> Before you use this information and the product it supports, read the information in "Notices" on page 193.

Contents

About this publication

This publication provides information to help you to perform the following tasks:

- Add IBM Storage Protect application program interface calls to an existing application
- Write programs with general-use program interfaces that obtain the services of IBM Storage Protect.

In addition to the application programming interface (API), the following programs are included on several operating systems:

- A backup-archive client program that backs up and archives files from your workstation or file server to storage, and restores and retrieves backup versions and archived copies of files to your local file systems.
- A Web backup-archive client that an authorized administrator, support person, or end user can use to perform backup, restore, archive, and retrieve services using a Web browser on a remote machine.
- An administrative client program that you can access from a Web browser or from the command line. An administrator controls and monitors server activities, defines storage management policies for backup, archive, and space management services, and sets up schedules to perform these services at regular intervals.

Who should read this publication

This publication provides instructions for you to add API calls to an existing application. You should be familiar with C programming language and IBM Storage Protect functions.

Publications

The IBM Storage Protect product family includes IBM Storage Protect Plus, IBM Storage Protect for Virtual Environments, IBM Storage Protect for Databases, and several other storage management products from IBM.

To view IBM product documentation, see IBM Documentation.

Conventions used in this publication

This publication uses the following typographical conventions:

Example	Description
autoexec.ncf hsmgui.exe	A series of lowercase letters with an extension indicates program file names.
DSMI_DIR	A series of uppercase letters indicates return codes and other values.
dsmQuerySessInfo	Boldface type indicates a command that you type on a command line, the name of a function call, the name of a structure, a field within a structure, or a parameter.
timeformat	Boldface italic type indicates a backup-archive client option. The bold type is used to introduce the option, or used in an example.
dateformat	Italic type indicates an option, the value of an option, a new term, a placeholder for information you provide, or for special emphasis in the text.
maxcmdretries	Monospace type indicates fragments of a program or information as it might appear on a display screen, such a command example.

Example	Description
plus sign (+)	A plus sign between two keys indicates that you press both keys at the same time.

What's new in version 8.1.19

IBM Storage Protect 8.1.19 introduces new features and updates.

For a list of new features and updates in this release, see API updates.

Any new and changed information in this product documentation is indicated by a vertical bar (|) to the left of the change.

Chapter 1. API overview

The IBM Storage Protect application program interface (API) enables an application client to use storage management functions.

The API includes function calls that you can use in an application to perform the following operations:

- Start or end a session
- Assign management classes to objects before they are stored on a server
- Back up or archive objects to a server
- Restore or retrieve objects from a server
- Query the server for information about stored objects
- Manage file spaces
- Send retention events

When you, as an application developer, install the API, you receive the files that an end user of an application needs:

- The API shared library.
- The messages file.
- The sample client options files.
- The source code for the API header files that your application needs.
- The source code for a sample application, and the makefile to build it.

For 64-bit applications, all compiles should be performed using compiler options that enable 64-bit support. For example, '-q64' should be used when building API applications on AIX®, and '-m64' should be used on Linux®. See the sample make files for more information.

Important: When you install the API, ensure that all files are at the same level.

For information about installing the API, see Installing the IBM Storage Protect backup-archive clients.

References to UNIX and Linux include AIX, HP-UX, Linux, Mac OS X, and Oracle Solaris operating systems.

Understanding configuration and options files

Configuration and options files set the conditions and boundaries under which your session runs.

You, an administrator, or an end user can set option values to:

- Set up the connection to a server
- Control which objects are sent to the server and the management class to which they are associated

You define options in one or two files when you install the API on your workstation.

On UNIX and Linux operating systems, the options reside in two options files:

- dsm.opt - the client options file
- dsm.sys - the client system options file

On other operating systems, the client options file (dsm.opt) contains all of the options.

Restriction: The API does not support the following backup-archive client options:

- `autofsrename`
- `changingretries`
- `domain`
- `eventlogging`

- `groups`
- `subdir`
- `users`
- `virtualmountpoint`

You also can specify options on the **dsmInitEx** function call. Use the option string parameter or the API configuration file parameter.

The same option can derive from more than one configuration source. When this happens, the source with the highest priority takes precedence. lists the priority sequence.

Table 1. Configuration sources in order of decreasing priority

Priority	UNIX and Linux	Windows	Description
1	dsm.sys file (client system options)	not applicable	This file contains options that a system administrator sets only for UNIX and Linux.
			Tip: If your dsm.sys file contains server stanzas, ensure that the `passwordaccess` option specifies the same value (either `prompt` or `generate`) in each of the stanzas.
2	Option string (client options)	Option string (all options)	One of these options takes effect when it is passed as a parameter to a **dsmInitEx** call. The list can contain client options such as `compressalways`, `servername` (UNIX and Linux only), or `tcpserveraddr` (non-UNIX).
			With the API option string, an application client can make changes to the option values in the API configuration file and the client options file. For example, your application might query the end user if compression is required. Depending on the user responses, you can construct an API option string with this option and pass it into the call to **dsmInitEx**.
			For information about the API option string format, see "dsmInitEx" on page 106. You also can set this parameter to NULL. This indicates that there is no API option string for this session.
3	API configuration file (client options)	API configuration file (all options)	The values that you set in the API configuration file override the values that you set in the client options file. Set up the options in the API configuration file with values that are appropriate in the IBM Storage Protect session for the user. The values take effect when the API configuration file name is passed as a parameter in the **dsmInitEx** call.
			You also can set this parameter to NULL. This indicates that there is no API configuration file for this session.

Table 1. Configuration sources in order of decreasing priority (continued)

Priority	UNIX and Linux	Windows	Description
4	dsm.opt file (client options)	dsm.opt file (all options)	On UNIX and Linux operating systems the dsm.opt file contains the user options only. On other operating systems, the dsm.opt file contains all options. To override the options in these files, follow the methods that are described in this table.

Related information

Processing options

Setting up the API environment

The API uses unique environment variables to locate files. You can use different files for API applications from those that the backup-archive client uses. Applications can use the **dsmSetup** function call to override the values that the environment variables set.

Tip: On Windows, the default installation directory is: `%SystemDrive%\Program Files\Common Files\Tivoli\TSM\api`

Table 2 on page 3 lists the API environment variables by operating system.

Table 2. API environment variables

Variables	UNIX and Linux	Windows
DSMI_CONFIG	The fully-qualified name for the client options file (dsm.opt).	The fully-qualified name for the client options file (dsm.opt).
DSMI_DIR	Points to the path that contains the dsm.sys, en_US subdirectory, and any other national language support (NLS) language. The en_US subdirectory must contain dsmclientV3.cat.	Points to the path that contains dscenu.txt and any NLS message file.
DSMI_LOG	Points to the path for the dsierror.log file.	Points to the path for the dsierror.log file. If the client **errorlogname** option is set, the location specified by that option overrides the directory specified by DSMI_LOG.

Chapter 2. Building and running the sample API application

The API package includes sample applications that demonstrate the API function calls in context. Install a sample application and review the source code to understand how you can use the function calls.

Select one of the following sample API application packages:

- The interactive, single-threaded application package (dapi*)
- The multithreaded application package (callmt*)
- The logical object grouping test application (dsmgrp*)
- The event-based retention policy sample application (callevnt)
- The deletion hold sample application (callhold)
- The data retention protection sample application (callret)
- The IBM Storage Protect data buffer sample program (callbuff)

To help you get started, review the procedure to build the sample dapismp sample application by your platform:

- For UNIX or Linux applications, see "UNIX or Linux sample application source files" on page 5.
- For Windows applications, see "Windows 64-bit sample application" on page 7.

The dapismp sample application creates its own data streams when backing up or archiving objects. It does not read or write objects to the local disk file system. The object name does not correspond to any file on your workstation. The "seed string" that you issue generates a pattern that can be verified when the object is restored or retrieved. Once you compile the sample application and run **dapismp** to start it, follow the instructions that display on your screen.

UNIX or Linux sample application source files

To build and run the sample UNIX or Linux sample application, you need to ensure you have certain source files. Once you build the sample application you can compile and run it.

The files that are listed in Table 3 on page 5 include the source files and other files that you need to build the sample application that is included with the API package.

Table 3. Files that you need to build the UNIX or Linux API sample application

File names	Description
README_api_enu	README file
dsmrc.h	Return codes header file
dsmapitd.h	Common type definitions header file
dsmapips.h	Operating system-specific type definitions header file
dsmapifp.h	Function prototype header file
release.h	Release values header file

Table 3. Files that you need to build the UNIX or Linux API sample application (continued)

File names		Description
dapibkup.c dapidata.h dapiinit.c dapint64.h dapint64.c dapipref.c dapiproc.c dapiproc.h	dapipw.c dapiqry.c dapirc.c dapismp.c dapitype.h dapiutil.h dapiutil.c	Modules for the command line-driven sample application
makesmp[64].*xxx*		Makefile to build dapismp for your operating system. The *xxx* indicates the operating system.
callmt1.c callmt2.c		Multi-threaded sample files
callmtu1.c callmtu2.c		Multi-threaded Unicode sample files
libApiDS.xx libApiDS64.xx, or libApiTSM64.xx		Shared library (the suffix is platform-dependent)
dsmgrp.c callevnt.c callhold.c callret.c callbuff.c dpsthread.c		Grouping sample files Event-based retention policy sample source code Deletion hold sample source code Data retention protection sample source code

Building the UNIX or Linux sample application

You build the **dapismp** sample API application by using a compiler for your operating system.

About this task

You must install the following compilers to build the UNIX or Linux API sample application:

- IBM AIX - IBM Visual Age compiler version 6 or later
- HP-IA64 - aCC compiler A.05.50 or later
- Linux - GCC compiler version 3.3.3 or later
- Mac OS X - GCC compiler version 4.0 or later
- Oracle Solaris - Oracle Studio C++ compiler version 11 or later

Procedure

1. To build the API samples, run the following command:

```
gmake -f makesmp[64].xxx
```

Where *xxx* indicates the operating system.

2. After you build the samples, set up your environment variables, including the DSMI_DIR, and your options files. For more information, see "Understanding configuration and options files" on page 1.

3. The first time you log on, log on as the root user to register your password.

   Tip: Setting the `compressalways` option to no might not resend an object uncompressed. This behavior depends on the application functionality.

   To specify the Shared Memory communications method on AIX, the IBM Storage Protect API client user must comply with one of the following conditions:

   • Must be logged in as the root user.

   • Must have the same UID as the process that is running the IBM Storage Protect server.

   For more information, see the application program documentation.

4. Run the **dapismp** command to start the application.

5. Choose from the list of options that is displayed. Ensure that you run the sign-on action before you run any other actions.

   Requirement: Always prefix the file space, high-level, and low-level names with the correct path delimiter (/) when you enter the name, for example: `/myfilespace`. You must use this prefix even when you specify the asterisk (*) wildcard character.

Related information

Environment variables (UNIX and Linux systems)

Windows 64-bit sample application

To build and run the sample application for Microsoft Windows 64–bit systems, you must install the IBM Storage Protect API and ensure that you have certain source files.

Restrictions:

• For best results, use dynamic loading. For an example, see the file `dynaload.c` and the implementation in the sample code.

• Files for the sample application are in the following directories:

  api64\obj
    Contains the API sample program object files.

  api64\samprun
    Contains the sample program **dapismp**. The sample program contains the execution directory.

• The DLL tsmapi64.dll is a 64-bit DLL.

• Use the Microsoft C/C++ Compiler Version 15 and the makefile `makesmp64.mak` to compile the API sample application **dapismp**. You might have to adjust the makefiles to fit your environment, specifically the library or the include directories.

• After you compile the application, run the sample application by issuing the command **dapismp** from the `api64\samprun` directory.

• Choose from the list of options displayed that are displayed. Ensure that you run the sign-on action before you run any other actions.

• Always prefix the file space, high-level, and low-level names with the correct path delimiter (\) when you enter the name, for example: `\myfilespace`. You must use this prefix even when you specify the asterisk (*) wildcard character.

For Windows operating systems, the source files that you must have to build the sample application are listed in Table 4 on page 8. The sample application is included in the API package. For your convenience, a precompiled executable (dapismp.exe) is also included.

Table 4. Files for building the Windows 64-bit API sample application

File names	Description
`api.txt`	README file
`tsmapi64.dll`	API DLLs
`dsmrc.h`	Return codes header file
`dsmapitd.h`	Common type definitions header file
`dsmapips.h`	Operating system-specific type definitions header file
`dsmapifp.h`	Function prototype header file
`dsmapidl.h`	Dynamically loaded function prototype header file
`release.h`	Release values header file

`dapidata.h`
`dapint64.h`
`dapitype.h`
`dapiutil.h`
	Source code header files

`tsmapi64.lib`	Implicit library

`dapibkup.c`
`dapiinit.c`
`dapint64.c`
`dapipref.c`
`dapiproc.c`
`dapiproc.h`
`dapipw.c`
`dapiqry.c`
`dapirc.c`
`dapismp64.c`
`dapiutil.c`
`dynaload.c`
	Source code files for dapismp.exe

`makesmpx64.mak`
(Windows x64)
`makesmp64.mak`
(Windows IA64)
	Makefiles to build sample applications

`callmt1.c`
`callmt2.c`
`callmtu164.c`
`callmtu264.c`
	Multithreaded sample files

`dpsthread.c`	Sample file source code

`callevnt.c`
`callhold.c`
`callret.c`
`callbuff.c`
	Event-Based retention policy source code
	Deletion hold sample source code
	Data retention protection sample source code
	Shared buffer (no copy) sample source code.

Chapter 3. Considerations for designing an application

When you design an application, you must have a broad understanding of many aspects of the API.

To gain an understanding of the API, review the following topics:

- "Determining size limits" on page 12
- "Maintaining API version control" on page 12
- "Using multithreading" on page 14
- "Signals and signal handlers" on page 15
- "Starting or ending a session" on page 15
- "Object names and IDs" on page 20
- "Controlling access to password files" on page 18
- "Accessing objects as session owner" on page 21
- "Accessing objects across nodes and owners" on page 22
- "Managing file spaces" on page 22
- "Associating objects with management classes" on page 25
- "Expiration/deletion hold and release" on page 27
- "Querying the IBM Storage Protect system" on page 29
- "Sending data to a server" on page 32
- "Example flow diagrams for backup and archive" on page 51
- "File grouping" on page 55
- "State diagram summary for the IBM Storage Protect API" on page 66

When you design your application, review the considerations in Table 5 on page 9. Start structures with **memset** fields might change in subsequent releases. The `stVersion` value increments with each product enhancement.

Table 5. API Considerations for designing an application

Design item	Considerations
Setting locale	The application must set the locale before the API is called. To set the locale to the default value, add the following code to the application: `setlocale(LC_ALL,"");` To set the locale to another value, use the same call with the proper locale in the second parameter. Check for specifics in the documentation for each operating system that you are using.

Table 5. API Considerations for designing an application (continued)

Design item	Considerations

Session control	Apply the following guidelines to session control:
	
	 • Assign a unique node name for each IBM Storage Protect backup-archive client and IBM Storage Protect API client product. The following products are examples of these clients:
	
	   – IBM Storage Protect for Mail
	   – or IBM Storage Protect HSM for Windows
	
	 • Use a consistent owner name across a backup and restore procedure.
	 • Use the `passwordaccess` option to manage access to the protected password file.
	 • Ensure that sessions for data movement end when the task is completed so that devices on the server are freed for use by other sessions.
	 • To permit LAN-free data transfer, use the **dsmSetup** function call with the `multithread` flag set to on.
	 • On AIX, when you are using multithreaded applications or LAN-free, especially running on machines with multiple processors, set the environment variable AIXTHREAD_SCOPE to S in the environment before you start the application, for better performance and more solid scheduling. For example:
	
	 ``` EXPORT AIXTHREAD_SCOPE=S ```
	
	 By setting AIXTHREAD_SCOPE to S, user threads that are created with default attributes are placed into system-wide contention scope. The user thread is bound to a kernel thread and is scheduled by the kernel. The underlying kernel thread is not shared with any other user thread. For more information, see "Using multithreading" on page 14.
	
	 • Ensure that only one thread in a session calls any API function at any time. Applications that use multiple threads with the same session handle must synchronize the API calls. For example, use a **mutex** to synchronize API calls:
	
	   getTSMMutex()
	   issue TSM API call
	   releaseTSMMutex()
	
	 Use this approach only when the threads share a handle. You can use parallel calls to API functions if the calls have different session handles.

Table 5. API Considerations for designing an application (continued)

Design item	Considerations
Session control (continued)	• Implement a threaded consumer/producer model for data movement. API calls are synchronous and the calls for **dsmGetData function** and **dsmSendData function** block until they are finished. By using a consumer/producer model, the application can read the next buffer during waiting periods for the network. Also, decoupling the data read/write and the network increases performance when there is a network bottleneck or delays. In general, the following holds: ``` Data thread <---> shared queue of buffers <---> communication thread (issue calls to the IBM Storage Protect API) ``` • Use the same session for multiple operations to avoid incurring an overhead. For applications that deal with many small objects, implement session-pooling so that the same session can be used across multiple small operations. An overhead is associated with opening and closing a session to the IBM Storage Protect server. The dsmInit/ dsmInitEX call is serialized so even in a multithreaded application only one thread can sign on at any time. Also, during sign-on the API sends a number of one-time queries to the server so that the server can do all operations. These queries include policy, option, file spaces, and local configuration.
Operation sequence	The IBM Storage Protect server locks file space database entries during some operations. The following rules apply when you are designing IBM Storage Protect API applications: • Queries lock the file space during the entire transaction. • The query lock can be shared with other query operations, so multiple query operations on the same file space can execute concurrently. • The following operations are used to modify the IBM Storage Protect server database (**DB Chg**): send, get, rename, update, and delete. • Completion of a **DB Chg** operation requires a file space lock during the database change at the end of the transaction. • Multiple **DB Chg** operations on the same file space can execute concurrently. There might be a delay while the sequence waits for the lock at the end transaction. • The query lock cannot be shared with **DB Chg** operations. A **DB Chg** operation delays the beginning of a query on the same file space, so design your applications to separate and serialize queries from **DB Chg** operations on the same file space.
Object naming	When you name objects, consider the following factors: • The specific object names are the high-level and low-level object names. If a unique identifier, such as a date stamp, is included in the name, then backup objects are always active. The objects expire only when they are marked inactive by the **dsmDeleteObj** function call. • The restore method for objects determines how to format the name for easy queries. If you plan to use a partial object restore (POR), you cannot use compression. To suppress compression, use the **dsmSendObj objAttr objCompressed=bTrue** function.
Object grouping	Group objects logically by using file spaces. A file space is a container on the server that provides a grouping category for the objects. The API queries all file spaces during the initial sign-on and also during queries, so the number of file spaces must be restricted. A reasonable assumption is that an application sets up 20 - 100 file spaces per node. The API can cater for more file spaces, but each file space incurs an overhead for the session. To create a more granular separation, use the `directory` object in the application.

Table 5. API Considerations for designing an application (continued)

Design item	Considerations
Object handling	Do not store `objectID` values to use for future restores. These values are not guaranteed to be persistent during the life of the object. During a restore, pay special attention to the restore order. After the query, sort on this value before the restore. If you are using multiple types of serial media, then access the different types of media in separate sessions. For more information, see the following topic: "Selecting and sorting objects by restore order" on page 60
Management class	Consider how much control the application must have over the management class that is associated with the application objects. You can define include statements, or you can specify a name on the **dsmSendObj** function call.
Object size	IBM Storage Protect needs to know a size estimate for each object. Consider how your application estimates the size of an object. An overestimation of the object size is better than an underestimation.

Determining size limits

Certain data structures or fields in the API have size limits. These structures are often names or other text fields that cannot exceed a predetermined length.

The following fields are examples of data structures that have size limits:

- Application type
- Archive description
- Copy group destination
- Copy group name
- File space information
- Management class name
- Object owner name
- Password

These limits are defined as constants within the header file dsmapitd.h. Any storage allocation is based on these constants rather than on numbers that you enter. For more information, see Appendix B, "API type definitions source files," on page 147.

Maintaining API version control

All APIs have some form of version control. The API version that you use in your application must be compatible with the version of the API library that is installed on the user workstation.

The **dsmQueryApiVersionEx** should be the first API call that you enter when you use the API. This call performs the following tasks:

- Confirms that the API library is installed and available on the end user's system
- Returns the version level of the API library that the application accesses

The API is designed to be upwardly compatible. Applications that are written to older versions or releases of the API library operate correctly when you run a later version.

Determining the release of the API library is very important because some releases might have different memory requirements and data structure definitions. Downward compatibility is unlikely. See Table 6 on page 13 for information about your platform.

Table 6. Platform compatibility information

Platform	Description
Windows	The message files must be at the same level as the library (DLL).
UNIX or Linux	The API library and the message files must be at the same level.

The **dsmQueryApiVersionEx** call returns the version of the API library that is installed on the end user workstation. You can then compare the returned value with the version of the API that the application client is using.

The API version number of the application client is entered in the compiled object code as a set of four constants defined in dsmapitd.h:

```
DSM_API_VERSION
DSM_API_RELEASE
DSM_API_LEVEL
DSM_API_SUB_LEVEL
```

See Appendix B, "API type definitions source files," on page 147.

The API version of the application client should be less than, or equal to, the API library that is installed on the user's system. Be careful about any other condition. You can enter the **dsmQueryApiVersionEx** call at any time, whether the API session has been started or not.

Data structures that the API uses also have version control information in them. Structures have version information as the first field. As enhancements are made to structures, the version number is increased. When initializing the version field, use the defined structure Version value in dsmapitd.h.

Figure 1 on page 14 demonstrates the type definition of the structure, **dsmApiVersionEx** from the header file, dsmapitd.h. The example then defines a global variable that is named *apiLibVer*. It also demonstrates how you can use it in a call to **dsmQueryApiVersionEx** to return the version of the end user's API library. Finally, the returned value is compared to the API version number of the application client.

```
typedef struct
{
        dsUint16_t stVersion;      /* Structure version                */
        dsUint16_t version;        /* API version                      */
        dsUint16_t release;        /* API release                      */
        dsUint16_t level;          /* API level                        */
        dsUint16_t subLevel;       /* API sub level                    */
} dsmApiVersionEx;

dsmApiVersionEx apiLibVer;

memset(&apiLibVer,0x00,sizeof(dsmApiVersionEx));
dsmQueryApiVersionEx(&apiLibVer);

/* check for compatibility problems */
dsInt16_t appVersion= 0, libVersion = 0;
  appVersion=(DSM_API_VERSION * 10000)+(DSM_API_RELEASE * 1000) +
             (DSM_API_LEVEL * 100) + (DSM_API_SUBLEVEL);
  libVersion = (apiLibVer.version * 10000) + (apiLibVer.release * 1000) +
               (apiLibVer.level * 100) + (apiLibVer.subLevel);
   if (libVersion < appVersion)
   {
      printf("\n*************************************************************\n");
      printf("The IBM Storage Protect API library is lower than the application version\n");
      printf("Install the current library version.\n");
      printf("*************************************************************\n");
      return 0;
   }
printf("* API Library Version = %d.%d.%d.%d  *\n",
      apiLibVer.version,
      apiLibVer.release,
      apiLibVer.level,
      apiLibVer.subLevel);
```

Figure 1. An example of obtaining the version level of the API

Using multithreading

The multithreaded API permits applications to create multiple sessions with the IBM Storage Protect server within the same process. The API can be entered again. Any calls can run in parallel from within different threads.

Tip: When you run applications that assume a multithreaded API, use the **dsmQueryAPIVersionEx** call.

To run the API in multithreaded mode, set the *mtflag* value to DSM_MULTITHREAD on the **dsmSetUp** call. The **dsmSetUp** call must be the first call after the **dsmQueryAPIVersionEx** call. This call must return before any thread calls the **dsmInitEx** call. When all threads complete processing, enter a call to **dsmCleanUp**. The primary process should not end before all the threads complete processing. See callmt1.c in the sample application.

Restriction: The default for the API is single-thread mode. If an application does not call **dsmSetUp** with the *mtflag* value set to DSM_MULTITHREAD, the API permits only one session for each process.

Once **dsmSetUp** successfully completes, the application can begin multiple threads and enter multiple **dsmInitEx** calls. Each **dsmInitEx** call returns a handle for that session. Any subsequent calls on that thread for that session must use that handle value. Certain values are process-wide, environmental variables (values that are set on **dsmSetUp**). Each **dsmInitEx** call parses options again. Each thread can run with different options by specifying an overwrite file or an options string on the **dsmInitEx** call. This enables different threads to go to different servers, or use different node names.

Recommendation: On HP, set the thread stack to 64K or greater. The default value of the thread stack (32K) might not be sufficient

To permit application users to have a LAN-free session, use **dsmSetUp** *mtFlag DSM_MULTITHREAD* in your application. This is necessary even if the application is single threaded. This flag activates the threading necessary for the IBM Storage Protect LAN-free interface.

Signals and signal handlers

The application handles signals from the user or the operating system. If the user enters a **CTRL+C** keystroke sequence, the application must catch the signal and send **dsmTerminate** calls for each of the active threads. Then, call **dsmCleanUp** to exit. If sessions are not closed properly, unexpected results might occur on the server.

The application requires signal handlers, such as SIGPIPE and SIGUSR1, for signals that cause the application to end. The application then receives the return code from the API. For example, to ignore SIGPIPE add the following instruction in your application: `signal(SIGPIPE, SIG_IGN)`. After this information is added, instead of the application exiting on a broken pipe, the proper return code is returned.

Starting or ending a session

IBM Storage Protect is a session-based product, and all activities must be performed within an IBM Storage Protect session. To start a session, the application starts the **dsmInitEx** call. This call must be performed before any other API call other than **dsmQueryApiVersionEx**, **dsmQueryCliOptions**, or **dsmSetUp**.

The **dsmQueryCliOptions** function can be called only before the **dsmInitEx**call. The function returns the values of important options, such as option files, compression settings, and communication parameters. The **dsmInitEx** call sets up a session with the server as indicated in the parameters that are passed in the call or defined in the options files.

The client node name, the owner name, and the password parameters are passed to the **dsmInitEx** call. The owner name is case-sensitive, but the node name and password are not. The application client nodes must be registered with the server before a session starts.

Each time an API application client starts a session with the server, the client application type is registered with the server. Always specify an operating system abbreviation for the application type value because this value is entered in the platform field on the server. The maximum string length is DSM_MAX_PLATFORM_LENGTH.

The **dsmInitEx** function call establishes the IBM Storage Protect session with the API configuration file and option list of the application client. The application client can use the API configuration file and option list to set a number of IBM Storage Protect options. These values override the values that are set in the user configuration files during installation. Users cannot change the options that the administrator defines. If the application client does not have a specific configuration file and option list, you can set both of these parameters to NULL. For more information about configuration files, see the following topic:

"Understanding configuration and options files" on page 1

The **dsmInitEx** function call establishes the IBM Storage Protect session, by using parameters that permit extended verification.

Check the **dsmInitEx** function call and the **dsmInitExOut** information return code. The administrator canceled the last session if the return code is okay (RC=ok) and the information return code (infoRC) is DSM_RC_REJECT_LASTSESS_CANCELED. To end the current session immediately, call **dsmTerminate**.

The **dsmQuerySessOptions** call returns the same fields as the **dsmQueryCliOptions** call. The call can be sent only within a session. The values reflect the client options that are valid during that session, from option files, and from any overrides from the **dsmInitEx** call.

After a session starts, the application can send a call to **dsmQuerySessInfo** to determine the server parameters that are set for this session. Items such as the policy domain and transaction limits are returned to the application with this call.

End sessions with a **dsmTerminate** call. Any connection with the server is closed and all resources that are associated with this session are freed.

For an example of starting and ending a session, see the following topic:

Figure 2 on page 17

The example defines a number of global and local variables that are used in calls to **dsmInitEx** and **dsmTerminate**.

The **dsmInitEx** call takes a pointer to dsmHandle as a parameter. The the **dsmTerminate** call takes the dsmHandle as a parameter.

The example in Figure 3 on page 18 displays the details of **rcApiOut**. The function **rcApiOut** calls the API function **dsmRCMsg**, which translates a return code into a message.

The **rcApiOut** call then prints the message for the user. A version of **rcApiOut** is included in the API sample application. The **dsmApiVersion** function is a type definition that is found in the header file dsmapitd.h.

Session security

The IBM Storage Protect session-based system has security components that permit applications to start sessions in a secure manner. These security measures prohibit unauthorized access to the server and help to insure system integrity.

Every session that is started with the server must complete a sign-on process, requires a password. When the password is coupled with the node name of the client, it insures proper authorization when connecting to the server. The application client provides this password to the API to start the session.

Two methods of password processing are available: *passwordaccess=prompt* or *passwordaccess=generate*. If you use the *passwordaccess=prompt* option, you must include the password value on each **dsmInitEx** call. Or, you can supply the node name and owner name on the **dsmInitEx** call.

Passwords have expiration times associated with them. If a **dsmInitEx** call fails with a password-expired return code (DSM_RC_REJECT_VERIFIER_EXPIRED), the application client must enter the **dsmChangePW** call using the handle that is returned by **dsmInitEx**. This updates the password before the session can be established successfully. The example in Figure 4 on page 18 demonstrates the procedure to change a password by using **dsmChangePW**. The login owner must use a root user ID or an authorized user ID to change the password.

The second method, *passwordaccess=generate*, encrypts and stores the password value in a file. The node name and owner name cannot be supplied on the **dsmInitEx** call, and the system default values are used. This protects the security of the password file. When the password expires, the generate parameter creates a new one and updates the password file automatically.

Tips:

1. If two different physical machines have the same IBM Storage Protect node name or multiple paths are defined on one node using several server stanzas, *passwordaccess=generate* might only work for the stanza which is used first after password expiration. During the first client-server contact, the user is prompted for the same password for each server stanza separately, and for each stanza, a copy of the password is stored separately. When the password expires, a new password is generated for the stanza which connects the first client-server contact. All subsequent attempts to connect via other server stanzas fail, because there is no logical link between their respective copies of the old password, and the updated copy generated by the stanza used first after password expiration. In this case, you must update the passwords prior to expiration or after expiration as a recovery from the situation, as follows:

   a. Run **dsmadmc** and update the password on the server.

   b. Run **dsmc -servername=stanza1** and use the new password to generate a proper entry.

   c. Run **dsmc -servername=stanza2** and use the new password to generate a proper entry.

2. For UNIX or Linux: Only the root user or an authorized user can change the password when using *passwordaccess=prompt*. Only the root user or an authorized user can start the password file when using *passwordaccess=generate*.

   Restriction: The options users and groups are not recognized.

An application can restrict user access by other means, such as setting access filters.

Applications that use multiple IP connections to a single IBM Storage Protect server should use the same node name and IBM Storage Protect client password for each session. Follow these steps to enable this support:

1. Define one IBM Storage Protect server stanza in the dsm.sys file.
2. For the connections not using the default IP address, specify the option values for *TCPserver* address and *TCPport* on the **dsmInitEx** call.

These values override the IP connection information, but the session still uses the same dsm.sys stanza node and password information.

Note: Nodes in a cluster share a single password.

}
return 0;
```

Figure 4. An example of changing a password

Controlling access to password files

To control access to the protected password files on UNIX and Linux systems, you can log on as an authorized user and set the passwordaccess option to generate.

Procedure

Complete the following steps when you set the passwordaccess to generate:

1. Write the application with a call to **dsmSetUp** which passes *argv[0]*. The *argv[0]* contains the name of the application that calls the API. The application is permitted to run an authorized user; however, the administrator must decide on the login name for the authorized user.
2. Set the effective user ID bit (S bit) for the application executable to On. The owner of the application executable file can then become an authorized user and can create a password file, update passwords, and run applications. The owner of the application executable file must be the same as the user ID that runs the program. In the following example, *User* is user1, the name of the application executable file is applA, and user1 has read/write permissions on the /home/user1 directory. The applA executable file has the following permissions:

   ```
   -rwsr-xr-x user1    group1    applA
   ```

3. Instruct the users of the application to use the authorized user name to log in. IBM Storage Protect verifies that the login ID matches the application executable owner before it permits access to the protected password file.
4. Set the passworddir option in the dsm.sys file to point to a directory where this user has read/write access.
   For example, enter the following line in the server stanza of the dsm.sys file:

```
passworddir /home/user1
```

5. Create the password file and ensure that the authorized user owns the file.
6. Log on as `user1` and run `app1A`.
7. Call **dsmSetUp** and pass in *argv*.

Creating an administrative user with client owner authority

An administrative user with client owner authority can set parameters on the **dsmInitEx** function call to start sessions. This user can function as an "administrative user" with backup and restore authority for the defined nodes.

Procedure

To receive client owner authority, complete the following steps on the server:

1. Define the administrative user:

    ```
    REGister Admin admin_name password
    ```

    Where:

    - *admin_name* is the administrative user name.
    - *password* is the admin password.

2. Define the authority level. Users with system or policy authority also have client owner authority.

    ```
    Grant Authority admin_name classes authority node
    ```

    Where:

    - *admin_name* is the administrative user.
    - *classes* is the node.
    - *authority* has one of the following levels of authority:

        – `owner`: full backup and restore authority for the node
        – `node`: single node
        – `domain`: group of nodes

3. Define access to a single node.

    ```
    Register Node node_name password userid=user_id
    ```

    Where:

    - *node_name* is the client user node
    - *password* is the client user node password
    - *user_id* is the administrative user name

Results

When the application uses the administrative user, the **dsmInitEx** function is called with the `userName` and `userNamePswd` parameters.

```
dsmInitEx
        clientNodeName = NULL
        clientOwnerName = NULL
     clientPassword = NULL
     userName = 'administrative user' name
     userNamePswd = 'administrative user' password
```

You can set the `passwordaccess` option to `generate` or `prompt`. With either parameter, the `userNamePswd` value starts the session. When the session starts, any backup or restore process can occur for that node.

Object names and IDs

The IBM Storage Protect server is an object storage server whose primary function is to efficiently store and retrieve named objects. The object ID is unique for each object and remains with the object for the life of the object *except* when you use export or import.

To meet this requirement IBM Storage Protect has two main storage areas, database and data storage.

- The database contains all metadata, such as the name or attributes associated with objects.
- The data storage contains the object data. The data storage is actually a storage hierarchy that the system administrator defines. Data are efficiently stored and managed on either online or offline media, depending on cost and access needs.

