- **Contents** of type `xIdNode *`. This is an array containing references to the `xSrvIdNodes` of the services and service instances in this process.

- **ToId** of type `xIdNode *`. This is an array of `xIdNode`, where each array component is a pointer to an IdNode representing an SDL object that this process or process instance is connected to (connected to in the sense: to the SDL objects that signals are sent forward to).

  The SDL objects that may be referenced in `ToId` are channels, signal routes, gates, processes, and services. The last component in the array is always a `NULL` pointer (the value `(xIdNode)0`). See also section "Channels and Signal Routes" on page 3106.

- **MaxNoOfInst** of type `int`. This represents the maximum number of concurrent processes that may exist according to the specification for the current process or process instance. An infinite number of concurrent processes is represented by -1.

- **NextNo** of type `int`. This is the instance number that will be assigned to the next instance that is created of this process instance set.

- **NoOfStaticInst** of type `int`.This component contains the number of static instance of this process instance set that should be present at start up. Used for process and process instance.

- **ActivePrsList** of type `xPrsNode *`. This is the address of a pointer to the "first" in the (single linked) list of active process instances of the current process or process instantiation.

The list is continued using the `NextPrs` component in the `xPrsRec` struct that is used to represent a process instance. The order in the list is such that the first created of the active process instances is last, and the latest created is first.

- **`VarSize`** of type `xptrint`. The size, in bytes, of the data area used to represent the process (the struct: `yVDef_`*`ProcessName`*).
- **`Prio`** of type `int`. This represents the process priority.
- **`AvailPrsList`** of type `xPrsNode`. This is the address to the avail list pointer for process instances that have stopped. The data area can later be reused in subsequent Create actions on this process or process instantiation.
- **`Trace_Default`** of type `int`. This component contains the current value of the trace defined for the process.
- **`GRTrace`** of type `int`. This component contains the current value of the GR trace defined for the process.
- **`GRrefFunc`**, which is a pointer to a function that, given a symbol number (number assigned to a process symbol), will return a string containing the SDT reference to that symbol.
- **`MaxSymbolNumber`** of type `int`. This component is the number of symbols contained in the current process or process type.
- **`SignalSetLength`** of type `int`. This component is the number of signals contained in the signal set of the current process or process type.
- **`MSCETrace`** of type `int`. This component contains the current MSCE (Message Sequence Chart Editor) trace value defined for the process.
- **`CoverageArray`** of type `long int *`. This component is used as an array over all symbols in the process. Each time a symbol is executed the corresponding array component is increased by 1.
- **`NoOfStartTransitions`** of type `long int`. This component is used to count the number of times the start transition of the current process is executed. This information is presented in the coverage tables.

- **MaxQueueLength** of type `long int`. This component is used to register the maximum input port length for any instance of the current process. The information is presented in the coverage tables.
- **PAD_Function**, which is a pointer to a function. This pointer refers to the `yPAD_`*`ProcessName`* function for the current process. This function is called when a process instance of this type is to execute a transition. The `PAD_Functions` will of course be part of generated code, as they contain the action defined in the process graphs.
- **Free_Vars**, which is a pointer to a function. This pointer refers to the `yFree_`*`ProcessName`* function for the current process. This function is called when the process performs a stop action to deallocate memory used by the local variables in the process.
- **Super** of type `xPrsIdNode`. In a process this component is `NULL`. In a process type this component is a reference to the process type that this process type inherits from (`NULL` if no inheritance). In a process instance set, this is a reference to the process type that is instantiated.
- **VirtPrdList** of type `xPrdIdNode *`. This is a list of all virtual procedures in this process instantiation.
- **InBlockInst** of type `xBlockIdNode`. This component is a reference to the block instance set (if any) that this process or process instantiation is part of.
- **RefToDefinition** of type `char *`. This is the SDT reference to this process.

Service, Service Type, Service Instance

- **StateList** of type `xStateIdNode *`. This is a list of the references to the `xStateIdNodes` for this service or service type. Using the state value of an executing service, this list can be used to find the corresponding `xStateIdNode`.
- **SignalSet** of type `xIdNode *`. This represents the valid input signal set of the service or service type.

  `SignalSet` is an array with components that refer to `xSignalIdNodes` that represent the signals and timers which are part of the signal set. The last component in the array is always a `NULL` pointer (the value `(xSignalIdNode)0`).

- **ToId** of type `xIdNode *`. This is an array of `xIdNode`, where each array component is a pointer to an IdNode representing an SDL object that this service or service instance is connected to (connected to in the sense: to the SDL objects that signals are sent forward to).

  The SDL objects that may be referenced in `ToId` are channels, signal routes, gates, processes, and service. The last component in the array is always a `NULL` pointer (the value `(xIdNode)0)`. See also section "Channels and Signal Routes" on page 3106.

- **VarSize** of type `xptrint`. The size, in bytes, of the data area used to represent the service (the struct: `yVDef_`*`ServiceName`*).

- **GRrefFunc**, which is a pointer to a function that, given a symbol number (number assigned to a service symbol), will return a string containing the SDT reference to that symbol.

- **MaxSymbolNumber** of type `int`. This component is the number of symbols contained in the current service or service type.

- **SignalSetLength** of type `int`. This component is the number of signals contained in the signal set of the current service or service type.

- **CoverageArray** of type `long int`. This component is used as an array over all symbols in the service. Each time a symbol is executed the corresponding array component is increased by 1.

- **NoOfStartTransitions** of type `long int`. This component is used to count the number of times the start transition of the current service is executed. This information is presented in the coverage tables.

- **AvailSrvList** of type `xSrvNode`. This is the address to the avail list pointer for service instances that have stopped. The data area can later be reused.

- **PAD_Function**, which is a pointer to a function. This pointer refers to the `yPAD_`*`ServiceName`* function for the current service. This function is called when a service instance of this type is to execute a transition. The `PAD_Functions` will of course be part of generated code, as they contain the action defined in the service graphs.

- **Free_Vars**, which is a pointer to a function. This pointer refers to the `yFree_`*`SeriveName`* function for the current service. This func-

tion is called when the service performs a stop action to deallocate memory used by the local variables in the service.

- **Super** of type xSrvIdNode. In a service this component is NULL. In a service type this component is a reference to the service type that this service type inherits from (NULL if no inheritance). In a service instantiation this is a reference to the service type that is instantiated.
- **VirtPrdList** of type xPrdIdNode *. This is a list of all virtual procedures in this service instantiation.

Procedure, Operator Diagram, Compound Statement

Note that operator diagrams and compound statements containing variable declarations are treated as procedures. However, such objects can, for example, not contain states.

