DEDUPSTATS	Displays data deduplication statistics.

DELETE DEVCLASS (Delete a device class)

Use this command to delete a device class.

To use this command, you must first delete all storage pools that are assigned to the device class and, if necessary, cancel any database export or import processes that are using the device class.

You cannot delete the device class DISK, which is predefined at installation, but you can delete any device classes defined by the IBM Spectrum Protect™ administrator.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DELete DEVclass--device_class_name--------------------------><
```

Parameters

device_class_name (Required)
Specifies the name of the device class to be deleted.

Example: Delete a device class

Delete the device class named MYTAPE. There are no storage pools assigned to the device class.

```
delete devclass mytape
```

Related commands

Table 1. Commands related to DELETE DEVCLASS

Command	Description
DEFINE DEVCLASS	Defines a device class.
AIX Linux DEFINE DEVCLASS (z/OS® media server)	AIX Linux Defines a device class to use storage managed by a z/OS media server.
QUERY DEVCLASS	Displays information about device classes.
QUERY DIRSPACE	Displays information about FILE directories.
UPDATE DEVCLASS	Changes the attributes of a device class.
AIX Linux UPDATE DEVCLASS (z/OS media server)	AIX Linux Changes the attributes of a device class for storage managed by a z/OS media server.

DELETE DOMAIN (Delete a policy domain)

Use this command to delete a policy domain. All associated policy sets, including the ACTIVE policy set, management classes, and copy groups are deleted along with the policy domain.

You cannot delete a policy domain to which client nodes are registered. To determine if any client nodes are registered to a policy domain, issue the QUERY DOMAIN or the QUERY NODE command. Move any client nodes to another policy domain, or delete the nodes.

You can delete the predefined STANDARD policy domain. However, if you later reinstall the IBM Spectrum Protect™ server, the process restores all STANDARD policy objects.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DELete DOmain--domain_name----------------------------------><
```

Parameters

domain_name (Required)
Specifies the policy domain to delete.

Examples: Delete a policy domain

Delete the EMPLOYEE_RECORDS policy domain.

```
delete domain employee_records
```

Related commands

Table 1. Commands related to DELETE DOMAIN

Command	Description
COPY DOMAIN	Creates a copy of a policy domain.
DEFINE DOMAIN	Defines a policy domain that clients can be assigned to.
QUERY DOMAIN	Displays information about policy domains.
UPDATE DOMAIN	Changes the attributes of a policy domain.

DELETE DRIVE (Delete a drive from a library)

Use this command to delete a drive from a library. A drive that is in use cannot be deleted.

All paths related to a drive must be deleted before the drive itself can be deleted.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DELete DRive--library_name--drive_name---------------------><
```

Parameters

library_name (Required)
Specifies the name of the library where the drive is located.
drive_name (Required)
Specifies the name of the drive to be deleted.

Example: Delete a drive from a library

Delete DRIVE3 from the library named AUTO.

```
delete drive auto drive3
```

Related commands

Table 1. Commands related to DELETE DRIVE

Command	Description
DEFINE DRIVE	Assigns a drive to a library.
DEFINE LIBRARY	Defines an automated or manual library.
DELETE LIBRARY	Deletes a library.
DELETE PATH	Deletes a path from a source to a destination.
PERFORM LIBACTION	Defines all drives and paths for a library.
QUERY DRIVE	Displays information about drives.
QUERY LIBRARY	Displays information about one or more libraries.
UPDATE DRIVE	Changes the attributes of a drive.

DELETE EVENT (Delete event records)

Use this command to delete event records from the database. An event record is created whenever processing of a scheduled command is started or missed.

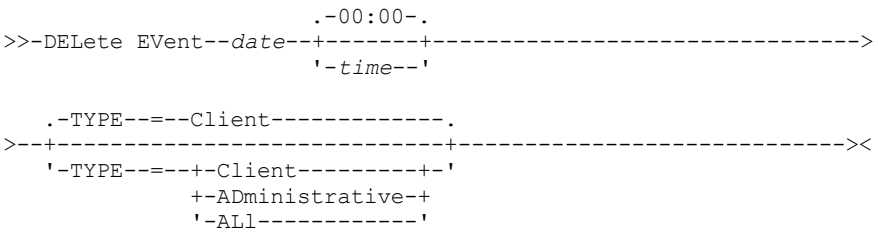
This command only deletes the event records that exist at the time the command is processed. An event record will not be found:

- If the event record has never been created (the event is scheduled for the future)
- If the event has passed and the event record has already been deleted.

Privilege class

To issue this command, you must have system privilege or unrestricted policy privilege.

Syntax



Parameters

date (Required)
Specifies the date used to determine which event records to delete. The maximum number of days you can specify is 9999.

Use this parameter in conjunction with the TIME parameter to specify a date and time for deleting event records. Any record whose scheduled start occurs before the specified date and time is deleted. However, records are not deleted for

events whose startup window has not yet passed.

You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY-days *or* -days	The current date minus days specified	TODAY-3 *or* -3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

time

Specifies the time used to determine which event records to delete. Use this parameter in conjunction with the DATE parameter to specify a date and time for deleting event records. Any record whose scheduled start occurs before the specified date and time is deleted. However, records are not deleted for events whose startup window has not yet passed. The default is 00:00.

You can specify the time by using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes specified	NOW+03:00 or +03:00 Attention: If you issue this command at 9:00 using NOW+03:00 *or* +03:00, IBM Spectrum Protect™ deletes records with a time of 12:00 or later on the date you specify.
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes specified	NOW-03:00 *or* –03:00

TYPE

Specifies the type of events to be deleted. This parameter is optional. The default is CLIENT. Possible values are:

Client
: Specifies to delete event records for client schedules.

ADministrative
: Specifies to delete event records for administrative command schedules.

ALl
: Specifies to delete event records for both client and administrative command schedules.

Example: Delete event records

Delete records for events with scheduled start times prior to 08:00 on May 26, 1998 (05/26/1998), and whose startup window has passed. Records for these events are deleted regardless of whether the retention period for event records, as specified with the SET EVENTRETENTION command, has passed.

```
delete event 05/26/1998 08:00
```

Related commands

Table 1. Commands related to DELETE EVENT

Command	Description
QUERY EVENT	Displays information about scheduled and completed events for selected clients.
SET EVENTRETENTION	Specifies the number of days to retain records for scheduled operations.

DELETE EVENTSERVER (Delete the definition of the event server)

Use this command to delete the definition of the event server. You must issue this command before you issue the DELETE SERVER command. If you specify the server defined as the event server on the DELETE SERVER command, you will receive an error message.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DELete EVENTSERVer-----------------------------------------><
```

Example: Delete an event server definition

Delete the definition for the event server ASTRO.

```
delete eventserver
```

Related commands

Table 1. Commands related to DELETE EVENTSERVER

Command	Description
DEFINE EVENTSERVER	Defines a server as an event server.
QUERY EVENTSERVER	Displays the name of the event server.

DELETE FILESPACE (Delete client node data from the server)

Use this command to delete file spaces from the server. Files that belong to the file space are deleted from primary, active-data, and copy storage pools, and any file space collocation groups.

IBM Spectrum Protect™ deletes one or more file spaces as a series of batch database transactions, thus preventing a rollback or commit for an entire file space as a single action. If the process is canceled or if a system failure occurs, a partial deletion can occur. A subsequent DELETE FILESPACE command for the same node or owner can delete the remaining data.

If this command is applied to a WORM (write once, read many) volume, the volume is returned to scratch if it has space on which data can be written. (Data on WORM volumes, including deleted and expired data, cannot be overwritten. Therefore, data can be written only in space that does not contain current, deleted, or expired data.) If a WORM volume does not have any space available on which data can be written, it remains private. To remove the volume from the library, you must use the CHECKOUT LIBVOLUME command.

Tips:

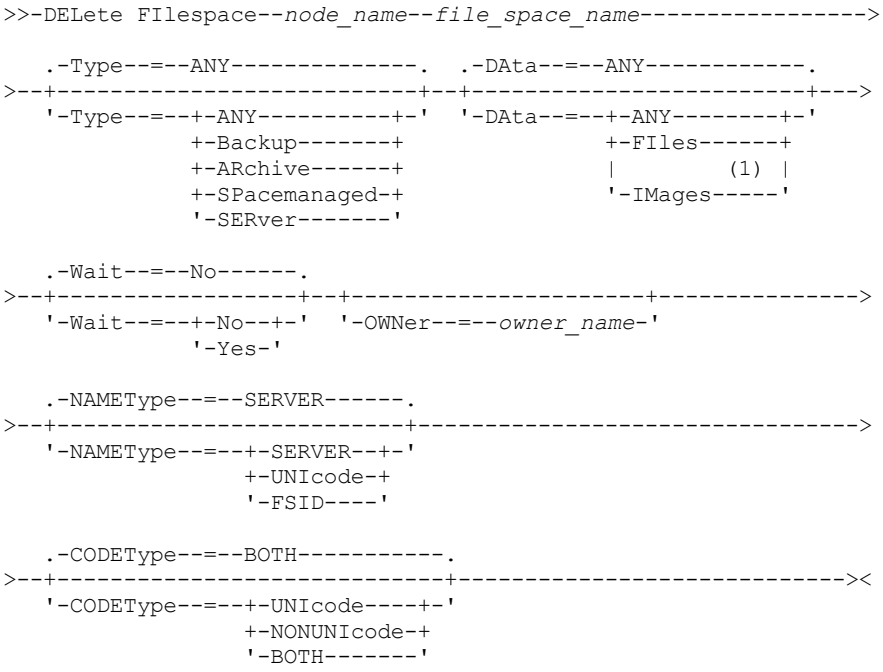
- If archive retention protection is enabled, the server deletes archive files with expired retention periods. For more information, see the SET ARCHIVERETENTIONPROTECTION command.
- The server does not delete archive files that are on deletion hold until the hold is released.
- Reclamation does not start while the DELETE FILESPACE command is running.
- If a file space is part of a collocation group and you remove the file space from a node, the file space is removed from the collocation group.

- If you delete a file space in a deduplicated storage pool, the file space name DELETED is displayed in the output of the QUERY OCCUPANCY command until all deduplication dependencies are removed.
- When replication is configured for a file space, the DELETE FILESPACE command deletes only the file space on the server where you issued the command. If you issue the REPLICATE NODE command, the file space is not deleted on the other replication server.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the client node is assigned.

Syntax



Notes:

1. This parameter can be used only when `TYPE=ANY` or `TYPE=BACKUP` is specified.

Parameters

node_name (Required)
: Specifies the name of the client node to which the file space belongs.

file_space_name (Required)
: Specifies the name of the file space to be deleted. This name is case-sensitive and must be entered exactly as it is known to the server. To determine how to enter the name, use the QUERY FILESPACE command. You can use wildcard characters to specify this name.

  For a server that has clients with support for Unicode, you might have the server convert the file space name that you enter. For example, you might want to have the server convert the name that you entered from the server's code page, to Unicode. See the NAMETYPE parameter for details. If you do not specify a file space name, or specify only a single wildcard character for the name, you can use the CODETYPE parameter to limit the operation to Unicode file spaces or to non-Unicode file spaces.

Type
: Specifies the type of data to be deleted. This parameter is optional. The default value is ANY. You can use the following values:

  ANY
  : Delete only backed-up versions of files and archived copies of files.

If you specify `delete filespace node_name * type=any`, all backed-up data and archived data in all file spaces for that node are deleted. File spaces are deleted only if they do not contain files that are moved from an IBM Spectrum Protect for Space Management client.

Backup
: Delete backup data for the file space.

ARchive
: Delete all archived data on the server for the file space.

SPacemanaged
: Delete files that are migrated from a user's local file system by an IBM Spectrum Protect for Space Management client. The OWNER parameter is ignored when you specify TYPE=SPACEMANAGED.

SERver
: Delete all archived files in all file spaces for a node that is registered as TYPE=SERVER.

DAta
: Specifies objects to delete. This parameter is optional. The default value is ANY. You can specify one of the following values:

  ANY
  : Delete files, directories, and images.

  FIles
  : Delete files and directories.

  IMages
  : Delete image objects. You can use this parameter only if you specified TYPE=ANY or TYPE=BACKUP.

Wait
: Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default value is No. You can specify one of the following values:

  No
  : Specifies that the server processes this command in the background. You can continue with other tasks while the command is being processed.

    Messages that are created from the background process are displayed either in the activity log or the server console, depending on where messages are logged.

  Yes
  : Specifies that the server processes this command in the foreground. Wait for the command to complete before you continue with other tasks. The server displays the output messages to the administrative client when the command completes.
    Restriction: You cannot specify WAIT=YES from the server console.

OWNer
: Restricts the data that is deleted to files that belong to the owner. This parameter is optional; it is ignored when TYPE=SPACEMANAGED. This parameter applies to only multiuser client systems such as AIX®, Linux, and Solaris OS.

NAMEType
: Specify how you want the server to interpret the file space names that you enter. This parameter is useful when the server has clients with support for Unicode. A backup-archive client with support for Unicode is available only for the following operating systems: Windows, Macintosh OS X, and NetWare operating systems.

  Use this parameter only when you enter a partly or fully qualified file space name. The default value is SERVER. You can specify one of the following values:

  SERVER
  : The server uses the server's code page to interpret the file space names.

  UNIcode
  : The server converts the file space names from the server code page to the UTF-8 code page. The success of the conversion depends on the actual characters in the name and the server's code page. Conversion can fail if the string includes characters that are not available in the server code page or if the server cannot access system conversion routines.

  FSID
  : The server interprets the file space names as their file space IDs (FSIDs).

CODEType

Specify what type of file spaces are to be included in the operation. The default is BOTH, meaning that file spaces are included regardless of code page type. Use this parameter only when you enter a single wildcard character for the file space name. You can specify one of the following values:

UNIcode
: Include file spaces that are in Unicode.

NONUNIcode
: Include file spaces that are not in Unicode.

BOTH
: Include file spaces regardless of code page type.

Delete a file space

Delete the C_Drive file space that belongs to the client node HTANG.

```
delete filespace htang C_Drive
```

Delete all space-managed files for a client node

Delete all files that are migrated from client node APOLLO (that is, all space-managed files).

```
delete filespace apollo * type=spacemanaged
```

Related commands

Table 1. Commands related to DELETE FILESPACE

Command	Description
CANCEL PROCESS	Cancels a background server process.
QUERY ACTLOG	Displays messages from the server activity log.
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.
QUERY OCCUPANCY	Displays file space information by storage pool.
QUERY PROCESS	Displays information about background processes.
REMOVE NODE	Removes a client from the list of registered nodes for a specific policy domain.
RENAME FILESPACE	Renames a client filespace on the server.

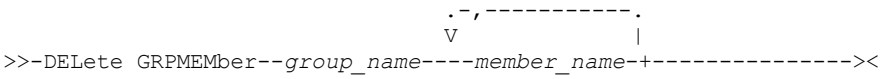
DELETE GRPMEMBER (Delete a server from a server group)

Use this command to delete a server or server group from a server group.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

group_name (Required)
: Specifies the group.

member_name (Required)

Specifies the server or group to delete from the group. To specify multiple names, separate the names with commas and no intervening spaces.

Example: Delete a server from a server group

Delete member PHOENIX from group WEST_COMPLEX.

```
delete grpmember west_complex phoenix
```

Related commands

Table 1. Commands related to DELETE GRPMEMBER

Command	Description
DEFINE GRPMEMBER	Defines a server as a member of a server group.
DEFINE SERVERGROUP	Defines a new server group.
DELETE SERVER	Deletes the definition of a server.
DELETE SERVERGROUP	Deletes a server group.
MOVE GRPMEMBER	Moves a server group member.
QUERY SERVER	Displays information about servers.
QUERY SERVERGROUP	Displays information about server groups.
RENAME SERVERGROUP	Renames a server group.
UPDATE SERVERGROUP	Updates a server group.

DELETE LIBRARY (Delete a library)

Use this command to delete a library. Before you delete a library, you must delete other associated objects, such as the path.

Use this command to delete a library. Before you delete a library, delete the path and all associated drives.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DELete LIBRary--library_name-------------------------------><
```

Parameters

library_name (Required)
Specifies the name of the library to be deleted.

Example: Delete a manual library

Delete the manual library named LIBR1.

```
delete library libr1
```

Related commands

Table 1. Commands related to DELETE LIBRARY

Command	Description
DEFINE DRIVE	Assigns a drive to a library.

Command	Description
DEFINE LIBRARY	Defines an automated or manual library.
DEFINE PATH	Defines a path from a source to a destination.
DELETE DRIVE	Deletes a drive from a library.
DELETE PATH	Deletes a path from a source to a destination.
PERFORM LIBACTION	Defines all drives and paths for a library.
QUERY DRIVE	Displays information about drives.
QUERY LIBRARY	Displays information about one or more libraries.
QUERY PATH	Displays information about the path from a source to a destination.
UPDATE DRIVE	Changes the attributes of a drive.
UPDATE LIBRARY	Changes the attributes of a library.
UPDATE PATH	Changes the attributes associated with a path.

DELETE MACHINE (Delete machine information)

Use this command to delete machine description information. To replace existing information, issue this command and then issue an INSERT MACHINE command.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DELete MACHine--machine_name---------------------------------->

   .-Type--=--All----------------------.
>--+-----------------------------------+------------------------><
   '-Type--=--+-All------------------+-'
              +-RECOVERYInstructions-+
              '-CHaracteristics------'
```

Parameters

machine_name (Required)
: Specifies the name of the machine whose information is to be deleted.

Type
: Specifies the type of machine information. This parameter is optional. The default is ALL. Possible values are:

  All
  : Specifies all information.

  RECOVERYInstructions
  : Specifies the recovery instructions.

  CHaracteristics
  : Specifies the machine characteristics.

Example: Delete a specific machine's information

Delete the machine characteristics associated with the DISTRICT5 machine.

```
delete machine district5 type=characteristics
```

Related commands

Table 1. Commands related to DELETE MACHINE

Command	Description
DEFINE MACHINE	Defines a machine for DRM.
INSERT MACHINE	Inserts machine characteristics or recovery instructions into the IBM Spectrum ProtectIBM Spectrum Protect™ database.
QUERY MACHINE	Displays information about machines.
QUERY RECOVERYMEDIA	Displays media available for machine recovery.
UPDATE MACHINE	Changes the information for a machine.

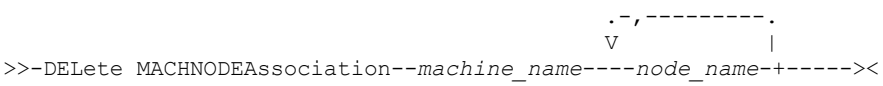
DELETE MACHNODEASSOCIATION (Delete association between a machine and a node)

Use this command to delete the association between a machine and one or more nodes. This command does not delete the node from IBM Spectrum Protect™.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

machine_name (Required)
: Specifies the name of a machine that is associated with one or more nodes.

node_name (Required)
: Specifies the name of a node associated with a machine. If you specify a list of node names, separate the names with commas and no intervening spaces. You can use wildcard characters to specify a name. If a node is not associated with the machine, that node is ignored.

Example: Delete an association between a node and a machine

Delete the association between the DISTRICT5 machine and the ACCOUNTSPAYABLE node.

```
delete machnodeassociation district5 accountspayable
```

Related commands

Table 1. Commands related to DELETE MACHNODEASSOCIATION

Command	Description
DEFINE MACHNODEASSOCIATION	Associates an IBM Spectrum Protect node with a machine.
QUERY MACHINE	Displays information about machines.

DELETE MGMTCLASS (Delete a management class)

Use this command to delete a management class. You cannot delete a management class in the ACTIVE policy set. All copy groups in the management class are deleted along with the management class.

You can delete the management class assigned as the default for a policy set, but a policy set cannot be activated unless it has a default management class.

You can delete the predefined STANDARD management class in the STANDARD policy domain. However, if you later reinstall the IBM Spectrum Protect™ server, the process restores all STANDARD policy objects.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the management class belongs.

Syntax

```
>>-DELete MGmtclass--domain_name--policy_set_name--class_name--><
```

Parameters

domain_name (Required)
: Specifies the policy domain to which the management class belongs.

policy_set_name (Required)
: Specifies the policy set to which the management class belongs.

class_name (Required)
: Specifies the management class to delete.

Example: Delete a management class

Delete the ACTIVEFILES management class from the VACATION policy set of the EMPLOYEE_RECORDS policy domain.

```
delete mgmtclass employee_records
vacation activefiles
```

Related commands

Table 1. Commands related to DELETE MGMTCLASS

Command	Description
ASSIGN DEFMGMTCLASS	Assigns a management class as the default for a specified policy set.
COPY MGMTCLASS	Creates a copy of a management class.
DEFINE MGMTCLASS	Defines a management class.
QUERY MGMTCLASS	Displays information about management classes.
UPDATE MGMTCLASS	Changes the attributes of a management class.

DELETE NODEGROUP (Delete a node group)

Use this command to delete a node group. You cannot delete a node group if it has any members in it.

Attention: You can remove all the members in the node group by issuing the DELETE NODEGROUPMEMBER command with a wildcard in the node_name parameter.

Privilege class

To issue this command, you must have system or unrestricted policy privilege.

Syntax

```
>>-DELete NODEGroup--group_name-------------------------------><
```

Parameters

group_name
Specifies the name of the node group that you want to delete.

Example: Delete a node group

Delete a node group named `group1`.

```
delete nodegroup group1
```

Related commands

Table 1. Commands related to DELETE NODEGROUP

Command	Description
DEFINE BACKUPSET	Defines a previously generated backup set to a server.
DEFINE NODEGROUP	Defines a group of nodes.
DEFINE NODEGROUPMEMBER	Adds a client node to a node group.
DELETE BACKUPSET	Deletes a backup set.
DELETE NODEGROUPMEMBER	Deletes a client node from a node group.
GENERATE BACKUPSET	Generates a backup set of a client's data.
QUERY BACKUPSET	Displays backup sets.
QUERY NODEGROUP	Displays information about node groups.
UPDATE BACKUPSET	Updates a retention value associated with a backup set.
UPDATE NODEGROUP	Updates the description of a node group.

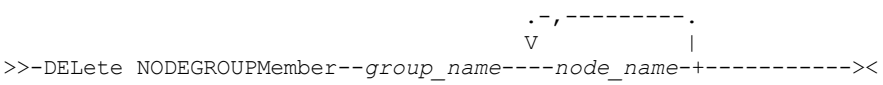
DELETE NODEGROUPMEMBER (Delete node group member)

Use this command to delete a client node from a node group.

Privilege class

To issue this command, you must have system or unrestricted policy privilege.

Syntax



Parameters

group_name
Specifies the name of the node group from which you want to delete a client node.

node_name
Specifies the name of the client node that you want to delete from the node group. You can specify one or more names. When specifying multiple names, separate the names with commas; do not use intervening spaces. You can also use wildcard characters to specify multiple nodes.

Example: Delete node group members

Delete two nodes, `node1` and `node2`, from a node group, `group1`.

```
delete nodegroupmember group1 node1,node2
```

Related commands

Table 1. Commands related to DELETE NODEGROUPMEMBER

Command	Description
DEFINE BACKUPSET	Defines a previously generated backup set to a server.
DEFINE NODEGROUP	Defines a group of nodes.
DEFINE NODEGROUPMEMBER	Adds a client node to a node group.
DELETE BACKUPSET	Deletes a backup set.
DELETE NODEGROUP	Deletes a node group.
GENERATE BACKUPSET	Generates a backup set of a client's data.
QUERY BACKUPSET	Displays backup sets.
QUERY NODEGROUP	Displays information about node groups.
UPDATE BACKUPSET	Updates a retention value associated with a backup set.
UPDATE NODEGROUP	Updates the description of a node group.

DELETE PATH (Delete a path)

Use this command to delete a path definition

Privilege class

To issue this command you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DELete PATH--source_name--destination_name------------------->

                           (1)
>--SRCType--=--+-DATAMover-----+-------------------------------->
               '-SERVer--------'

                        (2)
>--DESTType--=--+-DRive------LIBRary--=--library_name-+-------><
                '-LIBRary-----------------------------'
```

Notes:

1. This parameter is only available on AIX, HP-UX, Linux, Solaris, Windows operating systems.
2. This parameter is only available on AIX, HP-UX, Linux, Solaris, Windows operating systems.

Parameters

source_name (Required)
: Specifies the name of the source of the path to be deleted. This parameter is required.

  The name specified must be that of a server or data mover that is already defined to the server.

destination_name (Required)
: Specifies the name of the destination of the path to be deleted. This parameter is required.

SRCType (Required)
: Specifies the source type of the path to be deleted. This parameter is required. Possible values are:

  DATAMover
  : Specifies that a data mover is the source.

  SERVer
  : Specifies that a storage agent is the source.

DESTType (Required)

Specifies the type of the destination. Possible values are:

DRive LIBRary=library_name
: Specifies that a drive is the destination. The DRIVE and LIBRARY parameters are both required when the destination type is drive.

LIBRary
: Specifies that a library is the destination.
Attention: If the path from a data mover to a library is deleted, or the path from the server to a library is deleted, the server will not be able to access the library. If the server is halted and restarted while in this state, the library will not be initialized.

Example: Delete a NAS data mover path

Delete a path from a NAS data mover NAS1 to the library NASLIB.

```
delete path nas1 naslib srctype=datamover desttype=library
```

Related commands

Table 1. Commands related to DELETE PATH

Command	Description
DEFINE DATAMOVER	Defines a data mover to the IBM Spectrum Protect server.
DEFINE PATH	Defines a path from a source to a destination.
PERFORM LIBACTION	Defines all drives and paths for a library.
QUERY PATH	Displays information about the path from a source to a destination.
UPDATE PATH	Changes the attributes associated with a path.

DELETE POLICYSET (Delete a policy set)

Use this command to delete a policy set. When you delete a policy set, all management classes and copy groups that belong to the policy set are also deleted.

The ACTIVE policy set in a policy domain cannot be deleted. You can replace the contents of the ACTIVE policy set by activating a different policy set. Otherwise, the only way to remove the ACTIVE policy set is to delete the policy domain that contains the policy set.

You can delete the predefined STANDARD policy set. However, if you later reinstall the IBM Spectrum Protect™ server, the process restores all STANDARD policy objects.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the policy set belongs.

Syntax

```
>>-DELete POlicyset--domain_name--policy_set_name--------------><
```

Parameters

domain_name (Required)
: Specifies the policy domain to which the policy set belongs.

policy_set_name (Required)
: Specifies the policy set to delete.

Example: Delete a policy set

Delete the VACATION policy set from the EMPLOYEE_RECORDS policy domain by issuing the following command:

```
delete policyset employee_records vacation
```

Related commands

Table 1. Commands related to DELETE POLICYSET

Command	Description
ACTIVATE POLICYSET	Validates and activates a policy set.
COPY POLICYSET	Creates a copy of a policy set.
DEFINE POLICYSET	Defines a policy set within the specified policy domain.
QUERY POLICYSET	Displays information about policy sets.
UPDATE POLICYSET	Changes the description of a policy set.
VALIDATE POLICYSET	Verifies and reports on conditions the administrator must consider before activating the policy set.

DELETE PROFASSOCIATION (Delete a profile association)

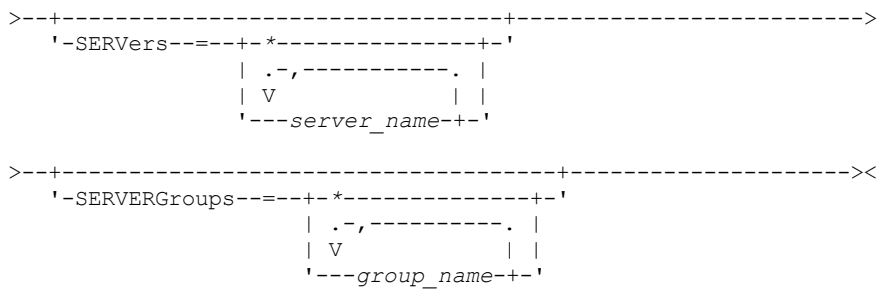
Use this command on a configuration manager to delete the association of one or more objects from a profile. If associations are deleted, the objects are no longer distributed to subscribing managed servers. When managed servers request updated configuration information, the configuration manager notifies them of the object deletions.

A managed server deletes the objects that were deleted from the profile, unless the objects are associated with another profile to which that server subscribes.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

profile_name (Required)
: Specifies the profile from which to delete associations.

ADMins
: Specifies the administrators whose association with the profile is deleted. You can specify more than one name by separating the names with commas and no intervening spaces. Use the match-all character (*) to delete all administrators from the profile. If you specify a list of administrators and a match-all definition exists for the profile, the command fails. Administrator definitions are not changed on the configuration manager. However, they are automatically deleted from all subscribing managed servers at the next configuration refresh, with the following exceptions:

  - An administrator is not deleted if that administrator has an open session on the server.
  - An administrator is not deleted if, as a result, the managed server would have no administrators with system privilege class.

DOmains
: Specifies the domains whose association with the profile is deleted. You can specify more than one name by separating the names with commas and no intervening spaces. Use the match-all character (*) to delete all domains from the profile. If you specify a list of domains and a match-all domain definition exists for the profile, the command fails.

  The domain information is automatically deleted from all subscribing managed servers. However, a policy domain that has client nodes assigned will not be deleted. To delete the domain at the managed server, assign those client nodes to another policy domain.

ADSCHeds
: Specifies a list of administrative schedules whose association with the profile is deleted. You can specify more than one name by separating the names with commas and no intervening spaces. If you specify a list of administrative schedules and a match-all administrative schedule definition exists for the profile, the command fails. Use the match-all character (*) to delete all administrative schedules from the profile.

  The administrative schedules are automatically deleted from all subscribing managed servers. However, an administrative schedule is not deleted if the schedule is active on the managed server. To delete an active schedule, make the schedule inactive.

SCRipts
: Specifies the server command scripts whose association with the profile is deleted. You can specify more than one name by separating the names with commas and no intervening spaces. Use the match-all character (*) to delete all scripts from the profile. If you specify a list of scripts and a match-all script definition exists for the profile, the command fails. The server command scripts are automatically deleted from all subscribing managed servers.

CLOptsets
: Specifies the client option sets whose association with the profile is deleted. You can specify more than one name by separating the names with commas and no intervening spaces. Use the match-all character (*) to delete all client option sets from the profile. If you specify a list of client option sets and a match-all client option set definition exists for the profile, the command fails. The client option sets are automatically deleted from all subscribing managed servers.

SERVers
: Specifies the servers whose association with the profile is deleted. You can specify more than one name by separating the names with commas and no intervening spaces. You can use the match-all character (*) to delete all servers from the profile. If you specify a list of servers and a match-all server definition exists for the profile, the command fails. The server definitions are automatically deleted from all subscribing managed servers with the following exceptions:

  - A server definition is not deleted if the managed server has an open connection to another server.

- A server definition is not deleted if the managed server has a device class of the device type SERVER that refers to the other server.
- A server definition is not deleted if the server is the event server for the managed server.

SERVERGroups
: Specifies the server groups whose association with the profile is deleted. You can specify more than one name by separating the names with commas and no intervening spaces. You can use the match-all character (*) to delete all server groups from the profile. If you specify a list of server groups and a match-all group definition exists for the profile, the command fails. The server group definitions are automatically deleted from all subscribing managed servers.

Example: Delete the domain associations for a specific profile

Delete all domain associations from a profile named MIKE.

```
delete profassociation mike domains=*
```

Related commands

Table 1. Commands related to DELETE PROFASSOCIATION

Command	Description
COPY PROFILE	Creates a copy of a profile.
DEFINE PROFASSOCIATION	Associates objects with a profile.
DEFINE PROFILE	Defines a profile for distributing information to managed servers.
DELETE PROFILE	Deletes a profile from a configuration manager.
LOCK PROFILE	Prevents distribution of a configuration profile.
NOTIFY SUBSCRIBERS	Notifies servers to refresh their configuration information.
QUERY PROFILE	Displays information about configuration profiles.
SET CONFIGMANAGER	Specifies whether a server is a configuration manager.
UNLOCK PROFILE	Enables a locked profile to be distributed to managed servers.
UPDATE PROFILE	Changes the description of a profile.

DELETE PROFILE (Delete a profile)

Use this command on a configuration manager to delete a profile and stop its distribution to managed servers.

You cannot delete a locked profile. You must first unlock the profile with the UNLOCK PROFILE command.

Deleting a profile from a configuration manager does not delete objects associated with that profile from the managed servers. You can use the DELETE SUBSCRIPTION command with the DISCARDOBJECTS=YES parameter on each subscribing managed server to delete subscriptions to the profile and associated objects. This also prevents the managed servers from requesting further updates to the profile.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                                .-Force--=--No------.
>>-DELete PROFIle--profile_name--+-------------------+---------><
                                '-Force--=--+-No--+-'
                                            '-Yes-'
```

Parameters

profile_name (Required)
Specifies the profile to delete.

Force
Specifies whether the profile is deleted if one or more managed servers have subscriptions to that profile. The default is NO. Possible values are:

No
Specifies that the profile is not deleted if one or more managed servers have subscriptions to that profile. You can delete the subscriptions on each managed server using the DELETE SUBSCRIPTION command.

Yes
Specifies that the profile is deleted even if one or more managed servers have subscriptions to that profile. Each subscribing server continues to request updates for the deleted profile until the subscription is deleted.

Examples: Delete a profile

Delete a profile named BETA, even if one or more managed servers subscribe to it.

```
delete profile beta force=yes
```

Related commands

Table 1. Commands related to DELETE PROFILE

Command	Description
COPY PROFILE	Creates a copy of a profile.
DEFINE PROFASSOCIATION	Associates objects with a profile.
DEFINE PROFILE	Defines a profile for distributing information to managed servers.
DEFINE SUBSCRIPTION	Subscribes a managed server to a profile.
DELETE PROFASSOCIATION	Deletes the association of an object with a profile.
DELETE SUBSCRIPTION	Deletes a specified profile subscription.
LOCK PROFILE	Prevents distribution of a configuration profile.
QUERY PROFILE	Displays information about configuration profiles.
QUERY SUBSCRIPTION	Displays information about profile subscriptions.
SET CONFIGMANAGER	Specifies whether a server is a configuration manager.
UNLOCK PROFILE	Enables a locked profile to be distributed to managed servers.
UPDATE PROFILE	Changes the description of a profile.

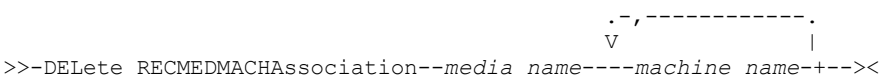
DELETE RECMEDMACHASSOCIATION (Delete recovery media and machine association)

Use this command to remove the association of one or more machines with a recovery media. This command does not delete the machine from IBM Spectrum Protect™.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

media_name (Required)
: Specifies the name of the recovery media that is associated with one or more machines.

machine_name (Required)
: Specifies the name of the machine associated with the recovery media. To specify a list of machine names, separate the names with commas and no intervening spaces. You can use wildcard characters to specify a name. If a machine is not associated with the recovery media, the machine is ignored.

Example: Delete a machine's association with recovery media

Delete the association between the DIST5RM recovery media and the DISTRICT1 and DISTRICT5 machines.

```
delete recmedmachassociation
dist5rm district1,district5
```

Related commands

Table 1. Commands related to DELETE RECMEDMACHASSOCIATION

Command	Description
DEFINE RECMEDMACHASSOCIATION	Associates recovery media with a machine.
QUERY MACHINE	Displays information about machines.
QUERY RECOVERYMEDIA	Displays media available for machine recovery.

DELETE RECOVERYMEDIA (Delete recovery media)

Use this command to delete a recovery media definition from IBM Spectrum Protect™.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DELete RECOVERYMedia--media_name---------------------------><
```

Parameters

media_name (Required)
: Specifies the name of the recovery media.

Example: Delete a recovery media definition

Delete the DIST5RM recovery media.

```
delete recoverymedia dist5rm
```

Related commands

Table 1. Commands related to DELETE RECOVERYMEDIA

Command	Description
DEFINE RECOVERYMEDIA	Defines the media required to recover a machine.
QUERY RECOVERYMEDIA	Displays media available for machine recovery.
UPDATE RECOVERYMEDIA	Changes the attributes of recovery media.

DELETE SCHEDULE (Delete a client or an administrative command schedule)

Use this command to delete schedules from the database.

The DELETE SCHEDULE command takes two forms: one if the schedule applies to client operations, one if the schedule applies to administrative commands. The syntax and parameters for each form are defined separately.

Table 1. Commands related to DELETE SCHEDULE

Command	Description
COPY SCHEDULE	Creates a copy of a schedule.
DEFINE SCHEDULE	Defines a schedule for a client operation or an administrative command.
QUERY SCHEDULE	Displays information about schedules.
UPDATE SCHEDULE	Changes the attributes of a schedule.

- DELETE SCHEDULE (Delete a client schedule)
  Use the DELETE SCHEDULE command to delete one or more client schedules from the database. Any client associations to a schedule are removed when the schedule is deleted.
- DELETE SCHEDULE (Delete an administrative schedule)
  Use this command to delete one or more administrative command schedules from the database.

DELETE SCHEDULE (Delete a client schedule)

Use the DELETE SCHEDULE command to delete one or more client schedules from the database. Any client associations to a schedule are removed when the schedule is deleted.

Privilege class

To delete a client schedule, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the specified policy domain.

Syntax

```
>>-DELete SCHedule--domain_name--schedule_name------------------>

   .-Type--=--Client-.
>--+-----------------+----------------------------------------><
```

Parameters

domain_name (Required)
: Specifies the name of the policy domain to which the schedule belongs.

schedule_name (Required)
: Specifies the name of the schedule to delete. You can use a wildcard character to specify this name.

Type=Client
: Specifies to delete a client schedule. This parameter is optional. The default is CLIENT.

Example: Delete a specific schedule from a specific policy domain

Delete the WEEKLY_BACKUP schedule, which belongs to the EMPLOYEE_RECORDS policy domain.

```
delete schedule employee_records weekly_backup
```

DELETE SCHEDULE (Delete an administrative schedule)

Use this command to delete one or more administrative command schedules from the database.

Privilege class

To delete an administrative command schedule, you must have system authority.

Syntax

```
>>-DELete SCHedule--schedule_name--Type--=--Administrative-----><
```

Parameters

schedule_name (Required)
: Specifies the name of the schedule to delete. You can use a wildcard character to specify this name.

Type=Administrative (Required)
: Specifies to delete an administrative command schedule.

Example: Delete an administrative command schedule

Delete the administrative command scheduled named DATA_ENG.

```
delete schedule data_eng type=administrative
```

DELETE SCRATCHPADENTRY (Delete a scratch pad entry)

Use this command to delete one or more lines of data from a scratch pad.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DELete SCRATCHPadentry--major_category--minor_category------->

            .-Line--=--*------.
>--subject--+-----------------+------------------------------><
            '-Line--=--number-'
```

Parameters

major_category (Required)
: Specifies the major category from which one or more lines of data are to be deleted. This parameter is case sensitive.

minor_category (Required)
: Specifies the minor category from which one or more lines of data are to be deleted. This parameter is case sensitive.

subject (Required)
: Specifies the subject from which one or more lines of data are to be deleted. This parameter is case sensitive.

Line
: Specifies a line of data that is to be deleted. For number, enter the number of the line that is to be deleted. All data on the line is deleted. The numbering of other lines in the subject section is not affected. You can delete all lines of data from a subject section by omitting the Line parameter in this command.

Example: Delete all lines of data from a subject in a scratch pad

Delete all lines of data about the location of an administrator, Jane, from a database that stores information about administrators:

```
delete scratchpadentry admin_info location jane
```

Related commands

Table 1. Commands related to DELETE SCRATCHPADENTRY

Command	Description
DEFINE SCRATCHPADENTRY	Creates a line of data in the scratch pad.
QUERY SCRATCHPADENTRY	Displays information that is contained in the scratch pad.
SET SCRATCHPADRETENTION	Specifies the amount of time for which scratch pad entries are retained.
UPDATE SCRATCHPADENTRY	Updates data on a line in the scratch pad.

DELETE SCRIPT (Delete command lines from a script or delete the entire script)

Use this command to delete a single line from an IBM Spectrum Protect™ script or to delete the entire IBM Spectrum Protect script.

Privilege class

To issue this command, the administrator must have previously defined the script or must have system privilege.

Syntax

```
>>-DELete SCRipt--script_name--+-----------------+------------><
                               '-Line--=--number-'
```

Parameters

script_name (Required)
: Specifies the name of the script to delete. The script is deleted unless you specify a line number.

Line
: Specifies the line number to delete from the script. If you do not specify a line number, the entire script is deleted.

Example: Delete a specific line from a script

Using the following script named QSAMPLE and issue a command to delete line 005 from it.

```
001  /* This is a sample script */
005  QUERY STATUS
010  QUERY PROCESS

delete script qsample line=5
```

Related commands

Table 1. Commands related to DELETE SCRIPT

Command	Description
COPY SCRIPT	Creates a copy of a script.
DEFINE SCRIPT	Defines a script to the IBM Spectrum Protect server.
QUERY SCRIPT	Displays information about scripts.
RENAME SCRIPT	Renames a script to a new name.
RUN	Runs a script.
UPDATE SCRIPT	Changes or adds lines to a script.

DELETE SERVER (Delete a server definition)

Use this command to delete a server definition.

This command fails if the server:

- Is defined as the event server.
- Is named in a device class definition whose device type is SERVER.
- Has an open connection to or from another server.
- Is a target server for virtual volumes.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DELete--SERver--server_name---------------------------------><
```

Parameters

server_name (Required)
Specifies a server name.

Example: Delete a server's definition

Delete the definition for a server named SERVER2.

```
delete server server2
```

Related commands

Table 1. Commands related to DELETE SERVER

Command	Description
DEFINE SERVER	Defines a server for server-to-server communications.
QUERY EVENTSERVER	Displays the name of the event server.
QUERY SERVER	Displays information about servers.
RECONCILE VOLUMES	Reconciles source server virtual volume definitions and target server archive objects.
UPDATE SERVER	Updates information about a server.

DELETE SERVERGROUP (Delete a server group)

Use this command to delete a server group. If the group you delete is a member of other server groups, IBM Spectrum Protect™ also removes the group from the other groups.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DELete SERVERGroup--group_name------------------------------><
```

Parameters

group_name (Required)
: Specifies the server group to delete.

Example: Delete a server group

Delete a server group named WEST_COMPLEX.

```
delete servergroup west_complex
```

Related commands

Table 1. Commands related to DELETE SERVERGROUP

Command	Description
COPY SERVERGROUP	Creates a copy of a server group.
DEFINE GRPMEMBER	Defines a server as a member of a server group.
DEFINE SERVERGROUP	Defines a new server group.
DELETE GRPMEMBER	Deletes a server from a server group.
MOVE GRPMEMBER	Moves a server group member.
QUERY SERVERGROUP	Displays information about server groups.
RENAME SERVERGROUP	Renames a server group.
UPDATE SERVERGROUP	Updates a server group.

DELETE SPACETRIGGER (Delete the storage pool space triggers)

Use this command to delete the definition of the storage pool space trigger.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-DELete SPACETrigger--STG------------------------------------>

>--+-------------------------------+--------------------------><
   '-STGPOOL--=--storage_pool_name-'
```

Parameters

STG
: Specifies a storage pool space trigger.

STGPOOL
: Specifies the storage pool trigger to be deleted. If STG is specified without specifying STGPOOL, the default storage pool space trigger is the deletion target.

Example: Delete a space trigger definition

Delete the space trigger definition for the WINPOOL1 storage pool.

```
delete spacetrigger stg stgpool=winpool1
```

Related commands

Table 1. Commands related to DELETE SPACETRIGGER

Command	Description
DEFINE SPACETRIGGER	Defines a space trigger to expand the space for a storage pool.
QUERY SPACETRIGGER	Displays information about a storage pool space trigger.
UPDATE SPACETRIGGER	Changes attributes of storage pool space trigger.

DELETE STATUSTHRESHOLD (Delete a status monitoring threshold)

Use this command to delete an existing status monitoring threshold.

Status monitoring thresholds compare the defined conditions to the status monitoring server queries and inserts the results in the status monitoring table.

Multiple thresholds can be defined for an activity. For example, you can create a threshold that provides a warning status if storage pool capacity utilization is greater than 80%. You can then create another threshold that provides error status if storage pool capacity utilization is greater than 90%.

Note: If a threshold is already defined for an EXISTS condition, you cannot define another threshold with one of the other condition types.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DELete STAtusthreshold--threshold_name----------------------><
```

Parameters

threshold_name (Required)
Specifies the threshold name that you want to delete.

Delete an existing status threshold

Delete an existing status threshold by issuing the following command:

```
delete statusthreshold avgstgpl
```

Related commands

Table 1. Commands related to DELETE STATUSTHRESHOLD

Command	Description
DEFINE STATUSTHRESHOLD (Define a status monitoring threshold)	Defines a status monitoring threshold.
QUERY MONITORSTATUS (Query the monitoring status)	Displays information about monitoring alerts and server status settings.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
QUERY STATUSTHRESHOLD (Query status monitoring thresholds)	Displays information about a status monitoring thresholds.
SET STATUSMONITOR (Specifies whether to enable status monitoring)	Specifies whether to enable status monitoring.

Command	Description
SET STATUSREFRESHINTERVAL (Set refresh interval for status monitoring)	Specifies the refresh interval for status monitoring.
UPDATE STATUSTHRESHOLD (Update a status monitoring threshold)	Changes the attributes of an existing status monitoring threshold.

DELETE STGPOOL (Delete a storage pool)

Use this command to delete a storage pool. To delete a storage pool, you must first delete all volumes that are assigned to the storage pool.

You cannot delete a storage pool that is identified as the next storage pool for another storage pool. For more information about storage pool hierarchy, see the NEXTSTGPOOL parameter in the DEFINE STGPOOL command.

Restrictions:

- For container storage pools, delete all storage pool directories before you delete the storage pool.
- Do not delete a storage pool that is specified as a destination for a management class or copy group in the ACTIVE policy set. Client operations might fail as a result.
- When you delete a copy storage pool that was previously included in a primary storage-pool definition (specifically in the COPYSTGPOOLS list), you must remove the copy storage pool from the list before deletion. Otherwise, the DELETE STGPOOL command fails until all references to that copy pool are removed. For each primary storage pool with a reference to the copy storage pool to be deleted, remove the reference by entering the UPDATE STGPOOL command with the COPYSTGPOOLS parameter with all previous copy storage pools except the copy storage pool to be deleted.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DELete STGpool--pool_name-----------------------------------><
```

Parameters

pool_name (Required)
: Specifies the storage pool to delete.

Example: Delete a storage pool

Delete the storage pool named POOLA.

```
delete stgpool poola
```

Related commands

Table 1. Commands related to DELETE STGPOOL

Command	Description
BACKUP STGPOOL	Backs up a primary storage pool to a copy storage pool.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DEFINE STGPOOLDIRECTORY	Defines a storage pool directory to a directory-container or cloud-container storage pool.
DELETE STGPOOLDIRECTORY	Deletes a storage pool directory from a directory-container or cloud-container storage pool.

Command	Description
QUERY STGPOOL	Displays information about storage pools.
QUERY STGPOOLDIRECTORY	Displays information about storage pool directories.
AIX Windows SET DRMCOPYSTGPOOL	AIX Windows Specifies that copy storage pools are managed by DRM.
UPDATE STGPOOL	Changes the attributes of a storage pool.
UPDATE STGPOOLDIRECTORY	Changes the attributes of a storage pool directory.

DELETE STGPOOLDIRECTORY (Deleting a storage pool directory)

Use this command to delete a definition for a storage pool directory.

You might want to delete a storage pool directory for the following reasons:

- To decommission old storage.
- To discontinue using the local disk before moving data to the cloud.
- To no longer maintain the data in the storage pool directory because there is no requirement to do so.

Restrictions:

- You can issue this command only when no containers are assigned to the storage pool directory. Issue the QUERY CONTAINER command to determine whether any containers are assigned to the storage pool directory.
- To remove containers from a storage pool directory, you must issue the UPDATE STGPOOLDIRECTORY command and specify the ACCESS=DESTROYED parameter. Then, issue the AUDIT CONTAINER command and specify the ACTION=REMOVEDAMAGED parameter. Verify that the containers are removed.
  The ACTION=REMOVEDAMAGED parameter removes the inventory information of the objects that were backed up or archived. You should only remove the inventory information if you do not need the backups.

If you experience a hardware failure or a loss of your directory, see the relevant AUDIT and REPAIR commands. You should make any repairs to the IBM Spectrum Protect™ environment before you delete the storage pool directory.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DELete STGPOOLDIRectory--pool_name--directory--------------><
```

Parameters

pool_name (Required)
: Specifies the storage pool that contains the directory to delete. This parameter is required.

directory (Required)
: Specifies the file system directory of the storage pool to delete. This parameter is required.

Example: Update a storage pool directory to prepare for deletion

Update the storage pool directory that is named DIR1 in storage pool POOLA to mark as destroyed. When a storage pool is marked as destroyed, you can delete it.

AIX Linux

```
update stgpooldirectory poola /storage/dir1 access=destroyed
```

Windows

```
update stgpooldirectory poola e:\storage\dir1 access=destroyed
```

Example: Delete a storage pool directory

Delete the storage pool directory that is named DIR1 in storage pool POOLA.

AIX | Linux

```
delete stgpooldirectory poola /storage/dir1
```

Windows

```
delete stgpooldirectory poola e:\storage\dir1
```

Table 1. Commands related to DELETE STGPOOLDIRECTORY

Command	Description
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
DEFINE STGPOOLDIRECTORY	Defines a storage pool directory to a directory-container or cloud-container storage pool.
QUERY STGPOOLDIRECTORY	Displays information about storage pool directories.
UPDATE STGPOOLDIRECTORY	Changes the attributes of a storage pool directory.
QUERY EXTENTUPDATES	Displays information about updates to data extents in directory-container storage pools.

DELETE SUBSCRIBER (Delete subscriptions from a configuration manager database)

Use this command on a configuration manager to delete managed server subscriptions from the configuration manager database. Use this command when a managed server no longer exists or cannot notify the configuration manager after deleting a subscription.

Attention: Use this command only in rare situations in which the configuration manager's database contains an entry for a subscription, but the managed server does not have such a subscription. For example, use this command if a managed server no longer exists or cannot notify the configuration manager after deleting a subscription.

Under normal circumstances, use the DELETE SUBSCRIPTION command to delete a subscription from the managed server. The managed server notifies the configuration manager, which then deletes the subscription from its database.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DELete SUBSCRIBer--server_name------------------------------><
```

Parameters

server_name (Required)
Specifies the name of the managed server with subscription entries to be deleted.

Example: Delete subscription entries for a specific managed server

Delete all subscription entries for a managed server named DAN.

```
delete subscriber dan
```

Related commands

Table 1. Commands related to DELETE SUBSCRIBER

Command	Description
DEFINE SUBSCRIPTION	Subscribes a managed server to a profile.
DELETE SUBSCRIPTION	Deletes a specified profile subscription.
NOTIFY SUBSCRIBERS	Notifies servers to refresh their configuration information.
QUERY SUBSCRIBER	Displays information about subscribers and their subscriptions to profiles.
QUERY SUBSCRIPTION	Displays information about profile subscriptions.

DELETE SUBSCRIPTION (Delete a profile subscription)

Use this command on a managed server to delete a profile subscription. You can also delete from the managed server all objects associated with the profile.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DELete SUBSCRIPtion--profile_name---------------------------->

   .-DISCARDobjects--=--No------.
>--+----------------------------+------------------------------><
   '-DISCARDobjects--=--+-No--+-'
                        '-Yes-'
```

Parameters

profile_name (Required)
: Specifies the name of the profile for which the subscription is to be deleted.

DISCARDobjects
: Specifies whether objects associated with the profile are to be deleted on the managed server. This parameter is optional. The default is NO.

  No
  : Specifies that the objects are not to be deleted.

  Yes
  : Specifies that the objects are to be deleted, unless they are associated with another profile for which a subscription is defined.

Example: Delete a profile subscription

Delete a subscription to a profile named ALPHA and its associated objects from a managed server.

```
delete subscription alpha discardobjects=yes
```

Related commands

Table 1. Commands related to DELETE SUBSCRIPTION

Command	Description
DEFINE SUBSCRIPTION	Subscribes a managed server to a profile.
DELETE SUBSCRIBER	Deletes obsolete managed server subscriptions.
NOTIFY SUBSCRIBERS	Notifies servers to refresh their configuration information.

Command	Description
QUERY SUBSCRIBER	Displays information about subscribers and their subscriptions to profiles.
QUERY SUBSCRIPTION	Displays information about profile subscriptions.

DELETE VIRTUALFSMAPPING (Delete a virtual file space mapping)

Use this command to delete a virtual file space mapping definition. Virtual file spaces containing data cannot be deleted unless you use the DELETE FILESPACE command first.

Privilege class

To issue this command, you must have one of the following privilege classes:

- System privilege
- Unrestricted policy privilege
- Restricted policy privilege for the domain to which the NAS node is assigned

Syntax

```
>>-DELete VIRTUALFSmapping  -node_name-------------------------->

>--virtual_filespace_name--------------------------------------><
```

Parameters

node_name (Required)
: Specifies the NAS node on which the file system and path reside. You cannot use wildcard characters or specify a list of names.

virtual_filespace_name (Required)
: Specifies the name of the virtual file space mapping definition to be deleted. Wildcard characters are allowed.

Example: Delete a virtual file space mapping

Delete the virtual file space mapping definition /mikeshomedir for the NAS node named NAS1.

```
delete virtualfsmapping nas1 /mikeshomedir
```

Related commands

Table 1. Commands related to DELETE VIRTUALFSMAPPING

Command	Description
DEFINE VIRTUALFSMAPPING	Define a virtual file space mapping.
QUERY VIRTUALFSMAPPING	Query a virtual file space mapping.
UPDATE VIRTUALFSMAPPING	Update a virtual file space mapping.

DELETE VOLHISTORY (Delete sequential volume history information)

Use this command to delete volume history file records that are no longer needed (for example, records for obsolete database backup volumes).

When you delete records for volumes that are not in storage pools (for example, database backup or export volumes), the volumes return to scratch status even if IBM Spectrum Protect™ acquired them as private volumes. Scratch volumes of device type FILE are deleted. When you delete the records for storage pool volumes, the volumes remain in the IBM Spectrum Protect database. When you delete records for recovery plan file objects from a source server, the objects on the target server are marked for deletion.

Restriction: Do not use the DELETE VOLHISTORY command to delete information about backup set volumes from the volume history file. Instead, use the DELETE BACKUPSET command for this purpose.

For users of DRM, the database backup expiration should be controlled with the SET DRMDBBACKUPEXPIREDAYS command instead of this DELETE VOLHISTORY command. Use the DELETE VOLHISTORY command to remove a record of the volume. This can cause volumes to be lost that were managed by the MOVE DRMEDIA command. Use the SET DRMDBBACKUPEXPIREDAYS command to manage the automatic expiration of DRM database backup volumes.

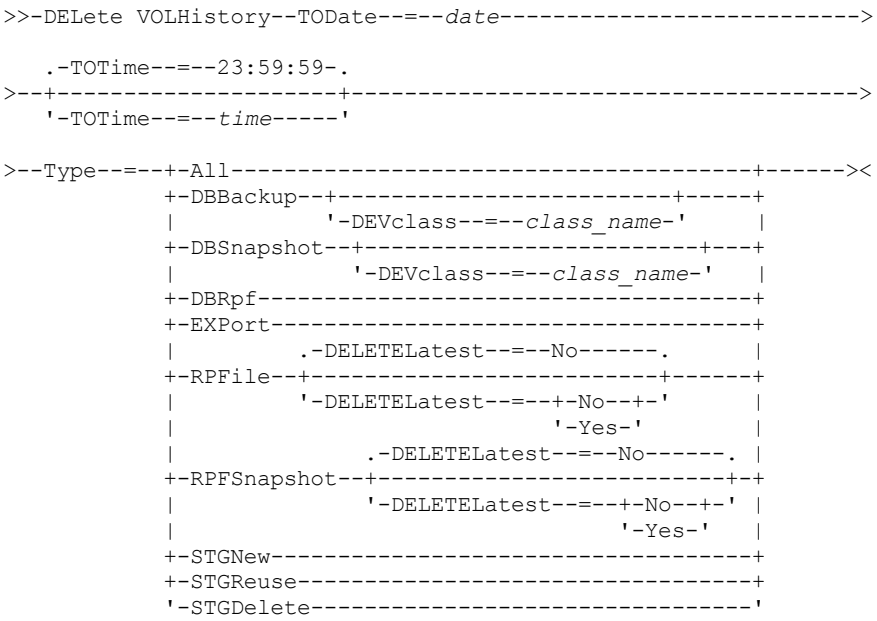
Tips:

- Volumes for the most recent database backup series are not deleted.
- Existing volume history files are not automatically updated with this command.
- You can use the DEFINE SCHEDULE command to periodically delete volume history records.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

TODate (Required)

Specifies the date to use to select sequential volume history information to be deleted. You can delete only those records with a date on or before the date that you specify. You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	01/23/1999
TODAY	The current date	TODAY
TODAY-days or -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY–30 or –30. To delete records that are 30 or more days old, you can specify TODAY-30 or simply -30.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.

Value	Description	Example
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

TOTime

Specifies that you want to delete records that are created on or before this time on the specified date. This parameter is optional. The default is the end of the day (23:59:59). You can specify the time by using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time on the specified date	12:30:22
NOW	The current time on the specified date	NOW
NOW+HH:MM or +HH:MM	The current time plus hours and minutes on the specified date	NOW+03:00 or +03:00. If you issue the DELETE VOLHISTORY command at 9:00 with TOTIME=NOW+03:00 or TOTIME=+03:00, IBM Spectrum Protect deletes records with a time of 12:00 or earlier on the specified date.
NOW-HH:MM or -HH:MM	The current time minus hours and minutes on the specified date	NOW-03:30 or -03:30. If you issue the DELETE VOLHISTORY command at 9:00 with TOTIME=NOW-3:30 or TOTIME=-3:30, IBM Spectrum Protect deletes records with a time of 5:30 or earlier on the specified date.

Type (Required)

Specifies the type of records, which also meet the date and time criteria, to delete from the volume history file. Possible values are:

All

Specifies to delete all records.
Restriction: The DELETE VOLHISTORY command does not delete records of remote volumes.

DBBackup

Specifies to delete only records that contain information about volumes that are used for database full and incremental backups, that is, with volume types of BACKUPFULL and BACKUPINCR, and that meet the specified date and time criteria. The records from the latest full and incremental database backup series will not be deleted.

DEVclass=class_name

Specifies the device class name that was used to create the database backups. This optional parameter can be used to delete database backups that are created by using a server-to-server virtual volume device class. The type of the device class must be SERVER. This parameter can be used only to delete volume history entries of type BACKUPFULL, BACKUPINCR, or DBSNAPSHOT.
A full or incremental database backup volume is eligible to be deleted if all of the following conditions are met:

- The device class that was used to create the database backup volume matches the specified device class.
- The volume was created on or before the specified date and time.
- The volume is not part of the latest full plus incremental database backup series.
- The volume is not part of a full plus incremental backup series with an incremental database backup that was created after the specified date and time.

DBSnapshot

Specifies to delete only records that contain information about volumes that are used for snapshot database backups, and that meet the specified date and time criteria. Records that are related to the latest snapshot database backup will not be deleted.

DEVclass=classname

Specifies the device class name that was used to create the database backups. This optional parameter can be used to delete database backups that are created by using a server-to-server virtual volume device class. The type of the device class must be SERVER. This parameter can only be used to delete volume history entries of type BACKUPFULL, BACKUPINCR, or DBSNAPSHOT.
A snapshot database backup volume is eligible to be deleted if all of the following conditions are met:

- The device class that is used to create the database backup volume matches the specified device class
- The volume was created on or before the specified date and time
- The volume is not part of the latest snapshot database backup series

DBRpf
: Specifies to delete only records that contain information about full and incremental database backup volumes and recovery plan file volumes.