Each object that is stored on the server has a name associated with it. The client controls the following key components of that name:

- File space name
- High-level name
- Low-level name
- Object type

When making decisions about naming objects for an application, you might need to use an external name for the full object names to the end user. Specifically, the end user might need to specify the object in an Include or Exclude statement when the application is run. The exact syntax of the object name in these statements is platform-dependent. On the Windows operating system, the drive letter associated with the file space rather than the file space name itself is used in the Include or Exclude statement.

The object ID value that was assigned when you created the object might not be the same as when you perform a restore process. Applications should save the object name and then query to obtain the current object ID before doing a restore.

File space name

The file space name is one of the most important storage components. It can be the name of a file system, disk drive, or any other high-level qualifier that groups related data together.

IBM Storage Protect uses the file space to identify the file system or disk drive on which the data are located. In this way, actions can be performed on all entities within a file space, such as querying all objects within a specified file space. Because the file space is such an important component of the IBM Storage Protect naming convention, you use special calls to register, update, query, and delete file spaces.

The server also has administrative commands to query the file spaces on any node in IBM Storage Protect storage, and delete them if necessary. All data stored by the application client must have a file space name associated with it. Select the name carefully to group similar data together in the system.

To avoid possible interference, an application client should select different file space names from those that a backup-archive client would use. The application client should publish its file space names so that end users can identify the objects for include-exclude statements, if necessary.

Note: On Windows platforms, a drive letter is associated with a file space. When you register or update a file space, you must supply the drive letter. Because the include-exclude list refers to the drive letter, you must keep track of each letter and its associated file space. In the sample program dapismp, the drive letter is set to "G" by default.

High-level and low-level names

Two other components of the object name are the high-level name qualifier and the low-level name qualifier. The high-level name qualifier is the directory path in which the object belongs, and the low-level name qualifier is the actual name of the object in that directory path.

When the file space name, high-level name, and low-level name are concatenated, they must form a syntactically correct name on the operating system on which the client runs. It is not necessary for the name to exist as an object on the system or resemble the actual data on the local file system. However, the name must meet the standard naming rules to be properly processed by the **dsmBindMC** calls. See "Understanding backup and archive objects" on page 37 for naming considerations that are related to policy management.

Object type

The object type identifies the object as either a file or a directory. A file is an object that contains both attributes and binary data, and a directory is an object that contains only attributes.

Table 7 on page 21 shows what the application client would code is for object names by platform.

Table 7. Application object name examples by platform	
Platform	**Client code for object name**
UNIX or Linux	/myfs/highlev/lowlev
Windows	"myvol\\highlev\\lowlev" **Note:** On a Windows platform, a double backslash translates into a single backslash, because a backslash is the escape character. File space names start with a slash on the UNIX or Linux platform, but do not start with a slash on the Windows platform.

Accessing objects as session owner

Each object has an owner name associated with it. The rules determining what objects are accessed depend on what owner name is used when a session is started. Use this session owner value to control access to the object.

The session owner is set during the call to **dsmInitEx** in the *clientOwnerNameP* parameter. If you start a session with **dsmInitEx** owner name of *NULL* and you use *passwordaccess=prompt,* that session owner is handled with session (root or authorized user) authority. This is also true if you log in with a root user ID or an authorized user ID and you use *passwordaccess= generate*. During a session started in this manner, you can perform any action on any object that is owned by this node regardless of the actual owner of that object.

If a session is started with a specific owner name, the session can only perform actions on objects that have that object owner name associated with them. Backups or archives into the system all must have this owner name associated with them. Any queries performed return only the values that have this owner name associated with them. The object owner value is set during the **dsmSendObj** call in the **Owner** field of the **ObjAttr** structure. An owner name is case-sensitive. Table 8 on page 21 summarizes the conditions under which a user has access to an object.

Table 8. Summary of user access to objects

Session owner	Object owner	User access
NULL (root, system owner)	" " (empty string)	Yes
NULL	Specific name	Yes
Specific name	" " (empty string)	No

Table 8. Summary of user access to objects (continued)

Session owner	Object owner	User access
Specific name	Same name	Yes
Specific name	Different name	No

Accessing objects across nodes and owners

Three function calls support cross-node, cross-owner access on the same platform: **dsmSetAccess**, **dsmDeleteAccess**, and **dsmQueryAccess**. These functions, along with the *-fromnode* and *-fromowner* string options that are passed on **dsmInitEx**, permit a complete cross-node query, restore and retrieve process through the API.

For example, User A on node A uses the **dsmSetAccess** function call to give access to its backups under the /db file space to User B from Node B. The access rule is displayed as:

ID	Type	Node	User	Path
1	Backup	Node B	User B	/db/*/*

When User B logs on at Node B, the option string to **dsmInitEx** is:

```
-fromnode=nodeA -fromowner=userA
```

These options are set for this session. Any queries access the file spaces, and files of Node A. Backups and archives are not permitted. Only query, restore, and retrieve processes are permitted from the file spaces for which User B has access. If the application tries to execute any operation using a **dsmBeginTxn** (for examples, backup or update) while signed in with a *-fromnode* or *-fromowner* option set, then the **dsmBeginTxn** fails with the return code DSM_RC_ABORT_NODE_NOT_AUTHORIZED. See the individual function calls and "dsmInitEx" on page 106 for more information.

Tip: On UNIX and Linux you can specify *—fromowner=root* in the option string that is passed on the **dsmInitEx** function call. This permits non-root users access to files that the root owns if a set access was performed.

Use the *asnodename* option on the **dsmInitEx** option string with the appropriate function to back up, archive, restore, retrieve, query or delete data under the target node name on the IBM Storage Protect server. See "Backing up multiple nodes with client node proxy support" on page 72 for information on enabling this option.

Managing file spaces

Because file spaces are important to the operation of the system, a separate set of calls is used to register, update, and delete file space identifiers. Before you can store any objects that are associated with a file space on the system, you must first register the file space with IBM Storage Protect.

Use the **dsmRegisterFS** call to accomplish this task. For more information about object names and IDs, see "Object names and IDs" on page 20.

The file space identifier is the top-level qualifier in a three-part name hierarchy. Grouping related data together within a file space makes management of that data much easier. For example, either the application client or the IBM Storage Protect server administrator can delete a file space and all the objects within that file space.

File spaces also permit the application client to provide information about the file space to the server that the administrator can then query. This information is returned on the query in the **qryRespFSData** structure and includes the following file system information:

Type	Definition
fstype	The file space type. This field is a character string that the application client sets.
fsAttr[platform].fsInfo	A client information field that is used for client-specific data.
capacity	The total amount of space in the file space.
occupancy	The amount of space that is currently occupied in the file space.
backStartDate	The time stamp when the latest backup started (set by sending a **dsmUpdateFS** call).
backCompleteDate	The time stamp when the latest backup completed (set by sending a **dsmUpdateFS** call).

Using capacity and occupancy depends on the application client. Some applications might not need information about the size of the file space, in which case these fields can default to 0. For more information about querying file spaces, see "Querying the IBM Storage Protect system" on page 29.

After a file space is registered with the system, you can back up or archive objects at any time. To update the occupancy and the capacity fields of the file space after a backup or archive operation, call **dsmUpdateFS**. This call ensures that the values for the occupancy and capacity of the file system are current. You can also update the **fsinfo**, **backupstart**, and **backupcomplete** fields.

If you want to monitor your last backup dates, enter a **dsmUpdateFS** call before you start the backup. Set the update action to DSM_FSUPD_BACKSTARTDATE. This forces the server to set the **backStartDate** field of the file space to the current time. After the backup is complete for that file space, enter a **dsmUpdateFS** call with the update action that is set to DSM_FSUPD_BACKCOMPLETEDATE. This call creates a time stamp on the end of the backup.

If a file space is no longer needed, you can delete it with the **dsmDeleteFS** command. On a UNIX or Linux operating system, only the root user or authorized users can delete file spaces.

The examples in Figure 5 on page 24 demonstrate how to use the three file space calls for UNIX or Linux. For an example of how to use the three file space calls for Windows, see the sample program code that is installed on your system.

```
/*  Register the file space if it has not already been done.  */

dsInt16       rc;
regFSData     fsData;
char          fsName[DSM_MAX_FSNAME_LENGTH];
char          smpAPI[] = "Sample-API";

strcpy(fsName,"/home/tallan/text");
memset(&fsData,0x00,sizeof(fsData));
fsData.stVersion = regFSDataVersion;
fsData.fsName = fsName;
fsData.fsType = smpAPI;
strcpy(fsData.fsAttr.unixFSAttr.fsInfo,"Sample API FS Info");
fsData.fsAttr.unixFSAttr.fsInfoLength =
       strlen(fsData.fsAttr.unixFSAttr.fsInfo) + 1;
fsData.occupancy.hi=0;
fsData.occupancy.lo=100;
fsData.capacity.hi=0;
fsData.capacity.lo=300;

rc = dsmRegisterFS(dsmHandle,fsData);
if (rc == DSM_RC_FS_ALREADY_REGED) rc = DSM_RC_OK;  /* already done */
if (rc)
{
   printf("Filespace registration failed: ");
   rcApiOut(dsmHandle, rc);
   free(bkup_buff);
   return (RC_SESSION_FAILED);
}
```

if (rc)
{
   printf("  FAILED!!! ");
   rcApiOut(dsmHandle, rc);
}
else printf("  OK!\n");
```

Figure 7. An example of working with file spaces, Part 3

Associating objects with management classes

A primary feature of IBM Storage Protect is the use of policies (management classes) to define how objects are stored and managed in IBM Storage Protect storage. An object is associated with a management class when the object is backed up or archived.

This management class determines:

- How many versions of the object are kept if backed up
- How long to keep archive copies
- Where to insert the object in the storage hierarchy on the server

Management classes consist of both backup copy groups and archive copy groups. A copy group is a set of attributes that define the management policies for an object that is being backed up or archived. If a backup operation is being performed, the attributes in the backup copy group apply. If an archive operation is being performed, the attributes in the archive copy group apply.

The backup or archive copy group in a particular management class can be empty or NULL. If an object is bound to the NULL backup copy group, that object cannot be backed up. If an object is bound to the NULL archive copy group, the object cannot be archived.

Because the use of a policy is a very important component of IBM Storage Protect, the API requires that all objects sent to the server are first assigned a management class by using the **dsmBindMC** call. With IBM Storage Protect software, you can use an include-exclude list to affect management class binding. The **dsmBindMC** call uses the current Include-Exclude list to perform management class binding.

Include statements can associate a specific management class with a backup or archive object. Exclude statements can prevent objects from being backed up but not from being archived.

The API requires that **dsmBindMC** is called before you back up or archive an object. The **dsmBindMC** call returns a mcBindKey structure that contains information on management class and copy groups that are associated with the object. Check the copy group destination before proceeding with a send. When you send multiple objects in a single transaction, they must have the same copy group destination. The **dsmBindMC** function call returns the following information:

Table 9. Information returned on the dsmBindMC call

Information	Description
Management Class	The name of the management class that was bound to the object. The application client can send the **dsmBeginQuery** call to determine all attributes of this management class.
Backup Copy Group	Informs you if a backup copy group exists for this management class. If a backup operation is being performed and a backup copy group does not exist, this object cannot be sent to storage. You receive an error code if you attempted to send it using the **dsmSendObj** call.
Backup Copy Destination	This field identifies the storage pool to which the data is sent. If you are performing a multiple object backup transaction, all copy destinations within that transaction must be the same. If an object has a different copy destination than previous objects in the transaction, end the current transaction and begin a new transaction before you can send the object. You receive an error code if you attempt to send objects to different copy destinations within the same transaction.
Archive Copy Group	Informs you if an archive copy group exists for this management class. If an archive operation is being performed and an archive copy group does not exist, this object cannot be sent to storage. You receive an error code if you attempted to send it using the **dsmSendObj** call.

Table 9. Information returned on the dsmBindMC call (continued)

Information	Description
Archive Copy Destination	This field identifies the storage pool to which the data are sent. If you are performing a multiple object archive transaction, all copy destinations within that transaction must be the same. If an object has a different copy destination than previous objects in the transaction, end the current transaction and begin a new transaction before you send the object. You receive an error code if you attempt to send objects to different copy destinations within the same transaction.

Backup copies of an object can be rebound to a different management class if a subsequent back up with the same object name is done that uses a management class different than the original. For example, if you back up ObjectA and bind it to Mgmtclass1, and later you back up ObjectA and bind it to Mgmtclass2, the most current backup rebinds any inactive copies to Mgmtclass2. The parameters defined in Mgmtclass2 would now control all copies. However the data does not move if the destination is different.

You can also rebind backup copies to a different management class using the **dsmUpdateObj** or **dsmUpdateObjEx** call with the DSM_BACKUPD_MC action.

Deduplication option

Query management classes

Applications can query management classes to determine what management classes are possible for a given node and to determine what the attributes are within the management class.

You can only bind objects to management classes by using the **dsmBindMC** call. You might want your applications to query the management class attributes and display them to end users. See "Querying the IBM Storage Protect system" on page 29 for more information.

In the example in Figure 8 on page 26, a switch statement is used to distinguish between backup and archive operations when calling **dsmBindMC**. The information returned from this call is stored in the **MCBindKey** structure.

```
dsUint16_t     send_type;
dsUint32_t     dsmHandle;
dsmObjName     objName;      /* structure containing the object name  */
mcBindKey      MCBindKey;    /* management class information          */
char           *dest;        /* save destination value               */

switch (send_type)
{
   case (Backup_Send) :
      rc = dsmBindMC(dsmHandle,&objName,stBackup,&MCBindKey);
      dest = MCBindKey.backup_copy_dest;
      break;
   case (Archive_Send) :
      rc = dsmBindMC(dsmHandle,&objName,stArchive,&MCBindKey);
      dest = MCBindKey.archive_copy_dest;
      break;
   default : ;
}

if (rc)
{
   printf("*** dsmBindMC failed: ");
   rcApiOut(dsmHandle, rc);
   rc = (RC_SESSION_FAILED);
   return;
}
```

Figure 8. An example of associating a management class with an object

Expiration/deletion hold and release

You can hold deletion and expiration of specific archive objects in response to a pending or ongoing action that requires that particular data be held. In the event an action is initiated that might require access to data, that data must be available until the action is concluded and access to the data is no longer required as part of that process. After determining that the suspension is no longer required (released), normal deletion and expiration timing resumes per the original retention period.

Before you begin

Verify that the server is licensed by issuing a test **dsmRetentionEvent** call:

1. Query for one object you want to hold and get the ID.
2. Issue the **dsmBeginTxn**, **dsmRetentionEvent** with Hold, and **dsmEndTxn**.
3. If the server is not licensed, you receive a vote of abort with reason code DSM_RC_ABORT_LICENSE_VIOLATION.

Restrictions:

1. You cannot issue more than one **dsmRetentionEvent** call in a single transaction.
2. You cannot issue a hold on an object that is already under hold.

Procedure

1. To hold objects, complete the following steps:
   a) Query the server for all the objects that you want to place under hold. Get the object ID for each object.
   b) Issue a **dsmBeginTxn** call, then issue a **dsmRetentionEvent** call with the list of objects, followed by a **dsmEventType**: eventHoldObj call. If the number of objects exceeds the value of maxObjPerTxn, use multiple transactions.
   c) Use the qryRespArchiveData response on the **dsmGetNextQObj** function call to confirm that the objects are put under hold. Check the value of objHeld in qryRespArchiveData.
2. To release objects from hold, complete the following steps:
   a) Query the server for all the objects that you want to release from hold. Get the object ID for each object.
   b) Issue a **dsmBeginTxn** call, then issue a **dsmRetentionEvent** call with the list of objects, followed by a **dsmEventType**: eventReleaseObj call. If the number of objects exceeds the value of maxObjPerTxn, use multiple transactions.
   c) Use the **qryRespArchiveData** response on the dsmGetNextQObj function call to confirm if the objects were released from hold. Check the value of objHeld in **qryRespArchiveData**.

Archive data retention protection

Data that is under the control of IBM Storage Protect cannot be modified by unauthorized agents, such as an individual or a program. This protection extends to preventing the deletion of data, such as archive objects, by any agent before the expiration of the retention period.

About this task

Protecting archive retention helps to ensure that no individual or program can maliciously or accidentally delete data that is under the control of IBM Storage Protect. An archive object that is sent to an archive retention protection server is protected from accidental deletes and has an enforced retention period. Archive retention protection has the following restrictions:

- Only archive operations are allowed on a retention protection server.

- Any object that is not bound explicitly to a management class through a value in the **dsmBindMc** function call or through include-exclude statements is bound to the explicit name of the default management class. For example, if the default management class in the node policy is MC1, the object is bound explicitly to MC1 rather than to DEFAULT. On a query response, the object displays as bound to MC1.
- After you enable archive data retention protection, any attempt to delete an object before the retention period expires returns the code DSM_RC_ABORT_DELETE_NOT_ALLOWED on the end transaction.

See the IBM Storage Protect server documentation for instructions for setting retention protection for an archive object.

Procedure

To set up archive data retention protection, complete the following steps:

1. On a new server installation with no previous data, run the **SET ARCHIVERETENTIONPROTECTION ON** command.
2. In the API option string on the **dsmInit** or **dsmInitEx** function calls, enter the following instruction:

```
-ENABLEARCHIVERETENTIONPROTECTION=yes
```

You can also set the enablearchiveretentionprotection option in your dsm.opt file on systems other than UNIX, or in your dsm.sys file on UNIX systems:

```
SERVERNAME srvr1.ret
   TCPPORT                          1500
   TCPSERVERADDRESS                 node.domain.company.com
   COMMMETHOD                       TCPIP
   ENABLEARCHIVERETENTIONPROTECTION YES
```

For more information about this option, see "The enablearchiveretentionprotection option" on page 28.
3. Issue a query to the server to confirm that the IBM Storage Protect server is enabled for archive retention protection. Check the value of the archiveRetentionProtection field in the dsmQuerySessInfo structure.

The enablearchiveretentionprotection option

The enablearchiveretentionprotection option specifies whether to enable data retention protection for archive objects on the IBM Storage Protect server that is dedicated for this purpose. Your server administrator must activate data retention protection on a new server that does not already have stored objects (backup, archive, or space-managed). If the API application attempts to store a backup version or space-managed object on the server, an error message is issued.

The note in Chapter 3, "Considerations for designing an application," on page 9 states: "Do not store objectID values to use for future restores. They are not guaranteed to be persistent during the life of the object." can be relaxed for Archive manager applications since the archive-manager server does not support export or import. Archive-manager applications can save and use the objectID to improve the performance during object restore.

If the server issues the **SET ARCHIVERETENTIONPROTECTION ON** command, you cannot delete an archived object from the server by using the **delete filespace** command, until the policy parameters of the archive copy group are satisfied. See the appropriate server documentation for information about how to set up a management class.

Event-based retention policy

In an event-based retention policy, the retention time of an archive object is initiated by a business event, such as closing a bank account. Event-based retention closely aligns the IBM Storage Protect data retention policy with business requirements for data. When the event occurs, the application sends an **eventRetentionActivate** event for that object to the server to initiate the retention.

Procedure

To use an event-based retention policy, complete the following steps:

1. On the server, create a management class with an archive **copygroup** of type EVENT. For more information, see the IBM Storage Protect server documentation.
2. Query the management class to confirm that the class is event-based. If the management class is event-based, the **retainInit** field in the **archDetailCG** structure is ARCH_RETINIT_EVENT.
3. Bind the objects to the event-based management class by using include, **archmc**, or explicitly through the **mcNameP** attribute in the **ObjAttr** structure on the **dsmSendObj** function call.
4. At the point that you want to start the retention for the object, query the server for all of the objects that are affected. Check to see whether they are in a PENDING state, and get the object ID. In a pending state, the **retentionInitiated** field in the **qryRespArchiveData** structure indicates DSM_ARCH_RETINIT_PENDING.
5. Issue a **dsmBeginTxn** call, then issue a **dsmRetentionEvent** call with the list of objects, followed by a **dsmEventType**: eventRetentionActivate call. If the number of objects exceeds the value of maxObjPerTxn, use multiple transactions.

   Restriction: You can issue only one **dsmRetentionEvent** call per transaction.
6. Query the objects to confirm that the retention is activated. If retention is initiated, the **retentionInitiated** field in the **qryRespArchiveData** structure has a value of I.

Querying the IBM Storage Protect system

The API has several queries, such as management class query, that applications can use.

Procedure

All queries that use the **dsmBeginQuery** call follow these steps:

1. Send the **dsmBeginQuery** call with the appropriate query type:

   - Backup
   - Archive
   - Active backed-up objects
   - File space
   - Management class

   The **dsmBeginQuery** call informs the API of the data format that is returned from the server. The appropriate fields can be placed in the data structures that are passed by the **dsmGetNextQObj** calls. The begin query call also permits the application client to set the scope of the query by properly specifying the parameters on the begin query call.

   Restriction: On UNIX or Linux systems, only the root user can query active backed-up objects. This query type is known as "fast path".
2. Enter the **dsmGetNextQObj** call to obtain each record from the query. This call passes a buffer that is large enough to hold the data that is returned from the query. Each query type has a corresponding data structure for the data returned. For example, a backup query type has an associated **qryRespBackupData** structure that is populated when the **dsmGetNextQObj** call is sent.
3. The **dsmGetNextQObj** call usually returns one of the following codes:

   - DSM_RC_MORE_DATA: Send the **dsmGetNextQObj** call again.
   - DSM_RC_FINISHED: There is no more data. Send the **dsmEndQuery** call.
4. Send the **dsmEndQuery** call. When all query data are retrieved or more query data are not needed, enter the **dsmEndQuery** call to end the query process. The API flushes any remaining data from the query stream and releases any resources that were used for the query.

Results

Figure 9 on page 30 displays the state diagram for query operations.
Figure 9. State diagram for general queries

Figure 10 on page 30 displays the flowchart for query operations.
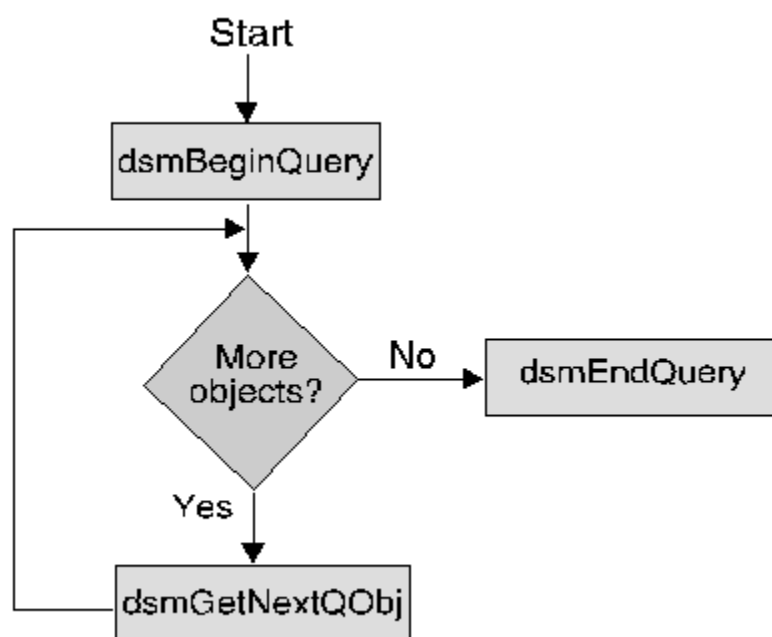

Figure 10. Flowchart for general queries

Example of querying the system

In this example a management class query prints out the values of all the fields in the backup and archive copy groups for a particular management class.

```
dsInt16                rc;
qryMCData              qMCData;
DataBlk                qData;
qryRespMCDetailData    qRespMCData, *mcResp;
char                   *mc, *s;
dsBool_t               done = bFalse;
dsUint32_t             qry_item;

/* Fill in the qMCData structure with the query criteria we want */
qMCData.stVersion = qryMCDataVersion;   /* structure version      */
qMCData.mcName    = mc;                  /* management class name */
qMCData.mcDetail  = bTrue;               /* want full details?    */

/* Set parameters of the data block used to get or send data     */
qData.stVersion = DataBlkVersion;
qData.bufferLen = sizeof(qryRespMCDetailData);
qData.bufferPtr = (char *)&qRespMCData;

qRespMCData.stVersion = qryRespMCDetailDataVersion;
```

```
if ((rc = dsmBeginQuery(dsmHandle,qtMC,(dsmQueryBuff *)&qMCData)))
{
   printf("*** dsmBeginQuery failed: ");
   rcApiOut(dsmHandle, rc);
   rc = (RC_SESSION_FAILED);
}
else
{
   done = bFalse;
   qry_item = 0;
   while (!done)
   {
      rc = dsmGetNextQObj(dsmHandle,&qData);
      if ((   (rc == DSM_RC_MORE_DATA)
           || (rc == DSM_RC_FINISHED))
         && qData.numBytes)
      {
         qry_item++;
         mcResp = (qryRespMCDetailData *)qData.bufferPtr;
         printf("Mgmt. Class
         printf("             Name:
         printf("   Backup CG Name:
            .
            .  /* other fields of backup and archive copy groups */
            .
         printf("   Copy Destination:
      }
      else
      {
         done = bTrue;
         if (rc != DSM_RC_FINISHED)
         {
            printf("*** dsmGetNextQObj failed: ");
            rcApiOut(dsmHandle, rc);
         }
      }
      if (rc == DSM_RC_FINISHED) done = bTrue;
   }
   rc = dsmendQuery (dsmHandle);
}
```

Figure 11. An example of performing a system query

Server efficiency

Use these guidelines when you retrieve from, or send objects to, the IBM Storage Protect server.

• When you retrieve objects from the IBM Storage Protect server, follow these guidelines:

- Retrieve data in the restore order that is provided by the IBM Storage Protect server. The restore order is especially important for tape devices, because retrieving data that is not ordered can result in tape rewinds and mounts.
- Even when data is stored on a disk device, you can save time when the retrieves are ordered.
- Perform as much work as possible in a single IBM Storage Protect server session.
- Do not start and stop multiple sessions.
- When you send objects to the IBM Storage Protect server, follow these guidelines:
  - Send multiple objects in a single transaction.
  - Avoid sending one object per transaction, especially when the data is sent directly to a tape device. Part of the tape device transaction is to ensure that the data in the RAM buffers of the tape is written to media.

Related concepts
"Selecting and sorting objects by restore order" on page 60
After the backup or archive query is performed, the application client must determine which objects, if any, are to be restored or retrieved.

Related information
"Starting or ending a session" on page 15
IBM Storage Protect is a session-based product, and all activities must be performed within an IBM Storage Protect session. To start a session, the application starts the **dsmInitEx** call. This call must be performed before any other API call other than **dsmQueryApiVersionEx**, **dsmQueryCliOptions**, or **dsmSetUp**.

Sending data to a server

The API permits application clients to send data or named objects and their associated data to IBM Storage Protect server storage.

Tip: You can either back up or archive data. Perform all send operations within a transaction.

The transaction model

All data sent to IBM Storage Protect storage during a backup or archive operation is done within a transaction. A transaction model provides a high level of data integrity, but it does impose some restrictions that an application client must take into consideration.

Start a transaction by a call to **dsmBeginTxn** or end a transaction by a call to **dsmEndTxn**. A single transaction is an atomic action. Data sent within the boundaries of a transaction is either committed to the system at the end of the transaction or rolled back if the transaction ends prematurely.

Transactions can consist of either single object sends or multiple object sends. To improve system performance by decreasing system overhead, send smaller objects in a multiple object transaction. The application client determines whether single or multiple transactions are appropriate.

Send all objects within a multiple object transaction to the same copy destination. If you need to send an object to a different destination than the previous object, end the current transaction and start a new one. Within the new transaction, you can send the object to the new copy destination.

Note: Objects that do not contain any bit data ($sizeEstimate=0$) are not checked for copy destination consistency.

IBM Storage Protect limits the number of objects that can be sent in a multiple object transaction. To find this limit, call **dsmQuerySessInfo** and examine the **maxObjPerTxn** field. This field displays the value of the *TXNGroupmax* option that is set on your server.

The application client must keep track of the objects sent within a transaction to perform retry processing or error processing if the transaction ends prematurely. Either the server or the client can stop a transaction at any time. The application client must be prepared to handle sudden transaction ends that it did not start.

File aggregation

IBM Storage Protect servers use a function that is called file aggregation. With file aggregation, all objects sent in a single transaction are stored together, which saves space and improves performance. You can still query and restore the objects separately.

To use this function, all of the objects in a transaction should have the same file space name. If the file space name changes within a transaction, the server closes the existing aggregated object and begins a new one.

LAN-free data transfer

The API can take advantage of LAN-free data transfer if the **dsmSetUp** option for multithreading is ON. The API returns the existence of a LAN-free destination in the **Query Mgmt Class** response structure **archDetailCG** or **backupDetailCG** field **bLanFreeDest**.

You can use LAN-free operations on platforms that are supported by the storage agent. Macintosh platform is excluded.

LAN-free information is provided in the following output structures. The out structure (**dsmEndGetDataExOut_t**) for **dsmEndGetData** includes the field, **totalLFBytesRecv**. This is the total number of LAN-free bytes that are received. The out structure (**dsmEndSendObjExOut_t**) for **dsmEndSendObjEx** includes the field, **totalLFBytesSent**. This is the total number of LAN-free bytes that were sent.

Related information
LAN-free data movement: Storage agent overview

Simultaneous-write operations

You can configure IBM Storage Protect server storage pools to write simultaneously to a primary storage pool and copy storage pool or pools during a backup or archive. Use this configuration to create multiple copies of the object.

If a simultaneous-write operation fails, the return code on the **dsmEndTxn** function might be DSM_RC_ABORT_STGPOOL_COPY_CONT_NO, which indicates that the write to one of the copy storage pools failed, and the IBM Storage Protect storage pool option COPYCONTINUE was set to NO. The application terminates and the problem must be resolved by the IBM Storage Protect server administrator.

For more information about setting up simultaneous-write operations, see the IBM Storage Protect server documentation.

Enhancing API performance

You can use the tcpbuffsize and tcpnodelay client options and the **DataBlk** API parameter to enhance API performance.

Table 10 on page 33 describes the actions that you can take to enhance the API performance.

Table 10. Backup-archive options and the API parameter that enhance performance	
Backup-archive client options	**Description**
tcpbuffsize	Specifies the size of the TCP buffer. The default value is 31 KB. To enhance performance, set the value to 32 KB.
tcpnodelay	Specifies whether to send small buffers to the server rather than holding them. To enhance performance, set this option to *yes* for all platforms. This option is valid for Windows and AIX only.
API parameter	**Description**

Table 10. Backup-archive options and the API parameter that enhance performance (continued)	
Backup-archive client options	**Description**
`DataBlk`	This parameter is used with the **dsmSendData** function call to determine the application buffer size. For best results, set the parameter as a multiple of the *tcpbuffsize* value that is specified with the `tcpbuffsize` minus 4 bytes. For example, set a value of 28 for this parameter when the value of `tcpbuffsize` is set to 32 KB.

Each **dsmSendData** call is synchronous and does not return until the data transferred to the API in the **dataBlkPtr** is flushed to the network. The API adds a 4-byte overhead to each transaction buffer that is placed on the network.

For example, when the transaction buffer size is 32 KB and the application **DataBlk** buffer size is 31 KB, then each application **DataBlk** buffer fits in a communications buffer and can be flushed immediately. However, if the application **DataBlk** buffer is exactly 32 KB, and because the API is adding 4 bytes per transaction buffer, two flushes are required; one of 32 KB and one of 4 bytes. Also, if you set the `tcpnodelay` option to no, flushing the 4 bytes might take up to 200 milliseconds.

Set up the API to send performance data to the client performance monitor

The client performance monitor is a component of the Tivoli® Storage Manager Administration Center that is used to display performance data that is collected by the API. The client performance monitor records and displays performance data for client backup, archive, and restore operations.

With performance monitoring enabled, you can display performance data that is collected by the API by using the performance monitor; the performance monitor is available in the Tivoli Storage Manager Administration Center. Starting with version 7.1, the Administration Center component is no longer included in Tivoli Storage Manager or IBM Storage Protect distributions. If you have an Administration Center that was installed with a previous server release, you can continue to use it to display performance data. If you do not already have an Administration Center installed, you can download the previously-released version from ftp://public.dhe.ibm.com/storage/tivoli-storage-management/maintenance/admincenter/v6r3/. For information about using the performance monitor, see the Tivoli Storage Manager version 6.3 server documentation.

Configuring client performance monitor options

You enable IBM Storage Protect clients to use the performance monitor by specifying parameters in the client options file. You specify these options for each client that you want to monitor.

Before you begin
When you monitor performance on UNIX and Linux computers, set the open file descriptor limit to at least 1024, by using the following command:

```
ulimit -n 1024
```

Procedure

To configure the client performance monitor options, complete the following steps:

1. Open the client options file for each client that you are monitoring. Depending on your configuration, the client options are in one of the following files:

   - dsm.opt
   - dsm.sys

2. Add the following options to the client options file:

```
PERFMONTCPSERVERADDRESS
PERFMONTCPPORT
PERFMONCOMMTIMEOUT
```

PERFMONTCPSERVERADDRESS

The PERFMONTCPSERVERADDRESS option specifies the host name or IP address of the system where the client performance monitor is installed.

Supported clients

This option is platform independent and is supported for all clients.

Options file

Set this option in the client options file (`dsm.opt` or `dsm.sys`).

Syntax

▶▶─ PERFMONTCPServeraddress   *server* ─▶◀

Parameters

server
    The server host name or IP address of the system that has the client performance monitor installed (this is the same server that runs the Administration Center).

Examples

Options file:
    `PERFMONTCPSERVERADDRESS 131.222.10.5`

Command line:
    This option cannot be set using the command line.

PERFMONTCPPORT

The port number that the client performance monitor listens on for performance data from the clients.
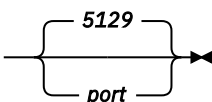

Supported clients

This option is platform independent and is supported for all clients.

Options file

Set this option in the client options file (`dsm.opt` or `dsm.sys`).

Syntax