- **StateList** of type xStateIdNode *. This is a list of references to the xStateIdNodes for this process or process type. Using the state value of an executing process, this list can be used to find the corresponding xStateIdNode.
- **SignalSet** of type xIdNode *. This represents the valid input signal set of the process or process type.

  SignalSet is an array with components that refer to xSignalIdNodes that represent the signals and timers which are part of the signal set. The last component in the array is always a NULL pointer (the value (xSignalIdNode)0).
- **Assoc_Function**, which is a pointer to a function. This pointer refers to the *yProcedureName* function for the current procedure. This function is called when the SDL procedure is called and will execute the appropriate actions. The *yProcedureName* functions will, of course, be part of generated code as they contain the action defined in the procedure graphs.
- **Free_Vars**, which is a pointer to a function. This pointer refers to the yFree_*ProcedureName* function for the current procedure. This function is called when the procedure performs a return action to deallocate memory used by the local variables in the procedure.
- **VarSize** of type xptrint. The size, in bytes, of the data area used to represent the procedure (struct yVDef_*ProcedureName*).

- **AvailPrdList** of type `xPrdNode *`. This is the address of the avail list pointer for the data areas used to represent procedure instances. At a return action the data area is placed in the avail list and can later be reused in subsequent Calls of this procedure type.
- **GRrefFunc**, which is a pointer to a function that given a symbol number (number assigned to a procedure symbol) will return a string containing the SDT reference to that symbol.
- **MaxSymbolNumber** of type `int`. This component is the number of symbols contained in the current procedure.
- **SignalSetLength** of type `int`. This component is the number of signals contained in the signal set of the current procedure.
- **CoverageArray** of type `long int`. This component is used as an array over all symbols in the procedure. Each time a symbol is executed the corresponding array component is increased by 1.
- **Super** of type `xPrdIdNode`. This component is a reference to the procedure that this procedure inherits from (`NULL` if no inheritance).
- **VirtPrdList** of type `xPrdIdNode *`. This is a list of all virtual procedures in this procedure.

Remote Procedure

- **RemoteList** of type `xRemotePrdListNode`. This component is the start of a list of all processes that exports this procedure. This list is a linked list of `xRemotePrdListStructs`, where each node contains a reference to the exporting process.

Signal, Timer, StartUpSignal, and RPC Signals

- **VarSize** of type `xptrint`. The size, in bytes, of the data area used to represent the signal (the struct: `yPDef_`*`SignalName`*).
- **AvailSignalList** of type `xSignalNode *`. This is the address to the avail list pointer for signal instances of this signal type.
- **Equal_Timer**, which is a pointer to a function. This pointer only refers to a function when this node is used to represent a timer with parameters.

  In this case the referenced function can be used to investigate if the parameters of two timers are equal or not, which is necessary at reset

actions. The `Equal_Timer` functions will be part of generated code. These functions are called from the functions `xRemoveTimer` and `xRemoveTimerSignal`, both defined in `sctsdl.c`

- **`Free_Signal`**, which is a function. This function takes a signal reference and returns any dynamic data referenced from the signal parameters to the pool of available memory.
- **`RefToDefinition`** of type `char *`. The SDT reference to the definition of the signal or timer.
- **Prio**, of type int. The priority of the signal.

State

- **`StateNumber`** of type `int`. The int value used to represent this state.
- **`SignalHandlArray`** of type `xInputAction` *. This component refers to an array of `xInputAction`, where `xInputAction` is an enum type with the possible values `xDiscard`, `xInput`, `xSave`, `xEnablCond`, `xPrioInput`.

  The array will have the same number of components as the `SignalSet` array in the node representing the process in which this state is contained. Each position in the `SignalHandlArray` represents the way the signal in the corresponding position in the `SignalSet` array in the process should be treated in this state.

  The last component in the `SignalHandlArray` is equal to `xDiscard`, which corresponds to the `0` value last in the `SignalSet`.

  If the `SignalHandlArray` contains the value `xInput`, `xSave`, or `xDiscard` at a given index, the way to handle the signal is obvious. If the `SignalHandlArray` contains the value `xEnablCond`, it is, however, necessary to calculate the enabling condition expression to know if the signal should cause an input or should be saved. This calculation is exactly the purpose of the `EnablCond_Function` described below.
- **`InputRef`** of type `int *`. This component is an array. If the `SignalHandlArray` contains `xInput`, `xPrioInput`, or `xEnablCond` at a certain index, this `InputRef` contains the symbol number for the corresponding input symbol in the graph.

- **EnablCond_Function**, which is a function that returns xInputAction. If the state contains any enabling conditions, this pointer will refer to a function. Otherwise it refers to 0. An EnablCond_Function takes a reference to an xSignalIdNode (referring to a signal) and a reference to a process instance and calculates the enabling condition for the input of the current signal in the current state of the given process instance.

  The function returns either of the values xInput or xSave. The EnablCond_Functions will of course be part of generated code, as they contain enabling condition expressions. These functions are called from the function xFindInputAction in the file sctsdl.c. xFindInputAction is used by the SDL_Output and SDL_Nextstate functions.

- **ContSig_Function**, which is a function returning int. If the state contains any continuous signals, this pointer will refer to a function. Otherwise it refers to 0.

- **StateProperties** of type int. In this component the three least significant bits are used to indicate:

  – If any enabling condition or continuous signal expression in the state contains a reference to an object that might change its value even though the process does not execute any actions.
  – If there are any priority inputs in the state.
  – If there are any virtual priority inputs in the state.

  Objects according to the first item in the list are: Now, Active (timer is active), Import, View, and Sender. StateProperties is used in the function SDL_Nextstate to take appropriate actions when a process enters a state.

- **CoverageArray** of type long int. This component is used as an array over the signalset (+1) of the process. Each time an input operation is performed, the corresponding array component is increased by 1. The last component, at index equal to the length of the signalset, is used to record the number of continuous signals “received” in the state. The information stored in this component is presented in the coverage table.

- **Super** of type xPrdIdNode. This component is a reference to the procedure that this procedure inherits from (NULL if no inheritance).

- **RefToDefinition** of type `char *`. The SDT reference to the definition of the state (one of the symbols where this state is defined).

Sort and Syntype

- **Free_Function**, which is a function. This function pointer is non-`0` for types represented using dynamic memory (Charstring, Octet_string, Strings, Bags, for example). The `Free_Functions` are used to return dynamic memory to the pool of dynamic memory.
- **Test_Function**, which is a function returning `xbool`. This function is non-0 for all types containing range conditions. The function pointers are used by the monitor system to check the validity of a value when assigning it to a variable.
- **SortSize** of type `xptrint`. This component represents the size, in bytes, of a variable of the current sort.
- **SortType** of type `xTypeOfSort`. This component indicates the type of sort. Possible values are: `xPredef`, `xUserdef`, `xEnum`, `xStruct`, `xArray`, `xGArray`, `xCArray`, `xRef`, `xString`, `xPowerSet`, `xBag`, `xGPowerSet`, `xInherits`, `xSyntype`, `xUnion`, `xUnionC`, and `xChoice`.