EXPort
: Specifies to delete only records that contain information about export volumes.

RPFile
: Specifies to delete only records that contain information about recovery plan file objects that are stored on a target server and that meet the specified date and time criteria.

DELETELatest
: Specifies whether the latest recovery plan file is eligible for deletion. This optional parameter can be used to delete the latest recovery plan files that are created by using a server-to-server virtual volume device class.

This parameter can be used only to delete volume history entries of type RPFILE (for instance, those recovery plan files that were created by using the DEVCLASS parameter with the PREPARE command). If this parameter is not specified, the latest RPFILE entries are not deleted.

No
: Specifies the latest RPFILE file is not deleted.

Yes
: Specifies the latest RPFILE file is deleted if it meets the specified date and time criteria.

RPFSnapshot
: Specifies to delete only records that contain information about recovery plan file objects that were created for snapshot database backups, that are stored on a target server and that meet the specified date and time criteria. The latest RPFSNAPSHOT file will not be deleted unless it meets the specified date and time criteria, and the DELETE parameter is set to Yes.

DELETELatest
: Specifies whether the latest recovery plan file is eligible for deletion. This optional parameter can be used to delete the latest recovery plan files that are created by using a server-to-server virtual volume device class.

This parameter can only be used to delete volume history entries of type RPFSNAPSHOT (for instance, those recovery plan files that were created by using the DEVCLASS parameter with the PREPARE command). If this parameter is not specified, the latest RPFSNAPSHOT entries are not deleted.

No
: Specifies the latest RPFSNAPSHOT file is not deleted.

Yes
: Specifies the latest RPFSNAPSHOT file is deleted if it meets the specified date and time criteria.

STGNew
: Specifies to delete only records that contain information about new sequential access storage volumes.

STGReuse
: Specifies to delete only records that contain information about reused sequential storage pool volumes.

STGDelete
: Specifies to delete only records that contain information about deleted sequential storage pool volumes.

Example: Delete recovery plan file information

Delete all recovery plan file information that is created on or before 03/28/2016.

```
delete volhistory type=rpfile todate=03/28/2016
```

Related commands

Table 1. Commands related to DELETE VOLHISTORY

Command	Description
BACKUP VOLHISTORY	Records volume history information in external files.
DEFINE SCHEDULE	Defines a schedule for a client operation or an administrative command.
DELETE VOLUME	Deletes a volume from a storage pool.
EXPIRE INVENTORY	Manually starts inventory expiration processing.
MOVE DRMEDIA	Moves DRM media onsite and offsite.
PREPARE	Creates a recovery plan file.
QUERY RPFILE	Displays information about recovery plan files.
QUERY VOLHISTORY	Displays sequential volume history information that has been collected by the server.
SET DRMRPFEXPIREDAYS	Set criteria for recovery plan file expiration.
SET DRMDBBACKUPEXPIREDAYS	Specifies criteria for database backup series expiration.

DELETE VOLUME (Delete a storage pool volume)

Use this command to delete a storage pool volume and, optionally, the files stored in the volume.

If the volume has data, to delete the volume you must do one of the following:

- Before deleting the volume, use the MOVE DATA command to move all files to another volume.
- Explicitly request to discard all files in the volume when the volume is deleted (by specifying DISCARDDATA=YES).

If you are deleting several volumes, delete the volumes one at a time. Deleting more than one volume at a time can adversely affect server performance.

Storage pool volumes cannot be deleted if they are in use. For example, a volume cannot be deleted if a user is restoring or retrieving a file residing in the volume, if the server is writing information to the volume, or if a reclamation process is using the volume.

If you issue the DELETE VOLUME command, volume information is deleted from the IBM Spectrum Protect™ database. However, the physical files that are allocated with DEFINE VOLUME command are not removed from the file space.

If this command is applied to a WORM (write once, read many) volume, the volume returns to scratch if it has space remaining in which data can be written. Data on WORM volumes, including deleted and expired data, cannot be overwritten. Therefore, data can only be written in space that does not contain current, deleted, or expired data. If a WORM volume does not have any space available in which data can be written, it remains private. To remove the volume from the library, you must use the CHECKOUT LIBVOLUME command.

The DELETE VOLUME command automatically updates the server library inventory for sequential volumes if the volume is returned to scratch status when the volume becomes empty. To determine whether a volume will be returned to scratch status, issue the QUERY VOLUME command and look at the output. If the value for the attribute "Scratch Volume?" is "Yes," then the server library inventory is automatically updated.

If the value is "No," you can issue the UPDATE LIBVOLUME command to specify the status as scratch. It is recommended that you issue the UPDATE LIBVOLUME command after issuing the DELETE VOLUME command.

Attempting to use the DELETE VOLUME command to delete WORM FILE volumes in a storage pool with RECLAMATIONTYPE=SNAPLOCK fails with an error message. Deletion of empty WORM FILE volumes is performed only by the reclamation process.

If you issue the DELETE VOLUME command for a volume in a storage pool that has a SHRED parameter value greater than 0, the volume is placed in the pending state until shredding is run. Shredding is necessary to complete the deletion, even if the volume is empty.

If you issue the DELETE VOLUME command for a volume in a storage pool that is set up for data deduplication, the server destroys any object that is referencing data on that volume.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the storage pool to which the volume is defined.

Syntax

```
                                .-DISCARDdata--=--No------.
>>-DELete Volume--volume_name--+-------------------------+------>
                                '-DISCARDdata--=--+-No--+-'
                                                  '-Yes-'

   .-Wait--=--No------.
>--+------------------+---------------------------------------><
   '-Wait--=--+-No--+-'
              '-Yes-'
```

Parameters

volume_name (Required)
: Specifies the name of the volume to delete.

DISCARDdata
: Specifies whether files stored in the volume are deleted. This parameter is optional. The default value is NO. Possible values are:

  No
  : Specifies that files stored in the volume are not deleted. If the volume contains any files, the volume is not deleted.

  Yes
  : Specifies that all files stored in the volume are deleted. The server does not need to mount the volume for this type of deletion.
  Remember:

    1. The server does not delete archive files that are on deletion hold.
    2. If archive retention protection is enabled, the server deletes only archive files whose retention period has expired.

  If the volume being deleted is a primary storage pool volume, the server checks whether any copy storage pool has copies of files that are being deleted. When files stored in a primary storage pool volume are deleted, any copies of these files in copy storage pools are also deleted.

  When you delete a disk volume in a primary storage pool, the command also deletes any files that are cached copies (copies of files that have been migrated to the next storage pool). Deleting cached copies of files does not delete the files that have already been migrated or backed up to copy storage pools. Only the cached copies of the files are affected.

  If the volume being deleted is a copy storage pool volume, only files on the copy pool volume are deleted. The primary storage pool files are not affected.

  Do not use the DELETE VOLUME command with DISCARDDATA=YES if a restore process (RESTORE STGPOOL or RESTORE VOLUME) is running. The DELETE VOLUME command could cause the restore to be incomplete.

  If you cancel the DELETE VOLUME operation during processing or if a system failure occurs, some files might remain on the volume. You can delete the same volume again to have the server delete the remaining files and then the volume.

Wait
: Specifies whether to wait for the server to complete processing this command in the foreground. This parameter affects processing only when you have also requested that any data on the volume be discarded. This parameter is optional. The default value is No. Possible values are:

  No

Specifies that the server processes this command in the background. You can continue with other tasks while the command is being processed.

The server displays messages that are created from the background process either in the activity log or the server console, depending on where messages are logged.

Yes

Specifies that the server processes this command in the foreground. You wait for the command to complete before continuing with other tasks. The server then displays the output messages to the administrative client when the command completes.
Remember: You cannot specify WAIT=YES from the server console.

Example: Delete a storage pool volume

Delete storage pool volume stgvol.1 from the storage pool FILEPOOL.

```
delete volume stgvol.1
```

Related commands

Table 1. Commands related to DELETE VOLUME

Command	Description
CANCEL PROCESS	Cancels a background server process.
DEFINE VOLUME	Assigns a volume to be used for storage within a specified storage pool.
MOVE DATA	Moves data from a specified storage pool volume to another storage pool volume.
MOVE DRMEDIA	Moves DRM media onsite and offsite.
QUERY CONTENT	Displays information about files in a storage pool volume.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY PROCESS	Displays information about background processes.
QUERY VOLUME	Displays information about storage pool volumes.
UPDATE VOLUME	Updates the attributes of storage pool volumes.

DISABLE commands

Use DISABLE commands to prevent some types of operations by the server.

- DISABLE EVENTS (Disable events for event logging)
- DISABLE REPLICATION (Prevent outbound replication processing on a server)
- DISABLE SESSIONS (Prevent new sessions from accessing IBM Spectrum Protect)

DISABLE EVENTS (Disable events for event logging)

Use this command to disable the processing of one or more events. If you specify a receiver that is not supported on any platform, or if you specify an invalid event or name, IBM Spectrum Protect™ issues an error message. However, any valid receivers, events, or names that you specified are still enabled.

Tip: Messages in the SEVERE category and message ANR9999D can provide valuable diagnostic information if there are serious server problems. For this reason, you should not disable these messages.
Restriction:

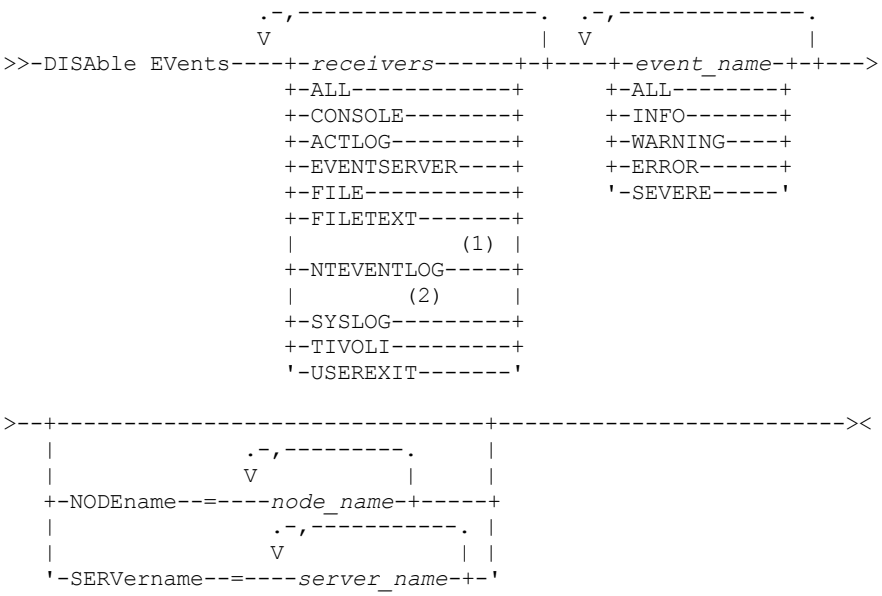
- Certain messages are displayed on the console even if they are disabled. These include some messages issued during server startup and shutdown and responses to administrative commands.
- Server messages from the server on which this command is issued cannot be disabled for the activity log.

ANR1822I indicates that event logging is being ended for the specified receiver. When the DISABLE EVENTS command is issued, this message is logged to the receiver even if it is one of the events that has been disabled. This is done to confirm that event logging has ended to that receiver, but subsequent ANR1822I messages are not logged to that receiver.

Privilege class

To issue this command, you must have system privilege.

Syntax



Notes:

1. NTEVENTLOG is available only on Windows.
2. SYSLOG is available only on Linux.

Parameters

receivers (Required)
: Specifies the name of the receivers for which to disable events. Specify multiple receivers by separating them with commas and no intervening spaces. Possible values are:

  ALL
  : All receivers, except for server events on the activity log receiver (ACTLOG). Only client events can be disabled for the activity log receiver.

  CONSOLE
  : The standard server console as a receiver.

  ACTLOG
  : The activity log as a receiver. You can disable only client events, not server events, for the activity log.

  EVENTSERVER
  : The event server as a receiver.

  FILE
  : A user file as a receiver. Each logged event is a record in the file. The records are not easily readable by people.

  FILETEXT
  : A user file as a receiver. Each logged event is a fixed-size, readable line.

  NTEVENTLOG
  : The Windows application log as a receiver.

  Linux SYSLOG
  : Linux Writes messages directly to the system log on Linux.

  TIVOLI
  : The Tivoli Enterprise Console® (TEC) as a receiver.

USEREXIT
A user-written program as a receiver. The server writes information to the program.

events (Required)
Specifies the events to be disabled. You can specify multiple events by separating them with commas and no intervening spaces. Possible values are:

ALL
All events.
event_name
A four-digit message number preceded by `ANR` for a server event or `ANE` for a client event. Valid ranges are from ANR0001 to ANR9999 and from ANE4000 to ANE4999. Specify the NODENAMES parameter if client events are to be disabled for matching nodes. Specify the SERVERNAME parameter if server events are to be disabled for matching servers.
For the TIVOLI event receiver only, you can specify the following events names for the IBM Spectrum Protect application clients:

IBM Spectrum Protect application client	Prefix	Range
Data Protection for Microsoft Exchange Server	ACN	3500–3649
Data Protection for Lotus® Domino®	ACD	5200–5299
Data Protection for Oracle	ANS	500–599
Data Protection for Informix®	ANS	600–699
Data Protection for Microsoft SQL Server	ACO	3000–3999

Remember: Specifying ALL disables these messages. However, the INFO, WARNING, ERROR, and SEVERE options have no effect on the messages.
severity categories
If the event list contains a severity category, all events of that severity are disabled for the specified nodes. The message types are:

INFO
Information messages (type of I).
WARNING
Warning messages (type of W).
ERROR
Error messages (type of E).
SEVERE
Severe error messages (type of S).

NODEname
Specifies the name of one or more node names for which events are to be disabled. You can use the wildcard character (*) to specify all nodes. You can specify NODENAME or SERVERNAME. If neither parameter is specified, the events are disabled for the server running this command.
SERVername
Specifies the name of one or more server names for which events are to be disabled. You can use the wildcard character (*) to specify all servers other than the server running this command. You can specify NODENAME or SERVERNAME. If neither parameter is specified, the events are disabled for the server running this command.

Example: Disable specific categories of events

Disable all client events in the INFO and WARNING categories for the activity log and console receivers for all nodes.

```
disable events actlog,console
info,warning nodename=*
```

Related commands

Table 1. Commands related to DISABLE EVENTS

Command	Description
BEGIN EVENTLOGGING	Starts event logging to a specified receiver.

Command	Description
ENABLE EVENTS	Enables specific events for receivers.
END EVENTLOGGING	Ends event logging to a specified receiver.
QUERY ENABLED	Displays enabled or disabled events for a specific receiver.
QUERY EVENTRULES	Displays information about rules for server and client events.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

DISABLE REPLICATION (Prevent outbound replication processing on a server)

Use this command to prevent a source replication server from starting new replication processes.

The use of this command does not stop running replication processes. Running replication processes continue until they complete or until they end without completing. Use this command and the ENABLE REPLICATION command to control replication processing.

Issue this command on the server that acts as a source for replicated data.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-DISAble REPLication----------------------------------------><
```

Parameters

None.

Example: Disable replication processing

Disable replication processing on a source replication server.

```
disable replication
```

Related commands

Table 1. Commands related to DISABLE REPLICATION

Command	Description
CANCEL REPLICATION	Cancels node replication processes.
DISABLE SESSIONS	Prevents new sessions from accessing IBM Spectrum Protect but permits existing sessions to continue.
ENABLE REPLICATION	Allows outbound replication processing on a server.
ENABLE SESSIONS	Resumes server activity following the DISABLE command or the ACCEPT DATE command.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.

DISABLE SESSIONS (Prevent new sessions from accessing IBM Spectrum Protect)

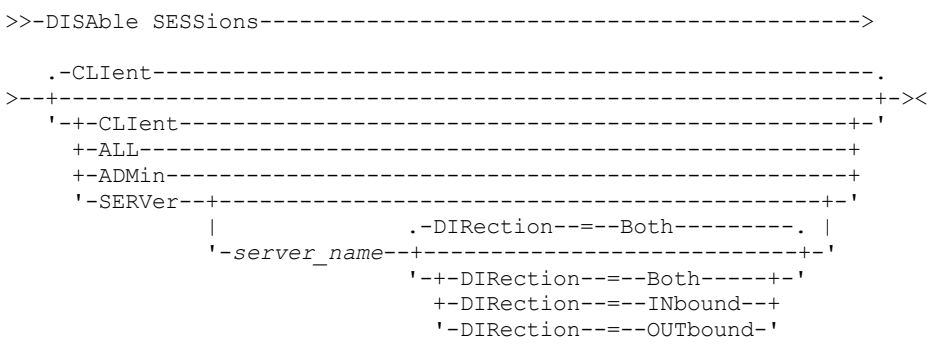
Use this command to prevent new sessions from accessing IBM Spectrum Protect™. Active sessions will complete. For a particular server, you can specify whether to disable inbound sessions, outbound sessions, or both.

Server processes, such as migration and reclamation, are not affected when you issue the DISABLE SESSIONS command.

Privilege class

To issue this command, you must have system privilege or operator privilege.

Syntax



Parameters

Specifies the type of session to be disabled. This parameter is optional. The default value is CLIENT. You can specify one of the following values:

CLIent
: Disables only backup and archive client sessions.

ALL
: Disables all session types.

ADMin
: Disables only administrative sessions.

SERVer
: Disables only server-to-server sessions. Only the following types of sessions are disabled:

  - Server-to-server event logging
  - Enterprise management
  - Server registration
  - LAN-free: storage agent - server
  - Virtual volumes
  - Node replication

  You can also specify whether to disable inbound sessions, outbound sessions, or both for a particular server.

  server_name
  : Specifies the name of a server whose sessions you want to disable. This parameter is optional. If you do not specify this parameter, new sessions with other servers do not start. Running sessions are not canceled.

    DIRection
    : Specifies whether to disable inbound sessions, outbound sessions, or both. This parameter is optional. The default is BOTH. The following values are possible:

      Both
      : Specifies that inbound sessions from the specified server and outbound sessions to the specified server are disabled.

INbound
: Specifies that only inbound sessions from the specified server are disabled.

OUTbound
: Specifies that only outbound sessions to the specified server are disabled.

Example: Prevent new client node backup and archive sessions on the server

Temporarily prevent new client node sessions from accessing the server.

```
disable sessions
```

Example: Prevent all new sessions on the server

Temporarily prevent any new sessions from accessing the server.

```
disable sessions all
```

Example: Disable outbound sessions to a server

Disable outbound sessions to a server named REPLSRV.

```
disable sessions server replsrv direction=outbound
```

Related commands

Table 1. Commands related to DISABLE SESSIONS

Command	Description
CANCEL SESSION	Cancels active sessions with the server.
DISABLE REPLICATION	Prevents outbound replication processing on a server.
ENABLE SESSIONS	Resumes server activity following the DISABLE command or the ACCEPT DATE command.
QUERY SESSION	Displays information about all active administrator and client sessions with IBM Spectrum Protect.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

DISMOUNT command

Use the DISMOUNT command to dismount a volume by the real device address or by volume name.

- DISMOUNT VOLUME (Dismount a volume by volume name)

DISPLAY OBJNAME (Display a full object name)

Use this command when you want IBM Spectrum Protect™ to display a full object name if the name displayed in a message or query output has been abbreviated due to length. Object names that are very long can be difficult to display and use through normal operating system facilities. The IBM Spectrum Protect server will abbreviate long names and assign them a token ID which might be used if the object path name exceeds 1024 bytes. The token ID is displayed in a string that includes identifiers for the node, filespace, and object name. The format is: [TSMOBJ:*nID.fsID.objID*]. When specified with the DISPLAY OBJNAME command, the token ID can be used to show the full object name.

Privilege class

Any administrator can issue this command

Syntax

```
>>-DISplay OBJname--token_ID---------------------------------><
```

Parameters

token_ID (Required)
: Specifies the ID reported in the [TSMOBJ:] tag, when an object name is too long to display.

Example: Display the full object name of a token ID in a message

Assume the you receive the following message:

```
ANR9999D file.c(1999) Error handling file [TSMOBJ:1.1.649498] because
of lack of server resources.
```

Display the full object name for the file referenced in the error message by specifying the token ID on the DISPLAY OBJNAME command.

```
display obj 1.1.649498
```

Related commands

Table 1. Commands related to DISPLAY OBJNAME

Command	Description
QUERY CONTENT	Displays information about files in a storage pool volume.

ENABLE commands

Use ENABLE commands to allow some types of operations by the server.

- ENABLE EVENTS (Enable server or client events for logging)
- ENABLE REPLICATION (Allow outbound replication processing on a server)
- ENABLE SESSIONS (Resume user activity on the server)

ENABLE EVENTS (Enable server or client events for logging)

Use this command to enable the processing of one or more events. If you specify a receiver that is not supported on any platform, or if you specify an invalid event or name, IBM Spectrum Protect™ issues an error message. However, any valid receivers, events, or names that you specified are still enabled.

Restriction: Certain events, such as some messages issued during server start-up and shutdown, automatically go to the console. They do not go to other receivers even if they are enabled.

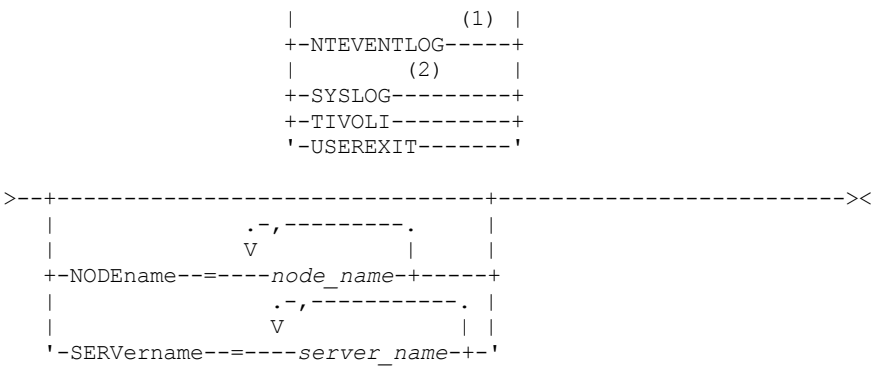
Administrative commands are returned to the command issuer and are only logged as numbered events. These numbered events are not logged to the system console, but are logged to other receivers, including administrative command-line sessions running in console mode.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                  .-,------------------.   .-,--------------.
                  V                    |   V                |
>>-ENable--EVents----+-ALL-------------+-+----+-event_name-+-+--->
                     +-CONSOLE--------+      +-ALL--------+
                     +-ACTLOG---------+      +-INFO-------+
                     +-EVENTSERVER----+      +-WARNING----+
                     +-FILE-----------+      +-ERROR------+
                     +-FILETEXT-------+      '-SEVERE-----'
```



Notes:

1. NTEVENTLOG is available only on Windows.
2. This parameter is only available for the Linux operating system.

Parameters

receivers (Required)
Specifies one or more receivers for which to log enabled events. You can specify multiple receivers by separating them with commas and no intervening spaces. Valid values are:

ALL
All receivers.
CONSOLE
The standard server console as a receiver.
ACTLOG
The server activity log as a receiver.
EVENTSERVER
The event server as a receiver.
FILE
A user file as a receiver. Each logged event is a record in the file. The records are not easily readable by people.
FILETEXT
A user file as a receiver. Each logged event is a fixed-size, readable line.
Windows NTEVENTLOG
Windows The Windows application log as a receiver.
Linux SYSLOG
Linux Specifies the Linux system log as a receiver.
TIVOLI
The Tivoli Enterprise Console® (TEC) as a receiver.
USEREXIT
A user-written program as a receiver. The server writes information to the program.

events (Required)
Specifies the type of events to be enabled. You can specify multiple events by separating them with commas and no intervening spaces. Possible values are:

ALL
All events.
event_name
A four-digit message number preceded by ANR for a server event or ANE for a client event. Valid ranges are from ANR0001 to ANR9999 and from ANE4000 to ANE4999. Specify the NODENAME parameter if client events are to be enabled for matching nodes. Specify the SERVERNAME parameter if server events are to be enabled for matching servers.
For the TIVOLI event receiver, you can specify the following additional ranges for the IBM Spectrum Protect application clients:

IBM Spectrum Protect application client	Prefix	Range
Data Protection for Microsoft Exchange Server	ACN	3500–3649
Data Protection for Lotus® Domino®	ACD	5200–5299

IBM Spectrum Protect application client	Prefix	Range
Data Protection for Oracle	ANS	500–599
Data Protection for Informix®	ANS	600–699
Data Protection for Microsoft SQL Server	ACO	3000–3999

Restriction: The application client must have enhanced Tivoli® Event Console support enabled in order to route these messages to the Tivoli Event Console.
Tip:

- Specifying the ALL option enables these messages. However, the INFO, WARNING, ERROR, and SEVERE options have no effect on the messages.
- Because of the number of messages, you should not enable all messages from a node to be logged to the Tivoli Event Console.

severity categories
If the event list contains a severity category, all events of that severity are enabled for the specified nodes. The message types are:

INFO
Information messages (type of I) are enabled.
WARNING
Warning messages (type of W) are enabled.
ERROR
Error messages (type of E) are enabled.
SEVERE
Severe error messages (type of S) are enabled.

NODEname
Specifies one or more client nodes for which events are enabled. You can use a wildcard character to specify all client nodes. You can specify NODENAME or SERVERNAME. If neither parameter is specified, events are enabled for the server running this command.
SERVername
Specifies one or more servers for which events are to be enabled. You can use a wildcard character to specify all servers other than the server from which this command is issued. You can specify SERVERNAME or NODENAME. If neither parameter is specified, the events are enabled for the server running this command.

Example: Enable specific categories of events

Enable all ERROR and SEVERE client events to the USEREXIT receiver for the node BONZO.

```
enable events userexit error,severe nodename=bonzo
```

Related commands

Table 1. Commands related to ENABLE EVENTS

Command	Description
BEGIN EVENTLOGGING	Starts event logging to a specified receiver.
DISABLE EVENTS	Disables specific events for receivers.
END EVENTLOGGING	Ends event logging to a specified receiver.

QUERY EVENTRULES	Displays information about rules for server and client events.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

ENABLE REPLICATION (Allow outbound replication processing on a server)

Use this command to allow a source replication server to begin normal replication processing after a database restore. You can also use this command to resume replication processing after issuing the DISABLE REPLICATION command.

Attention: Before enabling replication after a database restore, determine whether copies of data that are on the target server are needed. If they are, you must synchronize client node data by replicating the data from the target replication server to the source replication server. The replication process replaces the data on the source server that was lost because of the database restore.

Issue this command on the server that acts as a source for replicated data.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-ENable REPLication-----------------------------------------><
```

Parameters

None.

Example: Allow replication processing

Allow replication processing on a source replication server.

```
enable replication
```

Related commands

Table 1. Commands related to ENABLE REPLICATION

Command	Description
DISABLE REPLICATION	Prevents outbound replication processing on a server.
DISABLE SESSIONS	Prevents new sessions from accessing IBM Spectrum Protect but permits existing sessions to continue.
ENABLE SESSIONS	Resumes server activity following the DISABLE command or the ACCEPT DATE command.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.

ENABLE SESSIONS (Resume user activity on the server)

Use this command after issuing the DISABLE SESSIONS command to start new sessions that can access a server. For a particular server, you can specify whether to enable inbound sessions, outbound sessions, or both.

The processing of this command does not affect system processes, such as migration and reclamation.

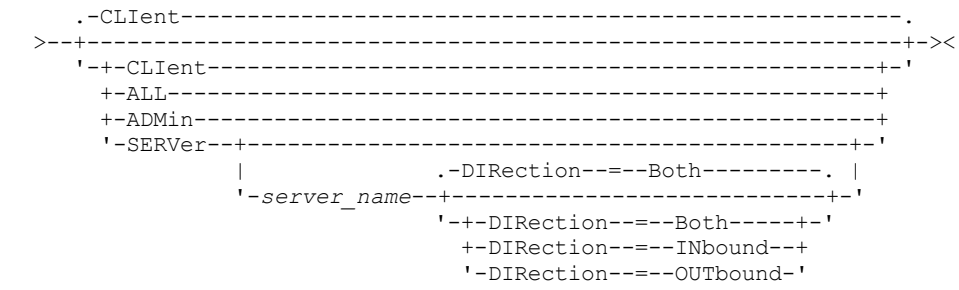
Use the QUERY STATUS command to display the availability of the server.

Privilege class

To issue this command, you must have system privilege or operator privilege.

Syntax

```
>>-ENable SESSions-------------------------------------------->
```



Parameters

Specifies the type of session to be enabled. This parameter is optional. The default value is CLIENT. You can specify one of the following values:

CLIent
: Enables only backup and archive client sessions.

ALL
: Enables all session types.

ADMin
: Enables only administrative sessions.

SERVer
: Enables only server-to-server sessions. You can also specify whether to enable inbound sessions, outbound sessions, or both for a particular server.

  server_name
  : Specifies the name of a particular server whose sessions you want to enable. This parameter is optional. If you do not specify this parameter, new sessions with all other servers are enabled.

    DIRection
    : Specifies whether to enable inbound sessions, outbound sessions, or both. This parameter is optional. The default is BOTH. The following values are possible:

      Both
      : Specifies that inbound sessions from the specified server and outbound sessions to the specified server are enabled.

      INbound
      : Specifies that only inbound sessions to the specified server are enabled.

      OUTbound
      : Specifies that only outbound sessions from the specified server are enabled.

Example: Resume client node activity on the server

Resume normal operation, permitting client nodes to access the server.

```
enable sessions
```

Example: Resume all activity on the server

Resume normal operation, permitting all sessions to access the server.

```
enable sessions all
```

Example: Enable outbound sessions to a server

Enable outbound sessions to a server named REPLSRV.

```
enable sessions server replsrv direction=outbound
```

Related commands

Command	Description
ACCEPT DATE	Accepts the current date on the server.
CANCEL SESSION	Cancels active sessions with the server.
ENABLE REPLICATION	Allows outbound replication processing on a server.
DISABLE SESSIONS	Prevents new sessions from accessing IBM Spectrum Protect but permits existing sessions to continue.
QUERY SESSION	Displays information about all active administrator and client sessions with IBM Spectrum Protect.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

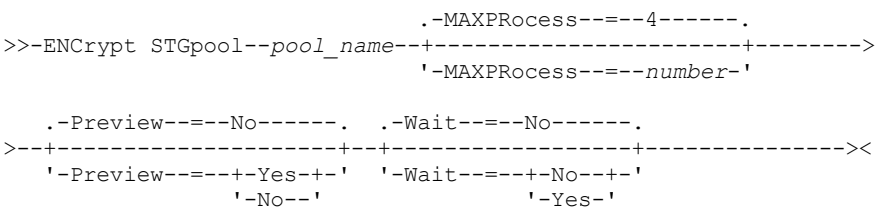
ENCRYPT STGPOOL (Encrypt data in a storage pool)

Use this command to encrypt data in a directory-container or cloud-container storage pool.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

pool_name (Required)
: Specifies the name of the storage pool that contains data that must be encrypted.
Restrictions:

- You can specify only directory-container storage pools or cloud-container storage pools.
- You can specify up to 30 characters for the storage pool name. If you specify more than 30 characters, the command fails.

MAXPRocess
: Specifies the maximum number of parallel processes that can occur when the storage pool is encrypting data. This parameter is optional. Enter a value in the range 1 - 99. The default value is 4.

Preview
: Specifies whether a preview is displayed of all the commands that are processed as part of the ENCRYPT STGPOOL command. This parameter is optional. The following values are possible:

No
: Specifies that a preview of the commands is not displayed. This is the default value.

Yes
: Specifies that a preview of the commands is displayed.

Wait
: Specifies whether the storage pool encryption occurs in the foreground or background. This parameter is optional. You can specify one of the following values:

No

Specifies that the operation is completed in the background. You can continue with other tasks while the command is processing. Messages that are related to the background process are displayed in the activity log file or the server console, depending on where the messages are logged. This is the default value.

Yes

Specifies that the operation is completed in the foreground. It might take a long time to complete the operation. The operation must end before you can continue with other tasks. Messages are displayed in the activity log file or the server console, or both, depending on where the messages are logged.
Restriction: You cannot specify the WAIT=YES parameter from the server console.

Example: Encrypt data in a storage pool

Encrypt data in a storage pool that is named POOL1 and specify a maximum number of 30 parallel processes.

```
encrypt stgpool pool1 maxprocess=30
```

Related commands

Table 1. Commands related to ENCRYPT STGPOOL

Command	Description
DEFINE STGPOOL (directory-container)	Define a directory-container storage pool.

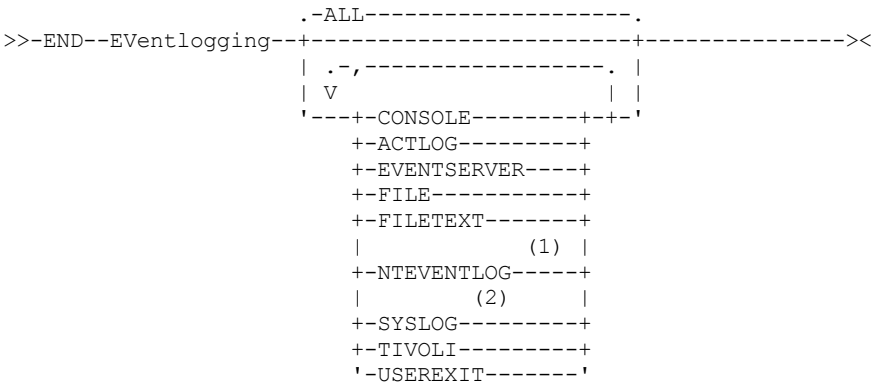
END EVENTLOGGING (Stop logging events)

Use this command to stop logging events to an active receiver.

Privilege class

To issue this command, you must have system privilege.

Syntax



Notes:

1. This parameter is only available for Windows operating system.
2. This parameter is only available for the Linux operating system.

Parameters

Specify a type of receiver. You can specify multiple receivers by separating them with commas and no intervening spaces. This is an optional parameter. The default is ALL. If you specify ALL or no receiver, logging ends for all receivers.

ALL
: Specifies all receivers.

CONSOLE
: Specifies the server console as a receiver.

ACTLOG
: Specifies the IBM Spectrum Protect™ activity log as a receiver. Logging can be stopped only for client events.

EVENTSERVER
: Specifies the event server as a receiver.

FILE
: Specifies a user file as a receiver. Each logged event is a record in the file and a person cannot read each logged event easily.

FILETEXT
: Specifies a user file as a receiver. Each logged event is a fixed-size, readable line.

Windows NTEVENTLOG
: Windows Specifies the Windows application log as a receiver.

Linux SYSLOG
: Linux Specifies the Linux system log as a receiver.

TIVOLI
: Specifies the Tivoli Management Environment (TME) as a receiver.

USEREXIT
: Specifies a user-written routine to which IBM Spectrum Protect writes information as a receiver.

Example: Stop logging events

End logging of events to the user exit.

```
end eventlogging userexit
```

Related commands

Table 1. Commands related to END EVENTLOGGING

Command	Description
BEGIN EVENTLOGGING	Starts event logging to a specified receiver.
DISABLE EVENTS	Disables specific events for receivers.
ENABLE EVENTS	Enables specific events for receivers.
QUERY ENABLED	Displays enabled or disabled events for a specific receiver.
QUERY EVENTRULES	Displays information about rules for server and client events.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.

EXPIRE INVENTORY (Manually start inventory expiration processing)

Use this command to manually start inventory expiration processing. The inventory expiration process removes client backup and archive file copies from server storage. Removal is based on policy specifications in the backup and archive copy groups of the management classes to which the files are bound.

When you have the disaster recovery manager function for your IBM Spectrum Protect™ server, the inventory expiration process also removes eligible virtual volumes that are used by the following processes:

- Database backups of type BACKUPFULL, BACKUPINCR, and DBSNAPSHOT. The SET DRMDBBACKUPEXPIREDAYS command controls when these volumes are eligible for expiration.
- Recovery plan files of type RPFILE and RPFSNAPSHOT. The SET DRMRPFEXPIREDAYS command controls when these volumes are eligible for expiration.

The inventory expiration process that runs during server initialization does not remove these virtual volumes.

Only one expiration process is allowed at any time, but this process can be distributed among a maximum of 40 threads. If an expiration process is running, you cannot start another process.

You can set up automatic expiration processing with the EXPINTERVAL server option. If you set the EXPINTERVAL option to 0, the server does not run expiration automatically, and you must issue the EXPIRE INVENTORY command to start expiration processing.

This command creates a background process that can be canceled with the CANCEL PROCESS command. To display information about background processes, use the QUERY PROCESS command.

If this command is applied to a WORM volume, the volume returns to being a scratch volume if it has remaining space in which data can be written. Data on WORM volumes, including deleted and expired data, cannot be overwritten. Therefore, data can be written only in space that does not contain current, deleted, or expired data. If a WORM volume does not have any space available in which data can be written, it remains private. To remove the volume from the library, you must use the CHECKOUT LIBVOLUME command.

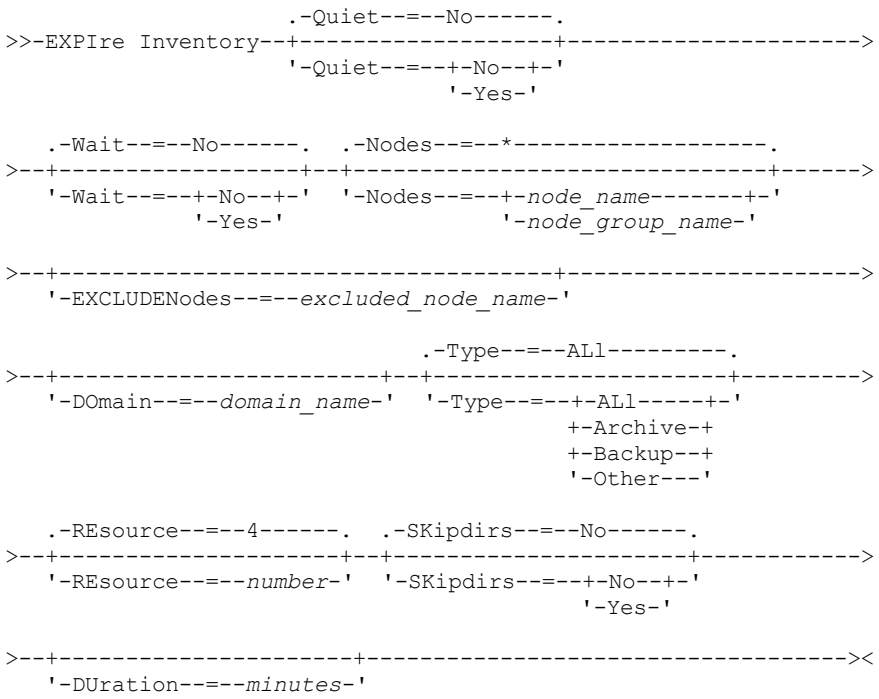
Run the EXPIRE INVENTORY command to delete files from server storage if they were not deleted when you used client delete operations.

For more information about client delete operations, see Backup-archive client options and commands.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

Quiet
: Specifies whether the server suppresses detailed messages about policy changes during the expiration processing. This parameter is optional. The default is NO. Possible values are:

  No
  : Specifies that the server sends detailed informational messages.

  Yes
  : Specifies that the server sends only summary messages. The server issues messages about policy changes only when files are deleted and either the default management class or retention grace period for the domain was used to expire the files.

    You can also specify the EXPQUIET option in the server options file to automatically determine whether expiration processing is run with summary messages.

Wait

Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default value is NO. Possible values are:

No
: Specifies that the server processes this command in the background. You can continue with other tasks while the command is being processed.

  The server displays messages that are created from the background process either in the activity log or the server console, depending on where messages are logged.

Yes
: Specifies that the server processes this command in the foreground. You wait for the command to complete before you continue with other tasks. The server then displays the output messages to the administrative client when the command completes.
  Restriction: You cannot specify WAIT=YES from the server console.

SKipdirs
: Specifies whether the server skips directory type objects during the expiration processing. This parameter is optional. The default is NO. Possible values are:

  No
  : Specifies that the server expires files and directories that are based on the appropriate policy criteria.

  Yes
  : Specifies that the server skips directory type backup and archive objects during expiration processing, even if the directories are eligible for expiration. By specifying YES, you prevent deletion of directories, and expiration processing can occur more quickly.
    Attention: Do not use this option all of the time. With IBM Spectrum Protect Version 6.0 and later, you can run multiple threads (resources) for an expiration process. Also, if you specify YES often, the database grows as the directory objects accumulate, and the time that is spent for expiration increases. Run SKIPDIRS=NO periodically to expire the directories and reduce the size of the database.

Nodes
: Specifies the name of the client nodes or node groups whose data is to be processed. To specify multiple node and node group names, separate the names with commas and no intervening spaces. Node names can contain wildcard characters, but node group names cannot. This parameter is optional.

  You can specify NODES, EXCLUDENODES, DOMAIN, or any combination. If you specify more than one of these parameters, only those nodes that match the criteria for both NODES and DOMAIN and does not match the criteria for EXCLUDENODES command options are processed. If you do not specify NODES, EXCLUDENODES, or DOMAIN with a value, data for all nodes is processed.

EXCLUDENodes
: Specifies the name of the client nodes or node groups whose data is not to be processed. To specify multiple node and node group names, separate the names with commas and no intervening spaces. Node names can contain wildcard characters, but node group names cannot. This parameter is optional.

  You can specify NODES, EXCLUDENODES, DOMAIN, or any combination. If you specify more than one of these parameters, only those nodes that match the criteria for both NODES and DOMAIN and does not match the criteria for EXCLUDENODES command options are processed. If you do not specify NODES, EXCLUDENODES, or DOMAIN with a value, data for all nodes is processed.

Domain
: Specifies that only data for client nodes that are assigned to the specified domain is to be processed. This parameter is optional. You can specify NODES, EXCLUDENODES, DOMAIN, or any combination. If you specify more than one of these parameters, only those nodes that match the criteria for both NODES and DOMAIN and does not match the criteria for EXCLUDENODES command options are processed. If you do not specify NODES, EXCLUDENODES, or DOMAIN with a value, data for all nodes is processed.

Type
: Specifies the type of data to be processed. This parameter is optional. The default value is ALL. Possible values are:

  ALl
  : Process all types of data that is eligible for expiration

  Archive
  : Process only client archive data

  Backup

Process only client backup data

Other

Process only items for disaster recovery manager functions, such as recovery plan files and obsolete database backups

REsource

Specifies the number of threads that can run in parallel. Specify a value in the range 1 - 40. This parameter is optional. The default is four.

Expiration runs as a single process, although the resources represent parallel work by the server within the single expiration process. Archive data for a node runs only on a single resource, but backup data can be spread across resources on a file space level. For example, if you specify `NODE=X,Y,Z` each with three file spaces and `RESOURCE=5`, then expiration processing for the three X, Y, and Z client nodes runs in parallel. At least one resource processes each node, and at least one node uses multiple resources for processing backup data across the multiple file spaces.

DUration

Specifies the maximum number of minutes for the expiration process to run. The process stops when the specified number of minutes pass or when all eligible expired objects are deleted, whichever comes first. Specify a value in the range 1 - 2880. This parameter is optional. If this parameter is not specified, the duration of the expiration process is not limited by time.

Example: Run inventory expiration processing for a specific time period

Run the expiration process for two hours.

```
expire inventory duration=120
```

Example: Run inventory expiration processing for backup data for two client nodes

Run inventory expiration processing for the backup data for two client nodes, CHARLIE and ROBBIE. Allow the server to run expiration processing until completed.

```
expire inventory nodes=charlie,robbie resource=2 type=backup
```

Example: Run inventory expiration processing for all client nodes except two nodes

Run inventory expiration processing for all client nodes except two nodes, CHARLIE and ROBBIE. Allow the server to run expiration processing until completed.

```
expire inventory excludenodes=charlie,robbie
```

Example: Run inventory expiration processing for all client nodes in a domain except one node

Run inventory expiration processing for all client nodes in a domain except one node, ROBBIE. Allow the server to run expiration processing until completed.

```
expire inventory domain=standard excludenodes=robbie
```

Related commands

Table 1. Commands related to EXPIRE INVENTORY

Command	Description
AUDIT LICENSES	Verifies compliance with defined licenses.
CANCEL EXPIRATION	Cancels inventory expiration processing.
CANCEL PROCESS	Cancels a background server process.
QUERY PROCESS	Displays information about background processes.

EXPORT commands

Use the EXPORT commands to copy information from an IBM Spectrum Protect™ server to sequential removable media.

Important: For commands that export administrators or nodes, you must consider the method of authentication. The IBM Spectrum Protect server cannot export or import passwords for nodes or administrators that are authenticating with LDAP directory servers. If the current authentication method uses an LDAP directory server and the password is not already synchronized by that server, you must update the password. After issuing the EXPORT command, set the password by issuing the UPDATE ADMIN or UPDATE NODE command.

- EXPORT ADMIN (Export administrator information)
- EXPORT NODE (Export client node information)
- EXPORT POLICY (Export policy information)
- EXPORT SERVER (Export server information)

EXPORT ADMIN (Export administrator information)

Use this command to export administrator and authority definitions from a server. You can export the information to sequential media for later importing to another server, or you can export the information directly to another server for immediate import.

Important: For commands that export administrators or nodes, you must consider the method of authentication. The IBM Spectrum Protect™ server cannot export or import passwords for nodes or administrators that are authenticating with LDAP directory servers. If the current authentication method uses an LDAP directory server and the password is not already synchronized by that server, you must update the password. After issuing the EXPORT command, set the password by issuing the UPDATE ADMIN or UPDATE NODE command.

IBM Spectrum Protect exports administrator information such as:

- Administrator name, password, and contact information
- Administrative privilege classes that are granted to the administrator
- Whether the administrator ID is locked from server access

You can use the QUERY ACTLOG command to view the status of the export operation. You can also view this information from the server console.

This command generates a background process that can be canceled with the CANCEL PROCESS command. If you export information to sequential media and the background process is canceled, the sequential media that is holding the exported data is incomplete, it must not be used for importing data. If a server-to-server export background process is canceled, a partial import might result. Evaluate any imported data on the target server to determine whether you want to keep or delete the imported data. Review the import messages for details. To display information about background processes, use the QUERY PROCESS command.

The following restrictions apply to the export function:

- Export operations from a later version and release to an earlier version and release is not supported.
- Export operations between servers that are at the same version and release but with different fix packs might fail. For example, you cannot export from a V7.1.3 server to a V7.1.1 or earlier server.
- Exported data from a server with retention protection enabled is not protected by retention when it is imported to another server.
- Export processing excludes nodes of type network-attached storage (NAS).
- Exporting data to a Centera device class or importing data from a Centera device class is not supported. However, files that are stored in Centera storage pools can be exported and files that must be imported can be stored on a Centera storage device.

Limitation: The IBM Spectrum Protect server does not convert code pages during export, import, and node replication operations. If servers are running in different locales, some information in databases or system output might become unreadable. Invalid characters might be displayed, for example, in the contact information for the administrator and client nodes, and in descriptions of policy domains. Any field that is stored in the server character set and that includes extended ASCII characters can be affected. To resolve the issue after the import or node replication operation, update the fields with the appropriate UPDATE commands. This server limitation does not affect client data. Any client data that was exported, imported, or replicated can be restored, retrieved, and recalled.

The EXPORT ADMIN command takes two forms: Export directly to another server on the network, or export to sequential media. The syntax and parameters for each form are defined separately.

Table 1. Commands related to EXPORT ADMIN

Command	Description
CANCEL PROCESS	Cancels a background server process.

Command	Description
EXPORT NODE	Copies client node information to external media or directly to another server.
EXPORT POLICY	Copies policy information to external media or directly to another server.
EXPORT SERVER	Copies all or part of the server to external media or directly to another server.
IMPORT ADMIN	Restores administrative information from external media.
QUERY ACTLOG	Displays messages from the server activity log.
QUERY PROCESS	Displays information about background processes.

- EXPORT ADMIN (Export administrator definitions to sequential media)
  You can export administrator and authority definitions from a server to sequential media for later importing to another server.
- EXPORT ADMIN (Export administrator information directly to another server)
  Use this command to export administrator and authority definitions directly to another server on the network. This results in an immediate import on the target server.

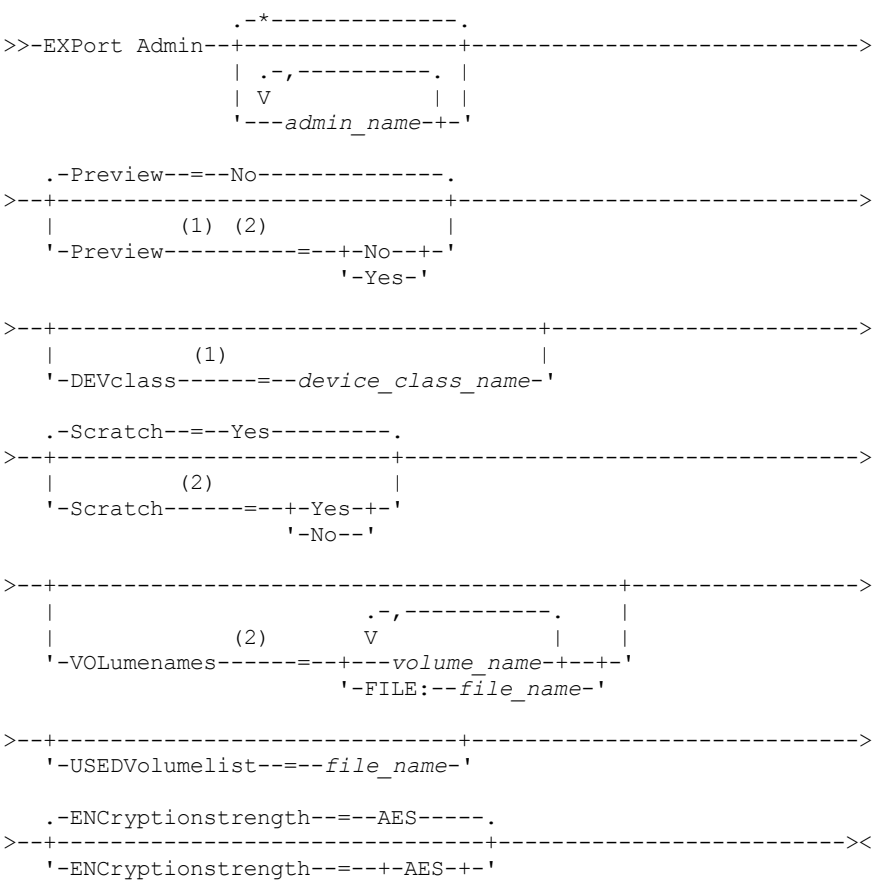
EXPORT ADMIN (Export administrator definitions to sequential media)

You can export administrator and authority definitions from a server to sequential media for later importing to another server.

Privilege class

To issue this command, you must have system privilege.

Syntax



```
                    '-DES-'
```

Notes:

1. If PREVIEW=NO, a device class must be specified.
2. If PREVIEW=NO and SCRATCH=NO, one or more volumes must be specified.

Parameters

admin_name
: Specifies the administrators for which information is to be exported. This parameter is optional. The default is all administrators.

  Separate the items in the list by commas, with no intervening spaces. You can use wildcard characters to specify names.

Preview
: Specifies whether to preview the results of the export operation, without exporting information. You can use this parameter to preview how many bytes of data are transferred, and determine how many volumes are required. The following parameter values are supported:

  No
  : Specifies that the administrator information is to be exported. If you specify this value, you must specify a device class.

  Yes
  : Specifies that the operation is previewed but not completed. Information is reported to the server console and the activity log. If you specify this value, you do not need to specify a device class.

  This parameter is optional. The default value is NO.

DEVclass
: Specifies the device class to which export data is to be written. This parameter is required if you specify PREVIEW=NO.

  You cannot specify the DISK, NAS, or CENTERA device classes.

  If all drives for the device class are busy when the export runs, IBM Spectrum Protect™ cancels lower priority operations to make a drive available.

  Tip: You can export data to a storage pool on another server by specifying a device class whose device type is SERVER.

Scratch
: Specifies whether scratch volumes can be used. The default value is YES. You can specify one of the following values:

  Yes
  : Specifies that scratch volumes can be used for export. If you also specify a list of volumes, scratch volumes are used only if there is not enough space on the volumes specified.

  No
  : Specifies that scratch volumes cannot be used for export. To determine how many volumes you might need, you can run the command specifying PREVIEW=YES.

VOLumenames
: Specifies the volumes to be used to contain exported data. This parameter is optional, unless you specify SCRATCH=NO and PREVIEW=NO. If you do not specify a volume name, scratch volumes are used.

  You can specify one of the following values:

  volume_name
  : Specifies the volume name. To specify multiple volumes, separate the names with commas and no intervening spaces.

  FILE:file_name
  : Specifies the name of a file that contains a list of volumes. In the file, each volume name must be on a separate line. Blank and comment lines that begin with an asterisk are ignored.

  Use these naming conventions when specifying volumes associated with the following device types:

For this device	Specify
Tape	1-6 alphanumeric characters.

For this device	Specify
FILE	Any fully qualified file name string. For example: AIX Linux /imdata/mt1. Windows d:\program files\tivoli\tsm\data1.dsm.
AIX Linux Windows REMOVABLEFILE	AIX Linux Windows 1-6 alphanumeric characters.
SERVER	1-250 alphanumeric characters.

USEDVolumelist
Specifies the file where a list of volumes used in the export operation are stored. This parameter is optional.

This file can be used in the import operation. This file contains comment lines with the date and time the export was done, and the command issued to create the export.

Attention: If you specify an existing file, the file is overwritten.

ENCryptionstrength
Indicates which algorithm to use to encrypt passwords when exporting administrative and node records. This parameter is optional. The default value is AES. If you are exporting to a server that does not support AES, specify DES. You can specify one of the following values:

AES
Specifies the Advanced Encryption Standard.

DES
Specifies the Data Encryption Standard.

Example: Export administrator definitions to tape volumes

From the server, export the information for all defined administrators to tape volumes TAPE01, TAPE02, and TAPE03. Specify that these tape volumes be read by a device that is assigned to the MENU1 device class. The number and types of objects that are exported are reported to the system console and in the activity log. Issue the command:

```
export admin devclass=menu1
volumenames=tape01,tape02,tape03
```

Example: Export administrator definitions to tape volumes listed in a file

From the server, export the information for all defined administrators to tape volumes that are listed in the following file:

- AIX Linux TAPEVOL
- Windows TAPEVOL.DATA

This file contains the following lines:

```
TAPE01
TAPE02
TAPE03
```

Specify that these tape volumes be used by a device that is assigned to the MENU1 device class. Issue the command:
AIX Linux

```
export admin devclass=menu1 volumenames=file:tapevol
```

Windows

```
export admin devclass=menu1 volumenames=file:tapevol.data
```

The number and types of objects that are exported are reported to the system console and in the activity log.

EXPORT ADMIN (Export administrator information directly to another server)

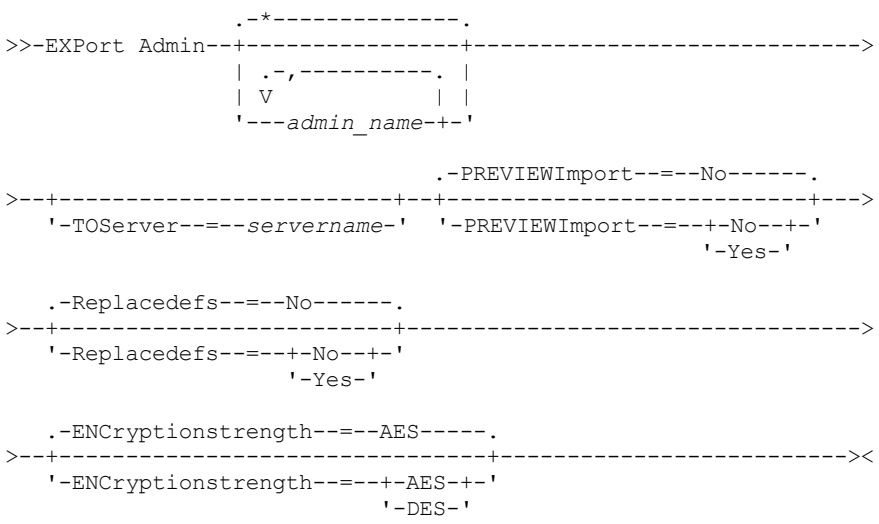
Use this command to export administrator and authority definitions directly to another server on the network. This results in an immediate import on the target server.

You can issue a QUERY PROCESS command from the target server to monitor the progress of the import operation. See EXPORT ADMIN (Export administrator information) for a list of restrictions that apply to the export function.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

admin_name
: Specifies the administrators for which information is to be exported. This parameter is optional. The default is all administrators.

  Separate the items in the list by commas, with no intervening spaces. You can use wildcard characters to specify names.

TOServer
: Specifies the name of a server to which the export data is sent directly over the network for immediate import.
  Important: The target server must be defined on the originating server with the DEFINE SERVER command. The administrator that issues the export command must be defined with the same administrator name and password and have system authority on the target server.

  When you specify TOSERVER, you cannot specify the DEVCLASS, VOLUMENAMES, and SCRATCH, USEDVOLUMELIST, and PREVIEW parameters.

PREVIEWImport
: Specifies whether to view how much data is transferred, without actually moving any data. This information can be used to determine how much storage pool space is required on the target server. The default is NO.
  Valid values are:

  Yes
  : Specifies that you want to preview the results of the import operation on the target server, without importing the data. Information is reported to the server console and the activity log.

  No
  : Specifies that you want the data to be imported on the target server without previewing the results.

Replacedefs
: Specifies whether to replace definitions (not file data) on the server. The default is NO.

  Valid values are:

  Yes

Specifies that definitions are replaced on the server if definitions having the same name as those being imported exist on the target server.

No
Specifies that imported definitions are skipped if their names conflict with definitions that are already defined on the target server.

ENCryptionstrength
Indicates which algorithm to use to encrypt passwords when exporting administrative and node records. This parameter is optional. The default value is AES. If you are exporting to a server that does not support AES, specify DES. You can specify one of the following values:

AES
Specifies the Advanced Encryption Standard.

DES
Specifies the Data Encryption Standard.

Example: Export administrator definitions to a target server

Export all the administrator definitions to the target server defined as OTHERSERVER. Preview the import operations on the target server. Issue the command:

```
export admin * toserver=otherserver previewimport=yes
```

From the target server, OTHERSERVER, you can view the import operations by issuing the command:

```
query process
```

EXPORT NODE (Export client node information)

Use this command to export client node definitions or file data to sequential media or directly to another server for immediate import.

Important: For commands that export administrators or nodes, you must consider the method of authentication. The IBM Spectrum Protect™ server cannot export or import passwords for nodes or administrators that are authenticating with LDAP directory servers. If the current authentication method uses an LDAP directory server and the password is not already synchronized by that server, you must update the password. After issuing the EXPORT command, set the password by issuing the UPDATE ADMIN or UPDATE NODE command.
The following information is included in each client node definition:

- User ID, password, and contact information.
- Name of the client's assigned policy domain.
- File compression status.
- Whether the user has the authority to delete backed-up or archived files from server storage.
- Whether the client node ID is locked from server access.

Optionally, you can also export the following items:

- File space definitions.
- Backed-up, archived, and files that were migrated by an IBM Spectrum Protect for Space Management client.
- Access authorization information that pertains to the file spaces exported.
- Archive data that is in deletion hold status (the hold status is preserved). When the archive data is imported, it remains in deletion hold.

If you use an LDAP directory server to authenticate passwords, any servers that you export to must be configured for LDAP passwords. Node data that is exported from a node that authenticates with an LDAP directory server is inaccessible if the target server is not properly configured. If your target server is not configured, exported data from an LDAP node can still be exported. But the target server must be configured to use LDAP, to access the data.

The following restrictions apply to the export function:

- Export operations from a later version and release to an earlier version and release is not supported.
- Export operations between servers that are at the same version and release but with different fix packs might fail. For example, you cannot export from a V7.1.3 server to a V7.1.1 or earlier server.

- Exported data from a server with retention protection enabled is not protected by retention when it is imported to another server.
- Export processing excludes nodes of type network-attached storage (NAS).
- Exporting data to a Centera device class or importing data from a Centera device class is not supported. However, files that are stored in Centera storage pools can be exported and files that must be imported can be stored on a Centera storage device.

- The EXPORT NODE and EXPORT SERVER commands do not export data from a shred pool unless you explicitly allow it by setting the ALLOWSHREDDABLE parameter to the YES value. If this value is specified, and the exported data includes data from shred pools, that data cannot be shredded. A warning is not issued if the export operation includes data from shred pools.

- Incrementally exporting or importing the following types of client data to another IBM Spectrum Protect server is not supported:
    - VMware backups where full plus incremental backups need to be periodically, incrementally transferred to another server
    - Backups groups where full plus differential backups must be periodically, incrementally transferred to another server
    - Windows System State data that is periodically, incrementally transferred to another server

  Full export or import of this data to a new file system on the target is supported by exporting the entire file space that contains the data. The export must not use the FILEDATA=ALLACTIVE, FROMDATE, TODATE, or MERGEFILESPACES parameters.

  Using node replication to incrementally transfer this type of client data between two servers is optimal.

Limitation: The IBM Spectrum Protect server does not convert code pages during export, import, and node replication operations. If servers are running in different locales, some information in databases or system output might become unreadable. Invalid characters might be displayed, for example, in the contact information for the administrator and client nodes, and in descriptions of policy domains. Any field that is stored in the server character set and that includes extended ASCII characters can be affected. To resolve the issue after the import or node replication operation, update the fields with the appropriate UPDATE commands. This server limitation does not affect client data. Any client data that was exported, imported, or replicated can be restored, retrieved, and recalled.

The EXPORT NODE command generates a background process that can be canceled with the CANCEL PROCESS command. If you are exporting node information to sequential media and the background process is canceled, the sequential media that is holding the exported data is incomplete, it must not be used to import data. If a server-to-server export background process is canceled, a partial import might result. Evaluate any imported data on the target server to determine whether you want to keep or delete the imported data. Review the import messages for details. To display information about background processes, issue the QUERY PROCESS command.

To display information about any running and suspended server-to-server export operations, issue the QUERY EXPORT command. The QUERY EXPORT command displays information only for exports that are, or can be, suspended. Export operations that can be suspended, and then restarted, are those server-to-server exports whose FILEDATA has a value other than NONE. You can issue the QUERY ACTLOG command to view the status of the export operation.

Because of unpredictable results, do not run expiration, migration, backup, or archive when you are issuing the EXPORT NODE command.

For a server that has clients with support for Unicode, you can get the server to convert the file space name that you enter, or use one of the following parameters:

- FSID
- UNIFILESPACE

The EXPORT NODE command takes two forms: export directly to another server on the network, or export to sequential media. The syntax and parameters for each form are defined separately.

Table 1. Commands related to EXPORT NODE

Command	**Description**
CANCEL EXPORT	Deletes a suspended export operation.
CANCEL PROCESS	Cancels a background server process.
COPY ACTIVEDATA	Copies active backup data.

Command	Description
EXPORT ADMIN	Copies administrative information to external media or directly to another server.
EXPORT POLICY	Copies policy information to external media or directly to another server.
EXPORT SERVER	Copies all or part of the server to external media or directly to another server.
IMPORT NODE	Restores client node information from external media.
QUERY ACTLOG	Displays messages from the server activity log.
QUERY EXPORT	Displays the export operations that are currently running or suspended.
QUERY PROCESS	Displays information about background processes.
RESTART EXPORT	Restarts a suspended export operation.
SUSPEND EXPORT	Suspends a running export operation.

- EXPORT NODE (Export node definitions to sequential media)
  You can export node definitions or file data from a server to sequential media for later importing to another server.
- EXPORT NODE (Export node definitions or file data directly to another server)
  Use this command to export client node definitions or file data directly to another server for immediate import.

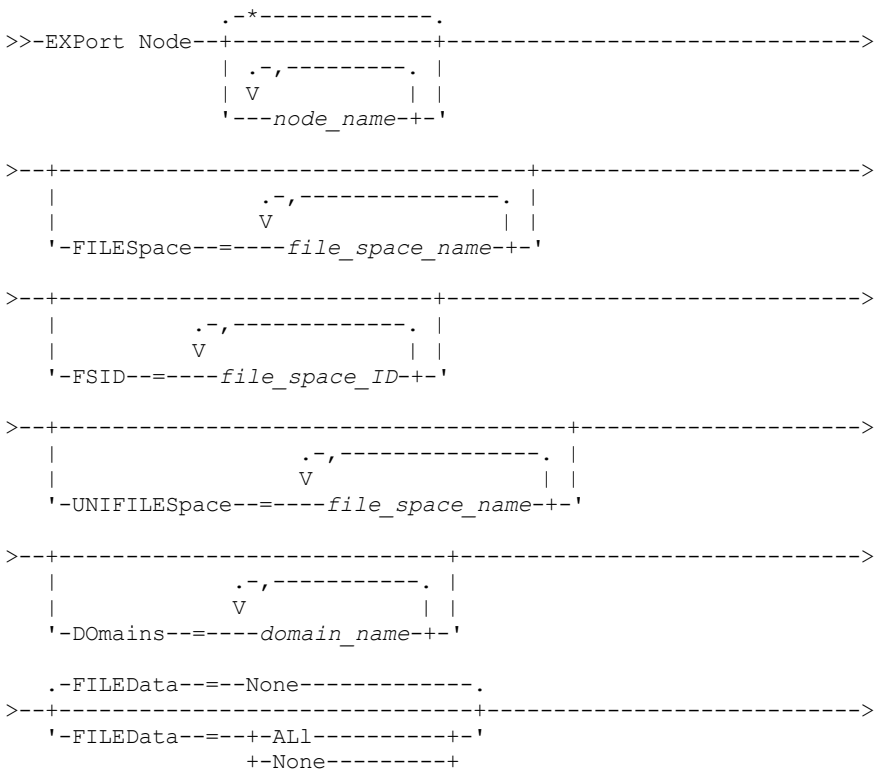
EXPORT NODE (Export node definitions to sequential media)

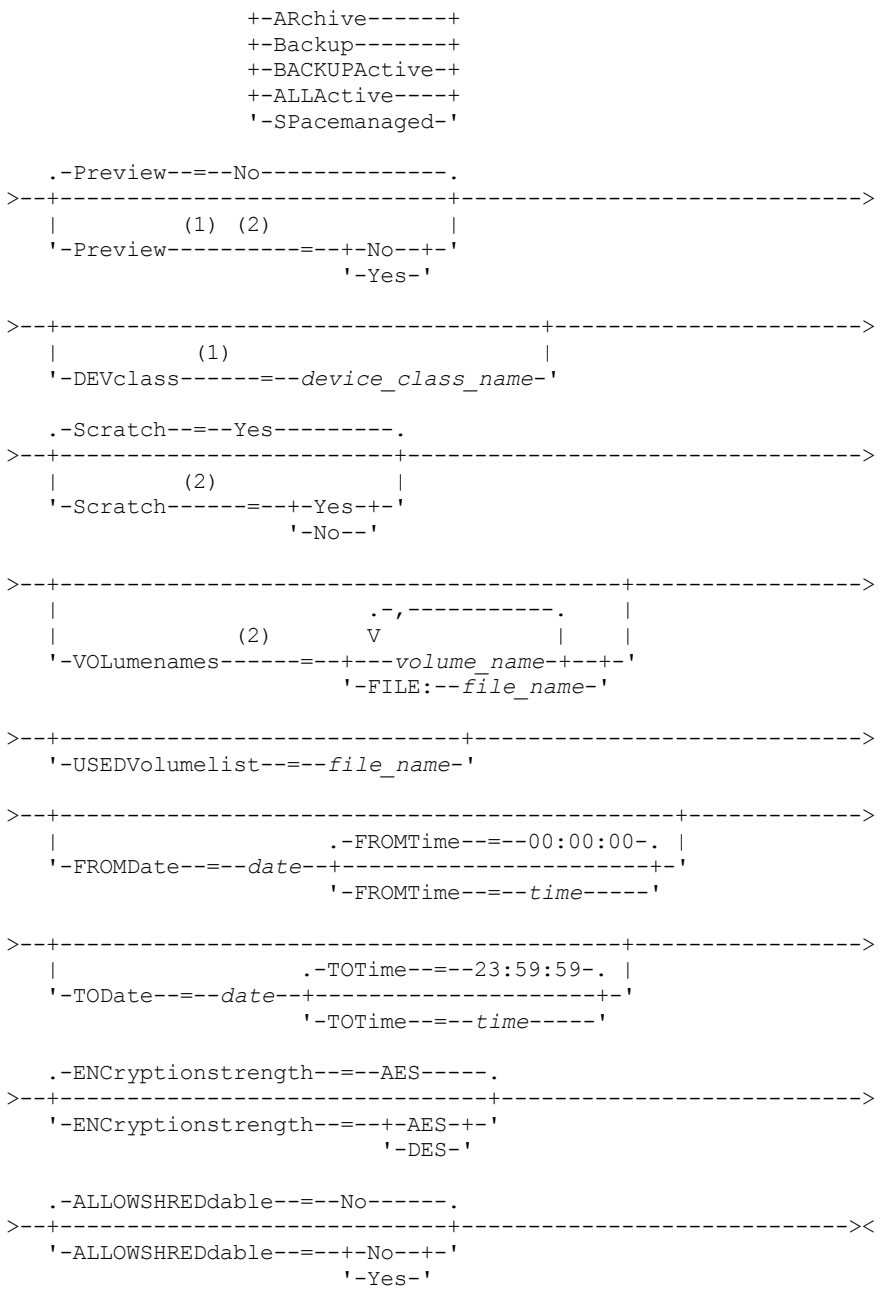
You can export node definitions or file data from a server to sequential media for later importing to another server.

Privilege class

To issue this command, you must have system privilege.

Syntax





Notes:

1. If PREVIEW=NO, a device class must be specified.
2. If PREVIEW=NO and SCRATCH=NO, one or more volumes must be specified.

Parameters

node_name
: Specifies the client node names for which information is to be exported. This parameter is optional. Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify names. For each node entered, all file spaces in the file space, FSID, and Unicode enabled lists are searched.
Restriction: If you use wildcard characters to specify a pattern for node names, the server does not report the node names or patterns that do not match any entries in the database. Check the summary statistics in the activity log to verify that the server exported all intended nodes.

FILESpace
: Specifies the file spaces for which data is to be exported. This parameter is optional. Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify a name.
Restriction: If a file space is specified, Unicode enabled file spaces are not exported.

FSID

Specifies the file spaces by using their file space IDs (FSIDs). The server uses the FSIDs to find the file spaces to export. To find the FSID for a file space, use the QUERY FILESPACE command. Separate multiple file space IDs with commas and no intervening spaces. This parameter is optional.

UNIFILESpace
Specifies the file spaces that are known to the server as Unicode enabled. The server converts the names that you enter from the server code page to the UTF-8 code page to find the file spaces to export. The success of the conversion depends on the actual characters in the name and the server's code page. Separate multiple names with commas and no intervening spaces. A wildcard character can be used to specify a name. This parameter is optional.

DOmains
Specifies the policy domains from which nodes are to be exported. This parameter is optional. Separate multiple names with commas and no intervening spaces. If you specify domains, a node is exported only if it belongs to one of the specified domains. You can use wildcard characters to specify a name.

FILEData
Specifies the type of files that are to be exported for all nodes that are being exported to the server. This parameter is optional. The default value is NONE.
Note: If you are exporting a node that has group data, data that is not a part of the target objects might be exported. An example of group data is virtual machine data or system state backup data. For example, if FILEDATA=BACKUPACTIVE when the FROMDATE or TODATE parameters are specified, it is possible to include inactive backup data. The incremental backup processing for the data can cause extra files that do not meet the filtering criteria to be exported.

If you are exporting to sequential media: the device class that is used by the file data is determined by the device class for the storage pool. If it is the same device class that is specified in this command, two drives are needed to export node information. The mount limit for the device class must be at least 2.

Important: If client nodes registered as TYPE=SERVER are being exported, specify ALL, ARCHIVE, or ALLACTIVE.

The following descriptions mention *active* and *inactive* backup file versions. An active backup file version is the most recent backup version for a file that still exists on the client workstation. All other backup file versions are called inactive copies. This parameter supports the following values:

ALl
The server exports all backup versions of files, all archived files, and all files that were migrated by an IBM Spectrum Protect™ for Space Management client.

None
The server does not export files, only node definitions.

ARchive
The server exports only archived files.

Backup
The server exports only backup versions, whether active or inactive.

BACKUPActive
The server exports only active backup versions. These active backup versions are the active versions in the IBM Spectrum Protect database at the time that the EXPORT command is issued.

ALLActive
The server exports all active backup versions of files, all archived files, and all files that were migrated by an IBM Spectrum Protect for Space Management client. The active backup versions are the active versions in the IBM Spectrum Protect database at the time that the EXPORT command is issued.

SPacemanaged
The server exports only files that were migrated by an IBM Spectrum Protect for Space Management client.

Preview
Specifies whether to preview the results of the export operation, without exporting information. You can use this parameter to preview how many bytes of data would be transferred so that you can determine how many volumes are required. This parameter supports the following values:

No
Specifies that the node information is to be exported. If you specify this value, you must also specify a device class.

Yes
Specifies that the operation is previewed but not completed. Information is reported to the server console and the activity log. If you specify this value, you do not need to specify a device class.

This parameter is optional. The default value is NO.

DEVclass
Specifies the device class to which export data is to be written. This parameter is required if you specify PREVIEW=NO.

You cannot specify the DISK, NAS, or CENTERA device classes.

If all drives for the device class are busy when the export runs, IBM Spectrum Protect cancels lower priority operations to make a drive available.

Tip: You can export data to a storage pool on another server by specifying a device class whose device type is SERVER.

Scratch

Specifies whether scratch volumes can be used. The default value is YES. You can specify one of the following values:

Yes
: Specifies that scratch volumes can be used for export. If you also specify a list of volumes, scratch volumes are used only if there is not enough space on the volumes specified.

No
: Specifies that scratch volumes cannot be used for export. To determine how many volumes you might need, you can run the command specifying PREVIEW=YES.

VOLumenames

Specifies the volumes to be used to contain exported data. This parameter is optional, unless you specify SCRATCH=NO and PREVIEW=NO. If you do not specify a volume name, scratch volumes are used.

You can specify one of the following values:

volume_name
: Specifies the volume name. To specify multiple volumes, separate the names with commas and no intervening spaces.

FILE:file_name
: Specifies the name of a file that contains a list of volumes. In the file, each volume name must be on a separate line. Blank and comment lines that begin with an asterisk are ignored.

Use these naming conventions when specifying volumes associated with the following device types:

For this device	Specify
Tape	1-6 alphanumeric characters.
FILE	Any fully qualified file name string. For example: AIX Linux /imdata/mt1. Windows d:\program files\tivoli\tsm\data1.dsm.
AIX Linux Windows REMOVABLEFILE	AIX Linux Windows 1-6 alphanumeric characters.
SERVER	1-250 alphanumeric characters.

USEDVolumelist

Specifies the file where a list of volumes used in the export operation are stored. This parameter is optional.

This file can be used in the import operation. This file contains comment lines with the date and time the export was done, and the command issued to create the export.

Attention: If you specify an existing file, the file is overwritten.

FROMDate

Specifies the earliest date for which files to be exported were stored on the server. Files that were stored on the server earlier than the specified date are not exported. This parameter only applies to client file data. This parameter does not affect other information that might be exported, for example, policy. IBM Spectrum Protect ignores the FROMDATE parameter when the FILEDATA parameter is set to NONE.

Directory processing: The FROMDATE parameter does not apply to directories. All directories in a file space are processed even if the directories were not backed up in the specified date range.

Important: If you have group data on the node that you are exporting, data that was backed up before the designated FROMDATE and FROMTIME can also be exported. Group data on the node is, for example, virtual machine data or system state backup data. This export is a result of incremental backup processing for the data. The incremental backup processing can cause extra files that do not meet the filtering criteria to be exported, so that there is a consistent image for the backup data.

Use one of the following values to specify the date:

Value	Description	Example

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY -3 **or** -3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

If this parameter is not specified, IBM Spectrum Protect exports all objects stored before the TODATE parameter and as qualified by the FILEDATA parameter. If no TODATE parameter is specified, then all data as qualified by the FILEDATA parameter is exported.

When a server-to-server export operation uses a relative FROMDATE, for example, TODAY-1, and the operation is restarted at a later date, the restarted process still uses the date that was used during the original operation. For example, if a server-to-server export operation is started on 07/04/2009 and the FROMDATE is specified as TODAY-1, the date that is used for selecting files is 07/03/2009. If this same export operation is suspended and restarted ten days later (07/14/2009), the date that is used for selecting files is still 07/03/2009. This behavior ensures that the entire export operation uses the same cutoff date for selecting files to export.

TODate

Specifies the latest date for files to be exported from the server. Files stored on the server on a date later than the TODATE value are not exported. TODATE only applies to client file data and does not affect other information that is being exported, such as policy.

- IBM Spectrum Protect ignores the TODATE parameter when the FILEDATA parameter is set to NONE.
- If a TODATE parameter is specified without a TOTIME parameter, the server exports all objects that are inserted on or before the day specified by the TODATE parameter.
- If you specified the FROMDATE parameter, the value of TODATE must be later than or equal to the FROMDATE value. If the TODATE and FROMDATE are equal, then the TOTIME parameter must be later that the FROMTIME parameter.
- The TODATE parameter does not apply to directories. All directories in a file space are processed even if the directories were not backed up in the specified date range.

Important: If you have group data on the node that you are exporting, data that was backed up after the TODATE or TOTIME parameters can be exported. An example of group data is virtual machine data or system state backup data. The incremental backup processing can cause extra files that do not meet the filtering criteria to be exported, so that there is a consistent image for the backup data.

Use one of the following values to specify the date:

Value	Description	Example
MM/DD/YYYY	A specific date	10/15/2006
TODAY	The current date	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY –3 **or** –3.

Value	Description	Example
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

When a server-to-server export operation uses a relative TODATE, for example, TODAY-1, and the operation is restarted at a later date, the restarted process still uses the date that was used during the original operation. For example, if a server-to-server export operation is started on 07/04/2009 and the TODATE is specified as TODAY-1, the date that is used for selecting files is 07/03/2009. If this same export operation is suspended and restarted 10 days later (07/14/2009), the date that is used for selecting files is still 07/03/2009. This behavior ensures that the entire export operation uses the same cutoff date for selecting files to export.

FROMTime

Specifies the earliest time for which objects to be exported were stored on the server. When you specify FROMTIME, you must also use the FROMDATE parameter. This parameter only applies to client file data. This parameter does not affect other information that might be exported, for example, policy. Objects that were stored on the server before the specified time and date are not exported. IBM Spectrum Protect ignores the FROMTIME parameter when the FILEDATA parameter is set to NONE.
Important: If you have group data on the node that you are exporting, data that was backed up before the designated FROMDATE and FROMTIME can also be exported. An example of group data on the node is virtual machine data or system state backup data, This export is a result of incremental backup processing for the data. The incremental backup processing can cause extra files that do not meet the filtering criteria to be exported so that there is a consistent image for the backup data.

The default value for this parameter when used with the FROMDATE parameter is midnight (00:00:00).

Use one of the following values to specify the time:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes specified. The FROMTIME+ can only be used with a FROMDATE before today.	NOW+02:00 **or** +02:00. If you issue this command at 5:00 with FROMTIME=NOW+02:00 or FROMTIME=+02:00, the export operation only contains files that were put on the server after 7:00 on the FROMDATE that you specify.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes specified	NOW -02:00 **or** -02:00. If you issue this command at 5:00 with FROMTIME=NOW-02:00 or FROMTIME=-2:00, the export includes files that were put on the server after 3:00.

TOTime

Specifies the latest time that objects to be exported were stored on the server. You must specify the TODATE parameter in order to use the TOTIME parameter. TOTIME only applies to client file data and does not affect other information that is being exported, such as policy. IBM Spectrum Protect ignores the TOTIME parameter if the FILEDATA parameter is set to NONE.

The default value for this parameter, when used with the TODATE parameter, is midnight minus one second (23:59:59).

Important: The value of the TOTIME and TODATE parameters must be later than the FROMDATE and the FROMTIME value.
Use one of the following values to specify the time:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW+HH:MM **or**+HH:MM	The current time plus hours and minutes specified.	NOW+02:00 **or** +02:00. If you issue this command at 05:00 with FROMTIME=01:00 and TOTIME=NOW+02:00, the export includes files that were stored from 01:00 until 07:00.
NOW-HH:MM **or**-HH:MM	The current time minus hours and minutes specified.	NOW-02:00 **or** -02:00. If you issue this command at 05:00 with FROMTIME=01:00 and TOTIME=NOW-02:00, the export includes files that were stored from 01:00 until 03:00.

ENCryptionstrength
Indicates which algorithm to use to encrypt passwords when exporting administrative and node records. This parameter is optional. The default value is AES. If you are exporting to a server that does not support AES, specify DES. You can specify one of the following values:

AES
Specifies the Advanced Encryption Standard.
DES
Specifies the Data Encryption Standard.

ALLOWSHREDdable
Specifies whether data from a storage pool that enforces shredding is exported. This parameter supports the following values:

No
Specifies that data is not exported from a storage pool that enforces shredding.
Yes
Specifies that data can be exported from a storage pool that enforces shredding. The data on the export media is not shredded.

This parameter is optional. The default value is NO.

Example: Export client node information to specific tape volumes

From the server, export client node information to tape volumes TAPE01, TAPE02, and TAPE03. Specify that these tape volumes be used by a device that is assigned to the MENU1 device class.

```
export node devclass=menu1 volumenames=tape01,tape02,tape03
```

Example: Export client node information by using the FSID

From the server, use the FSID to export active backup versions of file data for client node JOE to tape volume TAPE01. To determine the FSID, first issue a QUERY FILESPACE command.

1. To determine the FSID, issue a QUERY FILESPACE command.

```
query filespace joe

Node Name Filespace  FSID Platform Filespace    Is     Capacity   Pct
          Name                     Type      Filespace    (MB)   Util
                                               Unicode?
--------- ---------- ---- -------  ---------  --------- -------- ----
JOE       \\joe\c$      1  WinNT    NTFS         Yes     2,502.3  75.2
JOE       \\joe\d$      2  WinNT    NTFS         Yes     6,173.4  59.6
```

2. Export the active backup versions of file data and specify that the tape volume is used by a device that is assigned to the MENU1 device class.

```
export node joe fsid=1,2 filedata=backupactive devclass=menu1
volumenames=tape01
```

Example: Export client node information to tape volumes listed in a file

From the server, export client node information to tape volumes that are listed in the following file:

- AIX | Linux TAPEVOL
- Windows TAPEVOL.DATA

The file contains the following lines:

```
TAPE01
TAPE02
TAPE03
```

Specify that the tape volumes be used by a device that is assigned to the MENU1 device class. Issue the following command:
AIX | Linux

```
export node devclass=menu1 volumenames=file:tapevol
```

Windows

```
export node devclass=menu1 volumenames=file:tapevol.data
```

EXPORT NODE (Export node definitions or file data directly to another server)

Use this command to export client node definitions or file data directly to another server for immediate import.

Important: You cannot export nodes of type NAS. Export processing excludes these nodes.

You can suspend and restart a server-to-server export operation that has a FILEDATA value other than NONE. The server saves the state and status of the export operation so that it can be restarted from the point at which the operation failed or was suspended. The export operation can be restarted later by issuing the RESTART EXPORT command.

Important: An export operation is suspended when any of the following conditions are detected:

- A SUSPEND EXPORT command is issued for the running export operation
- Segment preemption - the file that is being read for export is deleted by some other process
- Communication errors on a server-to-server export
- No available mount points
- Necessary volumes are unavailable
- I/O errors encountered

Issue the QUERY EXPORT command to display information on any running and suspended export operations.

The export operation cannot be restarted if the export operation fails before transmitting the eligible node and file space definitions to the target server. You must reenter the command to begin a new export operation.

You can issue a QUERY PROCESS command from the target server to monitor the progress of the import operation. Issue the QUERY EXPORT command to list all restartable server-to-server export operations. See EXPORT ADMIN (Export administrator information) for a list of restrictions that apply to the export function.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                .-*---------.
>>-EXPort Node--+-----------+---------------------------------->
                '-node_name-'

>--+-------------------------------+--------------------------->
```

Parameters

node_name
: Specifies the client node names for which information is to be exported. This parameter is optional. Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify names. For each node entered, all file spaces in the file space, FSID, and Unicode enabled lists are searched.

Restriction: If you specify a list of node names or node patterns, the server does not report the node names or node patterns that do not match any of the entries in the database. Check the summary statistics in the activity log to verify that the server exported all intended nodes.

FILESpace

Specifies the file spaces for which data is to be exported. This parameter is optional. Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify a name.
Restriction: If a file space is specified, no Unicode enabled file spaces are exported.

FSID

Specifies the file spaces by using their file space IDs (FSIDs). The server uses the FSIDs to find the file spaces to export. To find the FSID for a file space, use the QUERY FILESPACE command. Separate multiple file space IDs with commas and no intervening spaces. This parameter is optional.

UNIFILESpace

Specifies the file spaces that are known to the server to be Unicode enabled. The server converts the names that you enter from the server code page to the UTF-8 code page to find the file spaces to export. The success of the conversion depends on the actual characters in the name and the server's code page. Separate multiple names with commas and no intervening spaces. A wildcard character can be used to specify a name. This parameter is optional.

DOmains

Specifies the policy domains from which nodes are exported. This parameter is optional. Separate multiple names with commas and no intervening spaces. If you specify domains, IBM Spectrum Protect™ exports a node only if it belongs to one of the specified domains. You can use wildcard characters to specify a name.

FILEData

Specifies the type of files to export for all nodes. This parameter is optional. The default value is NONE.
Note: If you are exporting a node that has group data, data that is not a part of the target objects might be exported. An example of group data is virtual machine data or system state backup data. For example, if FILEDATA=BACKUPACTIVE when the FROMDATE or TODATE parameters are specified, it is possible to include inactive backup data. The incremental backup processing for the data can cause extra files that do not meet the filtering criteria to be exported.

If you are exporting to sequential media, the device class that is used by the file data is determined by the device class for the storage pool. If it is the same device class that is specified in this command, IBM Spectrum Protect requires two drives to export node information. The mount limit for the device class must be at least 2.

Important: If you export client nodes that are registered as TYPE=SERVER, specify ALL, ARCHIVE, or ALLACTIVE.
The following descriptions mention *active* and *inactive* backup file versions. An active backup file version is the most recent backup version for a file that still exists on the client workstation. All other backup file versions are called inactive copies. The values are as follows:

ALl

The server exports all backup versions of files, all archived files, and all files that are migrated by an IBM Spectrum Protect for Space Management client.

None

The server does not export files, only node definitions.

ARchive

The server exports only archived files.

Backup

The server exports only backup versions, whether they are active or inactive.

BACKUPActive

The server exports only active backup versions. These active backup versions are the active versions in the IBM Spectrum Protect database at the time that the EXPORT command is issued.

ALLActive

The server exports all active backup versions of files, all archived files, and all files that were migrated by an IBM Spectrum Protect for Space Management client. The active backup versions are the active versions in the IBM Spectrum Protect database at the time that the EXPORT command is issued.

SPacemanaged

The server exports only files that were migrated by an IBM Spectrum Protect for Space Management client.

FROMDate

Specifies the earliest date for which files to be exported were stored on the server. Files that were stored on the server earlier than the specified date are not exported. This parameter only applies to client file data. This parameter does not affect other information that might be exported, for example, policy. IBM Spectrum Protect ignores the FROMDATE parameter when the FILEDATA parameter is set to NONE.
Directory processing: The FROMDATE parameter does not apply to directories. All directories in a file space are processed even if the directories were not backed up in the specified date range.

Important: If you have group data on the node that you are exporting, data that was backed up before the designated FROMDATE and FROMTIME can also be exported. Group data on the node is, for example, virtual machine data or system state backup data. This export is a result of incremental backup processing for the data. The incremental backup processing can cause extra files that do not meet the filtering criteria to be exported, so that there is a consistent image for the backup data.

Use one of the following values to specify the date:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY -3 **or** -3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

If this parameter is not specified, IBM Spectrum Protect exports all objects stored before the TODATE parameter and as qualified by the FILEDATA parameter. If no TODATE parameter is specified, then all data as qualified by the FILEDATA parameter is exported.

When a server-to-server export operation uses a relative FROMDATE, for example, TODAY-1, and the operation is restarted at a later date, the restarted process still uses the date that was used during the original operation. For example, if a server-to-server export operation is started on 07/04/2009 and the FROMDATE is specified as TODAY-1, the date that is used for selecting files is 07/03/2009. If this same export operation is suspended and restarted ten days later (07/14/2009), the date that is used for selecting files is still 07/03/2009. This behavior ensures that the entire export operation uses the same cutoff date for selecting files to export.

TODate

Specifies the latest date for files to be exported from the server. Files that are stored on the server on a date later than the TODATE value are not exported. TODATE only applies to client file data and does not affect other information that is being exported, such as policy.

- IBM Spectrum Protect ignores the TODATE parameter when the FILEDATA parameter is set to NONE.
- If a TODATE parameter is specified without a TOTIME parameter, the server exports all objects that are inserted on or before the day specified by the TODATE parameter.
- If you specified the FROMDATE parameter, the value of TODATE must be later than or equal to the FROMDATE value. If the TODATE and FROMDATE are equal, then the TOTIME parameter must be later that the FROMTIME parameter.
- The TODATE parameter does not apply to directories. All directories in a file space are processed even if the directories were not backed up in the specified date range.

Important: If you have group data on the node that you are exporting, data that was backed up after the TODATE or TOTIME parameters can be exported. An example of group data is virtual machine data or system state backup data. The incremental backup processing can cause extra files that do not meet the filtering criteria to be exported, so that there is a consistent image for the backup data.

Use one of the following values to specify the date:

Value	Description	Example
MM/DD/YYYY	A specific date	10/15/2006
TODAY	The current date	TODAY

Value	Description	Example
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY –3 **or** –3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

When a server-to-server export operation uses a relative TODATE, for example, TODAY-1, and the operation is restarted at a later date, the restarted process still uses the date that was used during the original operation. For example, if a server-to-server export operation is started on 07/04/2009 and the TODATE is specified as TODAY-1, the date that is used for selecting files is 07/03/2009. If this same export operation is suspended and restarted 10 days later (07/14/2009), the date that is used for selecting files is still 07/03/2009. This behavior ensures that the entire export operation uses the same cutoff date for selecting files to export.

FROMTime

Specifies the earliest time for which objects to be exported were stored on the server. When you specify FROMTIME, you must also use the FROMDATE parameter. This parameter only applies to client file data. This parameter does not affect other information that might be exported, for example, policy. Objects that were stored on the server before the specified time and date are not exported. IBM Spectrum Protect ignores the FROMTIME parameter when the FILEDATA parameter is set to NONE.

Important: If you have group data on the node that you are exporting, data that was backed up before the designated FROMDATE and FROMTIME can also be exported. An example of group data on the node is virtual machine data or system state backup data, This export is a result of incremental backup processing for the data. The incremental backup processing can cause extra files that do not meet the filtering criteria to be exported so that there is a consistent image for the backup data.

The default value for this parameter when used with the FROMDATE parameter is midnight (00:00:00).

Use one of the following values to specify the time:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes specified. The FROMTIME+ can only be used with a FROMDATE before today.	NOW+02:00 **or** +02:00. If you issue this command at 5:00 with FROMTIME=NOW+02:00 or FROMTIME=+02:00, the export operation only contains files that were put on the server after 7:00 on the FROMDATE that you specify.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes specified	NOW -02:00 **or** -02:00. If you issue this command at 5:00 with FROMTIME=NOW-02:00 or FROMTIME=-2:00, the export includes files that were put on the server after 3:00.

TOTime

Specifies the latest time that objects to be exported were stored on the server. You must specify the TODATE parameter in order to use the TOTIME parameter. TOTIME only applies to client file data and does not affect other information that is

being exported, such as policy. IBM Spectrum Protect ignores the TOTIME parameter if the FILEDATA parameter is set to NONE.

The default value for this parameter, when used with the TODATE parameter, is midnight minus one second (23:59:59).

Important: The value of the TOTIME and TODATE parameters must be later than the FROMDATE and the FROMTIME value. Use one of the following values to specify the time:

Value	**Description**	**Example**
HH:MM:SS	A specific time	10:30:08
NOW+HH:MM **or**+HH:MM	The current time plus hours and minutes specified.	NOW+02:00 **or** +02:00. If you issue this command at 05:00 with FROMTIME=01:00 and TOTIME=NOW+02:00, the export includes files that were stored from 01:00 until 07:00.
NOW-HH:MM **or**-HH:MM	The current time minus hours and minutes specified.	NOW-02:00 **or** -02:00. If you issue this command at 05:00 with FROMTIME=01:00 and TOTIME=NOW-02:00, the export includes files that were stored from 01:00 until 03:00.

TOServer

Specifies the name of a server to which the export data is sent directly over the network for immediate import. Important: The target server must be defined on the originating server with the DEFINE SERVER command. The administrator that issues the export command must be defined with the same administrator name and password and have system authority on the target server.

When you specify TOSERVER, you cannot specify the DEVCLASS, VOLUMENAMES, and SCRATCH, USEDVOLUMELIST, and PREVIEW parameters.

PREVIEWImport

Specifies whether to view how much data is transferred, without actually moving any data. This information can be used to determine how much storage pool space is required on the target server. The default is NO.
Valid values are:

Yes

Specifies that you want to preview the results of the import operation on the target server, without importing the data. Information is reported to the server console and the activity log.

No

Specifies that you want the data to be imported on the target server without previewing the results.

MERGEfilespaces

Specifies whether IBM Spectrum Protect merges client files into existing file spaces on the target server (if they exist), or if IBM Spectrum Protect generates new file space names. The default is NO.

Valid values are:

Yes

Specifies that imported data on the target server is merged with the existing file space, if a file space with the same name exists on the target server.

No

Specifies that IBM Spectrum Protect generates a new file space name for imported data on the target server if file spaces with the same name exists.

Replacedefs

Specifies whether to replace definitions (not file data) on the server. The default is NO.

Valid values are:

Yes

Specifies that definitions are replaced on the server if definitions having the same name as those being imported exist on the target server.

No

Specifies that imported definitions are skipped if their names conflict with definitions that are already defined on the target server.

PROXynodeassoc
: Specifies if proxy node associations are exported. This parameter is optional. The default value is NO.

ENCryptionstrength
: Indicates which algorithm to use to encrypt passwords when exporting administrative and node records. This parameter is optional. The default value is AES. If you are exporting to a server that does not support AES, specify DES. You can specify one of the following values:

  AES
  : Specifies the Advanced Encryption Standard.

  DES
  : Specifies the Data Encryption Standard.

ALLOWSHREDdable
: Specifies whether data from a storage pool that enforces shredding is exported. This parameter is optional. The default value is NO. Possible values are:

  No
  : Specifies that the server does not export data from a storage pool that enforces shredding.

  Yes
  : Specifies that the server does export from a storage pool that enforces shredding. The data on the export media is not shredded.

  Restriction: After an export operation finishes identifying files for export, any changes to the storage pool ALLOWSHREDABLE value is ignored. An export operation that is suspended retains the original ALLOWSHREDABLE value throughout the operation. You might want to consider canceling your export operation if changes to the storage pool ALLOWSHREDABLE value jeopardize the operation. You can reissue the export command after any needed cleanup.

EXPORTIDentifier
: This optional parameter specifies the name that you select to identify this export operation. If you do not specify an identifier name, the server generates one for you. The export identifier name cannot be more than 64 characters, cannot contain wildcard characters, and is not case-sensitive. You can use the identifier name to reference export operations in the QUERY EXPORT, SUSPEND EXPORT, RESTART EXPORT, or CANCEL EXPORT commands.
  Restriction: You must specify the TOSERVER parameter if you are specifying the EXPORTIDENTIFIER parameter. EXPORTIDENTIFIER is ignored if FILEDATA=NONE.

Example: Export client node information and all client files

To export client node information and all client files for `NODE1` directly to `SERVERB`, issue the following command:

```
export node node1 filedata=all toserver=serverb
```

Example: Export client node information and all client files for a specific date range

To export client node information and all client files for `NODE1` directly to `SERVERB` between February 1, 2009 and today.

```
export node node1 filedata=all toserver=serverb
fromdate=02/01/2009 todate=today
```

Example: Export client node information and all client files for a specific date and time range

To export client node information and all client files for `NODE1` directly to `SERVERB` from 8:00 AM on February 1, 2009 until today at 8:00 AM, issue the following command:

```
export node node1 filedata=all toserver=serverb
fromdate=02/01/2009 fromtime=08:00:00
todate=today totime=08:00:00
```

Example: Export client node information and all client files for the past three days

To export client node information and all client files for `NODE1` directly to `SERVERB` for the past three days, issue the following command:

```
export node node1 filedata=all toserver=serverb
fromdate=today -3
```

EXPORT POLICY (Export policy information)

Use this command to export policy information from an IBM Spectrum Protect™ server to sequential media or directly to another server for immediate import. When a policy is exported by using the EXPORT POLICY command, the active data pool information in the domain is not exported.

The server exports policy information, such as:

- Policy domain definitions
- Policy set definitions, including the active policy set
- Management class definitions, including the default management class
- Backup copy group and archive copy group definitions
- Schedule definitions for each policy domain
- Client node associations, if the client node exists on the target server

You can use the QUERY ACTLOG command to view the status of the export operation. You can also view this information from the server console.

This command generates a background process that can be canceled with the CANCEL PROCESS command. If you export policy information to sequential media and the background process is canceled, the sequential media that is holding the exported data is incomplete and must not be used to import data. If a server-to-server export background process is canceled, a partial import might result. Evaluate any imported data on the target server to determine whether you want to keep or delete the imported data. Review the import messages for details. To display information about background processes, use the QUERY PROCESS command.

The following restrictions apply to the export function:

- Export operations from a later version and release to an earlier version and release is not supported.
- Export operations between servers that are at the same version and release but with different fix packs might fail. For example, you cannot export from a V7.1.3 server to a V7.1.1 or earlier server.
- Exported data from a server with retention protection enabled is not protected by retention when it is imported to another server.
- Export processing excludes nodes of type network-attached storage (NAS).
- Exporting data to a Centera device class or importing data from a Centera device class is not supported. However, files that are stored in Centera storage pools can be exported and files that must be imported can be stored on a Centera storage device.

Limitation: The IBM Spectrum Protect server does not convert code pages during export, import, and node replication operations. If servers are running in different locales, some information in databases or system output might become unreadable. Invalid characters might be displayed, for example, in the contact information for the administrator and client nodes, and in descriptions of policy domains. Any field that is stored in the server character set and that includes extended ASCII characters can be affected. To resolve the issue after the import or node replication operation, update the fields with the appropriate UPDATE commands. This server limitation does not affect client data. Any client data that was exported, imported, or replicated can be restored, retrieved, and recalled.

The EXPORT POLICY command takes two forms: Export directly to another server on the network, or export to sequential media. The syntax and parameters for each form are defined separately.

Table 1. Commands related to EXPORT POLICY

Command	Description
CANCEL PROCESS	Cancels a background server process.
EXPORT ADMIN	Copies administrative information to external media or directly to another server.
EXPORT NODE	Copies client node information to external media or directly to another server.
EXPORT SERVER	Copies all or part of the server to external media or directly to another server.
IMPORT POLICY	Restores policy information from external media.

Command	Description
QUERY ACTLOG	Displays messages from the server activity log.
QUERY PROCESS	Displays information about background processes.

- EXPORT POLICY (Export policy information to sequential media)
  Use this command to export policy information from an IBM Spectrum Protect server to sequential media for later import to another server.
- EXPORT POLICY (Export a policy directly to another server)
  Use this command to export policy information directly to another server on the network. This results in an immediate import on the target server.

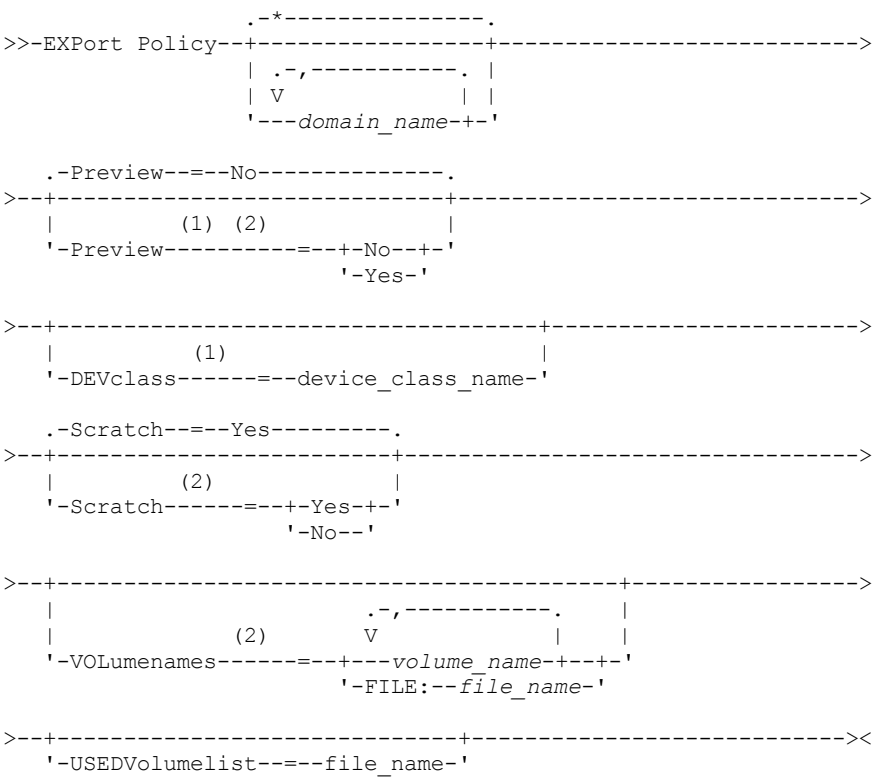
EXPORT POLICY (Export policy information to sequential media)

Use this command to export policy information from an IBM Spectrum Protect™ server to sequential media for later import to another server.

Privilege class

To issue this command, you must have system privilege.

Syntax



Notes:

1. If PREVIEW=NO, a device class must be specified.
2. If PREVIEW=NO and SCRATCH=NO, one or more volumes must be specified.

Parameters

domain_name
: Specifies the policy domains for which information is to be exported. This parameter is optional. The default is all policy domains. Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify

names.

Preview

Specifies whether to preview the results of the export operation, without exporting information. You can use this parameter to preview how many bytes of data are transferred so that you can determine how many volumes are required. This parameter supports the following values:

No

Specifies that the policy information is to be exported. If you specify this value, you must also specify a device class.

Yes

Specifies that the operation is previewed but not completed. Information is reported to the server console and the activity log. If you specify this value, you do not need to specify a device class.

This parameter is optional. The default value is NO.

DEVclass

Specifies the device class to which export data is to be written. This parameter is required if you specify PREVIEW=NO.

You cannot specify the DISK, NAS, or CENTERA device classes.

If all drives for the device class are busy when the export runs, IBM Spectrum Protect cancels lower priority operations to make a drive available.

Tip: You can export data to a storage pool on another server by specifying a device class whose device type is SERVER.

Scratch

Specifies whether scratch volumes can be used. The default value is YES. You can specify one of the following values:

Yes

Specifies that scratch volumes can be used for export. If you also specify a list of volumes, scratch volumes are used only if there is not enough space on the volumes specified.

No

Specifies that scratch volumes cannot be used for export. To determine how many volumes you might need, you can run the command specifying PREVIEW=YES.

VOLumenames

Specifies the volumes to be used to contain exported data. This parameter is optional, unless you specify SCRATCH=NO and PREVIEW=NO. If you do not specify a volume name, scratch volumes are used.

You can specify one of the following values:

volume_name

Specifies the volume name. To specify multiple volumes, separate the names with commas and no intervening spaces.

FILE:file_name

Specifies the name of a file that contains a list of volumes. In the file, each volume name must be on a separate line. Blank and comment lines that begin with an asterisk are ignored.

Use these naming conventions when specifying volumes associated with the following device types:

For this device	**Specify**
Tape	1-6 alphanumeric characters.
FILE	Any fully qualified file name string. For example: AIX Linux /imdata/mt1. Windows d:\program files\tivoli\tsm\data1.dsm.
AIX Linux Windows REMOVABLEFILE	AIX Linux Windows 1-6 alphanumeric characters.
SERVER	1-250 alphanumeric characters.

USEDVolumelist

Specifies the file where a list of volumes used in the export operation are stored. This parameter is optional.

This file can be used in the import operation. This file contains comment lines with the date and time the export was done, and the command issued to create the export.

Attention: If you specify an existing file, the file is overwritten.

Example: Export policy information to specific tape volumes

From the server, export policy information to tape volumes TAPE01, TAPE02, and TAPE03. Specify that these tape volumes be read by a device that is assigned to the MENU1 device class.

```
export policy devclass=menu1
volumenames=tape01,tape02,tape03
```

Example: Export policy information to tape volumes listed in a file

From the server, export policy information to tape volumes that are listed in the following file:

- AIX Linux TAPEVOL
- Windows TAPEVOL.DATA

This file contains the following lines:

```
TAPE01
TAPE02
TAPE03
```

Specify that these tape volumes be used by a device that is assigned to the MENU1 device class. Issue the following command:
AIX Linux

```
export policy devclass=menu1 volumenames=file:tapevol
```

Windows

```
export policy devclass=menu1 volumenames=file:tapevol.data
```

EXPORT POLICY (Export a policy directly to another server)

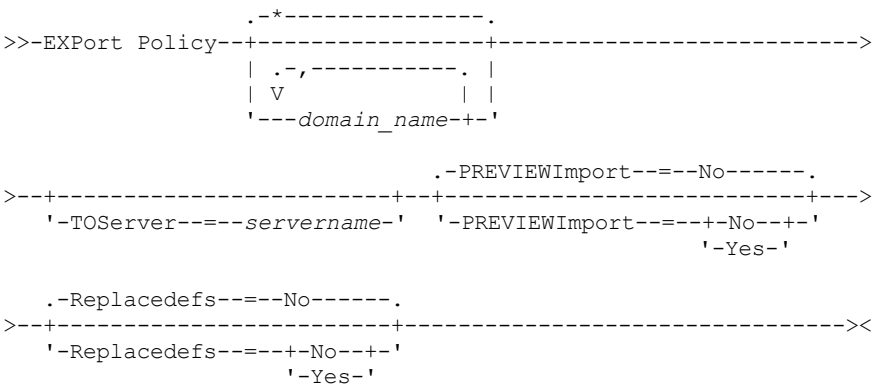
Use this command to export policy information directly to another server on the network. This results in an immediate import on the target server.

To monitor the progress of the import operation, you can issue a QUERY PROCESS command from the target server. See EXPORT ADMIN (Export administrator information) for a list of restrictions that apply to the export function.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

domain_name
: Specifies the policy domains for which information is to be exported. This parameter is optional. The default is all policy domains. Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify

names.

TOServer
: Specifies the name of a server to which the export data is sent directly over the network for immediate import.
Important: The target server must be defined on the originating server with the DEFINE SERVER command. The administrator that issues the export command must be defined with the same administrator name and password and have system authority on the target server.

When you specify TOSERVER, you cannot specify the DEVCLASS, VOLUMENAMES, and SCRATCH, USEDVOLUMELIST, and PREVIEW parameters.

PREVIEWImport
: Specifies whether to view how much data is transferred, without actually moving any data. This information can be used to determine how much storage pool space is required on the target server. The default is NO.
Valid values are:

Yes
: Specifies that you want to preview the results of the import operation on the target server, without importing the data. Information is reported to the server console and the activity log.

No
: Specifies that you want the data to be imported on the target server without previewing the results.

Replacedefs
: Specifies whether to replace definitions (not file data) on the server. The default is NO.

Valid values are:

Yes
: Specifies that definitions are replaced on the server if definitions having the same name as those being imported exist on the target server.

No
: Specifies that imported definitions are skipped if their names conflict with definitions that are already defined on the target server.

Example: Export policy to another server

To export policy information directly to SERVERB, issue the following command:

```
export policy replacedefs=yes toserver=othersrv
```

EXPORT SERVER (Export server information)

Use this command to export all or part of the server control information and client file data (if specified) from the server to sequential media.

When you export server information to sequential media, you can later use the media to import the information to another server with a compatible device type.
Important: For commands that import administrators or nodes, you must consider the method of authentication. The IBM Spectrum Protect™ server cannot export or import passwords for nodes or administrators that are authenticating with LDAP directory servers. If the current authentication method uses an LDAP directory server and the password is not already synchronized by that server, you must update the password. After issuing the IMPORT command, set the password by issuing the UPDATE ADMIN or UPDATE NODE command.

You also have the option of processing an export operation directly to another server on the network. This results in an immediate import process without the need for compatible sequential device types between the two servers.

You can export the following types of server information by issuing the EXPORT SERVER command:

- Policy domain definitions
- Policy set definitions
- Management class and copy group definitions
- Schedules defined for each policy domain
- Administrator definitions
- Client node definitions

You can optionally export the following types of data:

- File space definitions
- Access authorization information that pertains to the file spaces exported
- Backed-up, archived, and files that were migrated by an IBM Spectrum Protect for Space Management client

This command generates a background process that can be canceled by the CANCEL PROCESS command. If you export server information to sequential media, and the background process is canceled, the sequential media holding the exported data are incomplete and should not be used for importing data. If a server-to-server export background process is canceled, a partial import might result. Evaluate any imported data on the target server to determine whether you want to keep or delete the imported data. Review the import messages for details.

Issue the QUERY PROCESS command from the target server to monitor the progress of the import operation. Issue the QUERY EXPORT command to list all server-to-server export operations (that have a FILEDATA value other than NONE) that are running or suspended.

You can use the QUERY ACTLOG command to view the actual status information which indicates the size and the success or failure of the export operation.

The following restrictions apply to the export function:

- Export operations from a later version and release to an earlier version and release is not supported.
- Export operations between servers that are at the same version and release but with different fix packs might fail. For example, you cannot export from a V7.1.3 server to a V7.1.1 or earlier server.
- Exported data from a server with retention protection enabled is not protected by retention when it is imported to another server.
- Export processing excludes nodes of type network-attached storage (NAS).
- Exporting data to a Centera device class or importing data from a Centera device class is not supported. However, files that are stored in Centera storage pools can be exported and files that must be imported can be stored on a Centera storage device.

- The EXPORT NODE and EXPORT SERVER commands do not export data from a shred pool unless you explicitly allow it by setting the ALLOWSHREDDABLE parameter to the YES value. If this value is specified, and the exported data includes data from shred pools, that data cannot be shredded. A warning is not issued if the export operation includes data from shred pools.

- Incrementally exporting or importing the following types of client data to another IBM Spectrum Protect server is not supported:
    - VMware backups where full plus incremental backups need to be periodically, incrementally transferred to another server
    - Backups groups where full plus differential backups must be periodically, incrementally transferred to another server
    - Windows System State data that is periodically, incrementally transferred to another server

  Full export or import of this data to a new file system on the target is supported by exporting the entire file space that contains the data. The export must not use the FILEDATA=ALLACTIVE, FROMDATE, TODATE, or MERGEFILESPACES parameters.

  Using node replication to incrementally transfer this type of client data between two servers is optimal.

Limitation: The IBM Spectrum Protect server does not convert code pages during export, import, and node replication operations. If servers are running in different locales, some information in databases or system output might become unreadable. Invalid characters might be displayed, for example, in the contact information for the administrator and client nodes, and in descriptions of policy domains. Any field that is stored in the server character set and that includes extended ASCII characters can be affected. To resolve the issue after the import or node replication operation, update the fields with the appropriate UPDATE commands. This server limitation does not affect client data. Any client data that was exported, imported, or replicated can be restored, retrieved, and recalled.

The EXPORT SERVER command takes two forms: Export directly to another server on the network, or export to sequential media. The syntax and parameters for each form are defined separately.

Table 1. Commands related to EXPORT SERVER

Command	Description
CANCEL EXPORT	Deletes a suspended export operation.

Command	Description
CANCEL PROCESS	Cancels a background server process.
COPY ACTIVEDATA	Copies active backup data.
EXPORT ADMIN	Copies administrative information to external media or directly to another server.
EXPORT NODE	Copies client node information to external media or directly to another server.
EXPORT POLICY	Copies policy information to external media or directly to another server.
IMPORT SERVER	Restores all or part of the server from external media.
QUERY ACTLOG	Displays messages from the server activity log.
QUERY EXPORT	Displays the export operations that are currently running or suspended.
QUERY PROCESS	Displays information about background processes.
RESTART EXPORT	Restarts a suspended export operation.
SUSPEND EXPORT	Suspends a running export operation.

- EXPORT SERVER (Export a server to sequential media)
  You can export all or part of the server control information and client file data from a server to sequential media so that this information can be imported to another server.
- EXPORT SERVER (Export server control information and client file data to another server)
  Use this command to export all or part of the server control information and client file data directly to another server on the network. This results in an immediate import on the target server.

EXPORT SERVER (Export a server to sequential media)

You can export all or part of the server control information and client file data from a server to sequential media so that this information can be imported to another server.

Privilege class

To issue this command, you must have system privilege.

Syntax

Notes:

1. If PREVIEW=NO, a device class must be specified.
2. If PREVIEW=NO and SCRATCH=NO, one or more volumes must be specified.

Parameters

FILEData
: Specifies the type of files that are exported for all nodes that are defined to the server. This parameter is optional. The default value is NONE.

  If you are exporting to sequential media, the device class to access the file data is determined by the device class for the storage pool. If it is the same device class that is specified in this command, two drives are needed to export server information. The mount limit for the device class must be set to at least 2.

  The following descriptions mention *active* and *inactive* backup file versions. An active backup file version is the most recent backup version for a file that still exists on the client workstation. All other backup file versions are called inactive copies. The following values are available:

  ALl
  : IBM Spectrum Protect™ exports all backup versions of files, all archived files, and all files that were migrated by an IBM Spectrum Protect for Space Management client.

  None
  : IBM Spectrum Protect does not export files, only definitions.

  ARchive
  : IBM Spectrum Protect exports only archived files.

  Backup
  : IBM Spectrum Protect exports only backup versions, whether the versions are active or inactive.

  BACKUPActive
  : IBM Spectrum Protect exports only active backup versions.

  ALLActive
  : IBM Spectrum Protect exports all active backup versions of files, all archived files, and all files that were migrated by an IBM Spectrum Protect for Space Management client.

  SPacemanaged

IBM Spectrum Protect exports only files that were migrated by an IBM Spectrum Protect for Space Management client.

Preview
Specifies whether you want to preview the results of the export operation, without exporting information. You can use this parameter to preview how many bytes of data are transferred so that you can determine how many volumes are required. This parameter supports the following values:

No
Specifies that the server information is to be exported. If you specify this value, you must also specify a device class.
Yes
Specifies that the operation is previewed but not completed. Information is reported to the server console and the activity log. If you specify this value, you do not need to specify a device class.

This parameter is optional. The default value is NO.

DEVclass
Specifies the device class to which export data is to be written. This parameter is required if you specify PREVIEW=NO.

You cannot specify the DISK, NAS, or CENTERA device classes.

If all drives for the device class are busy when the export runs, IBM Spectrum Protect cancels lower priority operations to make a drive available.

Tip: You can export data to a storage pool on another server by specifying a device class whose device type is SERVER.

Scratch
Specifies whether scratch volumes can be used. The default value is YES. You can specify one of the following values:

Yes
Specifies that scratch volumes can be used for export. If you also specify a list of volumes, scratch volumes are used only if there is not enough space on the volumes specified.
No
Specifies that scratch volumes cannot be used for export. To determine how many volumes you might need, you can run the command specifying PREVIEW=YES.

VOLumenames
Specifies the volumes to be used to contain exported data. This parameter is optional, unless you specify SCRATCH=NO and PREVIEW=NO. If you do not specify a volume name, scratch volumes are used.

You can specify one of the following values:

volume_name
Specifies the volume name. To specify multiple volumes, separate the names with commas and no intervening spaces.
FILE:file_name
Specifies the name of a file that contains a list of volumes. In the file, each volume name must be on a separate line. Blank and comment lines that begin with an asterisk are ignored.

Use these naming conventions when specifying volumes associated with the following device types:

For this device	Specify
Tape	1-6 alphanumeric characters.
FILE	Any fully qualified file name string. For example: AIX Linux /imdata/mt1. Windows d:\program files\tivoli\tsm\data1.dsm.
AIX Linux Windows REMOVABLEFILE	AIX Linux Windows 1-6 alphanumeric characters.
SERVER	1-250 alphanumeric characters.

USEDVolumelist
Specifies the file where a list of volumes used in the export operation are stored. This parameter is optional.

This file can be used in the import operation. This file contains comment lines with the date and time the export was done, and the command issued to create the export.

Attention: If you specify an existing file, the file is overwritten.

FROMDate

Specifies the earliest date for which files to be exported were stored on the server. Files that were stored on the server earlier than the specified date are not exported. This parameter only applies to client file data. This parameter does not affect other information that might be exported, for example, policy. IBM Spectrum Protect ignores the FROMDATE parameter when the FILEDATA parameter is set to NONE.

Directory processing: The FROMDATE parameter does not apply to directories. All directories in a file space are processed even if the directories were not backed up in the specified date range.

Important: If you have group data on the node that you are exporting, data that was backed up before the designated FROMDATE and FROMTIME can also be exported. Group data on the node is, for example, virtual machine data or system state backup data. This export is a result of incremental backup processing for the data. The incremental backup processing can cause extra files that do not meet the filtering criteria to be exported, so that there is a consistent image for the backup data.

Use one of the following values to specify the date:

Value	**Description**	**Example**
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY -3 **or** -3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

If this parameter is not specified, IBM Spectrum Protect exports all objects stored before the TODATE parameter and as qualified by the FILEDATA parameter. If no TODATE parameter is specified, then all data as qualified by the FILEDATA parameter is exported.

When a server-to-server export operation uses a relative FROMDATE, for example, TODAY-1, and the operation is restarted at a later date, the restarted process still uses the date that was used during the original operation. For example, if a server-to-server export operation is started on 07/04/2009 and the FROMDATE is specified as TODAY-1, the date that is used for selecting files is 07/03/2009. If this same export operation is suspended and restarted ten days later (07/14/2009), the date that is used for selecting files is still 07/03/2009. This behavior ensures that the entire export operation uses the same cutoff date for selecting files to export.

TODate

Specifies the latest date for files to be exported from the server. Files stored on the server on a date later than the TODATE value are not exported. TODATE only applies to client file data and does not affect other information that is being exported, such as policy.

- IBM Spectrum Protect ignores the TODATE parameter when the FILEDATA parameter is set to NONE.
- If a TODATE parameter is specified without a TOTIME parameter, the server exports all objects inserted on or before the day specified by the TODATE parameter.
- If you specified the FROMDATE parameter, the value of TODATE must be later than or equal to the FROMDATE value. If the TODATE and FROMDATE are equal, then the TOTIME parameter must be later that the FROMTIME parameter.
- The TODATE parameter does not apply to directories. All directories in a file space are processed even if the directories were not backed up in the specified date range.