```
                              5129
▶▶─ PERFMONTCPPort ────┬──────────────┬──▶◀
                       └──── port ─────┘
```

Parameters

port
    The port that is monitored for client performance data. Port 5129 is the default port.

Examples

Options file:
    PERFMONTCPPPORT 5000

Command line:
    This option cannot be set using the command line.

PERFMONCOMMTIMEOUT

Specifies the maximum time, in seconds, that the `dsmTerminate` call waits for performance data to arrive after a session is ended.

Supported clients

This option is platform independent and is supported for all clients.

Options file

Set this option in the client options file (`dsm.opt` or `dsm.sys`).

Syntax

```
►►─ PERFMONCOMMtimeout ─┬─── 30 ────┬─ ►◄
                        └─ seconds ─┘
```

Parameters

seconds
    The time to wait for remaining performance data to arrive, before ending the session.

Examples

Options file:
    PERFMONCOMMTIMEOUT 60

Command line:
    This option cannot be set using the command line.

Sending objects to the server

Application clients can send data or named objects and their associated data to IBM Storage Protect storage by using the API backup and archive functions. The backup and archive components of the system permit use of different management procedures for data that is sent to storage.

The size estimate attribute is an estimate of the total size of the data object to send to the server. If the application does not know the exact object size, set the *sizeEstimate* to a higher estimate. If the estimate is smaller than the actual size, the IBM Storage Protect server uses extra resources to manage extra space allocations.

Tips:

- Be as accurate as is possible when you make this size estimate. The server uses this attribute for efficient space allocation and object placement within its storage resources.

- If the estimate is smaller than the actual size, a server with caching does not allocate extra space and stops the send.

You might encounter problems if the *sizeEstimate* is much too large. The server might not have enough space for the estimated size but does have space for the actual size; or the server might use slower devices.

You can back up or archive objects that are larger than two gigabytes in size. The objects can be either compressed or uncompressed.

To start a send operation, call **dsmSendObj**. If you have more data than you can send at one time, you can make repeated calls to **dsmSendData** to transfer the remainder of the information. Call **dsmEndSendObj** to complete the send operation.

Understanding backup and archive objects

The backup component of the IBM Storage Protect system supports several versions of named objects that are stored on the server.

Any object backed up to the server that has the same name as an object that is already stored on the server from that client is subject to version control. Objects are considered to be in active or inactive states on the server. The latest copy of an object on the server that has not been deactivated is in the active state. Any other object with the same name, whether it is an older version or a deactivated copy, is considered inactive. Management class constructs define different management criteria. They are assigned to active and inactive objects on the server.

Table 11 on page 37 lists the copy group fields that apply to active and inactive states:

Table 11. Backup copy group fields	
Field	**Description**
VEREXISTS	The number of inactive versions if active versions exist.
VERDELETED	The number of inactive versions if active versions do not exist.
RETEXTRA	The number of days to keep inactive versions.
RETONLY	The number of days to keep the last inactive versions if active versions do not exist.

If backup versions each have a unique name, such as using a time stamp in the name, then versioning does not happen automatically: every object is active. Active objects never expire, so an application would be responsible for deactivating these with the **dsmDeleteObj** call. In this situation, the application would need the deactivated objects to expire as soon as possible. The user would define a backup copy group with VERDELETED=0 and RETONLY=0.

The archive component of the IBM Storage Protect system permits objects to be stored on the server with retention or expiration period controls instead of version control. Each object stored is unique, even though its name might be the same as an object already archived. Archive objects have a description field associated with the metadata that can be used during query to identify a specific object.

Every object on the IBM Storage Protect server is assigned a unique object ID. The persistence of the original value is not guaranteed during the life of an object (specifically, after an export or import). Therefore, an application should not query and save the original object ID for use on later restores. Rather, an application should save the object name and insert date. You can use this information during a restore to query objects and verify the insert date. Then, the current object ID can be used to restore the object.

Compression

Configuration options on a given node and the **dsmSendObj** objCompressed option, determine whether IBM Storage Protect compresses the object during a send. Also, objects with a sizeEstimate less than DSM_MIN_COMPRESS_SIZE are never compressed.

If the object is compressed already (objCompressed=bTrue), it is not compressed again. If it is not compressed, IBM Storage Protect decides whether to compress the object, based on the values of the compression option that is set by the administrator and that is set in the API configuration sources.

The administrator can change compression thresholds on the server by using the register node command (`compression=yes`, `no`, or `client-determined`). If this is `client-determined`, then the compression behavior is determined by the compression option value in the configuration sources.

Some types of data, such as data that is already compressed, might actually get bigger when processed with the compression algorithm. When this happens, the return code DSM_RC_COMPRESS_GREW is generated. If you realize that this might happen, but you want the send operation to continue anyway, tell the end users to specify the following option in their options file:

```
COMPRESSAlways Yes
```

If, during a **dsmSendData** function, with compression enabled, you get DSM_RC_COMPRESS_GREW return code, you might want to start over and send the object again without compression. To enforce this, set the **dsmSendObj** ObjAttr.objCompressed to bTrue.

Information about the actual compression behavior during a **dsmSendObj** is returned by the **dsmEndSendObjEx** call. objCompressed specifies if compression was done. totalBytesSent is the number of bytes sent by the application. totalCompressedSize is the number of bytes after compression. The **dsmEndSendObjEx** call also has a totalLFBytesSent field that contains the total bytes sent over LAN-free.

> ⚠️ **Attention:** If your application plans to use partial object restore or retrieve, you cannot compress the data while sending it. To enforce this, set the **dsmSendObj** ObjAttr.objCompressed to bTrue.

Compression type

The type of compression that the client uses is determined by the combination of compression and client-side data deduplication that is used during backup or archive processing.

The compression algorithm that is used by the client is reported by the API in a new field in the **qryRespArchiveData** and **qryRespBackupData** structures:

```
dsChar_t        compressAlg[20];  /* compression algorithm name */
```

The following types of compression are reported:

LZ4
A faster and more efficient compression method that the client uses in any of the following situations:

- The client-side deduplicated object is sent to a container storage pool on the IBM Storage Protect server. The server must be at version 7.1.5 or later.
- The object does not undergo client-side data deduplication.
- The object undergoes only traditional server-side data deduplication.

LZW
A traditional type of compression that the client uses is when client-deduplicated objects are sent to traditional (non-container) storage pools on the server.

Blank field
The object is not compressed by the client. The object is not compressed because the `compression` option is set to *no*, or the option is not specified during backup or archive processing. Although the object is not compressed by the client, it might be compressed by the server.

The compression type is not configurable. It is determined by the backup-archive client at the time of backup or archive processing.

Example

The following example shows the `Compresssion Type` field in the output of the backup and archive queries from the 64-bit sample application **dapismp**:

```
Enter selection ==>1
                   Filespace:\fs1
                   Highlevel:\hl
                    Lowlevel:\ll
          Object Type(D/F/A):f
   Active(A),Inactive(I),Both(B):a
If root, query all owners? (Y/N):
            Object Owner Name:
   point in time date (MMDDYYYY):
   point in time time    (hhmm):
     Show detailed output? (Y/N):y
On Restore, Wait for mount?(Y/N):
Are the above responses correct (y/n/q)?

Item 1: \fs1\hl\ll
   Object type: File
   Object state: Active
   Insert date: 2016/2/3 10:57:41
   Expiration date: 0/0/0 0:0:0
   Owner:
   Restore order: 0-0-0-0-0
   Object id: 0-40967
   Copy group: 1
   Media class: Fixed

   Object info is        :IBM Storage Protect API Verify Data
   Object info length is :73
   Estimated size : 0   4000
   Compression : YES
   Compression Type: LZ4
   Encryption : NO
   Encryption Strength : NONE
   Client Deduplicated : YES
```

Buffer copy elimination

The buffer copy elimination function removes the copy of data buffers between an application and the IBM Storage Protect server, which results in better processor utilization. For maximum effect, use this approach in a LAN-free environment.

The buffers for data movement are allocated by IBM Storage Protect and a pointer is passed back to the application. The application places the data in the provided buffer, and that buffer is passed through the communication layers to the storage agent by using shared memory. The data is then moved to the tape device, which eliminates copies of data. This function can be used with either backup or archive operations.

Attention: When you use this method, pay extra attention to proper buffer handling and sizes of buffers. The buffers are shared between the components and any memory overwrite that is a result of a programming error results in severe errors.

The overall sequence of calls for backup/archive is as follows:

```
dsmInitEx (UseTsmBuffers = True, numTsmBuffers = [how many IBM Storage Protect
          -allocated buffers the application needs to allocate])
dsmBeginTxn
for each object in the txn
  dsmBindMC
    dsmSendObject
      dsmRequestBuffer
      dsmSendBufferData (sends and release the buffer used)
    dsmEndSendObjEx
dsmEndTxn
for each buffer still held
      dsmReleaseBuffer
dsmTerminate
```

The **dsmRequestBuffer** function can be called multiple times, up to the value that is specified by the numTsmBuffers option. An application can have two threads: a producer thread that fills buffers with data; and a consumer thread that sends those buffers to IBM Storage Protect with the **dsmSendBufferData** call. When a **dsmRequestBuffer** call is issued and the **numTsmBuffers** is reached, the **dsmRequestBuffer** call blocks until a buffer is released. The buffer release can happen by either calling **dsmSendBufferData**, which sends and releases a buffer or by calling **dsmReleaseBuffer**. For more information, see `callbuff.c` in the API sample directory.

If at any point there is a failure in the send, the application must release all the buffers that are held and terminate the session. For example:

```
If failure
   for each data buffer held by application
     call dsmReleaseBuffer
dsmTerminate
```

If an application calls **dsmTerminate** and a buffer is still held, the API does not exit. The following code is returned: DSM_RC_CANNOT_EXIT_MUST_RELEASE_BUFFER. If the application cannot release the buffer, the application must exit the process to force a cleanup.

Buffer copy elimination and restore and retrieve

The IBM Storage Protect server controls the amount of data to be placed in the buffer, based on tape access optimization with restore and retrieve. This method is not as beneficial to the application as the normal method of getting data. During prototyping, check the performance of the buffer copy elimination method and use this method only if you see a worthwhile improvement.

The maximum amount of data in a single buffer that is returned by the IBM Storage Protect server is (256K bytes – header overhead). As a consequence, only applications that deal with small buffer writes benefit from this data retrieval mechanism. The application must give special attention to the number of bytes in the buffer, depending on the object size, the network, and other boundary conditions. In some situations, the use of buffer copy elimination can actually perform worse than the normal restore. The API normally caches the data and returns a fixed length to the application. The application can then control the number of data writes back to the disk.

If you use buffer copy elimination, create a data-caching mechanism for buffers that are less than the preferred write buffer size. For example, if an application writes 64K data blocks to disk, the application must take these actions:

1. Call **dsmGetBufferData**.

2. Write out blocks of 64K.

3. On the final block, copy the remainder to a **tempBuff**, issue another **dsmGetBufferData** call, and fill the **tempBuff** with the rest of the data.

4. Continue writing blocks of 64K:

```
dsmGetBufferData #1 get 226K        dsmGetBufferData #2 get 240K
Block1 64K - write to disk          Block1 30K - copy to tempbuff-write to disk
Block2 64K - write to disk          Block2 64K - write to disk
Block3 64K - write to disk          Block3 64K - write to disk
Block4 34K - copy to tempbuff       Block4 64K - write to disk
Block5 18K - write to tempbuff        etc
```

In this example, six disk writes are direct and 1 is cached.

The overall sequence of calls for restore and retrieve is as follows:

dsmInitEx (UseTsmBuffers = True numTsmBuffers = how many buffers the application wants to allocate).

```
dsmBeginGetData
While obj id
  dsmGetObj (no data restored on this call- buffer set to NULL)
 While data to read
   dsmGetBufferData (returns the data in the data buffer)
```

```
  ...process data...
    dsmReleaseBuffer
  dsmEndGetObj
  dsmEndGetData
```

For every **dsmGetBufferData** call, implement a **dsmReleaseBuffer** call. The **dsmGetBufferData** and corresponding **dsmReleaseBuffer** do not need to be consecutive. An application might issue multiple **dsmGetBufferData** calls first to get several buffers, and then issue the corresponding **dsmReleaseBuffer** calls later. For sample code that uses this function, see `callbuff.c` in the API sample directory.

Restriction: Because the API provides the buffer and the goal is to minimize processor utilization, more processing of the data in the buffer is not permitted. The application cannot use encryption and compression with buffer copy elimination because both of these operations require data processing and copies.

Implement both the regular data movement path and the buffer copy elimination to enable the user to switch between both paths, based on their needs. If the user must compress or encrypt data, then use the existing mechanism. If there is a processor constraint, then use the new mechanism. Both of these mechanisms are complementary and do not completely replace each other.

API encryption

Two methods are available to encrypt data: application-managed encryption and IBM Storage Protect client encryption.

Select and use only one of these methods to encrypt data. The methods are mutually exclusive and if you encrypt data by using both methods, you will be unable to restore or retrieve some data. For example, assume that an application uses application-managed encryption to encrypt object A, and then uses IBM Storage Protect client encryption to encrypt object B. During a restore operation, if the application sets the option to use IBM Storage Protect client encryption and it tries to restore both objects, only object B can be restored; object A cannot be restored because it was encrypted by the application, not by the client.

Regardless of the encryption method that is used, the IBM Storage Protect must enable password authentication. By default, the server uses SET AUTHENTICATION ON.

The API uses either AES 128-bit or AES 256-bit encryption. AES 256-bit data encryption provides a higher level of data encryption than AES 128-bit data encryption. Files that are backed up by using AES 256-bit encryption cannot be restored with an earlier client. Encryption can be enabled with or without compression. If you use encryption, you cannot use the partial object restore and retrieve and buffer copy elimination functions.

Application-managed encryption

With application-managed encryption, the application provides the key password to the API (using key DSM_ENCRYPT_USER) and it is the application's responsibility to manage the key password.

⚠️ **Attention:** If the encryption key is not saved, and you forgot the key, your data is unrecoverable.

The application provides the key password in the **dsmInitEx** call and must provide the proper key password at restore time.

⚠️ **Attention:** If the key password is lost, there is no way to restore the data.

The same key password must be used for backup and restore (or archive and retrieve) operations for the same object. This method does not have a dependency on the IBM Storage Protect server level. To set up this method, the application needs to follow these steps:

1. Set the `bEncryptKeyEnabled` variable to `bTrue` in the call to **dsmInitEx**, and set the `encryptionPasswordP` variable to point to a string with the encrypt key password.

2. Set the `include.encrypt` for the objects to `encrypt`. For example, to encrypt all data, set:

```
include.encrypt /.../* (UNIX)
```

and

```
include.encrypt *\...\* (Windows)
```

To encrypt the object /FS1/DB2/FULL, set:

```
include.encrypt /FS1/DB2/FULL
```

3. Set ENCRYPTKEY=PROMPT|SAVE in the option string that is passed to the API in the **dsmInitEx** call on Windows. This option can also be set in `dsm.opt` (Windows) or `dsm.sys` (UNIX or Linux).

By default, the `encryptkey` option is set to `prompt`. This setting ensures that the key does not get stored automatically. If `encryptkey save` is specified, the key is stored by IBM Storage Protect on the local machine but then only one key can be valid for all IBM Storage Protect operations with the same node name.

After a send of an object, the **dsmEndSendObjEx** specifies whether an object was encrypted and which method was used. Possible values in the *encryptionType* field:

- DSM_ENCRYPT_NO
- DSM_ENCRYPT_USER
- DSM_ENCRYPT_CLIENTENCRKEY

The following table lists the API encryption types, prerequisites, and the functions that are available.

Table 12. API encryption types, prerequisites, and functions available

Type	Prerequisite	Function available
ENCRYPTIONTYPE	None	Set the ENCRYPTIONTYPE in the option string that is passed to the API in the **dsmInitEx** call on Windows. ENCRYPTIONTYPE=AES128 by default.
EncryptKey=save	None	API and backup-archive
EncryptKey=prompt	None	API and backup-archive
EncryptKey=generate	None	API and backup-archive
EnableClientEncryptKey	None	API only

Note: It is advised that the server has authentication turned ON. If authentication is turned OFF, the key is not encrypted, but the data is still encrypted. However, this is not recommended.

Table 13 on page 42 shows how both Authorized Users and non-Authorized Users can encrypt or decrypt data during a backup or restore operation, depending on the value that is specified for the `passwordaccess` option. To perform the following authorized-user and non-authorized-user operations, the TSM.KDB, TSM.sth, and TSM.IDX files must exist. The authorized user sets the `encryptkey` option to **save** and the `passwordaccess` option to **generate**.

Table 13. Encrypting or decrypting data with application managed key on UNIX or Linux

Operation	passwordaccess option	encryptkey option	Result
Authorized user backup	generate	save	Data encrypted.
	generate	prompt	Data encrypted if encryptionPasswordP contains an encryption password.
	prompt	save	Data encrypted if encryptionPasswordP contains an encryption password.
	prompt	prompt	Data encrypted if encryptionPasswordP contains an encryption password.

Table 13. Encrypting or decrypting data with application managed key on UNIX or Linux (continued)

Operation	passwordaccess option	encryptkey option	Result
Authorized user restore	generate	save	Data encrypted.
	generate	prompt	Data encrypted if `encryptionPasswordP` contains an encryption password.
	prompt	save	Data encrypted if `encryptionPasswordP` contains an encryption password.
	prompt	prompt	Data encrypted if `encryptionPasswordP` contains an encryption password.
Non-authorized user backup	generate	save	Data encrypted.
	generate	prompt	Data encrypted if `encryptionPasswordP` contains an encryption password.
	prompt	save	Data encrypted if `encryptionPasswordP` contains an encryption password.
	prompt	prompt	Data encrypted if `encryptionPasswordP` contains an encryption password.
Non-authorized user restore	generate	save	Data encrypted.
	generate	prompt	Data encrypted if `encryptionPasswordP` contains an encryption password.
	prompt	save	data encrypted if `encryptionPasswordP` contains an encryption password.
	prompt	prompt	Data encrypted if `encryptionPasswordP` contains an encryption password.

IBM Storage Protect client encryption

IBM Storage Protect client encryption uses the key that is managed by the DSM_ENCRYPT_CLIENTENCRKEY value to protect your data. Client encryption is transparent to the application that is using the API, with the exception that partial object restore operations and retrieve operations are not possible for objects that were encrypted or compressed.

For both IBM Storage Protect client encryption and application-managed encryption, the encryption password refers to a string value that is used to generate the actual encryption key. The value for the encryption password option is 1-63 characters in length, but the key that is generated from it is always 8 bytes for 56 DES, 16 bytes for 128 AES, and 32 bytes for 256 AES.

⚠️ **Attention:** If the encryption key is not available, data cannot be restored or retrieved. When you use ENABLECLIENTENCRYPTKEY for encryption, the encryption key is stored on the server database. For objects that use this method, the server database must exist and have the proper values for the objects for a proper restore. Ensure that you back up the server database frequently to prevent data loss.

This is the simpler method to implement, where one random encryption key is generated per session and it is stored on the IBM Storage Protect server with the object in the server database. During restore, the stored key is used for decryption. Using this method, the management of the key is the responsibility of IBM Storage Protect, and the application does not have to deal with the key at all. Because the key is stored in the server database, you must have a valid IBM Storage Protect database for a restore operation of an encrypted object. When the key is transmitted between the API and the server, it is also encrypted. The transmission of the key is secure, and when the key is stored in the IBM Storage Protect server database it is encrypted. The only time that the key is placed in the clear with the export data stream is when a node's data are exported between servers.

To enable IBM Storage Protect client encryption, complete the following steps:

1. Specify -ENABLECLIENTENCRYPTKEY=YES in the option string that is passed to the API on the dsmInitEx call or set the option in the system option file dsm.opt (Windows) or dsm.sys (UNIX or Linux).

2. Set the `include.encrypt` for the objects to encrypt. For example, to encrypt all data, set:

```
include.encrypt /.../* (UNIX)
```

and

```
include.encrypt *\...\* (Windows)
```

To encrypt the object /FS1/DB2/FULL, set:

```
include.encrypt /FS1/DB2/FULL
```

Data deduplication

Data deduplication is a method of reducing storage needs by eliminating redundant data.

Overview

Two types of data deduplication are available on IBM Storage Protect: *client-side data deduplication* and *server-side data deduplication*.

Client-side data deduplication is a data deduplication technique that is used on the backup-archive client to remove redundant data during backup and archive processing before the data is transferred to the IBM Storage Protect server. Using client-side data deduplication can reduce the amount of data that is sent over a local area network.

Server-side data deduplication is a data deduplication technique that is done by the server. The IBM Storage Protect administrator can specify the data deduplication location (client or server) to use with the **DEDUP** parameter on the **REGISTER NODE** or **UPDATE NODE** server command.

Enhancements

With client-side data deduplication, you can:

- Exclude specific files on a client from data deduplication.
- Enable a data deduplication cache that reduces network traffic between the client and the server. The cache contains extents that were sent to the server in previous incremental backup operations. Instead of querying the server for the existence of an extent, the client queries its cache.

  Specify a size and location for a client cache. If an inconsistency between the server and the local cache is detected, the local cache is removed and repopulated.

  Note: For applications that use the IBM Storage Protect API, the data deduplication cache must not be used because of the potential for backup failures caused by the cache being out of sync with the IBM Storage Protect server. If multiple, concurrent backup-archive client sessions are configured, there must be a separate cache configured for each session.

- Enable both client-side data deduplication and compression to reduce the amount of data that is stored by the server. Each extent is compressed before it is sent to the server. The tradeoff is between storage savings and the processing power that is required to compress client data. In general, if you compress and deduplicate data on the client system, you are using approximately twice as much processing power as data deduplication alone.

  The server can work with deduplicated, compressed data. In addition, backup-archive clients earlier than V6.2 can restore deduplicated, compressed data.

Client-side data deduplication uses the following process:

- The client creates extents. *Extents* are parts of files that are compared with other file extents to identify duplicates.
- The client and server work together to identify duplicate extents. The client sends non-duplicate extents to the server.

- Subsequent client data-deduplication operations create new extents. Some or all of those extents might match the extents that were created in previous data-deduplication operations and sent to the server. Matching extents are not sent to the server again.

Benefits

Client-side data deduplication provides several advantages:

- It can reduce the amount of data that is sent over the local area network (LAN).
- The processing power that is required to identify duplicate data is offloaded from the server to client nodes. Server-side data deduplication is always enabled for deduplication-enabled storage pools. However, files that are in the deduplication-enabled storage pools and that were deduplicated by the client, do not require additional processing.
- The processing power that is required to remove duplicate data on the server is eliminated, allowing space savings on the server to occur immediately.

Client-side data deduplication has a possible disadvantage. The server does not have whole copies of client files *until* you back up the primary storage pools that contain client extents to a non-deduplicated copy storage pool. (*Extents* are parts of a file that are created during the data-deduplication process.) During storage pool backup to a non-deduplicated storage pool, client extents are reassembled into contiguous files.

By default, primary sequential-access storage pools that are set up for data deduplication must be backed up to non-deduplicated copy storage pools before they can be reclaimed and before duplicate data can be removed. The default ensures that the server always has copies of whole files, in either a primary storage pool or a copy storage pool.

Important: For further data reduction, you can enable client-side data deduplication and compression together. Each extent is compressed before it is sent to the server. Compression saves space, but it increases the processing time on the client workstation.

The following options pertain to data deduplication:

- Deduplication
- Dedupcachepath
- Dedupcachesize
- Enablededupcache
- Exclude.dedup
- Include.dedup

API client-side data deduplication

Client-side data deduplication is used by the API on the backup-archive client, to remove redundant data during backup and archive processing before the data is transferred to the IBM Storage Protect server.

Client-side data deduplication is used by the API, to remove redundant data during backup and archive processing before the data is transferred to the IBM Storage Protect server. Using client-side data deduplication can reduce the amount of data that is sent over a local area network. Using client-side data deduplication can also reduce the IBM Storage Protect server storage space.

When the client is enabled for client-side data deduplication, and you perform a backup or archive operation, the data is sent to the server as extents. The next time a backup or archive operation is performed, the client and server identify which data extents have already been backed up or archived, and send only the unique extents of data to the server.

For client-side data deduplication, the server and API must be at version 6.2 or later.

Before you use client-side data deduplication to back up or archive your files, the system must meet the following requirements:

- The client must have the `deduplication` option enabled.

- The server must enable the client for client-side data deduplication with the **DEDUP=CLIENTORSERVER** parameter on either the **REGISTER NODE** or **UPDATE NODE** command.
- The storage pool destination for the data must be a data deduplication-enabled storage pool. The data deduplication-enabled storage pool is file device type only.
- Ensure that the files are bound to the correct management class.
- A file can be excluded from client-side data deduplication processing. By default, all files are included.
- Files must be larger than 2 KB.
- The server can limit the maximum transaction size for data deduplication by setting the CLIENTDEDUPTXNLIMIT option on the server. See the server documentation information about this option.

If any of these requirements are not met, data is processed normally, with no client-side data deduplication.

Here are some data deduplication restrictions:

- LAN-free data movement and client-side data deduplication are mutually exclusive. If you enable both LAN-free data movement and client-side data deduplication, LAN-free data movement operations complete and client-side data deduplication is ignored.
- Encryption and client-side data deduplication are mutually exclusive. If you enable both encryption and client-side data deduplication, encryption operations complete and client-side data deduplication is ignored. Encrypted files, and files that are eligible for client-side data deduplication, can be processed in the same operation, but are done in separate transactions.

  Requirements:

  1. In any transaction, all files must be either included for data deduplication or excluded. If the transaction has mixed files, the transaction fails, and a return code of DSM_RC_NEEDTO_ENDTXN is returned by the API.

  2. Use storage device encryption together with client-side data deduplication. Because SSL is used in combination with client-side deduplication, there is no need for client encryption.

- The following functions are not available for client-side data deduplication:

  – IBM Storage Protect for Space Management (HSM) client

  – API shared buffer

  – NAS

  – Subfile backup

- Buffer copy elimination cannot be used with data transformations like compression, encryption, and data deduplication.
- If you use client-side deduplication, the API detects and fails (with RC=254) backups of file extents that are marked as expired on the server during sending data to the server. If you want to retry the operation, you need to include that programming in the calling application.
- Simultaneous-write operations on the server takes precedence over client-side data deduplication. If simultaneous-write operations are enabled, client-side data deduplication does not occur.

  Restriction: When client side data deduplication is enabled, the API cannot recover from a state where the server has run out of storage on the destination pool, even if there is a next pool defined. A stop reason code of DSM_RS_ABORT_DESTINATION_POOL_CHANGED is returned and the operation fails. There are two ways to recover from this situation:

  1. Ask the administrator to add more scratch volumes to the original filepool.

  2. Retry the operation with data deduplication disabled.

For even greater bandwidth savings, you can enable a local cache for data deduplication. The local cache saves queries from going to the IBM Storage Protect server. The default value for ENABLEDEDUPCACHE is NO, so that the cache is not out of sync with the server. If the cache is out of sync with the server, the

application resends all data. If your application can retry on a failed transaction, and you want to use the local cache, set the ENABLEDEDUPCACHE option to YES in the dsm.opt (Windows) or dsm.sys (UNIX) file.

At the end of a restore, if *all* of the data was restored through the API, and the object was deduplicated by the client, an end-to-end digest is calculated and compared to the value calculated at backup time. If those values do not match, error DSM_RC_DIGEST_VALIDATION_ERROR is returned. If an application receives this error, the data is corrupt. This error can also be a result of a transient error on the network, so try the restore or retrieve again.

Here is an example of the query session command showing data deduplication information:

```
dsmQuerySessInfo Values:
Server Information:
Server name: SERVER1
Server Host: AVI
Server port: 1500
Server date: 2009/10/6 20:48:51
Server type: Windows
Server version: 6.2.0.0
Server Archive Retention Protection : NO
Client Information:
Client node type: API Test1
Client filespace delimiter: :
Client hl & ll delimiter: \
Client compression: Client determined (3u)
Client archive delete: Client can delete archived objects
Client backup delete: Client CANNOT delete backup objects
Maximum objects in multiple object transactions: 4096
Lan free Enabled: NO
Deduplication : Client Or Server
General session info:
Node: AVI
Owner:
API Config file:
```

Here is an example of the query management class command showing data deduplication information:

```
Policy Information:
Domain name: DEDUP
Policyset name: DEDUP
Policy activation date: 0/0/0 0:0:0
Default management class: DEDUP
Backup retention grace period: 30 days
Archive retention grace period: 365 days
Mgmt. Class 1:
Name: DEDUP
Description: dedup - values like standard
Backup CG Name: STANDARD
Frequency: 0
Ver. Data Exists: 2
Ver. Data Deleted: 1
Retain Extra Ver: 30
Retain Only Ver: 60
Copy Destination: AVIFILEPOOL
Lan free Destination: NO
Deduplicate Data: YES

Archive CG Name: STANDARD
Frequency: 10000
Retain versions: 365
Copy Destination: AVIFILEPOOL
Lan free Destination: NO
Retain Init : CREATE
Retain Minimum : 65534
Deduplicate Data: YES
```

Related information
Deduplication option

Exclude files from data deduplication

You can choose to exclude backup or archive files from data deduplication.

To exclude files from data deduplication processing, follow these steps:

1. Set the `exclude.dedup` option for the objects to exclude.

   For example, to exclude all dedup data for UNIX systems, set:

   ```
   exclude.dedup /.../*
   ```

2. To exclude all dedup data for Windows systems, set:

   ```
   exclude.dedup *\...\*
   ```

Important: If an object is sent to a data deduplication pool, data deduplication occurs on the server, even if the object is excluded from client-side data deduplication.

Include files for data deduplication

You can choose to include backup or archive files for data deduplication.

To refine the list of files to be included, the `include.dedup` option can be used in combination with the `exclude.dedup` option.

By default, all eligible objects are included for data deduplication.

Here are some UNIX and Linux examples:

```
exclude.dedup /FS1/.../*

include.dedup /FS1/archive/*
```

Here are some Windows examples:

```
exclude.dedup E:\myfiles\...\*

include.dedup E:\myfiles\archive\*
```

Server-side data deduplication

Server-side data deduplication is data deduplication that is performed by the server.

The IBM Storage Protect administrator can specify the data deduplication location (client or server) to use with the **DEDUP** parameter on the **REGISTER NODE** or **UPDATE NODE** server command.

In a data deduplication-enabled storage pool (file pool), only one instance of a data extent is retained. Other instances of the same data extent are replaced with a pointer to the retained instance.

For more information about server-side data deduplication, see the IBM Storage Protect server documentation.

Application failover

When the IBM Storage Protect server becomes unavailable because of an outage, applications that use the API can automatically fail over to a failover server for data recovery.

The IBM Storage Protect server that the client and API connects to during normal production processes is called the *primary server*. When the primary server is set up for node replication, that server is also known as the *source replication server*. The client node data on the source replication server can be replicated to the *target replication server*. This server is also known as the *failover server*, and is the server that the client automatically fails over to when the primary server fails.

The client and API must be configured for automated client failover, and must connect to a version 7.1 (or later) server that replicates client node data. The configuration for the API is the same as the configuration for the backup-archive client.

During normal operations, connection information for the failover server is automatically sent to the client from the primary server during the logon process. The failover server information is automatically saved to the client options file.

Each time the client application logs on to the IBM Storage Protect server, it attempts to contact the primary server. If the primary server is unavailable, the application automatically fails over to the failover server by using the failover server information in the client options file. In failover mode, the application can query the failover server and restore or retrieve replicated data.

You must back up the application at least one time to the primary server. The API can fail over to the failover server to recover data only if the data from the client node was replicated from the primary server to the failover server.

Automated client failover configuration and use

Failover status information

The API provides status information that applications can use to determine the failover status and the status of replicated client data on the secondary server also known as the failover server.

The replication status indicates whether the most recent backup was replicated to the failover server. If the time stamp of the most recent backup operation on the API matches the time stamp of the backup on the failover server, the replication status is current. If the two time stamps do not match, the replication status is not current and the replicated data might be out-of-date.

The following replication status information is returned on the **query filespace** response on the **dsmGetNextQObj** function call in the **qryRespFSData** structure:

Table 14. Replication status information reported by the API		
Status information	**Type**	**Definition**
Start of last replication	**lastReplStartDate**	The last time replication was started.
End of last replication	**lastReplCmpltDate**	The last time replication was completed, even if there was a failure.
Last backup store date (Server)	**lastBackOpDateFromServer**	The last store time stamp that was saved on the server.
Last backup store date (Local)	**lastBackOpDateFromLocal**	The last store time stamp that was saved on the client.

The failover status is reported by the **bIsFailOverMode** field in the **dsmInitExOut_t** structure.

See Appendix B, "API type definitions source files," on page 147 for the structure and type definitions of the API.

The DSM_RC_SIGNON_FAILOVER_MODE return code indicates that the client and API failed over to the failover server, and is running in failover mode.

Example of signon during a failover

The following sample output is an example of signing on the server during a failover:

```
signon
Doing signon for node khoyt, owner , with password khoytpass
ANS2106I Connection to primary IBM Storage Protect server 123.45.6.78 failed

ANS2107I Attempting to connect to failover server TARGET at 123.45.6.79 : 1501

ANS2108I Connected to failover server TARGET.
Handle on return = 1

**************************************************************
After dsmInitEx:
Server TARGET ver/rel/lev 7/1/0/0

The **dsmGetNextQObj** function call gets the next query response from a previous **dsmBeginQuery** call and places the response in the caller buffer.

Example flow diagrams for backup and archive

The API is designed for straightforward logic flows and clear transitions between the various states of the application client. This clean state transition catches logic flaws and program errors early in the development cycle, greatly enhancing the quality and reliability of the system.

For example, you cannot make a **dsmSendObj** call unless a transaction was started and a **dsmBindMC** call was previously made for the object that you are backing up.

displays the state diagram for performing backup or archive operations within a transaction. The arrow pointing from "In Send Object" to **dsmEndTxn** indicates that a **dsmEndTxn** call can be started after a call to **dsmSendObj** or **dsmSendData**. You might want to do this if an error condition occurred during the send of an object and you want to stop the entire operation. In this case, you must use a vote of DSM_VOTE_ABORT. In normal circumstances, however, call **dsmEndSendObj** before you end the transaction.