SortType is `xArray, xGArray, xCArray`

- **CompOrFatherSort** of type `xSortIdNode`. This is a pointer to the `SortIdNode` that represents the component sort.
- **IndexSort** of type `xSortIdNode`. This is a pointer to the `SortIdNode` that represents the index sort. In a xCArray the index sort in always Integer.
- In xGArray, **LowestValue** is used as the offset of `Data` in the `xxx_ystruct`.
  In xArray and xCArray it is 0.
- In xGArray, **HighestValue** is used as the size of the `xxx_ystruct`.
  In xArray it is 0.
  In xCArray it is the highest index, i.e. the Length - 1.
- In xGArray, **yrecIndexOffset** is used as the offset of `Index` in the `xxx_ystruct`.
  In xArray and xCArray it is 0.

- In xGArray, **yrecDataOffset** is used as the offset of `Data` in the type (i.e. the value representing the default value).
  In xArray and xCArray it is 0.

SortType is `xString, xGPowerSet, xBag`

- **`CompOrFatherSort`** of type `xSortIdNode`. This is a pointer to the `SortIdNode` that represents the component sort.
- **`LowestValue`** is used as the offset of `Data` in the `xxx_ystruct`.
- **`HighestValue`** is used as the size of the `xxx_ystruct`.

SortType is `xPowerSet, xRef, xOwn, xORef`

- **`CompOrFatherSort`** of type `xSortIdNode`. This is a pointer to the `SortIdNode` that represents the component sort.

SortType is `xInherits`

- **`CompOrFatherSort`**, of type `xSortIdNode`. This is a pointer to the `SortIdNode` that represents the inherited sort.

SortType is `xSyntype`

- **`CompOrFatherSort`,** of type `xSortIdNode`. This is a pointer to the `SortIdNode` that represents the father sort (the newtype from which the syntype originates, even if it is a syntype of a syntype).
- **`IndexSort`**, of type `xSortIdNode`. This is a pointer to the SortIdNode that represents the represents the father sort (the newtype or syntype from which the syntype originates).
- **`LowestValue`**, of type `long int`. If the syntype can be used as an index in an array (translated to a C array) then this value is the lowest value in the syntype range, otherwise it is 0.
- **`HighestValue`**, of type `long int`. If the syntype can be used as an index in an array (translated to a C array) then this value is the highest value in the syntype range, otherwise it is 0. The `LowestValue` and `HighestValue` are used by the monitor when it handles arrays with this type as index type.

Variable, FormalPar, SignalPar, and Struct Components

- **`SortNode`** of type `xSortIdNode`. This component is a pointer to the SortIdNode that represents the sort of this variable or parameter.
- **`Offset`** of type `xptrint`. This component represents the offset, in bytes, within the struct that represents the process or procedure variables, the signal parameter, or the SDL struct. In other words, this is the relative place of this component within the struct.
- **`Offset2`** of type `xptrint`. For a formal parameter in a process this component represents the offset, in bytes, of a formal parameter in the `StartUpSignal`. For an exported variable in a process this component represents the offset, in bytes, of the exported value for this variable.
- **`IsAddress`** of type `int`. This component is only used for procedure and operator formal parameters and is then used to indicate if the parameter in IN or IN/OUT or a result variable.

Remote Variable

- **`SortSize`** of type `xptrint`. This component is the size of the type of the exported variables.
- **`RemoteList`** of type `xRemoteVarListNode`. This component is the start of a list of all processes that exports this variable. This list is a linked list of `xRemoteVarListStruct`s, where each node contains a reference to the exporting process and the `Offset` where to find the exported value.

Type Info Nodes

This section describes the most important implementation details regarding the type info node. Type info nodes are data structures that are used during run-time by the functions providing generic implementations of SDL operators. As the type info nodes contain essentially the same information as the xSortIdNodes, the type info nodes are used in more and more places in the code where xSortIdNode previously were used. In the longer perspective the xSortIdNode will be removed completely.

The type definitions that describe the type info nodes are listed in the `sctpred.h` file.

Each type info node is a struct that consists of:

- general components that are available for all type info nodes
- type-specific components that describe each specific type.

The following utility macros can be used to configure the type info nodes:

```
#ifndef T_CONST
#define T_CONST const
#endif

#ifndef T_SDL_EXTRA_COMP
#define T_SDL_EXTRA_COMP
#define T_SDL_EXTRA_VALUE
#endif

#ifndef T_SDL_USERDEF_COMP
#define T_SDL_USERDEF_COMP
#endif

#if defined(XREADANDWRITEF) && !defined(T_SDL_NAMES)
#define T_SDL_NAMES
#endif

#ifdef T_SDL_NAMES
#define T_SDL_Names(P) , P
#else
#define T_SDL_Names(P)
#endif

#ifdef T_SIGNAL_SDL_NAMES
#define T_Signal_SDL_Names(P) , P
#else
#define T_Signal_SDL_Names(P)
#endif

#ifdef T_SDL_INFO
#define T_SDL_Info(P) , P
#else
#define T_SDL_Info(P)
#endif

#ifndef XNOUSE_OPFUNCS
#define T_SDL_OPFUNCS(P) , P
#else
#define T_SDL_OPFUNCS(P)
#endif

struct tSDLFuncInfo;
```

General Components

The following components are available for all type info nodes. The definition of the components is only listed in this section, but it is valid for each type info node listed in the next section.

```
/* --- General type information for SDL types --- */

typedef T_CONST struct tSDLTypeInfoS {
  tSDLTypeClass   TypeClass;
  unsigned char   OpNeeds;
  xptrint         SortSize;
  struct tSDLFuncInfo *OpFuncs;
  T_SDL_EXTRA_COMP
#ifdef T_SDL_NAMES
  char           *Name;
#endif
#ifdef XREADANDWRITEF
  xIdNode         FatherScope;
  xSortIdNode     SortIdNode;
#endif
} tSDLTypeInfo;
```