Use one of the following values to specify the date:

Value	**Description**	**Example**

Value	Description	Example
MM/DD/YYYY	A specific date	10/15/2006
TODAY	The current date	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY -3 **or** -3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

When a server-to-server export operation uses a relative TODATE, for example, TODAY-1, and the operation is restarted at a later date, the restarted process still uses the date that was used during the original operation. For example, if a server-to-server export operation is started on 07/04/2009 and the TODATE is specified as TODAY-1, the date that is used for selecting files is 07/03/2009. If this same export operation is suspended and restarted ten days later (07/14/2009), the date that is used for selecting files is still 07/03/2009. This behavior ensures that the entire export operation uses the same cutoff date for selecting files to export.

FROMTime

Specifies the earliest time for which objects to be exported were stored on the server. When you specify FROMTIME, you must also use the FROMDATE parameter. This parameter only applies to client file data. This parameter does not affect other information that might be exported, for example, policy. Objects that were stored on the server before the specified time and date are not exported. IBM Spectrum Protect ignores the FROMTIME parameter when the FILEDATA parameter is set to NONE.

Important: If you have group data on the node that you are exporting, data that was backed up before the designated FROMDATE and FROMTIME can also be exported. An example of group data on the node is virtual machine data or system state backup data, This export is a result of incremental backup processing for the data. The incremental backup processing can cause extra files that do not meet the filtering criteria to be exported so that there is a consistent image for the backup data.

The default value for this parameter when used with the FROMDATE parameter is midnight (00:00:00).

Use one of the following values to specify the time:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes specified. The FROMTIME+ can only be used with a FROMDATE before today.	NOW+02:00 **or** +02:00. If you issue this command at 5:00 with FROMTIME=NOW+02:00 or FROMTIME=+02:00, the export operation only contains files that were put on the server after 7:00 on the FROMDATE that you specify.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes specified	NOW -02:00 **or** -02:00. If you issue this command at 5:00 with FROMTIME=NOW-02:00 or FROMTIME=-2:00, the export includes files that were put on the server after 3:00.

TOTime
Specifies the latest time that objects to be exported were stored on the server. You must specify the TODATE parameter in order to use the TOTIME parameter. TOTIME only applies to client file data and does not affect other information that is being exported, such as policy. IBM Spectrum Protect ignores the TOTIME parameter if the FILEDATA parameter is set to NONE.

The default value for this parameter, when used with the TODATE parameter, is midnight minus one second (23:59:59).

Important: The value of the TOTIME and TODATE parameters must be later than the FROMDATE and the FROMTIME value. Use one of the following values to specify the time:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW+HH:MM **or**+HH:MM	The current time plus hours and minutes specified.	NOW+02:00 **or** +02:00. If you issue this command at 05:00 with FROMTIME=01:00 and TOTIME=NOW+02:00, the export includes files that were stored from 01:00 until 07:00.
NOW-HH:MM **or**-HH:MM	The current time minus hours and minutes specified.	NOW-02:00 **or** -02:00. If you issue this command at 05:00 with FROMTIME=01:00 and TOTIME=NOW-02:00, the export includes files that were stored from 01:00 until 03:00.

ENCryptionstrength
Indicates which algorithm to use to encrypt passwords when exporting administrative and node records. This parameter is optional. The default value is AES. If you are exporting to a server that does not support AES, specify DES. You can specify one of the following values:

AES
Specifies the Advanced Encryption Standard.
DES
Specifies the Data Encryption Standard.

ALLOWSHREDdable
Specifies whether data from a storage pool that enforces shredding is exported. This parameter is optional. The default value is NO. Possible values are:

No
Specifies that data is not exported from a storage pool that enforces shredding.
Yes
Specifies that data can be exported from a storage pool that enforces shredding. The data on the export media is not shredded.

Example: Export a server to specific tape volumes

From the server, export server information to tape volumes TAPE01, TAPE02, and TAPE03. Specify that these tape volumes be read by a device that is assigned to the MENU1 device class.

```
export server devclass=menu1
volumenames=tape01,tape02,tape03
```

Example: Export a server to tape volumes listed in a file

From the server, export server information to tape volumes that are listed in the following file:

- AIX Linux TAPEVOL
- Windows TAPEVOL.DATA

The file contains the following lines:

```
TAPE01
TAPE02
```

```
TAPE03
```

Specify that the tape volumes be used by a device that is assigned to the MENU1 device class. Issue the following command:

AIX | Linux

```
export server devclass=menu1 volumenames=file:tapevol
```

Windows

```
export server devclass=menu1 volumenames=file:tapevol.data
```

EXPORT SERVER (Export server control information and client file data to another server)

Use this command to export all or part of the server control information and client file data directly to another server on the network. This results in an immediate import on the target server.

Server-to-server export operations that have a FILEDATA value other than NONE can be restarted after the operation is suspended. The server saves the state and status of the export operation so that it may be restarted from the point at which the operation failed or was suspended. The export operation can be restarted at a later date by issuing the RESTART EXPORT command. These export operations can be manually suspended as well as restarted. Therefore, if an export fails, it is automatically suspended if it has completed the transmitting definitions phase.

An export operation is suspended when any of the following conditions is detected:

- A SUSPEND EXPORT command is issued for the running export operation
- Segment preemption - the file being read for export is deleted by some other process
- Communication errors on a server-to-server export
- No available mount points
- Necessary volumes are unavailable
- I/O errors encountered

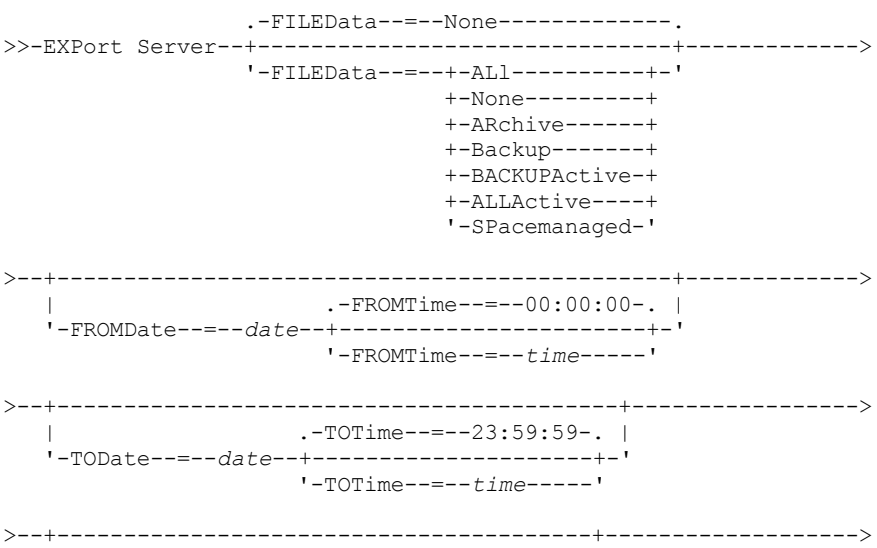
The export operation cannot be restarted if the export operation fails prior to transmitting the eligible node and filespace definitions to the target server. You must reenter the command to begin a new export operation.

Issue the QUERY PROCESS command from the target server to monitor the progress of the import operation. Issue the QUERY EXPORT command to list all server-to-server export operations (that have a FILEDATA value other than NONE) that are running or suspended. See EXPORT ADMIN (Export administrator information) for a list of restrictions that apply to the export function.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

FILEData
: Specifies the type of files to export for all nodes defined to the server. This parameter is optional. The default value is NONE.

  If you are exporting to sequential media: The device class to access the file data is determined by the device class for the storage pool. If it is the same device class specified in this command, IBM Spectrum Protect™ requires two drives to export server information. You must set the mount limit for the device class to at least 2.

  The following descriptions mention active and inactive backup file versions. An active backup file version is the most recent backup version for a file that still exists on the client workstation. All other backup file versions are called inactive copies. The values are:

  ALl
  : IBM Spectrum Protect exports all backup versions of files, all archived files, and all files that were migrated by an IBM Spectrum Protect for Space Management client.

  None
  : IBM Spectrum Protect does not export files, only definitions.

  ARchive
  : IBM Spectrum Protect exports only archived files.

  Backup
  : IBM Spectrum Protect exports only backup versions, whether they are active or inactive.

  BACKUPActive
  : IBM Spectrum Protect exports only active backup versions.

  ALLActive
  : IBM Spectrum Protect exports all active backup versions of files, all archived files, and all files that were migrated by an IBM Spectrum Protect for Space Management client.

  SPacemanaged
  : IBM Spectrum Protect exports only files that were migrated by an IBM Spectrum Protect for Space Management client.

FROMDate
: Specifies the earliest date for which files to be exported were stored on the server. Files that were stored on the server earlier than the specified date are not exported. This parameter only applies to client file data. This parameter does not

affect other information that might be exported, for example, policy. IBM Spectrum Protect ignores the FROMDATE parameter when the FILEDATA parameter is set to NONE.
Directory processing: The FROMDATE parameter does not apply to directories. All directories in a file space are processed even if the directories were not backed up in the specified date range.
Important: If you have group data on the node that you are exporting, data that was backed up before the designated FROMDATE and FROMTIME can also be exported. Group data on the node is, for example, virtual machine data or system state backup data. This export is a result of incremental backup processing for the data. The incremental backup processing can cause extra files that do not meet the filtering criteria to be exported, so that there is a consistent image for the backup data.
Use one of the following values to specify the date:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY -3 **or** -3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

If this parameter is not specified, IBM Spectrum Protect exports all objects stored before the TODATE parameter and as qualified by the FILEDATA parameter. If no TODATE parameter is specified, then all data as qualified by the FILEDATA parameter is exported.

When a server-to-server export operation uses a relative FROMDATE, for example, TODAY-1, and the operation is restarted at a later date, the restarted process still uses the date that was used during the original operation. For example, if a server-to-server export operation is started on 07/04/2009 and the FROMDATE is specified as TODAY-1, the date that is used for selecting files is 07/03/2009. If this same export operation is suspended and restarted ten days later (07/14/2009), the date that is used for selecting files is still 07/03/2009. This behavior ensures that the entire export operation uses the same cutoff date for selecting files to export.

TODate

Specifies the latest date for files to be exported from the server. Files stored on the server on a date later than the TODATE value are not exported. TODATE only applies to client file data and does not affect other information that is being exported, such as policy.

- IBM Spectrum Protect ignores the TODATE parameter when the FILEDATA parameter is set to NONE.
- If a TODATE parameter is specified without a TOTIME parameter, the server exports all objects inserted on or before the day specified by the TODATE parameter.
- If you specified the FROMDATE parameter, the value of TODATE must be later than or equal to the FROMDATE value. If the TODATE and FROMDATE are equal, then the TOTIME parameter must be later that the FROMTIME parameter.
- The TODATE parameter does not apply to directories. All directories in a file space are processed even if the directories were not backed up in the specified date range.

Use one of the following values to specify the date:

Value	Description	Example
MM/DD/YYYY	A specific date	10/15/2006
TODAY	The current date	TODAY

Value	Description	Example
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY -3 **or** -3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

When a server-to-server export operation uses a relative TODATE, for example, TODAY-1, and the operation is restarted at a later date, the restarted process still uses the date that was used during the original operation. For example, if a server-to-server export operation is started on 07/04/2009 and the TODATE is specified as TODAY-1, the date that is used for selecting files is 07/03/2009. If this same export operation is suspended and restarted ten days later (07/14/2009), the date that is used for selecting files is still 07/03/2009. This behavior ensures that the entire export operation uses the same cutoff date for selecting files to export.

FROMTime

Specifies the earliest time for which objects to be exported were stored on the server. When you specify FROMTIME, you must also use the FROMDATE parameter. This parameter only applies to client file data. This parameter does not affect other information that might be exported, for example, policy. Objects that were stored on the server before the specified time and date are not exported. IBM Spectrum Protect ignores the FROMTIME parameter when the FILEDATA parameter is set to NONE.

Important: If you have group data on the node that you are exporting, data that was backed up before the designated FROMDATE and FROMTIME can also be exported. An example of group data on the node is virtual machine data or system state backup data, This export is a result of incremental backup processing for the data. The incremental backup processing can cause extra files that do not meet the filtering criteria to be exported so that there is a consistent image for the backup data.

The default value for this parameter when used with the FROMDATE parameter is midnight (00:00:00).

Use one of the following values to specify the time:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW
NOW+HH:MM **or** +HH:MM	The current time plus hours and minutes specified. The FROMTIME+ can only be used with a FROMDATE before today.	NOW+02:00 **or** +02:00. If you issue this command at 5:00 with FROMTIME=NOW+02:00 or FROMTIME=+02:00, the export operation only contains files that were put on the server after 7:00 on the FROMDATE that you specify.
NOW-HH:MM **or** -HH:MM	The current time minus hours and minutes specified	NOW -02:00 **or** -02:00. If you issue this command at 5:00 with FROMTIME=NOW-02:00 or FROMTIME=-2:00, the export includes files that were put on the server after 3:00.

TOTime

Specifies the latest time that objects to be exported were stored on the server. You must specify the TODATE parameter in order to use the TOTIME parameter. TOTIME only applies to client file data and does not affect other information that is

being exported, such as policy. IBM Spectrum Protect ignores the TOTIME parameter if the FILEDATA parameter is set to NONE.

The default value for this parameter, when used with the TODATE parameter, is midnight minus one second (23:59:59).

Important: The value of the TOTIME and TODATE parameters must be later than the FROMDATE and the FROMTIME value. Use one of the following values to specify the time:

Value	**Description**	**Example**
HH:MM:SS	A specific time	10:30:08
NOW+HH:MM **or**+HH:MM	The current time plus hours and minutes specified.	NOW+02:00 **or** +02:00. If you issue this command at 05:00 with FROMTIME=01:00 and TOTIME=NOW+02:00, the export includes files that were stored from 01:00 until 07:00.
NOW-HH:MM **or**-HH:MM	The current time minus hours and minutes specified.	NOW-02:00 **or** -02:00. If you issue this command at 05:00 with FROMTIME=01:00 and TOTIME=NOW-02:00, the export includes files that were stored from 01:00 until 03:00.

TOServer

Specifies the name of a server to which the export data is sent directly over the network for immediate import. Important: The target server must be defined on the originating server with the DEFINE SERVER command. The administrator that issues the export command must be defined with the same administrator name and password and have system authority on the target server.

When you specify TOSERVER, you cannot specify the DEVCLASS, VOLUMENAMES, and SCRATCH, USEDVOLUMELIST, and PREVIEW parameters.

PREVIEWImport

Specifies whether to view how much data is transferred, without actually moving any data. This information can be used to determine how much storage pool space is required on the target server. The default is NO.
Valid values are:

Yes

Specifies that you want to preview the results of the import operation on the target server, without importing the data. Information is reported to the server console and the activity log.

No

Specifies that you want the data to be imported on the target server without previewing the results.

MERGEfilespaces

Specifies whether IBM Spectrum Protect merges client files into existing file spaces on the target server (if they exist), or if IBM Spectrum Protect generates new file space names. The default is NO.

Valid values are:

Yes

Specifies that imported data on the target server is merged with the existing file space, if a file space with the same name exists on the target server.

No

Specifies that IBM Spectrum Protect generates a new file space name for imported data on the target server if file spaces with the same name exists.

Replacedefs

Specifies whether to replace definitions (not file data) on the server. The default is NO.

Valid values are:

Yes

Specifies that definitions are replaced on the server if definitions having the same name as those being imported exist on the target server.

No

Specifies that imported definitions are skipped if their names conflict with definitions that are already defined on the target server.

PROXynodeassoc
Specifies if proxy node associations are exported. This parameter is optional. The default value is NO.

ENCryptionstrength
Indicates which algorithm to use to encrypt passwords when exporting administrative and node records. This parameter is optional. The default value is AES. If you are exporting to a server that does not support AES, specify DES. You can specify one of the following values:

AES
Specifies the Advanced Encryption Standard.

DES
Specifies the Data Encryption Standard.

ALLOWSHREDdable
Specifies whether data from a storage pool that enforces shredding is exported. This parameter is optional. The default value is NO. Possible values are:

No
Specifies that the server does not allow data to be exported from a storage pool that enforces shredding.

Yes
Specifies that the server allows data to be exported from a storage pool that enforces shredding. The data on the export media will not be shredded.

Important: After an export operation finishes identifying files for export, any changes to the storage pool ALLOWSHREDABLE value is ignored. An export operation that is suspended retains the original ALLOWSHREDABLE value throughout the operation. You might want to consider canceling your export operation if changes to the storage pool ALLOWSHREDABLE value jeopardize the operation. You can reissue the export command after any needed cleanup.

EXPORTIDentifier
This optional parameter specifies the name that you selected to identify this export operation. If you do not specify a command name, the server generates one for you. The export identifier name cannot be more than 64 characters, cannot contain wildcard characters, and is not case sensitive. You can use the identifier name to reference export operations in the QUERY EXPORT, SUSPEND EXPORT, RESTART EXPORT, or CANCEL EXPORT commands. EXPORTIDENTIFIER is ignored if FILEDATA=NONE or if PREVIEWIMPORT=YES.

If you are specifying the EXPORTIDENTIFIER parameter, you must specify the TOSERVER parameter.

Example: Export server information directly to another server

To export server information directly to SERVERB, issue the following command.

```
export server filedata=all toserver=serverb
```

Example: Export server information directly to another server using a date range

To export directly to SERVERB between February 1, 2009 and today, issue the following command.

```
export server filedata=all toserver=serverb
fromdate=02/01/2009 todate=today
```

Example: Export server information and client file data directly to another server using a date and time range

To export directly to SERVERB from 8:00 a.m. on February 1, 2009 until today at 8:00 a.m., issue the following command.

```
export server filedata=all toserver=serverb
fromdate=02/01/2009 fromtime=08:00:00
todate=today totime=08:00:00
```

EXTEND DBSPACE (Increase space for the database)

Use this command to increase space for the database by adding directories for the database to use.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

When you issue the EXTEND DBSPACE command, directories are added to the database. With the default parameter settings, data is redistributed across all database directories, and storage space is reclaimed. This action improves parallel I/O performance and makes the new directory space available for immediate use.

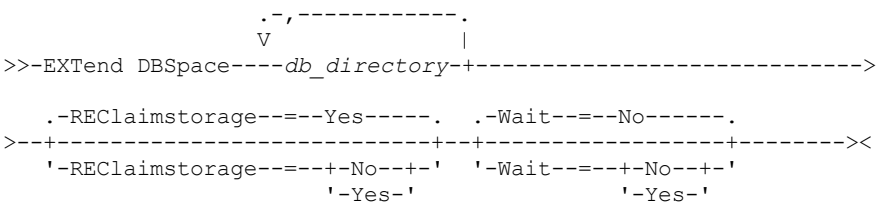
If you do not want to redistribute data when you add new directories, you can specify `RECLAIMSTORAGE=NO`. If you specify `No` for this parameter, all space in existing directories is filled before new directories are used. You can redistribute data and reclaim space later, but you must complete the manual procedure for this task by using DB2 commands.

Restriction: Redistribution of data and reclaiming of space as part of an operation to extend database space works only with DB2 Version 9.7 or later table spaces. The table spaces are created when you format a new IBM Spectrum Protect™ Version 6.2 or later server. If you upgraded or restored your IBM Spectrum Protect server from V6.1, you cannot redistribute data or reclaim space. You must issue the EXTEND DBSPACE command with `RECLAIMSTORAGE=NO`.
Important: The redistribution process uses considerable system resources, so ensure that you plan ahead when you want to add space to the database. Review the following guidelines:

- Complete the process when the server is not handling a heavy workload.
- The time that is required to redistribute data and reclaim space might vary. It is affected by factors such as the file system layout, the ratio of new paths to existing storage paths, server hardware, and concurrent operations. To get a rough estimate, you can try the operation with a small IBM Spectrum Protect database on a lab system. Use your results as a reference to estimate the time that is required for the procedure.
- Do not interrupt the redistribution process. If you try to stop it, for example, by halting the process that is completing the work, you must stop and restart the DB2® server. When the server is restarted, it will go into crash recovery mode, which takes several minutes, after which the redistribution process resumes.

After an operation to extend the database space is complete, halt and restart the server to fully use the new directories. If the existing database directories are nearly full when a new directory is added, the server might encounter an out of space condition (reported in the db2diag.log). You can fix the out of space condition by halting and restarting the server.

Syntax



Parameters

db_directory (Required)
: Specifies the directories for database storage. The directories must be empty and accessible by the user ID of the database manager. A directory name must be a fully qualified name and cannot exceed 175 characters in length. Enclose the name in quotation marks if it contains embedded blanks, an equal sign, or other special characters. If you are specifying a list of directories for database storage, the maximum length of the list can be 1400 characters.
Windows Restriction: You cannot specify Universal Naming Convention (UNC) paths.
Tip: Specify directories that are the same size as existing directories to ensure a consistent degree of parallelism for database operations. If one or more directories for the database are smaller than the others, they reduce the potential for optimized parallel prefetching and distribution of the database.

REClaimstorage
: Specifies whether data is redistributed across newly created database directories and space is reclaimed from the old storage paths. This parameter is optional. The default value is Yes.

Unless you specify `WAIT=YES`, the operation is completed as a background process.

Yes
: Specifies that data is redistributed so that new directories are available for immediate use.
Important: The redistribution process uses considerable system resources so ensure that you plan ahead.

After the process starts, messages are issued to inform you about the progress. You can use the QUERY PROCESS command to monitor the operation. To cancel the process, you can use the CANCEL PROCESS command, but if a data redistribution operation is in progress, it completes before the process is stopped.

No
Specifies that data is not redistributed across database directories and storage space is not reclaimed when space is added for the database.

Wait
Specifies whether this command is processed in the background or foreground.

No
Specifies background processing. The default is NO.

Yes
Specifies foreground processing.

AIX Linux You cannot specify YES from the server console.

AIX Linux

Example: Add directories to the storage space for the database, redistribute data, and reclaim storage

Add two directories (/tsm_db/stg1 and tsm_db/stg2) under the /tsm_db directory to the storage space for the database. Issue the command:

```
extend dbspace /tsm_db/stg1,/tsm_db/stg2
```

Windows

Example: Add drives to the storage space for the database, redistribute data, and reclaim storage

Add drives D and E to the storage space for the database. Issue the command:

```
extend dbspace D:,E:
```

Related commands

Table 1. Commands related to EXTEND DBSPACE

Command	Description
DSMSERV EXTEND DBSPACE	Adds directories to increase space for use by the database.
QUERY DB	Displays allocation information about the database.
QUERY DBSPACE	Displays information about the storage space defined for the database.

Related tasks:
Managing inventory capacity

GENERATE commands

Use the GENERATE commands for backup sets for a selected filespace or client node.

- GENERATE BACKUPSET (Generate a backup set of Backup-Archive Client data)
- GENERATE BACKUPSETTOC (Generate a table of contents for a backup set)
- AIX Linux Windows GENERATE DEDUPSTATS (Generate data deduplication statistics)

GENERATE BACKUPSET (Generate a backup set of Backup-Archive Client data)

Use this command to generate a backup set for a Backup-Archive Client node. A *backup set* is a collection of a Backup-Archive Client's active backed up data, which is stored and managed as a single object, on specific media, in server storage. Although you can create a backup set for any client node, a backup set can be used only by a Backup-Archive Client.

Restriction: A backup set in "deduplication format" has that designation as a result of a GENERATE BACKUPSET command with at least one of the following specifications:

- Includes a node at Backup-Archive Client Version 6.1.x (at least V6.1.0 but less than V6.2.0).
- Includes a node that has one or mode nodes that are authorized to act as a proxy. At least one of those proxy nodes is at Backup-Archive Client V6.1.x.

Backup sets in the deduplication format can be restored only by the V6.1.2 or later Backup-Archive Client. Backup-Archive Clients before V6.1.2 cannot restore from a backup set that is in the deduplication format.
A backup set in the "distributed deduplication format" has that designation as a result of a GENERATE BACKUPSET command with at least one of the following specifications:

- Includes a node at Backup-Archive Client level V6.2.0 or later.
- Includes a node that has one or mode nodes that are authorized to act as a proxy. At least one of those proxy nodes is at Backup-Archive Client V6.2.0.

Backup sets in the distributed deduplication format can be restored only by the V6.2.0 or later Backup-Archive Client.
Restriction: You cannot generate a backup set with files that were backed up to IBM Spectrum Protect™ using NDMP. However, you can create a backup set with files that were backed up using NetApp SnapShot Difference.

The server creates copies of active versions of a client's backed up objects that are within the one-or-more file spaces specified with this command. The server then consolidates them onto sequential media. Currently, the backup object types that are supported for backup sets include directories and files only.

The backup-archive client node can restore its backup set from the server and from the media to which the backup set was written.

This command generates a background process that can be canceled with the CANCEL PROCESS command. If the background process created by this command is canceled, the media might not contain a complete backup set. You can use the QUERY PROCESS command to show information about the background process that is created by this command.

Tip: When IBM Spectrum Protect generates a backup set, you can improve performance if the primary storage pools containing the client data are collocated. If a primary storage pool is collocated, client node data is likely to be on fewer tape volumes than it would be if the storage pool were not collocated. With collocation, less time is spent searching database entries, and fewer mount operations are required.

Privilege class

To issue this command, you must have system privilege or policy privilege for the domain to which the client node is assigned.

Parameters

node_name or node_group_name (Required)
: Specifies the name of the client node and node groups whose data is contained in the backup set. To specify multiple node names and node group names, separate the names with commas and no intervening spaces. You can use wildcard characters with node names but not with node group names. When multiple node names are specified, the server generates a backup set for each node and places all of the backup sets together on a single set of output volumes.

backup_set_name_prefix (Required)
: Specifies the name of the backup set for the client node. The maximum length of the name is 30 characters.

  When you select a name, IBM Spectrum Protect adds a suffix to construct your backup set name. For example, if you name your backup set *mybackupset*, IBM Spectrum Protect adds a unique number such as 3099 to the name. The backup set name is then identified to IBM Spectrum Protect as *mybackupset.3099*. To later show information about this backup set, you can include a wildcard with the name, such as *mybackupset.** or specify the fully qualified name, such as *mybackupset.3099*.

  When multiple node names or node group names are specified, the server generates a backup set for each node or node group and places all the backup sets on a single set of output volumes. Each backup set is given the same fully qualified name consisting of the *backup_set_name_prefix* and a suffix determined by the server.

file_space_name
: Specifies the names of one or more file spaces that contain the data to be included in the backup set. This parameter is optional. The file space name that you specify can contain wildcard characters. You can specify more than one file space by separating the names with commas and no intervening spaces. If you do not specify a file space, data from all the client nodes backed-up and active file spaces is included in the backup set.

For a server that has clients with support for Unicode-enabled file spaces, you can enter either a file space name or a file space ID (FSID). If you enter a file space name, you might need to have the server convert the file space name that you enter. For example, you might need to have the server convert the name that you enter from the server's code page to Unicode. See the NAMETYPE parameter for details. If you do not specify a file space name, or specify only a single wildcard character for the name, you can use the CODETYPE parameter to limit the operation to Unicode file spaces or to non-Unicode file spaces.

DEVclass (Required)
Specifies the name of the device class for the volumes to which the backup set is written. The maximum length of the name is 30 characters.
Restriction: You cannot specify a device class with a device type of NAS or CENTERA.

SCRatch
Specifies whether to use scratch volumes for the backup set. If you include a list of volumes using the VOLUMES parameter, the server uses scratch volumes only if the data cannot be contained in the volumes you specify. The default is SCRATCH=YES. The values are:

YES
Specifies to use scratch volumes for the backup set.

NO
Specifies not to use scratch volumes for the backup set.

VOLumes
Specifies the names of one or more volumes that will contain the backup set. This parameter is optional. You can specify more than one volume by separating each volume with a comma, with no intervening spaces.

If you do not specify this parameter, scratch volumes are used for the backup set.

RETention
Specifies the number of days to retain the backup set on the server. You can specify an integer from 0 to 30000. The default is 365 days. The values are:

days
Specifies the number of days to retain the backup set on the server.

NOLimit
Specifies that the backup set should be retained on the server indefinitely.

If you specify NOLIMIT, the server retains the volumes containing the backup set forever, unless a user or administrator deletes the volumes from server storage.

DESCription
Specifies the description to associate with the backup set. This parameter is optional. The maximum length of the description is 255 characters. Enclose the description in quotation marks if it contains any blank characters.

Wait
Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default is NO. The values are:

Yes
Specifies the command processes in the foreground. Messages that are created are not displayed until the command completes processing. You cannot specify WAIT=YES from the server console.

No
Specifies that the command processes in the background. Use the QUERY PROCESS command to monitor the background processing of this command.

NAMEType
Specify how you want the server to interpret the file space names that you enter. This parameter is useful when the server has clients with support for Unicode-enabled file spaces. You can use this parameter for IBM Spectrum Protect clients using Windows, NetWare, or Macintosh OS X operating systems.

Use this parameter only when you enter a partly or fully qualified file space name. The default value is SERVER. Possible values are:

SERVER
The server uses the server's code page to interpret the file space names.

UNIcode

The server converts the file space name that is entered from the server code page to the UTF-8 code page. The success of the conversion depends on the actual characters in the name and the server's code page. Conversion can fail if the string includes characters that are not available in the server code page, or if the server has a problem accessing system conversion routines.

FSID

The server interprets the file space names as their file space IDs (FSIDs).
Important: Use care when specifying this parameter if multiple node names are also specified. Different nodes might use the same file space ID for different file spaces, or different file space IDs for the same file space name. Therefore, specifying a file space ID as the file space names can result in the wrong data being written to the backup set for some nodes.

CODEType

Specify what type of file spaces are to be included in the operation. The default is BOTH, meaning that file spaces are included regardless of code page type. Use this parameter only when you enter a single wildcard character for the file space name or when you do not specify any file space names. Possible values are:

UNIcode

Include only file spaces that are in Unicode.

NONUNIcode

Include only file spaces that are not in Unicode.

BOTH

Include file spaces regardless of code page type.

PITDate

Specifies that files that were active on the specified date and that are still stored on the IBM Spectrum Protect server are to be included in the backup set, even if they are inactive at the time you issue the command. This parameter is optional. The default is the date on which the GENERATE BACKUPSET command is run. You can specify the date using one of the following values:

Value	**Description**	**Example**
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY-days**or**-days	The current date minus days specified	TODAY-7 or -7. To include files that were active a week ago, specify PITDATE=TODAY-7 or PITDATE=-7
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

PITTime

Specifies that files that were active on the specified time and that are still stored on the IBM Spectrum Protect server are to be included in the backup set, even if they are inactive at the time you issue the command. This parameter is optional. IF a PITDate was specified, the default is midnight (00:00:00); otherwise the default is the time at which the GENERATE BACKUPSET command is started. You can specify the time using one of the following values:

Value	**Description**	**Example**
HH:MM:SS	A specific time on the specified PIT date	12:33:28
NOW	The current date on the specified PIT date	NOW

Value	Description	Example
NOW+HH:MM or +HH:MM	The current time plus hours and minutes on the specified PIT date	NOW+03:00 or +03:00 If you issue this command at 9:00 with PITTIME=NOW+03:00 or PITTIME=+03:00. IBM Spectrum Protect includes files that were active at 12:00 on the PIT date.

DATAType

Specifies that backup sets containing the specified types of data that are to be generated. This parameter is optional. The default is that file level backup sets are to be generated. To specify multiple data types, separate data types with commas and no intervening spaces.

The server generates a backup set for each data type and places all the backup sets on a single set of output volumes. Each backup set is given the same fully qualified name consisting of the *backup_set_name_prefix* and a suffix determined by the server. However, each backup set has a different data type, as shown by the QUERY BACKUPSET command. Possible values are:

ALL
: Specifies that backup sets for all types of data (file level, image, and application) that have been backed up on the server are to be generated.

FILE
: Specifies that a file level backup set is to be generated. File level backup sets contain files and directories that are backed up by the backup client. If no files or directories have been backed up by the backup client, a file level backup set is not generated. This is the default.

IMAGE
: Specifies that an image backup set is to be generated. Image backup sets contain images that are created by the backup client BACKUP IMAGE command. Image backup sets are generated only if an image has been backed up by the backup client.

TOC

Specifies whether a table of contents (TOC) is saved for each file level backup set. Tables of contents are always saved for backup sets containing image or application data. The TOC parameter is ignored when generating image and application backup sets. A table of contents will always be generated for image and application backup sets.
Consider the following in determining whether you want to save a table of contents:

- If a table of contents is saved for a backup set, you can use the IBM Spectrum Protect web backup-archive client to examine the entire file system tree and choose files and directories to restore. To create a table of contents, you must define the TOCDESTINATION attribute in the backup copy group for the management class that is specified by the TOCMGMTCLASS parameter. Creating a table of contents requires additional processing, storage pool space, and possibly a mount point during the backup set operation.
- If a table of contents is not saved for a backup set, you can still restore individual files or directory trees using the backup-archive client RESTORE BACKUPSET command, if you know the fully qualified name of each file or directory to be restored.

To display the contents of backup sets, you can also use the QUERY BACKUPSETCONTENTS command.

This parameter is optional. Possible values are:

No
: Specifies that table of contents information is not saved for file level backup sets.

Preferred
: Specifies that table of contents information should be saved for file level backup sets. This is the default. However, a backup set does not fail just because an error occurs during creation of the table of contents.

Yes
: Specifies that table of contents information must be saved for each file level backup set. A backup set fails if an error occurs during creation of the table of contents.

TOCMGmtclass

Specifies the name of the management class to which the table of contents should be bound. If you do not specify a management class, the table of contents is bound to the default management class for the policy domain to which the node

is assigned. In this case, creation of a table of contents requires that you define the TOCDESTINATION attribute in the backup copy group for the specified management class.

ALLOWSHREDdable

Specifies whether data from a storage pool that enforces shredding is included in the backup set. This parameter is optional. Possible values are:

No

Specifies that data from a storage pool that enforces shredding is not included in the backup set. This is the default.

Yes

Specifies that data from a storage pool that enforces shredding can be included in the backup set. The data on the backup set media will not be shredded.

Example: Generate a backup set for a file space

Generate a backup set of a file space that is called /srvr that belongs to client node JANE. Name the backup set PERS_DATA and retain it for 75 days. Specify that volumes VOL1 and VOL2 contain the data for the backup set. The volumes are to be read by a device that is assigned to the AGADM device class. Include a description.

```
generate backupset jane pers_data /srvr devclass=agadm
retention=75 volumes=vol1,vol2
description="area 51 base image"
```

Example: Generate a backup set of a Unicode-enabled file space

Generate a backup set of the Unicode-enabled file space, \\joe\c$, that belongs to client node JOE. Name the backup set JOES_DATA. Specify that volume VOL1 contain the data for the backup set. The volume is to be read by a device that is assigned to the AGADM device class. Have the server convert the \\joe\c$ file space name from the server code page to the UTF-8 code page.

```
generate backupset joe joes_data \\joe\c$ devclass=agadm
volumes=vol1 nametype=unicode
```

Related commands

Table 1. Commands related to GENERATE BACKUPSET

Command	Description
CANCEL PROCESS	Cancels a background server process.
COPY ACTIVEDATA	Copies active backup data.
DEFINE COPYGROUP	Defines a copy group for backup or archive processing within a specified management class.
DEFINE NODEGROUP	Defines a group of nodes.
DEFINE NODEGROUPMEMBER	Adds a client node to a node group.
DEFINE BACKUPSET	Defines a previously generated backup set to a server.
DELETE BACKUPSET	Deletes a backup set.
DELETE NODEGROUP	Deletes a node group.
DELETE NODEGROUPMEMBER	Deletes a client node from a node group.
QUERY BACKUPSET	Displays backup sets.
GENERATE BACKUPSETTOC	Generates a table of contents for a backup set.
QUERY NODEGROUP	Displays information about node groups.
QUERY BACKUPSETCONTENTS	Displays contents contained in backup sets.
UPDATE BACKUPSET	Updates a retention value associated with a backup set.
UPDATE COPYGROUP	Changes one or more attributes of a copy group.
UPDATE NODEGROUP	Updates the description of a node group.

GENERATE BACKUPSETTOC (Generate a table of contents for a backup set)

Use this command to generate a table of contents for a backup set that does not already have one. The backup-archive client uses the table of contents to display the backup set, which allows users to select individual files to be restored from the backup set.

Creating a table of contents for a backup set requires storage pool space and possibly one or more mount points during the creation operation.

Privilege class

To issue this command, you must have system privilege or policy privilege for the domain to which the client node is assigned.

Syntax

```
>>-GENerate BACKUPSETTOC--node_name--backup_set_name------------>

   .-DATAType--=--ALL-----------.
>--+----------------------------+------------------------------->
   |              .-,---------. |
   |              V           | |
   '-DATAType--=-----+-FILE--+-+-'
                     '-IMAGE-'

>--+----------------------------+----------------------------><
   '-TOCMGmtclass--=--class_name-'
```

Parameters

node_name (Required)
: Specifies the name of the client node whose data is contained in the backup set. You cannot use wildcard characters to specify a name, nor can you specify a list of client node names.

backup_set_name (Required)
: Specifies the name of the backup set for the client node. You cannot use wildcard characters to specify a name, nor can you specify a list of backup set names.

DATAType
: Specifies the type of data to be included in the table of contents. This parameter is optional. By default, all data is included. To specify multiple data types, separate the data types with commas and no intervening spaces. Possible values are:

  ALL
  : Specifies that the table of contents includes all types of data (file-level, image, and application) stored in the backup set. This is the default.

  FILE
  : Specifies that the table of contents includes only file-level data. File-level data consists of files and directories backed up by the backup-archive client. If the backup set contains no files or directories, the table of contents is not generated.

  IMAGE
  : Specifies that the table of contents will include only image backups. Image backups consist of file system images created by the backup client BACKUP IMAGE command. If the backup set contains no image backups, the table of contents will not be generated.

TOCMGmtclass
: Specifies the name of the management class to which the table of contents should be bound. If you do not specify a management class, the table of contents is bound to the default management class for the policy domain to which the node is assigned. If you create a table of contents you must define the TOCDESTINATION attribute in the backup copy group for the specified management class.

Example: Generate a table of contents

Generate a table of contents for a backup set named PROJX_DATA that contains the data for client node GARY. The table of contents is to be bound to the default management class.

```
generate backupsettoc gary projx_data
```

Related commands

Table 1. Commands related to GENERATE BACKUPSETTOC

Command	Description
COPY ACTIVEDATA	Copies active backup data.
DEFINE COPYGROUP	Defines a copy group for backup or archive processing within a specified management class.
DEFINE NODEGROUP	Defines a group of nodes.
DEFINE NODEGROUPMEMBER	Adds a client node to a node group.
DEFINE BACKUPSET	Defines a previously generated backup set to a server.
DELETE BACKUPSET	Deletes a backup set.
DELETE NODEGROUP	Deletes a node group.
DELETE NODEGROUPMEMBER	Deletes a client node from a node group.
GENERATE BACKUPSET	Generates a backup set of a client's data.
QUERY BACKUPSET	Displays backup sets.
QUERY NODEGROUP	Displays information about node groups.
QUERY BACKUPSETCONTENTS	Displays contents contained in backup sets.
UPDATE BACKUPSET	Updates a retention value associated with a backup set.
UPDATE COPYGROUP	Changes one or more attributes of a copy group.
UPDATE NODEGROUP	Updates the description of a node group.

AIX | Linux | Windows

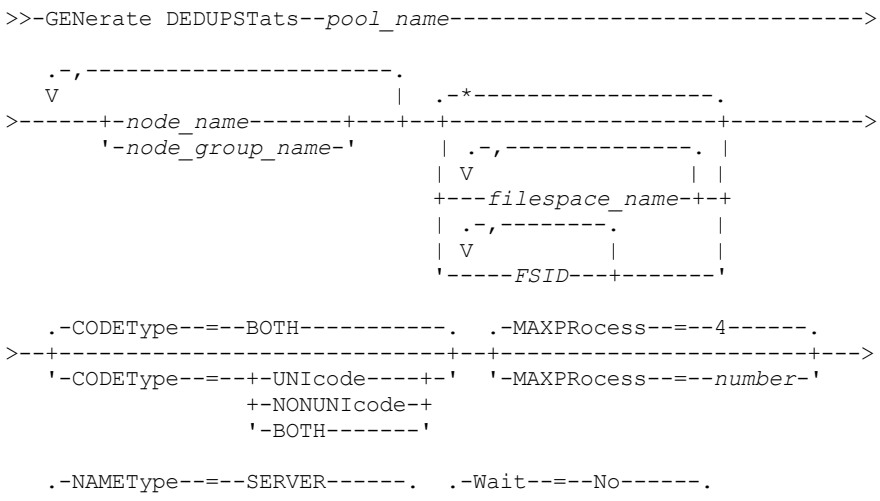
GENERATE DEDUPSTATS (Generate data deduplication statistics)

Use this command to generate data deduplication statistics for a directory-container storage pool or a cloud-container storage pool to determine data deduplication performance.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the storage pool.

Syntax



```
>--+--------------------------+--+-----------------+---------><
   '-NAMEType--=--+-SERVER--+-'  '-Wait--=--+-No--+-'
                  +-UNIcode-+               '-Yes-'
                  '-FSID----'
```

Parameters

pool_name (Required)
: Specifies the name of the storage pool that is reported in the data deduplication statistics. You can specify up to 30 characters for the storage pool name. If you specify more than 30 characters, the command fails.
Restriction: You can specify only directory-container storage pools or cloud storage pools.

node_name or node_group_name (Required)
: Specifies the name of the client node or defined group of client nodes that is reported in the data deduplication statistics. You can also specify a combination of client node names and client-node group names. To specify multiple client node names or client-node group names, separate the names with commas with no intervening spaces. You can use wildcard characters with client node names but not with client-node group names.

filespace_name or FSID
: Specifies the names of one or more file spaces in the data deduplication statistics. This parameter is optional. You can use wildcard characters to specify this name. An asterisk is the default. Specify one of the following values:

  *
  : Specify an asterisk (*) to show all file spaces or IDs.

  filespace_name
  : Specifies the name of the file space. Specify more than one file space by separating the names with commas and no intervening spaces. FSID specifies a file space identifier. This parameter is valid for clients with file spaces that are in Unicode format. Specify more than one file space by separating the names with commas and no intervening spaces.

  For clients with file spaces that are in Unicode format, you can enter either a file space name or an FSID. If you enter a file space name, the server might have to convert the file space name that you enter. For example, the server might have to convert the name that you enter from the server's code page to Unicode.
  Restrictions: The following restrictions apply to file space names and FSIDs:

  - You must specify a node name if you specify a file space name.
  - Do not specify both file space names and FSIDs on the same command.

CODEType
: Specifies what type of file spaces to include in the record. The default value is BOTH, which specifies that file spaces are included regardless of code page type. Use this parameter only when you enter an asterisk to display information about all file spaces. This parameter is optional. Specify one of the following values:

  UNIcode
  : Include file spaces that are in Unicode format.

  NONUNIcode
  : Include file spaces that are not in Unicode format.

  BOTH
  : Include file spaces regardless of code page type. This is the default.

MAXPRocess
: Specifies the maximum number of parallel processes to generate statistics for a container in a directory-container or cloud-container storage pool. This parameter is optional. Enter a value in the range 1 - 99. The default value is 4.

NAMEType
: Specifies how you want the server to interpret the file space names that you enter. Use this parameter when IBM Spectrum Protect™ clients have file spaces that are in Unicode format, and are on Windows, NetWare, or Macintosh OS X operating systems. This parameter is optional.
This parameter is required if you specify a node name and a file space name or FSID.
Restriction: When you specify this parameter, the file space name cannot contain an asterisk.

  Specify one of the following values:

  SERVER
  : The server uses the server's code page to interpret the file space names. This is the default.

  UNIcode
  : The server converts the file space name that is entered from the server code page to the UTF-8 code page. The success of the conversion depends on the characters in the name and the server's code page.

Tip: Conversion can fail if the string includes characters that are not available in the server code page, or if the server cannot access system conversion routines.

FSID

The server interprets the file space names as their FSIDs.

Wait

Specifies whether the data deduplication statistics are generated in the foreground or background. This parameter is optional. You can specify one of the following values:

No

Specifies that the operation is completed in the background. You can continue with other tasks while the command is processing. Messages that are related to the background process are displayed in the activity log file or the server console, depending on where the messages are logged. This is the default value.

Yes

Specifies that the operation is completed in the foreground. It might take a long time to complete the operation. The operation must end before you can continue with other tasks. Messages are displayed in the activity log file or the server console, or both, depending on where the messages are logged.
Restriction: You cannot specify the WAIT=YES parameter from the server console.

Example: Generate data deduplication statistics for a file space

Generate data deduplication statistics for a file space that is called /srvr that belongs to a directory-container storage pool, POOL1, that is stored on client node NODE1.

```
generate dedupstats pool1 node1 /srvr
```

Example: Generate data deduplication statistics for a Unicode-enabled file space

Generate data deduplication statistics for a Unicode-enabled file space that is called \\abc\c$ that belongs to client node NODE2. Convert the \\abc\c$ file space name from the server code page to the UTF-8 code page.

```
generate dedupstats node2 \\abc\c$ nametype=unicode
```

Related commands

Table 1. Commands related to GENERATE DEDUPSTATS

Command	Description
AIX Linux Windows DELETE DEDUPSTATS	Deletes data deduplication statistics.
AIX Linux Windows QUERY DEDUPSTATS	Displays data deduplication statistics.

GRANT commands

Use the GRANT command to grant appropriate privileges or access.

- GRANT AUTHORITY (Add administrator authority)
- GRANT PROXYNODE (Grant proxy authority to a client node)

GRANT AUTHORITY (Add administrator authority)

Use this command to grant an administrator one or more administrative privilege classes, and authority to access client nodes.

You cannot grant restricted privilege to an unrestricted policy or unrestricted storage administrator. You must use the REVOKE AUTHORITY command to remove the administrator's unrestricted privilege, then use this command to grant restricted privilege to the administrator.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-GRant AUTHority--admin_name---------------------------------->

                    .-,---------------.
           (1)      V                 |
>--CLasses------=----+-SYstem------+-+------------------------->
                     +-Policy------+

   '-AUTHority--=--+-Access-+-'  '-NOde--=--node_name------'
                   '-Owner--'
```

Notes:

1. You must specify one or more of these parameters.

Parameters

admin_name (Required)
: Specifies the name of the administrator being granted an administrative privilege class.

CLasses
: Specifies one or more privilege classes to grant to an administrator. This parameter is required, except when you specify the STGPOOLS parameter. You can specify more than one privilege class by separating each with a comma. Possible classes are:

  SYstem
  : Specifies that you want to grant system privilege to an administrator. A system administrator has the highest level of authority in IBM Spectrum Protect™. A system administrator can issue any administrative command and has authority to manage all policy domains and all storage pools. Do not specify additional privilege classes or the DOMAINS or STGPOOLS parameters when granting system privilege to an administrator. Only a system administrator can grant authority to other administrators.

  Policy
  : Specifies that you want to grant policy privilege to an administrator. If you do not specify the DOMAINS parameter, unrestricted policy privilege is granted. An unrestricted policy administrator can issue commands that affect all existing policy domains as well as any policy domains that are defined in the future. An unrestricted policy administrator cannot define, delete, or copy policy domains. Use the GRANT AUTHORITY command with CLASSES=POLICY and no DOMAINS parameter to upgrade a restricted policy administrator to an unrestricted policy administrator.

  STorage
  : Specifies that you want to grant storage privilege to an administrator. If the STGPOOLS parameter is not specified, unrestricted storage privilege is granted. An unrestricted storage administrator can issue all commands that allocate and control storage resources for the server. An unrestricted storage administrator can issue commands that affect all existing storage pools as well as any storage pools that are defined in the future. An unrestricted storage administrator cannot define or delete storage pools. Using the GRANT AUTHORITY command with CLASSES=STORAGE and no STGPOOLS parameter upgrades a restricted storage administrator to an unrestricted storage administrator.

  Operator
  : Specifies that you want to grant operator privilege to an administrator. An administrator with operator privilege can issue commands that control the immediate operation of the server and the availability of storage media.

  Node

Specifies that you want to grant a node privilege to a user. A user with client node privilege can remotely access a web backup-archive client with an administrative user ID and password if they have been given owner authority or access authority. Access authority is the default for a node privilege class.
Attention: When you specify the node privilege class, you must also specify either the DOMAIN parameter or the NODE parameter, but not both.

AUTHority
Specifies the authority level of a user with node privilege. This parameter is optional.

If an administrator already has system or policy privilege to the policy domain to which the node belongs, this command will not change the administrator's privilege.

Possible authority levels are:

Access
Specifies that you want to grant client access authority to a user with the node privilege class. This is the default when CLASSES=NODE is specified. A user with client access authority can access a web backup-archive client and perform backup and restore actions on that client.
Attention: A user with client access authority cannot access that client from another system by using the -NODENAME or -VIRTUALNODENAME parameter.

A client node can set the REVOKEREMOTEACCESS option to restrict a user that has node privilege with client access authority from accessing a client workstation that is running a web client. This option does not apply to administrators with client owner authority, system privilege, or policy privilege to the policy domain to which the node belongs.

Owner
Specifies that you want to grant client owner authority to a user with the node privilege class. A user with client owner authority can access a web backup-archive client through the web client interface and also access their data from another client using the -NODENAME or -VIRTUALNODENAME parameter.

DOmains
Specifies that you want to grant to the administrator client access or client owner authority to all clients in the specified policy domain. You cannot use this parameter together with the NODE parameter.

NOde
Specifies that you want to grant the administrator client access or client owner authority to the node. You cannot use this parameter together with the DOMAIN parameter.

DOmains
When used with CLASSES=POLICY, specifies that you want to grant restricted policy privilege to an administrator.

Restricted policy privilege permits an administrator to issue a subset of the policy commands for the domains to which the administrator is authorized. You can use this parameter to grant additional policy domain authority to a restricted policy administrator. This parameter is optional. You can specify more than one policy domain by delimiting each policy domain name with a comma.

You can use wildcard characters to specify a name. Authority for all matching policy domains is granted.

STGpools
Specifies that you want to grant restricted storage privilege to an administrator. If the STGPOOLS parameter is specified, then CLASSES=STORAGE is optional.

Restricted storage privilege permits you to issue a subset of the storage commands for the storage pools to which the administrator is authorized. You can use this parameter to grant additional storage pool authority to a restricted storage administrator. This parameter is optional. You can specify more than one storage pool by delimiting each storage pool name with a comma.

You can use wildcard characters to specify a name. Authority for all matching storage pools is granted.

Example: Grant system privilege to an administrator

Grant system privilege to administrator Larry.

```
grant authority larry classes=system
```

Example: Grant access to additional policy domains

Specify additional policy domains that the restricted policy administrator CLAUDIA can manage.

```
grant authority claudia domains=employee_records,prog1
```

Example: Provide an administrator with unrestricted storage privilege and restricted policy privilege

Provide administrator TOM with unrestricted storage privilege and restricted policy privilege for the domains whose names start with EMP.

```
grant authority tom classes=storage domains=emp*
```

Example: Grant an administrator authority restricted to a specific node

Grant node privilege to user HELP so that help desk personnel can assist the client node LABCLIENT in backing up or restoring data without having other higher-level IBM Spectrum Protect privileges.

```
grant authority help classes=node node=labclient
```

Related commands

Table 1. Commands related to GRANT AUTHORITY

Command	Description
QUERY ADMIN	Displays information about one or more IBM Spectrum Protect administrators.
REVOKE AUTHORITY	Revokes one or more privilege classes or restricts access to policy domains and storage pools.

GRANT PROXYNODE (Grant proxy authority to a client node)

Use this command to grant proxy authority to a client node on the IBM Spectrum Protect™ server.

Target client nodes own the data and agent nodes act on behalf of the target nodes. When granted proxy authority to a target client node, an agent node can perform backup and restore operations for the target node. Data that the agent node stores on behalf of the target node is stored under the target node's name in server storage.

Privilege class

To issue this command, you must have one of the following privilege classes:

- System privilege
- Unrestricted policy privilege

Syntax

```
>>-GRant PROXynode TArget--=--target_node_name------------------>

>--AGent--=--agent_node_name----------------------------------><
```

Parameters

TArget (Required)
: Specifies the name of the node that owns the data. Wildcard names cannot be used to specify the target node name.

AGent (Required)
: Specifies the name of the node performing operations for the target node. The agent node does not have to be in the same domain as the target node. Wildcard characters and comma-separated lists of node names are allowed.

Example: Grant proxy authority to a client node

Assume that MOE and JOE are agent nodes in a NAS cluster and are used to backup and restore shared NAS data. To create a proxy authority relationship for target node NASCLUSTER, issue the following command:

```
grant proxynode target=nascluster agent=moe,joe
```

Issue the following command on agent node MOE to back up NAS cluster data stored on the E: drive. The name of the target node is NASCLUSTER.

```
dsmc -asnode=nascluster incremental e:
```

Related commands

Table 1. Commands related to GRANT PROXYNODE

Command	Description
QUERY PROXYNODE	Display nodes with authority to act as proxy nodes.
REVOKE PROXYNODE	Revoke proxy authority from an agent node.

HALT (Shut down the server)

Use this command to shut down the server. The HALT command forces an abrupt shutdown, which cancels all the administrative and client node sessions even if they are not completed.

Any transactions in progress interrupted by the HALT command are rolled back when you restart the server. Use the HALT command only after the administrative and client node sessions are completed or canceled. To shut down the server without severely impacting administrative and client node sessions, perform the following steps:

1. Use the DISABLE SESSIONS command to prevent starting new client node sessions.
2. Use the QUERY SESSIONS command to identify any existing administrative and client node sessions.
3. Notify any existing administrative and client node sessions that you plan to shut down the server (you must do this outside of IBM Spectrum Protect™).
4. Use the CANCEL SESSIONS command to cancel any existing administrative or client node sessions.
5. Issue the HALT command to shut down the server and stop any administrative and client node sessions.

Tip:

The HALT command can be replicated using the ALIASHALT server option. Use the server option to define a term other than HALT that performs the same function. The HALT command retains its normal function however, the server option provides an additional method for issuing the HALT command. See ALIASHALT for additional information.

Privilege class

To issue this command, you must have system or operator privilege.

Syntax

```
>>-HALT-----------------------------------------------------><
```

Parameters

None.

Example: Shut down the server

Shut down the server, either from the server console or from an administrative client. All user activity stops immediately and no new activity can start.

```
halt
```

Related commands

Table 1. Commands related to HALT

Command	Description
CANCEL PROCESS	Cancels a background server process.
CANCEL SESSION	Cancels active sessions with the server.
DISABLE SESSIONS	Prevents new sessions from accessing IBM Spectrum Protect but permits existing sessions to continue.
ENABLE SESSIONS	Resumes server activity following the DISABLE command or the ACCEPT DATE command.
QUERY PROCESS	Displays information about background processes.
QUERY SESSION	Displays information about all active administrator and client sessions with IBM Spectrum Protect.

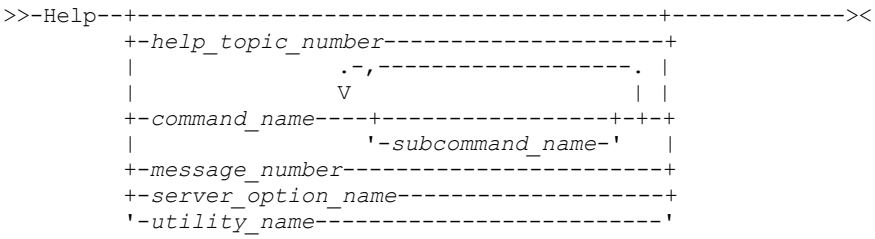
HELP (Get help on commands and error messages)

Use this command to display administrative commands and error messages. You can issue the command from an administrative command line client.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

help_topic_number
: Specifies the number of your selection from the help topics. This parameter is optional.
Topic numbers are displayed in the table of contents, for example:

```
3.0 Administrative commands
  ...
  3.13.10 DEFINE DEVCLASS (Define a device class)
      3.13.10.1 DEFINE DEVCLASS (Define a 3590 device class)
      3.13.10.2 DEFINE DEVCLASS (Define a 3592 device class)
      ...
```

The topic number for the command DEFINE DEVCLASS for a 3592 device class is 3.13.10.2.

command_name
: Specifies the name of the administrative command you want to display. This parameter is optional.

subcommand_name
: Specifies up to two of the subcommand names that are associated with the name of the administrative command that you want to display. This parameter is optional.

message_number
: Specifies the number of the message for which you want to display information. This parameter is optional. You can get help information about server messages (prefixed by ANR) and client messages (prefixed by ANE or ANS). Do not include

the prefix and severity code when specifying an error message number.

server_option_name
: Specifies the name of the server option for which you want to display information. This parameter is optional.

utility_name
: Specifies the name of the server utility for which you want to display information. This parameter is optional.

Example: Display the help topics

Display the help topics for the command-line interface.

```
help
```

Partial output:

```
1.0 Administering the server from the command line
  1.1 Issuing commands from the administrative client
     1.1.1 Starting and stopping the administrative client
     1.1.2 Monitoring server activities from the administrative client
```

Example: Display a help topic by using the help topic number

Display help information by using the help topic number. The topic number for the command DEFINE DEVCLASS for a 3592 device class is 3.13.10.2.

```
help 3.13.10.2
```

Example: Display help for one command

Display help information about the REMOVE commands.

```
help remove
```

```
3.44 REMOVE commands
Use the REMOVE commands to remove an object.
The following is a list of REMOVE commands:
*  3.44.1, "REMOVE ADMIN (Delete an administrator)"
*  3.44.2, "REMOVE NODE (Delete a node or an associated machine node)"
```

Example: Display help for a specific error message

Display help information about the error message ANR2535E.

```
help 2535
```

```
ANR2535E  Command: The node node name cannot be removed or renamed
      because it has an associated data mover.
Explanation: You attempted to remove or rename a node that has an
associated data mover.
System action: The server does not remove or rename the node.
User response: To remove or rename the node, delete the associated data
mover and reissue the command.
```

Example: Display help for a specific option

Display the description, syntax, and an example for the COMMMETHOD server option.

```
help commmethod
```

Example: Display help for a specific utility

Display the description, syntax, and an example for the DSMSERV utility.

```
help dsmserv
```

IDENTIFY DUPLICATES (Identify duplicate data in a storage pool)

Use this command to start or stop processes that identify duplicate data in a storage pool. You can specify the number of duplicate-identification processes and their duration.

When you create a new storage pool for data deduplication, you can specify 0 - 50 duplicate-identification processes. IBM Spectrum Protect™ starts the specified number of duplicate-identification processes automatically when the server is started. If you do not stop them, they run indefinitely.

This command affects only server-side deduplication processing. In client-side data deduplication processing, duplicates are identified on the backup-archive client.

With the IDENTIFY DUPLICATES command, you can start more processes, stop some or all of the processes, and specify an amount of time that the change remains in effect. If you increased or decreased the number of duplicate-identification processes, you can use the IDENTIFY DUPLICATES command to reset the number of processes to the number that is specified in the storage pool definition.

If you did not specify any duplicate-identification processes in the storage pool definition, you can use the IDENTIFY DUPLICATES command to start and stop all processes manually.

This command starts or stops a background process or processes that you can cancel with the CANCEL PROCESS command. To display information about background processes, use the QUERY PROCESS command.

Important:

- You can also change the number of duplicate-identification processes by updating the storage pool definition by using the UPDATE STGPOOL command. However, when you update a storage pool definition, you cannot specify a duration. The processes that you specify in the storage pool definition run indefinitely, or until you issue the IDENTIFY DUPLICATES command, update the storage pool definition again, or cancel a process.

  Issuing the IDENTIFY DUPLICATES does not change the setting for the number of duplicate-identification processes in the storage pool definition.

- Duplicate-identification processes can be either active or idle. Processes that are deduplicating files are active. Processes that are waiting for files to deduplicate are idle. Processes remain idle until volumes with data to be deduplicated become available. Processes stop only when canceled or when you change the number of duplicate-identification processes for the storage pool to a value less than what is specified. Before a duplicate-identification process stops, it must finish the file that it is deduplicating.

  The output of the QUERY PROCESS command for a duplicate-identification process includes the total number of bytes and files that have been processed since the process first started. For example, if a duplicate-identification process processes four files, becomes idle, and then processes five more files, then the total number of files that are processed is nine.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-IDentify DUPlicates--stgpool_name---------------------------->

>--+----------------------+--+---------------------+--------><
   '-NUMPRocess--=--number-'  '-DURation--=--minutes-'
```

Parameters

stgpool_name (Required)
: Specifies the storage pool name in which duplicate data is to be identified. You can use wildcards.