Figure 12. State diagram for backup and archive operations

displays the flowchart for performing backup or archive operations within a transaction.
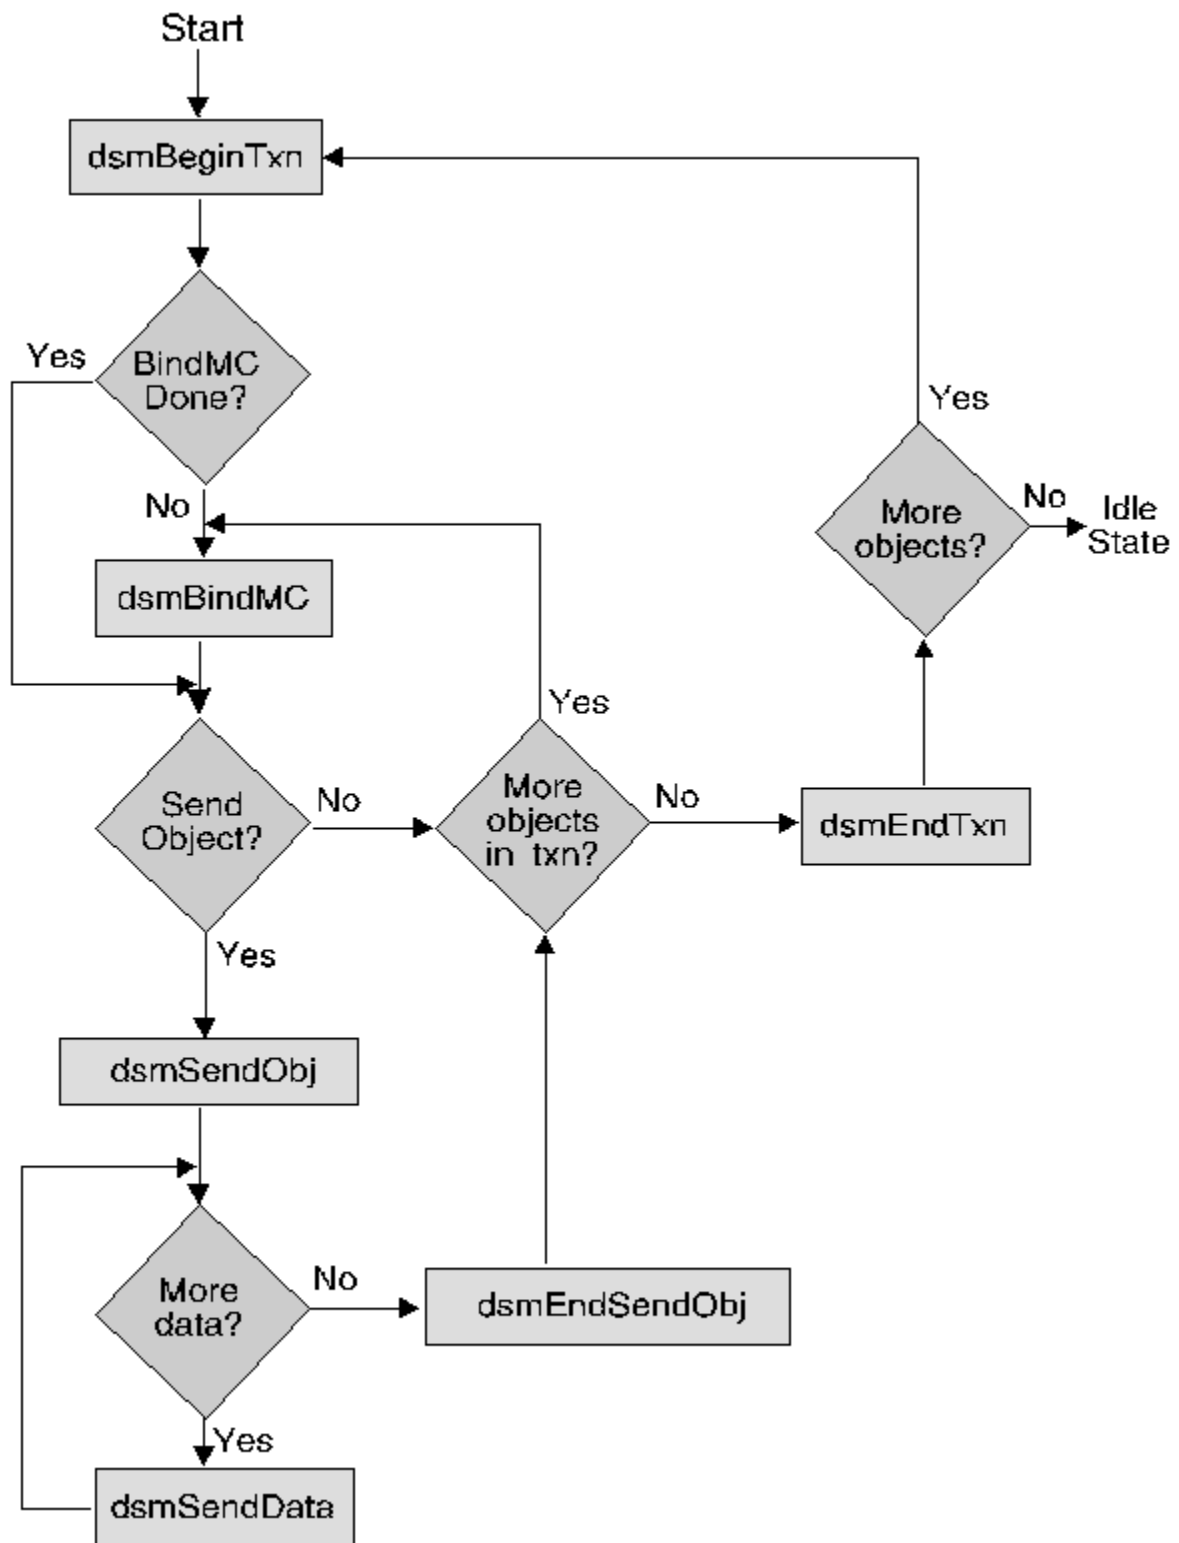

Figure 13. Flowchart for backup and archive operations

The primary feature in these two diagrams is the loop between the following API calls from within a transaction:

- **dsmBindMC**
- **dsmSendObj**

- **dsmSendData**
- **dsmEndSendObj**

The **dsmBindMC** call is unique in that you can start it from inside or outside of a transaction boundary. You can also start it from a different transaction, if required. The only requirement for the **dsmBindMC** call is that it is made prior to backing up or archiving an object. If the object that you are backing up or archiving is not associated with a management class, an error code is returned from **dsmSendObj**. In this situation, the transaction is ended by calling **dsmEndTxn** (this error condition is not shown in the flowchart).

The flowchart illustrates how an application would use multiple object transactions. It shows where decision points can be placed to determine if the object that is sent fits within the transaction or whether to start a new transaction.

Code example of API functions that send data to IBM Storage Protect storage

This example demonstrates the use of the API functions that send data to IBM Storage Protect storage. The **dsmSendObj** call appears inside a switch statement, so that different parameters can be called depending on whether a backup or archive operation is being performed.

The **dsmSendData** call is called from inside a loop that repeatedly sends data until a flag is set that permits the program execution to exit the loop. The entire send operation is performed from within the transaction.

The third parameter on the **dsmSendObj** call is a buffer that contains the archive description. Because backup objects do not have a description, this parameter is NULL when backing up an object.

Figure 8 on page 26 displays an example that shows the use of the **dsmBindMC** function call.

```
if ((rc = dsmBeginTxn(dsmHandle)) )        /* API session handle  */
{
   printf("*** dsmBeginTxn failed: ");
   rcApiOut(dsmHandle, rc);
   return;
}

/*  Call dsmBindMC if not done previously */
objAttr.sizeEstimate.hi = 0;        /* estimate of          */
objAttr.sizeEstimate.lo = 32000;   /*        object size */
switch (send_type)
{
   case (Backup_Send) :
       rc = dsmSendObj(dsmHandle,stBackup,
       NULL,&objName,&objAttr,NULL);
       break;
   case (Archive_Send) :
       archData.stVersion = sndArchiveDataVersion;
       archData.descr = desc;
       rc = dsmSendObj(dsmHandle,stArchive,
   &archData,&objName,&objAttr,NULL);
       break;
   default : ;
}
if (rc)
{
   printf("*** dsmSendObj failed: ");
   rcApiOut(dsmHandle, rc);
   return;
}
done = bFalse;
while (!done)
{
   dataBlk.stVersion = DataBlkVersion;
   dataBlk.bufferLen = send_amt;
   dataBlk.numBytes  = 0;
   dataBlk.bufferPtr = bkup_buff;
   rc = dsmSendData(dsmHandle,&dataBlk);
   if (rc)
   {
      printf("*** dsmSendData failed: ");
      rcApiOut(dsmHandle, rc);
      done = bTrue;
   }
   /* Adjust the dataBlk buffer for the next piece to send */
}
rc = dsmEndSendObj(dsmHandle);
if (rc)
{
   printf("*** dsmEndSendObj failed: ");
   rcApiOut(dsmHandle, rc);
}
txn_reason = 0;
rc = dsmEndTxn(dsmHandle,              /* API session handle     */
            DSM_VOTE_COMMIT,       /* Commit transaction     */
            &txn_reason);          /* Reason if txn aborted   */
if (rc || txn_reason)
{
   printf("*** dsmEndTxn failed: rc = ");
   rcApiOut(dsmHandle, rc);
   printf("   reason =
}
```

Figure 14. An example of sending data to a server

File grouping

The IBM Storage Protect API has a logical file grouping protocol that relates several individual objects together. You can reference and manage these groups as a logical group on the server. A logical group requires that all group members and the group leader belong to the same node and file space on the server.

Each logical group has a group leader. If the group leader is deleted, the group is deleted. You cannot delete a member that is part of a group. Expiration of all members in a group is dependent on the group leader. For example, if a member is marked for expiration, the member does not expire unless the group

leader expires. However, if a member is not marked for expiration, and the group leader is expired, then all members are expired.

File groups contain backup data only, and cannot contain archive data. Archive objects can use the **Archive Description** field to facilitate a type of grouping if required by an application.

The **dsmGroupHandler** call groups the operations. The **dsmGroupHandler** function must be called from within a transaction. Most group error conditions are caught on either the **dsmEndTxn**l or **dsmEndTxnEx** calls.

The out structure in **dsmEndTxnEx** includes a new field, **groupLeaderObjId**. This field contains the object ID of the group leader if a group was opened in that transaction. You can create a group across more than one transaction. A group is not committed, or saved, on the server until a close is performed. The **dsmGroupHandler** is an interface that can accept five different operations. They include:

- DSM_GROUP_ACTION_OPEN
- DSM_GROUP_ACTION_CLOSE
- DSM_GROUP_ACTION_ADD
- DSM_GROUP_ACTION_ASSIGNTO
- DSM_GROUP_ACTION_REMOVE

lists the **dsmGroupHandler** function call actions:

Table 15. dsmGroupHanlder functions	
Action	**Description**
OPEN	The OPEN action creates a group. The next object that is sent becomes the group leader. The group leader cannot have content. All objects after the first object become members that are added to the group. To create a group, open a group and pass in a unique string to identify the group. This unique identifier allows several groups with the same name to be opened. After the group is opened, the next object that is sent is the group leader. All other objects that are sent are group members.

CLOSE	The CLOSE action commits and saves an open group. To close the group, pass in the object name and the unique string that is used in the open operation. The application must check for open groups and, if necessary, close or delete the groups. A group is not committed or saved until the group is closed. A CLOSE action fails in the following conditions:
	
	• The group that you are trying to close has the same name as an existing open group.
	• A management class incompatibility exists between the current closed group and the new group to be closed of the same name. In this case, complete the following steps:
	
	  1. Query the previous closed group.
	  2. If the management class of the existing closed group is different from the management class associated with the current open group, issue a **dsmUpdateObject** with type DSM_BACKUPD_MC. This command updates the existing group to the new management class.
	  3. Issue the CLOSE action.

ADD	The ADD action appends an object to a group. All objects that are sent after the ADD action are assigned to the group.

Table 15. dsmGroupHanlder functions (continued)	
Action	**Description**
ASSIGNTO	The ASSIGNTO action permits the client to assign objects that exist on the server to the declared peer group. This transaction sets up the PEER group relationship. The ASSIGNTO action is similar to the ADD action, with the following exceptions: • The ADD action applies to objects within an in-flight transaction. • The ASSIGNTO action applies to an object that is on the server.
REMOVE	The REMOVE action removes a member, or a list of members, from a group. A group leader cannot be removed from a group. A group member must be removed before the member can be deleted.

Use the following query types for group support:

• **qtBackupGroups**

• **qtOpenGroups**

The **qtBackupGroups** queries groups that are closed while **qtOpenGroups** queries groups that are open. The query buffer for the new types has fields for **groupLeaderObjId** and **objType**. The query performs differently depending on the values for these two fields. The following table includes some query possibilities:

Table 16. Examples of queries

groupLeaderObjId. hi	groupLeaderObjId.l o	objType	Result
0	0	NULL	Returns a list of all group leaders
grpLdrObjId.hi	grpLdrObjId.lo	0	Returns a list for all group members that are assigned to the specified group leader (**grpLdrObjId**).
grpLdrObjId.hi	grpLdrObjId.lo	objType	Returns a list by using **BackQryRespEnhanced3**, for each group member that is assigned to the specified group leader (**grpLdrObjId**), and matching the object type (**objType**).

The response structure (**qryRespBackupData**) from **dsmGetNextQObj** includes two fields for group support:

• **isGroupLeader**

• **isOpenGroup**

These fields are Boolean flags. The following example displays the creation of the group, adding members to the group, and closing the group to commit the group on the IBM Storage Protect server.

```
dsmBeginTxn
    dsmGroupHandler (PEER, OPEN, leader, uniqueId)
    dsmBeginSendObj
        dsmEndSendObj
dsmEndTxnEx (With objId of leader)
Loop for multiple txns
{
    dsmBeginTxn
        dsmGroupHandler (PEER, ADD, member, groupLeaderObjID)
        Loop for multiple objects
        {
            dsmBeginSendObj
            Loop for data
            {
                dsmSendData
            }
            dsmEndSendObj
        }
    dsmEndTxn
}
dmBeginTxn
    dsmGroupHandler(CLOSE)
dsmEndTxn
```

Figure 15. Example of pseudo-code that is used to create a group

For a code example, see the sample group program `dsmgrp.c` that is included in the API `sampsrc` directory.

Receiving data from a server

Application clients can receive data or named objects and their associated data from IBM Storage Protect storage by using the restore and retrieve functions. The restore function accesses objects that previously were backed up, and the retrieve function accesses objects that previously were archived.

Restriction: The API can only restore or retrieve objects that were backed up or archived using API calls.

Both restore and retrieve functions start with a query operation. The query returns different information depending on whether the data was originally backed up or archived. For instance, a query on backup objects returns information on whether an object is active or inactive, while a query on archive objects returns information such as object descriptions. Both queries return object IDs that are used to uniquely identify the object on the server.

Partial object restore or retrieve

The application client can receive only a portion of the object. This is called a partial object restore or a partial object retrieve.

⚠️ **Attention:** Partial restore or retrieve of compressed or encrypted objects produces unpredictable results.

Note: If you code your application to use a partial object restore or retrieve, you cannot compress the data while sending it. To enforce this, set *ObjAttr.objCompressed* to *bTrue*.

To perform a partial object restore or retrieve, associate the following two data fields with each object **GetList** entry:

offset
    The byte offset into the object from which to begin returning data.

length
    The number of object bytes to return.

Use DSM_MAX_PARTIAL_GET_OBJ to determine the maximum number of objects that can perform a partial object restore or retrieve for a specific **dsmBeginGetData** list.

The following data fields, used on the **dsmBeginGetData** call, determine what portion of the object is restored or retrieved:

- If both the offset and length are zero, the entire object is restored or retrieved from IBM Storage Protect storage.
- If the offset is greater than zero, but the length is zero, the object is restored or retrieved from the offset to the end.
- If the length is greater than zero, only the portion of the object from the offset for the specified length is restored or retrieved.

Restoring or retrieving data

After a query is made and a session is established with the IBM Storage Protect server, you can run a procedure to restore or retrieve data.

Procedure

To restore or retrieve data, complete the following steps:

1. Query the IBM Storage Protect server for either backup or archive data.
2. Determine the objects to restore or retrieve from the server.
3. Sort the objects on the **Restore Order** field.
4. Send the **dsmBeginGetData** call with the list of objects that you want to access.
5. Send the **dsmGetObj** call to obtain each object from the system. Multiple **dsmGetData** calls might be needed for each object to obtain all associated object data. Send the **dsmEndGetObj** call after all data for an object is obtained.
6. Send the **dsmEndGetData** call after all data for all objects is received, or to end the receive operation.

Querying the server

Before you begin any restore or retrieve operation, first query the IBM Storage Protect server to determine what objects you can receive from storage.

To send the query, the application must enter the parameter lists and structures for the **dsmBeginQuery** call. The structure must include the file space that the query examines and pattern-match entries for the high-level and low-level name fields. If the session was initialized with a NULL owner name, you do not need to specify the owner field. However, if the session was initialized with an explicit owner name, only objects that are associated with that owner name are returned.

The point-in-time **BackupQuery** query provides a snapshot of the system at a specific time. By specifying a valid date, you can query all files that are backed up to that time. Even if an object has an active backup from a later date, point-in-time overrides an object state so that the previous inactive copy is returned. For more information, see the following example: pitDate.

A query returns all information that is stored with the object, in addition to the information in the following table.

Table 17. Query to the server return information

Field	Description
copyId	The copyIdHi and copyIdLo values provide an 8-byte number that uniquely identifies this object for this node in IBM Storage Protect storage. Use this ID to request a specific object from storage for restore or retrieve processing.
restoreOrderExt	The restoreOrderExt value provides a mechanism for receiving objects from IBM Storage Protect storage in the most efficient manner possible. Sort the objects to restore on this value to ensure that tapes are mounted only one time and are read from front to back.

You must keep some or all of the query information for later processing. Keep the `copyId` and `restoreOrderExt` fields because they are needed for the actual restore operation. You must also keep any other information needed to open a data file or identify a destination.

Call **dsmEndQuery** to finish the query operation.

Selecting and sorting objects by restore order

After the backup or archive query is performed, the application client must determine which objects, if any, are to be restored or retrieved.

Then you sort the objects in ascending order (low to high). This sorting is very important to the performance of the restore operation. Sorting the objects on the **restoreOrderExt** fields ensures that the data is read from the server in the most efficient order.

All data on disk is restored first, followed by data on media classes that require volume mounts (such as tape). The **restoreOrderExt** field also ensures that data on tape is read in order with processing starting at the front of a tape and progressing towards the end.

Properly sorting on the **restoreOrderExt** field means that duplicate tape mounts and unnecessary tape rewinds do not occur.

A non-zero value in the **restoreOrderExt**.top field correlates to a unique serial access device on the IBM Storage Protect server. Since a serial access device can only be used by one session / mount point at a time, the application should ensure that if it uses multiple sessions there are not concurrent restores with the same **restoreOrderExt**.top value. Otherwise the first session are able to access the objects, but other sessions wait until the first session terminates and the device becomes available.

The following example shows how to sort objects by using **Restore Order** fields.

Figure 16. Sorting objects with the restore order fields

```
typedef struct {
dsStruct64_t     objId;
dsUint160_t      restoreOrderExt;

}  SortOrder;                  /* struct used for sorting */

        return(LESSTHAN);
     else if (a->restoreOrderExt.lo_lo > b->restoreOrderExt.lo_lo)
        return(GREATERTHAN);
     else if (a->restoreOrderExt.lo_lo < b->restoreOrderExt.lo_lo)
        return(LESSTHAN);
     else
        return(EQUAL);
 }
```

Starting the dsmBeginGetData call

After you select and sort the objects to receive, submit them to IBM Storage Protect for either a restore or retrieve operation. The **dsmBeginGetData** call begins a restore or retrieve operation. The objects are returned to the application client in the order you requested.

Complete the information for these two parameters in these calls:

mountWait
> This parameter tells the server whether the application client waits for offline media to be mounted in order to obtain data for an object, or whether that object should be skipped during processing of the restore or retrieve operation.

dsmGetObjListP
> This parameter is a data structure that contains the **objId** field which is a list of all object IDs that are restored or retrieved. Each **objId** is associated with a **partialObjData** structure that describes whether the entire **objId** or only a particular section of the object will be retrieved.
>
> Each **objId** is eight bytes in length, so a single restore or retrieve request can contain thousands of objects. The number of objects to request in a single call is limited to DSM_MAX_GET_OBJ or DSM_MAX_PARTIAL_GET_OBJ.

Receiving each object to restore or retrieve

After the **dsmBeginGetData** call is sent, you can perform a procedure to receive each object that is sent from the server.

About this task

The DSM_RC_MORE_DATA return code means that a buffer was returned and that you should call **dsmGetData** again. Check the **DataBlk.numBytes** for the actual number of returned bytes.

When you obtain all data for an object, you must send a **dsmEndGetObj** call. If more objects will be received, send **dsmGetObj** again.

If you want to stop the process, for example, to discard any remaining data in the restore stream for all objects that are not yet received, send the **dsmEndGetData** call. This call flushes the data from the server to the client. However, using this method might take time to complete. If you want to end a restore operation, use **dsmTerminate** to close the session.

Procedure

1. Send the **dsmGetObj** call to identify the object that you requested from the data stream and to obtain the first block of data that is associated with the object.
2. Send more **dsmGetData** calls, as necessary to obtain the remaining object data.

Example flow diagrams for restore and retrieve

A state diagram and a flowchart can be used to illustrate how to perform restore or retrieve operations.

The arrow pointing from "In Get Object" to **dsmEndGetData** indicates that you can send a **dsmEndGetData** call after a call to **dsmGetObj** or **dsmGetData**. You might need to do this if an error condition occurred while getting an object from IBM Storage Protect storage and you want to stop the operation. In normal circumstances, however, call **dsmEndGetObj** first.
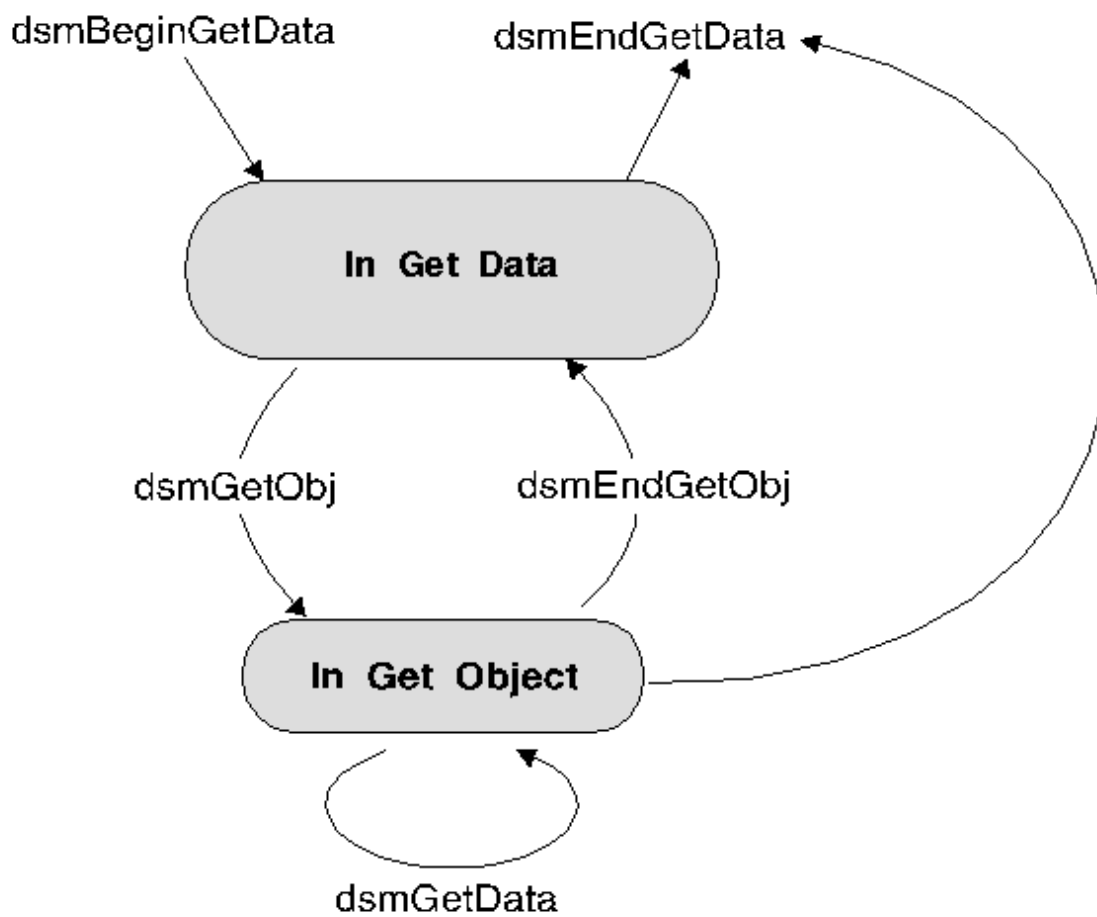

Figure 17. State diagram for restore and retrieve operations

Figure 18 on page 64 displays the flowchart for performing restore or retrieve operations.
Figure 18. Flowchart for restore and retrieve operations

Code example of receiving data from a server

This example demonstrates using the API functions to retrieve data from IBM Storage Protect storage.

The **dsmBeginGetData** function call appears inside a switch statement, so that different parameters can be called depending on whether a restore or retrieve operation is being performed. The **dsmGetData** function call is called from inside a loop that repeatedly gets data from the server until a flag is set that permits the program execution to exit the loop.

Figure 19. An example of receiving data from a server

```
/* Call dsmBeginQuery and create a linked list of objects to restore. */
/* Process this list to create the proper list for the GetData calls. */
/* Set up the getList structure to point to this list.                 */
/* This example is set up to perform a partial object retrieve.  To    */
/* retrieve only complete objects, set up:                             */
/*        getList.stVersion = dsmGetListVersion;                       */
/*        getList.partialObjData = NULL;                               */
dsmGetList getList;
getList.stVersion = dsmGetListPORVersion;   /* structure version     */
getList.numObjId  = items;                  /* number of items in list */
getList.objId     = (ObjID *)rest_ibuff;
                                  /* list of object IDs to restore  */
getList.partialObjData = (PartialObjData *) part_ibuff;
                                  /* list of partial object data    */
switch(get_type)
{
```

```
    case (Restore_Get) :
      rc = dsmBeginGetData(dsmHandle,bFalse,gtBackup,&getList);
      break;
    case (Retrieve_Get) :
      rc = dsmBeginGetData(dsmHandle,bFalse,gtArchive,&getList);
      break;
    default : ;
}
if (rc)
{
    printf("*** dsmBeginGetData failed: ");
    rcApiOut(dsmHandle, rc);
    return rc;
}
/* Get each object from the list and verify whether it is on the  */
/* server.  If so, initialize structures with object attributes for */
/* data validation checks.  When done, call dsmGetObj.            */
 rc = dsmGetObj(dsmHandle,objId,&dataBlk);
done = bFalse;
while(!done)
{
    if (   (rc == DSM_RC_MORE_DATA)
       || (rc == DSM_RC_FINISHED))
    {
        if (rc == DSM_RC_MORE_DATA)
        {
            dataBlk.numBytes = 0;
            rc = dsmGetData(dsmHandle,&dataBlk);
        }
        else
            done = bTrue;
    }
    else
    {
        printf("*** dsmGetObj or dsmGetData failed: ");
        rcApiOut(dsmHandle, rc);
        done = bTrue;
    }
} /* while */
rc = dsmEndGetObj(dsmHandle);
/* check rc from dsmEndGetObj */
/* check rc from dsmEndGetData */
rc = dsmEndGetData(dsmHandle);
return 0;
```

Updating and deleting objects on the server

Your API applications can use the **dsmUpdateObj** or **dsmUpdateObjEx** function call to update objects
that were archived or backed up. Use either call in the session state only, updating one object at a time.
Use **dsmUpdateObjEx** to update any of several archive objects containing the same name.

To select an archive object, set the **dsmSendType** function call to **stArchive**.

- With **dsmUpdateObj**, only the latest archive object with the assigned name is updated.
- With **dsmUpdateObjEx**, any archived object can be updated by specifying the proper object ID.

For an archived object, the application can update the following fields:

- Description
- Object information
- Owner

To select a backup object, set **dsmSendType** to **stBackup**. For backed-up objects, only the active copy is
updated.

For a backed-up object, the application can update the following fields:

- Management class
- Object information
- Owner

Deleting objects from the server

API applications can make calls to either delete objects that were archived or turn off objects that were backed up. Deleting archived objects is dependent on the node authorization that was given when the administrator registered the node. Administrators can specify that nodes can delete archived objects.

Use the **dsmDeleteObj** function call to delete archived objects and turn off backup objects. Using this **delType** removes the backup object from the server. This is based on **objID**, deletes an object from the server database. Only an owner of an object can delete it. You can delete any version (active or inactive) of an object. The server reconciles the versions. If you delete an active version of an object, the first inactive version becomes active. If you delete an inactive version of an object, all older versions advance. The node must be registered with **backDel** permission.

An archived object is marked for deletion in storage when the system performs its next object expiration cycle. Once you delete an archived object from the server, you cannot retrieve it.

When you inactivate a backup object at the server, the object moves from an active state to an inactive state. These states have different retention policies associated with them that are based on the management class that is assigned.

Similar to the **dsmSendObj** call, a call to **dsmDeleteObj** is sent within the boundary of a transaction. The state diagram in Figure 12 on page 52 displays how a call to **dsmDeleteObj** is preceded by a call to **dsmBeginTxn** and followed by a call to **dsmEndTxn**.

Logging events

An API application can log event messages to central locations. The application can direct logging to the IBM Storage Protect server, the local machine, or both. The **dsmLogEventEx** function call is performed in a session. To view messages logged on the server, use the query **actlog** command through the administrative client.

Use the IBM Storage Protect client option, `errorlogretention`, to prune the client error log file if the application writes numerous client messages to the client log dsmLogType, either `logLocal` or `logBoth`.

For more information about IBM Storage Protect logs, see the IBM Storage Protect server documentation.

State diagram summary for the IBM Storage Protect API

Once you review all the considerations for creating your own application with the IBM Storage Protect API, review this state diagram summary of an entire application.

Figure 20 on page 67 contains the state diagram for the API. It contains all previously displayed state diagrams in addition to several other calls previously not displayed.

The points in this diagram include:

- Call **dsmQueryApiVersionEx** at any time. It has no state associated with it. See Figure 1 on page 14 for an example.
- Call **dsmQueryCliOptions** before a **dsmInitEx** call only.
- Use **dsmRegisterFS**, **dsmUpdateFS**, and **dsmDeleteFS** to manage file spaces. These calls are made from within an idle session state. Use the **dsmBeginQuery** call to query file spaces. For more information about file space calls, see "Managing file spaces" on page 22.
- Send the **dsmBindMC** call from within an idle session state or from within a send object transaction state. See the example in Figure 8 on page 26.
- Send the **dsmChangePW** call from within an idle session state.

  Note: If the **dsmInitEx** call returns with a password-expired return code, the **dsmChangePW** call must be made before you start a valid session. See Figure 4 on page 18 for an example that uses **dsmChangePW**.

- If a call returns with an error, the state remains as it was. For example, if **dsmGetObj** returns with an error, the state remains In Get Data, and a call to **dsmEndGetObj** is a call sequence error.

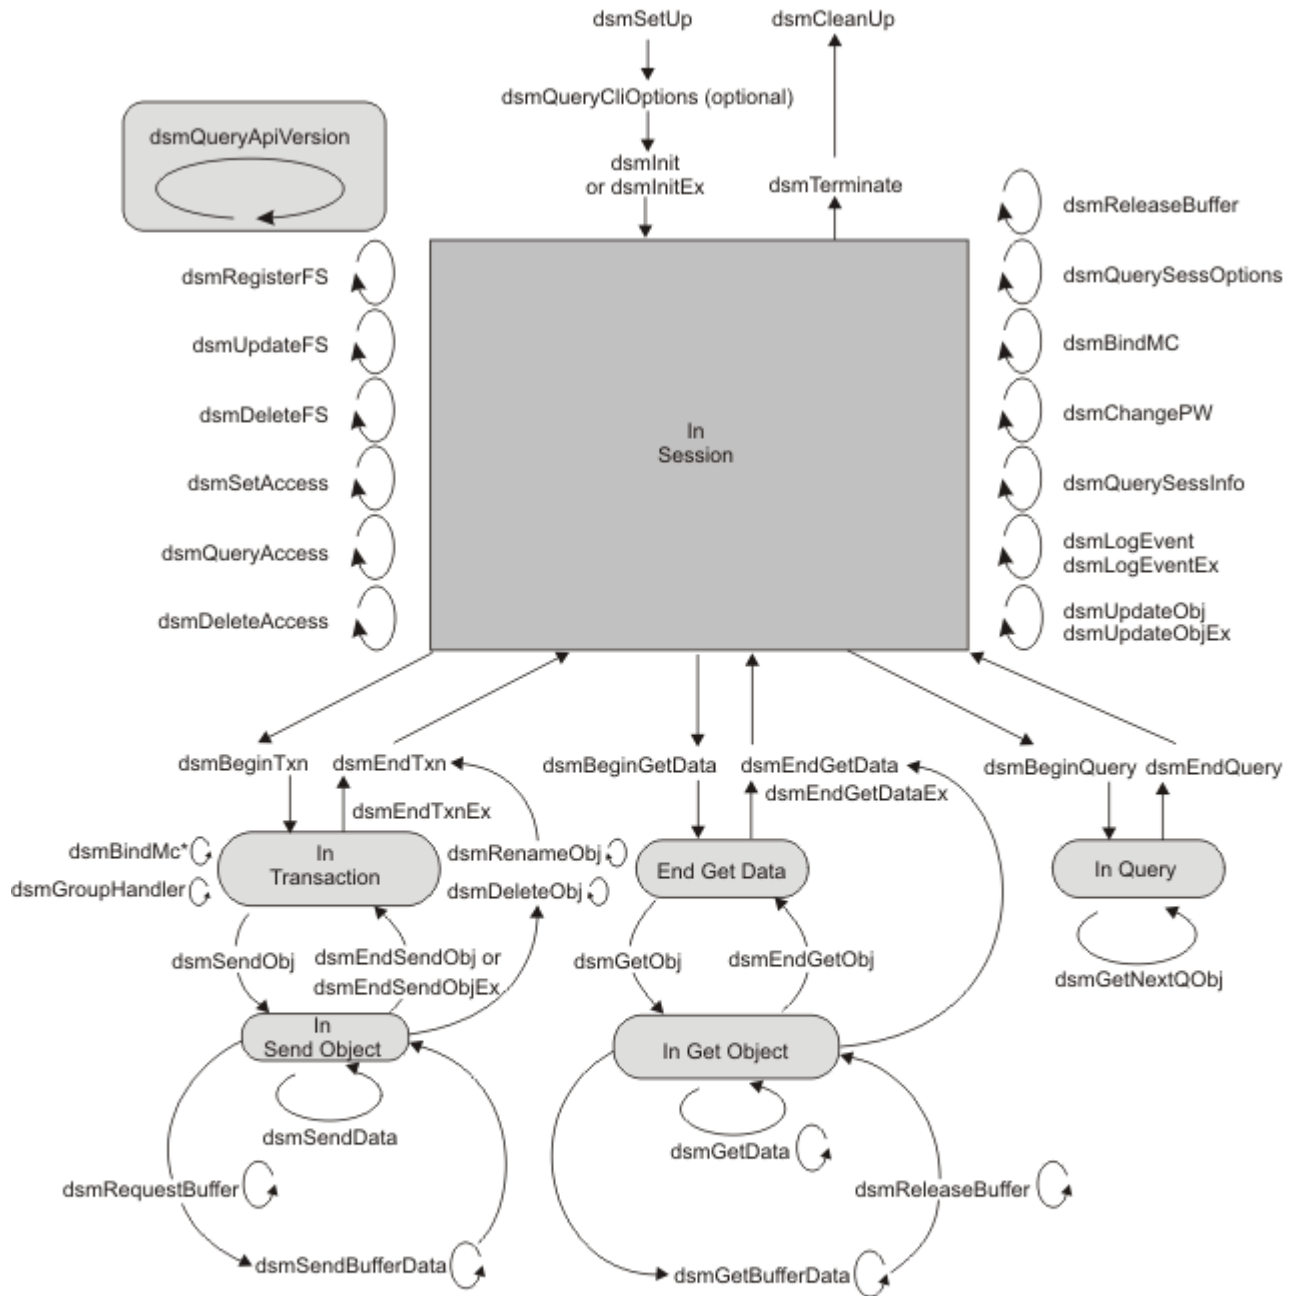

Figure 20. Summary state diagram for the API

Chapter 4. Understanding interoperability

The API has two types of interoperability: between the backup-archive client and API applications and between different operating systems.