- **TypeClass**: This component defines which type the info node describes. A list of available types and their corresponding values can be found in the enum type definition below:

```
typedef enum
{
  /*SDL - standard types*/
  type_SDL_Integer=128,
  type_SDL_Real=129,
  type_SDL_Natural=130,
  type_SDL_Boolean=131,
  type_SDL_Character=132,
  type_SDL_Time=133,
  type_SDL_Duration=134,
  type_SDL_Pid=135,
  type_SDL_Charstring=136,
  type_SDL_Bit=137,
  type_SDL_Bit_string=138,
  type_SDL_Octet=139,
  type_SDL_Octet_string=140,
  type_SDL_IA5String=141,
  type_SDL_NumericString=142,
  type_SDL_PrintableString=143,
  type_SDL_VisibleString=144,
  type_SDL_NULL=145,
  type_SDL_Object_identifier=146,

  /* SDL - standard ctypes */
  type_SDL_ShortInt=150,
  type_SDL_LongInt=151,
```

```
    type_SDL_UnsignedShortInt=152,
    type_SDL_UnsignedInt=153,
    type_SDL_UnsignedLongInt=154,
    type_SDL_Float=155,
    type_SDL_Charstar=156,
    type_SDL_Voidstar=157,
    type_SDL_Voidstarstar=158,

    /* SDL - user defined types */
    type_SDL_Syntype=170,
    type_SDL_Inherits=171,
    type_SDL_Enum=172,
    type_SDL_Struct=173,
    type_SDL_Union=174,
    type_SDL_UnionC=175,
    type_SDL_Choice=176,
    type_SDL_ChoicePresent=177,
    type_SDL_Powerset=178,
    type_SDL_GPowerset=179,
    type_SDL_Bag=180,
    type_SDL_String=181,
    type_SDL_LString=182,
    type_SDL_Array=183,
    type_SDL_Carray=184,
    type_SDL_GArray=185,
    type_SDL_Own=186,
    type_SDL_Oref=187,
    type_SDL_Ref=188,
    type_SDL_Userdef=189,
    type_SDL_EmptyType=190,

    /* SDL - signals */
    type_SDL_Signal=200,
    type_SDL_SignalId=201

} tSDLTypeClass;
```

- **OpNeeds**: This component contains four bits that give the properties of the type regarding assignment, equal test, free function, and initialization.

  – The first bit indicates if the type is a pointer that needs to be automatically freed, or if it contains a pointer that needs to be au-

tomatically freed. If the first bit is set, it is necessary to look for memory to be freed inside of a value of this type.
- The second bit indicates if memcmp can be used to test if two values of this type are equal or not. If the bit is set, special treatment is needed.
- The third bit indicates if memcpy can be used to perform assign of this type. If the bit is set, special treatment is needed.
- The fourth bit indicates if this type needs to be initialized to anything else than 0.

The following macros can be used to test these properties:

```
#define NEEDSFREE(P) \
  (((tSDLTypeInfo *)(P))->OpNeeds & (unsigned char)1)
#define NEEDSEQUAL(P) \
  (((tSDLTypeInfo *)(P))->OpNeeds & (unsigned char)2)
#define NEEDSASSIGN(P) \
  (((tSDLTypeInfo *)(P))->OpNeeds & (unsigned char)4)
#define NEEDSINIT(P) \
  (((tSDLTypeInfo *)(P))->OpNeeds & (unsigned char)8)
```

- **SortSize**: This component defines the size of the type.
- **OpFuncs**: This is a pointer to a struct containing references to specific assign, equal, free, read, and write functions. This component is only used in special cases. If assign, equal, free, read or write functions have been implemented using #ADT directives, information about this is stored in the OpFuncs field. The default value of the OpFuncs field is 0, but if you have provided any of these functions, the field will be a pointer to a tSDLFuncInfo struct. This struct will in turn refer to the provided functions.

```
typedef struct tSDLFuncInfo {
  void *(*AssFunc) (void *, void *, int);
  SDL_Boolean (*EqFunc) (void *, void *);
  void (*FreeFunc) (void **);
#ifdef XREADANDWRITEF
  char *(*WriteFunc) (void *);
  int (*ReadFunc) (void *);
#endif
} tSDLFuncInfo;
```

- **Name**: This is the name of the type as a string literal.
- **FatherScope**: This is a pointer to the IdNode for the scope that the type is defined in.
- **SortIdNode**: This is a pointer to the xSortIdNode that describes the same type. This field will in a longer perspective be removed.

Type Info Node Optimization

Depending on the operations used for data types in the translated system, some of the type info nodes might not be needed. The purpose of this described optimization is to remove such type info nodes.

The first step is to surround all type info nodes with #ifdefs according to the example for the predefined type integer below.

```
 #ifndef XTNOUSE_Integer
tSDLTypeInfo ySDL_SDL_Integer = {
  ....
  };
#endif
```

This means that the type info node for integer can be removed by defining XTNOUSE_Integer.

The names for the predefined data types in the `#ifndef` statements are:

```
#ifndef XTNOUSE_Integer
#ifndef XTNOUSE_Real
#ifndef XTNOUSE_Natural
#ifndef XTNOUSE_Boolean
#ifndef XTNOUSE_Character
#ifndef XTNOUSE_Time
#ifndef XTNOUSE_Duration
#ifndef XTNOUSE_Pid
#ifndef XTNOUSE_Charstring
#ifndef XTNOUSE_Bit
#ifndef XTNOUSE_Bit_string
#ifndef XTNOUSE_Octet
#ifndef XTNOUSE_Octet_string
#ifndef XTNOUSE_IA5String
#ifndef XTNOUSE_NumericString
#ifndef XTNOUSE_PrintableString
#ifndef XTNOUSE_VisibleString
#ifndef XTNOUSE_NULL
#ifndef XTNOUSE_Object_identifier
```

For user defined types the name is selected according to the following algorithm.

1. If the type name is unique (case sensitive, as C is case sensitive), that is there is only one data type in the system with this name, then name in the `#ifndef` will be:

```
XTNOUSE_typename
```

2. If the type name is not unique but type name plus the name of the scope where the type is defined is unique, the name in the `#ifndef` will be:

```
XTNOUSE_typename_scopename
```

3. In other cases the name in the `#ifndef` will be:

```
XTNOUSE_typename-with-prefix-or-suffix
```

Using only this part of the algorithm it is of course possible to manually write a `.h` file with the suitable defines to remove the type info nodes that are not used. The compiler/linker can help finding unused data.

However the code generator calculates the usage of type info nodes. This information will be stored in the file:

```
sdl_cfg.h
```

The last section in this file will contain the defines for the usage of type info nodes.

Example 509: Usage of type info nodes

```
 #ifdef XUSE_TYPEINFONODE_CFG
/* Type info node configuration */
#define XTNOUSE_Boolean
#define XTNOUSE_Character
#define XTNOUSE_Charstring
/* NOT #define XTNOUSE_Integer*/
....
....
/* NOT #define XTNOUSE_s*/
#endif
```

For every data type in the system there will be one line indicating if the type info node is used or not. Please note also that it is necessary to define XUSE_TYPEINFONODE_CFG at compilation, otherwise the automatically computed type info node optimization will not be used.