NUMPRocess
: Specifies the number of duplicate-identification processes to run after the command completes. You can specify 0 - 50 processes. The value that you specify for this parameter overrides the value that you specified in the storage pool definition or the most recent value that was specified when you last issued this command. If you specify zero, all duplicate-identification processes stop.

This parameter is optional. If you do not specify a value, the server starts or stops duplicate-identification processes so that the number of processes is the same as the number that is specified in the storage pool definition.

For example, suppose that you define a new storage pool and specify two duplicate-identification processes. Later, you issue the IDENTIFY DUPLICATES command to increase the number of processes to four. When you issue the IDENTIFY DUPLICATES command again without specifying a value for the NUMPROCESS parameter, the server stops two duplicate-identification processes.

If you specified 0 processes when you defined the storage pool definition and you issue IDENTIFY DUPLICATES without specifying a value for NUMPROCESS, any running duplicate-identification processes stop, and the server does not start any new processes.

Remember: When you issue IDENTIFY DUPLICATES without specifying a value for NUMPROCESS, the DURATION parameter is not available. Duplicate-identification processes specified in the storage pool definition run indefinitely, or until you reissue the IDENTIFY DUPLICATES command, update the storage pool definition, or cancel a process.

When the server stops a duplicate-identification process, the process completes the current physical file and then stops. As a result, it might take several minutes to reach the number of duplicate-identification processes that you specified as a value for this parameter.

DURation
Specifies the maximum number of minutes (1 - 9999) that this command remains in effect. At the end of the specified time, the server starts or stops duplicate-identification processes so that the number of processes is the same as the number that is specified in the storage pool definition.

This parameter is optional. If you do not specify a value, the processes that are running after the command is issued run indefinitely. They end only if you reissue the IDENTIFY DUPLICATES command, update the storage pool definition, or cancel a process.

For example, if you define a storage pool with two duplicate-identification processes and you issue the IDENTIFY DUPLICATES command with `DURATION=60` and `NUMPROCESS=4`, the server starts two more duplicate-identification processes that run for 60 minutes. At the end of that time, two processes finish the files that they are working on and stop. The two processes that stop might not be the same two processes that started as a result of issuing this command.

The server stops idle processes first. If after stopping all idle processes, more processes need to be stopped, the server notifies active processes to stop.

When the server stops a duplicate-identification process, the process completes the current physical file and then stops. As a result, it might take several minutes to reach the amount of time that you specified as a value for this parameter.

Example: Controlling the number and duration of duplicate-identification processes

In this example, you specified three duplicate-identification processes in the storage pool definition. You use the IDENTIFY DUPLICATES command to change the number of processes and to specify the amount of time the change is to remain in effect.

Table 1. Controlling duplicate-identification processes manually

The storage pool definition specifies three duplicate-identification processes. Using the IDENTIFY DUPLICATES command, you specify...	**...and a duration of...**	**The result is...**
2 duplicate-identification processes	None specified	One duplicate-identification process finishes the file that it is working on, if any, and then stops. Two processes run indefinitely, or until you reissue the IDENTIFY DUPLICATES command, update the storage pool definition, or cancel a process.
	60 minutes	One duplicate-identification process finishes the file that it is working on, if any, and then stops. After 60 minutes, the server starts one process so that three are running.

The storage pool definition specifies three duplicate-identification processes. Using the IDENTIFY DUPLICATES command, you specify...	...and a duration of...	The result is...
4 duplicate-identification processes	None specified	The server starts one duplicate-identification process. Four processes run indefinitely, or until you reissue the IDENTIFY DUPLICATES command, update the storage pool definition, or cancel a process.
	60 minutes	The server starts one duplicate-identification process. At the end of 60 minutes, one process finishes the file that it is working on, if any, and then stops. The additional process started by this command might not be the one that stops when the duration has expired.
0 duplicate-identification processes	None specified	All duplicate-identification processes finish the files that they are working on, if any, and stop. This change lasts indefinitely, or until you reissue the IDENTIFY DUPLICATES command, update the storage pool definition, or cancel a process.
	60 minutes	All duplicate-identification processes finish the files that they are working on, if any, and stop. At the end of 60 minutes, the server starts three processes.
None specified	Not available	The number of duplicate-identification processes resets to the number of processes that are specified in the storage pool definition. This change lasts indefinitely, or until you reissue the IDENTIFY DUPLICATES command, update the storage pool definition, or cancel a process.

Example: Identify duplicates in a storage pool

Identify duplicates in a storage pool, STGPOOLA, using three duplicate-identification processes. Specify that this change is to remain in effect for 60 minutes.

```
identify duplicates stgpoola duration=60 numprocess=3
```

Related commands

Table 2. Commands related to IDENTIFY DUPLICATES

Command	Description
CANCEL PROCESS	Cancels a background server process.
DEFINE STGPOOL	Defines a storage pool as a named collection of server storage media.
QUERY CONTENT	Displays information about files in a storage pool volume.
QUERY PROCESS	Displays information about background processes.
QUERY STGPOOL	Displays information about storage pools.
UPDATE STGPOOL	Changes the attributes of a storage pool.

IMPORT commands

Use the IMPORT commands to import information from export media to an IBM Spectrum Protect™ server.

Important: For commands that import administrators or nodes, you must consider the method of authentication. The IBM Spectrum Protect server cannot export or import passwords for nodes or administrators that are authenticating with LDAP directory servers. If the current authentication method uses an LDAP directory server and the password is not already

synchronized by that server, you must update the password. After issuing the IMPORT command, set the password by issuing the UPDATE ADMIN or UPDATE NODE command.

- IMPORT ADMIN (Import administrator information)
- IMPORT NODE (Import client node information)
- IMPORT POLICY (Import policy information)
- IMPORT SERVER (Import server information)

IMPORT ADMIN (Import administrator information)

Use this command to import administrator and authority definitions for one or more administrators from export media to the IBM Spectrum Protect™ server.

Important: For commands that import administrators or nodes, you must consider the method of authentication. The IBM Spectrum Protect server cannot export or import passwords for nodes or administrators that are authenticating with LDAP directory servers. If the current authentication method uses an LDAP directory server and the password is not already synchronized by that server, you must update the password. After issuing the IMPORT command, set the password by issuing the UPDATE ADMIN or UPDATE NODE command.

You can use the QUERY ACTLOG command to view the status of the import operation.

You can also view this information from the server console.

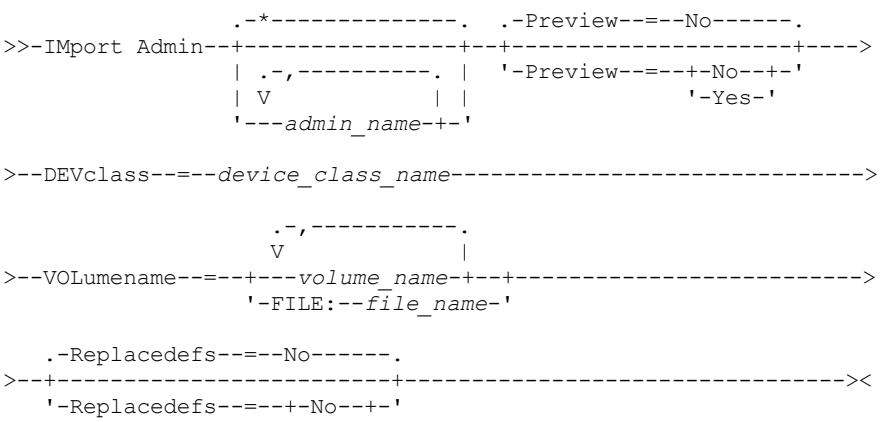
Limitation: The IBM Spectrum Protect server does not convert code pages during export, import, and node replication operations. If servers are running in different locales, some information in databases or system output might become unreadable. Invalid characters might be displayed, for example, in the contact information for the administrator and client nodes, and in descriptions of policy domains. Any field that is stored in the server character set and that includes extended ASCII characters can be affected. To resolve the issue after the import or node replication operation, update the fields with the appropriate UPDATE commands. This server limitation does not affect client data. Any client data that was exported, imported, or replicated can be restored, retrieved, and recalled.
This command generates a background process that can be canceled with the CANCEL PROCESS command. If an IMPORT ADMIN background process is canceled, some of the data is already imported. To display information about background processes, use the QUERY PROCESS command.
Restriction:

- If target and source server levels are not compatible, the operation might not work.
- If the administrator definition that is being imported includes analyst authority, the administrator definition is imported but not the analyst authority. Analyst authority is not valid for servers at V6.1 or later.
- Importing data from a CENTERA device class is not supported. However, files that are being imported can be stored on a CENTERA storage device.

Privilege class

To issue this command, you must have system privilege.

Syntax



```
'-Yes-'
```

Parameters

admin_name
: Specifies the administrators for which you want to import information. This parameter is optional. Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify names.

Preview
: Specifies whether you want to preview the results of the import operation, without importing administrator information. This parameter is optional. The following parameters values are supported:

  No
  : Specifies that the information is to be imported.

  Yes
  : Specifies that the operation is previewed but not completed. Information about the number and types of objects that are imported, together with the number of bytes transferred, are reported to the server console and the activity log.

  The default value is NO. If you specify YES for the value, you must mount the export volumes.

DEVclass (Required)
: Specifies the device class from which import data is to be read.

  You cannot specify the DISK, NAS, or CENTERA device classes.

  If all drives for the device class are busy when the import runs, IBM Spectrum Protect cancels lower priority operations, such as reclamation, to make a drive available.

VOLumename (Required)
: Specifies the volumes to be used for the import operation. Volumes must be imported in the same order as they were exported. The following parameter values are supported:

  volume_name
  : Specifies the volume name. To specify multiple volumes, separate names with commas and no intervening spaces.

  FILE:file_name
  : Specifies the name of a file that contains a list of volumes that are used for the imported data. In the file, each volume name must be on a separate line. Blank and comment lines that begin with an asterisk are ignored.

  Use these naming conventions when you specify volumes that are associated with the following device types:

For this device	Specify
Tape	1 - 6 alphanumeric characters.
FILE	Any fully qualified file name string. For example: AIX Linux /imdata/mt1. Windows d:\program files\tivoli\tsm\data1.dsm.
AIX Linux Windows REMOVABLEFILE	AIX Linux Windows 1 - 6 alphanumeric characters.
SERVER	1 - 250 alphanumeric characters.

Replacedefs
: Specifies whether to replace administrator definitions on the target server. The following parameter values are supported:

  No
  : Specifies that definitions are not to be replaced.

  Yes
  : Specifies that definitions are to be replaced.

  The default value is NO.

Example: Import administrator information from specific tape volumes

From the server, import the information for all defined administrators from tape volumes TAPE01, TAPE02, and TAPE03. Specify that these tape volumes be read by a device that is assigned to the MENU1 device class. Issue the command:

```
import admin devclass=menu1
volumenames=tape01,tape02,tape03
```

Example: Import administrator information from tape volumes listed in a file

From the server, import the information for all defined administrators from tape volumes that are listed in the following file:

- AIX | Linux TAPEVOL
- Windows TAPEVOL.DATA

This file contains these lines:

```
TAPE01
TAPE02
TAPE03
```

Specify that these tape volumes be read by a device that is assigned to the MENU1 device class. Issue the command:
AIX | Linux

```
import admin devclass=menu1 volumenames=file:tapevol
```

Windows

```
import admin devclass=menu1 volumenames=file:tapevol.data
```

Related commands

Table 1. Commands related to IMPORT ADMIN

Command	Description
CANCEL PROCESS	Cancels a background server process.
EXPORT ADMIN	Copies administrative information to external media or directly to another server.
IMPORT NODE	Restores client node information from external media.
IMPORT POLICY	Restores policy information from external media.
IMPORT SERVER	Restores all or part of the server from external media.
QUERY ACTLOG	Displays messages from the server activity log.
QUERY PROCESS	Displays information about background processes.

IMPORT NODE (Import client node information)

Use this command to import client node definitions from a server or sequential media to a target IBM Spectrum Protect™ server.

Important: For commands that import administrators or nodes, you must consider the method of authentication. The IBM Spectrum Protect server cannot export or import passwords for nodes or administrators that are authenticating with LDAP directory servers. If the current authentication method uses an LDAP directory server and the password is not already synchronized by that server, you must update the password. After issuing the IMPORT command, set the password by issuing the UPDATE ADMIN or UPDATE NODE command.

If you specify a domain on the source server and if that policy domain also exists on the target server, the imported nodes get associated with that same policy domain on the target server. Otherwise, imported nodes are associated with the STANDARD policy domain on the target server.

IBM Spectrum Protect servers with retention protection enabled do not allow import operations.

Restrictions:

1. If target and source server levels are not compatible, the operation might not work.
2. Importing data from a CENTERA device class is not supported. However, files that are being imported can be stored on a CENTERA storage device.
3. If you use an LDAP directory server to authenticate passwords, any target servers must be configured for LDAP passwords. Data that is imported from a node that authenticates with an LDAP directory server is inaccessible if the target server is not

properly configured. If your target server is not configured, imported data from an LDAP node can still go there. But the target server must be configured to use LDAP in order for you to access the imported data.

4. If target and source server levels are not compatible, the operation might not work.
5. You cannot use a CENTERA device class as the target medium for an export command, or as the source medium for an import command.
6. Incrementally exporting/importing the following types of client data to another IBM Spectrum Protect server is not supported:
   - VMWare backups where full plus incremental backups need to be periodically, incrementally transferred to another server.
   - Backups groups where full plus differential backups need to be periodically, incrementally transferred to another server.
   - Windows Windows System State data that is periodically, incrementally transferred to another server.

   Full export/import of this data to a new file system on the target is supported by exporting the entire filespace that contains the data. In other words, the export must not use the *FILEDATA=ALLACTIVE*, *FROMDATE*, *TODATE*, or *MERGEFILESPACES* options.

   The best practice for incrementally transferring this type of data between two servers is to use Node Replication.

You can use the QUERY ACTLOG command to view the status of the import operation. You can also view this information from the server console.

This command generates a background process that can be canceled with the CANCEL PROCESS command. If an IMPORT NODE background process is canceled, some of the data might already be imported. To display information about background processes, use the QUERY PROCESS command.

For a server that has clients with support for Unicode, you can get the server to convert the file space name that you enter, or use the following parameters:

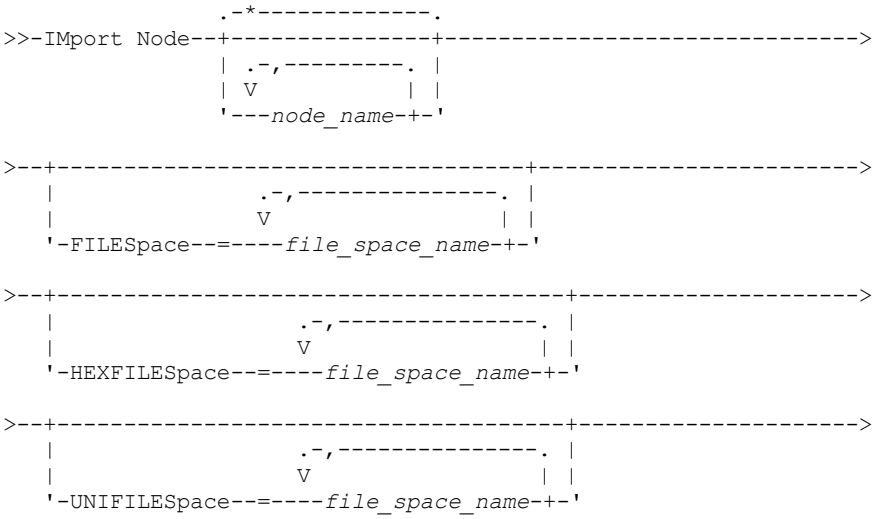
- HEXFILESPACE
- UNIFILESPACE

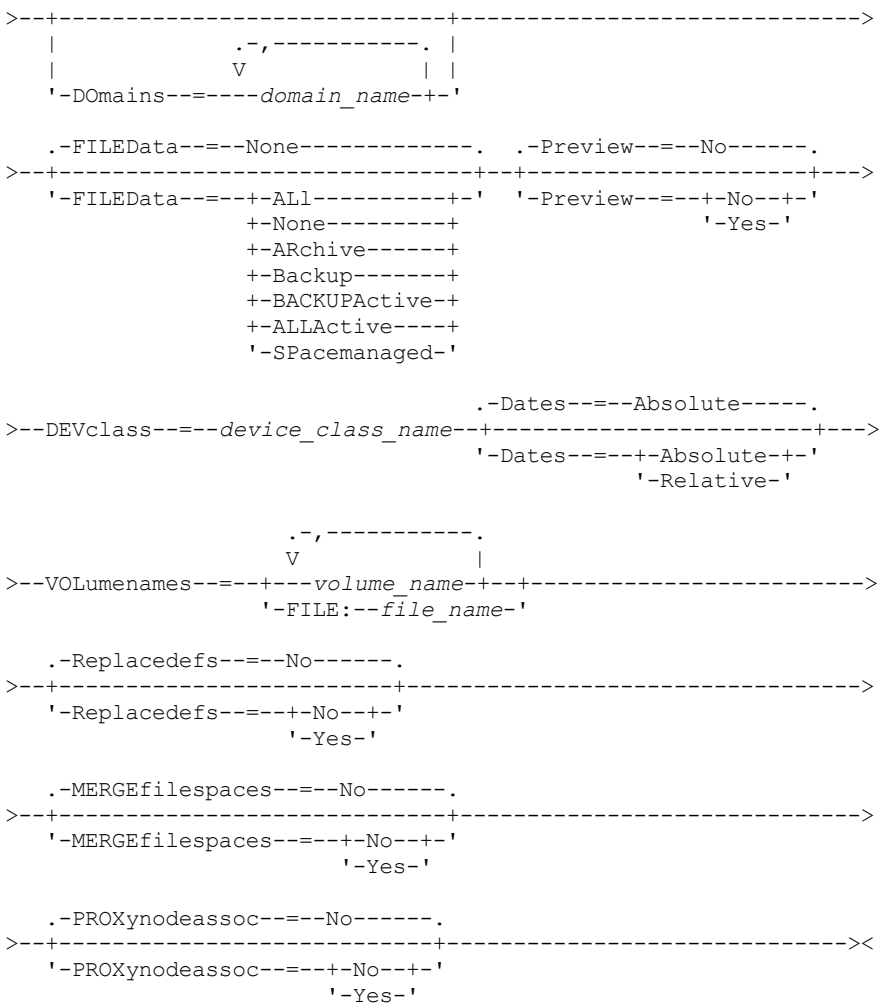
Limitation: The IBM Spectrum Protect server does not convert code pages during export, import, and node replication operations. If servers are running in different locales, some information in databases or system output might become unreadable. Invalid characters might be displayed, for example, in the contact information for the administrator and client nodes, and in descriptions of policy domains. Any field that is stored in the server character set and that includes extended ASCII characters can be affected. To resolve the issue after the import or node replication operation, update the fields with the appropriate UPDATE commands. This server limitation does not affect client data. Any client data that was exported, imported, or replicated can be restored, retrieved, and recalled.

Privilege class

To issue this command, you must have system privilege.

Syntax





Parameters

node_name
: Specifies the client nodes for which you want to import information. This parameter is optional.

  Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify names. All matching nodes are included in the list.

FILESpace
: Specifies file space names for which you want to import information. This parameter is optional. The default is all file spaces.

  Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify names.

  Important:

  1. Existing file spaces are not replaced. New file spaces are created when identical names are encountered. However, this new name might match an existing name on the client node, which can have file spaces that are not yet backed up to the server.
  2. This parameter is only specified for non-Unicode file spaces. To import all file spaces that are both Unicode and non-Unicode, use the FILEDATA=ALL parameter without the FILESPACE and UNIFILESPACE parameters.

DOmains
: Specifies the policy domains from which to import node information. These domains must be included in the data that was exported. This parameter is optional. The default is all domains that were exported.

  Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify a name.

FILEData

Specifies the type of files that can be imported for all nodes that are specified and found on the export media. This parameter is optional. The default value is NONE.

If you are importing from sequential media, the device class that is used by the file data is determined by the device class for the storage pool. If it is the same device class that is specified in this command, two drives are needed to import the node information. The mount limit for the device class must be at least 2.

The following descriptions mention *active* and *inactive* backup file copies. An active backup file copy is the most recent backup copy for a file that still exists on the client workstation. All other backup file copies are called inactive copies. The parameter supports the following values:

ALl
: The server imports all backup versions of files, all archived files, and all files that were migrated by an IBM Spectrum Protect for Space Management client. The file spaces that are included are both Unicode and non-Unicode.

None
: Only node definitions are imported. The server does not import any files.

ARchive
: The server imports only archived files.

Backup
: The server imports only backup versions, whether active or inactive.

BACKUPActive
: The server imports only active backup versions. These active backup versions are the active versions in the IBM Spectrum Protect database at the time that the IMPORT command is issued.

ALLActive
: The server imports all active backup versions of files, all archived files, and all files that were migrated by an IBM Spectrum Protect for Space Management client. The active backup versions are the active versions in the IBM Spectrum Protect database at the time that the IMPORT command is issued.

SPacemanaged
: The server imports only files that were migrated by an IBM Spectrum Protect for Space Management client.

Preview
: Specifies whether to preview the results of the import operation, without importing information. The PREVIEW=YES option requires that you mount the export volumes. The following values are supported:

  No
  : Specifies that the node information is to be imported.

  Yes
  : Specifies that you want to preview the results of the import operation, without importing files. Information is reported to the server console and the activity log.

  This parameter is optional. The default value is NO.

DEVclass (Required)
: Specifies the device class from which import data is to be read. You cannot specify the DISK, NAS, or CENTERA device classes.

  If all drives for the device class are busy when the import runs, the server cancels lower priority operations, such as identify duplicates, to make a drive available.

Dates
: Specifies whether the dates for the file copies are set as the same date when the files were exported, or is adjusted to the import date.
  This parameter supports the following values:

  Absolute
  : The dates for file copies are set to the values specified when the files were exported.

  Relative
  : The dates for file copies are adjusted to the import date.

  The default value is ABSOLUTE.

  If the export media is idle for some time after export, for example; if it is sitting on a shelf for six months, the original backup, or archive dates might be old enough to trigger the file copies to expire immediately when the data is imported into a server. The RELATIVE specification for this value adjusts for time that is elapsed since export so that the file copies are not immediately expired.

For example, assume that an export tape contains an archive file copy that was archived five days before the export operation. If the media is saved for six months and then imported, the archive file look like it is inserted six months and five days ago by default, the (DATES=ABSOLUTE) and might expire immediately depending on the retention value that is specified in the file's management class. Specifying DATES=RELATIVE results in resetting the archive date for the file to five days ago during import. The DATES=RELATIVE parameter thus adjusts file backup and archive dates for the time that elapsed since the export operation occurred.

VOLumenames (Required)
Specifies the volumes to be used for the import operation. Volumes must be imported in the same order as they were exported. The parameter supports the following values:

volume_name
Specifies the volume name. To specify multiple volumes, separate the names with commas and no intervening spaces.
FILE:file_name
Specifies the name of a file that contains a list of volumes that are used for the imported data. In the file, each volume name must be on a separate line. Blank and comment lines that begin with an asterisk are ignored.

Use these naming conventions when you specify volumes that are associated with the following device types:

For this device	Specify
Tape	1 - 6 alphanumeric characters.
FILE	AIX Linux Any fully qualified file name string. An example is /imdata/mt1. Windows Any fully qualified file name string. For example, d:\program files\tivoli\tsm\data1.dsm.
AIX Linux Windows REMOVABLEFILE	AIX Linux Windows 1 - 6 alphanumeric characters.
SERVER	1 - 250 alphanumeric characters.

Replacedefs
Specifies whether to replace definitions on the target server. The default value is NO. The parameter supports the following values:

No
Objects are not to be replaced.
Yes
Objects are to be replaced.

HEXFILESpace
Specifies the hexadecimal representation of the file space names in UTF-8 format. Separate multiple names with commas and no intervening spaces. This parameter is optional.

To view the hexadecimal representation of a file space name, you can use the QUERY FILESPACE command with FORMAT=DETAILED.

UNIFILESpace
Specifies that the file spaces that are known to the server are Unicode enabled. The server converts the names that you enter from the server code page to the UTF-8 code page to find the file spaces to import. The success of the conversion depends on the actual characters in the name and the server's code page. Separate multiple names with commas and no intervening spaces. A wildcard character can be used to specify a name. This parameter is optional.
MERGEfilespaces
Specifies whether IBM Spectrum Protect merges client files into existing file spaces on the target server (if they exist), or if IBM Spectrum Protect generates new file space names. The default is NO.

Valid values are:

Yes
Specifies that imported data on the target server is merged with the existing file space, if a file space with the same name exists on the target server.
No
Specifies that IBM Spectrum Protect generates a new file space name for imported data on the target server if file spaces with the same name exists.

PROXynodeassoc
Specifies whether proxy node associations are imported. This parameter is optional. The default value is NO.

Example: Import client node information from tapes

From the server, import client node information from tape volumes TAPE01, TAPE02, and TAPE03. Specify that these tape volumes be read by a device that is assigned to the MENU1 device class.

```
import node devclass=menu1 volumenames=tape01,tape02,tape03
```

Example: Import client node information from tapes listed in a file

AIX Linux From the server, import client node information from tape volumes that are listed in a file named TAPEVOL.

Windows From the server, import client node information from tape volumes that are listed in a file named TAPEVOL.DATA.

This file contains these lines:

```
TAPE01
TAPE02
TAPE03
```

Specify that these tape volumes be read by a device that is assigned to the MENU1 device class. AIX Linux

```
import node devclass=menu1 volumenames=file:tapevol
```

Windows

```
import node devclass=menu1 volumenames=file:tapevol.data
```

Example: Import the active backup for a client node

From the server, import the active backup versions of file data for client node JOE from tape volume TAPE01. The file space is Unicode.

```
import node joe unifilespace=\\joe\c$ filedata=backupactive devclass=menu1
    volumenames=tape01
```

Related commands

Table 1. Commands related to IMPORT NODE

Command	Description
CANCEL PROCESS	Cancels a background server process.
COPY ACTIVEDATA	Copies active backup data.
EXPORT NODE	Copies client node information to external media or directly to another server.
IMPORT ADMIN	Restores administrative information from external media.
IMPORT POLICY	Restores policy information from external media.
IMPORT SERVER	Restores all or part of the server from external media.
QUERY ACTLOG	Displays messages from the server activity log.
QUERY PROCESS	Displays information about background processes.

IMPORT POLICY (Import policy information)

Use this command to import policy domain information from sequential export media to the IBM Spectrum Protect™ server. IBM Spectrum Protect servers with retention protection enabled do not allow import operations.

IBM Spectrum Protect client data can be moved between servers with export and import processing, if the same removable media type is supported on both platforms.

Restriction:

1. If target and source server levels are not compatible, the import operation might not work.
2. Importing data from a CENTERA device class is not supported. However, files that are imported can be stored on a CENTERA storage device.

You can use the QUERY ACTLOG command to view the status of the import operation. You can also view this information from the server console.

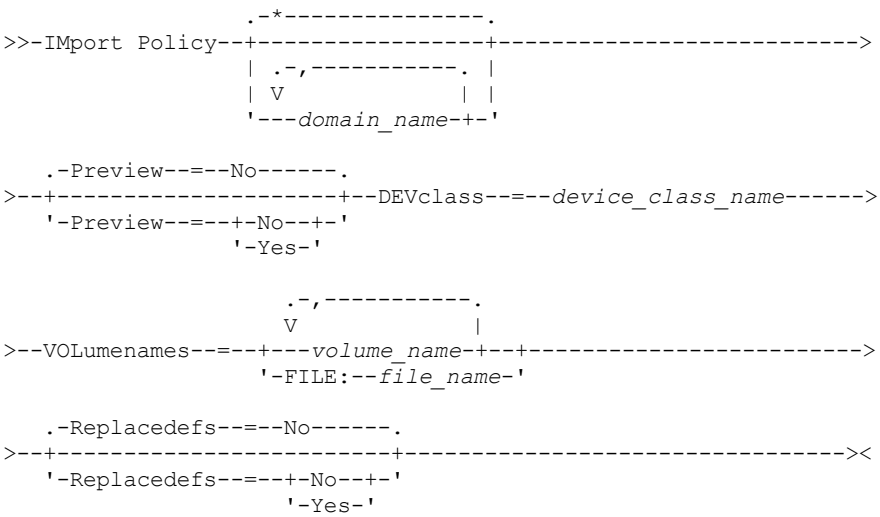
This command generates a background process that can be canceled with the CANCEL PROCESS command. If an IMPORT POLICY background process is canceled, some of the data is already imported. To display information about background processes, use the QUERY PROCESS command.

Limitation: The IBM Spectrum Protect server does not convert code pages during export, import, and node replication operations. If servers are running in different locales, some information in databases or system output might become unreadable. Invalid characters might be displayed, for example, in the contact information for the administrator and client nodes, and in descriptions of policy domains. Any field that is stored in the server character set and that includes extended ASCII characters can be affected. To resolve the issue after the import or node replication operation, update the fields with the appropriate UPDATE commands. This server limitation does not affect client data. Any client data that was exported, imported, or replicated can be restored, retrieved, and recalled.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

domain_name
: Specifies the policy domains for which information is to be imported. Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify names. The default (*) is all policy.

Preview
: Specifies whether you want to preview the results of the import operation without importing information.This parameter supports the following values:

  No
  : Specifies that the information is to be imported.

  Yes
  : Specifies that the operation is previewed but not completed. Information is reported to the server console and the activity log.

  The PREVIEW=YES option requires that you mount the export volumes. This parameter is optional. The default value is NO.

DEVclass (Required)

Specifies the device class from which import data is to be read. You cannot specify the DISK, NAS, or CENTERA device classes.

If all drives for the device class are busy when the import runs, IBM Spectrum Protect cancels lower priority operations, such as reclamation, to make a drive available.

VOLumenames (Required)
Specifies the volumes to be used for the import operation. Volumes must be imported in the same order as they were exported. This parameter supports the following values:

volume_name
Specifies the volume name. To specify multiple volumes, separate the names with commas and no intervening spaces.
FILE:file_name
Specifies the name of a file that contains a list of volumes. In the file, each volume name must be on a separate line. Blank and comment lines that begin with an asterisk are ignored.

Use these naming conventions when you specify volumes that are associated with the following device types:

For this device	Specify
Tape	1 - 6 alphanumeric characters.
FILE	Any fully qualified file name string. For example: • AIX Linux /imdata/mt1 • Windows d:\program files\tivoli\tsm\data1.dsm.
AIX Linux Windows REMOVABLEFILE	AIX Linux Windows 1 - 6 alphanumeric characters.
SERVER	1 - 250 alphanumeric characters.

Replacedefs
Specifies whether to replace policy definitions on the target server. This parameter supports the following values:

Yes
Specifies that objects are to be replaced by the imported objects.
No
Specifies that objects are not to be replaced by imported objects.

The default value is NO.

Example: Import policy information from specific tape volumes

From the server, import the information for all defined policies from tape volumes TAPE01, TAPE02, and TAPE03. Specify that these tape volumes be read by a device that is assigned to the MENU1 device class.

```
import policy devclass=menu1
volumenames=tape01,tape02,tape03
```

Example: Import policy information from tape volumes listed in a file

From the server, import the information for all defined policies from tape volumes that are listed in a file that is named thus:

- AIX Linux TAPEVOL
- TAPEVOL.DATA

Specify that these tape volumes be read by a device that is assigned to the MENU1 device class. The file contains the following lines:

```
TAPE01
TAPE02
TAPE03
```

AIX Linux

```
import policy devclass=menu1 volumenames=file:tapevol
```

Windows

```
import policy devclass=menu1 volumenames=file:tapevol.data
```

Related commands

Table 1. Commands related to IMPORT POLICY

Command	Description
CANCEL PROCESS	Cancels a background server process.
EXPORT POLICY	Copies policy information to external media or directly to another server.
IMPORT ADMIN	Restores administrative information from external media.
IMPORT NODE	Restores client node information from external media.
IMPORT SERVER	Restores all or part of the server from external media.
QUERY ACTLOG	Displays messages from the server activity log.
QUERY PROCESS	Displays information about background processes.

IMPORT SERVER (Import server information)

Use this command to copy all or part of the server control information and specified client file data from export media to the IBM Spectrum Protect™ server.

Important: For commands that import administrators or nodes, you must consider the method of authentication. The IBM Spectrum Protect server cannot export or import passwords for nodes or administrators that are authenticating with LDAP directory servers. If the current authentication method uses an LDAP directory server and the password is not already synchronized by that server, you must update the password. After issuing the IMPORT command, set the password by issuing the UPDATE ADMIN or UPDATE NODE command.

IBM Spectrum Protect servers with retention protection enabled do not allow import operations.

Restrictions:

- If target and source server levels are not compatible, the operation might not work.
- Importing data from a CENTERA device class is not supported. However, files that are imported can be stored on a CENTERA storage device.
- If you use an LDAP directory server to authenticate passwords, any target servers must be configured for LDAP passwords. Server data that is exported from a node that authenticates with an LDAP directory server is inaccessible if the target server is not properly configured. If your target server is not configured, exported data from an LDAP node can still go there. But the target server must be configured to use LDAP in order for you to access the data.

- Incrementally exporting or importing the following types of client data to another IBM Spectrum Protect server is not supported:
  - VMware backups where full plus incremental backups need to be periodically, incrementally transferred to another server
  - Backups groups where full plus differential backups must be periodically, incrementally transferred to another server
  - Windows System State data that is periodically, incrementally transferred to another server

  Full export or import of this data to a new file system on the target is supported by exporting the entire file space that contains the data. The export must not use the FILEDATA=ALLACTIVE, FROMDATE, TODATE, or MERGEFILESPACES parameters.

  Using node replication to incrementally transfer this type of client data between two servers is optimal.

You can also initiate an import of server information and client file data directly from the originating server. For more information, see the EXPORT commands.

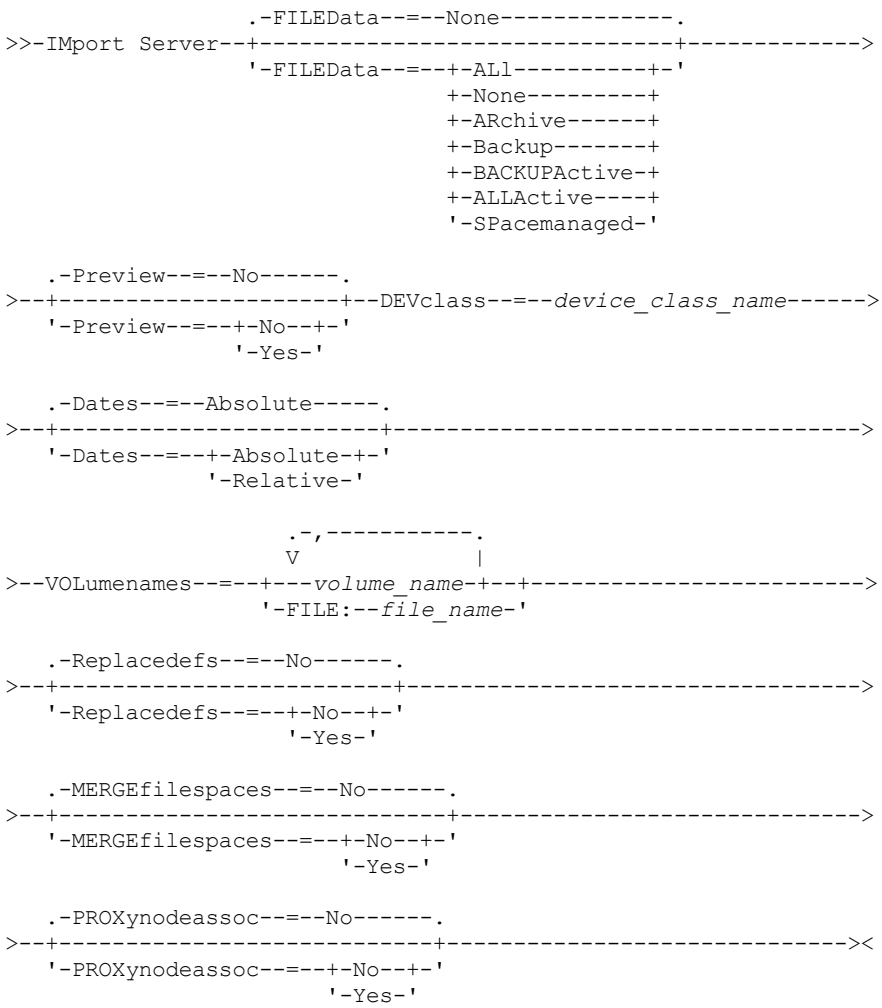
This command generates a background process that can be canceled with the CANCEL PROCESS command. If an IMPORT SERVER background process is canceled, some of the data is already imported. To display information about background processes, use the QUERY PROCESS command.

Limitation: The IBM Spectrum Protect server does not convert code pages during export, import, and node replication operations. If servers are running in different locales, some information in databases or system output might become unreadable. Invalid characters might be displayed, for example, in the contact information for the administrator and client nodes, and in descriptions of policy domains. Any field that is stored in the server character set and that includes extended ASCII characters can be affected. To resolve the issue after the import or node replication operation, update the fields with the appropriate UPDATE commands. This server limitation does not affect client data. Any client data that was exported, imported, or replicated can be restored, retrieved, and recalled.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

FILEData

Specifies the type of files that can be imported for all nodes that are defined to the server. This parameter is optional. The default value is NONE.

The device class that is used to access the file data is determined by the device class for the storage pool. If it is the same device class that is specified in this command, two drives are needed to import information. The mount limit for the device class must be set to at least 2.

The following descriptions mention active and inactive backup file copies. An active backup file copy is the most recent backup copy for a file that still exists on the client workstation. All other file copies are called inactive copies. This parameter supports the following values:

ALl
: IBM Spectrum Protect imports all backup versions of files, all archived files, and all files that were migrated by an IBM Spectrum Protect for Space Management client.

None
: IBM Spectrum Protect does not import files, only node definitions.

ARchive
: IBM Spectrum Protect imports only archived files.

Backup
: IBM Spectrum Protect imports only backup versions, whether the versions are active or inactive.

BACKUPActive
: IBM Spectrum Protect imports only active backup versions. These active backup versions are the active versions in the IBM Spectrum Protect database at the time that the IMPORT command is issued.

ALLActive
: IBM Spectrum Protect imports all active backup versions of files, all archived files, and all files that were migrated by an IBM Spectrum Protect for Space Management client. The active backup versions are the active versions in the IBM Spectrum Protect database at the time that the IMPORT command is issued.

SPacemanaged
: IBM Spectrum Protect imports only files that were migrated by an IBM Spectrum Protect for Space Management client.

Preview
: Specifies whether to preview the results of the import operation, without importing information. This parameter supports the following values:

  No
  : Specifies that the server information is to be imported.

  Yes
  : Specifies that the operation is previewed but not completed. Information is transferred to the server console and the activity log.

  This parameter is optional. The default value is NO. If the PREVIEW=YES option is specified, you must mount the export volumes.

DEVclass (Required)
: Specifies the device class from which import data is to be read. You cannot specify the DISK, NAS, or CENTERA device classes.

  If all drives for the device class are busy when the import runs, IBM Spectrum Protect cancels lower priority operations, such as reclamation, to make a drive available.

Dates
: Specifies whether the dates for the file copies are set as the same date when the files were exported, or is adjusted to the import date.

  If the import media is idle for some time after export, for example; if it is sitting on a shelf for six months, the original backup, or archive dates might be old enough to trigger the file copies to expire immediately when the data is imported into a server. The RELATIVE specification for this value adjusts for time that is elapsed since export so that the file copies are not immediately expired.

  For example, assume that an import tape contains an archive file copy that was archived five days before the export operation. If the export media are saved for six months and then imported, the archive file looks like it is inserted six months and five days ago by default (DATES=ABSOLUTE) and might expire immediately depending upon the retention value that is specified in the file's management class. Specifying DATES=RELATIVE results in resetting the archive date for the file to five days ago during import. DATES=RELATIVE parameter thus adjusts file backup and archive dates for the time that elapsed since the export operation occurred.

  This parameter supports the following values:

  Absolute
  : The dates for file copies are set to the values specified when the files were exported.

  Relative
  : The date for file copies are adjusted to the date of import.

  The default value is ABSOLUTE.

VOLumenames (Required)

Specifies the volumes to be used for the import operation. Volumes must be imported in the same order as they were exported. This parameter supports the following values:

volume_name
: Specifies the volume name. To specify multiple volumes, separate the names with commas and no intervening spaces.

FILE:file_name
: Specifies the name of a file that contains a list of volumes that are used for the imported data. In the file, each volume name must be on a separate line. Blank and comment lines that begin with an asterisk are ignored.

Use these naming conventions when you specify volumes that are associated with the following device types:

For this device	Specify
Tape	1 - 6 alphanumeric characters.
FILE	AIX Linux Any fully qualified volume or file name string. An example is /imdata/mt1. Windows Any fully qualified volume or file name string. For example, d:\program files\tivoli\tsm\data1.dsm.
AIX Linux Windows REMOVABLEFILE	AIX Linux Windows 1 - 6 alphanumeric characters.
SERVER	1 - 250 alphanumeric characters.

Replacedefs
: Specifies whether to replace objects on the server. Existing file spaces are not replaced. New file spaces are created when identical names are encountered. This parameter supports the following values:

No
: Specifies that objects are not to be replaced by imported objects.

Yes
: Specifies that objects are to be replaced by the imported objects.

The default value is NO.

MERGEfilespaces
: Specifies whether IBM Spectrum Protect merges client files into existing file spaces on the target server (if they exist), or if IBM Spectrum Protect generates new file space names. You cannot merge non-Unicode and Unicode file spaces together. This parameter supports the following values:

No
: Specifies that IBM Spectrum Protect generates a new file space name for imported data on the target server if file spaces with the same name exist.

Yes
: Specifies that imported data on the target server is merged with the existing file space, if a file space with the same name exists on the target server.

The default is NO.

PROXynodeassoc
: Specifies whether proxy node associations are imported. This parameter is optional. The default value is NO.

Example: Import the information for all defined servers from specific tapes

From the server, import the information for all defined servers from tape volumes TAPE01, TAPE02, and TAPE03. Specify that these tape volumes be read by a device that is assigned to the MENU1 device class.

```
import server devclass=menu1 volumenames=tape01,tape02,tape03
```

AIX Linux

Example: Import information for all defined servers from specific tapes and specify files are merged into existing file spaces

From the server, import the information for all defined servers from tape volumes TAPE01, TAPE02, and TAPE03. Specify that these tape volumes be read by a device that is assigned to the MENU1 device class and that client files be merged into file spaces on the target server if file spaces of the same names exist.

```
import server devclass=menu1 volumenames=tape01,tape02,tape03 mergefilespaces=yes
```

Example: Import information for all defined servers from tapes listed in a file

From the server, import the information for all defined servers from tape volumes that are listed in a file named TAPEVOL. Specify that the tape volumes are read by a device that is assigned to the MENU1 device class. The input file contains these lines:

```
TAPE01
TAPE02
TAPE03

import server devclass=menu1 volumenames=file:tapevol
```

Windows

Example: Import information for all defined servers from tapes listed in a file

From the server, import the information for all defined servers from tape volumes that are listed in a file named TAPEVOL.DATA. Specify that the tape volumes are read by a device that is assigned to the MENU1 device class. The input file contains these lines:

```
TAPE01
TAPE02
TAPE03

import server devclass=menu1 volumenames=file:tapevol.data
```

Related commands

Table 1. Commands related to IMPORT SERVER

Command	Description
CANCEL PROCESS	Cancels a background server process.
COPY ACTIVEDATA	Copies active backup data.
EXPORT SERVER	Copies all or part of the server to external media or directly to another server.
IMPORT ADMIN	Restores administrative information from external media.
IMPORT NODE	Restores client node information from external media.
IMPORT POLICY	Restores policy information from external media.
QUERY ACTLOG	Displays messages from the server activity log.
QUERY PROCESS	Displays information about background processes.

INSERT MACHINE (Insert machine characteristics information or recovery instructions)

Use this command to add client machine characteristics or recovery instructions to existing machine information in the database.

You can write a program to read files containing the information and generate the appropriate INSERT MACHINE commands.

You can use QUERY commands to retrieve the information if a disaster occurs.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-INsert MAchine--machine_name--sequence_number---------------->

>--+-CHaracteristics--=--text------+-------------------------><
```

```
'-RECOVERYInstructions--=--text-'
```

Parameters

machine_name (Required)
: Specifies the name of the client machine.

sequence_number (Required)
: Specifies the sequence number for the line of text in the database.

CHaracteristics
: Specifies machine characteristics information. You must specify the characteristics or recovery instructions, but not both. Enclose the text in quotation marks if it contains blank characters. The text can be up to 1024 characters.

RECOVERYInstructions
: Specifies recovery instructions. You must specify the characteristics or recovery instructions, but not both. Enclose the text in quotation marks if it contains blank characters. The text can be up to 1024 characters.

Example: Update a machine's information

For the machine DISTRICT5, insert this characteristics text on line 1: "Machine owner is Mary Smith".

```
insert machine district5 1
characteristics="Machine owner is Mary Smith"
```

Related commands

Table 1. Commands related to INSERT MACHINE

Command	Description
DEFINE MACHINE	Defines a machine for DRM.
DELETE MACHINE	Deletes a machine.
QUERY MACHINE	Displays information about machines.

Related information:

Specifying information about your server and client node machines

ISSUE MESSAGE (Issue a message from a server script)

Use this command with return code processing in a script to issue a message from a server script to determine where the problem is with a command in the script.

Privilege class

Any administrator can issue this command.

Syntax

```
>>-ISSUE MESSAGE--message_severity--message_text--------------><
```

Parameters

message_severity (Required)
: Specifies the severity of the message. The message severity indicators are:

  I
  : Information. ANR1496I is displayed in the message text.

  W
  : Warning. ANR1497W is displayed in the message text.

  E
  : Error. ANR1498E is displayed in the message text.

  S

Severe. ANR1499S is displayed in the message text.

message_text (Required)
Specifies the description of the message.

Example: Issue a message from a server script

Assume you have a script called backupscript that quiesces a client's database, takes a backup of that database, and then restarts the client's database. For illustration, your script results in a non-zero return code. Use the ISSUE MESSAGE command with the message severity and message text. The following is an example of a server script that calls backupscript on the client machine and issues messages based on the return code from backupscript.

```
issue message i "Starting backup"
define clientaction nodename action=command objects="c:\backupscript" wait=yes
if (101) goto qfail
if (102) goto qwarn
if (103) goto backupf
if (104) goto restartf
issue message i "Backup of database complete"
exit
qfail: issue message e "Quiesce of database failed"
exit
qwarn: issue message w "Quiesce of database failed, taking fuzzy backup"

exit
backupf: issue message e "Backup of database failed"
exit
restartf: issue message s "Database restart failed"
exit
```

Command
```
issue message e "quiesce of database failed"
```

Related commands

Table 1. Commands related to ISSUE MESSAGE

Command	Description
COPY SCRIPT	Creates a copy of a script.
DEFINE SCRIPT	Defines a script to the IBM Spectrum Protect server.
DELETE SCRIPT	Deletes the script or individual lines from the script.
RENAME SCRIPT	Renames a script to a new name.
RUN	Runs a script.
UPDATE SCRIPT	Changes or adds lines to a script.

LABEL LIBVOLUME (Label a library volume)

Use this command to label tape volumes or, in an automated library, to label the volumes automatically as they are checked in. With this command, the server uses the full-length label with which the volumes are often prelabeled.

Restriction: Use this command only for MANUAL, SCSI, ACSLS, and 349X libraries. The command processing does not wait for a drive to become available, even if the drive is only in the IDLE state. If necessary, you can make a library drive available by issuing the DISMOUNT VOLUME command to dismount the volume in that particular drive. When the library drive becomes available, you can reissue the LABEL LIBVOLUME command.
For detailed and current drive and library support information, see the Supported Devices website for your operating system:

- AIX Windows Supported devices for AIX and Windows
- Linux Supported devices for Linux

AIX Linux

To use the LABEL LIBVOLUME command, at least one drive must exist that is not in use by another IBM Spectrum Protect™ process. This includes idle volumes that are mounted. If necessary, use the DISMOUNT VOLUME command to dismount the idle

volume to make that drive available.

By default, the LABEL LIBVOLUME command does not overwrite an existing label. However, if you want to overwrite an existing label, you can specify the `OVERWRITE=YES` option.

Attention:

- By overwriting a volume label, you destroy all data on the volume. Use caution when you overwrite volume labels to avoid deleting valid data.
- The labels on VolSafe volumes can be overwritten only once. Therefore, use the LABEL LIBVOLUME command only once for VolSafe volumes. You can guard against overwriting the label by using the `OVERWRITE=NO` option with the LABEL LIBVOLUME command.

When you use the LABEL LIBVOLUME command, you can identify the volumes to be labeled in one of the following ways:

- Explicitly name one volume.
- Enter a range of volumes by using the VOLRANGE parameter.
- Use the VOLLIST parameter to specify a file that contains a list of volume names or to explicitly name one or more volumes.

For automated libraries, you are prompted to insert the volume in the entry/exit slot of the library. If no I/O convenience station is available, insert the volume into an empty slot. For manual libraries, you are prompted to load the volume directly into a drive.

Tip: To automatically label tape volumes, you can use the AUTOLABEL parameter on the DEFINE LIBRARY and UPDATE LIBRARY commands. By using the AUTOLABEL parameter, you eliminate the need to pre-label a set of tapes. This method is more efficient than using the LABEL LIBVOLUME command, which requires you to mount volumes separately. If you use the AUTOLABEL parameter with a SCSI library, you must check in tapes by specifying `CHECKLABEL=BARCODE` on the CHECKIN LIBVOLUME command. The AUTOLABEL parameter defaults to YES for all non-SCSI libraries and to NO for SCSI libraries.
Windows

To label volumes with the LABEL LIBVOLUME command, specify the CHECKIN parameter.

To automatically label tape volumes in SCSI-type libraries, use the AUTOLABEL parameter on the DEFINE LIBRARY and UPDATE LIBRARY commands. By using this parameter, you eliminate the need to pre-label a set of tapes. This method is also more efficient than using the LABEL LIBVOLUME command, which requires you to mount volumes separately. If you use the AUTOLABEL parameter, you must check in tapes by specifying CHECKLABEL=BARCODE on the CHECKIN LIBVOLUME command.

A label cannot include embedded blanks or periods and must be valid when used as a file name on the media.

You must label CD-ROM, Zip, or Jaz volumes with the device utilities from the manufacturer or the Windows utilities. IBM Spectrum Protect does not provide utilities to format or label these media types. The operating system utilities include the Disk Administrator program (a graphical user interface) and the label command.

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax for a manual library

```
>>-LABEl LIBVolume--library_name------volume_name--------------->

   .-OVERWRITE---=--No------.  .-WAITTime--=--60----.
>--+----------------------+--+--------------------+-----------><

```

```
'-VOLList--=--+---volume_name-+--+-----------'
              '-FILE:--file_name-'
```

Parameters

library_name (Required)
: Specifies the name of the library that contains the storage volume.

volume_name
: Specifies the name of the volume to be labeled.

  - For SCSI libraries: The server requests that the volume is inserted into a slot in the library or, if available, into an entry/exit port. The server identifies a slot by the slot's element address. If you are labeling a volume in a SCSI library with multiple entry/exit ports, the volume in the lowest numbered slot is labeled.
    Warning: If you specify a volume name, the name you specify overrides the label that is printed on the cartridge.
  - For MANUAL libraries: The server requests that the volume is inserted into a drive.
  - For 349X libraries: The volume might already be in the library, or you might be prompted to put it into the I/O station.

  Remember: If the specified volume name is already defined in a storage pool or in a volume history file, the volume is not labeled, and a message is displayed.

CHECKIN
: Specifies whether the server checks in the volume. This parameter is optional. The following are possible values:

  SCRatch
  : Specifies that the server checks in the volumes and adds them to the library's scratch pool. If a volume has an entry in volume history, you cannot check it in as a scratch volume.

  PRIvate
  : Specifies that the server checks in the volumes and designates them as private. Private volumes are available only when you request them by name.

  If you do not specify a value for this parameter, the command labels the volume, but does not check it in. If you do not specify a value for this parameter and you want to check in the volume, you must issue the CHECKIN LIBVOLUME command.

SEARCH
: Specifies that the server searches the library for usable volumes to label. This parameter applies to SCSI, 349X, and ACSLS libraries.
  The following values are valid:

  Yes
  : Specifies that the server labels only volumes that are stored in the library, unless the volume is already labeled or its bar code cannot be read.

    If you specify the `LABELSOURCE=PROMPT` option, the volume is moved into the drive from its location in the library or entry and exit ports. The server prompts you to issue the REPLY command that contains the label string, and that label is written to the tape.

  Bulk
  : Specifies that the server searches the library entry/exit ports for usable volumes to label. This option is only valid for SCSI libraries.

    If you specify LABELSOURCE=BARCODE, the volume bar code is read. Then, the tape is moved from its location in the library or in the entry/exit ports to a drive where the bar code label is written. After the tape is labeled, it is moved back to its location in the library, to the entry/exit ports, or to a storage slot if the CHECKIN option is specified. For bar code support to work correctly for libraries that are supported by IBM Spectrum Protect, the IBM Spectrum Protect server and the device driver must be at the same level. Bar code support is available for libraries that are supported by IBM Spectrum Protect and that use the IBM Spectrum Protect device driver or the IBM® Magstar® or LTO Ultrium device driver.

    Tip: You can use the VOLRANGE or VOLLIST parameter to limit the search.

VOLRange
: Specifies a range of volume names that are separated by a comma. Use this parameter to limit the search for volumes to be labeled when you specify SEARCH=YES (349X, ACSLS, and SCSI libraries) or SEARCH=BULK (SCSI libraries only). If there are no volumes in the library that are within the specified range, the command completes without errors.

You can specify only volume names that can be numerically incremented. In addition to the incremental area, a volume name can include an alphanumeric prefix and an alphanumeric suffix, for example:

Parameter	Description
`volrange=bar110,bar130`	The 21 volumes are labeled: bar110, bar111, bar112,...bar129, bar130.
`volrange=bar11a,bar13a`	The 3 volumes are labeled: bar11a, bar12a, bar13a.
`volrange=123400,123410`	The 11 volumes are labeled: 123400, 123401, ...123409, 123410.

VOLList

Specifies a list of volumes. Use this parameter to limit the search for volumes to be labeled when you specify SEARCH=YES (349X, ACSLS, and SCSI libraries) or SEARCH=BULK (SCSI libraries only). If there are no volumes in the library that are in the list, the command completes without errors. The VOLLIST parameter can also be the source of names to be used to label volumes if the LABELSOURCE parameter is set to VOLLIST. If LABELSOURCE=VOLLIST, you must specify the VOLLIST parameter.

The following values are valid:

volume_name

Specifies the names of one or more values that are used for the command. For example: `VOLLIST=TAPE01,TAPE02`.

FILE:file_name

Specifies the name of a file that contains a list of volumes for the command. In the file, each volume name must be on a separate line. Blank lines and comment lines that begin with an asterisk are ignored. For example, to use volume TAPE01, TAPE02 and TAPE03, create a file that is named TAPEVOL that contains these lines:

```
TAPE01
TAPE02
TAPE03
```

You can specify the volumes for the command as follows: `VOLLIST=FILE:TAPEVOL`.

Remember: The file name is case-sensitive.

LABELSource

Specifies how or whether the server reads sequential media labels of volumes. This option is only valid for SCSI libraries. Specify this parameter only when SEARCH=YES or SEARCH=BULK.

You can specify the following values:

Prompt

The server prompts for volume names as necessary.

Barcode

The server attempts to read the bar code label. If the attempt fails, the server does not label the volume and displays a message.

Important: For bar code support to work properly, the appropriate device drivers must be installed for the libraries.

Vollist

This option applies only to SCSI libraries. The server attempts to read the specified file or list of files. If the attempt fails, the server does not label the volumes and displays a message.

OVERWRITE

Specifies whether the server attempts to overwrite existing labels. This parameter is optional. The default is NO. You can specify the following values:

No

Specifies that the server labels only unlabeled volumes. For StorageTek VolSafe volumes, the value must be NO.

Yes

Specifies that the server overwrites existing labels only if both the existing label and the prompted or bar code label are not already defined in either the server storage pool or volume history list.

WAITTime

Specifies the number of minutes that the server waits for you to reply or respond to a request. Specify a value in the range 0-9999. If you want to be prompted by the server, specify a wait time greater than zero. The default value is 60 minutes. For example, suppose that the server prompts you to insert a tape into the entry/exit port of a library. If you specified a wait time of 60 minutes, the server issues a request and wait 60 minutes for you to reply. Alternatively, suppose that you specify

a wait time of 0. If you inserted a tape, a wait time of zero causes the operation to continue without prompting. If you did not insert a tape, a wait time of zero causes the operation to fail.

Example: Automatically label library volumes

Label tapes in a SCSI library named `AUTO` automatically as you are checking in the volumes.

```
label libvolume auto checkin=scratch search=yes labelsource=barcode
overwrite=yes
```

Example: Label sequential library volumes

Label 3 volumes from `bar11a` to `bar13a` in a SCSI library named ABC. When you issue the following command, the three volumes are labeled: `bar11a`, `bar12a`, `bar13a`.

```
label libvolume abc checkin=scratch search=yes volrange=bar11a,bar13a
labelsource=barcode
```

Related commands

Table 1. Commands related to LABEL LIBVOLUME

Command	Description
AUDIT LIBRARY	Ensures that an automated library is in a consistent state.
CANCEL PROCESS	Cancels a background server process.
CHECKIN LIBVOLUME	Checks a storage volume into an automated library.
CHECKOUT LIBVOLUME	Checks a storage volume out of an automated library.
DEFINE LIBRARY	Defines an automated or manual library.
DEFINE VOLUME	Assigns a volume to be used for storage within a specified storage pool.
QUERY LIBRARY	Displays information about one or more libraries.
QUERY LIBVOLUME	Displays information about a library volume.
QUERY PROCESS	Displays information about background processes.
REPLY	Allows a request to continue processing.
UPDATE LIBVOLUME	Changes the status of a storage volume.

LOAD DEFALERTTRIGGERS (Load the default set of alert triggers)

Use this command to load the default set of alert triggers to the IBM Spectrum Protect™ server.

For a newly installed server, a default set of messages is defined to trigger alerts. You can modify or delete default alert triggers. Use this command to complete the following tasks:

- Load the default set of alert triggers, restoring any that were deleted.
- Replace all alert triggers with the original default set.

By default, this command does not delete other alert triggers that were created, and does not replace default alert triggers that were modified. To delete all alert triggers and restore the original set of default alert triggers, specify RESET=yes.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                          .-REset--=--No------.
>>-LOad DEFALerttriggers--+-------------------+----------------><
```

```
'-REset--=--+-No--+-'
            '-Yes-'
```

Parameters

REset
: Specifies whether you want to replace all of your alert triggers with the default set of alert triggers. This parameter is optional. The default value is No. Possible values are:

  No
  : Specifies that the default alert triggers are added only. The original default alert triggers are added to the server. Existing triggers are not deleted. If a default trigger exists on the server, it is not replaced or modified.