Backup-archive client interoperability

The backup-archive command line can access API objects to provide limited interoperability. API objects can only be viewed and accessed from the backup-archive command line client and cannot be viewed or accessed from any of the graphical interfaces. The backup-archive command-line client can only restore content of the file and nothing else, so you should only use it for a salvage type of operation.

The following command-line actions are provided:

- Delete archive
- Delete filespace
- Query
- Restore
- Retrieve
- Set access

The path information is actual directories for backup-archive client objects. In contrast, the API object path information might not have any relationship to existing directories: the path might be completely contrived. Interoperability does not change this aspect of these object types. To use this feature successfully, follow the restrictions and conventions.

Notes:

1. There is no interoperability between the backup-archive client and API objects stored on a retention protection server.
2. You cannot use the backup-archive client GUIs to access files that were stored using the API client. You can only use the command line to access these files.

Naming your API objects

Establish a consistent naming convention for API object names. The naming convention must cater for the file space name, the high-level qualifier, and the low-level qualifier. The file space name and high-level qualifiers can refer to actual directory names. Each object name can consist of more than one directory name that applies to the low-level qualifier.

For convenience, use the name of the object that is not prefixed with directory information as the low-level qualifier. For more information, see "Object names and IDs" on page 20.

File space names must be fully qualified when they are referred to from either the API or the backup-archive command line. For example, on a UNIX or Linux operating system, you register the following file spaces:

- /a
- /a/b

When you refer to /a, objects that are related only to file space /a are displayed. To view objects that are related to /a/b, you must specify /a/b as the file space name.

After you register both file spaces, if you back up object b into file space /a, then a query for /a/b continues to display objects that are related only to file space /a/b.

The exception to this restriction occurs in file space references when you attempt to query or delete file spaces with the API. In both cases, the file space names do not have to be fully qualified if you use a wildcard character. For example, /a* refers to both /a and /a/b.

Tip: If interoperability is important for you, then avoid file space names that overlap.

On Windows systems, enclose file space names in braces { } for API objects when you access the objects from the backup-archive command line interface. Windows operating systems automatically place file space names in uppercase letters when you register or refer the names. However, this automatic function does not occur for the remainder of the object name specification. If you want full interoperability, place the high-level qualifier and the low-level qualifier in uppercase letters in the application when you back up API objects. If your application does not uppercase high-level qualifiers (directory names) and low-level qualifiers (file names) before it sends objects to the server, you will be unable to access the objects directly by name through the backup-archive client.

For example, if an object is stored on the server as {"FileSpacename"} \TEST\MYDIRNAME\file.txt, you cannot directly restore or query the file.txt object because your application did not uppercase the file name before the file was copied to the server.
The only way to manipulate these objects is to use wildcard characters. For example, to query \TEST\MYDIRNAME\file.txt, a backup-archive client user must use wildcard characters for all parts of the object name that were not uppercased before they were sent to the server. The following command must be used to query this file.txt file:

```
dsmc query backup {"FileSpaceName"}\TEST\MYDIRNAME\*
```

If any other of the other qualifiers are also saved in lowercase text, those qualifiers must also be queried by using wildcards. For example, to query an object that is stored as {"FileSpaceName"} \TEST\mydirname\file.txt, use the following command:

```
dsmc query backup {"FileSpaceName"}\TEST\*\*
```

The examples that follow demonstrate these concepts. In both Windows and UNIX or Linux environments, you do not have to specify either the complete high-level or low-level qualifier. However, if you do not specify the complete qualifier, then you must use the wildcard character.

Platform	Example
Windows	To query all backed-up files in file space MYFS, enter the following string: ```dsmc q ba "{MYFS}**"``` You must use at least one asterisk (*) for each of the high-level and low-level qualifiers.
UNIX or Linux	To query all backed-up files in file space /A, enter the following string: ```dsmc q ba "/A/*/*"``` You must use at least one asterisk (*) for each of the high-level and low-level qualifiers.

Backup-archive client commands you can use with the API

You can use a subset of backup-archive client commands within an application. For example, you can view and manage objects that other users own either on the same node or on a different node.

To view and manage objects that other users own either on the same node or on a different node, perform these steps:

1. Give access with the **set access** command.
2. Specify the owner and the node. Use the *fromowner* and *fromnode* options from the backup-archive command line to specify the owner and the node. For example:

   ```
   dsmc q ba "/A/*/*" -fromowner=other_owner -fromnode=other_node
   ```

Table 18 on page 71 describes the commands that you can use with API objects.

Table 18. Backup-archive client commands you can use with API objects

Command	Description
Delete Archive	Archived files that the current user owns can be deleted. The set access command settings have no effect on this command.
Delete Filespace	The **delete filespace** command affects API objects.
Query	From the backup-archive command line, you can query backed up and archived API objects and objects that other users own, or that exist on other nodes. See "Naming your API objects" on page 69 for information about querying API objects.
	Use the existing *–fromowner* option to query objects that a different user owns for which the set access permission has been given. Use the existing *–fromnode* option to query objects that exist on another node for which the set access permission has been given. For more information, see "dsmInitEx" on page 106.
Restore **Retrieve**	**Note:** Use these commands only for exception situations. API objects that are encrypted using the application managed key can be restored or retrieved if the encryption key is known or saved in the password file. API objects encrypted by using transparent encryption cannot be restored or retrieved by using the backup-archive client.
	These commands return data as bit files that are created by using default file attributes. You can restore or retrieve API objects that other users own, or that are from a different node. The set access command determines which objects qualify.
Set Access	The **set access** command permits users to manage API objects that another user owns, or that are from another node.

Examples

```
dsmc query backup f:\*\*
```

```
        Size         Backup Date          Mgmt Class       A/I File
        ----         -----------          ----------       --- ----
           1  B  11/14/2018 08:22:24         DEFAULT         A  \\viola\f$\dir1\test
 API       1  B  11/14/2018 08:21:41         DEFAULT         A  \\viola\f$\dir1\test
```

```
dsmc query backup "/home/*/*"
```

```
        Size         Backup Date          Mgmt Class       A/I File
        ----         -----------          ----------       --- ----
           1  B  11/15/2018 08:22:24         DEFAULT         A  /home/user1/test
 API       1  B  11/15/2018 08:21:41         DEFAULT         A  /home/user1/test
```

Operating system interoperability

The IBM Storage Protect API supports cross-platform interoperability. Applications on a UNIX or Linux system can operate on file spaces and objects that are backed up from a Windows system. Similarly, a Windows system can operate on file spaces and objects that are backed up from a UNIX or Linux system.

About this task

By default, the names of objects from one UNIX system are compatible with the names of objects from other UNIX systems. By default, names of objects from Windows systems are not compatible with names of objects from UNIX systems. Several parameters control the naming of objects in IBM Storage Protect file spaces. If you set up an application appropriately, the names of objects can be used by applications

that run on both Windows systems and UNIX systems. Use the same parameters to back up and restore objects.

Restriction: A Windows application that uses Unicode creates a file space that is not compatible with applications that run on UNIX systems.

Procedure

To achieve interoperability, complete the following setup tasks:

1. Establish a consistent naming convention. Select a character for the `dir` delimiter, such as forward slash (/) or backslash (\). Place the directory delimiter character in front of the file space name, the high-level qualifier, and the low-level qualifier.

2. When you call **dsmInitEx**, set the value of the **dirDelimiter** field to the directory delimiter character that you selected and set **bCrossPlatform** to **bTrue**.

3. Set the **useUnicode** flag to **bFalse** when you use the IBM Storage Protect interface. Unicode file names are not compatible with non-Unicode file names.

Backing up multiple nodes with client node proxy support

Backups of multiple nodes which share storage can be consolidated to a common target node name on the IBM Storage Protect server. This method is useful when the system that runs the backup can change over time, such as with a cluster. You can also use the `asnodename` option to restore data from a different system other than the one which ran the backup.

About this task

Use the `asnodename` option on the **dsmInitEx** option string to back up, archive, restore, and retrieve, query, or delete data under the target node name on the IBM Storage Protect server. You can also specify the `asnodename` option in the `dsm.opt` or `dsm.sys` file.

Restriction: Do not use target nodes as traditional nodes, especially if you encrypt your files before you back up to the server.

Procedure

To enable this option, complete the following steps:

1. Install the API client on all nodes in a shared data environment.

2. If not already registered, register each node with the IBM Storage Protect server. Register the common "target" node name to be shared by each of the agent nodes that are used in your shared data environment.

3. Register each of the agent nodes in the shared data environment with the server. The agent node name is used for authentication. Data is not stored by using the agent node name when the `asnodename` option is used.

4. Ask your administrator to grant proxy authority to all nodes in the shared environment to access the target node name on the IBM Storage Protect server, by using the **grant proxynode** command.

5. Use the **query proxynode** administrative client command to display the client nodes that have the authority to perform client operations on behalf of another node. This authority is granted by the **grant proxynode** command. Or use the **dsmQuery** command with the query type **qtProxyNodeAuth** to see the nodes to which this node can proxy.

6. If the application is using user encryption of data, not TSMENCRKEY, ensure that all nodes use the same encryption key. You must use the same encryption key for all files that are backed up in the shared node environment.

Backing up data with client-node proxy support (Windows systems)

Chapter 5. Using the API with Unicode

The IBM Storage Protect API supports Unicode UCS2, a fixed length, double-byte code page that has code points for all known code pages, such as Japanese, Chinese, or German. It supports as many as 65,535 unique code points.

Restriction: This feature is only available on Windows.

With Unicode, your application can back up and restore file names in any character set from the same machine. For example, on an English machine, you can back up and restore file names in any other language code page.

When to use Unicode

You can simplify your application that supports multiple languages by writing a Unicode application and by taking advantage of the IBM Storage Protect Unicode interface.

Use the IBM Storage Protect Unicode interface if any of the following conditions are true:

- If your application is already compiled for Unicode and it was converting to a multibyte character set (mbcs) before calling the IBM Storage Protect API.
- If you are writing a new application and want to enable your application to support Unicode.
- If your application uses a string passed to it from an operating system or other application that uses Unicode.

If you do not need Unicode, it is not necessary to compile your application again.

The API continues to support the dsm interface. The API SDK contains callmtu1.c and callmtu2.c sample programs that demonstrate how to use the Unicode API. Use **makemtu** to compile these programs.

Setting up Unicode

To set up and use Unicode you must perform a particular procedure so the API registers a Unicode file space on the server and all file names in that file space become Unicode strings.

Restriction: You cannot store Unicode and non-Unicode file names in the same file space.

1. Compile the code with the `-DUNICODE` flag.
2. All strings in your application must be wchar strings.
3. Follow the structures in the tsmapitd.h file, and the function definitions in the tsmapifp.h file for calls to the API.
4. Set the *useUnicode* flag to *bTrue* on the **tsmInitEx** function call. Any new file space is registered as a Unicode file space.

When you send data to previously registered, non-Unicode file spaces, the API continues to send file names as non-Unicode. Rename the old file spaces on the server to fsname_old and start a new Unicode file space for new data. The API restores non-Unicode data from the old file spaces. Use the **bIsUnicode** field in the **tsmQryRespFSData** structure that is returned on a query file space to determine whether or not a file space is Unicode.

Each **dsmXXX** function call has a matching **tsmXXX** function call. The difference between the two are the structures that are used. All **tsmXXX** function call structures have dsChar_t types for string values when they are compiled with the UNICODE flag. The dsChar_r maps to wchar. There is no other difference between these interfaces.

Restriction: Use either one interface or the other. Do not mix the **dsmXXX** function call and **tsmXXX** function call interfaces. Ensure that you use the IBM Storage Protect structures and IBM Storage Protect version definitions.

Some constants continue to be defined in the dsmapitd.h file, so you need both the dsmapitd.h and the tsmapitd.h files when you compile.

You can use the IBM Storage Protect interface on other operating systems, such as UNIX or Linux, but on these operating systems, the dsChar_t type maps to char because Unicode is supported on only Windows operating systems. You can write only one variation of the application and compile on more than one operating system using the IBM Storage Protect interface. If you are writing a new application, use the IBM Storage Protect interface.

If you are upgrading an existing application:

1. Convert the **dsmXXX** function call structures and calls to the IBM Storage Protect interface.
2. Migrate existing file spaces.
3. Back up new file spaces with the *useUnicode* flag set to *true*.

Note: After you use a Unicode-enabled client to access a node, you cannot connect to the same node name with an older version of the API or with an API from another operating system. If your application uses cross-platform capability, do not use the Unicode flag. There is no cross-platform support between Unicode and non-Unicode operating systems.

When you enable the *useUnicode* flag, all string structures are treated as Unicode strings. On the server, only the following fields are true Unicode:

• File space name
• High level
• Low level
• Archive description

All remaining fields convert to mbcs in the local code page before they are sent to the server. Fields, such as nodename, are wchar strings. They must be valid in the current locale. For example, on a Japanese machine, you can back up files with Chinese names, but the node name must be a valid string in Japanese. The option file remains in the current code page. If you need to create a Unicode include-exclude list, use the *inclexcl* option with a file name and create a Unicode file with Unicode patterns in it.

Related information
inclexcl option

Chapter 6. API function calls

provides an alphabetical list of the API function calls, a brief description and the location of more detailed information about the function call, which includes:

Element	Description
Purpose	Describes the function call.
Syntax	Contains the actual C code for the function call. This code is copied from the UNIX or Linux version of the dsmapifp.h header file. See Appendix C, "API function definitions source file," on page 183. This file differs slightly on other operating systems. Application programmers for other operating systems should check their version of the header file, dsmapifp.h, for the exact syntax of the API definitions.
Parameters	Describes each parameter in the function call, identifying it as either input (I) or output (O), depending on how it is used. Some parameters are designated as both input and output (I/O). The data types that are referenced in this section are defined in the dsmapitd.h header file. See Appendix B, "API type definitions source files," on page 147.
Return codes	Contains a list of the return codes that are specific to the function call. General system errors, such as communication errors, server problems, or user errors that might appear on any call are not listed. The return codes are defined in the dsmrc.h header file. See Appendix A, "API return codes source file: dsmrc.h," on page 137.

Table 19. API function calls

Function call and location	Description
"dsmBeginGetData" on page 79	Starts a restore or retrieve operation on a list of objects in storage.
"dsmBeginQuery" on page 80	Starts a query request to IBM Storage Protect for information.
"dsmBeginTxn" on page 85	Starts one or more transactions that begins a complete action. Either all of the actions succeed, or none succeed.
"dsmBindMC" on page 86	Associates, or binds, a management class to the object that is passed.
"dsmChangePW" on page 87	Changes an IBM Storage Protect password.
"dsmCleanUp" on page 88	This call is used if **dsmSetUp** was called.
"dsmDeleteAccess" on page 88	Deletes current authorization rules for backup versions or archived copies of your objects.
"dsmDeleteFS" on page 89	Deletes a file space from storage.
"dsmDeleteObj" on page 90	Turns off backup objects, or deletes archive objects in storage.
"dsmEndGetData" on page 91	Ends a **dsmBeginGetData** session that gets objects from storage.
"dsmEndGetDataEx" on page 91	Provides the total of LAN-free bytes that were sent.
"dsmEndGetObj" on page 92	Ends a **dsmGetObj** session that obtains data for a specified object.
"dsmEndQuery" on page 92	Signifies the end of a **dsmBeginQuery** action.
"dsmEndSendObj" on page 93	Indicates the end of data that is sent to storage.

Table 19. API function calls (continued)

Function call and location	Description
"dsmEndSendObjEx" on page 93	Provides compression information and the number of bytes that were sent.
"dsmEndTxn" on page 94	Ends an IBM Storage Protect transaction.
"dsmEndTxnEx" on page 95	Provides group leader object ID information to use with the **dsmGroupHandlerfunction** call.
"dsmGetData" on page 97	Obtains a byte stream of data from IBM Storage Protect and place it in the caller's buffer.
"dsmGetBufferData" on page 97	Gets an IBM Storage Protect-allocated buffer of data from the IBM Storage Protect server.
"dsmGetNextQObj" on page 98	Gets the next query response from a previous **dsmBeginQuery** call and places it in the caller's buffer.
"dsmGetObj" on page 101	Obtains the requested object data from the data stream and places it in the caller's buffer.
"dsmGroupHandler" on page 102	Performs an action on a logical file group depending on the input that is given.
"dsmInit" on page 103	Starts an API session and connects the client to storage.
"dsmInitEx" on page 106	Starts an API session using the additional parameters that permit extended verification.
"dsmLogEvent" on page 110	Logs a user message to the server log file, to the local error log, or to both.
"dsmLogEventEx" on page 111	Logs a user message to the server log file, to the local error log, or to both.
"dsmQueryAccess" on page 112	Queries the server for all access authorization rules for either backup versions or archived copies of your objects.
"dsmQueryApiVersion" on page 113	Performs a query request for the API library version that the application client accesses.
"dsmQueryApiVersionEx" on page 113	Performs a query request for the API library version that the application client accesses.
"dsmQueryCliOptions" on page 114	Queries important option values in the user's option files.
"dsmQuerySessInfo" on page 114	Starts a query request to IBM Storage Protect for information that is related to the operation of the specified session in **dsmHandle**.
"dsmQuerySessOptions" on page 115	Queries important option values that are valid in the specified session in **dsmHandle**.
"dsmRCMsg" on page 116	Obtains the message text that is associated with an API return code.
"dsmRegisterFS" on page 117	Registers a new file space with the server.
"dsmReleaseBuffer" on page 118	Returns an IBM Storage Protect-allocated buffer.
"dsmRenameObj" on page 119	Renames the high-level or low-level object name.
"dsmRequestBuffer" on page 120	Obtains an IBM Storage Protect-allocated buffer for buffer copy elimination.

Table 19. API function calls (continued)

Function call and location	Description
"dsmRetentionEvent" on page 121	Sends a list of object IDs to the server with a retention event operation to be performed on these objects.
"dsmSendBufferData" on page 122	Sends data from an IBM Storage Protect-allocated buffer.
"dsmSendData" on page 123	Sends a byte stream of data to IBM Storage Protect via a buffer.
"dsmSendObj" on page 124	Starts a request to send a single object to storage.
"dsmSetAccess" on page 127	Gives other users, or nodes, access to backup versions or archived copies of your objects, access to all your objects, or access to a selective set.
"dsmSetUp" on page 129	Overwrites environment variable values.
"dsmTerminate" on page 130	Ends a session with the server and cleans up the IBM Storage Protect environment.
"dsmUpdateFS" on page 131	Updates a file space in storage.
"dsmUpdateObj" on page 132	Updates the objInfo information that is associated with an active backup object already on the server, or it updates archived objects.
"dsmUpdateObjEx" on page 133	Updates the objInfo information that is associated with a specific archive object even when there are multiple objects with same name, or it updates active backup objects.

Related information

API return codes

dsmBeginGetData

The **dsmBeginGetData** function call starts a restore or retrieve operation on a list of objects in storage. This list of objects is contained in the **dsmGetList** structure. The application creates this list with values from the query that preceded a call to **dsmBeginGetData**.

The caller first must use the restore order fields that are obtained from the object query to sort the list that is contained in this call. This ensures that the objects are restored from storage in the most efficient way possible without rewinding or remounting data tapes.

When getting whole objects, the maximum *dsmGetList.numObjID* is DSM_MAX_GET_OBJ. When getting partial objects, the maximum is DSM_MAX_PARTIAL_GET_OBJ.

Follow the call to **dsmBeginGetData** with one or more calls to **dsmGetObj** to obtain each object within the list. After each object is obtained, or additional data for the object is not needed, the **dsmEndGetObj** call is sent.

When all objects are obtained, or the **dsmEndGetObj** is canceled, the **dsmEndGetData** call is sent. You then can start the cycle again.

Syntax

```
dsInt16_t dsmBeginGetData (dsUint32_t        dsmHandle,
    dsBool_t     mountWait,
    dsmGetType   getType,
    dsmGetList   *dsmGetObjListP);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

dsBool_t mountWait (I)
A Boolean true or false value indicates whether or not the application client waits for offline media to be mounted if the data that is needed is currently offline. If mountWait is true, the application waits for the server to mount the required media. The application waits until the media is mounted or the request is canceled.

dsmGetType getType (I)
An enumerated type consisting of **gtBackup** and **gtArchive** that indicates what type of object to get.

dsmGetList *dsmGetObjListP (I)
The structure that contains information about the objects or partial objects to restore or retrieve. The structure points to a list of object IDs and, in the case of a partial object restore or retrieve, a list of associated offsets and lengths. If your application uses the partial object restore or retrieve function, set the **dsmGetList.stVersion** field to **dsmGetListPORVersion**. In a partial object restore or retrieve, you cannot compress data while sending it. To enforce this, set **ObjAttr.objCompressed** to *bTrue*.

See Figure 19 on page 64 and Appendix B, "API type definitions source files," on page 147 for more information on this structure.

See "Partial object restore or retrieve" on page 58 for more information on partial object restore or retrieve.

Return codes

The return code numbers are provided in parentheses ( ).

Table 20. Return codes for dsmBeginGetData

Return code	Explanation
DSM_RC_ABORT_INVALID_OFFSET (33)	The offset that was specified during a partial object retrieve is greater than the length of the object.
DSM_RC_ABORT_INVALID_LENGTH (34)	The length that was specified during a partial object retrieve is greater than the length of the object, or the offset in addition to the length extends past the end of the object.
DSM_RC_NO_MEMORY (102)	There is no RAM remaining to complete the request.
DSM_RC_NUMOBJ_EXCEED (2029)	The **dsmGetList.numObjId** is greater than DSM_MAX_GET_OBJ.
DSM_RC_OBJID_NOTFOUND (2063)	The object ID was not found. The object was not restored.
DSM_RC_WRONG_VERSION_PARM (2065)	The API version of the application client is different from the IBM Storage Protect library version.

dsmBeginQuery

The **dsmBeginQuery** function call starts a query request to the server for information about data, file spaces, and management classes.

Specifically, **dsmBeginQuery** can query:

- Archived data
- Backed-up data
- Active backed-up data

- File spaces
- Management classes

The query data that is returned from the call is obtained by one or more calls to **dsmGetNextQObj**. When the query is complete, the **dsmEndQuery** call is sent.

Syntax

```
dsInt16_t dsmBeginQuery  (dsUint32_t        dsmHandle,
    dsmQueryType  queryType,
    dsmQueryBuff  *queryBuffer);
```

Parameters

dsUint32_t dsmHandle (I)

The handle that associates this call with a previous **dsmInitEx** call.

dsmQueryType queryType (I)

Identifies the type of query to run. Assign one of the following options:

qtArchive

Queries archived objects.

qtBackup

Queries backed-up objects.

qtBackupActive

Queries active, backed-up objects only for the entire file space name that you pass. This query is called a "fast path" and is an efficient way to query active objects from storage.

Prerequisite: You must be logged on as a root user on a UNIX or Linux operating system.

qtFilespace

Queries registered file spaces.

qtMC

Queries defined management classes.

qtBackupGroups

Queries groups that are closed.

qtOpenGroups

Queries groups that are open.

qtProxyNodeAuth

Queries nodes to which this node can proxy.

qtProxyNodePeer

Queries peer nodes with the same target.

dsmQueryBuff *queryBuffer (I)

Identifies a pointer to a buffer that is mapped to a particular data structure. This structure is associated with the query type that you pass. These structures contain the selection criteria for each query type. Complete the fields in each structure to specify the scope of the query that you want to run. The stVersion field in each structure contains the structure version number.

The data structures and their related fields include the following items:

qryArchiveData

objName

The complete object name. You can use a wildcard character, such as an asterisk (*) or a question mark (?), in the high-level or low-level portion of the name. An asterisk matches zero or more characters, and a question mark matches one character. The objType field of objName can have one of the following values:

- DSM_OBJ_FILE
- DSM_OBJ_DIRECTORY
- DSM_OBJ_ANY_TYPE

For more information about high-level and low-level names, see the following topic: "High-level and low-level names" on page 21.

owner

The owner name of the object.

insDateLowerBound

The lower boundary for the insert date that the object was archived. Set the year component to DATE_MINUS_INFINITE for an unbounded lower boundary.

insDateUpperBound

The upper boundary for the insert date that the object was archived. Set the year component to DATE_PLUS_INFINITE for an unbounded upper boundary.

expDateLowerBound

The lower boundary for the expiration date. Set the year component to DATE_MINUS_INFINITE for an unbounded lower boundary.

expDateUpperBound

The upper boundary for the expiration date. To match a management class **RETVer** setting of NOLIMIT, set the year component to DATE_PLUS_INFINITE.

descr

The archive description. Enter an asterisk (*) to search all descriptions.

qryBackupData

objName

The complete object name. You can use a wildcard character, such as an asterisk (*) or a question mark (?), in the high-level or low-level portion of the name. An asterisk matches zero or more characters, and a question mark matches one character. The objType field of objName can have one of the following values:

- DSM_OBJ_FILE
- DSM_OBJ_DIRECTORY
- DSM_OBJ_ANY_TYPE

For more information about high-level and low-level names, see the following topic: "High-level and low-level names" on page 21.

owner

The owner name of the object.

objState

You can query for one of the following object states:

- DSM_ACTIVE

- DSM_INACTIVE
- DSM_ANY_MATCH

pitDate

The point-in-time value. A query with this field returns the most recent object that is backed up before this date and time. The `objState` can be active or inactive. Objects that are deleted before the `pitDate` are not returned. For example:

```
Mon - backup ABC(1), DEF, GHI
Tue - backup ABC(2), delete DEF
Thr - backup ABC(3)
```

On Friday, call the query with a point-in-time value of Wednesday at 12:00:00 a.m. The call returns the following information:

```
ABC(2) - an Inactive copy
GHI    - an Active copy
```

The call does not return DEF because that object as deleted prior to the point-in-time value.

qryABackupData

objName

The complete object name. You can use a wildcard character, such as an asterisk (*) or a question mark (?), in the high-level or low-level portion of the name. An asterisk matches zero or more characters, and a question mark matches one character. The `objType` field of `objName` can have one of the following values:

- DSM_OBJ_FILE
- DSM_OBJ_DIRECTORY
- DSM_OBJ_ANY_TYPE

For more information about high-level and low-level names, see the following topic: "High-level and low-level names" on page 21.

qryFSData

fsName

Enter the name of a specific file space in this field, or enter an asterisk (*) to retrieve information about all registered file spaces.

qryMCData

mcName

Enter the name of a specific management class, or enter an empty string (" ") to retrieve information about all management classes.

Note: You cannot use an asterisk (*).

mcDetail

Determines whether information on the backup and archive copy groups of the management class is returned. The following values are valid:

- bTrue
- bFalse

qryBackupGroup:

groupType

The group type is DSM_GROUPTYPE_PEER.

fsName

The file space name.

owner

The owner ID.

groupLeaderObjId

The group leader object ID.

objType
The object type.

qryProxyNodeAuth:

targetNodeName

The target node name.

peerNodeName

The peer node name.

hlAddress

The peer address of the high-level name.

llAddress

The peer address of the low-level name.

qryProxyNodePeer:

targetNodeName

The target node name.

peerNodeName

The peer node name.

hlAddress

The peer address of the high-level name.

llAddress

The peer address of the low-level name.

Return codes

The following table describes the return codes for the **dsmBeginQuery** function call.

Table 21. Return codes for dsmBeginQuery

Return code	Return code number	Explanation
DSM_RC_NO_MEMORY	102	There is not enough memory to complete the request.
DSM_RC_FILE_SPACE_NOT_FOUND	124	The specified file space was not found.
DSM_RC_NO_POLICY_BLK	2007	Server policy information was not available.
DSM_RC_INVALID_OBJTYPE	2010	Invalid object type.
DSM_RC_INVALID_OBJOWNER	2019	Invalid object owner name.
DSM_RC_INVALID_OBJSTATE	2024	Invalid object condition.

Table 21. Return codes for dsmBeginQuery (continued)

Return code	Return code number	Explanation
DSM_RC_WRONG_VERSION_PARM	2065	The API version of the application client is different from the IBM Storage Protect library version.

dsmBeginTxn

The **dsmBeginTxn** function call begins one or more IBM Storage Protect transactions that begin a complete action; either all the actions succeed or none succeed. An action can be either a single call or a series of calls. For example, a **dsmSendObj** call that is followed by a number of **dsmSendData** calls can be considered a single action. Similarly, a **dsmSendObj** call with a **dataBlkPtr** that indicates a data area containing the object to back up is also considered a single action.

Try to group more than one object together in a single transaction for data transfer operations. Grouping objects results in significant performance improvements in the IBM Storage Protect system. From both a client and a server perspective, a certain amount of overhead is incurred by starting and ending each transaction.

There are limits to what you can perform within a single transaction. These restrictions include:

- A maximum number of objects that you can send or delete in a single transaction. This limit is located in the data that **dsmQuerySessInfo** returns in the *ApiSessInfo.maxObjPerTxn* field. This corresponds to the *TxnGroupMax* server option.
- All objects that are sent to the server (either backup or archive) within a single transaction must have the same copy destination that is defined in the management class binding for the object. This value is located in the data that **dsmBindMC** returns in the **mcBindKey.backup_copy_dest** or **mcBindKey.archive_copy_dest** fields.

With the API, either the application client can monitor and control these restrictions, or the API can monitor these restrictions. If the API is monitoring restrictions, appropriate return codes from the API calls inform the application client when one or more restrictions are reached.

Always match a **dsmBeginTxn** call with a **dsmEndTxn** call to optimize the set of actions within a pair of **dsmBeginTxn** and **dsmEndTxn** calls.

Syntax

```
dsInt16_t dsmBeginTxn  (dsUint32_t dsmHandle);
```

Parameters

dsUint32_t dsmHandle (I)
    The handle that associates this call with a previous **dsmInitEx** call.

Return codes

The return code numbers are provided in parentheses ( ).

Table 22. Return codes for dsmBeginTxn

Return code	Explanation
DSM_RC_ABORT_NODE_NOT_AUTHORIZED (36)	FROMNODE or FROMOWNER is not allowed for TXN operations.

dsmBindMC

The **dsmBindMC** function call associates, or binds, a management class to the passed object. The object is passed through the include-exclude list that is pointed to in the options file. If a match is not found in the Include list for a specific management class, the default management class is assigned. The Exclude list can prevent objects from a backup but not from an archive.

The application client can use the parameters that are returned in the mcBindKey structure to determine if this object should be backed up or archived, or whether a new transaction must be started because of different copy destinations. See **dsmBeginTxn** for more information.

Call **dsmBindMC** before you call **dsmSendObj** because every object must have a management class associated with it. This call can be performed within a transaction or outside of a transaction. For example, within a multiple object transaction, if **dsmBindMC** indicates that the object has a different copy destination than the previous object, the transaction must be ended and a new transaction started. In this case, another **dsmBindMC** is not required because one has already been performed for this object.

Syntax

```
dsInt16_t dsmBindMC  (dsUint32_t        dsmHandle,
    dsmObjName  *objNameP,
    dsmSendType  sendType,
    mcBindKey   *mcBindKeyP);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

dsmObjName *objNameP (I)
A pointer to the structure that contains the file space name, high-level object name, low-level object name, and object type.

dsmSendType sendType (I)
Identifies whether this management class bind is performed for archive or backup sends. The possible values for this call include:

Name	Description
stBackup	A backup object
stArchive	An archive object
stBackupMountWait	A backup object
stArchiveMountWait	An archive object

For the **dsmBindMC** call, stBackup and stBackupMountWait are equivalent, and stArchive and stArchiveMountWait are equivalent.

mcBindKey *mcBindKeyP (O)
This is the address of an mcBindKey structure where the management class information is returned. The application client can use the information that is returned here to determine if this object fits within a multiple object transaction, or to perform a management class query on the management class that is bound to the object.

Return codes

The return code numbers are provided in parentheses ().