The file sdl_cfg.h is automatically included and used in Cmicro. In Cadvanced and C Code Generator the following code can be found in sctypes.h:

```
#ifdef USER_CONFIG
#include "sct_mcf.h"
#elif defined(AUTOMATIC_CONFIG)
#include "sdl_cfg.h"
#endif
```

So by defining USER_CONFIG and including sdl_cfg.h in sct_mcf.h or by defining AUTOMATIC_CONFIG the computed type info node optimization is used.

Sometimes the automatic computation on used type info nodes might fail. The most obvious case is usage inside inline C code. As the code generator does not parse such code, it has no chance to know of such usage. To cope with these situations the user has the possibility to tell the code generator that certain type info nodes are used, and thereby also the nodes that the particular node depends on. It is of course possible for a user to manually handle these situations be inserting proper #define and `#undef` after the type info node configuration. However this might prove difficult due to all the dependencies between type info nodes.

A user can tell the code generator that certain type info nodes are used by specifying this in a file. The code generator will look for such a file according to the following:

If the environment variable TAU_TYPEINFOCFG is defined, the value of this variable is treated as a file name (including path) and this file is read. If the code generator can not open this file it will produce an error.

If the environment variable is not defined a file with the name 'typeinfo.cfg' is looked for. In SDL Suite the code generator will first look in the source directory and if it can not find the file there it will look in the directory where SDL Suite is started from. If a 'typeinfo.cfg' file is found it is read. If no such file is found the code generator assumes that the user does not have a type info configuration file.

The contents of the type info configuration file should be:

Each type that should be registered as used should be mentioned on a line of its own, starting with the type name. If the several data types with the same name exist in the system the type name can be followed be the name of the scope that the data is defined in. One or more spaces or tabs should separate the type name and the scope name.

Example 510: Type name and scope name ----------

```
typename1
typename2 scopename2
typename3
```

The code generator will search for data types that match the criteria (name or name/scope) given above. The search will in SDL Suite follow the case sensitivity option in the tool. The following rules then apply:

- The type info node in all data types that matches the criteria (type name or type name/scope name) will be registered as used.
- All type info nodes that the registered node depends on will also be registered as used.
- An error message will be given if no data type matches a criteria.

If case sensitive search is used the predefined types should be given according to the following table:

```
Integer
Real
Natural
Boolean
Character
Time
Duration
Pid
Charstring
Bit
Bit_string
Octet
Octet_string
IA5String
NumericString
PrintableString
VisibleString
NULL
Object_identifier
```

The name of the scope for these types is: **Predefined**

Memory optimization

In the kernel file sctpred.c the following functions are conditionally defined (using #ifdef) to save memory when they are not needed:

```
GenericIsAssigned
IsPointerToMake
GenericMakeStruct
GenericGetValue
GenericSetValue
```

The conditional definitions are based on usage in the kernel or generated code. However if there is a need for some reason to use them directly, it is needed to make them accessible by manually defining a flag corresponding to each function named XMK_USE_FUNC_<function name in capital letters>:

```
XMK_USE_FUNC_GENERICISASSIGNED
XMK_USE_FUNC_ISPOINTERTOMAKE
```

```
XMK_USE_FUNC_GENERICMAKESTRUCT
XMK_USE_FUNC_GENERICGETVALUE
XMK_USE_FUNC_GENERICSETVALUE
```

Furthermore the function GenericDefault has additional #ifdef constructions inside the function to save memory in some cases.

Type-Specific Components

The following section lists the components that defines the type info nodes. Only the type-specific components are explained. The general components are listed and explained in the section above.

Enumeration types

```
/* ------------- Enumeration type --------------- */
typedef T_CONST struct {
  int             LiteralValue;
  char           *LiteralName;
} tSDLEnumLiteralInfo;

typedef T_CONST struct tSDLEnumInfoS {
  tSDLTypeClass   TypeClass;
  unsigned char   OpNeeds;
  xptrint         SortSize;
  struct tSDLFuncInfo *OpFuncs;
  T_SDL_EXTRA_COMP
#ifdef T_SDL_NAMES
  char           *Name;
#endif
#ifdef XREADANDWRITEF
  xIdNode         FatherScope;
  xSortIdNode     SortIdNode;
#endif
#ifdef XREADANDWRITEF
  int             NoOfLiterals;
  tSDLEnumLiteralInfo *LiteralList;
#endif
} tSDLEnumInfo;
```

- **NoOfLiterals**: The number of literals in the enum type.
- **LiteralList**: a pointer to an array of `tSDLEnumLiteralInfo` elements. This list implements a translation table between enum values and literal names as strings

Syntypes, types with inheritance, and Own, Ref, Oref instantiations

```
/* ------ Syntype, Inherits, Own, Oref, Ref ----- */
typedef T_CONST struct tSDLGenInfoS {
```

```
  tSDLTypeClass   TypeClass;
  unsigned char   OpNeeds;
  xptrint         SortSize;
  struct tSDLFuncInfo *OpFuncs;
  T_SDL_EXTRA_COMP
#ifdef T_SDL_NAMES
  char           *Name;
#endif
#ifdef XREADANDWRITEF
  xIdNode         FatherScope;
  xSortIdNode     SortIdNode;
#endif
  tSDLTypeInfo   *CompOrFatherSort;
} tSDLGenInfo;
```

- **CompOrFatherSort**: Reference to the type info node of the father sort (syntype, inherits) or component sort (Own, Ref, Oref).

Powersets (implemented as unsigned in [ ])

```
/* ------------------ Powerset ------------------ */
typedef T_CONST struct tSDLPowersetInfoS {
  tSDLTypeClass   TypeClass;
  unsigned char   OpNeeds;
  xptrint         SortSize;
  struct tSDLFuncInfo *OpFuncs;
  T_SDL_EXTRA_COMP
#ifdef T_SDL_NAMES
  char           *Name;
#endif
#ifdef XREADANDWRITEF
  xIdNode         FatherScope;
  xSortIdNode     SortIdNode;
#endif
  tSDLTypeInfo   *CompSort;
  int             Length;
  int             LowestValue;
} tSDLPowersetInfo;
```

- **CompSort**: Reference to the type info node of the component sort.
- **Length**: The number of possible values in the component sort.
- **LowestValue**: The value of the lowest value in the component sort.