  Yes
  : Specifies that the alert triggers are restored to the original defaults. All alert triggers are deleted and then the original set of default alert triggers are added.

Example: Load the default alert triggers on the server

Load the default triggers to restore any that were deleted. Issue the command:

```
load defalerttriggers
```

Example: Replace all alert triggers on the server with the default alert triggers

Delete all alert triggers on the server and replace them with the original defaults. Issue the command:

```
load defalerttriggers reset=yes
```

Related commands

Table 1. Commands related to LOAD DEFALERTTRIGGERS

Command	Description
DEFINE ALERTTRIGGER (Define an alert trigger)	Associates specified messages to an alert trigger.
DELETE ALERTTRIGGER (Remove a message from an alert trigger)	Removes a message number that can trigger an alert.
QUERY ALERTTRIGGER (Query the list of defined alert triggers)	Displays message numbers that trigger an alert.
UPDATE ALERTTRIGGER (Update a defined alert trigger)	Updates the attributes of one or more alert triggers.

LOCK commands

Use the LOCK command to prevent users from accessing the server.

- LOCK ADMIN (Lock out an administrator)
- LOCK NODE (Lock out a client node)
- LOCK PROFILE (Lock a profile)

LOCK ADMIN (Lock out an administrator)

Use this command to prevent an administrator from accessing the server. The administrator is locked out until a system administrator uses the UNLOCK ADMIN command to reestablish access for the administrator.

You can use the authentication filter to lock all administrators, excluding console administrators. After configuring an LDAP directory server for password authentication, you can lock administrators to force them to create passwords that authenticate with an LDAP server.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-LOCK Admin--+-*----------+--+------------------------------+->< 
               '-admin_name-'  '-AUTHentication--=--+-LOcal-+-'
                                                    '-LDap--'
```

Parameters

admin_name (Required)
: Specifies the name of the administrator to be locked out. You can use wildcard characters to specify the administrator name. You do not have to enter an administrator name if you want to lock all of the administrators according to their authentication method. Use the wildcard with an authentication method to lock multiple administrators.

AUTHentication
: Specifies the method of authentication that the administrator uses to log in.

  LOcal
  : Specifies to lock administrators who authenticate to the IBM Spectrum Protect™ server.

  LDap
  : Specifies to lock administrators who authenticate to the LDAP directory server.

Example: Lock out an administrator

Lock out the administrator CLAUDIA. Issue the command:

```
lock admin claudia
```

Example: Lock out all administrators who authenticate to the IBM Spectrum Protect server database

Use the wildcard character (*) to lock all the administrators who authenticate their passwords locally. Console administrators are not affected by this command. Issue the following command:

```
lock admin * authentication=local
```

Related commands

Table 1. Commands related to LOCK ADMIN

Command	Description
QUERY ADMIN	Displays information about one or more IBM Spectrum Protect administrators.
UNLOCK ADMIN	Enables a locked administrator to access IBM Spectrum Protect.

LOCK NODE (Lock out a client node)

Use this command to prevent a client node from accessing the server. A locked client node cannot perform any IBM Spectrum Protect™ operations, even if the operations are scheduled.

After configuring an LDAP directory server for password authentication, you can lock nodes to force them to use passwords that authenticate with an LDAP server.

Privilege class

To issue this command, you must have system privilege, unrestricted policy privilege, or restricted policy privilege for the policy domain to which the client node belongs.

Syntax

```
>>-LOCK Node--+-*---------+--+------------------------------+--><
             '-node_name-'  '-AUTHentication--=--+-LOcal-+-'
                                                 '-LDap--'
```

Parameters

node_name
: Specifies the name of the client node to lock out. You can use a wildcard character instead of a node name if you want to lock all of the nodes according to their method of authentication.

AUTHentication
: Specifies the method of password authentication that is needed to log into a node.

  LOcal
  : Specifies to lock nodes that authenticate with the IBM Spectrum Protect server.

  LDap
  : Specifies to lock nodes that authenticate with an LDAP directory server.

Example: Lock a specific client node

Lock the client node SMITH.

```
lock node smith
```

Example: Lock all nodes that authenticate to the local IBM Spectrum Protect database

Issue the following command to lock all nodes that authenticate with the IBM Spectrum Protect server:

```
lock node * authentication=local
```

Related commands

Table 1. Commands related to LOCK NODE

Command	Description
QUERY NODE	Displays partial or complete information about one or more clients.
UNLOCK NODE	Enables a locked user in a specific policy domain to access the server.

LOCK PROFILE (Lock a profile)

Use this command on a configuration manager to temporarily lock a profile so that configuration information is not distributed to subscribing managed servers.

You can use this command when you are making multiple updates to your configuration and do not want to distribute this information until the changes are completed.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
                              .-60------.
>>-LOCK PROFIle--profile_name--+---------+---------------------><
                              '-minutes-'
```

Parameters

profile_name (Required)
: Specifies the profile to lock. You can use wildcard characters to indicate multiple names.

minutes
: Specifies the time, in minutes, before IBM Spectrum Protect™ unlocks the configuration profile. Specify an integer from 0 to 10000. The default is 60 minutes. If you specify 0, the configuration profile will not unlock automatically. Use the UNLOCK PROFILE command to unlock the profile before the time period elapses, or to unlock it if you have specified a value of 0. This parameter is optional.

Example: Lock a profile for a specific amount of time

Lock a profile named DELTA for 30 minutes.

```
lock profile delta 30
```

Related commands

Table 1. Commands related to LOCK PROFILE

Command	Description
COPY PROFILE	Creates a copy of a profile.
DEFINE PROFASSOCIATION	Associates objects with a profile.
DEFINE PROFILE	Defines a profile for distributing information to managed servers.
DELETE PROFASSOCIATION	Deletes the association of an object with a profile.
DELETE PROFILE	Deletes a profile from a configuration manager.
QUERY PROFILE	Displays information about configuration profiles.
SET CONFIGMANAGER	Specifies whether a server is a configuration manager.
UNLOCK PROFILE	Enables a locked profile to be distributed to managed servers.
UPDATE PROFILE	Changes the description of a profile.

MACRO (Invoke a macro)

Use this command to invoke a file from the administrative command line that contains one or more IBM Spectrum Protect™ administrative commands to be performed.

Restriction: Use this command with administrative command-line clients only.

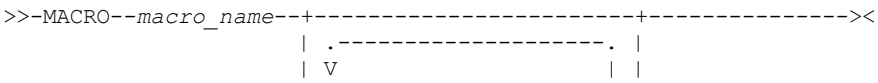
A macro is a file that contains one or more IBM Spectrum Protect administrative commands. You can only issue a macro from the administrative client in batch or interactive mode. A macro is stored as a file on the administrative client machine (or system). Macros are not distributed across servers and cannot be scheduled on the server.

Creating a macro to enter commands can be helpful when you want to issue commands that are used repeatedly, to issue commands that contain several parameters, or to process related commands in a specific order. After you create a macro, you can update the information it contains and use it again, or you can copy the macro file, make changes to the copy, and then run the copy.

Privilege class

Any administrator can issue this command.

Syntax



```
'---substitution_value-+-'
```

Parameters

macro_name (Required)
: Specifies the name of the macro.

substitution_value
: Specifies the value for a substitution variable in a macro. When you use a substitution variable, you can reuse a macro whenever you need to perform the same task for different objects or with different parameter values. To specify a value that contains blanks, you must enclose the value in quotation marks. This parameter is optional.

Example: Create a macro to register a new administrator

Create a macro file named REGNG. Use the macro to register and grant authority to a new administrator. Write the macro as follows:

```
/* Register and grant authority to a new administrator */
REGister Admin jones passwd        -
CONtactinfo="x1235"
GRant AUTHority jones              -
CLasses=Policy
```

Issue the following command to run the macro:

```
macro regng.mac
```

Example: Write a macro using substitution variables

Create a macro file named AUTHRG, containing substitution variables, to register and grant authority to a new administrator. Write the macro as follows:

```
/*   Register and grant authority to a new administrator */
REGister Admin %1 %2  -        /*  Enter userid and password  */
CONtact=%3         /* Enter contact info (in quotes if nec.) */
GRant AUTHority %1  -        /*  Server uses variable already */
-                                      /*  defined by you */
CLasses=%4                    /*  Enter the privilege class  */
```

Issue a command similar to the following, entering the values you want to pass to the server to process the command when you run the macro.

```
macro authrg.mac jones passwd x1235 Policy
```

MIGRATE STGPOOL (Migrate storage pool to next storage pool)

Use this command to migrate files from one storage pool to the next storage pool in the storage hierarchy.

This command can only be used with primary storage pools. The storage pool data format cannot be NETAPPDUMP, CELERRADUMP, or NDMPDUMP. Data cannot be migrated into or out of storage pools that are defined with a CENTERA device class.

Only one migration or reclamation process for a given storage pool is allowed at any given time. If a migration or reclamation process is already running for the storage pool, you cannot start another migration process for the storage pool.

You should only use this command if you are not going to use automatic migration for the storage pool. To prevent automatic migration from running, set the HIGHMIG attribute of the storage pool definition to 100.

If you use this command to start a migration process, but the storage pool does not have a next storage pool identified in the hierarchy, a reclamation process is triggered for the source storage pool. To prevent the reclamation process, define the next storage pool in the hierarchy. Then, start the migration process.

The MIGRATE STGPOOL command honors the values of the following parameters on the DEFINE STGPOOL and UPDATE STGPOOL commands:

- MIGPROCESS
- MIGDELAY
- MIGCONTINUE
- NEXTPOOL
- LOWMIG
  Tip: You can override the value of the LOWMIG parameter on DEFINE STGPOOL and UPDATE STGPOOL by specifying a value for the LOWMIG parameter on the MIGRATE STGPOOL command.

The MIGRATE STGPOOL command ignores the value of the HIGHMIG parameter of the storage pool definition. Migration occurs regardless of the value of the HIGHMIG parameter.

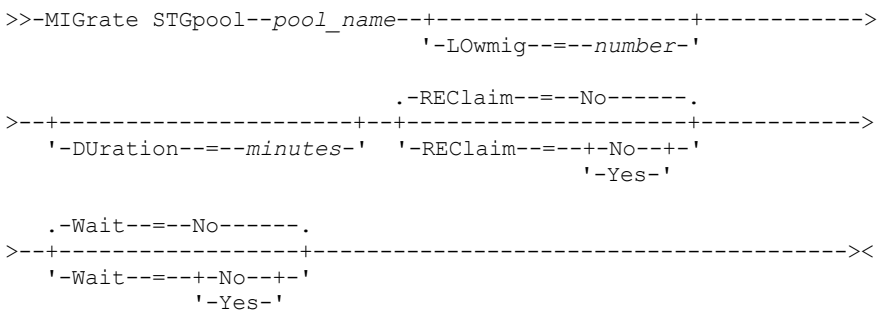
This command creates one or more migration processes that can be canceled with the CANCEL PROCESS command. The number of processes is limited by the MIGPROCESS attribute of the storage pool definition. To display information about background processes, use the QUERY PROCESS command.

Remember: Migrating data from a primary storage pool that is set up for data deduplication to another primary storage pool that is also set up for data deduplication removes duplicate data.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for both the storage pool from which the files are to be migrated and the next storage pool to which files are to be migrated.

Syntax



Parameters

pool_name (Required)
: Specifies the primary storage pool from which files are to be migrated.

DUration
: Specifies the maximum number of minutes the migration runs before being automatically canceled. When the specified number of minutes elapses, the server will automatically cancel all migration processes for this storage pool. As soon as the processes recognize the automatic cancellation, they end. As a result, the migration might run longer than the value you specified for this parameter. You can specify a number from 1 to 9999. This parameter is optional. If not specified, the server will stop only after the low migration threshold is reached.

LOwmig
: For random-access and sequential-access disk storage pools, specifies that migration should stop when the amount of data in the pool is at or below this percentage of the pool's estimated capacity. This parameter is optional.

The calculation for sequential-access disk storage pools includes the capacity of all the scratch volumes that are specified for the pool. Because migration is by node or filespace, depending upon collocation, the occupancy of the storage pool can fall below the value that you specified for this parameter. To empty the storage pool, set LOWMIG=0. For other types of sequential-access storage pools, the server stops migration when the ratio of volumes containing data to the total number of volumes in the storage pool is at or below this percentage. The total number of volumes includes the maximum number of scratch volumes. You can specify a number from 0 to 99 for this optional parameter. The default value is the LOWMIG attribute of the storage pool definition.

RECLaim

Specifies whether reclamation is attempted for the storage pool before completing the migration. This parameter can only be specified for a sequential-access storage pool. This parameter is optional. The default is No. Possible values are:

No

Specifies that the server will not attempt a reclamation before starting the migration.

Yes

Specifies that the server will attempt reclamation before starting the migration. Any volumes in the storage pool that meet the reclamation threshold as specified by the RECLAIM attribute of the storage pool definition will be reclaimed before completing the migration. If no volumes meet the reclamation threshold or if, after reclamation, the LOWMIG threshold has not been reached, the server will begin the migration. Before reclaiming space for storage pools defined with RECLAMATIONTYPE=SNAPLOCK, the server deletes all empty WORM FILE volumes during reclamation processing that have exceeded their reclaim period.

Wait

Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. This default is No. Possible values are:

No

Specifies that the server processes this command in the background.

You can continue with other tasks while the command is being processed. Messages that are created from the background process are displayed either in the activity log or the server console, depending on where messages are logged.

To cancel a background process, use the CANCEL PROCESS command. If you cancel this process, some files may have already been migrated before the cancellation.

Yes

Specifies that the server processes this command in the foreground. The operation must complete before you can continue with other tasks. The server then displays the output messages to the administrative client when the operation completes. Messages are also displayed either in the activity log or the server console, or both, depending on where the messages are logged.
Note: You cannot specify WAIT=YES from the server console.

Example: Migrate a storage pool to the next storage pool

Migrate data from the storage pool named BACKUPPOOL to the next storage pool. Specify that the server should end the migration as soon as possible after 90 minutes.

```
migrate stgpool backuppool duration=90
```

Related commands

Table 1. Commands related to MIGRATE STGPOOL

Command	Description
CANCEL PROCESS	Cancels a background server process.
QUERY PROCESS	Displays information about background process.
QUERY STGPOOL	Displays information about storage pools.
RECLAIM STGPOOL	Performs reclamation for the storage pool.

Migrating files in a storage pool hierarchy

MOVE commands

Use the MOVE commands to either transfer backup or archive data between storage pools, or to move disaster recovery media on and off site.

- MOVE CONTAINER (Move a container)
- MOVE DATA (Move files on a storage pool volume)
- MOVE DRMEDIA (Move disaster recovery media offsite and back onsite)
- MOVE GRPMEMBER (Move a server group member)
- MOVE MEDIA (Move sequential-access storage pool media)
- MOVE NODEDATA (Move data by node in a sequential access storage pool)

AIX | Linux | Windows

MOVE CONTAINER (Move a container)

Use this command to move the contents of a storage pool container to another container if a storage pool directory is removed or if a container is damaged.

You can also use this command to move the contents of a storage pool container under these conditions:

- When you upgrade hardware
- If I/O errors occur on a disk

Privilege class

To issue this command, you must have restricted storage privilege.

Syntax

```
>>-MOVe CONTainer--container_name------------------------------>

>--+-------------------------------------+---------------------->
   '-STGPOOLDIRectory--=--directory_name-'

   .-Wait--=--Yes-----.
>--+------------------+----------------------------------------><
   '-Wait--=--+-Yes-+-'
              '-No--'
```

Parameters

container_name(Required)
: Specifies the name of the container to move. You must specify the full path name of the container.

STGPOOLDIRectory
: Specifies the name of the storage pool directory where the container is moved. This parameter is optional.

  If you specify a storage pool directory, it must be in the same storage pool as the original container. The storage pool directory is used for the new container. If you don't specify a storage pool directory, the IBM Spectrum Protect™ server selects a storage pool directory from the same storage pool.

Wait
: Specifies whether to wait for the IBM Spectrum Protect server to complete processing this command in the foreground. This parameter is optional. Specify the following values:

  No
  : The server processes this command in the background and you can continue with other tasks while the command is processing. Messages that are related to the background process are shown either in the activity log file or the server console, depending on where the messages are logged. This is the default.

  Yes
  : The server processes this command in the foreground. The operation must complete before you can continue with other tasks. Messages are shown either in the activity log file or the server console, or both, depending on where the

messages are logged.
Restriction: You cannot specify the WAIT=YES parameter from the server console.

Example: Move a container

AIX | Linux Move a container, 0000000000000001.dcf, from the /data1/storage/dir1 storage pool directory to the /data/storage/dir2 storage pool directory.

```
move container /data1/storage/dir1/00/0000000000000001.dcf
stgpooldir=/data/storage/dir2
```

Windows Move a container, 0000000000000001.dcf, from the e:\data1\storage\dir1 storage pool directory to the e:\data\storage\dir2 storage pool directory.

```
move container e:\data1\storage\dir1\00\0000000000000001.dcf
stgpooldir=e:\data\storage\dir2
```

Table 1. Commands related to MOVE CONTAINER

Command	Description
AUDIT CONTAINER	Audit a directory-container storage pool.
QUERY CONTAINER	Displays information about a container.

MOVE DATA (Move files on a storage pool volume)

Use this command to move files from one storage pool volume to other storage pool volumes.

Restriction: You cannot use this command for volumes that are assigned to copy-container storage pools.
You can move files from a primary storage pool volume only to volumes in the same or a different primary storage pool. You can move files from a copy storage pool volume only to volumes in the same copy storage pool. You can move files from an active-data pool volume only to volumes in the same active-data pool.

In addition to moving data from volumes in storage pools that have NATIVE or NONBLOCK data formats, you can use this command to move data from volumes in storage pools that have NDMP data formats (NETAPPDUMP, CELERRADUMP, or NDMPDUMP). The target storage pool must have the same data format as the source storage pool. If you are moving data out of a storage pool for the purpose of upgrading to new tape technology, the target primary storage pool must be associated with a library that has the new device for the tape drives. IBM Spectrum Protect™ supports backend data movement for NDMP images.

You cannot move data into or out of a storage pool that is defined with a CENTERA device class.

If you are moving files to volumes in the same storage pool, sufficient space must be available on the volumes. Otherwise, the operation fails.

When you move files from a sequential access volume, multiple sequential access volume mounts are required to move files that span volumes.

When you move files from a random access volume, the server erases any cached copies of files on the volume.

After a move data operation completes, a volume might not be empty if one or more files cannot be relocated to another volume because of input/output errors on the device or because errors were found in the file. If needed, you can delete the volume using the option to discard any data. The files with I/O or other errors are then deleted.

You can use this command to move files from an offsite volume in a copy storage pool or active-data pool. Because the offsite volume cannot be mounted, the server obtains the files that are on the offsite volume from either a primary storage pool or another copy storage pool. These files are then written to the destination volumes in the original copy storage pool or active-data pool.

During the data movement process, active-data pools cannot be used to obtain data.

If you run the MOVE DATA command on an offsite volume that contains collocated data, it might be necessary to issue the MOVE DATA command multiple times to move all of the data out of the volume. For example, if you are using filespace collocation groups with an offsite volume that contains filespaces in a collocation group and filespaces that are not in the group, you must issue two MOVE DATA commands. Each MOVE DATA command moves the data for a single collocated or non-collocated group of files.

Do not use the MOVE DATA command if a restore process (RESTORE STGPOOL or RESTORE VOLUME) is running. The MOVE DATA command might cause the restore to be incomplete. If you issue the MOVE DATA command during a restore operation and you receive an error message indicating that one or more files are locked and cannot be moved, you must reissue the MOVE DATA command after the restore operation completes in order to move any remaining files.

Remember:
Issuing this command removes duplicate data when:

- Moving data from a primary storage pool that is set up for data deduplication to another primary storage pool that is also set up for data deduplication.
- Moving data within a copy storage pool that is set up for data deduplication.
- Moving data within an active-data pool that is set up for data deduplication.

A volume in a deduplicated storage pool might contain files that are logically deleted but are still linked by files on other volumes. If you use the MOVE DATA command to move the contents of a deduplicated storage pool volume to a non-deduplicated storage pool, the logically deleted files are not written to the new volume since they do not exist logically. The deleted files are kept on the original volumes for other files to reference. The MOVE DATA process ends successfully but none of the deleted files are moved to the new target volume and the source volume is not deleted. You can issue the QUERY CONTENT command with the FOLLOWLINKS=YES or FOLLOWLINKS=JUSTLINKS parameter to verify whether the volume contains files that are linked by files on other volumes.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the storage pool to which the volume belongs and also for the new storage pool, if one is specified.

Syntax

```
>>-MOVe Data--volume_name--+----------------------+------------>
                           '-STGpool--=--pool_name-'

   .-SHREDTONOshred--=--No------.
>--+----------------------------+------------------------------>
   '-SHREDTONOshred--=--+-No--+-'
                        '-Yes-'

                               (1) (2)
   .-RECONStruct--=--No or Yes---------.
>--+-----------------------------------+------------------------>
   '-RECONStruct--=--+-No--+-----------'
                     '-Yes-'

   .-Wait--=--No------.
>--+------------------+---------------------------------------><
   '-Wait--=--+-No--+-'
              '-Yes-'
```

Notes:

1. The default is NO if either the source or target storage pool is random access. The default is YES if both the source and target storage pools are sequential access.
2. This parameter is not available or is ignored if the data format is NETAPPDUMP, CELERRADUMP, or NDMPDUMP data.

Parameters

volume_name (Required)
: Specifies the storage pool volume from which to move files.

STGpool
: Specifies the primary storage pool to which you want to move files (the target storage pool). This parameter is optional and applies only to moving data from primary storage pool volumes. If you do not specify a value for this parameter, files are moved to other volumes within the same storage pool.

SHREDTONOshred
: Specifies whether data is moved from a storage pool that enforces shredding to a storage pool that does not enforce shredding. This parameter is optional. The default value is NO. Possible values are:

No
Specifies that the server will not allow data to be moved from a storage pool that enforces shredding to a storage pool that does not enforce shredding. If the source storage pool enforces shredding and the target storage pool does not, the operation fails.

Yes
Specifies that the server allows data to be moved from a storage pool that enforces shredding to a storage pool that does not enforce shredding. The source data is shredded when the operation is complete. The target data will not be shredded when it is deleted.

RECONStruct
Specifies whether to reconstruct file aggregates during data movement. Reconstruction removes empty space that has accumulated during deletion of logical files from an aggregate. This parameter is optional. If both the source and target storage pools are sequential access, the default value is YES. If either the source or target storage pool is random access, the default is NO.
The parameter is not available or is ignored if any of the following conditions are true:

- The data format is NETAPPDUMP, CELERRADUMP, or NDMPDUMP.
- The data is in a storage pool that is configured for data deduplication.
- The target storage pool for the data movement is configured for data deduplication.

Attention: Reconstruction removes inactive backup files in active-data pools. If you specify RECONSTRUCT=NO when moving the data in an active-data pool that is not configured for data deduplication, inactive backup files remain in the storage pool.

Possible values are:

No
Specifies that reconstruction of file aggregates is not completed during data movement.

Yes
Specifies that reconstruction of file aggregates is completed during data movement. You can only specify this option when both the source and the target storage pools are sequential-access.

Wait
Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default value is No. Possible values are:

No
Specifies that the server processes this command in the background. You can continue with other tasks while the command is being processed.

The server displays messages that are created from the background process either in the activity log or the server console, depending on where messages are logged.

To cancel a background process, use the CANCEL PROCESS command. If a MOVE DATA background process is canceled, some files may have already moved before the cancellation.

Yes
Specifies that the server processes this command in the foreground. You wait for the command to complete before continuing with other tasks. The server then displays the output messages to the administrative client when the command completes.
Restriction: You cannot specify WAIT=YES from the server console.

Example: Move files on a storage pool volume

Move files from storage pool volume STGVOL.1 to any available volumes assigned to the 8MMPOOL storage pool.

```
move data stgvol.1 stgpool=8mmpool
```

Related commands

Table 1. Commands related to MOVE DATA

Command	Description
CANCEL PROCESS	Cancels a background server process.

Command	Description
DEFINE VOLUME	Assigns a volume to be used for storage within a specified storage pool.
DELETE VOLUME	Deletes a volume from a storage pool.
MOVE DRMEDIA	Moves DRM media onsite and offsite.
QUERY ACTLOG	Displays messages from the server activity log.
QUERY CONTENT	Displays information about files in a storage pool volume.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY PROCESS	Displays information about background processes.
QUERY SHREDSTATUS	Displays information about data waiting to be shredded.
SHRED DATA	Manually starts the process of shredding deleted data.

MOVE DRMEDIA (Move disaster recovery media offsite and back onsite)

Use this command to track volumes that are to be moved offsite and to identify the expired or empty volumes that are to be moved onsite. You can track database backup volumes, and volumes in copy storage pools, container-copy storage pools, and active-data storage pools.

The processing of volumes by this command depends on what the volumes are used for:

Backups of the server database
: To control whether the command processes database backup volumes, use the SOURCE parameter on this command. The command can process volumes that are used for full plus incremental or snapshot database backups. You cannot specify virtual volumes (backup objects that are stored on another server). You can change volumes through each state, or you can use the TOSTATE parameter and skip states to simplify the movements.

Copy storage pools
: The MOVE DRMEDIA command always processes copy storage-pool volumes.

Container-copy storage pools
: By default, volumes in container-copy storage pools are not eligible for processing by the MOVE DRMEDIA command. To process container-copy storage pool volumes, you must issue the SET DRMCOPYCONTAINERSTGPOOL command first, or specify the COPYCONTAINERSTGPOOL parameter on the MOVE DRMEDIA command.

Active-data storage pools
: By default, volumes in active-data storage pools are not eligible for processing by the MOVE DRMEDIA command. To process active-data pool volumes, you must issue the SET DRMACTIVEDATASTGPOOL command first, or specify the ACTIVEDATASTGPOOL parameter on the MOVE DRMEDIA command.

You can use the QUERY ACTLOG command to see whether the MOVE DRMEDIA command was successful. You can also view this information from the server console.

Restriction: Do not run the MOVE DRMEDIA and BACKUP STGPOOL commands concurrently. Ensure that the storage pool backup processes are complete before you issue the MOVE DRMEDIA command.

Privilege class

To issue this command, you must have one of the following privilege classes:

- If the CMD parameter is specified and the REQSYSAUTHOUTFILE server option is set to NO: operator, unrestricted storage, or system privilege.
- If the CMD parameter is specified and the REQSYSAUTHOUTFILE server option is set to YES (the default): system privilege.

Syntax

```
>>-MOVe DRMedia--volume_name----------------------------------->

>--+-------------------------------------+---------------------->
   '-WHERESTate--=--+-MOuntable-------+-'
                    +-NOTMOuntable----+

              '-Yes-'
```

Parameters

volume_name (Required)

Specifies the name of the volume to be processed. You can use wildcard characters. If you use wildcard characters to specify this name, you must also specify the WHERESTATE parameter. The server looks for matching names among the following eligible volumes:

- Database backup volumes, as specified by the SOURCE parameter of this command.
- Copy storage pool volumes from the storage pools named in the COPYSTGPOOL parameter. If you do not use the COPYSTGPOOL parameter, the server processes volumes from copy storage pools that were previously specified in the SET DRMCOPYSTGPOOL command.
- Container-copy storage pool volumes from the storage pools named in the COPYCONTAINERSTGPOOL parameter. If you do not use the COPYCONTAINERSTGPOOL parameter, the server processes volumes from container-copy storage pools that were previously specified in the SET DRMCOPYCONTAINERSTGPOOL command.

- Active-data storage pool volumes from the storage pools named in the ACTIVEDATASTGPOOL parameter. If you do not use the ACTIVEDATASTGPOOL parameter, the server processes volumes from active-data storage pools that were previously specified in the SET DRMACTIVEDATASTGPOOL command.

Other parameters can also limit the results of the command.

WHERESTate

Specifies the state of volumes to be processed. This parameter is required if the TOSTATE parameter is not specified or if you use a wildcard character in the volume name. For more information, see Table 2 and Table 3. Specify one of the following values:

MOuntable

These volumes contain valid data and are available for onsite processing. The values change to NOTMOUNTABLE if the TOSTATE parameter is not specified.

Depending on the outcome of the REMOVE parameter, the server might eject volumes in an automated library before you change the destination state.

For external libraries, the server sends requests to the external library manager to eject the volumes. It depends on the external library manager whether the volumes are ejected from the library.

NOTMOuntable

These volumes are onsite, contain valid data, and are not available for onsite processing. The values change to COURIER if the TOSTATE parameter is not specified.

COUrier

These volumes are with the courier and being moved offsite. The values change only to VAULT.

VAULTRetrieve

These volumes are at the offsite vault and do not contain valid data. The values change to COURIERRETRIEVE if the TOSTATE parameter is not specified.

COURIERRetrieve

These volumes are with the courier and being moved onsite. The values change only to ONSITERETRIEVE. The server deletes the volume records of the database backup and scratch copy storage pool volumes from the database.

BEGINDate

Specifies the beginning date that is used to select volumes. This parameter is optional. Volumes are considered eligible if the MOVE DRMEDIA command changes the volume to its current state on or after the specified date. The default is the earliest date for which volume information exists.

You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date.	`09/15/1998`
TODAY	The current date.	`TODAY`
TODAY-days or -days	The current date minus days specified.	`TODAY-7` or `-7` To identify volumes that were changed to their current state a week ago, you can specify `TODAY-7` or `-7`.
EOLM (end of last month)	The last day of the previous month.	`EOLM`
EOLM-days	The last day of the previous month minus days specified.	`EOLM-1` To include files that were active a day before the last day of the previous month.
BOTM (beginning of this month)	The first day of the current month.	`BOTM`
BOTM+days	The first day of the current month, plus days specified.	`BOTM+9` To include files that were active on the 10th day of the current month.

ENDDate

Specifies the ending date that is used to select volumes. This parameter is optional. Volumes are considered eligible if the MOVE DRMEDIA command changes the volume to its current state on or before the specified date. The default is the current date.

You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date.	`09/15/1998`
TODAY	The current date.	`TODAY` To identify volumes that were changed to their current state today, specify `TODAY`.
TODAY-days or -days	The current date minus days specified. The maximum number of days is 9999.	`TODAY-1` or `-1` To identify volumes that were changed to their current state a week ago, you can specify `TODAY-1` or `-1`.
EOLM (end of last month)	The last day of the previous month.	`EOLM`
EOLM-days	The last day of the previous month minus days specified.	`EOLM-1` To include files that were active a day before the last day of the previous month.
BOTM (beginning of this month)	The first day of the current month.	`BOTM`
BOTM+days	The first day of the current month, plus days specified.	`BOTM+9` To include files that were active on the 10th day of the current month.

BEGINTime

Specifies the beginning time that is used to select volumes for processing. This parameter is optional. Volumes are considered eligible if the MOVE DRMEDIA command changes the volume to its current state on or after the specified time and date. The default is midnight (00:00:00) on the date that is specified with the BEGINDATE parameter.

You can specify the time by using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time on the specified begin date.	`12:33:28`
NOW	The current time on the specified begin date.	`NOW`
NOW+HH:MM or +HH:MM	The current time plus hours and minutes on the specified begin date.	`NOW+03:00` or `+03:00`
NOW-HH:MM or -HH:MM	The current time minus hours and minutes on the specified begin date.	`NOW-03:30` or `-03:30` If you issue the MOVE DRMEDIA command at 9:00 with BEGINTIME=NOW-03:30 or BEGINTIME=-03:30, the server identifies the volumes that were changed to their current state at 5:30 on the begin date that you specify.

ENDTime

Specifies the ending time that is used to select volumes for processing. This parameter is optional. Volumes are considered eligible if the MOVE DRMEDIA command changes the volume to its current state on or after the specified time and date. The default is 23:59:59.

You can specify the time by using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time on the specified end date.	`12:33:28`
NOW	The current time on the specified end date.	`NOW`

Value	Description	Example
NOW+HH:MM or +HH:MM	The current time plus hours and minutes on the specified end date.	`NOW+03:00` or `+03:00` If you issue the MOVE DRMEDIA command at 9:00 with ENDTIME=NOW+03:30 or ENDTIME=+03:30, the server identifies the volumes that were changed to their current state at 12:30 on the end date you specify.
NOW-HH:MM or -HH:MM	The current time minus hours and minutes on the specified end date.	`NOW-03:30` or `-03:30`

COPYCONtainerstgpool
: Specifies the name of the container-copy storage pool whose volumes are to be processed. This parameter is optional. You can use wildcard characters to specify this name. If you use wildcard characters to specify this name, you must also specify the WHERESTATE parameter.

  The container-copy storage pools that are specified with this parameter override storage pools that are specified with the SET DRMCOPYCONTAINERSTGPOOL command. If this parameter is not specified, the server selects the storage pools as follows:

  - If the SET DRMCOPYCONTAINERSTGPOOL command was previously issued with valid container-copy storage pool names, the server processes only those storage pools.
  - If the SET DRMCOPYCONTAINERSTGPOOL command was not issued, or if all of the container-copy storage pools were removed by using the SET DRMCOPYCONTAINERSTGPOOL command, the server processes all container-copy storage pool volumes based on the setting of the WHERESTATE parameter. If the parameter is set to a value of NOTMOUNTABLE, COURIER, VAULTRETRIEVE, or COURIERRETRIEVE, the volumes are processed. If the value is MOUNTABLE, the volumes are not processed.

COPYstgpool
: Specifies the name of the copy storage pool whose volumes are to be processed. This parameter is optional. You can use wildcard characters to specify this name. If you use wildcard characters to specify this name, you must also specify the WHERESTATE parameter.

  The copy storage pools that are specified with this parameter override copy storage pools that are specified with the SET DRMCOPYSTGPOOL command. If this parameter is not specified, the server selects the storage pools as follows:

  - If the SET DRMCOPYSTGPOOL command was previously issued with valid copy storage pool names, the server processes only those storage pools.
  - If the SET DRMCOPYSTGPOOL command was not issued, or if all of the copy storage pools are removed by using the SET DRMCOPYSTGPOOL command, the server processes all copy storage pool volumes in the specified state. The states available are MOUNTABLE, NOTMOUNTABLE, COURIER, VAULTRETRIEVE, or COURIERRETRIEVE.

ACTIVEDatastgpool
: Specifies the name of the active-data pool whose volumes are to be processed. This parameter is optional. You can use wildcard characters to specify this name. If you use wildcard characters to specify this name, you must also specify the WHERESTATE parameter.

  The active-data pools that are specified with this parameter override active-data pools that are specified with the SET DRMACTIVEDATASTGPOOL command. If this parameter is not specified, the server selects the storage pools in the following way:

  - If the SET DRMACTIVEDATASTGPOOL command was previously issued with valid active-data pool names, the server processes only those storage pools.
  - If the SET DRMACTIVEDATASTGPOOL command was not issued, or all of the active-data pools are removed by using the SET DRMACTIVEDATASTGPOOL command, the server processes all active-data pool volumes in the specified state. The states available are NOTMOUNTABLE, COURIER, VAULTRETRIEVE, or COURIERRETRIEVE. Volumes in the MOUNTABLE state are not processed.

Source
: Specifies whether to include database backup volumes for processing. This parameter is optional. The default is DBBACKUP. Specify one of the following values:

  DBBackup
  : Specifies that the server includes full and incremental database backup volumes for processing.

DBSnapshot
Specifies that the server includes database snapshot backup volumes for processing.
DBNOne
Specifies that the server does not include any database backup volumes for processing.

REMove
Specifies that the server tries to move the volume out of the library and into the convenience I/O station or entry/exit ports. This parameter is optional. Possible values are YES, NO, BULK, and UNTILEEFULL. The default is BULK. The response of the server to each value and the default value depends on the type of library.
Restriction: You can use the REMOVE=UNTILEEFULL option only with the library type SCSI.

SCSI libraries
The response of the server to the command depends on whether the library has entry/exit ports, and if so, whether a port is available for use. See the following table.

Table 1. Server response for SCSI libraries

Library characteristic	**Server response when you specify REMOVE=YES**	**Server response when you specify REMOVE=BULK**	**Server response when you specify REMOVE=NO**	**Server response when you specify REMOVE=UNTILEEFULL**
Library has no entry/exit ports	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server then prompts you to remove the cartridge from the slot and to issue a REPLY command.	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server does not prompt you to remove the cartridge and does not require a REPLY command.	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server does not prompt you to remove the cartridge and does not require a REPLY command.	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server does not prompt you to remove the cartridge and does not require a REPLY command.
Library has entry/exit ports and an entry/exit port is available	The server moves the cartridge to the available entry/exit port and specifies the port address in a message. The server then prompts you to remove the cartridge from the slot and to issue a REPLY command.	The server moves the cartridge to the available entry/exit port and specifies the port address in a message. The server does not prompt you to remove the cartridge and does not request a REPLY command.	The server specifies the port address in a message. The server does not prompt you to remove the cartridge and does not request a REPLY command.	The server moves the cartridge to the available entry/exit port and specifies the port address in a message. The server does not prompt you to remove the cartridge and does not request a REPLY command.
Library has entry/exit ports, but no ports are available	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server then prompts you to remove the cartridge from the slot and to issue a REPLY command.	The server waits for a port to be made available.	The server specifies the port address in a message. The server does not prompt you to remove the cartridge and does not request a REPLY command.	The command fails and any remaining eligible volumes are not processed. Make the port available and issue the command again.

349X libraries

REMOVE=YES
The 3494 Library Manager ejects the cartridge to the convenience I/O station.
REMOVE=BULK
The 3494 Library Manager ejects the cartridge to the high-capacity output facility.
REMOVE=NO
The 3494 Library Manager does not eject the volume. The server leaves the cartridge in the library in the INSERT category for use by other applications.

ACSLS libraries

REMOVE=YES or REMOVE=BULK
The server ejects the cartridge to the convenience I/O station.

The server then deletes the volume entry from the server library inventory.

When you move volumes from the MOUNTABLE state with REMOVE=YES specified, the MOVE MEDIA command uses more than one slot in the CAP for a StorageTek library with ACSLS.

REMOVE=NO
The server does not eject the cartridge.

The server deletes the volume entry from the server library inventory and leaves the volume in the library.

External libraries
You can specify REMOVE=YES, REMOVE=BULK, or REMOVE=NO. For any value, the server requests the external library manager to eject the volume from the library.

It depends on the external library manager whether the volume is ejected from the library. Refer to the external library documentation for information about the procedures to follow when you use the MOVE DRMEDIA command to track volumes.

TOSTate
Specifies the destination state of the volumes that are processed. This parameter is required if the WHERESTATE parameter is not specified. If you specify TOSTATE parameter but not WHERESTATE parameter, you must specify the volume name. Wildcard characters are not allowed. See Table 2 and Table 3.
Specify one of the following values:

NOTMOuntable
Specifies that volumes are to change to the NOTMOUNTABLE state. This value is valid only if the volumes are in the MOUNTABLE state.

If volumes are in an automated library, the server might eject the volumes from the library before you change them to the NOTMOUNTABLE state, depending on the behavior of the REMOVE parameter.

For external libraries, the server sends requests to the external library manager to eject the volumes. Whether the volumes are ejected from the library depends on the external library manager. Refer to the external library documentation for information about the procedures to follow when you use the MOVE DRMEDIA command to track the volumes.

COUrier
Specifies that volumes are to change to the COURIER state. This value is valid only if the volumes are in the MOUNTABLE or NOTMOUNTABLE state.

Depending on the behavior of the REMOVE parameter and whether volumes are in an automated library, the server might eject the volumes from the library before you change them to the COURIER state.

For external libraries, the server sends requests to the external library manager to eject the volumes. Whether the volumes are ejected from the library depends on the external library manager. Refer to the external library documentation for information about the procedures to follow when you use the MOVE DRMEDIA command to track the volumes.

VAult
Specifies that volumes are to change to the VAULT state. This value is valid only if the volumes are in the MOUNTABLE, NOTMOUNTABLE, or COURIER state.

Depending on the behavior of the REMOVE parameter and whether volumes are in an automated library, the server might eject the volumes from the library before you change them to the VAULT state.

For external libraries, the server sends requests to the external library manager to eject the volumes. Whether the volumes are ejected from the library depends on the external library manager. Refer to the external library documentation for information about the procedures to follow when you use the MOVE DRMEDIA command to track the volumes.

COURIERRetrieve
: Specifies that volumes are to change to the COURIERRETRIEVE state. This value is valid only if the volumes are in the VAULTRETRIEVE state.

ONSITERetrieve
: Specifies that volumes are to change to the ONSITERETRIEVE state. This value is valid only if the volumes are in the VAULTRETRIEVE or COURIERRETRIEVE state. For database backup and scratch copy storage pool volumes that are changing to the ONSITERETRIEVE state, the server deletes the volume records from the database.

WHERELOcation
: Specifies the current location of the volumes. This parameter is optional. The maximum length of the location is 255 characters. Enclose the text in quotation marks if it contains any blank characters.

TOLOcation
: Specifies the destination location of the volumes. This parameter is optional. The maximum length of the location that is specified is 255 characters. Enclose the text in quotation marks if it contains any blank characters. If you do not specify the destination location, the location that is defined by the SET DRMNOTMOUNTABLE command is used.

CMd
: Specifies a command to be issued for each volume that is processed by the MOVE DRMEDIA command. DRM writes the commands to a file that is specified by the CMDFILENAME parameter. After the MOVE DRMEDIA operation is completed, the commands in the file can be issued. The command can contain up to 255 characters. If the command contains more than 240 characters, it is split into multiple lines, and continuation characters (+) are added. You might need to alter the continuation character based on the operating system. This parameter is optional.

command
: The command string that is enclosed in quotation marks. The string must not include embedded quotation marks. For example, the following CMD parameter is valid:

```
cmd="checkin libvol lib8mm &vol status=scratch"
```

The following example is not a valid way to specify the CMD parameter:

```
cmd=""checkin libvol lib8mm" &vol status=scratch""
```

The command can include substitution variables. The variables are not case-sensitive, and must not contain blank spaces after the ampersand (&). You can specify the following values:

&VOL
: A volume name.

&LOC
: A volume location.

&VOLDSN
: The file name to be written into the sequential access media labels. For example, if the applicable device class sets BKP as the tape volume prefix, a copy storage pool tape volume file name might be BKP.BFS and a database backup tape volume file name might be BKP.DBB.

&NL
: The new line character. When you use the new line character, the command is split at the &NL variable. If required, you must specify the appropriate continuation character before the &NL character. If the &NL character is not specified and the command line is greater than 240 characters, the line is split into multiple lines and continuation characters (+) are added.

AIX Linux CMDFilename
: AIX Linux Specifies the fully qualified name of the file that contains the commands that are specified by CMD parameter. This parameter is optional.

If you do not specify a file name or if you specify a null string (""), DRM uses the file name that is specified by the SET DRMCMDFILENAME command. If you do not specify a file name with the SET DRMCMDFILENAME command, DRM generates a file name by appending `exec.cmds` to the directory path name of the current working directory of the server.

If the operation fails after the command file is created, the file is not deleted.

Windows CMDFilename

Windows Specifies the fully qualified name of the file that contains the commands that are specified by CMD parameter. This parameter is optional.

The maximum length of the file name is 259 characters. If you do not specify a file name or if you specify a null string (""), DRM uses the file name that is specified by the SET DRMCMDFILENAME command. If you do not specify a file name with the SET DRMCMDFILENAME command, DRM generates a file name by appending `exec.cmd` to the directory that represents this instance of the server (typically the directory from which the server was installed). The DRM allocates the file name that is specified or generated. If the file name exists, DRM tries to use it; any existing data is overwritten. If this happens and the executable commands in the file have not been run, issue QUERY DRMEDIA command to rebuild the executable commands for the desired date and volume transition.

If the MOVE DRMEDIA command fails and none of the command string that is specified with the CMD parameter is written for the volume that successfully moved, the allocated file name is deleted.

APPend

Specifies whether to overwrite any existing contents of the command file or append the commands to the file. This parameter is optional. The default is NO. Specify one of the following values:

No
: DRM overwrites the contents of the file.

Yes
: DRM appends the commands to the file.

Wait

Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default value is NO. Specify one of the following values:

No
: Specifies that the server processes this command in the background.

  Messages that are created from the background process are displayed either in the activity log or the server console, depending on where messages are logged.

  To see whether the operation was successful, issue the QUERY ACTLOG command.

Yes
: Specifies that the server processes this command in the foreground. Wait for the command to complete before you continue with other tasks. The server then displays the output messages to the administrative client.
  Restriction: You cannot specify WAIT=YES from the server console.

CAP

Specifies which cartridge access port (CAP) to use for ejecting volumes if you specify REMOVE=YES. This parameter applies to volumes in ACSLS libraries only. If the CAP priority value is set to 0 in the library, this parameter is required. If a CAP priority value greater than 0 is set in the library, this parameter is optional. By default, all CAPs initially have a priority value of 0, which means that ACSLS does not automatically select the CAP.
To display valid CAP identifiers (*x,y,z*), issue the QUERY CAP command with ALL specified from the Automated Cartridge System System Administrator (ACSSA) console on the ACSLS server host. The identifiers are as follows:

x
: The Automated Cartridge System (ACS) ID. This identifier can be a number in the range 0 - 126.

y
: The Library Storage Module (LSM) ID. This identifier can be a number in the range 0 - 23.

z
: The CAP ID. This identifier can be a number in the range 0 - 11.

For more information, see the StorageTek documentation.

Rules for destination states and destination locations

The following table shows how DRM determines the destination state and location of a volume.

Destination state

- The value of the TOSTATE parameter that was specified
- The next state of the WHERESTATE parameter that was specified, if the TOSTATE parameter was not specified

Destination location

- The value of the TOLOCATION parameter that was specified
- The location of the TOSTATE parameter that was specified, if the TOLOCATION parameter was not specified
- The location of the next state of the WHERESTATE parameter that was specified, if the TOLOCATION and TOSTATE parameters are not specified

Table 2. Volume destination and location

Parameters specified	Destination state	Destination location
WHERESTATE	The next state of the WHERESTATE	Location of the next state
WHERESTATE, TOSTATE	TOSTATE	Location of the TOSTATE
WHERESTATE, TOLOCATION	The next state of the WHERESTATE	TOLOCATON
WHERESTATE, TOSTATE, TOLOCATION	TOSTATE	TOLOCATION
TOSTATE	TOSTATE	Location of the TOSTATE
TOSTATE, WHERELOCATION	TOSTATE	Location of the TOSTATE
TOSTATE, WHERELOCATION, TOLOCATION	TOSTATE	TOLOCATION

Rules for state transitions

The following tables show the state transitions that volumes are eligible for, based on their current state.

Table 3. State transitions for volumes

	Destination state		
The current state of the volume	**MOUNTABLE**	**NOTMOUNTABLE**	**COURIER**
MOUNTABLE	N	Y	Y
NOTMOUNTABLE	N	N	Y
COURIER	N	N	N
VAULT	N	N	N
VAULTRETRIEVE	N	N	N
COURIERRETRIEVE	N	N	N
ONSITERETRIEVE	N	N	N

Table 4. State transitions for volumes

	Destination state	
The current state of the volume	**VAULT**	**VAULTRETRIEVE**
MOUNTABLE	Y	N
NOTMOUNTABLE	Y	N
COURIER	Y	N
VAULT	N	N
VAULTRETRIEVE	N	N
COURIERRETRIEVE	N	N
ONSITERETRIEVE	N	N

Table 5. State transitions for volumes

	Destination state	
The current state of the volume	**COURIERRETRIEVE**	**ONSITERETRIEVE**

The current state of the volume	Destination state	
	COURIERRETRIEVE	ONSITERETRIEVE
MOUNTABLE	N	N
NOTMOUNTABLE	N	N
COURIER	N	N
VAULT	N	N
VAULTRETRIEVE	Y	Y
COURIERRETRIEVE	N	Y
ONSITERETRIEVE	N	N

Example: Move disaster recovery media from the NOTMOUNTABLE state

Move disaster recovery media that is in the NOTMOUNTABLE state to the COURIER state, and then query the results.

```
move drmedia * wherestate=notmountable
tostate=courier

query actlog search="MOVE DRMEDIA"

 08/11/1999 11:12:24   ANR0984I Process 10 for MOVE DRMEDIA started
                        in the BACKGROUND at 11:12:24.
 08/11/1999 11:12:24   ANR0610I MOVE DRMEDIA started by HSIAO as
                        process 10.
 08/11/1999 11:12:25   ANR6683I MOVE DRMEDIA: Volume TAPE0P was moved
                        from NOTMOUNTABLE state to COURIER.
 08/11/1999 11:12:25   ANR6683I MOVE DRMEDIA: Volume TAPE1P was moved
                        from NOTMOUNTABLE state to COURIER.
 08/11/1999 11:12:25   ANR6683I MOVE DRMEDIA: Volume DBTP02 was moved
                        from NOTMOUNTABLE state to COURIER.
 08/11/1999 11:12:25   ANR6683I MOVE DRMEDIA: Volume DBTP01 was moved
                        from NOTMOUNTABLE state to COURIER.
 08/11/1999 11:12:25   ANR6682I MOVE DRMEDIA command ended: 4 volumes
                        processed.
 08/11/1999 11:12:25   ANR0611I MOVE DRMEDIA started by HSIAO as
                        process 10 has ended.
 08/11/1999 11:12:25   ANR0985I Process 10 for MOVE DRMEDIA running in
                        the BACKGROUND processed 4 items with a
                        completion state of SUCCESS at 11:12:25.
```

Example: Move disaster recovery media from the MOUNTABLE state

Move disaster recovery media from the MOUNTABLE state to the COURIER state. If the media is in an automated library, MOVE DRMEDIA ejects the media before you change the state.

```
move drmedia * wherestate=mountable tostate=courier wait=yes

ANR0984I Process 12 for MOVE DRMEDIA started
 in the FOREGROUND at 09:57:17.
ANR0609I MOVE DRMEDIA started as process 12.
ANR0610I MOVE DRMEDIA started by HSIAO as
 process 12.
ANR6696I MOVE DRMEDIA: CHECKOUT LIBVOLUME for
 volume TAPE01 in library LIB8MM starting.
ANR6697I MOVE DRMEDIA: CHECKOUT LIBVOLUME for
 volume TAPE01 in library LIB8MM completed
 successful.
ANR6683I MOVE DRMEDIA: Volume TAPE01 was moved
 from MOUNTABLE state to COURIER.
ANR6696I MOVE DRMEDIA: CHECKOUT LIBVOLUME for
 volume TAPE02 in library LIB8MM starting.
ANR6697I MOVE DRMEDIA: CHECKOUT LIBVOLUME for
 volume TAPE02 in library LIB8MM completed
 successful.
ANR6683I MOVE DRMEDIA: Volume TAPE02 was moved
 from MOUNTABLE state to COURIER.
```

```
ANR6696I MOVE DRMEDIA: CHECKOUT LIBVOLUME for
 volume DBTP05 in library LIB8MM starting.
ANR6697I MOVE DRMEDIA: CHECKOUT LIBVOLUME for
 volume DBTP05 in library LIB8MM completed
 successful.
ANR6683I MOVE DRMEDIA: Volume DBTP05 was moved
 from MOUNTABLE state to COURIER.
ANR6696I MOVE DRMEDIA: CHECKOUT LIBVOLUME for
 volume DBTP04 in library LIB8MM starting.
ANR6697I MOVE DRMEDIA: CHECKOUT LIBVOLUME for
 volume DBTP04 in library LIB8MM completed
 successful.
ANR6683I MOVE DRMEDIA: Volume DBTP04 was moved
 from MOUNTABLE state to COURIER.
ANR6682I MOVE DRMEDIA command ended: 4 volumes
 processed.
ANR0611I MOVE DRMEDIA started by HSIAO as
 process 12 has ended.
ANR0985I Process 12 for MOVE DRMEDIA running
 in the FOREGROUND processed 4 items with a
 completion state of SUCCESS at 10:12:25.
```

Example: Move disaster recovery media from the VAULTRETRIEVE state

Move disaster recovery media that is in the VAULTRETRIEVE state to the ONSITERETRIEVE state. Generate a CHECKIN LIBVOLUME command for each volume that is successfully processed and store the commands in a file:

AIX | Linux

```
move drmedia * wherestate=vaultretrieve tostate=onsiteretrieve
cmdfilename=/drm/move/exec.cmds
cmd="checkin libvol lib8mm &vol status=scratch"
```

Windows

```
move drmedia * wherestate=vaultretrieve tostate=onsiteretrieve
cmdfilename=c:\drm\move\exec.cmd
cmd="checkin libvol lib8mm &vol status=scratch"
```

Query the results:

```
query actlog search="MOVE DRMEDIA"
```

```
08/13/1999 09:12:24  ANR0984I Process 15 for MOVE DRMEDIA started in
                      the BACKGROUND at 09:12:24.
08/13/1999 09:12:24  ANR0610I MOVE DRMEDIA started by HSIAO as
                      process 15.
08/13/1999 09:12:24  ANR6684I MOVE DRMEDIA: Volume CSTP01 was deleted.
08/13/1999 09:12:24  ANR6684I MOVE DRMEDIA: Volume CSTP02 was deleted.
08/13/1999 09:12:24  ANR6684I MOVE DRMEDIA: Volume DBTP10 was deleted.
08/13/1999 09:12:24  ANR6684I MOVE DRMEDIA: Volume DBTP11 was deleted.
08/13/1999 09:12:27  ANR6682I MOVE DRMEDIA command ended: 4 volumes
                      processed.
08/13/1999 09:12:42  ANR0611I MOVE DRMEDIA started by HSIAO as process
                       15 has ended.
08/13/1997 09:12:42  ANR0985I Process 15 for MOVE DRMEDIA running in
                      the BACKGROUND processed 4 items with a
                      completion state of SUCCESS at 09:12:42.
```

The volume check-in commands were also created in the file that was specified with the CMDFILENAME parameter:

- AIX | Linux /drm/move/exec.cmds
- Windows c:\drm\move\exec.cmd

The file contains these lines:

```
checkin libvol lib8mm CSTP01 status=scratch
checkin libvol lib8mm CSTP02 status=scratch
checkin libvol lib8mm DBTP10 status=scratch
checkin libvol lib8mm DBTP11 status=scratch
```

Tip: To process the CHECKIN LIBVOLUME commands, issue the MACRO command with the file name as the macro name.

Related commands

Table 6. Commands related to MOVE DRMEDIA

Command	Description
BACKUP DB	Backs up the IBM Spectrum Protect database to sequential access volumes.
BACKUP STGPOOL	Backs up a primary storage pool to a copy storage pool.
CANCEL PROCESS	Cancels a background server process.
CHECKOUT LIBVOLUME	Checks a storage volume out of an automated library.
DISMOUNT VOLUME	Dismounts a sequential, removable volume by the volume name.
PREPARE	Creates a recovery plan file.
QUERY ACTLOG	Displays messages from the server activity log.
QUERY DRMEDIA	Displays information about disaster recovery volumes.
QUERY DRMSTATUS	Displays DRM system parameters.
QUERY PROCESS	Displays information about background processes.
SET DRMACTIVEDATASTGPOOL	Specifies that active-data storage pools are managed by DRM.
AIX Linux Windows SET DRMCOPYCONTAINERSTGPOOL	AIX Linux Windows Specifies the container-copy storage pools that are used in DRM commands.
SET DRMCOPYSTGPOOL	Specifies that copy storage pools are managed by DRM.
SET DRMCOURIERNAME	Specifies the name of the courier for the disaster recovery media.
SET DRMDBBACKUPEXPIREDAYS	Specifies criteria for database backup series expiration.
SET DRMVAULTNAME	Specifies the name of the vault where DRM media is stored.
SET DRMCMDFILENAME	Specifies a file name for containing DRM executable commands.
SET DRMFILEPROCESS	Specifies whether the MOVE DRMEDIA or QUERY DRMEDIA command processes files associated with a device type of file.
SET DRMNOTMOUNTABLENAME	Specifies the location name of the DRM media to be sent offsite.

MOVE GRPMEMBER (Move a server group member)

Use this command to move a member from one server group to another server group. The command fails if the member you are moving has the same name as a current member of the group.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-MOVe GRPMEMber--member_name--from_group--to_group----------><
```

Parameters

member_name (Required)
Specifies the member (a server or a server group) to move.

from_group (Required)

Specifies the server group with which the member is currently associated.

to_group (Required)

Specifies the new server group for the member.

Example: Move a server to another server group

Move member PAYSON from REGION1 group to REGION2 group.