Table 23. Return codes for dsmBindMC

Return code	Explanation
DSM_RC_NO_MEMORY (102)	There is no RAM remaining to complete the request.
DSM_RC_INVALID_PARM (109)	One of the parameters that was passed has an invalid value.
DSM_RC_TL_NOBCG (184)	The management class for this file has no valid backup copy group.
DSM_RC_TL_EXCLUDED (185)	The backup object is excluded and cannot be sent.
DSM_RC_TL_NOACG (186)	The management class for this file has no valid archive copy group.
DSM_RC_INVALID_OBJTYPE (2010)	Invalid object type.
DSM_RC_INVALID_SENDTYPE (2022)	Invalid send type.
DSM_RC_WRONG_VERSION_PARM (2065)	Application client API version is different from the IBM Storage Protect library version.

Note: Ensure that a valid copy group exists for a management class, otherwise the **dsmBindMC** function can return DSM_RC_TL_NOBCG (184) or DSM_RC_TL_NOACG (186) error messages.

dsmChangePW

The **dsmChangePW** function call changes an IBM Storage Protect password. On a multiple-user operating system such as UNIX or Linux, only the root user or the authorized user can use this call.

On Windows operating systems, you can specify the password in the dsm.opt file. In this situation, **dsmChangePW** does not update the dsm.opt file. After the call to **dsmChangePW** is made, you must update the dsm.opt file separately.

This call must process successfully if **dsmInitEx** returns DSM_RC_VERIFIER_EXPIRED. The session ends if the **dsmChangePW** call fails in this situation.

If **dsmChangePW** is called for some other reason, the session remains open regardless of the return code.

Syntax

```
dsInt16_t dsmChangePW  (dsUint32_t   dsmHandle,
    char    *oldPW,
    char    *newPW);
```

Parameters

dsUint32_t dsmHandle (I)
    The handle that associates this call with a previous **dsmInitEx** call.

char *oldPW (I)
    The old password of the caller. The maximum length is DSM_MAX_VERIFIER_LENGTH.

char *newPW (I)
    The new password of the caller. The maximum length is DSM_MAX_VERIFIER_LENGTH.

Return codes

The return code numbers are provided in parentheses ( ).

Table 24. Return codes for dsmChangePW

Return code	Explanation
DSM_RC_ABORT_BAD_VERIFIER (6)	An incorrect password was entered.
DSM_RC_AUTH_FAILURE (137)	Authentication failure. Old password is incorrect.
DSM_RC_NEWPW_REQD (2030)	A value must be entered for the new password.
DSM_RC_OLDPW_REQD (2031)	A value must be entered for the old password.
DSM_RC_PASSWD_TOOLONG (2103)	The specified password is too long.
DSM_RC_NEED_ROOT (2300)	The API caller must be a root user or an authorized user.

dsmCleanUp

The **dsmCleanUp** function call is used if **dsmSetUp** was called. The **dsmCleanUp** function call should be called after **dsmTerminate**. You cannot make any other calls after you call **dsmCleanUp**.

There are no return codes that are specific to this call.

Syntax

```
dsInt16_t DSMLINKAGE dsmCleanUp
     (dsBool_t        mtFlag);
```

Parameters

dsBool_t mtFlag (I)
This parameter specifies that the API was used either in a single thread or a multithread mode. Possible values include:

- DSM_SINGLETHREAD
- DSM_MULTITHREAD

dsmDeleteAccess

The **dsmDeleteAccess** function call deletes current authorization rules for backup versions or archived copies of your objects. When you delete an authorization rule, you revoke the access a user has to any files that are specified by the rule.

When you use **dsmDeleteAccess**, you can only delete one rule at a time. Obtain the rule ID through the **dsmQueryAccess** command.

There are no return codes that are specific to this call.

Syntax

```
dsInt16_t DSMLINKAGE dsmDeleteAccess
            (dsUint32_t        dsmHandle,
             dsUint32_t        ruleNum) ;
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

dsUint32_t ruleNum (I)
The rule ID for the access rule that is deleted. This value is obtained from a **dsmQueryAccess** function call.

dsmDeleteFS

The **dsmDeleteFS** function call deletes a file space from storage. To delete a file space, you must have the appropriate permissions that your IBM Storage Protect administrator gave you. To determine whether you have the necessary permissions, call **dsmQuerySessInfo**. This function call returns a data structure of type *ApiSessInfo*, that includes two fields, *archDel* and *backDel*.

Note:

- On a UNIX or Linux operating system, only a root user or an authorized user can delete a file space.

- If the file space that you need to delete contains backup versions, you must have backup delete authority (***backDel*** = BACKDEL_YES). If the file space contains archive copies, you must have archive delete authority (*archDel* = ARCHDEL_YES). If the file space contains both backup versions and archive copies, you must have both types of delete authority.

- When using an archive manager server, a file space cannot actually be removed. This function call returns *rc=0* even though the file space was not actually deleted. The only way to verify that the file space has been deleted is to issue a filespace query to the server.

- The IBM Storage Protect server delete file-space function is a background process. If errors other than those detected before passing a return code happen, they are recorded in the IBM Storage Protect server log.

Syntax

```
dsInt16_t dsmDeleteFS  (dsUint32_t          dsmHandle,
    char           *fsName,
    unsigned char   repository);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

char *fsName (I)
A pointer to the file space name to delete. The wildcard character is not permitted.

unsigned char repository (I)
Indicates whether the file space to delete is a backup repository, archive repository, or both. The possible values for this field include:

```
DSM_ARCHIVE_REP      /* archive repository  */
DSM_BACKUP_REP       /* backup repository   */
DSM_REPOS_ALL        /* all repository types */
```

Return codes

The return code numbers are provided in parentheses ( ).

Table 25. Return codes for dsmDeleteFS

Return code	Explanation
DSM_RC_ABORT_NOT_AUTHORIZED (27)	You do not have the necessary authority to delete the file space.
DSM_RC_INVALID_REPOS (2015)	Invalid value for repository.

Table 25. Return codes for dsmDeleteFS (continued)

Return code	Explanation
DSM_RC_FSNAME_NOTFOUND (2060)	File space name not found.
DSM_RC_NEED_ROOT (2300)	API caller must be a root user.

dsmDeleteObj

The **dsmDeleteObj** function call inactivates backup objects, deletes backup objects, or it deletes archive objects in storage. The **dtBackup** type inactivates the currently active backup copy only. The **dtBackupID** type removes from the server whichever object ID is specified. Call this function from within a transaction.

See **dsmBeginTxn** for more information.

Restriction: You cannot delete backup objects that are contained in a retention set. To satisfy long-term data retention requirements, these files remain in server storage and expire according to the retention set's own expiration date after which they are eligible for deletion.

Before you send **dsmDeleteObj**, send the query sequence that is described in to obtain the information for **delInfo**. The call to **dsmGetNextQObj** returns a data structure named **qryRespBackupData** for backup queries or **qryRespArchiveData** for archive queries. These data structures contain the information that you need for **delInfo**.

The value of **maxObjPerTxn** determines the maximum number of objects that you can delete in a single transaction. To obtain this value, call **dsmQuerySessInfo**.

Tip: Your node must have the appropriate permission that your administrator set. To delete archive objects, you must have archive delete authority. You do not need backup delete authority to inactivate a backup object.

Syntax

```
dsInt16_t dsmDeleteObj  (dsUint32_t      dsmHandle,
    dsmDelType  delType,
    dsmDelInfo  delInfo)
```

Parameters

dsUint32_t dsmHandle (I)
    The handle that associates this call with a previous **dsmInitEx** call.

dsmDelType delType (I)
    Indicates what type of object (backup or archive) to delete. Possible values include:

Name	Description
dtArchive	The object to delete was previously archived.
dtBackup	The object to inactivate was previously backed up.
dtBackupID	The object to delete was previously backed up.

                              Restriction: Using this **delType** with *objID* removes the backup object from the server. Only an owner of an object can delete it.

                              You can delete any version (active or inactive) of an object. The server reconciles the versions. If you delete an active version of an object, the first inactive version becomes active. If you delete an inactive version of an object, all older versions will advance. The node must be registered with **backDel** permission.

dsmDelInfo delInfo (I)
A structure whose fields identify the object. The fields are different, depending on whether the object is a backup object or an archive object. The structure to inactivate a backup object, delBack, contains the object name and the object copy group. The structure for an archive object, delArch, contains the object ID.

The structure to remove a backup object, delBackID, contains the object ID.

Return codes

The return code numbers are provided in parentheses ( ).

Table 26. Return codes for dsmDeleteObj

Return code	Explanation
DSM_RC_FS_NOT_REGISTERED (2061)	File space name is not registered.
DSM_RC_WRONG_VERSION_PARM (2065)	Application client API version is different from the IBM Storage Protect library version.

dsmEndGetData

The **dsmEndGetData** function call ends a **dsmBeginGetData** session that obtains objects from storage.

The **dsmEndGetData** function call starts after all objects that you want to restore are processed, or ends the get process prematurely. Call **dsmEndGetData** to end a **dsmBeginGetData** session before you can continue other processing.

Depending on when **dsmEndGetData** is called, the API might need to finish processing a partial data stream before the process can be stopped. The caller, therefore, should not expect an immediate return from this call. Use **dsmTerminate** if the application needs to close the session and end the restore immediately.

There are no return codes that are specific to this call.

Syntax

```
dsInt16_t dsmEndGetData  (dsUint32_t dsmHandle);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

dsmEndGetDataEx

The **dsmEndGetDataEx** function call provides the total of LAN-free bytes that were sent. It is an extension of the **dsmEndGetData** function call.

Syntax

There are no return codes that are specific to this call.

```
dsInt16_t dsmEndGetDataEx (dsmEndGetDataExIn_t * dsmEndGetDataExInP,
                           dsmEndGetDataExOut_t * dsmEndGetDataExOutP);
```

Parameters

dsmEndGetDataExIn_t *dsmEndGetDataExInP (I)
Passes the end get object dsmHandle that identifies the session and associates it with subsequent calls.

dsmEndGetDataExOut_t *dsmEndGetDataExOutP (O)
This structure contains this input parameter:

totalLFBytesRecv
The total LAN-free bytes that are received.

dsmEndGetObj

The **dsmEndGetObj** function call ends a **dsmGetObj** session that obtains data for a specified object.

Start the **dsmEndGetObj** call after an end of data is received for the object. This indicates that all data was received, or that no more data will be received for this object. Before you can start another **dsmGetObj** call, you must call **dsmEndGetObj**.

Depending on when **dsmEndGetObj** is called, the API might need to finish processing a partial data stream before the process can stop. Do not expect an immediate return from this call.

Syntax

```
dsInt16_t dsmEndGetObj  (dsUint32_t dsmHandle);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

Return codes

The return code numbers are provided in parentheses ( ).

Table 27. Return codes for dsmEndGetObj

Return code	Explanation
DSM_RC_NO_MEMORY (102)	There is no RAM remaining to complete the request.

dsmEndQuery

The **dsmEndQuery** function call signifies the end of a **dsmBeginQuery** action. The application client sends **dsmEndQuery** to complete a query. This call either is sent after all query responses are obtained through **dsmGetNextQObj**, or it is sent to end a query before all data are returned.

Tip: IBM Storage Protect continues to send the query data from the server to the client in this case, but the API discards any remaining data.

Once a **dsmBeginQuery** is sent, a **dsmEndQuery** must be sent before any other activity can start.

There are no return codes that are specific to this call.

Syntax

```
dsInt16_t dsmEndQuery  (dsUint32_t dsmHandle);
```

Parameters

dsUint32_t dsmHandle (I)
    The handle that associates this call with a previous **dsmInitEx** call.

dsmEndSendObj

The **dsmEndSendObj** function call indicates the end of data that is sent to storage.

Enter the **dsmEndSendObj** function call to indicate the end of data from the **dsmSendObj** and **dsmSendData** calls. A protocol violation occurs if this is not performed.

Syntax

```
dsInt16_t dsmEndSendObj  (dsUint32_t dsmHandle);
```

Parameters

dsUint32_t dsmHandle (I)
    The handle that associates this call with a previous **dsmInitEx** call.

Return codes

The return code numbers are provided in parentheses ( ).

Table 28. Return codes for dsmEndSendObj

Return code	Explanation
DSM_RC_NO_MEMORY (102)	There is no RAM remaining to complete this request.

dsmEndSendObjEx

The **dsmEndSendObjEx** function call provides additional information regarding the number of bytes processed. The information includes: total bytes sent, compression information, lan-free bytes, and deduplication information.

The **dsmEndSendObjEx** function call is an extension of the **dsmEndSendObj** function call.

Syntax

```
dsInt16_t dsmEndSendObjEx (dsmEndSendObjExIn_t  *dsmEndSendObjExInP,
                           dsmEndSendObjExOut_t *dsmEndSendObjExOutP);
```

Parameters

dsmEndSendObjExIn_t *dsmEndSendObjExInP (I)
    This parameter passes the end send object dsmHandle that identifies the session and associates it with subsequent calls.

dsmEndSendObjExOut_t *dsmEndSendObjExOutP (O)
    This parameter passes the end send object information:

Name	Description
totalBytesSent	The total number of bytes that are read from the application.

Name	Description
objCompressed	A flag that displays if the object was compressed.
totalCompressedSize	The total byte size after compression.
totalLFBytesSent	The total LAN-free bytes that were sent.
objDeduplicated	A flag that displays if the object was deduplicated by the API.
totalDedupSize	Total bytes sent after deduplication.

Return codes

The return code numbers are provided in parentheses ( ).

Table 29. Return codes for dsmEndSendObjEx

Return code	Explanation
DSM_RC_NO_MEMORY (102)	There is no RAM remaining to complete this request.

dsmEndTxn

The **dsmEndTxn** function call ends an IBM Storage Protect transaction.

Pair the **dsmEndTxn** function call with **dsmBeginTxn** to identify the call or set of calls that are considered a transaction.

The application client can specify on the **dsmEndTxn** call whether the transaction must be committed or ended.

Perform all of the following calls within the bounds of a transaction:

- **dsmSendObj**
- **dsmSendData**
- **dsmEndSendObj**
- **dsmDeleteObj**

Syntax

```
dsInt16_t dsmEndTxn (dsUint32_t   dsmHandle,
    dsUint8_t    vote,
    dsUint16_t  *reason);
```

Parameters

dsUint32_t dsmHandle (I)
    The handle that associates this call with a previous **dsmInitEx** call.

dsUint8_t vote (I)
    Indicates whether the application client commits all the actions that are done between the previous **dsmBeginTxn** call and this call. The following values are possible:

```
    DSM_VOTE_COMMIT     /* commit current transaction    */
    DSM_VOTE_ABORT      /* roll back current transaction */
```

Use DSM_VOTE_ABORT only if your application finds a reason to stop the transaction.

dsUint16_t *reason (O)
> If the call to **dsmEndTxn** ends with an error, or the value of vote is not agreed to, this parameter has a reason code that indicates why the vote failed. The return code for the call might be zero, and the reason code might be non-zero. Therefore, the application client must always check for errors on both the return code and the reason (if (rc || reason)) before you can assume a successful completion.

> If the application specifies a vote of DSM_VOTE_ABORT, the reason code is DSM_RS_ABORT_BY_CLIENT (3). See Appendix A, "API return codes source file: dsmrc.h," on page 137 for a list of the possible reason codes. Numbers 1 through 50 in the return codes list are reserved for the reason codes. If the server ends the transaction, the return code is DSM_RC_CHECK_REASON_CODE. In this case, the reason value contains more information on the cause of the abort.

Return codes

The return code numbers are provided in parentheses ().

Table 30. Return codes for dsmEndTxn

Return code	Explanation
DSM_RC_ABORT_CRC_FAILED (236)	The CRC that was received from the server does not match the CRC that was calculated by the client.
DSM_RC_INVALID_VOTE (2011)	The value that was specified for vote is not valid.
DSM_RC_CHECK_REASON_CODE (2302)	The transaction was aborted. Check the reason field.
DSM_RC_ABORT_STGPOOL_COPY_CONT_NO (241)	The write to one of the copy storage pools failed, and the IBM Storage Protect storage pool option COPYCONTINUE is set to NO. The transaction terminates.
DSM_RC_ABORT_RETRY_SINGLE_TXN (242)	This abort code indicates that the current transaction was aborted because of a problem during a store operation. The problem can be resolved by sending each file in an individual transaction. This error is typical in the following circumstances: • The next storage pool has a different copy storage pool list. • The operation is switched to this pool in the middle of a transaction. .

dsmEndTxnEx

The **dsmEndTxnEx** function call provides group leader object ID information for you to use with the **dsmGroupHandler** function call. It is an extension of the **dsmEndTxn** function call.

Syntax

```
dsInt16_t dsmEndTxnEx (dsmEndTxnExIn_t *dsmEndTxnExInP
                       dsmEndTxnExOut_t *dsmEndTxnExOutP);
```

Parameters

dsmEndTxnExIn_t *dsmEndTxnExInP (I)
> This structure contains the following parameters:

dsmHandle
> The handle that identifies the session and associates it with subsequent IBM Storage Protect calls.

dsUint8_t vote (I)
> Indicates whether or not the application client commits all the actions that are done between the previous **dsmBeginTxn** call and this call. The possible values are:

```
DSM_VOTE_COMMIT     /* commit current transaction    */
DSM_VOTE_ABORT      /* roll back current transaction */
```

> Use DSM_VOTE_ABORT only if your application has found a reason to stop the transaction.

dsmEndTxnExOut_t *dsmEndTxnExOutP (O)
> This structure contains the following parameters:

dsUint16_t *reason (O)
> If the call to **dsmEndTxnEx** ends with an error or the value of *vote* is not agreed to, this parameter has a reason code indicating why the vote failed.
>
> **Tip:** The return code for the call might be zero, and the reason code might be non-zero. Therefore, the application client must always check for errors on both the return code and the reason (`if (rc || reason)`) before you can assume a successful completion.
>
> If the application specifies a vote of DSM_VOTE_ABORT, the reason code is DSM_RS_ABORT_BY_CLIENT (3). See Appendix A, "API return codes source file: dsmrc.h," on page 137 for a list of the possible reason codes. Numbers 1 through 50 in the return codes list are reserved for the reason codes. If the server ends the transaction, the return code is DSM_RC_CHECK_REASON_CODE. In this case, the reason value contains more information on the cause of the abort.

groupLeaderObjId
> The group leader object ID that is returned when the DSM_ACTION_OPEN flag is used with the **dsmGroupHandler** call.

Return codes

The return code numbers are provided in parentheses ( ).

Table 31. Return codes for dsmEndTxnEx

Return code	Explanation
DSM_RC_INVALID_VOTE (2011)	The value that was specified for vote is invalid.
DSM_RC_CHECK_REASON_CODE (2302)	The transaction was aborted. Check the reason field.
DSM_RC_ABORT_STGPOOL_COPY_CONT_NO (241)	The write to one of the copy storage pools failed, and the IBM Storage Protect storage pool option COPYCONTINUE was set to NO. The transaction terminates.
DSM_RC_ABORT_RETRY_SINGLE_TXN (242)	During a simultaneous-write operation, an object in the transaction is going to a destination with different copy storage pools. End the current transaction and send each object again in its own transaction.

dsmGetData

The **dsmGetData** function call obtains a byte stream of data from IBM Storage Protect and places it in the caller's buffer. The application client calls **dsmGetData** when there is more data to receive from a previous **dsmGetObj** or **dsmGetData** call.

Syntax

```
dsInt16_t dsmGetData  (dsUint32_t   dsmHandle,
    DataBlk *dataBlkPtr);
```

Parameters

dsUint32_t dsmHandle (I)
  The handle that associates this call with a previous **dsmInitEx** call.

DataBlk *dataBlkPtr (I/O)
  Points to a structure that includes both a pointer to the buffer for the data that is received and the size of the buffer. On return, this structure contains the number of bytes that is actually transferred. See Appendix B, "API type definitions source files," on page 147 for the type definition.

Return codes

The return code numbers are provided in parentheses ( ).

Table 32. Return codes for dsmGetData

Return code	Explanation
DSM_RC_ABORT_INVALID_OFFSET (33)	The offset that was specified during a partial object retrieve is greater than the length of the object.
DSM_RC_ABORT_INVALID_LENGTH (34)	The length that was specified during a partial object retrieve is greater than the length of the object, or the offset in addition to the length extends beyond the end of the object.
DSM_RC_FINISHED (121)	Finished processing. The last buffer was received. Check numBytes for the amount of data and then call IBM Storage ProtectdsmEndGetObj.
DSM_RC_NULL_DATABLKPTR (2001)	Datablock pointer is null.
DSM_RC_ZERO_BUFLEN (2008)	Buffer length is zero for datablock pointer.
DSM_RC_NULL_BUFPTR (2009)	Buffer pointer is null for datablock pointer.
DSM_RC_WRONG_VERSION_PARM (2065)	The application client's API version is different from the IBM Storage Protect library version.
DSM_RC_MORE_DATA (2200)	There is more data to get.

dsmGetBufferData

The **dsmGetBufferData** function call receives a byte stream of data from IBM Storage Protect through a buffer. After each call the application needs to copy the data and release the buffer through a call to **dsmReleaseBuffer**. If the number of buffers held by the application equals the numTsmBuffers specified in the **dsmInitEx** call, the **dsmGetBufferData** function blocks until a **dsmReleaseBuffer** is called.

Syntax

```
dsInt16_t  dsmGetBufferData  (getDatatExIn_t       *dsmGetBufferDataExInP,
                              getDataExOut_t        *dsmGetBufferDataExOutP) ;
```

Parameters

getDataExIn_t * dsmGetBufferDataExInP (I)
    This structure contains the following input parameter.

dsUint32_t dsmHandle
    The handle that identifies the session and associates it with a previous **dsmInitEx** call.

getDataExOut_t * dsmGetBufferDataExOutP (O)
    This structure contains the following output parameters.

dsUint8_t tsmBufferHandle(O)
    The handle that identifies the buffer received.

char *dataPtr(O)
    The address to which the data was written.

dsUint32_t numBytes(O)
    Actual number of bytes written by IBM Storage Protect.

Return codes

The return code numbers are provided in parentheses ( ).

Table 33. Return codes for dsmGetBufferData

Return code	Explanation
DSM_RC_BAD_CALL_SEQUENCE (2041)	The call was not issued in the proper state.
DSM_RC_OBJ_ENCRYPTED (2049)	This function cannot be used for encrypted objects.
DSM_RC_OBJ_COMPRESSED (2048)	This function cannot be used for compressed objects.
DSM_RC_BUFF_ARRAY_ERROR (2045)	A buffer array error occurred.

dsmGetNextQObj

The **dsmGetNextQObj** function call gets the next query response from a previous **dsmBeginQuery** call and places the response in the caller buffer.

The **dsmGetNextQObj** call is called one or more times. Each time the function is called, either a single query record is retrieved, or an error or a DSM_RC_FINISHED reason code is returned. If DSM_RC_FINISHED is returned, there is no more data to process. When all query data is retrieved, or if no more query data is needed, send the **dsmEndQuery** call to end the query process.

The **dataBlkPtr** parameter must point to a buffer that is defined with the **qryResp*Data** structure type. The context in which **dsmGetNextQObj** is called determines the type of structure that is entered on the query response.

Syntax

```
dsInt16_t dsmGetNextQObj (dsUint32_t   dsmHandle,
    DataBlk *dataBlkPtr);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

DataBlk *dataBlkPtr (I/O)
Points to a structure that includes both a pointer to the buffer for the data to be received and the size of the buffer. This buffer is the **qryResp*Data** response structure. On return, this structure contains the number of bytes that is transferred. The structure that is associated with each type of query is described in the following table. For more information about the type definition of **DataBlk**, see the following topic: Appendix B, "API type definitions source files," on page 147.

Table 34. DataBlk pointer structure

Query	Response structure	Fields of special interest
qtArchive	**qryRespArchiveData**	**sizeEstimate** Contains the value that is passed on a previous **dsmSendObj** call. **mediaClass** Can have a value of MEDIA_FIXED if the object is on disk, or MEDIA_LIBRARY if the object is on tape. **clientDeduplicated** Indicates whether this object is deduplicated by the client.
qtBackup	**qryRespBackupData**	**restoreOrderExt** Is of type dsUint16_t. Sort on this field when several objects are restored on a **dsmBeginGetData** call. An example of sorting code for this call is in the API sample, dapiqry.c. For a sorting example, see the following topic: Figure 16 on page 60. **sizeEstimate** Contains the value that is passed on a previous **dsmSendObj** call. **mediaClass** Can have a value of MEDIA_FIXED if the object is on disk or MEDIA_LIBRARY if the object is on tape. **clientDeduplicated** Indicates whether this object is deduplicated by the client.
qtBackupActive	**qryARespBackupData**	
qtBackupGroups	**qryRespBackupData**	**dsBool_t isGroupLeader** If true, signifies this object is a group leader.
qtOpenGroups	**qryRespBackupData**	**dsBool_t isOpenGroup;** If true, signifies this group is open and not complete.

Table 34. DataBlk pointer structure (continued)

Query	Response structure	Fields of special interest
qtFilespace	**qryRespFSData**	**backStartDate** Contains the server time stamp when the file space is updated with the **backStartDate** action. **backCompleteDate** Contains the server time stamp when the file space is updated with the **backCompleteDate** action. **lastReplStartDate** Contains the time stamp for the last time that replication was started on the server. **lastReplCmpltDate** Contains the time stamp for the last time that replication was completed, even if there was a failure. **lastBackOpDateFromServer** Contains the last store time stamp that was saved on the server. **lastBackOpDateFromLocal** Contains the last store time stamp that was saved on the client.
qtMC	**qryRespMCData** **qryRespMCDetailData**	
qtProxyNodeAuth	**qryRespProxyNodeData** **targetNodeName** **peerNodeName** **hlAddress** **llAddress**	
qtProxyNodePeer	**qryRespProaxyNodeData** **targetNodeName** **peerNodeName** **hlAddress** **llAddress**	

Return codes

The following table describes the return codes for the **dsmGetNextQObj** function call.

*Table 35. Return codes for the **dsmGetNextQObj** function call*

Return code	Return code number	Description
DSM_RC_ABORT_NO_MATCH	2	No match for the query was requested.
DSM_RC_FINISHED	121	Finished processing (start **dsmEndQuery**). There is no more data to process.

*Table 35. Return codes for the **dsmGetNextQObj** function call (continued)*

Return code	Return code number	Description
DSM_RC_UNKNOWN_FORMAT	122	The file that IBM Storage Protect attempted to restore or retrieve has an unknown format.
DSM_RC_COMM_PROTOCOL_ERRO R	136	Communication protocol error.
DSM_RC_NULL_DATABLKPTR	2001	Pointer is not pointing to a data block.
DSM_RC_INVALID_MCNAME	2025	Invalid management class name.
DSM_RC_BAD_CALL_SEQUENCE	2041	The sequence of calls is invalid.
DSM_RC_WRONG_VERSION_PARM	2065	The version of the application client API is different from the IBM Storage Protect library version.
DSM_RC_MORE_DATA	2200	There is more data to get.
DSM_RC_BUFF_TOO_SMALL	2210	Buffer is too small.

dsmGetObj

The **dsmGetObj** function call obtains the requested object data from the IBM Storage Protect data stream and places it in the caller's buffer. The **dsmGetObj** call uses the object ID to obtain the next object or partial object from the data stream.

The data for the indicated object is placed in the buffer to which **DataBlk** points. If more data is available, you must make one or more calls to **dsmGetData** to receive the remaining object data until a return code of DSM_RC_FINISHED is returned. Check the numBytes field in **DataBlk** to see whether any data remains in the buffer.

Objects should be asked for in the order that they were listed on the **dsmBeginGetData** call in the **dsmGetList** parameter. The exception is when the application client needs to pass over an object in the data stream to get to an object later in the list. If the object that is indicated by the object ID is not the next object in the stream, the data stream is processed until the object is located, or the stream is completed. Use this feature with care, because it might be necessary to process and discard large amounts of data to locate the requested object.

Requirement: If **dsmGetObj** returns a failure code (NOT FINISHED or MORE_DATA), the session must be terminated to stop the restore operation. This is especially important when you use encryption and receive a RC_ENC_WRONG_KEY. You must start a new session with the proper key.

Syntax

```
dsInt16_t dsmGetObj (dsUint32_t dsmHandle,
    ObjID    *objIdP,
    DataBlk  *dataBlkPtr);
```

Parameters

dsUint32_t dsmHandle (I)
    The handle that associates this call with a previous **dsmInitEx** call.

ObjID *objIdP (I)
    A pointer to the ID of the object to restore.

DataBlk *dataBlkPtr (I/O)
    A pointer to the buffer where the restored data are placed.

Return codes

The return code numbers are provided in parentheses ( ).

Table 36. Return codes for dsmGetObj

Return code	Explanation
DSM_RC_ABORT_INVALID_OFFSET (33)	The offset that is specified during a partial object retrieve is greater than the length of the object.
DSM_RC_ABORT_INVALID_LENGTH (34)	The length that is specified during a partial object retrieve is greater than the length of the object, or the offset in addition to the length extends past the end of the object.
DSM_RC_FINISHED (121)	Finished processing (start **dsmEndGetObj**).
DSM_RC_WRONG_VERSION_PARM (2065)	Application client's API version is different from the IBM Storage Protect library version.
DSM_RC_MORE_DATA (2200)	There is more data to get.
RC_ENC_WRONG_KEY (4580)	The key provided in the **dsmInitEx** call, or the saved key, does not match the key that was used to encrypt this object. Terminate the session and provide the proper key.

dsmGroupHandler

The **dsmGroupHandler** function call performs an action on a logical file group depending on the input that is given. The client relates a number of individual objects together to reference and manage on the IBM Storage Protect server as a logical group.

For more information, see .

Syntax

```
dsInt16_t dsmGroupHandler (dsmGroupHandlerIn_t   *dsmGroupHandlerInP,
                           dsmGroupHandlerOut_t  *dsmGroupHandlerOutP);
```

Parameters

dsmGroupHandlerIn_t *dsmGroupHandlerInP (I)
Passes group attributes to the API.

groupType
The type of the group. Values include:

- DSM_GROUPTYPE_PEER - peer group

actionType
The action to be executed. Values include:

- DSM_GROUP_ACTION_OPEN - creates a new group
- DSM_GROUP_ACTION_CLOSE - commits and saves an open group
- DSM_GROUP_ACTION_ADD - appends to a group
- DSM_GROUP_ACTION_ASSIGNTO - assigns to another group
- DSM_GROUP_ACTION_REMOVE- removes a member from a group

memberType.
The group type of the object. Values include:

- DSM_MEMBERTYPE_LEADER - group leader
- DSM_MEMBERTYPE_MEMBER - group member

*uniqueGroupTagP
A unique string ID that is associated with a group.

leaderObjId
The Object ID for the group leader.

*objNameP
A pointer to the object name of the group leader.

memberObjList
A list of objects to remove or assign.

dsmGroupHandlerOut_t *dsmGroupHandlerOutP (O)
Passes the address of the structure that the API completes. The structure version number is returned.

Return codes

The return code numbers are provided in parentheses ( ).

Table 37. Return codes for dsmGroupHandler

Return code	Explanation
DSM_RC_ABORT_INVALID_GROUP_ACTION (237)	An invalid operation was attempted on a group leader or member.

dsmInit

The **dsmInit** function call starts an API session and connects the client to IBM Storage Protect storage. The application client can have only one active session open at a time. To open another session with different parameters, use the **dsmTerminate** call first to end the current session.

To permit cross-node query and restore or retrieve, use the -*fromnode* and -*fromowner* string options. See "Accessing objects across nodes and owners" on page 22 for more information.

Syntax