Structs

```
/* ------------------- Struct ------------------- */
typedef int (*tGetFunc) (void *);
typedef void (*tAssFunc) (void *, int);
```

```
typedef T_CONST struct {
  xptrint     OffsetPresent; /* 0 if not optional */
  void       *DefaultValue;
} tSDLFieldOptInfo;

typedef T_CONST struct {
  tGetFunc        GetTag;
  tAssFunc        AssTag;
} tSDLFieldBitFInfo;

typedef T_CONST struct {
  tSDLTypeInfo   *CompSort;
#ifdef T_SDL_NAMES
  char           *Name;
#endif
  xptrint         Offset;     /* ~0 for bitfield */
  tSDLFieldOptInfo *ExtraInfo;
} tSDLFieldInfo;

typedef T_CONST struct tSDLStructInfoS {
  tSDLTypeClass   TypeClass;
  unsigned char   OpNeeds;
  xptrint         SortSize;
  struct tSDLFuncInfo *OpFuncs;
  T_SDL_EXTRA_COMP
#ifdef T_SDL_NAMES
  char           *Name;
#endif
#ifdef XREADANDWRITEF
  xIdNode         FatherScope;
  xSortIdNode     SortIdNode;
#endif
  tSDLFieldInfo  *Components;
  int             NumOfComponents;
} tSDLStructInfo;
```

- **Components**: An array of tSDLFieldInfo; one component in the array for each field of the struct.
- **NumOfComponents**: The number of fields in the struct.
- **CompSort in tSDLFieldInfo**: The reference to the type info node of the field sort.
- **Name in tSDLFieldInfo**: The name of the field as a string.

- **Offset in tSDLFieldInfo**: The offset of the field in the C struct that represents the SDL struct. This component is ~0 for bitfield in SDL (offsets cannot be calculated for bitfields).
- **ExtraInfo in tSDLFieldInfo**: The interpretation of this component depends on the properties in the SDL field.
  - if Offset is ~0, the field is a bitfield and ExtraInfo is a pointer to a tSDLFieldBitFInfo struct containing two functions to set and get the value of the bitfield.
  - if Offset is not ~0 and ExtraInfo != 0, the SDL field is either optional or has a default value. ExtraInfo is a pointer to a tSDLFieldOptInfo struct containing the offset for the Present flag (0 if not optional) and a pointer to the default value (0 if no default value).

Choice and #union

```
/* ---------------- Choice, Union --------------- */

typedef T_CONST struct {
  tSDLTypeInfo        *CompSort;
#ifdef T_SDL_NAMES
  char                *Name;
#endif
} tSDLChoiceFieldInfo;

typedef T_CONST struct tSDLChoiceInfoS {
  tSDLTypeClass   TypeClass;
  unsigned char   OpNeeds;
  xptrint         SortSize;
  struct tSDLFuncInfo *OpFuncs;
  T_SDL_EXTRA_COMP
#ifdef T_SDL_NAMES
  char           *Name;
#endif
#ifdef XREADANDWRITEF
  xIdNode         FatherScope;
  xSortIdNode     SortIdNode;
#endif
  tSDLChoiceFieldInfo *Components;
  int                  NumOfComponents;
  xptrint              OffsetToUnion;
  xptrint              TagSortSize;
#ifdef XREADANDWRITEF
  tSDLTypeInfo        *TagSort;
#endif
} tSDLChoiceInfo;
```

- **Components**: An array of tSDLChoiceFieldInfo; one component in the array for each field in the choice/#union.
- **NumOfComponents**: The number of fields in the choice/#union.
- **OffsetToUnion**: The offset to where the union, within the representation of the choice/#union, starts.
- **TagSortSize**: The size of the tag type.
- **TagSort**: A reference to the type info node of the tag sort.

Array and Carray

```
/* ---------------- Array, CArray ---------------- */
typedef T_CONST struct tSDLArrayInfoS {
  tSDLTypeClass   TypeClass;
  unsigned char   OpNeeds;
  xptrint         SortSize;
  struct tSDLFuncInfo *OpFuncs;
  T_SDL_EXTRA_COMP
#ifdef T_SDL_NAMES
  char           *Name;
#endif
#ifdef XREADANDWRITEF
  xIdNode         FatherScope;
  xSortIdNode     SortIdNode;
#endif
  tSDLTypeInfo   *CompSort;
  int             Length;
#ifdef XREADANDWRITEF
  tSDLTypeInfo   *IndexSort;
  int             LowestValue;
#endif
} tSDLArrayInfo;
```

- **CompSort**: The reference to the type info node of the component sort.
- **Length**: The number of components in the array.
- **IndexSort**: The reference to the type info node of the index sort.
- **LowestValue**: The start value of the index range (as an int).

General arrays

A general array is an array that is represented as a linked list in C.

```
/* ------------------- GArray ------------------- */
typedef T_CONST struct tSDLGArrayInfoS {
  tSDLTypeClass   TypeClass;
  unsigned char   OpNeeds;
  xptrint         SortSize;
  struct tSDLFuncInfo *OpFuncs;
  T_SDL_EXTRA_COMP
#ifdef T_SDL_NAMES
  char           *Name;
#endif
#ifdef XREADANDWRITEF
  xIdNode         FatherScope;
  xSortIdNode     SortIdNode;
#endif
  tSDLTypeInfo   *IndexSort;
  tSDLTypeInfo   *CompSort;
  xptrint         yrecSize;
  xptrint         yrecIndexOffset;
  xptrint         yrecDataOffset;
  xptrint         arrayDataOffset;
} tSDLGArrayInfo;
```

- **IndexSort**: The reference to the type info node of the index sort.
- **CompSort**: The reference to the type info node of the component sort.
- **yrecSize**: The size of the type SDLType_yrec.
- **yrecIndexOffset**: The offset of Index in type SDLType_yrec.
- **yrecDataOffset**: The offset of Data in type SDLType_yrec.
- **arrayDataOffset**: The offset of Data in type SDLType, where SDLType is the name in C of the translated array type.

General powersets, Bags, Strings and Object_identifier

```
/* -- GPowerset, Bag, String, Object_Identifier - */
typedef T_CONST struct tSDLGenListInfoS {
  tSDLTypeClass   TypeClass;
  unsigned char   OpNeeds;
  xptrint         SortSize;
  struct tSDLFuncInfo *OpFuncs;
  T_SDL_EXTRA_COMP
#ifdef T_SDL_NAMES
  char           *Name;
#endif
#ifdef XREADANDWRITEF
  xIdNode         FatherScope;
  xSortIdNode     SortIdNode;
```

```
#endif
  tSDLTypeInfo   *CompSort;
  xptrint         yrecSize;
  xptrint         yrecDataOffset;
} tSDLGenListInfo;
```

- **CompSort**: The reference to the type info node of the component sort.
- **yrecSize**: The size of the type SDLType_yrec
- **yrecDataOffset**: The offset of Data in type SDLType_yrec

Limited strings

A limited string is a string that is implemented as an array in C.

```
/* ------------------ LString ------------------- */
typedef T_CONST struct tSDLLStringInfoS {
  tSDLTypeClass   TypeClass;
  unsigned char   OpNeeds;
  xptrint         SortSize;
  struct tSDLFuncInfo *OpFuncs;
  T_SDL_EXTRA_COMP
#ifdef T_SDL_NAMES
  char           *Name;
#endif
#ifdef XREADANDWRITEF
  xIdNode         FatherScope;
  xSortIdNode     SortIdNode;
#endif
  tSDLTypeInfo   *CompSort;
  int             MaxLength;
  xptrint         DataOffset;
} tSDLLStringInfo;
```

- **CompSort**: The reference to the type info node of the component sort.
- **MaxLength**: The maximum length of the string.
- **DataOffset**: The offset of Data in type SDLType, where SDLType is the name in C of the translated string type.