```
move grpmember payson region1 region2
```

Related commands

Table 1. Commands related to MOVE GRPMEMBER

Command	Description
DEFINE GRPMEMBER	Defines a server as a member of a server group.
DEFINE SERVERGROUP	Defines a new server group.
DELETE GRPMEMBER	Deletes a server from a server group.
DELETE SERVERGROUP	Deletes a server group.
QUERY SERVER	Displays information about servers.
QUERY SERVERGROUP	Displays information about server groups.
RENAME SERVERGROUP	Renames a server group.
UPDATE SERVERGROUP	Updates a server group.

MOVE MEDIA (Move sequential-access storage pool media)

Use this command to manage overflow storage pools. The database tracks media that is moved by using this command.

This command applies to sequential-access primary and copy storage pool volumes that are managed by an automated library (including an external library). The library does not have to be full. One or more sequential-access storage pool volumes can be processed at the same time.

Use the DAYS parameter to identify eligible volumes to be moved. Use the OVERFLOW LOCATION parameter to record the storage location for the moved media.

This command generates a background process that you can view by using the QUERY PROCESS command. To cancel, issue the CANCEL PROCESS command.

To determine whether the command was successful, issue the QUERY ACTLOG command or use the server console.

The volumes that are moved by the MOVE DRMEDIA command for offsite recovery are not processed by the MOVE MEDIA command.

The MOVE MEDIA command does not process copy storage pool volumes with a DRM STATUS value of NOTMOUNTABLE, COURIER, or VAULT.

Privilege class

To issue this command, you must have one of the following privilege classes:

- If the CMD parameter is NOT specified: operator or system privilege.
- If the CMD parameter is specified and the REQSYSAUTHOUTFILE server option is set to NO: operator, unrestricted storage, or system privilege.
- If the CMD parameter is specified and the REQSYSAUTHOUTFILE server option is set to YES (the default): system privilege.

Syntax

```
>>-MOVe MEDia--volume_name--STGpool--=--pool_name--------------->
```

Parameters

volume_name (Required)
: Specifies the name of the sequential access primary or copy storage pool volume to be processed. You can use a wildcard character to specify the name. All matching volumes are considered for processing.

STGpool (Required)
: Specifies the name of the sequential access primary or copy storage pool that is used to select the volumes for processing. You can use a wildcard character to specify the name. All matching storage pools are processed. If the storage pool specified is not managed by an automated library, no volumes are processed.

Days
: Specifies the number of days that must elapse after the volume is written or read before the volume is eligible for processing by the command. This parameter is optional. You can specify a number from 0 to 9999. The default value is 0. The most recent of the volumes' last written date or last read date is used to calculate the number of days elapsed.

WHERESTate
: Specifies the current state of the volumes to be processed. This parameter is used to restrict processing to the volumes that are in the specified state. This parameter is optional. The default value is MOUNTABLEINLIB.
Possible values are:

  MOUNTABLEInlib
  : Specifies that storage pool volumes are to move from the MOUNTABLEINLIB state to the MOUNTABLENOTINLIB state. Volumes in the MOUNTABLEINLIB state contain valid data and are in the library.

  MOUNTABLENotinlib
  : Specifies that storage pool volumes are to change from the MOUNTABLENOTINLIB state back to the MOUNTABLEINLIB state. Volumes in the MOUNTABLENOTINLIB state might contain valid data and are in the overflow location.

    - For empty scratch volumes, the MOVE MEDIA command deletes the volume records so that they can be used again.
    - For private volumes, the MOVE MEDIA command resets the volume location to blank, changes the volumes' state to CHECKIN, and changes the last update date to the current date.
    - For scratch volumes with data, the MOVE MEDIA command resets the volume location to blank, changes the volumes' state to CHECKIN, and changes the last update date to the current date.

Attention: Volumes in the CHECKIN state might contain valid data and must be checked into the library.

WHERESTATUs
: Specifies that the move process must be restricted by volume status. This parameter is optional. You can specify more than one status in a list by separating each status with a comma and no intervening spaces. If you do not specify this parameter, volumes moved from the MOUNTABLEINLIB state to the MOUNTABLENOTINLIB state are restricted to only full volumes, and volumes moved from the MOUNTABLENOTINLIB state to the MOUNTABLEINLIB state are restricted to only empty volumes.

  Possible values are:

  FULl
  : Moves volumes with a status of FULL.

  FILling
  : Moves volumes with a status of FILLING.

  EMPty
  : Moves volumes with a status of EMPTY.

ACCess
: Specifies how users and system processes access files in the storage pool volume that is moved out from an automated library and stored in an overflow location by the MOVE MEDIA command. This parameter is optional. If you do not specify this parameter, moving volumes from the MOUNTABLEINLIB state to the MOUNTABLENOTINLIB process updates the volumes' access mode to READONLY, and moving volumes from the MOUNTABLENOTINLIB state to the MOUNTABLEINLIB process updates the volumes' access mode to READWRITE.

  Possible values are:

  READWrite
  : Specifies that users and system processes can read from and write to files stored on the volume that is in the overflow location. If this value is specified, IBM Spectrum Protect™ requests the volume to be checked into the library when the volume is needed for a read or write operation.

  READOnly
  : Specifies that users and system processes can read but not write to files that are stored on the volume that is in the overflow location. The server requests the volume to be checked into the library only when the volume is needed for a read operation.

OVFLOcation
: Specifies the overflow location that is the destination of the volumes that are being processed. The maximum length of the location name is 255 characters. The location name information must be enclosed in quotation marks if it contains any blank characters. If you do not specify an overflow location and the storage pool also has no overflow location identified, the server changes the location of the ejected volume to a null string ("").

REMove

Specifies that the server tries to move the volume out of the library and into the convenience I/O station or entry/exit ports. This parameter is optional. Possible values are YES, BULK, and NO. The default is BULK. The response of the server to each of those options and the default values are described in the following tables.

349X libraries: The following table shows how the server responds for 349X libraries.

Table 1. How the Server Responds for 349X Libraries

REMOVE=YES	**REMOVE=BULK**	**REMOVE=NO**
The 3494 Library Manager ejects the cartridge to the convenience I/O station.	The 3494 Library Manager ejects the cartridge to the high-capacity output facility.	The 3494 Library Manager does not eject the volume. The server leaves the cartridge in the library in the INSERT category for use by other applications.

SCSI libraries: The following table shows how the server responds to YES, BULK, and NO for SCSI libraries.

Table 2. How the Server Responds for SCSI Libraries

If a library...	**And REMOVE=YES...**	**And REMOVE=BULK...**	**And REMOVE=NO**

If a library...	And REMOVE=YES...	And REMOVE=BULK...	And REMOVE=NO
Does not have entry/exit ports	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server then prompts you to remove the cartridge from the slot and issue a REPLY command.	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server does not prompt you to remove the cartridge and does not require a REPLY command.	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server does not prompt you to remove the cartridge and does not require a REPLY command.
Has entry/exit ports and an entry/exit port is available	The server moves the cartridge to the available entry/exit port and specifies the port address in a message. The server then prompts you to remove the cartridge from the slot and issue a REPLY command.	The server moves the cartridge to the available entry/exit port and specifies the port address in a message. The server does not prompt you to remove the cartridge and does not request a REPLY command.	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server does not prompt you to remove the cartridge and does not require a REPLY command.
Has entry/exit ports, but no ports are available	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server then prompts you to remove the cartridge from the slot and issue a REPLY command.	The server waits for an entry/exit port to be made available.	The server leaves the cartridge in its current slot within the library and specifies the slot address in a message. The server does not prompt you to remove the cartridge and does not require a REPLY command.

ACSLS libraries: The following table shows how the server responds for ACSLS libraries.

Table 3. How the Server Responds for ACSLS Libraries

REMOVE=YES or REMOVE=BULK	REMOVE=NO
The server ejects the cartridge to the convenience I/O station. The server then deletes the volume entry from the server library inventory. While moving volumes from the MOUNTABLE state with REMOVE=YES specified, the MOVE MEDIA command uses more than one slot in the CAP for a StorageTek library with ACSLS.	The server does not eject the cartridge. The server deletes the volume entry from the server library inventory and leaves the volume in the library.

External libraries: The following table shows how the server responds for external libraries.

Table 4. How the Server Responds for External Libraries

REMOVE=YES or REMOVE=BULK	REMOVE=NO
The server ejects the cartridge to the convenience I/O station. The server then deletes the volume entry from the server library inventory.	The server does not eject the cartridge. The server deletes the volume entry from the server library inventory and leaves the volume in the library.

CMd

Specifies the creation of executable commands. This parameter is optional. You must enclose your command specification in quotation marks. The maximum length of the command specification is 255 characters. For each volume successfully processed by the MOVE MEDIA command, the server writes the associated commands to a file. Specify the file name with the CMDFILENAME parameter.

AIX Linux If you do not specify the file name, the MOVE MEDIA command generates a default file name by appending the string exec.cmds.media to the IBM Spectrum Protect server directory.

Windows If you do not specify the file name, the MOVE MEDIA command generates a default file name by appending the string exec.cmd.media to the IBM Spectrum Protect server directory.

If the length of the command that is written to the file exceeds 255 characters, it is split into multiple lines and a continuation character, +, is added to all but the last line of the command. You must alter the continuation character according to the requirements of the product that runs the commands.

If you do not specify CMD, the MOVE MEDIA command might not generate any executable commands.

string
Specifies the string to build an executable command. You can specify any free form text for the string. Enclose the full string in quotation marks. For example, the following is a valid executable command specification:

```
CMD="UPDATE VOLUME &VOL"
```

The following is an invalid executable command specification:

```
CMD=""UPDATE VOLUME" &VOL"
```

substitution
Specifies a variable for which you want the command to substitute a value. The possible substitution variables are:

&VOL
Substitute the volume name for &VOL. You can specify lowercase characters, &vol. No spaces or blanks are allowed between ampersand, &, and VOL. If there are spaces or blanks between ampersand and VOL, the MOVE MEDIA command treats them as strings and no substitution is set. If &VOL is not specified, no volume name is set in the executable command.

&LOC
Substitute the volume location for &LOC. You can specify lowercase characters, &loc. No spaces or blanks are allowed between ampersand, &, and LOC. If there are spaces or blanks between ampersand and LOC, the MOVE MEDIA command treats them as strings and no substitution is set. If &LOC is not specified, no location name is set in the executable command.

&VOLDSN
Substitute the volume file name for &VOLDSN. An example of a storage pool tape volume file name that uses the default prefix ADSM is ADSM.BFS. If &VOLDSN is not specified, no volume file name is set in the executable command.

&NL
Substitute a new line character for &NL. When &NL is specified, the MOVE MEDIA command splits the command at the position where the &NL is and does not append any continuation character. The user is responsible for specifying the correct continuation character before the &NL if one is required. The user is also responsible for the length of the line written. If the &NL is not specified and the length of the command line exceeds 255, the command line is split into multiple lines and a continuation character, +, is added to all but the last line of the command.

CMDFilename
Specifies the full path name of a file that contains the commands that are specified with CMD. This parameter is optional. The maximum length of the file name is 1279 characters.

AIX Linux If you do not specify a file name, the MOVE MEDIA command generates a default file name by appending the string `exec.cmds.media` to the IBM Spectrum Protect server directory. The server directory is the current working directory of the IBM Spectrum Protect server process.

Windows If you do not specify a file name, the MOVE MEDIA command generates a default file name by appending the string *`exec.cmd.media`* to the IBM Spectrum Protect server directory. The server directory is the current working directory of the IBM Spectrum Protect server process.

The MOVE MEDIA command automatically allocates the file name that is specified or generated. If the file name exists, you can use the APPEND=YES parameter to add to the file. Otherwise, the file is overwritten. If a file is accidentally overwritten and you must run the commands that were in the file, issue the QUERY MEDIA command to rebuild the executable commands for the desired volumes. If the MOVE MEDIA command fails after the command file is allocated, the file is not deleted.

APPend

Specifies to write at the beginning or ending of the command file data. The default is NO. Possible values are:

No
: Specifies to write the data from the beginning of the command file. If the command file exists, its contents are overwritten.

Yes
: Specifies to append the command file by writing at the end of the command file data.

CHECKLabel
: Specifies whether the server reads volume labels for sequential media. For SCSI devices, you can suppress label checking by setting the CHECKLabel to NO. This parameter is not applicable to 349X libraries. This parameter is optional. The default is YES. Possible values are:

Yes
: Specifies that the server attempts to read the media label. Reading the media label verifies that the correct volume is being checked out.

No
: Specifies that the server does not attempt to read media label. This increases performance because the read process does not occur.

CAP
: Specifies which cartridge access port (CAP) to use for ejecting volumes if you specify REMOVE=YES. This parameter applies to volumes in ACSLS libraries only. If the CAP priority value is set to 0 in the library, this parameter is required. If a CAP priority value greater than 0 is set in the library, this parameter is optional. By default, all CAPs initially have a priority value of 0, which means that ACSLS does not automatically select the CAP.
To display valid CAP identifiers (*x,y,z*), issue the QUERY CAP command with ALL specified from the Automated Cartridge System System Administrator (ACSSA) console on the ACSLS server host. The identifiers are as follows:

x
: The Automated Cartridge System (ACS) ID. This identifier can be a number in the range 0 - 126.

y
: The Library Storage Module (LSM) ID. This identifier can be a number in the range 0 - 23.

z
: The CAP ID. This identifier can be a number in the range 0 - 11.

For more information, see the StorageTek documentation.

Example: Move all full volumes out of the library

Move all full volumes that are in the ARCHIVE sequential primary storage pool out of the library.

```
move media * stgpool=archive
```

Example: Generate the checkin commands

Generate the CHECKIN LIBVOLUME commands for full and partially full volumes that are in the ONSITE.ARCHIVE primary storage pool and stored in the overflow location, Room 2948/Bldg31.

AIX Linux MOVE MEDIA creates the executable commands in /tsm/move/media/checkin.vols

Windows MOVE MEDIA creates the executable commands in c:\tsm\move\media\checkin.vols

```
move media * stgpool=onsite.archive
wherestate=mountablenotinlib wherestatus=full,filling
ovflocation=room2948/bldg31
cmd="checkin libvol lib3494 &vol status=private"
cmdfilename=/tsm/move/media/checkin.vols

checkin libvolume lib3494 TAPE04 status=private
checkin libvolume lib3494 TAPE13 status=private
checkin libvolume lib3494 TAPE14 status=private
```

Tip: Run the CHECKIN LIBVOLUME commands by issuing the MACRO command with the following as the macro name:

- AIX Linux /tsm/move/media/checkin.vols
- Windows c:\tsm\move\media\checkin.vols

Related commands

Table 5. Commands related to MOVE MEDIA

Command	Description
CANCEL PROCESS	Cancels a background server process.
QUERY MEDIA	Displays information about storage pool volumes moved by the MOVE MEDIA command.
QUERY PROCESS	Displays information about background processes.

MOVE NODEDATA (Move data by node in a sequential access storage pool)

Use this command to move data that is in a sequential-access storage pool. You can move data for one or more nodes, a group of file spaces, or for a group of collocated nodes. You can also move selected file spaces for a single node. The data can be in a primary storage pool, a copy storage pool, or an active-data pool.

This command is helpful for reducing the number of volume mounts during client restore or retrieve operations by consolidating data for a specific node within a storage pool, or to move data to another storage pool. For example, you can use this command for moving data to a random-access storage pool in preparation for client restore processing.

Ensure that the access mode of the volumes from which you are moving the node data is read/write or read-only and that the access mode of the volumes to which you are moving the node data is set to read/write. This operation will not move data on volumes with access modes of offsite, unavailable, or destroyed.

The MOVE NODEDATA command takes two forms, depending on whether you are moving data only for selected filespaces. The syntax and parameters for each form are defined separately.

Restriction: You cannot move node data into or out of a storage pool that is defined with a CENTERA device class.

Table 1. Commands related to MOVE NODEDATA

Command	Description
CANCEL PROCESS	Cancels a background server process.
COPY ACTIVEDATA	Copies active backup data.
DEFINE COLLOCGROUP	Defines a collocation group.
DEFINE COLLOCMEMBER	Adds a client node or file space to a collocation group.
DELETE COLLOCGROUP	Deletes a collocation group.
DELETE COLLOCMEMBER	Deletes a client node or file space from a collocation group.
MOVE DATA	Moves data from a specified storage pool volume to another storage pool volume.
QUERY ACTLOG	Displays messages from the server activity log.
QUERY COLLOCGROUP	Displays information about collocation groups.
QUERY FILESPACE	Displays information about data in file spaces that belong to a client.
QUERY NODEDATA	Displays information about the location and size of data for a client node.
QUERY OCCUPANCY	Displays file space information by storage pool.
QUERY PROCESS	Displays information about background processes.
QUERY STGPOOL	Displays information about storage pools.
QUERY VOLUME	Displays information about storage pool volumes.
UPDATE COLLOCGROUP	Updates the description of a collocation group.

- MOVE NODEDATA (Move data in file spaces for one or more nodes or a collocation group)
  Use this command to move data in file spaces that belong to; one or more nodes, a node collocation group, or a file space collocation group.
- MOVE NODEDATA (Move data from selected file spaces of a single node)
  Use this command to move data for selected file spaces belonging to a single node.

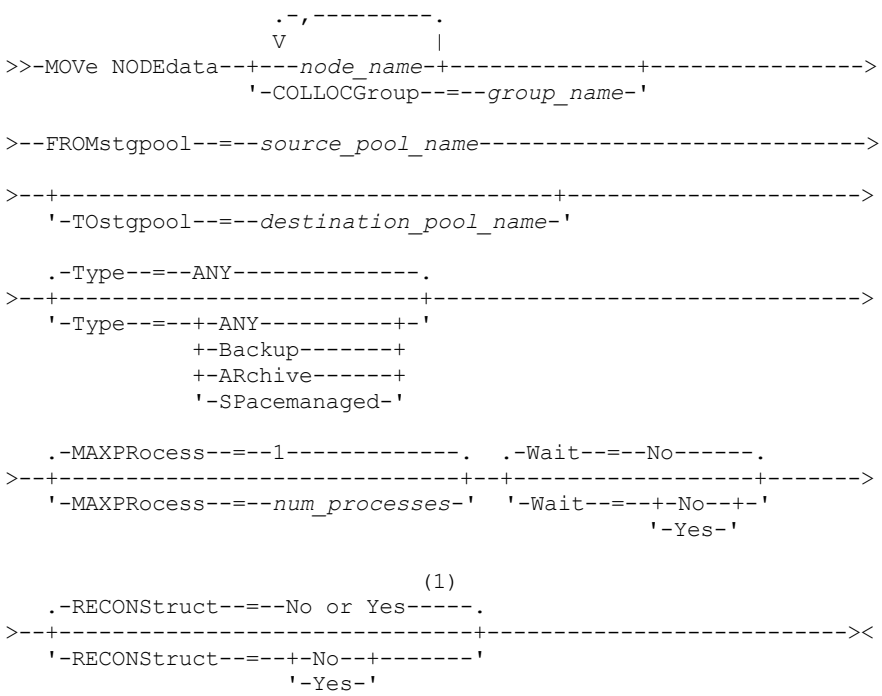
MOVE NODEDATA (Move data in file spaces for one or more nodes or a collocation group)

Use this command to move data in file spaces that belong to; one or more nodes, a node collocation group, or a file space collocation group.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the source storage pool. If your authorization is restricted storage privilege and you are moving data to another storage pool, you need the appropriate authority for the destination storage pool.

Syntax



Notes:

1. The default is NO if either the source or target storage pool is random access. The default is YES if both the source and target storage pools are sequential access.

Parameters

node_name (Required unless the COLLOCGROUP parameter is specified)
: Specifies the node name that is related to the data that is moved with this command. Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify names.

COLLOCGroup (Required unless the node_name parameter is specified)
: Specifies the name of the collocation group whose data is to be moved. Data for all nodes and file spaces that belong to the collocation group are moved.

FROMstgpool (Required)

Specifies the name of a sequential-access storage pool that contains data to be moved. This storage pool must be in the NATIVE or NONBLOCK data format.

TOstgpool

Specifies the name of a storage pool to where the data is moved. This storage pool must be in the NATIVE or NONBLOCK data format. This parameter is optional and does not apply when the source storage pool is a copy storage pool or an active-data pool. That is, if the source storage pool is a copy storage pool the destination must be the same copy storage pool. Similarly, if the source storage pool is an active-data pool, the destination must be the same active-data pool. If a value is not specified, data is moved to other volumes within the source pool.

Important: If you are moving data within the same storage pool, there must be volumes available that do not contain the node data that you are moving. That is, the server cannot use volumes that contain the data to be moved as destination volumes.

Type

Specifies the type of files to be moved. This parameter is optional. The default value is ANY. If the source storage pool is an active-data pool, the only valid values are ANY and BACKUP. However, only the active versions of backup data are moved if TYPE=ANY. Specify one of the following values:

ANY

Specifies that all types of files are moved.

Backup

Specifies that backup files are moved.

ARchive

Specifies that archive files are moved. This value is not valid for active-data pools.

SPacemanaged

Specifies that space-managed files (files that were migrated by an IBM Spectrum Protect™ for Space Management client) are moved. This value is not valid for active-data pools.

MAXPRocess

Specifies the maximum number of parallel processes to use for moving data. This parameter is optional. You can specify a value from 1 to 999, inclusive. The default value is 1. Increasing the number of parallel processes usually improves throughput.

When you determine this value, consider the number of logical and physical drives that can be dedicated to this operation. To access a sequential access volume, IBM Spectrum Protect uses a mount point and, if the device type is not FILE, a physical drive. The number of available mount points and drives depends on other IBM Spectrum Protect system activity. The mount points and drives also depend on the mount limits of the device classes for the sequential access storage pools that are involved in the move. Each process needs a mount point for storage pool volumes, and, if the device type is not FILE, each process also needs a drive.

Wait

Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default value is No. Specify one of the following values:

No

Specifies that the server processes this command in the background. You can continue with other tasks while the command is being processed.

The server displays messages that are created from the background process either in the activity log or the server console, depending on where messages are logged.

To cancel a background process, use the CANCEL PROCESS command. If a background process is canceled, some files might move before the cancellation.

Yes

Specifies that the server processes this command in the foreground. You wait for the command to complete before you can continue with other tasks. The server then displays the output messages to the administrative client when the command completes.

Restriction: You cannot specify WAIT=YES from the server console.

RECONStruct

Specifies whether to reconstruct file aggregates during data movement. Reconstruction removes empty space that accumulated during deletion of logical files from an aggregate. This parameter is optional. If both the source and target storage pools are sequential access, the default value is YES. If either the source or target storage pool is random access, the default is NO.

The parameter is not available or is ignored if any of the following conditions are true:

- The data format is NETAPPDUMP, CELERRADUMP, or NDMPDUMP.
- The data is in a storage pool that is configured for data deduplication.
- The target storage pool for the data movement is configured for data deduplication.

Attention: Reconstruction removes inactive backup files in active-data pools. If you specify RECONSTRUCT=NO when you move the data in an active-data pool that is not configured for data deduplication, inactive backup files remain in the storage pool.
You can specify one of the following values:

No
: Specifies that reconstruction of file aggregates are not run during the move.

Yes
: Specifies that reconstruction of file aggregates are run during the move. You can specify only this option when both the source and the target storage pools are sequential-access.

Move a specific node's data from a tape storage pool to a disk storage pool

Move all data that belongs to node MARY that is stored in storage pool TAPEPOOL. Data can be moved to disk storage pool BACKUPPOOL.

```
move nodedata mary
 fromstgpool=tapepool tostgpool=backuppool
```

Move data for a node collocation group from one storage pool to another

Move all data for node collocation group NODEGROUP1 from storage pool SOURCEPOOL to storage pool TARGETPOOL.

```
move nodedata collocgroup=nodegroup1 fromstgpool=sourcespool tostgpool=targetpool
```

Move data for a file space collocation group from one storage pool to another

Move all data for file space collocation group FSGROUP1 from storage pool SOURCEPOOL2 to storage pool TARGETPOOL2.

```
move nodedata collocgroup=fsgroup1 fromstgpool=sourcespool2 tostgpool=targetpool2
```

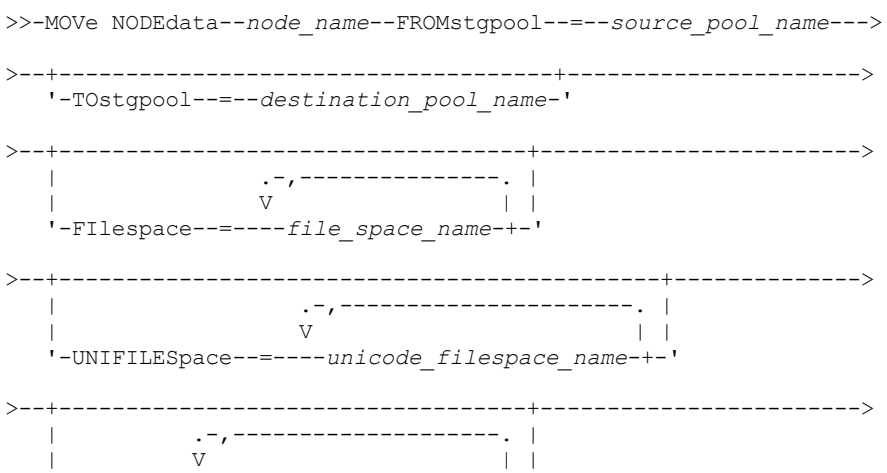
MOVE NODEDATA (Move data from selected file spaces of a single node)

Use this command to move data for selected file spaces belonging to a single node.

Privilege class

To issue this command, you must have system privilege, unrestricted storage privilege, or restricted storage privilege for the source storage pool. If your authorization is restricted storage privilege and you intend to move data to another storage pool, you must also have the appropriate authority for the destination storage pool.

Syntax



```
   '-FSID--=----filespace_identifier-+-'

   .-Type--=--ANY--------------.
>--+---------------------------+-------------------------------->
   '-Type--=--+-ANY----------+-'
              +-Backup-------+
              +-ARchive------+
              '-SPacemanaged-'

   .-MAXPRocess--=--1-------------.  .-Wait--=--No------.
>--+-------------------------------+--+------------------+------->
   '-MAXPRocess--=--num_processes-'  '-Wait--=--+-No--+-'
                                               '-Yes-'

                                (1)
   .-RECONStruct--=--No or Yes-----.
>--+-------------------------------+-------------------------><
   '-RECONStruct--=--+-No--+-------'
                     '-Yes-'
```

Notes:

1. The default is NO if either the source or target storage pool is random access. The default is YES if both the source and target storage pools are sequential access.

Parameters

node_name (Required)
: Specifies the node name related to the data that is moved with this command. Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify names.

FROMstgpool (Required)
: Specifies the name of a sequential-access storage pool that contains data to be moved. This storage pool must be in the NATIVE or NONBLOCK data format.

TOstgpool
: Specifies the name of a storage pool to which data will be moved. This storage pool must be in the NATIVE or NONBLOCK data format. This parameter is optional and does not apply when the source storage pool is a copy storage pool or an active-data pool. That is, if the source storage pool is a copy storage pool the destination must be the same copy storage pool. Similarly, if the source storage pool is an active-data pool, the destination must be the same active-data pool. If a value is not specified, data is moved to other volumes within the source pool.
  Important: If you are moving data within the same storage pool, there must be volumes available that do not contain the node data you are moving. That is, the server cannot use volumes that contain the data to be moved as destination volumes.

FILespace
: Specifies the name of the non-Unicode filespace that contains data to be moved. Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify names. This parameter is optional. If you do not specify a value for this parameter and values for UNIFILESPACE or the FSID or both, non-Unicode file spaces are not moved.

UNIFILESpace
: Specifies the name of the Unicode filespace that contains data to be moved. Separate multiple names with commas and no intervening spaces. You can use wildcard characters to specify names. This parameter is optional. If you do not specify a value for this parameter and values for FILESPACE or the FSID or both, non-Unicode file spaces are not moved.

FSID
: Specifies file space identifiers (FSIDs) for the file spaces to be moved. Separate multiple names with commas and no intervening spaces. This parameter is optional.

Type
: Specifies the type of files to be moved. This parameter is optional. The default value is ANY. If the source storage pool is an active-data pool, the only valid values are ANY and BACKUP. However, only the active versions of backup data are moved if TYPE=ANY. Possible values are:

  ANY
  : Specifies that all types of files are moved.

  Backup
  : Specifies that backup files are moved.

  ARchive
  : Specifies that archive files are moved. This value is not valid for active-data pools.

SPacemanaged
: Specifies that space-managed files (files that were migrated by an IBM Spectrum Protect™ for Space Management client) are moved. This value is not valid for active-data pools.

MAXPRocess
: Specifies the maximum number of parallel processes to use for moving data. This parameter is optional. You can specify a value from 1–999, inclusive. The default value is 1. Increasing the number of parallel processes should improve throughput.

When determining this value, consider the number of logical and physical drives that can be dedicated to this operation. To access a sequential access volume, IBM Spectrum Protect uses a mount point and, if the device type is not FILE, a physical drive. The number of available mount points and drives depends on other IBM Spectrum Protect system activity and on the mount limits of the device classes for the sequential access storage pools that are involved in the move. Each process needs a mount point for storage pool volumes, and, if the device type is not FILE, each process also needs a drive.

Wait
: Specifies whether to wait for the server to complete processing this command in the foreground. This parameter is optional. The default value is No. Possible values are:

No
: Specifies that the server processes this command in the background. You can continue with other tasks while the command is being processed.

The server displays messages that are created from the background process either in the activity log or the server console, depending on where messages are logged.

To cancel a background process, use the CANCEL PROCESS command. If a background process is canceled, some files may have already moved before the cancellation.

Yes
: Specifies that the server processes this command in the foreground. You wait for the command to complete before continuing with other tasks. The server then displays the output messages to the administrative client when the command completes.
Restriction: You cannot specify WAIT=YES from the server console.

RECONStruct
: Specifies whether to reconstruct file aggregates during data movement. Reconstruction removes empty space that has accumulated during deletion of logical files from an aggregate. This parameter is optional. If both the source and target storage pools are sequential access, the default value is YES. If either the source or target storage pool is random access, the default is NO.
The parameter is not available or is ignored if any of the following conditions are true:

- The data format is NETAPPDUMP, CELERRADUMP, or NDMPDUMP.
- The data is in a storage pool that is configured for data deduplication.
- The target storage pool for the data movement is configured for data deduplication.

Attention: Reconstruction removes inactive backup files in active-data pools. If you specify RECONSTRUCT=NO when moving the data in an active-data pool that is not configured for data deduplication, inactive backup files remain in the storage pool.
Possible values are:

No
: Specifies that reconstruction of file aggregates will not be performed during the move.

Yes
: Specifies that reconstruction of file aggregates will be performed during the move. You may only specify this option when both the source and the target storage pools are sequential-access.

Example: Move a node's non-Unicode and Unicode data

Move data for node TOM in storage pool TAPEPOOL. Restrict movement of data to files in non-Unicode file spaces as well as Unicode file spaces, \\jane\d$. Data should be moved to disk storage pool BACKUPPOOL.

```
move nodedata tom
 fromstgpool=tapepool tostgpool=backuppool
 filespace=* unifilespace=\\jane\d$
```

Example: Move all node data from tape storage pools to a disk storage pool

Move all data for node SARAH, from all primary sequential-access storage pools (for this example, TAPEPOOL*) to DISKPOOL. To obtain a list of storage pools that contain data for node SARAH, issue either of the following QUERY OCCUPANCY or SELECT commands:

```
query occupancy sarah
```

```
SELECT * from OCCUPANCY where node_name='sarah'
```

Attention: For this example assume that the results were TAPEPOOL1, TAPEPOOL4, and TAPEPOOL5.

```
move nodedata sarah
 fromstgpool=tapepool1 tostgpool=DISKPOOL

move nodedata sarah
 fromstgpool=tapepool4 tostgpool=DISKPOOL

move nodedata sarah
 fromstgpool=tapepool5 tostgpool=DISKPOOL
```

Example: Move a node's non-Unicode and Unicode file spaces

The following is an example of moving non-Unicode and Unicode file spaces for a node. For node NOAH move non-Unicode filespace \\servtuc\d$ and Unicode file space \\tsmserv1\e$ that has a filespace ID of 2 from sequential access storage pool TAPEPOOL to random access storage pool DISKPOOL.

```
move nodedata noah
 fromstgpool=tapepool tostgpool=diskpool
 filespace=\\tsmserv1\d$ fsid=2
```

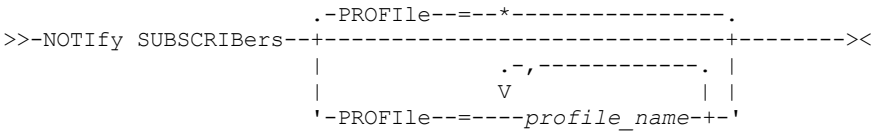
NOTIFY SUBSCRIBERS (Notify managed servers to update profiles)

Use this command on a configuration manager to notify one or more managed servers to request that their configuration information be immediately refreshed.

Privilege class

To issue this command, you must have system privilege.

Syntax



Parameters

PROFIle (Required)
: Specifies the name of the profile. Any managed servers that subscribe to the profile are notified. You can use wildcard characters to specify multiple profiles. To specify multiple profiles, separate the names with commas and no intervening spaces. The default is to notify all subscribers.

Example: Notify managed servers to update profiles

Notify all managed servers that subscribe to a profile named DELTA to request updated configuration information.

```
notify subscribers profile=delta
```

Related commands

Table 1. Commands related to NOTIFY SUBSCRIBERS

Command	Description
DEFINE SUBSCRIPTION	Subscribes a managed server to a profile.
DELETE SUBSCRIBER	Deletes obsolete managed server subscriptions.
DELETE SUBSCRIPTION	Deletes a specified profile subscription.
QUERY SUBSCRIBER	Displays information about subscribers and their subscriptions to profiles.
QUERY SUBSCRIPTION	Displays information about profile subscriptions.
SET CONFIGMANAGER	Specifies whether a server is a configuration manager.
SET CONFIGREFRESH	Specifies a time interval for managed servers to contact configuration managers.

PERFORM LIBACTION (Define or delete all drives and paths for a library)

Use this command to define or delete all drives and their paths for a single library in one step.

This command can be used when you set up a library environment or modify an existing hardware setup that requires changes to many drive definitions. After you define a library, issue PERFORM LIBACTION to define drives and their paths for the library. You can also delete all drives and paths for a library by issuing the command with ACTION=DELETE.

This command is only valid for library types of SCSI and VTL. To use this command with ACTION=DEFINE, the SANDISCOVERY option must be supported and enabled.

For detailed and current library support information, see the Supported Devices website for your operating system:

- AIX | Windows Supported devices for AIX and Windows
- Linux Supported devices for Linux

Privilege class

To issue this command, you must have system privilege or unrestricted storage privilege.

Syntax

```
>>-PERForm LIBACTion--library_name------------------------------>

>----ACTion--=--+-DEFine--| A |-+------------------------------>
                +-DELete--------+
                +-RESet--| B |--+
                '-QUIesce-------'

                                .-PREView--=--No------.
>--+-----------------------+--+---------------------+---------><
   '-SOURCe--=--source_name-'  '-PREView--=--+-Yes-+-'
                                             '-No--'

A (DEFine)

|--+-------------------------------+--------------------------->
   '-DEVIce--=--library_device_name-'

   .-PREFix--=--library_name------.
>--+-----------------------------+-----------------------------|
   '-PREFix--=--drive_prefix_name-'

B (RESet)

                          .-DRIVEsonly--=--No------.
|----ACTion--=--RESet-----+------------------------+-------------|
                          '-DRIVEsonly--=--+-Yes-+-'
```

```
'-No--'
```

Parameters

library_name (Required)
: Specifies the name of the library to be defined or deleted. The maximum length of this name is 30 characters unless you are issuing PERFORM LIBACTION with ACTION=DEFINE and using the default PREFIX value. In that case, the maximum length of the name is 25 characters.

ACTion
: Specifies the action for the PERFORM LIBACTION command. Possible values are:

  DEFine
  : Specifies that drives and their paths are defined for the specified library. SAN discovery must be enabled before you specify this parameter value.

  DELete
  : Specifies that drives and their paths are deleted for the specified library.

  RESet
  : Specifies that drives and their paths are updated online for the specified library.

    DRIVEsonly
    : Specifies that only drives are updated online for the specified library.
      Possible values are:

      No
      : Specifies that drives and paths are updated online.

      Yes
      : Specifies that only drives are updated online.

  QUIesce
  : Specifies that drives are updated offline.

DEVIce
: Specifies the library device name that is used when you define paths if a path to the library is not already defined. If a path is already defined, the DEVICE parameter is ignored. The maximum length for this value is 64 characters. This parameter is optional.

PREFix
: Specifies the prefix that is used for all drive definitions. For example, a PREFIX value of *DR* creates drives *DR0, DR1, DR2*, for as many drives as are created. If a value is not specified for the PREFIX parameter, the library name is used as the prefix for drive definitions. The maximum length for this value is 25 characters.

SOURCe
: Specifies the source server name to be used when you define or delete drive path definitions on a library client or LAN-free client. Use this parameter only if the drives in the library are set up for the local server. If no value is specified for the SOURCE parameter, the local server name, which is the default, is used. The maximum length for the source name is 64 characters.

  If you specify the SOURCE parameter, you can RESET only paths from specified SOURCE values. The SOURCE parameter is not compatible with the RESET DRIVESONLY=YES or QUIESCE options.

  If a source name other than the local server name is specified with ACTION=DEFINE, drive path definitions are defined with the token value of UNDISCOVERED. The path definitions are then updated dynamically by library clients that support SAN Discovery the first time the drive is mounted.

PREView
: Specifies the output of all commands that are processed for PERFORM LIBACTION before the command is issued. The PREVIEW parameter is not compatible with the DEVICE parameter. If you are issuing the PERFORM LIBACTION command to define a library, you cannot specify both the PREVIEW and the DEVICE parameter.
  Possible values are:

  No
  : Specifies that a preview of the commands that are issued for PERFORM LIBACTION is not displayed.

  Yes
  : Specifies that a preview of the commands that are issued for PERFORM LIBACTION is displayed.

Example: Define a shared library

Assume that you are working in a SAN and that you configured a library manager named LIBMGR1. Now, define a library that is named SHAREDTSM to a library client server named LIBCL1.

Issue DEFINE LIBRARY from the library client server, LIBCL1:

```
define library sharedtsm libtype=shared primarylibmanager=libmgr1
```

Then, issue PERFORM LIBACTION from the library manager, LIBMGR1, to define the drive paths for the library client:

```
perform libaction sharedtsm action=define source=libcl1
```

Note: The SANDISCOVERY option must be supported and enabled on the library client server.

Example: Define a library with four drives

Define a SCSI library named KONA:

```
define library kona libtype=scsi
```

Then issue the PERFORM LIBACTION command to define drives and paths for the library:

AIX

```
perform libaction kona action=define device=/dev/lb3
prefix=dr
```

The server then runs the following commands:

```
define path server1 kona srct=server destt=library
device=/dev/lb3
define drive kona dr0
define path server1 dr0 srct=server destt=drive library=kona
device=/dev/mt1
define drive kona dr1
define path server1 dr1 srct=server destt=drive library=kona
device=/dev/mt2
define drive kona dr2
define path server1 dr2 srct=server destt=drive library=kona
device=/dev/mt3
define drive kona dr3
define path server1 dr3 srct=server destt=drive library=kona
device=/dev/mt4
```

Linux

```
perform libaction kona action=define device=/dev/tsmscsi/lb3
prefix=dr
```

The server then runs the following commands:

```
define path server1 kona srct=server destt=library
device=/dev/tsmscsi/lb3
define drive kona dr0
define path server1 dr0 srct=server destt=drive library=kona
device=/dev/tsmscsi/mt1
define drive kona dr1
define path server1 dr1 srct=server destt=drive library=kona
device=/dev/tsmscsi/mt2
define drive kona dr2
define path server1 dr2 srct=server destt=drive library=kona
device=/dev/tsmscsi/mt3
define drive kona dr3
define path server1 dr3 srct=server destt=drive library=kona
device=/dev/tsmscsi/mt4
```

Windows

```
perform libaction kona action=define device=lb0.0.0.2
prefix=dr
```

The server then runs the following commands:

```
define path server1 kona srct=server destt=library
device=lb0.0.0.2
define drive kona dr0
define path server1 dr0 srct=server destt=drive library=kona
device=mt0.1.0.2
define drive kona dr1
define path server1 dr1 srct=server destt=drive library=kona
device=mt0.2.0.2
define drive kona dr2
define path server1 dr2 srct=server destt=drive library=kona
device=mt0.3.0.2
define drive kona dr3
define path server1 dr3 srct=server destt=drive library=kona
device=mt0.4.0.2
```

Related commands

Table 1. Commands related to PERFORM LIBACTION

Command	Description
AUDIT LIBRARY	Ensures that an automated library is in a consistent state.
DEFINE DRIVE	Assigns a drive to a library.
DEFINE LIBRARY	Defines an automated or manual library.
DEFINE PATH	Defines a path from a source to a destination.
DEFINE SERVER	Defines a server for server-to-server communications.
DELETE DRIVE	Deletes a drive from a library.
DELETE LIBRARY	Deletes a library.
DELETE PATH	Deletes a path from a source to a destination.
QUERY DRIVE	Displays information about drives.
QUERY LIBRARY	Displays information about one or more libraries.
QUERY PATH	Displays information about the path from a source to a destination.
UPDATE DRIVE	Changes the attributes of a drive.
UPDATE LIBRARY	Changes the attributes of a library.
UPDATE PATH	Changes the attributes associated with a path.

PING SERVER (Test the connection between servers)

Use this command to test the connection between the local server and a remote server.

Important: The name and password of the administrator client issuing this command must also be defined on the remote server. If the remote server is at the current level, the server credentials are verified automatically when you run the PING SERVER command. If the remote server is not at the current level, the server credentials are not verified.

Privilege class

To issue this command, you must have system privilege.

Syntax

```
>>-PING SERVER--server_name-----------------------------------><
```

Parameters

server_name (Required)

Specifies the name of the remote server.

Example: Ping a server

Test the connection to server FRED.

```
ping server fred
```

Related commands

Table 1. Commands related to PING SERVER

Command	Description
DEFINE SERVER	Defines a server for server-to-server communications.
QUERY SERVER	Displays information about servers.

PREPARE (Create a recovery plan file)

Use this command to create a recovery plan file, which contains the information that is needed to recover an IBM Spectrum Protect™ server. You can store a recovery plan file on a file system that is accessible to the source server or on a target server.

You can use the QUERY ACTLOG command to view whether the PREPARE command was successful.

You can also view this information from the server console or, if the WAIT parameter equals YES, an administrative client session.

Privilege class

To issue this command, you must have system privilege.

Syntax

Parameters

Source

Specifies the type of database backup series that IBM Spectrum Protect assumes when generating the recovery plan file. This parameter is optional. The default is DBBACKUP. The choices are:

DBBackup
: Specifies that IBM Spectrum Protect assumes the latest full database backup series.

DBSnapshot
: Specifies that IBM Spectrum Protect assumes the latest database snapshot backup series.

DEVclass
: Specifies the device class name that is used to create a recovery plan file object on a target server. The device class must have a device type of SERVER.
Important: The maximum capacity for the device class must be larger than the size of the recovery plan file. If the size of the recovery plan file exceeds the maximum capacity, the command fails.
The naming convention for the archive object that contains the recovery plan file on the target server is:

- **Filespace name:**
  - ADSM.SERVER
- **High-level qualifier:**
  - AIX Linux devclassprefix/servername.yyyymmdd.hhmmss
  - Windows devclassprefix\servername.yyyymmdd.hhmmss
- **Low-level qualifier:**
  - RPF.OBJ.1

The recovery plan file virtual volume name as recorded in the volume history table on the source server is in the format `servername.yyyymmdd.hhmmss`.

If the DEVCLASS parameter is not specified, the recovery plan file is written to a file based on the plan prefix.

If SOURCE=DBBACKUP is specified or is defaulted to, the volume history entry for the recovery plan file object specifies a volume type of RPFILE. If SOURCE=DBSNAPSHOT is specified, the volume history entry specifies a volume type of RPFSNAPSHOT.

PLANPrefix
: Specifies the path name prefix that is used in the recovery plan file name. This parameter is optional.

- AIX Linux The maximum length is 250 characters.
- Windows The maximum length is 200 characters.

Windows Specifies the path name prefix that is used in the recovery plan file name.

IBM Spectrum Protect appends to the prefix the sortable date and time format `yyyymmdd.hhmmss`. For example: 20081115.051421.

AIX Linux The prefix can be one of the following:

Directory path
: End the prefix with the forward slash (/). For example:

```
PLANPREFIX=/adsmsrv/recplans/
```

The resulting file name would look like this:

```
/adsmsrv/recplans/20081115.051421
```

Directory path followed by a string
: IBM Spectrum Protect treats the string as part of the file name. For example:

```
PLANPREFIX=/adsmsrv/recplans/accounting
```

The resulting file name looks like this:

```
/adsmsrv/recplans/accounting.20081115.051421
```

Note the period before the date and time.

String only
: IBM Spectrum Protect specifies the directory path. IBM Spectrum Protect uses the name of the current working directory. For example, the current working directory is /opt/tivoli/tsm/server/bin and you specify the following parameter:

```
PLANPREFIX=shipping
```

The resulting file name looks like this:

```
/opt/tivoli/tsm/server/bin/shipping.20081115.051421
```

Note the period before the date and time.

Windows The prefix can be one of the following:

Directory path
End the prefix with the back slash (\). For example:

```
PLANPREFIX=c:\adsmsrv\recplans\
```

The resulting file name looks like this:

```
c:\adsmsrv\recplans\20081115.051421
```

Tip: If you issue the PREPARE command from the administrative command line client and the last character in the command line is a back slash, it is interpreted as a continuation character. To avoid this, place the prefix value in double quotation marks. For example:

```
PLANPREFIX="c:\adsmsrv\recplans\"
```

Directory path followed by a string
IBM Spectrum Protect treats the string as part of the file name. For example:

```
PLANPREFIX=c:\adsmsrv\recplans\accounting
```

The resulting file name looks like this:

```
c:\adsmsrv\recplans\accounting.20081115.051421
```

Note the period before the date and time.

String only
IBM Spectrum Protect appends the date and time in the *.yyyymmdd.hhmmss* format (note the period before the date and time) to the prefix. The directory path used by the PREPARE command is the directory representing this "instance" of the IBM Spectrum Protect server. Typically, this directory is the original IBM Spectrum Protect server installation directory. For example, the directory representing this instance of the server is c:\Program Files\Tivoli\TSM;\server2 , and you issue a PREPARE command with the following parameter:

```
PLANPREFIX=shipping
```

The resulting recovery plan filename is:

```
c:\Program Files\Tivoli\TSM;\server2\shipping.20081115.051421
```

If the PLANPREFIX parameter is not specified, IBM Spectrum Protect selects the prefix in one of these ways:

- If the SET DRMPLANPREFIX command has been issued, IBM Spectrum Protect uses the prefix specified in that command.
- Windows If the SET DRMPLANPREFIX command is not defined, IBM Spectrum Protect uses as the path the directory representing this "instance" of the IBM Spectrum Protect server, which is typically the original IBM Spectrum Protect server installation directory. For example, the directory representing this instance of the server is the following:

  ```
  c:\Program Files\Tivoli\TSM;\server2
  ```

  The resulting recovery plan file name is the following:

  ```
  c:\Program Files\Tivoli\TSM;\server2\2008115.051421
  ```

- AIX | Linux If the SET DRMPLANPREFIX command has not been issued, IBM Spectrum Protect uses the directory path name of the current working directory. For example, the current working directory is the following:

  ```
  /opt/tivoli/tsm/server/bin
  ```

  The resulting file name looks like this:

  ```
  /opt/tivoli/txm/server/bin/20081115.051421
  ```

INSTRPrefix

Specifies the prefix of the path name used by IBM Spectrum Protect to locate the files that contain the recovery instructions. The maximum length is AIX Linux 250 Windows 200 characters.

AIX Linux The prefix can be one of the following:

Directory path
: End the prefix with the forward slash (/). For example:

```
INSTRPREFIX=/adsmsrv/recinstr/
```

```
/adsmsrv/recinstr/RECOVERY.INSTRUCTIONS.GENERAL
```

Directory path followed by a string
: IBM Spectrum Protect treats the string as part of the file name. For example:

```
INSTRPREFIX=/adsmsrv/recinstr/accounts
```

IBM Spectrum Protect appends the appropriate recovery plan file stanza name. For the RECOVERY.INSTRUCTIONS.GENERAL file, the resulting file name is:

```
/adsmsrv/recinstr/accounts.RECOVERY.INSTRUCTIONS.GENERAL
```

String only

- IBM Spectrum Protect specifies the directory path and appends the appropriate recovery plan file stanza name. IBM Spectrum Protect uses the name of the current working directory. For example, the current working directory is /opt/tivoli/tsm/server/bin and you specify the following parameter:

  ```
  INSTRPREFIX=shipping
  ```

  For the RECOVERY.INSTRUCTIONS.GENERAL file, the resulting file name looks like this:

  ```
  /opt/tivoli/tsm/server/bin/shipping.RECOVERY.INSTRUCTIONS.GENERAL
  ```

Windows The prefix can be one of the following:

Directory path
: End the prefix with the back slash (\). For example:

```
INSTRPREFIX=c:\adsmsrv\recinstr\
```

IBM Spectrum Protect appends the appropriate recovery plan file stanza name. For the RECOVERY.INSTRUCTIONS.GENERAL file, the resulting file name is:

```
c:\adsmsrv\recinstr\RECOVERY.INSTRUCTIONS.GENERAL
```

Tip: If you issue the PREPARE command from the administrative command line client and the last character in the command line is a back slash, it is interpreted as a continuation character. To avoid this, place the prefix value in double quotation marks. For example:

```
INSTRPREFIX="c:\adsmserv\recinstr\"
```

Directory path followed by a string
: IBM Spectrum Protect treats the string as part of the file name. For example:

```
INSTRPREFIX=c:\adsmsrv\recinstr\accounts
```

IBM Spectrum Protect appends the appropriate recovery plan file stanza name. For the RECOVERY.INSTRUCTIONS.GENERAL file, the resulting file name is:

```
c:\adsmsrv\recinstr\accounts.RECOVERY.INSTRUCTIONS.GENERAL
```

String only
: IBM Spectrum Protect specifies the directory path and appends the appropriate recovery plan file stanza name. IBM Spectrum Protect appends the recovery plan file stanza name to the prefix. If the prefix is only a string, the directory path used by the PREPARE command is the directory representing this instance of the IBM Spectrum Protect server. This is typically the original IBM Spectrum Protect server installation directory. For example, the directory representing this instance of the server is c:\Program Files\Tivoli\TSM;\server2, and you issue a PREPARE command with the following parameter:

```
INSTRPREFIX=dock
```

The resulting recovery plan filename is:

```
c:\Program Files\Tivoli\TSM;\server2\shipping.20081115.051421
```

If you do not specify the INSTRPREFIX parameter, IBM Spectrum Protect selects the prefix in one of these ways:

- If the SET DRMINSTRPREFIX command has been issued, IBM Spectrum Protect uses the prefix specified in that command.
- Windows If the SET DRMINSTRPREFIX command has not been issued, IBM Spectrum Protect uses as the path the directory representing this “instance” of the IBM Spectrum Protect server, which is typically the original server installation directory. For example, the directory representing this instance of the server is the following:

  ```
  c:\Program Files\Tivoli\TSM;\server2
  ```

  The resulting recovery plan file name is the following:

  ```
  c:\Program Files\Tivoli\TSM;\server2\RECOVERY.INSTRUCTIONS.GENERAL
  ```

- AIX Linux If the SET DRMINSTRPREFIX command has not been issued, IBM Spectrum Protect uses the current working directory.
  For example, if the current working directory is /opt/tivoli/tsm/server/bin, for the RECOVERY.INSTRUCTIONS.GENERAL file, the resulting file name would be:

  ```
  /opt/tivoli/tsm/server/bin/RECOVERY.INSTRUCTIONS.GENERAL
  ```

PRIMstgpool
: Specifies the names of the primary storage pools that you want to restore. Separate the storage pool names with commas and no intervening spaces. You can use wildcard characters. If this parameter is not specified, IBM Spectrum Protect selects the storage pools as follows:

  - If the SET DRMPRIMSTGPOOL command has been issued, IBM Spectrum Protect includes the primary storage pools named in that command.
  - If the SET DRMPRIMSTGPOOL command has not been issued, IBM Spectrum Protect includes all the primary storage pools.

COPYstgpool
: Specifies the names of the copy storage pools used to back up the primary storage pools that you want to restore (see the PRIMSTGPOOL parameter). Separate storage pool names with commas and no intervening spaces. You can use wildcard characters. If this parameter is not specified, IBM Spectrum Protect selects the storage pools as follows:

  - If the SET DRMCOPYSTGPOOL command has been issued, IBM Spectrum Protect includes those copy storage pools.
  - If the SET DRMCOPYSTGPOOL command has not been issued, IBM Spectrum Protect includes all copy storage pools.

ACTIVEDatastgpool
: Specifies the names of the active-data storage pools that you want to have available for offsite access. Separate active-data storage-pool names with commas and no intervening spaces. You can use wildcard characters. If this parameter is not specified, IBM Spectrum Protect selects the storage pools as follows:

  - If the SET ACTIVEDATASTGPOOL command has been previously issued with valid active-data storage pool names, IBM Spectrum Protect processes those storage pools.
  - If the SET ACTIVEDATASTGPOOL command has not been issued, or all of the active-data storage pools have been removed using the SET ACTIVEDATASTGPOOL command, IBM Spectrum Protect processes only the active-data pool volumes that were marked on-site at the time the PREPARE command is run. IBM Spectrum Protect will mark these volumes as UNAVAILABLE.

Wait
: Specifies whether this command is processed in the background or foreground.

  No
  : Specifies background processing. This is the default.

  Yes
  : Specifies foreground processing.

    AIX Linux You cannot specify YES from the server console.

Example: Create a recovery plan file

Issue the PREPARE command and query the activity log to check the results.

```
prepare
query actlog search=prepare
```

                      SUCCESS at 12:01:14.
```

Related commands

Table 1. Commands related to PREPARE

Command	Description
CANCEL PROCESS	Cancels a background server process.
DELETE VOLHISTORY	Removes sequential volume history information from the volume history file.
QUERY DRMSTATUS	Displays DRM system parameters.
QUERY RPFCONTENT	Displays the contents of a recovery plan file.
QUERY RPFILE	Displays information about recovery plan files.
QUERY SERVER	Displays information about servers.

Command	Description
QUERY VOLHISTORY	Displays sequential volume history information that has been collected by the server.
SET DRMACTIVEDATASTGPOOL	Specifies that active-data storage pools are managed by DRM.
SET DRMCOPYSTGPOOL	Specifies that copy storage pools are managed by DRM.
SET DRMINSTRPREFIX	Specifies the prefix portion of the path name for the recovery plan instructions.
SET DRMPLANVPOSTFIX	Specifies the replacement volume names in the recovery plan file.
SET DRMPLANPREFIX	Specifies the prefix portion of the path name for the recovery plan.
SET DRMPRIMSTGPOOL	Specifies that primary storage pools are managed by DRM.
SET DRMRPFEXPIREDAYS	Set criteria for recovery plan file expiration.
UPDATE VOLHISTORY	Adds or changes location information for a volume in the volume history file.

AIX | Linux | Windows

PROTECT STGPOOL (Protect data that belongs to a storage pool)

Use this command to protect data in a directory-container storage pool by storing a copy of the data in another storage pool on a replication target server or on the same server by protecting the data to tape. When you protect the directory-container storage pool, you can later try to repair damage in the storage pool by using the REPAIR STGPOOL command.

When you issue the PROTECT STGPOOL command for a directory-container storage pool, data that is stored in that storage pool is backed up to the target that you specify. The data can be backed up to the following target types:

- A directory-container storage pool on the target replication server.
  Prerequisite: For the storage pool that is being protected, you must specify the target pool by using the PROTECTSTGPOOL parameter on the DEFINE STGPOOL or UPDATE STGPOOL command.

  When you regularly use the PROTECT STGPOOL command, you can typically reduce the processing time for the REPLICATE NODE command. The data extents that are already copied to the target replication server by storage pool protection operations are skipped when node replication is started.

  As part of the PROTECT STGPOOL operation, processes might run to repair damaged extents in the target server's storage pool. The repair operation occurs under the following conditions:
  - Both the source server and the target server must be at V7.1.5 or later.
  - Extents that are already marked as damaged on the target server are repaired. The repair process does not run an audit process to identify damage.
  - Only target extents that match source extents are repaired. Target extents that are damaged but have no match on the source server are not repaired.

  Limitations: The repair operation that runs as part of the PROTECT STGPOOL operation has the following limitations:
  - Extents that belong to objects that were encrypted are not repaired.
  - The timing of the occurrence of damage on the target storage pool and the sequence of REPLICATE NODE and PROTECT STGPOOL commands can affect whether the repair process is successful. Some extents that were stored in the target storage pool by a REPLICATE NODE command might not be repaired.
- Container-copy storage pools on the same server, protected to tape.
  Prerequisite: For the storage pool that is being protected, you must specify the target storage pool by using the PROTECTLOCALSTGPOOLS parameter. For details about the parameter, see the commands for defining and updating directory-container storage pools (DEFINE STGPOOL and UPDATE STGPOOL commands).

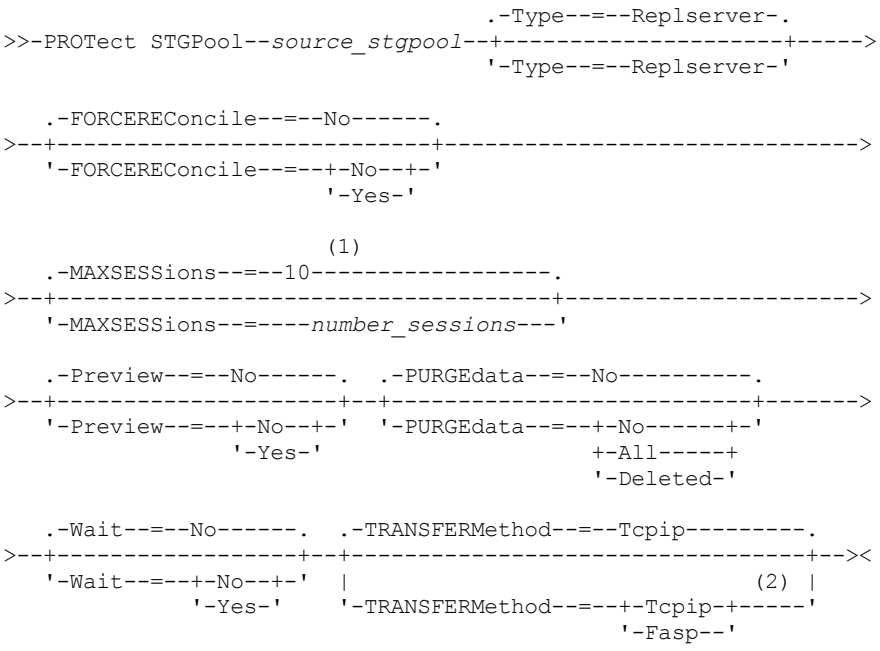
  As part of the PROTECT STGPOOL operation, volumes in the target pool might be reclaimed. The value of the RECLAIM parameter for the container-copy storage pool affects whether volumes are reclaimed. For details about the parameter, see the commands for defining and updating container-copy storage pools (DEFINE STGPOOL and UPDATE STGPOOL commands).

Restriction: You cannot schedule multiple PROTECT STGPOOL operations to run concurrently. Wait for one PROTECT STGPOOL operation to finish before you start another.

Privilege class

To issue this command, you must have system privilege.

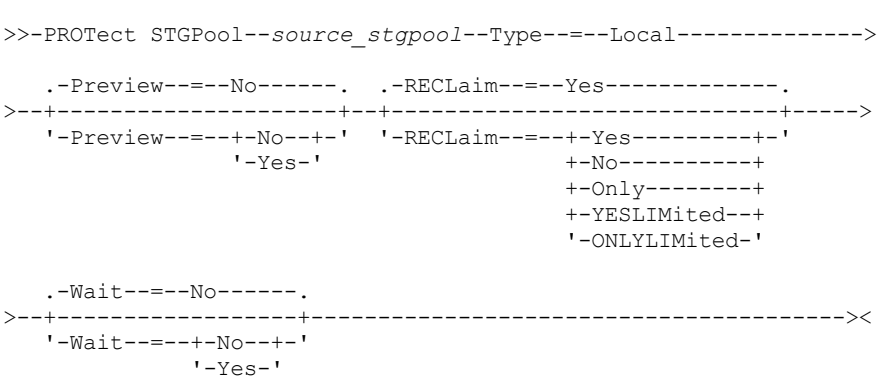
Syntax when the target is the replication server



Notes:

1. Linux If the TRANSFERMETHOD parameter is set to the default value of TCPIP, the default value of the MAXSESSIONS parameter is 10. If the TRANSFERMETHOD parameter is set to FASP, the default value of the MAXSESSIONS parameter is 2.
2. Linux The TRANSFERMETHOD parameter is available only on Linux x86_64 operating systems.

Syntax when the target is a tape storage pool on the same server



Parameters

source_stgpool (Required)
: Specifies the name of the directory-container storage pool on the source server.

Type
: Specifies the type of target for the protection operation. This parameter is optional. The default value is REPLSERVER. Specify one of the following values:

  Replserver

Specifies that the target is the storage pool on the replication target server, as defined for the source storage pool with the PROTECTSTGPOOL parameter on the DEFINE STGPOOL or UPDATE STGPOOL command.

Local

Specifies that the target is on the same server as the source storage pool. The target is the container-copy storage pool that is defined for the source storage pool with the PROTECTLOCALSTGPOOLS parameter on the DEFINE STGPOOL or UPDATE STGPOOL command.

Tip: By default, the server uses a maximum of two parallel processes to copy data to a local target. You can change the maximum number of parallel processes by updating the container-copy storage pool that is the target. Use the UPDATE STGPOOL command with the PROTECTPROCESS parameter.

FORCEREConcile

Specifies whether to reconcile the differences between data extents in the directory-container storage pool on the source server and target server. This parameter is optional. The default value is NO. Specify one of the following values:

No

Specifies that data backup does not compare all data extents in the directory-container storage pool on the source server with data extents on the target server. Instead, data backup tracks changes to the data extents on the source server since the last backup and synchronizes these changes on the target server.

Yes

Specifies that data backup compares all data extents on the source server with data extents on the target server and synchronizes the data extents on the target server with the source server.

MAXSESSions

Specifies the maximum number of data sessions that can send data to a target server. This parameter is optional. The value that you specify can be in the range 1 - 100.

AIX Windows The default value is 10.

Linux The default value varies:

- If TRANSFERMETHOD=TCPIP, the default value of the MAXSESSIONS parameter is 10.
- If TRANSFERMETHOD=FASP, the default value of the MAXSESSIONS parameter is 2.

If you increase the number of sessions, you can improve throughput for the storage pool.

When you set a value for the MAXSESSIONS parameter, ensure that the available bandwidth and the processor capacity of the source and target servers are sufficient.