```
dsInt16_t  dsmInit  (dsUint32_t       *dsmHandle,
    dsmApiVersion *dsmApiVersionP,
    char          *clientNodeNameP,
    char          *clientOwnerNameP,
    char          *clientPasswordP,
    char          *applicationType,
    char          *configfile,
    char          *options);
```

Parameters

dsUint32_t *dsmHandle (O)
The handle that identifies this initialization session and associates it with subsequent IBM Storage Protect calls.

dsmApiVersion *dsmApiVersionP (I)
A pointer to the data structure identifying the version of the API that the application client is using for this session. The structure contains the values of the three constants, DSM_API_VERSION, DSM_API_RELEASE, and DSM_API_LEVEL, that are set in the dsmapitd.h file. A previous call to **dsmQueryApiVersion** must be performed to ensure that compatibility exists between the application client API version and the version of the API library that is installed on the user's workstation.

char *clientNodeNameP (I)

This parameter is a pointer to the node for the IBM Storage Protect session. All sessions must have a node name associated with them. The constant, DSM_MAX_NODE_LENGTH, in the dsmapitd.h file sets the maximum size that is permitted for a node name.

The node name is not case-sensitive.

If this parameter is set both to NULL and *passwordaccess* is set to *prompt,* the API attempts to obtain the node name first from the options string that was passed. If it is not there, the API then attempts to obtain the node name from the configuration file or options files. If these attempts to find the node name fail, the UNIX or Linux API uses the system host name, while APIs on other operating systems return the DSM_RC_REJECT_ID_UNKNOWN code.

If this parameter is NULL, and the `passwordaccess` option in the `dsm.opt` file (for the Windows API) or in the `dsm.sys` file (for the UNIX or Linux API) is set to `generate`, the API uses the nodename option value or the system host name.

char *clientOwnerNameP (I)

This parameter is a pointer to the owner of the IBM Storage Protect session. If the operating system on which the session starts is a multi-user operating system, an owner name of NULL (the root user) has the authority to back up, archive, restore, or retrieve any objects belonging to the application, regardless of the owner of the object.

The owner name is case-sensitive.

If this parameter is NULL and the `passwordaccess` option in the `dsm.sys` file is set to `generate`, the API then uses the login user ID.

Note: On a multi-user operating system, it is not necessary for the owner name to match the active user ID of the session running the application.

char *clientPasswordP (I)

This parameter is a pointer to the password of the node on which the IBM Storage Protect session runs. The DSM_MAX_VERIFIER_LENGTH constant in the dsmapitd.h file sets the maximum size that is permitted for a password.

The password is not case-sensitive.

Except when the password file is first started, the value of this parameter is ignored if *passwordaccess* is set to *generate.*

char *applicationType (I)

This parameter identifies the application that is running the session. The application client defines the value.

Each time an API application client starts a session with the server, the application type (or platform) of the client is updated on the server. We recommend that the application type value contain an operating system abbreviation because this value is entered in the **platform** field on the server. The maximum string length is DSM_MAX_PLATFORM_LENGTH.

To see the current value of the application type, call **dsmQuerySessInfo**.

char *configfile (I)

This parameter points to a character string that contains the fully-qualified name of an API configuration file. Options specified in the API configuration file override their specification in the client options file. Options files are defined when IBM Storage Protect (client or API) is installed.

char *options (I)

Points to a character string that can contain user options such as:

- *Compressalways*
- *Servername* (UNIX or Linux only)
- *TCPServeraddr*
- *Fromnode*

- *Fromowner*
- *EnableClientEncryptKey*
- *Passwordaccess*

The application client can use the option list to override the values of these options that the configuration file sets.

The format of the options is:

1. Each option that is specified in the option list begins with a dash (-) and is followed by the option keyword.
2. The keyword, in turn, is followed by an equal sign (=) and then followed by the option parameter.
3. If the option parameter contains a blank space, enclose the parameter with single or double quotes.
4. If more than one option is specified, separate the options with blanks.

If options are NULL, values for all options are taken from the user options file or the API configuration file.

Return codes

The return code numbers are provided in parentheses ( ).

Table 38. Return codes for dsmInit

Return code	Explanation
DSM_RC_ABORT_SYSTEM_ERROR (1)	The server has detected a system error and has notified the clients.
DSM_RC_REJECT_VERIFIER_EXPIRED (52)	Password has expired and must be updated.
DSM_RC_REJECT_ID_UNKNOWN (53)	Could not find the node name.
DSM_RC_AUTH_FAILURE (137)	There was an authentication failure.
DSM_RC_NO_STARTING_DELIMITER (148)	There is no starting delimiter in pattern.
DSM_RC_NEEDED_DIR_DELIMITER (149)	A directory delimiter is needed immediately before and after the "match directories" meta-string ("...") and one was not located.
DSM_RC_NO_PASS_FILE (168)	The password file is not available.
DSM_RC_UNMATCHED_QUOTE (177)	An unmatched quote is in the option string.
DSM_RC_NLS_CANT_OPEN_TXT (0610)	Unable to open the message text file.
DSM_RC_INVALID_OPT (400)	An entry in the option string is invalid.
DSM_RC_INVALID_DS_HANDLE (2014)	Invalid DSM handle.
DSM_RC_NO_OWNER_REQD (2032)	Owner parameter must be NULL when *passwordaccess* is set to *generate*.
DSM_RC_NO_NODE_REQD (2033)	Node parameter must be NULL when *passwordaccess* is set to *generate*.
DSM_RC_WRONG_VERSION (2064)	The API version for the application client has a higher value than the IBM Storage Protect version.
DSM_RC_PASSWD_TOOLONG (2103)	The password that was specified is too long.

Table 38. Return codes for dsmInit (continued)

Return code	Explanation
DSM_RC_NO_OPT_FILE (2220)	A configuration file could not be located.
DSM_RC_INVALID_KEYWORD (2221)	A keyword that was specified in an options string is invalid.
DSM_RC_PATTERN_TOO_COMPLEX (2222)	The include-exclude pattern is too complex for IBM Storage Protect to interpret.
DSM_RC_NO_CLOSING_BRACKET (2223)	There is no closing bracket in the pattern.
DSM_RC_INVALID_SERVER (2225)	For a multi-user environment, the server in the system configuration file was not found.
DSM_RC_NO_HOST_ADDR (2226)	Not enough information to connect to host.
DSM_RC_MACHINE_SAME (2227)	The nodename that is defined in the options file cannot be the same as the system host name.
DSM_RC_NO_API_CONFIGFILE (2228)	Cannot open the configuration file.
DSM_RC_NO_INCLEXCL_FILE (2229)	The include-exclude file was not found.
DSM_RC_NO_SYS_OR_INCLEXCL (2230)	Either the `dsm.sys` file or the include-exclude file was not found.

Processing options

dsmInitEx

The **dsmInitEx** function call starts an API session by using the additional parameters for extended verification.

Syntax

```
dsInt16_t  dsmInitEx  (dsUint32_t       *dsmHandleP,
                       dsmInitExIn_t    *dsmInitExInP,
                       dsmInitExOut_t   *dsmInitExOutP) ;
```

Parameters

dsUint32_t *dsmHandleP (O)
    The handle that identifies this initialization session and associates it with subsequent IBM Storage Protect calls.

dsmInitExIn_t *dsmInitExInP
    This structure contains the following input parameters:

dsmApiVersion *dsmApiVersionP (I)
    This parameter is a pointer to the data structure that identifies the version of the API that the application client is using for this session. The structure contains the values of the four constants, DSM_API_VERSION, DSM_API_RELEASE, DSM_API_LEVEL, and DSM_API_SUBLEVEL that are set in the `dsmapitd.h` file. Call **dsmQueryApiVersionEx** and verify that the API version of the application client and the version of the API library that is installed on the user's workstation is compatible.

char *clientNodeNameP (I)

This parameter is a pointer to the node for the IBM Storage Protect session. All sessions must be associated with a node name. The DSM_MAX_NODE_LENGTH constant in the `dsmapitd.h` file sets the maximum size for a node name.

The node name is not case-sensitive.

If this parameter is set to NULL, and **passwordaccess** is set to `prompt`, the API attempts to obtain the node name first from the options string that was passed. If it is not there, the API then attempts to obtain the node name from the configuration file or options files. If these attempts to find the node name fail, the UNIX or Linux API uses the system host name, while the APIs from other operating systems return DSM_RC_REJECT_ID_UNKNOWN.

If this parameter is NULL, and the **passwordaccess** option in the `dsm.opt` file (for the Windows API) or in the `dsm.sys` file (for the UNIX or Linux API) is set to `generate`, the API uses the nodename option value or the system host name.

char *clientOwnerNameP (I)

This parameter is a pointer to the owner of the IBM Storage Protect session. If the operating system is a multi-user platform, an owner name of NULL (the root user) has the authority to back up, archive, restore, or retrieve any objects that belong to the application, regardless of the owner of the object.

The owner name is case-sensitive.

If this parameter is NULL and the **passwordaccess** option in the `dsm.sys` file is set to `generate`, the API then uses the login user ID.

Note: On a multi-user platform, it is not necessary for the owner name to match the active user ID of the session running the application.

char *clientPasswordP (I)

A pointer to the password of the node on which the IBM Storage Protect session runs. The DSM_MAX_VERIFIER_LENGTH constant in the `dsmapitd.h` file sets the maximum size that is allowed for a password.

The password is not case-sensitive.

Except when the password file is first started, the value of this parameter is ignored if **passwordaccess** is set to `generate`.

char *userNameP;

A pointer to the administrative user name that has client authority for this node.

char *userPasswordP;

A pointer to the password for the **userName** parameter, if a value is supplied.

char *applicationType (I)

Identifies the application that is running the IBM Storage Protect session. The application client identifies the value.

Each time an API application client starts a session with the server, the application type (or operating system) of the client is updated on the server. The value is entered in the **platform** field on the server. Consider using an operating system ID in the value. The maximum string length is defined in the DSM_MAX_PLATFORM_LENGTH constant.

To view the current value of the application type, call **dsmQuerySessInfo**.

char *configfile (I)

Points to a character string that contains the fully qualified name of an API configuration file. Options that are specified in the API configuration file override their specification in the client options file. Options files are defined when IBM Storage Protect (client or API) is installed.

char *options (I)

Points to a character string that can contain user options such as:

- Compressalways

- Servername (UNIX and Linux systems only)
- TCPServeraddr (not for UNIX systems)
- Fromnode
- Fromowner
- Passwordaccess

The application client can use the options list to override the values of these options that the configuration file sets.

Options have the following format:

1. Each option that is specified in the option list begins with a dash (-) and is followed by the option keyword.
2. The keyword is followed by an equal sign (=) and then the option parameter.
3. If the option parameter contains a blank space, enclose the parameter with single or double quotation marks.
4. If more than one option is specified, separate the options with blanks.

If options are NULL, the values for all options are taken from the user options file or the API configuration file.

dirDelimiter
The directory delimiter that is prefixed on the file space, high-level or low-level names. You must specify the **dirDelimiter** parameter only if the application overrides the system defaults. In a UNIX or Linux environment, the default is forward slash (/). In a Windows environment, the default is backslash (\).

useUnicode
A Boolean flag that indicates whether Unicode is enabled. The **useUnicode** flag must be `false` to achieve cross-platform interoperability between UNIX and Windows systems.

bCrossPlatform
A Boolean flag that must be set (bTrue) to achieve cross-platform interoperability between UNIX and Windows systems. When the bCrossPlatform flag is set, the API ensures that the file spaces are not Unicode and that the application does not use Unicode. A Windows application that uses Unicode is not compatible with applications that use non-Unicode encodings. The bCrossPlatform flag must not be set for a Windows application that uses Unicode.

UseTsmBuffers
Indicates whether to use buffer copy elimination.

numTsmBuffers
Number of buffers when useTsmBuffers=bTrue.

bEncryptKeyEnabled
Indicates whether encryption with application-managed key is used.

encryptionPasswordP
The encryption password.

Restriction: When encryptkey=save, if an encrypt key exists, the value that is specified in the **encryptionPasswordP** is ignored.

dsmAppVersion *appVersionP (I)
This parameter is a pointer to the data structure that identifies the version information of the application that is starting an API session. The structure contains the values of the four constants, applicationVersion, applicationRelease, applicationLevel, and applicationSubLevel, which are set in the `tsmapitd.h` file.

dsmInitExOut_t *dsmInitExOut P
This structure contains the output parameters.

dsUint32_t *dsmHandle (0)
>   The handle that identifies this initialization session and associates it with subsequent API calls.

infoRC
>   Additional information about the return code. Check both the function return code and the value of **infoRC**. An **infoRC** value of DSM_RC_REJECT_LASTSESS_CANCELED (69), the IBM Storage Protect indicates that the administrator canceled the last session.

Return codes

The return code numbers are provided in parentheses ( ).

*Table 39. Return codes for **dsmInitEx***

Return code	Explanation
DSM_RC_ABORT_SYSTEM_ERROR (1)	The IBM Storage Protect server detected a system error and notified the clients.
DSM_RC_REJECT_VERIFIER_EXPIRED (52)	Password expired and must be updated. The next call must be **dsmChangePW** with the handle returned on this call.
DSM_RC_REJECT_ID_UNKNOWN (53)	Cannot not find the node name.
DSM_RC_TA_COMM_DOWN (103)	The communications link is down.
DSM_RC_AUTH_FAILURE (137)	There was an authentication failure.
DSM_RC_NO_STARTING_DELIMITER (148)	There is no starting delimiter in pattern.
DSM_RC_NEEDED_DIR_DELIMITER (149)	A directory delimiter is needed immediately before and after the "match directories" meta-string ("..."), but was not found.
DSM_RC_NO_PASS_FILE (168)	The password file is not available.
DSM_RC_UNMATCHED_QUOTE (177)	An unmatched quotation mark is in the option string.
DSM_RC_NLS_CANT_OPEN_TXT (0610)	Unable to open the message text file.
DSM_RC_INVALID_OPT (2013)	An entry in the option string is invalid.
DSM_RC_INVALID_DS_HANDLE (2014)	Invalid DSM handle.
DSM_RC_NO_OWNER_REQD (2032)	Owner parameter must be NULL when **passwordaccess** is set to `generate`.
DSM_RC_NO_NODE_REQD (2033)	Node parameter must be NULL when **passwordaccess** is set to generate.
DSM_RC_WRONG_VERSION (2064)	Application client's API version has a higher value than the IBM Storage Protect version.
DSM_RC_PASSWD_TOOLONG (2103)	The specified password is too long.
DSM_RC_NO_OPT_FILE (2220)	No configuration file is found.
DSM_RC_INVALID_KEYWORD (2221)	A keyword that is specified in an options string is invalid.
DSM_RC_PATTERN_TOO_COMPLEX (2222)	Include-exclude pattern too complex to be interpreted by IBM Storage Protect.
DSM_RC_NO_CLOSING_BRACKET (2223)	There is no closing bracket in the pattern.

*Table 39. Return codes for **dsmInitEx** (continued)*

Return code	Explanation
DSM_RC_INVALID_SERVER (2225)	For a multi-user environment, the server in the system configuration file was not found.
DSM_RC_NO_HOST_ADDR (2226)	Not enough information to connect to the host.
DSM_RC_MACHINE_SAME (2227)	The node name that is defined in the options file cannot be the same as the system host name.
DSM_RC_NO_API_CONFIGFILE (2228)	Cannot open the configuration file.
DSM_RC_NO_INCLEXCL_FILE (2229)	The include-exclude file was not found.
DSM_RC_NO_SYS_OR_INCLEXCL (2230)	Either the dsm.sys or the include-exclude file was not found.

Client options file overview

Processing options

dsmLogEvent

The **dsmLogEvent** function call logs a user message (ANE4991 I) to the server log file, to the local error log, or to both. A structure of type **logInfo** is passed in the call. This call must be performed while at **InSession** state inside a session. Do not perform it within a send, get, or query. To retrieve messages logged on the server, use the **query actlog** command through the administrative client.

See the summary state diagram, Figure 20 on page 67.

Syntax

```
dsInt16_t dsmLogEvent
     (dsUint32_t    dsmHandle,
      logInfo       *logInfoP);
```

Parameters

dsUint32_t dsmHandle(I)
The handle that associates this call with a previous **dsmInitEx** call.

logInfo *logInfoP (I)
Passes the message and destination. The application client is responsible for allocating storage for the structure.

The fields in the **logInfo** structure are:

message
The text of the message to be logged. This must be a null-ended string. The maximum length is DSM_MAX_RC_MSG_LENGTH.

dsmLogtype
Specifies where to log the message. Possible values include: **logServer**, **logLocal**, **logBoth**.

Return codes

The return code numbers are provided in parentheses ( ).

Table 40. Return codes for dsmLogEvent

Return code	Explanation
DSM_RC_STRING_TOO_LONG (2120)	The message string is too long.

dsmLogEventEx

The **dsmLogEventEx** function call logs a user message to the server log file, to the local error log, or to both. This call must be made while at an **InSession** state within a session. The call cannot be made within a send, get, or query call.

Summary state diagram: For an overview of the session interactions, see the summary state diagram in the following topic:

The severity determines the IBM Storage Protect message number. To view messages that are logged on the server, use the **query actlog** command through the administrative client. Use the IBM Storage Protect client option, errorlogretention, to prune the client error log file if the application generates numerous client messages written to the client log, dsmLogType either logLocal or logBoth. For more information, see the IBM Storage Protect server documentation.

Syntax

```
extern dsInt16_t DSMLINKAGE   dsmLogEventEx(
      dsUint32_t             dsmHandle,
      dsmLogExIn_t           *dsmLogExInP,
      dsmLogExOut_t          *dsmLogExOutP
);
```

Parameters

dsUint32_t dsmHandle(I)
   The handle that associates this call with a previous **dsmInitEx** call.

dsmLogExIn_t *dsmLogExInP
   This structure contains the input parameters.

   dsmLogSeverity severity;
      This parameter is the event severity. The possible values are:

```
      logSevInfo,      /* information ANE4990 */
      logSevWarning,   /* warning     ANE4991 */
      logSevError,     /* Error       ANE4992 */
      logSevSevere     /* severe      ANE4993 */
```

   char appMsgID[8];
      This parameter is a string to identify the specific application message. A suitable format is three characters that are followed by four numbers, for example: DSM0250.

   dsmLogType logType;
      This parameter specifies where to direct the event. The parameter has the following possible values:

      • logServer
      • logLocal
      • logBoth

   char *message;
      This parameter is the text of the event message to log. The text must be a null-ended string. The maximum length is DSM_MAX_RC_MSG_LENGTH.

Restriction: Messages that go to the server must be in English. Non-English messages do not display correctly.

dsmLogExOut_t *dsmLogExOutP
This structure contains the output parameters. Currently, there are no output parameters.

Return codes

The return code numbers are provided in parentheses ( ).

Table 41. Return codes for dsmLogEventEx

Return code	Explanation
DSM_RC_STRING_TOO_LONG (2120)	The message string is too long.

dsmQueryAccess

The **dsmQueryAccess** function call queries the server for all access authorization rules for either backup versions or archived copies of your objects. A pointer to an array of access rules is passed in to the call, and the completed array is returned. A pointer to the number of rules is passed in to indicate how many rules are in the array.

There are no return codes that are specific to this call.

Syntax

```
dsInt16_t DSMLINKAGE dsmQueryAccess
                  (dsUint32_t          dsmHandle),
                   qryRespAccessData   **accessListP,
                   dsUint16_t          *numberOfRules) ;
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

qryRespAccessData **accessListP (O)
A pointer to an array of `qryRespAccessData` elements that the API library allocates. Each element corresponds to an access rule. The number of elements in the array is returned in the **numberOfRules** parameter. The information that is returned in each `qryRespAccessData` element includes the following:

Name	Description
ruleNumber	The ID for the access rule. This identifies the rule for deletion.
AccessType	The backup or archive type.
Node	The node on which you gave access.
Owner	The user to whom you gave access.
objName	The high-level, or low-level file space descriptors.

dsUint32_t *numberOfRules (O)
Returns the number of rules in the `accessList` array.

dsmQueryApiVersion

The **dsmQueryApiVersion** function call performs a query request for the API library version that the application client accesses.

All updates to the API are made in an upward-compatible format. Any application client with an API version or release less than, or equal to, the API library on the end user's workstation operates without change. Be aware before you proceed that should the **dsmQueryApiVersion** call return a version or version release older than that of the application clients, some API calls might be enhanced in a manner that is not supported by the end user's older version of the API.

The application API version number is stored in the dsmapitd.h header file as constants DSM_API_VERSION, DSM_API_RELEASE, and DSM_API_LEVEL.

There are no return codes that are specific to this call.

Syntax

```
void dsmQueryApiVersion  (dsmApiVersion *apiVersionP);
```

Parameters

dsmApiVersion *apiVersionP (O)
This parameter is a pointer to the structure that contains the API library version, release, and level components. For example, if the library is version 1.1.0, then, after returning from the call, the fields of the structure contain the following values:

```
dsmApiVersionP->version  = 1
dsmApiVersionP->release  = 1
dsmApiVersionP->level    = 0
```

dsmQueryApiVersionEx

The **dsmQueryApiVersionEx** function call performs a query request for the API library version that the application client accesses.

All updates to the API are made in an upward-compatible format. Any application client that has an API version or release less than or equal to the API library on the end user's workstation operates without change. See Summary of Code Changes in the README_api_enu file for exceptions to upward compatibility. If the **dsmQueryApiVersionEx** call returns a version or version release that is different from that of the application client, be aware before you proceed that some API calls might be enhanced in a manner that is not supported by the end user's older version of the API.

The application API version number is stored in the dsmapitd.h header file as constants DSM_API_VERSION, DSM_API_RELEASE, DSM_API_LEVEL, and DSM_API_SUBLEVEL.

There are no return codes that are specific to this call.

Syntax

```
void dsmQueryApiVersionEx (dsmApiVersionEx *apiVersionP);
```

Parameters

dsmApiVersionEx *apiVersionP (O)
This parameter is a pointer to the structure that contains the API library's version, release, level, and sublevel components. For example, if the library is version 5.5.0.0, then, after returning from the call, the fields of the structure contain the following values:

- `ApiVersionP->version = 5`
- `ApiVersionP->release = 5`
- `ApiVersionP->level = 0`
- `ApiVersionP->subLevel = 0`

dsmQueryCliOptions

The **dsmQueryCliOptions** function call queries important option values in the user's option files. A structure of type **optStruct** is passed in the call and contains the information. This call is performed before **dsmInitEx** is called, and it determines the setup before the session.

There are no return codes that are specific to this call.

Syntax

```
dsInt16_t dsmQueryCliOptions
    (optStruct      *optstructP);
```

Parameters

optStruct *optstructP (I/O)
This parameter passes the address of the structure that the API completes. The application client is responsible for allocating storage for the structure. On successful return, the appropriate information is entered in the fields in the structure.

The following information is returned in the **optStruct** structure:

Name	Description
dsmiDir	The value of the environment DSMI_DIR variable.
dsmiConfig	The client option file as specified by the DSMI_CONFIG environment variable.
serverName	The name of the IBM Storage Protect server.
commMethod	The communication method selected. See the #defines for DSM_COMM_* in the dsmapitd.h file.
serverAddress	The address of the server that is based on the communication method.
nodeName	The client node (machine) name.
compression	This field provides information regarding the compression option.
passwordAccess	The values are: *bTrue* for generate, and *bFalse* for prompt.

Related information
Processing options

dsmQuerySessInfo

The **dsmQuerySessInfo** function call starts a query request to IBM Storage Protect for information related to the operation of the specified session in **dsmHandle**. A structure of type **ApiSessInfo** is passed in the call, with all available session related information entered. This call is started after a successful **dsmInitEx** call.

The information that is returned in the **ApiSessInfo** structure includes the following:

- Server information: port number, date and time, and type

- Client defaults: application type, delete permissions, delimiters, and transaction limits
- Session information: login ID, and owner
- Policy data: domain, active policy set, and retention grace period

See Appendix B, "API type definitions source files," on page 147 for information about the content of the structure that is passed and each field within it.

Syntax

```
dsInt16_t dsmQuerySessInfo  (dsUint32_t          dsmHandle,
    ApiSessInfo   *SessInfoP);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

ApiSessInfo *SessInfoP (I/O)
This parameter passes the address of the structure that the API enters. The application client is responsible for allocating storage for the structure and for completing the field entries that indicate the version of the structure that is used. On successful return, the fields in the structure are completed with the appropriate information. The **adsmServerName** is the name that is given in the **define server** command on the IBM Storage Protect server. If the archiveRetentionProtection field is true, the server is enabled for retention protection.

Return codes

The return code numbers are provided in parentheses ( ).

Table 42. Return codes for dsmQuerySessInfo

Return code	Explanation
DSM_RC_NO_SESS_BLK (2006)	No server session block information.
DSM_RC_NO_POLICY_BLK (2007)	No server policy information available.
DSM_RC_WRONG_VERSION_PARM (2065)	Application client's API version is different from the IBM Storage Protect library version.

dsmQuerySessOptions

The **dsmQuerySessOptions** function call queries important option values that are valid in the specified session in **dsmHandle**. A structure of type optStruct is passed in the call and contains the information.

This call is started after a successful **dsmInitEx** call. The values that are returned might be different from the values returned on a **dsmQueryCliOptions** call, depending on values that are passed to the **dsmInitEx** call, primarily optString, and optFile. For information about option precedence, see "Understanding configuration and options files" on page 1.

There are no return codes that are specific to this call.

Syntax

```
dsInt16_t dsmQuerySessOptions
    (dsUint32_t    dsmHandle,
    optStruct      *optstructP);
```

Parameters

dsUint32_t dsmhandle(I)
The handle that associates this call with a previous **dsmInitEx** call.

optStruct *optstructP (I/O)
This parameter passes the address of the structure that the API completes. The application client is responsible for allocating storage for the structure. On successful return, the fields in the structure are completed with the appropriate information.

The information returned in the optStruct structure is:

Name	Description
dsmiDir	The value of the DSMI_DIR environment variable.
dsmiConfig	The dsm.opt file that the DSMI_CONFIG environment variable specifies.
serverName	The name of the IBM Storage Protect server stanza in the options file.
commMethod	The communication method that was selected. See the #defines for DSM_COMM_* in the dsmapitd.h file.
serverAddress	The address of the server that is based on the communication method.
nodeName	The name of the client's node (machine).
compression	The value of the compression option (bTrue=on and bFalse=off).
compressAlways	The value of the compressalways option (bTrue=on and bFalse=off).
passwordAccess	Value bTrue for generate, and bFalse for prompt.

Related information
Processing options

dsmRCMsg

The **dsmRCMsg** function call obtains the message text that is associated with an API return code.

Important: If **dsmRCMsg** is called after a **dsmInitEx** fail, the Servername option will be ignored and an error will be printed in a log file, which is defined for the server by default.

The **msg** parameter displays the message prefix return code in parentheses ( ), followed by the message text. For example, a call to **dsmRCMsg** might return the following:

```
ANS0264E (RC2300) Only root user can execute dsmChangePW or dsmDeleteFS.
```

For some languages where characters are different in ANSII and OEM code pages, it might be necessary to convert strings from ANSII to OEM before printing them out (for example, Eastern European single-byte character sets). The following is an example:

```
dsmRCMsg(dsmHangle, rc, msgBuf);
#ifdef WIN32
#ifndef WIN64
CharToOemBuff(msgBuf, msgBuf, strlen(msgBuf));
#endif
#endif
printf("
```

Syntax

```
dsInt16_t dsmRCMsg (dsUint32_t        dsmHandle,
    dsInt16_t        dsmRC,
    char        *msg);
```

Parameters

dsUint32_t dsmHandle (I)
> The handle that associates this call with a previous **dsmInitEx** call.

dsInt16_t dsmRC (I)
> The API return code of the associated message text. The API return codes are listed in the dsmrc.h file. See Appendix A, "API return codes source file: dsmrc.h," on page 137 for more information.

char *msg (O)
> This parameter is the message text that is associated with the return code, **dsmRC**. The caller is responsible for allocating enough space for the message text.
>
> The maximum length for **msg** is defined as DSM_MAX_RC_MSG_LENGTH.
>
> On platforms that have National Language Support and a choice of language message files, the API returns a message string in the national language.

Return codes

The return code numbers are provided in parentheses ( ).

Table 43. Return codes for dsmRCMsg

Return code	Explanation
DSM_RC_NULL_MSG (2002)	The **msg** parameter for dsmRCMsg call is a NULL pointer.
DSM_RC_INVALID_RETCODE (2021)	Return code that was passed to **dsmRCMsg** call is an invalid code.
DSM_RC_NLS_CANT_OPEN_TXT (0610)	Unable to open the message text file.

dsmRegisterFS

The **dsmRegisterFS** function call registers a new file space with the IBM Storage Protect server. Register a file space first before you can back up any data to it.

Application clients should not use the same file space names that a backup-archive client would use.

- On UNIX or Linux, run the **df** command for these names.
- On Windows, these names are generally the volume labels that are associated with the different drives on your system.

Syntax

```
dsInt16_t dsmRegisterFS  (dsUint32_t        dsmHandle,
    regFSData      *regFilespaceP);
```

Parameters

dsUint32_t dsmHandle (I)
> The handle that associates this call with a previous **dsmInitEx** call.

regFSData *regFilespaceP (I)
This parameter passes the name of the file space and associated information that you need to register with the IBM Storage Protect server.

Tip: The *fstype* field includes the prefix, **"API:".** All file space queries display this string. For example, if the user passes *myfstype* for *fstype* in **dsmRegisterFS**, the actual value string on the server is returned as API:myfstype when queried. This prefix distinguishes API objects from backup-archive objects.

The usable area for **fsInfo** is now DSM_MAX_USER_FSINFO_LENGTH.

Return codes

The return code numbers are provided in parentheses ( ).

Table 44. Return codes for dsmRegisterFS

Return code	Explanation
DSM_RC_INVALID_FSNAME (2016)	Invalid file space name.
DSM_RC_INVALID_DRIVE_CHAR (2026)	Drive letter is not an alphabetic character.
DSM_RC_NULL_FSNAME (2027)	Null file space name.
DSM_RC_FS_ALREADY_REGED (2062)	File space is already registered.
DSM_RC_WRONG_VERSION_PARM (2065)	Application client's API version is different from the IBM Storage Protect library version.
DSM_RC_FSINFO_TOOLONG (2106)	File space information is too long.

dsmReleaseBuffer

The **dsmReleaseBuffer** function returns a buffer to IBM Storage Protect. The application calls **dsmReleaseBuffer** after a **dsmGetDataEx** was called and the application has moved all the data out of the buffer and is ready to release it. **dsmReleaseBuffer** requires that **dsmInitEx** was called with the **UseTsmBuffers** set to *btrue* and a non-zero value was provided for *numTsmBuffers*. **dsmReleaseBuffer** should also be called if the application is about to call **dsmTerminate** and it still holds data buffers.

dsmReleaseBufferSyntax

```
dsInt16_t  dsmReleaseBuffer  (releaseBufferIn_t    *dsmReleaseBufferInP,
                              releaseBufferOut_t   *dsmReleaseBufferOutP) ;
```

Parameters

releaseBufferIn_t * dsmReleaseBufferInP (I)
This structure contains the following input parameters.

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

dsUint8_t tsmBufferHandle(I)
The handle that identifies this buffer.

char *dataPtr(I)
The address to which the application is written.

Return codes

The return code numbers are provided in parentheses ( ).

Table 45. Return codes for dsmReleaseBuffer

Return code	Explanation
DSM_RC_BAD_CALL_SEQUENCE	The call was not issued in the proper state.
DSM_RC_INVALID_TSMBUFFER	The handle or the value of **dataPtr** are invalid.
DSM_RC_BUFF_ARRAY_ERROR	A buffer array error occurred.

dsmRenameObj

The **dsmRenameObj** function call renames the high-level or low-level object name. For backup objects, pass in the current object name and changes either for high-level or low-level object names. For archive objects, pass in the current object file space name and object ID, and changes either for high-level or low-level object names. Use this function call within **dsmBeginTxn** and **dsmEndTxn** calls.

The merge flag determines whether or not a duplicate backup object name is merged with the existing backups. If the new name corresponds to an existing object and merge is true, the current object is converted to the new name and it becomes the active version of the new name while the existing active object that had that name becomes the top most inactive copy of the object. If the new name corresponds to an existing object and merge is false, the function then returns the return code, DSM_RC_ABORT_DUPLICATE_OBJECT.

Restrictions:

- Only the owner of the object can rename it.
- The **dsmRenameObj** function is not supported if data retention protection is enabled on the IBM Storage Protect server or if you are connected to the IBM Storage Protect for Data Retention server.

The **dsmRenameObj** function call tests for these merge conditions:

- The current **dsmObjName** object and the new high-level or low-level object must match on owner, copy group, and management class.
- The current **dsmObjName** must have been backed up more recently than the currently active object with the new name.
- There must be only an active copy of the current **dsmObjName** with no inactive copies.

Syntax

```
dsInt16_t dsmRenameObj  (dsmRenameIn_t     *dsmRenameInP,
                         dsmRenameOut_t    *dsmRenameOutP);
```

Parameters

dsUint32_t dsmHandle (I)
　　The handle that associates this call with a previous **dsmInitEx** call.

dsmRenameIn_t *dsmRenameInP
　　This structure contains the input parameters.

　　dsUint8_t repository (I);
　　　　This parameter indicates whether the file space to delete is in the backup repository or the archive repository.

dsmObjName *objNameP (I);
This parameter is a pointer to the structure that contains the current file space name, high-level object name, low-level object name, and object type.

char newHl [DSM_MAX_HL_LENGTH + 1];
This parameter specifies the new high-level name.

char newLl [DSM_MAX_LL_LENGTH + 1];
This parameter specifies the new low-level name.

dsBool_t merge;
This parameter determines whether or not a backup object is merged with duplicate named objects. The values are either true or false.

ObjID;
The object ID for archive objects.

dsmRenameOut_t *dsmRnameOutP
This structure contains the output parameters.

Note: There are no output parameters.

Return codes

The return code numbers are provided in parentheses ( ).

Table 46. Return codes for dsmRenameObj

Return code	Explanation
DSM_RC_ABORT_MERGE_ERROR (45)	Server detected a merge error.
DSM_RC_ABORT_DUPLICATE_OBJECT (32)	Object already exists and merge is false.
DSM_RC_ABORT_NO_MATCH (2)	Object not found.
DSM_RC_REJECT_SERVER_DOWNLEVEL (58)	The IBM Storage Protect server must be at V3.7.4.0 or later for this function to work.

dsmRequestBuffer

The **dsmRequestBuffer** function returns a buffer to IBM Storage Protect. The application calls **dsmRequestBuffer** after a **dsmGetDataEx** was called and the application has moved all the data out of the buffer and is ready to release it.

dsmReleaseBuffer requires that **dsmInitEx** was called with the *UseTsmBuffers* set to *btrue* and a non-zero value was provided for *numTsmBuffers*. **dsmReleaseBuffer** should also be called if the application is about to call **dsmTerminate** and it still holds IBM Storage Protect buffers.

Syntax

```
dsInt16_t  dsmRequestBuffer  (getBufferIn_t    *dsmRequestBufferInP,
                              getBufferOut_t   *dsmRequestBufferOutP) ;
```

Parameters

getBufferIn_t * dsmRequestBufferInP (I)
This structure contains the following input parameter:

dsUint32_t dsmHandle
The handle that identifies the session and associates it with a previous **dsmInitEx** call.

getBufferOut_t *dsmRequestBufferOut P (0)
This structure contains the output parameters.

    dsUint8_t tsmBufferHandle(0)
        The handle that identifies this buffer.

    char *dataPtr(0)
        The address to which application is written.

    dsUint32_t *bufferLen(0)
        Maximum number of bytes that can be written to this buffer.

Return codes

The return code numbers are provided in parentheses ( ).

Table 47. Return codes for dsmRequestBuffer

Return code	Explanation
DSM_RC_BAD_CALL_SEQUENCE (33)	The call was not issued in the proper state.
DSM_RC_SENDDATA_WITH_ZERO_SIZE (34)	If the object being sent is 0 length, no calls to **dsmReleaseBuffer** are allowed.
DSM_RC_BUFF_ARRAY_ERROR (121)	A valid buffer could not be obtained.

dsmRetentionEvent

The **dsmRetentionEvent** function call sends a list of object IDs to the IBM Storage Protect server, with a retention event operation to be performed on these objects. Use this function call within **dsmBeginTxn** and **dsmEndTxn** calls.

Note: The server must be at version 5.2.2.0 or later for this function to work.

The maximum number of objects in a call is limited to the value of *maxObjPerTxn* that is returned in the *ApisessInfo* structure from a **dsmQuerySessInfo** call.

Only an owner of an object can send an event on that object.

The following events are possible:

eventRetentionActivate
Can be issued only for objects that are bound to an event based management class. Sending this event activates the event for this object and the state of the retention for this object changes from DSM_ARCH_RETINIT_PENDING to DSM_ARCH_RETINIT_STARTED.

eventHoldObj
This event issues a retention or deletion hold on the object so that, until a release is issued, the object is not expired and cannot be deleted.

eventReleaseObj
This event can only be issued for an object that has a value of DSM_ARCH_HELD_TRUE in the *objectHeld* field and removes the hold on the object resuming the original retention policy.

Before you send **dsmRetentionEvent**, send the query sequence that is described in "Querying the IBM Storage Protect system" on page 29 to obtain the information for the object. The call to **dsmGetNextQObj** returns a data structure named **qryRespArchiveData** for archive queries. This data structure contains the information that is needed for **dsmRetentionEvent**.

Syntax

```
extern dsInt16_t DSMLINKAGE dsmRetentionEvent(
    dsmRetentionEventIn_t          *ddsmRetentionEventInP,
```

```
dsmRetentionEventOut_t        *dsmRetentionEventOutP
  );
```

Parameters

dsmRetentionEventIn_t *dsmRetentionEventP
  This structure contains the following input parameters:

  dsUint16_t stVersion;
    This parameter indicates the structure version.

  dsUint32_t dsmHandle (I)
    The handle that associates this call with a previous **dsmInitEx** call.

  dsmEventType_t evenType (I);
    This parameter indicates the event type. See the beginning of this section for the meaning of these possible values: **eventRetentionActivate**, **eventHoldObj**, **eventReleaseObj**

  dsmObjList_t objList;
    This parameter indicates a list of object IDs to signal.

Return codes

The return code numbers are provided in parentheses ( ).

Table 48. Return codes for dsmRetentionEvent

Return code	Explanation
DSM_RC_ABORT_NODE_NOT_AUTHORIZED (36)	The node or user does not have proper authority.
DSM_RC_ABORT_TXN_LIMIT_EXCEEDED (249)	Too many objects in the transaction.
DSM_RC_ABORT_OBJECT_ALREADY_HELD (250)	Object is already held, cannot issue another hold.
DSM_RC_REJECT_SERVER_DOWNLEVEL (58)	The server must be at V5.2.2.0 or later for this function to work.

dsmSendBufferData

The **dsmSendBufferData** function call sends a byte stream of data to IBM Storage Protect through a buffer that was provided in a previous **dsmReleaseBuffer** call. The application client can pass any type of data for storage on the server. Usually this data are file data, but it is not limited to file data. You can call **dsmSendBufferData** several times, if the byte stream of data that you are sending is large. Regardless of whether the call succeeds or fails, the buffer is released.

Restriction: When you use the *useTsmBuffers* option, even if an object is included for compression, the object is not compressed.

Syntax

```
dsInt16_t  dsmSendBufferData  (sendBufferDataIn_t      *dsmSendBufferDataExInP,
                               sendBufferDataOut_t     *dsmSendBufferDataOutP) ;
```

Parameters

sendBufferDataIn_t * dsmSendBufferDataInP (I)
This structure contains the following input parameters.

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

dsUint8_t tsmBufferHandle(I)
The handle that identifies the buffer to send.

char *dataPtr(I)
The address to which application data was written.

dsUint32_t numBytes(I)
The actual number of bytes written by the application (should always be less than the value provided in **dsmReleaseBuffer**).

Return codes

The return code numbers are provided in parentheses ( ).

Table 49. Return codes for dsmSendBufferData

Return code	Explanation
DSM_RC_BAD_CALL_SEQUENCE (2041)	The call was not issued in the proper state.
DSM_RC_INVALID_TSMBUFFER (2042)	The handle or the value of **dataPtr** are invalid.
DSM_RC_BUFF_ARRAY_ERROR (2045)	A buffer array error occurred.
DSM_RC_TOO_MANY_BYTES (2043)	The value of *numBytes* is bigger than the size of the buffer provided in the **dsmReleaseBuffer** call.

dsmSendData

The **dsmSendData** function call sends a byte stream of data to IBM Storage Protect through a buffer. The application client can pass any type of data for storage on the server. Usually, these data are file data, but are not limited to such. You can call **dsmSendData** several times, if the byte stream of data that you want to send is large.

Restriction: The application client cannot reuse the buffer that is specified in **dsmSendData** until the **dsmSendData** call returns.

Tip: If IBM Storage Protect returns code 157 (DSM_RC_WILL_ABORT), start a call to **dsmEndSendObj** and then to **dsmEndTxn** with a vote of DSM_VOTE_COMMIT. The application then receives return code 2302 (DSM_RC_CHECK_REASON_CODE) and passes the reason code back to the application user. This informs the user why the server is ending the transaction.

Syntax

```
dsInt16_t dsmSendData  (dsUint32_t   dsmHandle,
    DataBlk *dataBlkPtr);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

DataBlk *dataBlkPtr (I/O)
This parameter points to a structure that includes both a pointer to the buffer from which the data are to be sent, as well as the size of the buffer. On return, this structure contains the number of bytes that is actually transferred. See Appendix B, "API type definitions source files," on page 147 for the type definition.