SDL type (C representation decided with a #ADT directive)

```
/* ------------------ Userdef ------------------- */
/* used for user defined types #ADT(T(h)) */
typedef T_CONST struct tSDLUserdefInfoS {
  tSDLTypeClass   TypeClass;
  unsigned char   OpNeeds;
```

```
  xptrint         SortSize;
  struct tSDLFuncInfo *OpFuncs;
  T_SDL_EXTRA_COMP
#ifdef T_SDL_NAMES
  char           *Name;
#endif
#ifdef XREADANDWRITEF
  xIdNode         FatherScope;
  xSortIdNode     SortIdNode;
#endif
  T_SDL_USERDEF_COMP
} tSDLUserdefInfo;
```

SDL signal

A signal is treated in the same way as a struct.

```
/* ------------------- Signal ------------------- */
typedef T_CONST struct {
  tSDLTypeInfo       *ParaSort;
  xptrint             Offset;
} tSDLSignalParaInfo;

typedef T_CONST struct tSDLSignalInfoS {
  tSDLTypeClass   TypeClass;
  unsigned char   OpNeeds;
  xptrint         SortSize;
  struct tSDLFuncInfo *OpFuncs;
  T_SDL_EXTRA_COMP
#ifdef T_SIGNAL_SDL_NAMES
  char           *Name;
#endif
  tSDLSignalParaInfo *Param;
  int             NoOfPara;
} tSDLSignalInfo;
```

- **Param**: An array with a component of the type tSDLSignalParaInfo for each signal parameter type. For each parameter, the parameter sort is given as a reference to the type info node and as the offset for the parameter value within the struct representing the signal.
- **NoOfPara**: The number of parameters in the signal.

The SDL Model

Signals and Timers

Data Structure Representing Signals and Timers

A signal is represented by a struct type. The `xSignalRec` struct, defined in `scttypes.h`, is a struct containing general information about a signal except from the signal parameters. In `scttypes.h` the following information about signals can be found:

```
#ifdef XMSCE
#define GLOBALINSTID  int GlobalInstanceId;
#else
#define GLOBALINSTID
#endif

#if defined(XSIGPATH) && defined(XMSCE)
#define ENVCHANNEL  xChannelIdNode EnvChannel;
  /* Used if env split into channels in MSC trace */
#else
#define ENVCHANNEL
#endif

#ifdef XENV_CONFORM_2_3
#define XSIGNAL_VARP  void * VarP;
#else
#define XSIGNAL_VARP
#endif

define SIGNAL_VARS \
   xSignalNode   Pre; \
   xSignalNode   Suc; \
   int           Prio; \
   SDL_PId       Receiver; \
   SDL_PId       Sender; \
   xSignalIdNode NameNode; \
   GLOBALINSTID \
   ENVCHANNEL \
   XSIGNAL_VARP

typedef struct xSignalStruct  *xSignalNode;
typedef struct xSignalStruct {
   SIGNAL_VARS
}  xSignalRec;
```

The `xSignalNode` type is thus a pointer type which is used to refer to allocated data areas of type `xSignalRec`. The components in the `xSignalRec` struct are used as follows:

- **`Pre`** and **`Suc`**. These pointers are used to link a signal into the input port of the receiving process instance.

The input port is a doubly linked list of signals. `Suc` is also used to link a signal into the avail lists for the current signal type. This list can be found in the `SignalIdNode` that represents this signal type. If the signal is in the avail list `Pre` is `0`.

- **`Prio`** is used to represent the priority of the signal instance. Signal priorities are used by continuous signals and by ordinary signals if signal priorities are defined (signal priority is a possible extension provided in the product).
- **`Receiver`** is used to reference the receiver of the signal. It is either set in the output statement (OUTPUT TO), or calculated (OUTPUT without TO).
- **`Sender`** is the `PId` value of the sending process instance. This value is necessary to provide the SDL function SENDER.
- **`NameNode`** is a reference to the `xSignalIdNode` representing the signal type and thus defines the signal type of this signal instance.
- **`VarP`** is a pointer introduced via the macro `XSIGNAL_VARP` to make signal compatible with SDT 2.3. Normally this components is **not** present.
- **`EnvChannel`** is used to identify the outgoing channel in MSCE trace.
- **`GlobalInstanceId`** is used in the MSCE trace as a unique identification of the signal instance.

A signal without parameters are represented by a `xSignalStruct`, while for signals with parameters a struct type named `yPDef_`*`SignalName`* and a pointer type referencing this struct type (`yPDP_`*`SignalName`*) are defined in generated code. The struct type will start with the `SIGNAL_VARS` macro and then have one component for each signal parameter, in the same order as the signal parameters are defined. The components will be named Param1, Param2, and so on.

Example 511 ––

```
typedef struct {
    SIGNAL_VARS
    SDL_Integer  Param1;
    SDL_Boolean  Param2;
} yPDef_sig;
typedef yPDef_sig  *yPDP_sig;
```

These types would represent a signal sig(Integer, Boolean).

As all signals starts with the components defined in `SIGNAL_VARS` it is possible to type cast a pointer to a signal, to the `xSignalNode` type, if only the components in `SIGNAL_VARS` is to be accessed.

Allocation of Data Areas for Signals

In `sctos.c` there are two functions, `xGetSignal` and `xReleaseSignal`, where data areas for signal are handled:

```
xSignalNode xGetSignal(
  xSignalIdNode  SType,
  SDL_PId        Receiver,
  SDL_PId        Sender )

void xReleaseSignal( xSignalNode  *S )
```

`xGetSignal` takes a reference to the `SignalIdNode` identifying the signal type and two PId values (sending and receiving process instance) and returns a signal instance. `xGetSignal` first looks in the avail list for the signal type (the component `AvailSignalList` in the `SignalIdNode` for the signal type) and reuses any available signal there. Only if the avail list is empty new memory is allocated. The component `VarSize` in the `SignalIdNode` for the signal type provides the size information needed to correctly allocate the `yPDef_`*`SignalName`* even though the type is unknown for the `xGetSignal` function.