Tips:

- If you issue a QUERY SESSION command, the total number of sessions might exceed the number of data sessions. The difference is because of short control sessions that are used to query and set up operations.
- The number of sessions that are used for protection depends on the amount of data that is backed up. If you are backing up only a small amount of data, increasing the number of sessions provides no benefit.

Preview

Specifies whether to preview data. This parameter is optional. The default value is NO. Specify one of the following values:

No

Specifies that the data is backed up to the target server but that the data is not previewed.

Yes

Specifies that data is previewed but not backed up.

PURGEdata

Specifies that data extents are deleted from the target server. This parameter is optional. The default value is NO. You can specify one of the following values:

No

Specifies that data extents are not deleted from the target server.

All

Specifies that all data extents are deleted from the target server. Data extents that are referenced by other data in the target storage pool are not deleted.

Deleted

Specifies that data extents that were deleted on the source server are deleted from the target server. New data extents are not protected.

RECLaim
Specifies whether reclamation runs when the PROTECT STGPOOL command is processed. Reclamation runs on the local container-copy storage pool that is the target for the protection operation. This parameter is optional. The default value is YES. You can specify one of the following values:

Yes
Specifies that reclamation runs when the command is issued, along with the storage pool protection operation. Reclamation runs to completion, with no limitation on the number of volumes in the storage pool that are processed for reclamation.

No
Specifies that reclamation is not run when the command is issued. Only the storage pool protection operation runs.

Only
Specifies that reclamation is the only operation that runs when the command is issued. The storage pool protection operation does not run, so data in the directory-container storage pool that was updated since the last protection operation is not protected. Reclamation runs to completion, with no limitation on the number of volumes in the storage pool that are processed for reclamation.

YESLIMited
Specifies that reclamation runs when the command is issued, along with the storage pool protection operation. Reclamation runs until it reaches the reclaim limit that is defined for the container-copy storage pool. The reclaim limit is defined with the RECLAIMLIMIT parameter on the DEFINE STGPOOL or UPDATE STGPOOL command.

ONLYLIMited
Specifies that reclamation is the only operation that runs when the command is issued. The storage pool protection operation does not run, so data in the directory-container storage pool that was updated since the last protection operation is not protected. Reclamation runs until it reaches the reclaim limit that is defined for the container-copy storage pool. The reclaim limit is defined with the RECLAIMLIMIT parameter on the DEFINE STGPOOL or UPDATE STGPOOL command.

Wait
Specifies whether to wait for the server to process this command in the foreground. This parameter is optional. The default value is NO. You can specify one of the following values:

No
Specifies that the command is processed in the background. To monitor the background processes of this command, issue the QUERY PROCESS command.

Yes
Specifies that the command is processed in the foreground. Messages are not displayed until the command completes processing.
Restriction: You cannot specify `WAIT=YES` from the server console.

Linux TRANSFERMethod
Linux Specifies the method that is used for server-to-server data transfer. This parameter is optional. You can specify one of the following values:

Tcpip
Specifies that TCP/IP is used to transfer data. This value is the default.

Fasp
Specifies that Aspera® Fast Adaptive Secure Protocol (FASP®) technology is used to transfer data. Aspera FASP technology can help you optimize data transfer in a wide area network (WAN). If you specify TRANSFERMETHOD=FASP, you override any TRANSFERMETHOD parameters that you specified on the DEFINE SERVER or UPDATE SERVER commands.
Restrictions:

- Before you enable Aspera FASP technology, determine whether the technology is appropriate for your system environment and install the appropriate licenses. For instructions, see Determining whether Aspera FASP technology can optimize data transfer in your system environment. If the licenses are missing or expired, operations to protect storage pools fail.
- If WAN performance meets your business needs, do not enable Aspera FASP technology.

Example: Delete all data extents from the target server

Delete all data extents in a directory-container storage pool on the target server. The directory-container storage pool that is named POOL1 on the source server is no longer protected by the directory-container storage pool on the target server. You might delete all extents to clean the directory-container storage pool on the target server that no longer protects the source server.

```
protect stgpool pool1 purgedata=all
```

Example: Protect a storage pool and specify a maximum number of data sessions

Protect a storage pool that is named SPOOL1 on the source server by backing up the data to a target replication server, TPOOL1. Specify a maximum of 20 data sessions.

```
update stgpool spool1 protectstgpool=tpool1
protect stgpool spool1 maxsessions=20
```

Example: Copy the storage pool data to tape

Protect a directory-container storage pool by copying the data to a container-copy storage pool on the same server. In this example, the directory-container storage pool is named SPOOL1 and the container-copy storage pool, which uses tape for storage, is named TAPES1.

1. Update the directory-container storage pool to add TAPES1 as the local storage pool for protection. The TAPES1 storage pool must be a container-copy storage pool. Issue the following command:

   ```
   update stgpool spool1 protectlocalstgpools=tapes1
   ```

2. Protect the data in the directory-container storage pool with a local copy by issuing the following command:

   ```
   protect stgpool type=local spool1
   ```

   The data is copied to the TAPES1 storage pool.

Example: Reclaim space on tape volumes before you protect a storage pool

Reclaim space on the tape volumes that are used to protect a directory-container storage pool. Then, protect the data in the directory-container storage pool. In this example, the directory-container storage pool is named SPOOL1.

1. Reclaim space in the local container-copy storage pool that is defined as the target protection pool for SPOOL1.

   ```
   protect stgpool spool1 type=local reclaim=only
   ```

2. Protect the data in the directory-container storage pool that is named SPOOL1 without running reclamation.

   ```
   protect stgpool spool1 type=local reclaim=no
   ```

Table 1. Commands related to PROTECT STGPOOL

Command	Description
CANCEL PROCESS	Cancels a background server process.
DEFINE STGPOOL (container-copy)	Define a container-copy storage pool that stores copies of data from a directory-container storage pool.
DEFINE STGPOOL (directory-container)	Define a directory-container storage pool.
DEFINE STGPOOLDIRECTORY	Defines a storage pool directory to a directory-container or cloud-container storage pool.
REPAIR STGPOOL	Repairs a directory-container storage pool.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
SET REPLSERVER	Specifies a target replication server.
UPDATE STGPOOL (container-copy)	Update a container-copy storage pool that stores copies of data from a directory-container storage pool.

QUERY commands

Use the QUERY commands to request or display information about IBM Spectrum Protect™ objects.

- QUERY ACTLOG (Query the activity log)
- QUERY ADMIN (Display administrator information)

- QUERY ALERTTRIGGER (Query the list of defined alert triggers)
- QUERY ALERTSTATUS (Query the status of an alert)
- QUERY ASSOCIATION (Query client node associations with a schedule)
- QUERY AUDITOCCUPANCY (Query client node storage utilization)
- QUERY BACKUPSET (Query a backup set)
- QUERY BACKUPSETCONTENTS (Query contents of a backup set)
- AIX Linux Windows QUERY CLEANUP (Query the cleanup that is required in a source storage pool)
- QUERY CLOPTSET (Query a client option set)
- QUERY COLLOCGROUP (Query a collocation group)
- QUERY CONTENT (Query the contents of a storage pool volume)
- AIX Linux Windows QUERY CONTAINER (Query a container)
- AIX Linux Windows QUERY CONVERSION (Query conversion status of a storage pool)
- QUERY COPYGROUP (Query copy groups)
- QUERY DATAMOVER (Display data mover definitions)
- AIX Linux Windows QUERY DAMAGED (Query damaged data in a directory-container or cloud-container storage pool)
- QUERY DB (Display database information)
- QUERY DBSPACE (Display database storage space)
- AIX Linux Windows QUERY DEDUPSTATS (Query data deduplication statistics)
- QUERY DEVCLASS (Display information on one or more device classes)
- QUERY DIRSPACE (Query storage utilization of FILE directories)
- QUERY DOMAIN (Query a policy domain)
- QUERY DRIVE (Query information about a drive)
- QUERY DRMEDIA (Query disaster recovery media)
- QUERY DRMSTATUS (Query disaster recovery manager system parameters)
- QUERY ENABLED (Query enabled events)
- QUERY EVENT (Query scheduled and completed events)
- QUERY EVENTRULES (Query rules for server or client events)
- QUERY EVENTSERVER (Query the event server)
- QUERY EXPORT (Query for active or suspended export operations)
- AIX Linux Windows QUERY EXTENTUPDATES (Query updated data extents)
- QUERY FILESPACE (Query one or more file spaces)
- QUERY LIBRARY (Query a library)
- QUERY LIBVOLUME (Query a library volume)
- QUERY LICENSE (Display license information)
- QUERY LOG (Display information about the recovery log)
- QUERY MACHINE (Query machine information)
- QUERY MEDIA (Query sequential-access storage pool media)
- QUERY MGMTCLASS (Query a management class)
- QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)
- QUERY MONITORSTATUS (Query the monitoring status)
- QUERY MOUNT (Display information on mounted sequential access volumes)
- AIX Linux Windows QUERY NASBACKUP (Query NAS backup images)
- QUERY NODE (Query nodes)
- QUERY NODEDATA (Query client data in volumes)
- QUERY NODEGROUP (Query a node group)
- QUERY OCCUPANCY (Query client file spaces in storage pools)
- QUERY OPTION (Query server options)
- QUERY PATH (Display a path definition)
- QUERY POLICYSET (Query a policy set)
- QUERY PROCESS (Query one or more server processes)
- QUERY PROFILE (Query a profile)
- QUERY PROTECTSTATUS (Query the status of storage pool protection)
- QUERY PROXYNODE (Query proxy authority for a client node)
- QUERY PVUESTIMATE (Display processor value unit estimate)
- QUERY RECOVERYMEDIA (Query recovery media)
- QUERY REPLICATION (Query node replication processes)
- QUERY REPLNODE (Display information about replication status for a client node)
- QUERY REPLRULE (Query replication rules)
- QUERY REPLSERVER (Query a replication server)
- QUERY REQUEST (Query one or more pending mount requests)
- QUERY RESTORE (Query restartable restore sessions)

- QUERY RPFCONTENT (Query recovery plan file contents stored on a target server)
- QUERY RPFILE (Query recovery plan file information stored on a target server)
- AIX Linux Windows QUERY SAN (Query the devices on the SAN)
- QUERY SCHEDULE (Query schedules)
- QUERY SCRIPT (Query IBM Spectrum Protect scripts)
- QUERY SERVER (Query a server)
- QUERY SERVERGROUP (Query a server group)
- QUERY SESSION (Query client sessions)
- QUERY SHREDSTATUS (Query shredding status)
- QUERY SPACETRIGGER (Query the space triggers)
- QUERY STATUS (Query system parameters)
- QUERY STATUSTHRESHOLD (Query status monitoring thresholds)
- QUERY STGPOOL (Query storage pools)
- AIX Linux Windows QUERY STGPOOLDIRECTORY (Query a storage pool directory)
- QUERY SUBSCRIBER (Display subscriber information)
- QUERY SUBSCRIPTION (Display subscription information)
- QUERY SYSTEM (Query the system configuration and capacity)
- AIX Linux Windows QUERY TAPEALERTMSG (Display status of SET TAPEALERTMSG command)
- AIX Linux Windows QUERY TOC (Display table of contents for a backup image)
- QUERY VIRTUALFSMAPPING (Query a virtual file space mapping)
- QUERY VOLHISTORY (Display sequential volume history information)
- QUERY VOLUME (Query storage pool volumes)

QUERY ACTLOG (Query the activity log)

Use this command to display messages generated by the server and client. This command provides filtering options that can be used to limit the number of messages displayed and the time that it takes to process this query. If you do not specify any parameters with this command, all messages generated in the previous hour are displayed.

The activity log contains all messages that are sent to the server console under normal operation. The results of commands entered at the server console are not recorded in the activity log unless the command affects or starts a background process or client session. Error messages are displayed in the activity log.

Restriction: You cannot schedule the QUERY ACTLOG command by using the DEFINE SCHEDULE command.

Privilege class

Any administrator can issue this command.

Syntax

```
                .-BEGINDate--=--current_date-.
>>-Query ACtlog--+----------------------------+----------------><
                 '-BEGINDate--=--date---------'

```

Parameters

BEGINDate

Specifies the beginning date of the range for messages to be displayed. All messages meeting the time range criteria that occurred after this date are displayed. The default is the current date. This parameter is optional.

You can specify the date using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY –7 *or* –7. To display information beginning with messages created a week ago, you can specify BEGINDATE=TODAY-7 or BEGINDATE= -7.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

BEGINTime

Specifies the beginning time of the range for messages to be displayed. All messages meeting the time range criteria that occurred after this time are displayed. If you do not specify time, all messages that occurred in the last hour are displayed.

You can specify the time using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time on the specified begin date	10:30:08
NOW	The current time on the specified begin date	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes on the specified begin date	NOW+03:00 *or* +03:00. If you issue this command at 9:00 with BEGINTIME=NOW+3 or BEGINTIME=+3, IBM Spectrum Protect™ displays messages with a time of 12:00 or later on the begin date.

Value	Description	Example
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes on the specified begin date	NOW-04:00 *or* -04:00. If you issue the QUERY ACTLOG command at 9:00 with BEGINTime=NOW-3:30 or BEGINTime= -3:30, IBM Spectrum Protect displays messages with a time of 5:30 or later on the begin date.

ENDDate

Specifies the ending date of the range for messages to be displayed. All messages meeting the time range criteria that occurred before this date are displayed. If you do not specify a value, the current date is used. This parameter is optional. You can specify the date using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1998
TODAY	The current date	TODAY
TODAY-days **or** -days	The current date minus days specified. The maximum number of days you can specify is 9999.	TODAY–1 *or* –1. To display information created up to yesterday, you can specify ENDDATE=TODAY-1 or simply ENDDATE= -1.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

ENDTime

Specifies the ending time of the range for messages to be displayed. All messages meeting this time range criteria that occurred before this time are displayed. If you do not specify a value, all messages are displayed up to the time when you issued this command. This parameter is optional.
You can specify the time using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time on the specified end date	10:30:08
NOW	The current time on the specified end date	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes on the specified end date	NOW+03:00 *or* +03:00. If you issue this command at 9:00 with ENDTIME=NOW+3:00 or ENDTIME= +3:00, IBM Spectrum Protect displays messages with a time of 12:00 or earlier on the end date you specify.
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes on the specified end date	NOW-03:30 *or* -03:30. If you issue this command at 9:00 with ENDTIME=NOW-3:30 or ENDTIME= -3:30, IBM Spectrum Protect displays messages with a time of 5:30 or earlier on the end date you specify.

MSGno

Specifies an integer that defines the number of the message to be displayed from the activity log. This integer is just the numeric part of the message. This parameter is optional.

Search
: Specifies a text string that you want to search for in the activity log. Enclose the string expression in quotation marks if it contains blanks. You can use text and a wildcard character to specify this string. This parameter is optional.
Note: Do not enter as a text string either the IBM Spectrum Protect server name or text and a wildcard character that would find the server name. If you do so, the output includes messages that do not include the search string.

NODEname
: Specifies that the query displays messages logged for this node. If you do not specify a value for this parameter, messages for all nodes are displayed.

ORiginator
: Specifies that the query displays messages logged by the server, client, or both. The default is ALL. Possible values are:

  ALL
  : Specifies that the query displays messages that originated from the client and the server.

  SErver
  : Specifies that the query displays messages that originated from the server.

  CLient
  : Specifies that the query displays messages that originated from the client.
  You can specify one of the following values to minimize processing time when querying the activity log for messages logged by the client:

    OWNERname
    : Specifies that the query displays messages logged for a particular owner. If you do not specify a value for this parameter, messages for all owners are displayed.

    SCHedname
    : Specifies that the query displays messages logged by a particular scheduled client activity. If you do not specify a value for this parameter, messages for all schedules are displayed.

    DOmainname
    : Specifies that the query displays messages logged for a particular policy domain to which a named schedule belongs. This parameter is optional, unless you are specifying a schedule name.

    SESsnum
    : Specifies that the query displays messages logged from a particular client session number. If you do not specify a value for this parameter, messages for all client sessions are displayed.

Example: Search activity log for messages with specific text

Search the activity log for any message that contains the string "delete". The output includes only messages produced during the past hour. Issue the command:

```
query actlog search=delete

Date/Time            Message
-------------------- ----------------------------------------
08/27/1998 15:19:43  ANR0812I Inventory client file expiration
                      complete: 0 files deleted.
```

Example: Search activity log for messages within a specific time frame

Display messages that occurred yesterday between 9:30 and 12:30. Issue the command:

```
query actlog begindate=today-1
begintime=09:30:00 endtime=12:30:00

Date/Time           Message
------------------- ---------------------------------------------
10/21/1998 10:52:36 ANR0407I Session 3921 started for administrator
                    ADMIN (WebBrowser) (HTTP 9.115.20.100(2315)).
10/21/1998 11:06:08 ANR0405I Session 3922 ended for administrator
                    ADMIN (WebBrowser).
10/21/1998 12:16:50 ANR0405I Session 3934 ended for administrator
                    ADMIN (WebBrowser).
```

Example: Search activity log for messages from a specific client node

Search the activity log for IBM Spectrum Protect messages from the client for node JEE. Issue the command:

```
query actlog originator=client node=jee
```

```
Date/Time           Message
------------------- ----------------------------------------------
06/10/1998 15:46:22 ANE4007E (Session No: 3 Node: JEE) Error
                    processing '/jee/report.out': access to the
                    object is denied
06/11/1998 15:56:56 ANE4009E (Session No: 4 Node: JEE) Error
                    processing '/jee/work.lst': disk full condition
```

Example: Search activity log for client and server messages from a specific client node and session

Search the activity log for IBM Spectrum Protect messages from the client and server for node A associated with Session 1. The output includes all messages with the defined text string, "SESSION: 1". Issue the command:

```
query actlog search="(SESSION:1)"
```

```
Date/Time            Message
-------------------  ----------------------------------------------
02/13/2012 12:13:42   ANR0406I Session 1 started for node A (WinNT)
                       (Tcp/Ip colind(2463)). (SESSION: 1)
02/13/2012 12:13:56  ANE4952I (ANE4985I Session: 1, ANE4986I Node: A)
                       Total number of objects inspected:       34
                       (SESSION: 1)
02/13/2012 12:13:56  ANE4954I (ANE4985I Session: 1, ANE4986I Node: A)
                       Total number of objects backed up:       34
                       (SESSION: 1)
02/13/2012 12:13:56  ANE4958I (ANE4985I Session: 1, ANE4986I Node: A)
                       Total number of objects updated:          0
                       (SESSION: 1)
02/13/2012 12:13:56  ANE4964I (ANE4985I Session: 1, ANE4986I Node: A)
                       Elapsed processing time:           00:00:02
                       (SESSION: 1)
02/13/2012 12:13:59  ANR0403I Session 1 ended for node A (WinNT).
                       (SESSION: 1)
```

Example: Search activity log for client-generated messages from a client session

Search the activity log for IBM Spectrum Protect messages from a specific client session. The output includes only messages generated by the client. Issue the command:

```
query actlog sessnum=1
```

```
Date/Time            Message
-------------------  ----------------------------------------------
02/13/2012 12:13:56  ANE4952I (ANE4985I Session: 1, ANE4986I Node: A)
                       Total number of objects inspected:       34
                       (SESSION: 1)
02/13/2012 12:13:56  ANE4954I (ANE4985I Session: 1, ANE4986I Node: A)
                       Total number of objects backed up:       34
                       (SESSION: 1)
02/13/2012 12:13:56  ANE4958I (ANE4985I Session: 1, ANE4986I Node: A)
                       Total number of objects updated:          0
                       (SESSION: 1)
02/13/2012 12:13:56  ANE4964I (ANE4985I Session: 1, ANE4986I Node: A)
                       Elapsed processing time:           00:00:02
                       (SESSION: 1)
```

Field descriptions

Date/Time
: Specifies the date and time when the message was generated by the server or client.

Message
: Specifies the message that was generated by the server or client.

Related commands

Table 1. Command related to QUERY ACTLOG

Command	Description

Command	Description
SET ACTLOGRETENTION	Specifies the number of days to retain log records in the activity log.

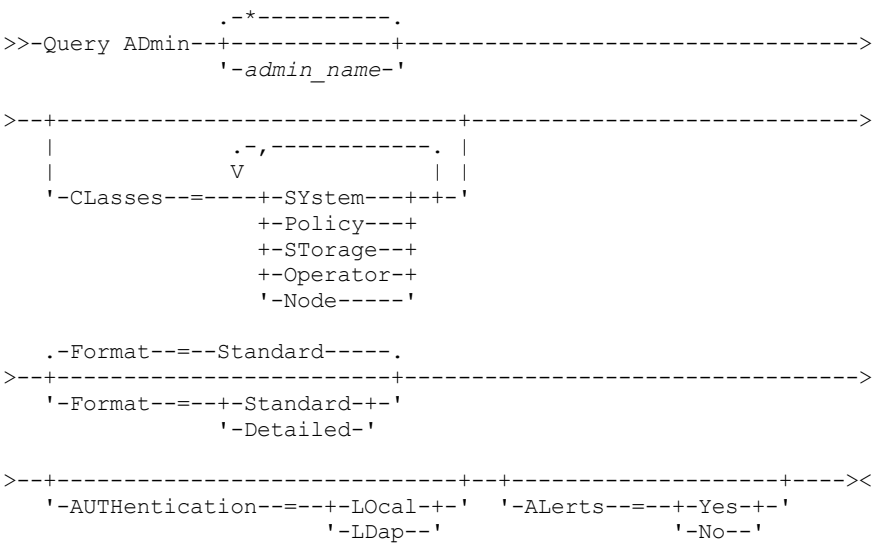
QUERY ADMIN (Display administrator information)

Use this command to display information about one or more administrators.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

admin_name
: Specifies the name of the administrator for which you want to display information. This parameter is optional. You can use wildcard characters to specify this name. If you do not specify a value for this parameter, all administrators are displayed.

CLasses
: Specifies that you want to restrict output to those administrators that have privilege classes that you specify. This parameter is optional. You can specify multiple privilege classes in a list by separating the names with commas and no intervening spaces. If you do not specify a value for this parameter, information about all administrators is displayed, regardless of privilege class. Possible values are:

  SYstem
  : Display information on administrators with system privilege.

  Policy
  : Display information on administrators with policy privilege.

  STorage
  : Display information on administrators with storage privilege.

  Operator
  : Display information on administrators with operator privilege.

  Node
  : Display information on users with client node privilege.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

  Standard

Specifies that partial information is displayed for the specified administrators.

Detailed
: Specifies that complete information is displayed for the specified administrators.

Authentication
: Specifies the password authentication method for the administrator.

LOcal
: Display those administrators authenticating to the IBM Spectrum Protect™ server.

LDap
: Display those administrators authenticating to an LDAP directory server. The administrator password is case-sensitive.

ALert
: Specifies whether alerts are sent to an administrators email address.

Yes
: Specifies that alerts are sent to the specified administrators email address.

No
: Specifies that alerts are not sent to the specified administrators email address. This is the default value.

Tip: Alert monitoring must be enabled, and email settings must be correctly defined to successfully receive alerts by email. To view the current settings, issue the QUERY MONITORSETTINGS command.

Example: Display information about all administrators

Display partial information on all administrators. Issue the command:

```
query admin
```

```
Administrator   Days Since  Days Since   Locked?   Privilege Classes
Name           Last Access    Password
                                 Set
-------------  -----------  ----------  ---------  ------------------
ADMIN                   <1          <1      No     System
SERVER_CONSOLE                          No     System
```

See Field descriptions for field descriptions.

Example: Display complete information about one administrator

From a managed server, display complete information for the administrator named ADMIN. Issue the command:

```
query admin admin format=detailed
```

```
        Administrator Name: ADMIN
     Last Access Date/Time: 1998.06.04 17.10.52
    Days Since Last Access: <1
    Password Set Date/Time: 1998.06.04 17.10.52
   Days Since Password Set: 26
     Invalid Sign-on Count: 0
                   Locked?: No
                   Contact:
          System Privilege: Yes
          Policy Privilege: **Included with system privilege**
         Storage Privilege: **Included with system privilege**
        Operator Privilege: **Included with system privilege**
   Client Access Privilege: **Included with system privilege**
    Client Owner Privilege: **Included with system privilege**
    Registration Date/Time: 05/09/1998 23:54:20
 Registering Administrator: SERVER_CONSOLE
          Managing profile:
Password Expiration Period: 90 Day (s)
             Email Address:
               Email Aerts: Yes
            Authentication: Local
              SSL Required: No
          Session Security: Strict
          Transport Method: TLS 1.2
```

See Field descriptions for field descriptions.

Field descriptions

Administrator Name
: Specifies the name of the administrator.

Last Access Date/Time
: Specifies the date and time that the administrator last accessed the server.

Days Since Last Access
: Specifies the number of days since the administrator last accessed the server.

Password Set Date/Time
: Specifies the date and time that the administrator's password was defined or most recently updated.

Days Since Password Set
: Specifies the number of days since the administrator's password was defined or most recently updated.

Invalid Sign-on Count
: Specifies the number of invalid sign-on attempts that have been made since the last successful sign-on. This count can only be non-zero when an invalid password limit (SET INVALIDPWLIMIT) is greater than zero. When the number of invalid attempts equals the limit set by the SET INVALIDPWLIMIT command, the administrator is locked out of the system.

Locked?
: Specifies whether the administrator is locked out of the system.

Contact
: Specifies any contact information for the administrator.

System Privilege
: Specifies whether the administrator has been granted system privilege.

Policy Privilege
: Specifies whether the administrator has been granted unrestricted policy privilege or the names of any policy domains that the restricted policy administrator can manage.

Storage Privilege
: Specifies whether the administrator has been granted unrestricted storage privilege or the names of any storage pools that the restricted storage administrator can manage.

Operator Privilege
: Specifies whether the administrator has been granted operator privilege.

Client Access Privilege
: Specifies that client access authority has been granted to a user with node privilege.

Client Owner Privilege
: Specifies that client owner authority has been granted to a user with node privilege.

Registration Date/Time
: Specifies the date and time that the administrator was registered.

Registering Administrator
: Specifies the name of the administrator who registered the administrator. If this field contains $$CONFIG_MANAGER$$, the administrator is associated with a profile that is managed by the configuration manager.

Managing Profile
: Specifies the profiles to which the managed server subscribed to get the definition of this administrator.

Password Expiration Period
: Specifies the administrator's password expiration period.

Email Address
: Specifies the email address for the administrator.

Email Alerts
: Specifies whether alerts are sent to the specified administrator by email.

Authentication
: Specifies the password authentication method: LOCAL, LDAP, or LDAP (pending).

Authentication Target	Authentication Method
IBM Spectrum Protect server	LOCAL
LDAP directory server	LDAP
This administrator is configured to authenticate with an LDAP directory server, but the administrator did not yet authenticate through a client node.	LDAP (pending)

SSL Required (deprecated)

Specifies whether the security setting for the administrator user ID requires the Secure Sockets Layer (SSL) protocol. Values can be YES, NO, or Default. You must have system level authority to update the administrator SSLREQUIRED setting. This parameter is deprecated.

Session Security
Specifies the level of session security that is enforced for the administrator ID. Values can be STRICT or TRANSITIONAL.

Transport Method
Specifies the transport method that was last used for the specified administrator. Values can be TLS 1.2, TLS 1.1, or NONE. A question mark (?) is displayed until a successful authentication is completed.

Related commands

Table 1. Commands related to QUERY ADMIN

Command	Description
GRANT AUTHORITY	Assigns privilege classes to an administrator.
QUERY NODE	Displays partial or complete information about one or more clients.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REGISTER ADMIN	Defines a new administrator without granting administrative authority.
REMOVE ADMIN	Removes an administrator from the list of registered administrators.
RENAME ADMIN	Changes an IBM Spectrum Protect administrator's name.
RESET PASSEXP	Resets the password expiration for nodes or administrators.
REVOKE AUTHORITY	Revokes one or more privilege classes or restricts access to policy domains and storage pools.
SET INVALIDPWLIMIT	Sets the number of invalid logon attempts before a node is locked.
SET MINPWLENGTH	Sets the minimum length for client passwords.
SET PASSEXP	Specifies the number of days after which a password is expired and must be changed.

QUERY ALERTTRIGGER (Query the list of defined alert triggers)

Use this command to display which server messages are defined as alerts.

Privilege class

Any administrator can issue this command.

Syntax

```
                        .-*------------------.
>>-Query ALERTTrigger--+--------------------+------------------><
                        '---message_number---'
```

Parameters

message_number
Specifies the message number that you want to query. Specify multiple message numbers, which are separated by commas, and no intervening spaces. Message numbers are a maximum of eight characters in length. Wildcard characters can be used to specify message numbers. If you do not specify a message number, all alert triggers are displayed.

Query alert triggers to display which messages are designated as alerts

Display all messages that are designated as alerts by issuing the following command:

```
query alerttrigger
```

Example output:

```
Alert Trigger        Category       Administrator
--------------       ---------      ------------------------------
ANR1067E             SERVER         HARRYH
ANR1073E             SERVER         CSDADMIN,DJADMIN,HARRYH
ANR1074E             STORAGE        CSDADMIN,DJADMIN,HARRYH
ANR1096E             STORAGE        CSDADMIN,DJADMIN,HARRYH,MHAYE
```

Query alert triggers for a specific message number

Display all alert triggers that have message number ANR1067E designated to them by issuing the following command:

```
query alerttrigger ANR1067E
```

Example output:

```
Alert Trigger        Category       Administrator
--------------       ---------      -------------
ANR1067E             SERVER         HARRYH
```

Field descriptions

Alert Trigger
: The message number for the alert trigger.

Category
: The category of the alert trigger.

Administrator
: The name of the administrator who receives alerts from this alert trigger.

Related commands

Table 1. Commands related to QUERY ALERTTRIGGER

Command	Description
DEFINE ALERTTRIGGER (Define an alert trigger)	Associates specified messages to an alert trigger.
DELETE ALERTTRIGGER (Remove a message from an alert trigger)	Removes a message number that can trigger an alert.
QUERY ALERTSTATUS (Query the status of an alert)	Displays information about alerts that have been issued on the server.
UPDATE ALERTTRIGGER (Update a defined alert trigger)	Updates the attributes of one or more alert triggers.
UPDATE ALERTSTATUS (Update the status of an alert)	Updates the status of a reported alert.

QUERY ALERTSTATUS (Query the status of an alert)

Use this command to display information about alerts that are reported on the IBM Spectrum Protect™ server.

Privilege class

Any administrator can issue this command.

Syntax

```
                        .-STAtus--=--ANy--------------.
>>-Query ALERTSTatus--+-----------------------------+----------->
```

Parameters

Status
: Specifies the status type that you want to display. If you do not specify a status, all alerts are queried and displayed. Specify one of the following values:

  ACtive
  : Displays alerts that are specified in the IBM Spectrum Protect server database as active.

  INactive
  : Displays alerts that are in the inactive state.

  CLosed
  : Displays alerts that are in the closed state.

  ANy
  : Displays all alerts, without regard to state.

MSGnum
: Specifies the message number that you want to display. Specify the numerical portion of an IBM Spectrum Protect server message. Values are in the range 0 - 9999. For example, the message number in message ANR2044E is 2044. Specify multiple message numbers by separating them with commas and no intervening spaces.

CATegory
: Specifies the category type for the alert, which is determined by the message types. Specify one of the following values:

  APplication
  : Alert is classified as application category. For example, you can specify this category for messages that are associated with application (TDP) clients.

  INventory
  : Alert is classified as inventory category. For example, you can specify this category for messages that are associated with the database, active log file, or archive log file.
  Note: The category of `CAtalog` is used instead of `INventory` in alerts from servers that were not upgraded to IBM Spectrum Protect 7.1.0 or later.

  CLient
  : Alert is classified as client category. For example, you can specify this category for messages that are associated with general client activities.

  DEvice
  : Alert is classified as device category. For example, you can specify this category for messages that are associated with device classes, libraries, drives, or paths.

SErver
: Alert is classified as general server category. For example, you can specify this category for messages that are associated with general server activities or events.

STorage
: Alert is classified as storage category. For example, you can specify this category for messages that are associated with storage pools.

SYstems
: Alert is classified under system clients category. For example, you can specify this category for messages that are associated with system backup and archive or hierarchical storage management (HSM) backup-archive clients.

VMclient
: Alert is classified under VMclient category. For example, you can specify this category for messages that are associated with virtual machine clients.

SOURCEType
: Specifies the source type that is being queried. Specify one of the following values:

LOcal
: Displays alerts that originated from the local IBM Spectrum Protect server.

CLient
: Displays alerts that originated from the IBM Spectrum Protect client.

REmote
: Displays alerts that originated from another IBM Spectrum Protect server.

SOURCEName
: Specifies the name of the source where the alert originated. SOURCENAME can be the name of a local or remote IBM Spectrum Protect server, or an IBM Spectrum Protect client.

ID
: This optional parameter specifies the unique ID of the alert that you want to display. Specify a value from 1 to 9223372036854775807.

ASSigned
: Specifies the administrator name that is assigned the alert that you want to query.

RESolvedby
: Specifies the administrator name that resolved the alert that you want to query.

Query active alerts

Display only alerts that are active in the server database by issuing the following command:

```
query alertstatus status=active
```

Query active alerts for two messages issued by the local server

Issue the following command to display only active alerts for message numbers ANE4958I and ANR4952E that were issued by the local server:

```
query alertstatus msgnum=4958,4952 status=active sourcetype=local
```

Query active alerts for messages ANR4958I and ANR4952E issued by a client

Issue the following command to display only active alerts for message numbers ANE4958I and ANE4952I that were issued by a client:

```
query alertstatus msgnum=4958,4952 status=active sourcetype=client
```

Query all alerts on a server

Issue the following command to display all alerts that are on the server:

```
query alertstatus
```

Example output: Display all the alerts that are on the server:

```
     Alert Identifier: 83
 Alert Message Number: 293
         Source Name: SEDONA
```

```
           Source Type: LOCAL
      First Occurrence: 03/07/2013 17:08:35

Field descriptions

Alert Identifier
: The unique identifier for the alert.

Alert Message Number
: The message number for the alert.

Source Name
: The name of the source from where the alert originated.

Source Type
: The type of the originating source.

First Occurrence
: The date and time when the alert first occurred.

Most Recent Occurrence
: The date and time when the alert occurred last.

Count
: The total number of times the alert has been triggered.

Status
: Specifies the status of the alert.

Last Status Change
: Specifies the time and date when the status for the alert last changed.

Category
: The category for the alert.

Message
: The message that triggers the alert.

Assigned
: Specifies the user whom this alert concerns.

Resolved By
: Species the user who has investigated and resolved the alert.

Remark
: An optional remark to be left by the resolver.

Related commands

Table 1. Commands related to QUERY ALERTSTATUS

Command	Description
DEFINE ALERTTRIGGER (Define an alert trigger)	Associates specified messages to an alert trigger.
DELETE ALERTTRIGGER (Remove a message from an alert trigger)	Removes a message number that can trigger an alert.
QUERY ALERTTRIGGER (Query the list of defined alert triggers)	Displays message numbers that trigger an alert.
QUERY MONITORSETTINGS (Query the configuration settings for monitoring alerts and server status)	Displays information about monitoring alerts and server status settings.
UPDATE ALERTTRIGGER (Update a defined alert trigger)	Updates the attributes of one or more alert triggers.
UPDATE ALERTSTATUS (Update the status of an alert)	Updates the status of a reported alert.

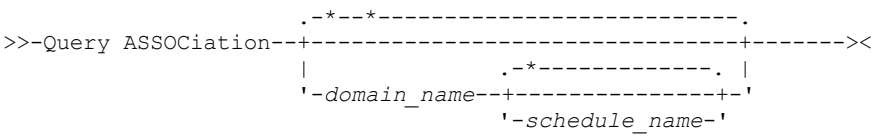
QUERY ASSOCIATION (Query client node associations with a schedule)

Use this command to display information about which client nodes are associated with one or more schedules. Client nodes associated with a schedule perform operations such as backup or archive according to that schedule.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

domain_name
: Specifies the name of the policy domain to display. You can use a wildcard character to specify this name. All matching policy domain names are displayed. If you do not specify a value for this parameter, all existing policy domains are queried.

If you specify a domain name, you do not have to specify a schedule name.

schedule_name
: Specifies the name of the schedule to display. You can use a wildcard character to specify this name. All matching schedule names are displayed. If you do not specify a value for this parameter, all existing schedules are queried. If you specify a schedule name, you must also specify a policy domain name.

Example: Display client nodes that are associated with a schedule

Display all the client nodes that are associated with each schedule that belongs to the EMPLOYEE_RECORDS policy domain. Issue the command:

```
query association employee_records *

Policy Domain Name: EMPLOYEE_RECORDS
     Schedule Name: WEEKLY_BACKUP
  Associated Nodes: JOE JOHNSON LARRY SMITH SMITHERS TOM
```

See Field descriptions for field descriptions.

Field descriptions

Policy Domain Name
: Specifies the name of the policy domain to which the schedule belongs.

Schedule Name
: Specifies the name of the schedule.

Associated Nodes
: Specifies the names of the client nodes that are associated with the specified schedule.

Related commands

Table 1. Commands related to QUERY ASSOCIATION

Command	Description
DEFINE ASSOCIATION	Associates clients with a schedule.
DELETE ASSOCIATION	Deletes the association between clients and a schedule.

QUERY AUDITOCCUPANCY (Query client node storage utilization)

Use this command to display information about client node server storage utilization. To display current license audit information from the server, use the AUDIT LICENSE command before you issue the QUERY AUDITOCCUPANCY command.

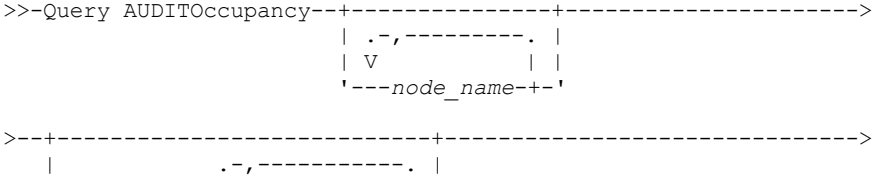
As part of a license audit operation, the server calculates, by node, the amount of backup, archive, and space management storage in use. For servers that manage large amounts of data, this calculation can take a great deal of processor time and can stall other server activity. You can use the AUDITSTORAGE server option to specify that storage is not to be calculated as part of a license audit.

You can use the information from this query to determine if and where client node storage utilization must be balanced. This information can also assist you with billing clients for storage usage.

Privilege class

Any administrator can issue this command.

Syntax



```
   |            V             | |
   '-DOmain--=----domain_name-+-'

   .-POoltype--=--ANY---------.
>--+--------------------------+-------------------------------><
   '-POoltype--=--+-ANY-----+-'
                  +-PRimary-+
                  '-COpy----'
```

Parameters

node_name
: Specifies a list of nodes for which to display server storage use information. Specify more than one node by separating the node names with commas, with no intervening spaces. You can use wildcard characters to specify names. The default (*) is to query all client nodes. Use the DOMAIN parameter to limit this list by policy domain. This parameter is optional.

DOmain
: Specifies a list of policy domains to restrict which nodes are displayed. Nodes belonging to the specified policy domains are displayed. Specify more than one policy domain by separating the policy domain names with commas, with no intervening spaces. You can use wildcard characters to specify names. This parameter is optional.

POoltype
: Specifies the type of storage pool to display. This parameter is optional. The default is ANY. Possible values are:

  ANY
  : Specifies both primary and copy storage pools. The value that is presented is the total for the two pools.

  PRimary
  : Specifies primary storage pools only.

  COpy
  : Specifies copy storage pools only.

Example: Display storage usage

Display combined storage use in primary and copy storage pools. Issue the command:

```
query auditoccupancy
```

```

See Field descriptions for field descriptions.

Field descriptions

Node Name
: Specifies the name of the client node.

Backup Storage Used (MB)
: Specifies the total backup storage use for the node. For this value, one MB = 1048576 bytes.

Archive Storage Used (MB)
: Specifies the total archive storage use for the node. For this value, one MB = 1048576 bytes.

Space-Managed Storage Used (MB)
: Specifies the amount of server storage that is used to store files that are migrated from the client node by an IBM Spectrum Protect™ for Space Management client. For this value, one MB = 1048576 bytes.

Total Storage Used (MB)
: Specifies the total storage use for the node. For this value, one MB = 1048576 bytes.

Related commands

Table 1. Commands related to QUERY AUDITOCCUPANCY

Command	Description
AUDIT LICENSES	Verifies compliance with defined licenses.
QUERY LICENSE	Displays information about licenses and audits.
QUERY STATUS	Displays the settings of server parameters, such as those selected by the SET commands.
REGISTER LICENSE	Registers a license with the IBM Spectrum Protect server.
SET LICENSEAUDITPERIOD	Specifies the number of days between automatic license audits.

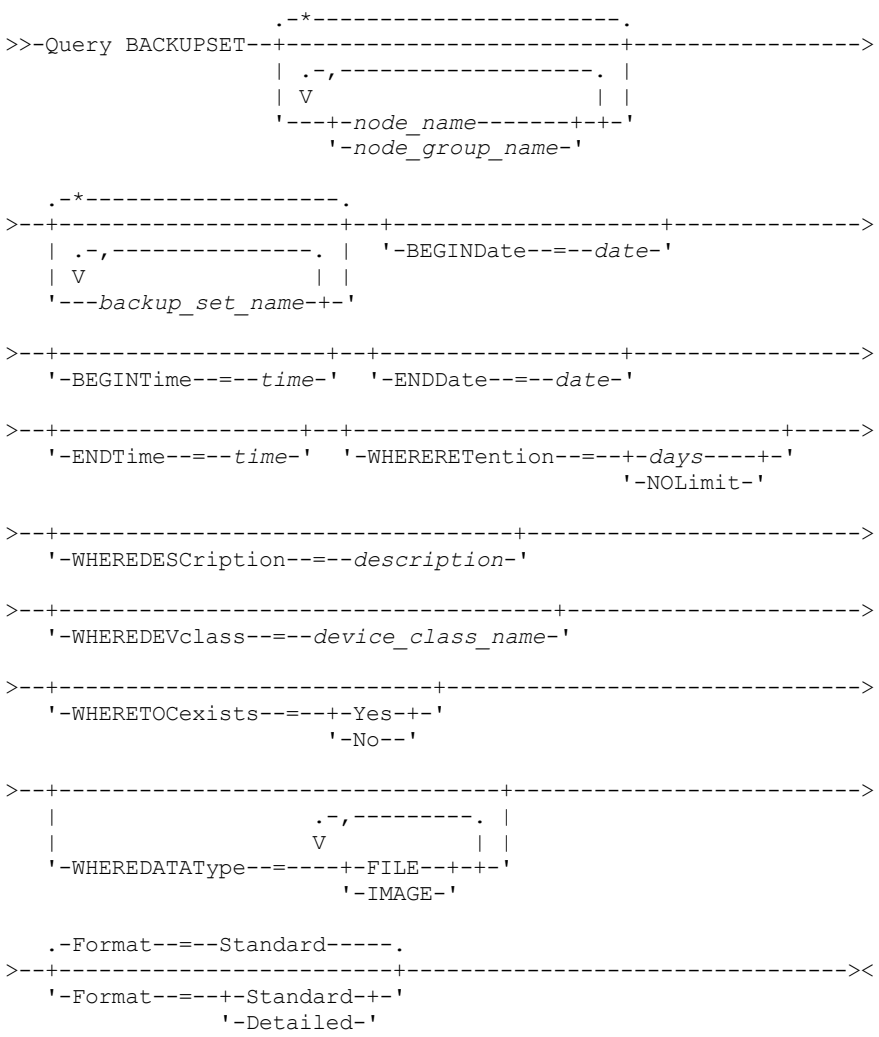
QUERY BACKUPSET (Query a backup set)

Use this command to display information about one or more backup sets.

Privilege class

Any administrator can issue this command.

Syntax



Parameters

node_name or node_group_name

Specifies the name of the client node and node groups whose data is contained in the backup set to be displayed. To specify multiple node names and node group names, separate the names with commas and no intervening spaces. You can use wildcard characters with node names but not with node group names.

backup_set_name

Specifies the name of the backup set whose information is to be displayed. The backup set name you specify can contain wildcard characters. You can specify more than one backup set name by separating the names with commas and no intervening spaces.

BEGINDate

Specifies the beginning date of the range in which the point-in-time date of the backup set to be displayed must fall. This parameter is optional. You can use this parameter with the BEGINTIME parameter to specify a range for the date and time. If you specify a begin date without a begin time, the time will be at 12:00 a.m. (midnight) on the date you specify.

You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1999
TODAY	The current date	TODAY
TODAY+days *or* +days	The current date plus days specified.	TODAY +3 *or* +3.
TODAY-days *or* -days	The current date minus days specified.	TODAY -3 *or* -3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

BEGINTime

Specifies the beginning time of the range in which the point-in-time date of the backup set to be displayed must fall. This parameter is optional. You can use this parameter with the BEGINDATE parameter to specify a range for the date and time. If you specify a begin time without a begin date, the date will be the current date at the time you specify.

You can specify the time by using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes specified	NOW+02:00 *or* +02:00.
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes specified	NOW-02:00 *or* –02:00.

ENDDate

Specifies the ending date of the range in which the point-in-time date of the backup set to be displayed must fall. This parameter is optional. You can use this parameter with the ENDTIME parameter to specify an ending date and time. If you specify an end date without an end time, the time will be at 11:59:59 p.m. on the specified end date.

You can specify the date by using one of the following values:

Value	Description	Example
MM/DD/YYYY	A specific date	09/15/1999
TODAY	The current date	TODAY

Value	Description	Example
TODAY+days *or* +days	The current date plus days specified. The maximum number of days you can specify is 9999.	TODAY +3 *or* +3.
TODAY-days *or* -days	The current date minus days specified.	TODAY -3 *or* -3.
EOLM (End Of Last Month)	The last day of the previous month.	EOLM
EOLM-days	The last day of the previous month minus days specified.	EOLM-1 To include files that were active a day before the last day of the previous month.
BOTM (Beginning Of This Month)	The first day of the current month.	BOTM
BOTM+days	The first day of the current month, plus days specified.	BOTM+9 To include files that were active on the 10th day of the current month.

ENDTime

Specifies the ending time of the range in which the point-in-time date of the backup set to be displayed must fall. This parameter is optional. You can use this parameter with the ENDDATE parameter to specify a date and time. If you specify an end time without an end date, the date will be the current date at the time you specify.
You can specify the time by using one of the following values:

Value	Description	Example
HH:MM:SS	A specific time	10:30:08
NOW	The current time	NOW
NOW+HH:MM *or* +HH:MM	The current time plus hours and minutes specified	NOW+02:00 *or* +02:00.
NOW-HH:MM *or* -HH:MM	The current time minus hours and minutes specified	NOW-02:00 *or* –02:00.

WHERERETention

Specifies the retention value, specified in days, that must be associated with the backup sets to be displayed. You can specify an integer from 0 to 30000. The values are:

days
: Specifies that backup sets that are retained this number of days are displayed.

NOLimit
: Specifies that backup sets that are retained indefinitely are displayed.

WHEREDESCription

Specifies the description that must be associated with the backup set to be displayed. The description you specify can contain wildcard characters. This parameter is optional. Enclose the description in quotation marks if it contains any blank characters.

WHEREDEVclass

Specifies the name of the device class that must be associated with the backup set to be displayed. You can use wildcard characters to specify a device class name. This parameter is optional.

WHERETOCexists

Specifies whether a backup set must have a table of contents in order to be displayed. This parameter is optional. The default is to display all backup sets whether or not they have a table of contents.

WHEREDATAType

Specifies the data type of a backup set to be displayed. This parameter is optional. The default is to display all types of backup sets. To specify multiple data types, separate data types with commas and no intervening spaces.

FILE
: Specifies that a file level backup set is to be displayed. File level backup sets contain files and directories backed up by the backup-archive client.

IMAGE

Specifies that an image backup set is to be displayed. Image backup sets contain images created by the backup-archive client BACKUP IMAGE command.

Format
: Specifies how the information is displayed. This parameter is optional. The default value is STANDARD. Possible values are:

  Standard
  : Specifies that partial information is displayed for the specified backup sets.

  Detailed
  : Specifies that complete information is displayed for the specified backup sets.

Example: Query a backup set

Display information for backup sets whose names begin with PERS_DATA. The backup sets belong to the node JANE and are assigned to the DVLMENT device class.

```
query backupset jane pers_data*

                 Node Name: JANE
           Backup Set Name: PERS_DATA.3089
                 Data Type: File
                 Date/Time: 03/17/2007 16:17:47
          Retention Period: 60
        Device Class Name: DVLMENT
              Description: backupset created from /srvr
Has Table of Contents (TOC)?: Yes
```

Field descriptions

Node Name
: Specifies the name of the client node whose data is contained in the backup set.

Backup Set Name
: Specifies the name of the backup set.

Data Type
: Displays the data type of the backup sets. Possible types are file, image, and application.

Date/Time
: Specifies the date and time (PITDate and PITTime) of the GENERATE BACKUPSET command. The PITDate and PITTime specify that files that were active on the specified date and time and that are still stored on the IBM Spectrum Protect™ server are to be included in the backup set, even if they are inactive at the time you issue the GENERATE BACKUPSET command. The default is the date on which the GENERATE BACKUPSET command is run.

Retention Period
: Specifies the number of days that the backup set is retained on the server.

Device Class Name
: Specifies the name of the device class for which the volumes containing the backup set is assigned.

Description
: Specifies the description associated with the backup set.

Has Table of Contents (TOC)?
: Specifies whether the backup set has a table of contents.

Related commands

Table 1. Commands related to QUERY BACKUPSET

Command	Description
DEFINE BACKUPSET	Defines a previously generated backup set to a server.
DEFINE NODEGROUP	Defines a group of nodes.
DEFINE NODEGROUPMEMBER	Adds a client node to a node group.
GENERATE BACKUPSET	Generates a backup set of a client's data.
GENERATE BACKUPSETTOC	Generates a table of contents for a backup set.
DELETE BACKUPSET	Deletes a backup set.
DELETE NODEGROUP	Deletes a node group.

Command	Description
DELETE NODEGROUPMEMBER	Deletes a client node from a node group.
QUERY BACKUPSETCONTENTS	Displays contents contained in backup sets.
QUERY NODEGROUP	Displays information about node groups.
UPDATE BACKUPSET	Updates a retention value associated with a backup set.
UPDATE NODEGROUP	Updates the description of a node group.

QUERY BACKUPSETCONTENTS (Query contents of a backup set)

Use this command to display information about the files and directories contained in a backup set for a client node.

Remember: Processing this command can use considerable network resources and mount points.

Privilege class

To issue this command, you must have system privilege or policy privilege for the domain to which the client node is assigned.

Syntax

```
>>-Query BACKUPSETCONTENTS--node_name--backup_set_name---------->

   .-DATAType--=--FILE------.
>--+------------------------+--------------------------------><
   '-DATAType--=--+-FILE--+-'
                  '-IMAGE-'
```

Parameters

node_name (Required)
: Specifies the name of the client node whose data is contained in the backup set to display. The name you specify cannot contain wildcard characters nor can it be a list of node names separated by commas.

backup_set_name (Required)
: Specifies the name of the backup set to display. The name that you specify cannot contain wildcard characters nor can it be a list of node names that are separated by commas.

DATAType
: Specifies that the backup set containing the specified types of data is to be queried. This parameter is optional. The default is that a file level backup set is to be queried. Possible values are:

  FILE
  : Specifies that a file level backup set is to be queried. File level backup sets contain files and directories backed up by the backup-archive client.

  IMAGE
  : Specifies that an image backup set is to be queried. Image backup sets contain images created by the backup-archive client BACKUP IMAGE command.

Example: Query contents of a backup set for a specific node

Display the contents from backup set named PERS_DATA.3099 belonging to client node JANE. Issue the command:

```
query backupsetcontents jane pers_data.3099

Node Name                Filespace  Client's Name for File
                         Name
----------------------- ---------- -----------------------
JANE                     /srvr      /deblock
JANE                     /srvr      /deblock.c
JANE                     /srvr      /dsmerror.log
JANE                     /srvr      /dsmxxxxx.log
JANE                     ...        ......
```

Field descriptions

Node Name
: Specifies the name of the client node whose data is contained in the backup set.

Filespace Name
: Specifies the name of the file space to which the specified file belongs.

  File space names can be in a different code page or locale than the server. If they are, the names in the Operations Center and the administrative command-line interface might not be displayed correctly. Data is backed up and can be restored normally, but the file space name or file name might be displayed with a combination of invalid characters or blank spaces.

  If the file space name is Unicode-enabled, the name is converted to the server code page for display. The success of the conversion depends on the operating system, the characters in the name, and the server code page. Conversion can be incomplete if the string includes characters that are not available in the server code page or if the server cannot access system conversion routines. If the conversion is incomplete, the name might contain question marks, blanks, unprintable characters, or ellipses (...).

Client's Name for File
: Specifies the name of the file.

  File space names and file names that can be in a different code page or locale than the server do not display correctly in the Operations Center or the administrative command-line interface. The data itself is backed up and can be restored properly, but the file space or file name may display with a combination of invalid characters or blank spaces.

  If the file space name is Unicode enabled, the name is converted to the server's code page for display. The results of the conversion for characters not supported by the current code page depends on the operating system. For names that IBM Spectrum Protect™ is able to partially convert, you may see question marks (??), blanks, unprintable characters, or "...". These characters indicate to the administrator that files do exist. If the conversion is not successful, the name is displayed as "...". Conversion can fail if the string includes characters that are not available in the server code page, or if the server has a problem accessing system conversion routines.

  A file name that is displayed as "....." indicates that both the file path and file name were not successfully converted. An example of the path and name could be:

  ```
  my\dir\...
  ```

Related commands

Table 1. Commands related to QUERY BACKUPSETCONTENTS

Command	Description
DEFINE BACKUPSET	Defines a previously generated backup set to a server.
GENERATE BACKUPSET	Generates a backup set of a client's data.
GENERATE BACKUPSETTOC	Generates a table of contents for a backup set.
DELETE BACKUPSET	Deletes a backup set.
QUERY BACKUPSET	Displays backup sets.
UPDATE BACKUPSET	Updates a retention value associated with a backup set.

AIX Linux Windows

QUERY CLEANUP (Query the cleanup that is required in a source storage pool)

Use this command to display information about damaged files that are identified during a storage pool conversion process.

When you issue the CONVERT STGPOOL command to convert a FILE device class, a tape device class, or a virtual tape library (VTL) to a directory-container storage pool, some files in the source storage pool might not convert because of damaged data. To display damaged data that is identified during the conversion process, issue the QUERY CLEANUP command on a source storage pool.

To recover an undamaged version of the data from a copy or active-data storage pool, issue the RESTORE STGPOOL command. To recover an undamaged version of the data from a target replication server issue the REPLICATE NODE command and specify the RECOVERDAMAGED=YES parameter.

Privilege class

To issue this command, you must have restricted storage privilege.

Syntax

```
>>-Query CLeanup--pool_name-----------------------------------><
```

Parameters

pool_name(Required)
: Specifies the storage pool to query.

Example: Display damaged files that are identified by a storage pool conversion process

Display damaged files in a storage pool that is named POOL1. See Field descriptions for field descriptions.

```
query cleanup pool1
```

```
              File Name: \RTC\BDAT\GIGFILES\BF1.GB
                  State: Active
            Stored Size: 1 GB
         Filespace Name: \\ibm838-r90gf0gx\c$
                   Type: Backup
            Client Name: CAKINProtection
        Protection Date: 03/25/2016 16:47:57
```

Field descriptions

File Name
: The name of the damaged file.

State
: The state of the data in the inventory. The following states are possible:

  Active
  : The version of the file in the inventory is active. You can have only one active version of the file in the inventory.

  Inactive
  : The version of the file in the inventory is inactive. You can have multiple inactive versions of the file in the inventory.

Stored Size
: The size of the data, in megabytes (MB) or gigabytes (GB), that is stored in the storage pool.

Filespace Name
: The name of the file space where the file is assigned.

Type
: The type of operation that was used to store the file. The following types are possible:

  Backup
  : Files that are backed up.

  Archive
  : Files that are archived.

  SpaceMg
  : Files that are migrated from an IBM Spectrum Protect™ for Space Management client.

Client Name
: The name of the client that owns the file.

Protection Date

The time and date that the file was backed up, archived, or migrated by an IBM Spectrum Protect for Space Management client.

Related commands

Table 1. Commands related to QUERY CLEANUP

Command	Description
CONVERT STGPOOL	Convert a storage pool to a directory-container storage pool.
PROTECT STGPOOL	Protects a directory-container storage pool.
QUERY CONVERSION	Query conversion status of a storage pool.
REMOVE DAMAGED	Removes damaged data from a source storage pool.
REPAIR STGPOOL	Repairs a directory-container storage pool.
REPLICATE NODE	Replicates data in file spaces that belong to a client node.
RESTORE STGPOOL	Restores files to a primary storage pool from copy storage pools.

QUERY CLOPTSET (Query a client option set)

Use this command to query a client option set.

Privilege class

Any administrator can issue this command.

Syntax

```
                    .-*---------------.
>>-Query CLOptset--+-----------------+-------------------------->
                    '-option_set_name-'

>--+-----------------------------+-----------------------------><
   '-DESCription--=--description-'
```

Parameters

option_set_name
: Specifies the name of the client option set to be queried. You can use wildcard characters to specify this name. This parameter is optional. The default is option set names.

DESCription
: Specifies the description used on the DEFINE or UPDATE CLOPTSET commands to be used as a filter. If the description contains spaces, enclose it in quotation marks. This parameter is optional.

Example: Query a client option set

From a managed server, query a client option set named ENG. Issue the following command:

```
query cloptset eng

                     Optionset:  ENG
                   Description:
Last Update by (administrator): $$CONFIG_MANAGER$$
              Managing profile:
            Replica Option Set: Yes

                        Option: SCROLLINES
                Sequence number: 0
  Use Option Set Value (FORCE): No
                  Option Value: 40
```

```
                     Option: SCROLLPROMPT
              Sequence number: 0
  Use Option Set Value (FORCE): No
                 Option Value: yes
```

Field descriptions

Optionset
: Specifies the name of the option set.

Description
: Specifies the description of the client option set.

Last Update by (administrator)
: Specifies the name of the administrator that most recently updated the option set. If this field contains $$CONFIG_MANAGER$$, the client option set is associated with a profile that is managed by the configuration manager.

Managing profile
: Specifies the profile to which the managed server subscribed to get the definition of the client option set.

Replica Option Set
: Specifies the replica option set is replicated by the source replication server.

Option
: Specifies the name of the option.

Sequence number
: Specifies the sequence number of the option.

Use Option Set Value (FORCE)
: Specifies whether the server option setting overrides the option setting for the client. NO indicates that the server option setting does not override the client option. YES indicates that the server option setting overrides the client option setting. This option is set with the FORCE parameter on the DEFINE CLIENTOPT command.

Option Value
: Specifies the value of the option.

Related commands

Table 1. Commands related to QUERY CLOPTSET

Command	Description
COPY CLOPTSET	Copies a client option set.
DEFINE CLIENTOPT	Adds a client option to a client option set.
DEFINE CLOPTSET	Defines a client option set.
DELETE CLIENTOPT	Deletes a client option from a client option set.
DELETE CLOPTSET	Deletes a client option set.
UPDATE CLIENTOPT	Updates the sequence number of a client option in a client option set.
UPDATE CLOPTSET	Updates the description of a client option set.
DEFINE PROFASSOCIATION	Associates objects with a profile.

QUERY COLLOCGROUP (Query a collocation group)

Use this command to display the collocation groups defined on the server.

Privilege class

Any administrator can issue this command.

Syntax

```
                    .-*----------.
>>-Query COLLOCGroup--+------------+---------------------------->
```

```
                    '-group_name-'

   .-Format--=--Standard-----.
>--+-------------------------+--------------------------------><
   '-Format--=--+-Standard-+-'
                '-Detailed-'
```

Parameters

group_name