Return codes

The return code numbers are provided in parentheses ( ).

Table 50. Return codes for dsmSendData

Return code	Explanation
DSM_RC_NO_COMPRESS_MEMORY (154)	Insufficient memory available to perform data compression or expansion.
DSM_RC_COMPRESS_GREW (155)	During compression the compressed data grew in size compared to the original data.
DSM_RC_WILL_ABORT (157)	An unknown and unexpected error occurred, causing the transaction to halt.
DSM_RC_WRONG_VERSION_PARM (2065)	Application client's API version is different than the IBM Storage Protect library version.
DSM_RC_NEEDTO_ENDTXN (2070)	Need to end the transaction.
DSM_RC_OBJ_EXCLUDED (2080)	The include-exclude list excludes the object.
DSM_RC_OBJ_NOBCG (2081)	The object has no backup copy group and will not be sent to the server.
DSM_RC_OBJ_NOACG (2082)	The object has no archive copy group and is not sent to the server.
DSM_RC_SENDDATA_WITH_ZERO_SIZE (2107)	The object cannot send data with a zero byte *sizeEstimate*.

dsmSendObj

The **dsmSendObj** function call starts a request to send a single object to storage. Multiple **dsmSendObj** calls and associated **dsmSendData** calls can be made within the bounds of a transaction for performance reasons.

The **dsmSendObj** call processes the data for the object as a byte stream passed in memory buffers. The **dataBlkPtr** parameter in the **dsmSendObj** call permits the application client to either:

- Pass the data and the attributes (the attributes are passed through the **objAttrPtr**) of the object in a single call.
- Specify part of the object data through the **dsmSendObj** call and the remainder of the data through one or more **dsmSendData** calls.

Alternatively, the application client can specify only the attributes through the **dsmSendObj** call and specify the object data through one or more calls to **dsmSendData**. For this method, set **dataBlkPtr** to NULL on the **dsmSendObj** call.

Tip: For certain object types, byte stream data might not be associated with the data; for example, a directory entry with no extended attributes.

Before **dsmSendObj** is called, a preceding **dsmBindMC** call must be made to properly bind a management class to the object that you want to back up or archive. The API keeps this binding so that it can associate the proper management class with the object when it is sent to the server. If you

permit the management class that is bound on a **dsmSendObj** call to default for an object type of directory (DSM_OBJ_DIRECTORY), the default might not be the default management class. Instead, the management class with the greatest retention time is used. If more than one management class exists with this retention time, the first one that is encountered is used.

Follow all object data that is sent to storage with a **dsmEndSendObj** call. If you do not have object data to send to the server, or all data was contained within the **dsmSendObj** call, start a **dsmEndSendObj** call before you can start another **dsmSendObj** call. If multiple data sends were required through the **dsmSendData** call, the **dsmEndSendObj** follows the last send to indicate the state change.

Tip: If IBM Storage Protect returns code 157 (DSM_RC_WILL_ABORT), start a call to **dsmEndTxn** with a vote of DSM_VOTE_COMMIT. The application receives return code 2302 (DSM_RC_CHECK_REASON_CODE) and passes the reason code back to the application user. This informs the user why the server is ending the transaction.

If the reason code is 11 (DSM_RS_ABORT_NO_REPOSIT_SPACE), it is possible that the *sizeEstimate* is too small for the actual amount of data. The application needs to determine a more accurate *sizeEstimate* and send the data again.

Syntax

```
dsInt16_t dsmSendObj  (dsUint32_t       dsmHandle,
    dsmSendType  sendType,
    void        *sendBuff,
    dsmObjName  *objNameP,
    ObjAttr     *objAttrPtr,
    DataBlk     *dataBlkPtr);
```

Parameters

dsUint32_t dsmHandle (I)
   The handle that associates this call with a previous **dsmInitEx** call.

dsmSendType sendType (I)
   This parameter specifies the type of send that is being performed. Possible values include:

Name	Description
stBackup	A backup object that is sent to the server.
stArchive	An archive object that is sent to the server.
stBackupMountWait	A backup object for which you want the server to wait until the necessary device, such as a tape, is mounted.
stArchiveMountWait	An archive object for which you want the server to wait until the necessary device, such as a tape, is mounted.

   Note: Use the **MountWait** types if there is any possibility that your application user might send data to a tape.

void *sendBuff (I)
   This parameter is a pointer to a structure that contains other information specific to the **sendType** on the call. Currently, only a **sendType** of **stArchive** has an associated structure. This structure is called **sndArchiveData** and it contains the archive description.

dsmObjName *objNameP (I)
   This parameter is a pointer to the structure that contains the file space name, high-level object name, low-level object name, and object type. See "Object names and IDs" on page 20 for more information.

ObjAttr *objAttrPtr (I)
   This parameter passes object attributes of interest to the application. See Appendix B, "API type definitions source files," on page 147 for the type definition.

The attributes are:

- **owner** refers to the owner of the object. Determining whether the owner is declared to be a specific name or an empty string is important when getting the object back from IBM Storage Protect storage. See "Accessing objects as session owner" on page 21 for more information.
- **sizeEstimate** is a best estimate of the total size of the data object to send to the server. Be as accurate as possible on this size, because the server uses this attribute for efficient space allocation and object placement within its storage resources.

  If the size estimate that you specified is significantly smaller than the actual number of bytes that are sent, the server might have difficulty allocating enough space and end the transaction with a reason code of 11 (DSM_RS_ABORT_NO_REPOSIT_SPACE).

  Note: The size estimate is for the total size of the data object in bytes.

  Objects with a size smaller than DSM_MIN_COMPRESS_SIZE do not compress.

  If your object has no bit data (only the attribute information from this call), the **sizeEstimate** should be zero.

  Note: Starting with version 5.1.0, the copy destination within a transaction is not checked for consistency on zero-length objects.
- **objCompressed** is a Boolean value that states whether or not the object data have already been compressed.

  If the object is compressed (object `compressed=bTrue`), IBM Storage Protect does not try to compress it again. If it is not compressed, IBM Storage Protect decides whether to compress the object, based on the values of the `compression` option set by the administrator and set in the API configuration sources.

  If your application plans to use partial object restore or retrieve, you cannot compress the data while sending it. To enforce this, set `ObjAttr.objCompressed` to `bTrue`.
- **objInfo** saves information about the particular object.

  Restriction: Information is not stored here automatically. When this attribute is used, you must set the attribute, `objInfoLength`, to show the length of `objInfo`.
- **mcNameP** contains the name of a management class that overrides the management class that is obtained from **dsmBindMC**.
- **disableDeduplication** is a Boolean value. When it is set to true, this object is not deduplicated by the client.

If the client-side deduplication is enabled and the object that is being sent is a directory, then the object attribute and the object name type must be configured as follows:

```
objAttrArea.disableDeduplication = bTrue;
objName.objType = DSM_OBJ_DIRECTORY;
```

DataBlk *dataBlkPtr (I/O)
This parameter points to a structure that includes both a pointer to the buffer of data that is to be backed up or archived and the size of that buffer. This parameter applies to **dsmSendObj** only. If you want to begin sending data on a subsequent **dsmSendData** call, rather than on the **dsmSendObj** call, set the buffer pointer in the DataBlk structure to NULL. On return, this structure contains the number of bytes that is actually transferred. See Appendix B, "API type definitions source files," on page 147 for the type definition.

Return codes

The return code numbers are provided in parentheses ( ).

Table 51. Return codes for dsmSendObj

Return code	Explanation
DSM_RC_NO_COMPRESS_MEMORY (154)	Insufficient memory available to perform data compression or expansion.
DSM_RC_COMPRESS_GREW (155)	During compression, the compressed data grew in size compared to the original data.
DSM_RC_WILL_ABORT (157)	An unknown and unexpected error occurred, causing the transaction to be halted.
DSM_RC_TL_NOBCG (184)	The management class for this file has no valid backup copy group.
DSM_RC_TL_NOACG (186)	The management class for this file does not have a valid copy group for the send type.
DSM_RC_NULL_OBJNAME (2000)	Null object name.
DSM_RC_NULL_OBJATTRPTR (2004)	Null object attribute pointer.
DSM_RC_INVALID_OBJTYPE (2010)	Invalid object type.
DSM_RC_INVALID_OBJOWNER (2019)	Invalid object owner.
DSM_RC_INVALID_SENDTYPE (2022)	Invalid send type.
DSM_RC_WILDCHAR_NOTALLOWED (2050)	Wildcard characters not allowed.
DSM_RC_FS_NOT_REGISTERED (2061)	File space not registered.
DSM_RC_WRONG_VERSION_PARM (2065)	Application client's API version is different from the IBM Storage Protect library version.
DSM_RC_NEEDTO_ENDTXN (2070)	Need to end transaction.
DSM_RC_OBJ_EXCLUDED (2080)	The include-exclude list excluded the object.
DSM_RC_OBJ_NOBCG (2081)	The object has no backup copy group, and it is not sent to the server.
DSM_RC_OBJ_NOACG (2082)	The object has no archive copy group, and it is not sent to the server.
DSM_RC_DESC_TOOLONG (2100)	Description is too long.
DSM_RC_OBJINFO_TOOLONG (2101)	Object information is too long.
DSM_RC_HL_TOOLONG (2102)	High-level qualifier is too long.
DSM_RC_FILESPACE_TOOLONG (2104)	File space name is too long.
DSM_RC_LL_TOOLONG (2105)	Low-level qualifier is too long.
DSM_RC_NEEDTO_CALL_BINDMC (2301)	**dsmBindMC** must be called first.

dsmSetAccess

The **dsmSetAccess** function call gives other users or nodes access to backup versions or archived copies of your objects, access to all your objects, or access to a selective set. When you give access to

another user, that user can query, restore, or retrieve your files. This command supports wildcards for the following fields: *fs, hl, ll, node, owner*.

Note: You cannot give access to both backup versions and archive copies by using a single command. You must specify either backup or archive.

Syntax

```
dsInt16_t DSMLINKAGE dsmSetAccess
        (dsUint32_t          dsmHandle,
         dsmSetAccessType    accessType,
         dsmObjName          *objNameP,
         char                *node,
         char                *owner);
```

Parameters

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

dsmAccessType accessType (I)
This parameter specifies the type of objects for which you want to give access. Possible values include:

Name	Description
atBackup	Specifies that access is being set to backup objects.
atArchive	Specifies that the access is being set for archive objects.

dsmObjName *objNameP (I)
This parameter is a pointer to the structure that contains the file space name, the high-level object name, and the low-level object name.

Note: To specify all file spaces, use an asterisk (*) for the file space name.

char *node (I)
This parameter is a pointer to the node name for which access is given. For any node, specify an asterisk (*).

char *owner (I)
This parameter is a pointer to the user name on the node to which you gave access. For all users, specify an asterisk (*).

Return codes

The return code numbers are provided in parentheses ( ).

Table 52. Return codes for dsmSetAccess

Return code	Explanation
DSM_RC_INVALID_ACCESS_TYPE (2110)	Invalid access type specified.
DSM_RC_FILE_SPACE_NOT_FOUND (124)	Specified file space was not found on the server.
DSM_RC_QUERY_COMM_FAILURE (2111)	Communication error during server query.
DSM_RC_NO_FILES_BACKUP (2112)	No files were backed up for this file space.
DSM_RC_NO_FILES_ARCHIVE (2113)	No files were archived for this file space.
DSM_RC_INVALID_SETACCESS (2114)	Invalid formulation of set access.

dsmSetUp

The **dsmSetUp** function call overwrites environment variable values. Call **dsmSetUp** before **dsmInitEx**. The values that were passed in the **envSetUp** structure overwrite any existing environment variables or defaults. If you specify NULL for a field, values are taken from the environment. If you do not set a value, the values are taken from the defaults.

Requirements:

1. If you use **dsmSetUp**, always call **dsmTerminate** before **dsmCleanUp**.
2. API instrumentation can only be activated if the testflag INSTRUMENT: API is set in the configuration file and the **dsmSetUp** or **dsmCleanUp** calls are used in the application.

Syntax

```
dsInt16_t DSMLINKAGE dsmSetUp
        (dsBool_t    mtFlag,
         envSetUp    *envSetUpP);
```

Parameters

dsBool_t mtFlag (I)
>   This parameter specifies if the API will be used in a single thread, or a multithread mode. Values include:

```
        DSM_SINGLETHREAD
        DSM_MULTITHREAD
```

>   **Requirement:** The multithread flag must be on for LAN-free data transfer to occur.

envSetUp *envSetUpP(I)
>   This parameter is a pointer to the structure that holds the overwrite values. Specify NULL if you do not want to override existing environment variables. The fields in the **envSetUp** structure include:

Name	Description
dsmiDir	A fully-qualified directory path that contains a message file on UNIX or Linux. It also specifies the dsm.sys directories.
dsmiConfig	The fully-qualified name of the client options file.
dsmiLog	The fully-qualified path of the error log directory.
argv	Pass the argv[0] name of the calling program if the application must run with authorized user authority. See "Controlling access to password files" on page 18 for more information.
logName	The file name for an error log if the application does not use dsierror.log.
inclExclCaseSensitive	Indicates whether include/exclude rules are case-sensitive or case-insensitive. This parameter can be used on Windows only, it is ignored elsewhere.

Return codes

The return code numbers are provided in parentheses ( ).

Table 53. Return codes for dsmSetUp

Return code	Explanation
DSM_RC_ACCESS_DENIED (106)	Access to the specified file or directory is denied.
DSM_RC_INVALID_OPT (0400)	An invalid option was found.
DSM_RC_NO_HOST_ADDR (0405)	The TCPSERVERADDRESS for this server is not defined in the server name stanza in the system options file.
DSM_RC_NO_OPT_FILE (0406)	The options file specified by filename cannot be found.
DSM_RC_MACHINE_SAME (0408)	The NODENAME defined in the options file cannot be the same as the system *HostName*.
DSM_RC_INVALID_SERVER (0409)	The system options file does not contain the SERVERNAME option.
DSM_RC_INVALID_KEYWORD (0410)	An invalid option keyword was found in the **dsmInitEx** configuration file, the option string, dsm.sys, or dsm.opt.
DSM_RC_PATTERN_TOO_COMPLEX (0411)	The include or exclude pattern issued is too complex to be accurately interpreted by IBM Storage Protect.
DSM_RC_NO_CLOSING_BRACKET (0412)	The include or exclude pattern is incorrectly constructed. The closing bracket is missing.
DSM_RC_NLS_CANT_OPEN_TXT (0610)	The system is unable to open the message text file.
DSM_RC_NLS_INVALID_CNTL_REC (0612)	The system is unable to use the message text file.
DSM_RC_NOT_ADSM_AUTHORIZED (0927)	You must be the authorized user to have multithreading and *passwordaccess* generate.
DSM_RC_NO_INCLEXCL_FILE (2229)	The include-exclude file was not found.
DSM_RC_NO_SYS_OR_INCLEXCL (2230)	Either the dsm.sys or the include-exclude file was not found.

dsmTerminate

The **dsmTerminate** function call ends a session with the IBM Storage Protect server and cleans up the IBM Storage Protect environment.

Syntax

There are no return codes that are specific for this call.

```
dsInt16_t dsmTerminate (dsUint32_t dsmHandle);
```

Parameters

dsUint32_t dsmHandle (I)
    The handle that associates this call with a previous **dsmInitEx** call.

dsmUpdateFS

The **dsmUpdateFS** function call updates a file space in IBM Storage Protect storage. This update ensures that the administrator has a current record of your file space.

Syntax

```
dsInt16_t dsmUpdateFS (dsUint32_t      dsmHandle,
    char        *fs,
    dsmFSUpd     *fsUpdP,
    dsUint32_t    fsUpdAct);
```

Parameters

dsUint32_t dsmHandle (I)
　　The handle that associates this call with a previous **dsmInitEx** call.

char *fs (I)
　　This parameter is a pointer to the file space name.

dsmFSUpd *fsUpdP (I)
　　This parameter is a pointer to the structure that has the correct fields for the update that you want. Complete only those fields that need updating.

dsUint32_t fsUpdAct (I)
　　A 2-byte bit map that indicates which of the fields to update. The bit masks have the following values:

- DSM_FSUPD_FSTYPE
- DSM_FSUPD_FSINFO

　　Tip: For Windows operating systems, the drive letter value from **dsmDOSAttrib** is also updated when **FSINFO** is selected.

- DSM_FSUPD_OCCUPANCY
- DSM_FSUPD_CAPACITY
- DSM_FSUPD_BACKSTARTDATE
- DSM_FSUPD_BACKCOMPLETEDATE

For a description of these bit masks, see the DSM_FSUPD definitions in the following topic: .

Return codes

The following table lists return codes for the **dsmUpdateFS** function call.

Table 54. Return codes for dsmUpdateFS

Return code	Return code number	Description
DSM_RC_FS_NOT_REGISTERED	2061	File space name is not registered.
DSM_RC_WRONG_VERSION_PARM	2065	The API version of the application client is different from the IBM Storage Protect library version.
DSM_RC_FSINFO_TOOLONG	2106	File space information is too long.

dsmUpdateObj

The **dsmUpdateObj** function call updates the meta information associated with an active backup or archive object already on the server. The application bit data is not affected. To update an object, you must give a specific non-wildcard name. To update an archived object, set the **dsmSendType** to **stArchive**. Only the latest named archive object is updated.

You can only start the **dsmUpdateObj** call in the session state; it cannot be called inside a transaction because it performs its own transaction. And, you can update only one object at a time.

Restriction: On a UNIX or Linux operating system, if you change the owner field, you cannot query or restore the object unless you are the root user.

Syntax

```
dsInt16_t  dsmUpdateObj
   (dsUint32_t      dsmHandle,
    dsmSendType     sendType,
    void            *sendBuff,
    dsmObjName      *objNameP,
    ObjAttr         *objAttrPtr,  /* objInfo */
    dsUint16_t       objUpdAct);  /* action bit vector */
```

Parameters

The field descriptions are the same as those in **dsmSendObj**, with the following exceptions:

dsmObjName *objNameP (I)
> You cannot use a wildcard.

ObjAttr *objAttrPtr (I)
> The **objCompressed** field is ignored for this call.
>
> Other differences are:
>
> - **owner**. If you specify a new **owner** field, the owner changes.
> - **sizeEstimate**. If you specify a non-zero value it should be the actual amount of data sent, in bytes. The value is stored in the IBM Storage Protect metadata for future use.
> - **objInfo**. This attribute contains the new information to be placed in the **objInfo** field. Set the **objInfoLength** to the length of the new **obiInfo**.

dsUint16_t objUpdAct
> The bit masks and possible actions for **objUpdAct** are:
>
> **DSM_BACKUPD_MC**
> > Updates the management class for the object.
>
> **DSM_BACKUPD_OBJINFO**
> > Updates **objInfo**, **objInfoLength**, and **sizeEstimate**.
>
> **DSM_BACKUPD_OWNER**
> > Updates the owner of the object.
>
> **DSM_ARCHUPD_DESCR**
> > Updates the **Description** field. Enter the value for the new description through the **SendBuff** parameter. See the sample program for proper use.
>
> **DSM_ARCHUPD_OBJINFO**
> > Updates **objInfo**, **objInfoLength**, and **sizeEstimate**.
>
> **DSM_ARCHUPD_OWNER**
> > Updates the owner of the object.

Return codes

The return code numbers are provided in parentheses ( ).

Table 55. Return codes for dsmUpdateObj

Return code	Explanation
DSM_RC_INVALID_ACTION (2232)	Invalid action.
DSM_RC_FS_NOT_REGISTERED (2061)	File space not registered.
DSM_RC_BAD_CALL_SEQUENCE (2041)	Sequence of calls is invalid.
DSM_RC_WILDCHAR_NOTALLOWED (2050)	Wildcard characters are not allowed.
DSM_RC_ABORT_NO_MATCH (2)	Previous query does not match.

dsmUpdateObjEx

The **dsmUpdateObjEx** function call updates the meta information that is associated with an active backup or archive object that is on the server. The application bit data is not affected. To update an object, you must specify a non-wildcard name, or you can specify the object ID to update a specific archived object. You cannot use wildcard characters when specifying the name. To update a backup object, set the **dsmSendType** parameter to **stBackup**. To update an archived object, set the **dsmSendType** parameter to **stArchive**.

You can only start the **dsmUpdateObjEx** call in the session state; it cannot be called inside a transaction because it performs its own transaction. You can update only one object at a time.

Restriction: On a UNIX or Linux operating system, if you change the owner field, you cannot query or restore the object unless you are the root user. Only the current active version of a backup object can be updated.

Syntax

```
dsInt16_t  dsmUpdateObjEx
   (dsmUpdateObjExIn_t   *dsmUpdateObjExInP,
    dsmUpdateObjExOut_t  *dsmUpdateObjExOutP);
```

Parameters

dsmUpdateObjExIn_t *dsmUpdateObjExInP
This structure contains the following input parameters:

dsUint16_t stVersion (I)
The current version of the structure that is used.

dsUint32_t dsmHandle (I)
The handle that associates this call with a previous **dsmInitEx** call.

dsmSendType sendType (I)
The type of send that is being performed. The value can be:

stBackup
A backup object that is sent to the server.

stArchive
An archive object that is sent to the server.

dsmObjName *objNameP (I)
A pointer to the structure that contains the filespace name, high-level object name, low-level object name, and object type. You cannot use a wildcard.

ObjAttr *objAttrPtr (I)
Passes object attributes to the application. The values that are updated depend on the flags in the **objUpdAct** field. The **objCompressed** attribute is ignored for this call.

The attributes are:

- **owner** changes the owner if a new name is entered.
- **sizeEstimate** is the actual amount of data that is sent in bytes. The value is stored in the IBM Storage Protect meta data for future use.
- **objCompressed** is a Boolean value that states whether or not the object data have already been compressed.
- **objInfo** is an attribute that contains the new information to be placed in the **objInfo** field. Set the **objInfoLength** to the length of the new **objInfo**.
- **mcNameP** contains the name of a management class that overrides the management class that is obtained from **dsmBindMC**.

dsUint32_t objUpdAct
Specifies the bit masks and actions for **objUpdAct** are:

DSM_BACKUPD_MC
Updates the management class for the object.

DSM_BACKUPD_OBJINFO
Updates the information object (**objInfo**), the length of the information object (**objInfoLength**), and the amount of data that is sent (**sizeEstimate**) for the backup object.

DSM_BACKUPD_OWNER
Updates the owner for the backup object.

DSM_ARCHUPD_DESCR
Updates the **Description** field for the archive object. Enter the value for the new description through the **sendBuff** parameter.

DSM_ARCHUPD_OBJINFO
Updates the information object (**objInfo**), the length of the information object (**objInfoLength**), and the amount of data that is sent (**sizeEstimate**) for the archive object.

DSM_ARCHUPD_OWNER
Updates the owner of the archive object.

ObjID archObjId
Specifies the unique object ID for a specific archive object. Because multiple archive objects can have the same name, this parameter identifies a specific one. You can obtain the object ID by using a query archive call.

dsmUpdateObjExOut_t *dsmUpdateObjExOutP
This structure contains the output parameter:

dsUint16_t stVersion (I)
The current version of the structure that is used.

Return codes

The return code numbers are provided in parentheses ( ) in the following table.

Table 56. Return codes for dsmUpdateObjEx

Return code	Explanation
DSM_RC_INVALID_ACTION (2012)	Invalid action.
DSM_RC_FS_NOT_REGISTERED (2061)	File space not registered.
DSM_RC_BAD_CALL_SEQUENCE (2041)	Sequence of calls is invalid.
DSM_RC_WILDCHAR_NOTALLOWED (2050)	Wildcard characters are not allowed.
DSM_RC_ABORT_NO_MATCH (2)	Previous query does not match.

Appendix A. API return codes source file: `dsmrc.h`

The `dsmrc.h` header file contains all return codes that the API can return to an application.

The information that is provided here contains a point-in-time copy of the `dsmrc.h` file that is distributed with the API. View the file in the API distribution package for the latest version.

Appendix B. API type definitions source files

This appendix contains structure definitions, type definitions, and constants for the API.

- The first header files, `dsmapitd.h` and `tsmapitd.h`, illustrate the definitions that are common to all operating systems.
- The second header file, `dsmapips.h`, provides an example of definitions that are specific to a particular operating system; in this example, the Windows platform.
- The third header file, `release.h`, includes the version and release information.

The information that is provided here contains a point-in-time copy of the files that are distributed with the API. View the files in the API distribution package for the latest version.

dsmapitd.h

 *                   *********************************************
 *
 * Design Notes:     This file contains basic data types and constants
 *                   includable by all client source files. The constants
 *                   within this file should be set properly for the
 *                   particular machine and operating system on which the
 *                   client software is to be run.
 *
 *                   Platform specific definitions are included in dsmapips.h
 *
 * Descriptive-name: Definitions for IBM Storage Protect API constants

Appendix C. API function definitions source file

This appendix contains the `dsmapifp.h` header file, so you can see the function definitions for the API.

Note: DSMLINKAGE is defined differently for each operating system. See the definitions in the `dsmapips.h` file for your specific operating system.

The information that is provided here contains a point-in-time copy of the files that are distributed with the API. View the files in the API distribution package for the latest version.

dsmapifp.h

Appendix D. Accessibility features for the IBM Storage Protect product family

Accessibility features assist users who have a disability, such as restricted mobility or limited vision, to use information technology content successfully.

Overview

The IBM Storage Protect family of products includes the following major accessibility features:

- Keyboard-only operation
- Operations that use a screen reader

The IBM Storage Protect family of products uses the latest W3C Standard, WAI-ARIA 1.0 (www.w3.org/TR/wai-aria/), to ensure compliance with US Section 508 and Web Content Accessibility Guidelines (WCAG) 2.0 (www.w3.org/TR/WCAG20/). To take advantage of accessibility features, use the latest release of your screen reader and the latest web browser that is supported by the product.

The product documentation in IBM Documentation is enabled for accessibility.

Keyboard navigation

This product uses standard navigation keys.

Interface information

User interfaces do not have content that flashes 2 - 55 times per second.

Web user interfaces rely on cascading style sheets to render content properly and to provide a usable experience. The application provides an equivalent way for low-vision users to use system display settings, including high-contrast mode. You can control font size by using the device or web browser settings.

Web user interfaces include WAI-ARIA navigational landmarks that you can use to quickly navigate to functional areas in the application.

Vendor software

The IBM Storage Protect product family includes certain vendor software that is not covered under the IBM license agreement. IBM makes no representation about the accessibility features of these products. Contact the vendor for accessibility information about its products.

Related accessibility information

In addition to standard IBM help desk and support websites, IBM has a TTY telephone service for use by deaf or hard of hearing customers to access sales and support services:

TTY service
800-IBM-3383 (800-426-3383)
(within North America)

For more information about the commitment that IBM has to accessibility, see IBM Accessibility (www.ibm.com/able).

Notices

This information was developed for products and services offered in the US. This material might be available from IBM in other languages. However, you may be required to own a copy of the product or product version in that language in order to access it.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing
IBM Corporation
North Castle Drive, MD-NC119
Armonk, NY 10504-1785
US

For license inquiries regarding double-byte character set (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Intellectual Property Licensing
Legal and Intellectual Property Law
IBM Japan Ltd.
19-21, Nihonbashi-Hakozakicho, Chuo-ku
Tokyo 103-8510, Japan

INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some jurisdictions do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM websites are provided for convenience only and do not in any manner serve as an endorsement of those websites. The materials at those websites are not part of the materials for this IBM product and use of those websites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

IBM Director of Licensing
IBM Corporation
North Castle Drive, MD-NC119
Armonk, NY 10504-1785
US

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

The performance data discussed herein is presented as derived under specific operating conditions. Actual results may vary.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

Each copy or any portion of these sample programs or any derivative work must include a copyright notice as follows: © (your company name) (year). Portions of this code are derived from IBM Corp. Sample Programs. © Copyright IBM Corp. _enter the year or years_.

Trademarks

IBM, the IBM logo, and ibm.com® are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the Web at "Copyright and trademark information" at www.ibm.com/legal/copytrade.shtml.

Adobe is a registered trademark of Adobe Systems Incorporated in the United States, and/or other countries.

Linear Tape-Open, LTO, and Ultrium are trademarks of HP, IBM Corp. and Quantum in the U.S. and other countries.

Intel and Itanium are trademarks or registered trademarks of Intel Corporation or its subsidiaries in the United States and other countries.

The registered trademark Linux is used pursuant to a sublicense from the Linux Foundation, the exclusive licensee of Linus Torvalds, owner of the mark on a worldwide basis.

Microsoft, Windows, and Windows NT are trademarks of Microsoft Corporation in the United States, other countries, or both.

Java™ and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle and/or its affiliates.

Red Hat®, OpenShift®, Ansible®, and Ceph® are trademarks or registered trademarks of Red Hat, Inc. or its subsidiaries in the United States and other countries.

UNIX is a registered trademark of The Open Group in the United States and other countries.

VMware, VMware vCenter Server, and VMware vSphere are registered trademarks or trademarks of VMware, Inc. or its subsidiaries in the United States and/or other jurisdictions.

Terms and conditions for product documentation

Permissions for the use of these publications are granted subject to the following terms and conditions.

Applicability

These terms and conditions are in addition to any terms of use for the IBM website.

Personal use

You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

Commercial use

You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

Rights

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or, as determined by IBM, the above instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM MAKES NO GUARANTEE ABOUT THE CONTENT OF THESE PUBLICATIONS. THE PUBLICATIONS ARE PROVIDED "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT, AND FITNESS FOR A PARTICULAR PURPOSE.

Privacy policy considerations

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user, or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth below.

This Software Offering does not use cookies or other technologies to collect personally identifiable information.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, see IBM's Privacy Policy at http://www.ibm.com/privacy and IBM's Online Privacy Statement at http://www.ibm.com/privacy/details in the section entitled "Cookies, Web Beacons and Other Technologies," and the "IBM Software Products and Software-as-a-Service Privacy Statement" at http://www.ibm.com/software/info/product-privacy.