The function `xReleaseSignal` takes the address of an `xSignalNode` pointer and returns the referenced signal to the avail list for the signal type. The `xSignalNode` pointer is then set to `0`.

The function `xGetSignal` is used:

- In generated code (output, set, reset)
- In a number of places in the library:
  SDL_Create
  SDL_SimpleReset
  SDL_Nextstate (to handle continuous signals)
- In the postmaster communication section and in the monitor to obtain signal instances.

The function `xReleaseSignal` is used by:

- SDL_Nextstate
- SDL_Stop, in both cases to release the signal that initiated the transition.

Overview of Output and Input of Signals

In this subsection the signal handling operation is only outlined. More details will be given in the section treating processes. See "Output and Input of Signals" on page 3088.

Signal instances are sent using the function SDL_Output. That function takes a signal instance and inserts it into the input port of the receiving process instance.

If the receiver is not already in the ready queue (the queue containing the processes that can perform a transition, but which have not yet been scheduled to do so) and the current signal may cause an immediate transition, the process instance is inserted into the ready queue.

If the receiver is already in the ready queue or in a state where the current signal should be saved, the signal instance is just inserted into the input port.

If the signal instance can neither cause a transition nor should be saved, it is immediately discarded (the data area for the signal instance is returned to the avail list).

The input port is scanned during nextstate operations, according the rules of SDL, to find the next signal in the input port that can cause a transition. Signal instances may then be saved or discarded.

There is no specific input function, instead this behavior is distributed both in the runtime library and in the generated code. The signal instance that should cause the next transition to be executed is removed from the input port in the main loop (the scheduler), immediately before the PAD function for the current process is called. The PAD function is the function where the behavior of the process is implemented and is part of the generated code. The assignment of the signal parameters to local SDL variables is one of the first actions performed by the PAD function.

The signal instance that caused a transition is released and returned to the avail list in the nextstate or stop action that ends the current transition.

Timers and Operations on Timers

A timer with parameters is represented by a type definition, where the timer parameters are defined, in exactly the same way as for a signal definition, see "Data Structure Representing Signals and Timers" on page 3070. At runtime, all timers that are set and where the timer time has not expired, are represented by a xTimerRec struct and a signal instance:

```
#define TIMER_VARS \
   xSignalNode   Pre; \
   xSignalNode   Suc; \
   int           Prio; \
   SDL_PId       Receiver; \
   SDL_PId       Sender; \
   xSignalIdNode NameNode; \
   GLOBALINSTID \
   ENVCHANNEL \
   SDL_Time      TimerTime;

typedef xTimerRec  *xTimerNode;

typedef struct xTimerStruct {
   TIMER_VARS
}  xTimerRec;
```

The TIMER_VARS is and must be identical to the SIGNAL_VARS macro, except for the TimerTime component last in the macro. A timer with parameters have yPDef_timername and yPDP_timername types in generated code exactly as a signal (see previous section), except that SIGNAL_VARS is replaced by TIMER_VARS.

During its life-time a timer have two different appearances. First it is a timer waiting for the timer time to expire. In that phase the timer is inserted in the `xTimerQueue`. When the timer time expires the timer becomes a signal and is inserted in the input port of the receiver just like any other signal. Due to the identical typedefs for `xSignalRec` and `xTimerRec`, there are no problems with type casting between `xTimerNode` and `xSignalNode` types.

When a timer is treated as a signal the components in the `xTimerRec` are used in the same ways as for a `xSignalRec`. While the timer is in the timer queue, the components are used as follows:

- **`Pre`** and **`Suc`** are pointers used to link the `xTimerRec` into the timer queue (the queue of active timers, see below).
- **`TimerTime`** is the time given in the `Set` operation.

The queue mentioned above, the timer queue for active timers is represented by the component xTimerQueue in the variable `xSysD`:

```
xTimerNode xTimerQueue;
```

The variable is initialized in the function `xInitKernel` in `sctsdl.c`. `xTimerQueue` is initialized it refers to the queue head of the timer queue.

The queue head is an extra element in the timer queue that does not represent a timer, but is introduced as it simplifies the algorithms for queue handling. The `TimerTime` component in the queue head is set to a very large time value (`xSysD.xMaxTime`).

The timer queue is thus a doubly linked list with a list head and it is sorted according to the timer times, so that the timer with lowest time is at the first position.

To optimize the case where there are many active timers, one extra pointer is introduced for each timer in the data area for the process instances. This pointer is used to refer to the active timer and to the timer signal up to the point where the signal is received in an input. A reset or active operation is then trivial, as there is a pointer to the timer object. If the pointer is NULL no timer is set.

For timers with parameters this model is extended, so a list of timers can be accessed from the process.

The xTimerRec structs are allocated and reused in the same way as signal.

From the SDL point of view, timers are handled in:

- Timer definitions
- Set and reset operations
- Timer outputs.

The timer output is the event when the timer time has expired and the timer signal is sent. After that, a timer signal is treated as an ordinary signal. These operations are implemented as follows:

```
void SDL_Set(
  SDL_Time     T,
  xSignalNode  S )
```

This function, which represents the Set operation, takes the timer time and a signal instance as parameters. It first uses the signal instance to make an implicit reset (see reset operation below) It then updates the TimerTime component in S and inserts S into the timer queue at the correct position.

The SDL_Set operation is used in generated code, together with xGetSignal, in much the same way as SDL_Output. First a signal instance is created (by xGetSignal), then timer parameters are assigned their values, and finally the Set operation is performed (by SDL_Set).

```
void SDL_Reset( xSignalNode  *TimerS )

void SDL_SimpleReset(
  xPrsNode       P,
  xSignalIdNode  TimerId )
```

Two functions are used to represent the SDL action reset. SDL_SimpleReset is used for timers without parameters and SDL_Reset for timers with parameters.

SDL_Reset uses the two functions xRemoveTimer and xRemoveTimerSignal to remove a timer in the timer queue and to remove a signal instance in the input port of the process. It then releases the signal instance given as parameter. This signal is only used to carry the parameter values given in the reset action.

The function SDL_SimpleReset is implemented in the same way as SDL_Reset, except that it creates its own signal instance (without parameters).

At a reset action the possibly found timer is removed from the timer queue and returned to the avail list. A found signal instance (in the input port) is removed from the input port and returned to the avail list for the current signal type.

```
static void SDL_OutputTimerSignal( xTimerNode  T )
```

The SDL_OutputTimerSignal is called from the main loop (the scheduler) when the timer time has expired for the timer first in the timer queue. The corresponding signal instance is then sent.

SDL_OutputTimerSignal takes a pointer to an xTimerRec as parameter, removes it from the timer queue and sends as an ordinary output using the function SDL_Output.

It can be checked if timer is active by using a call to the function SDL_Active. This function is used in generated code to represent the SDL operator active.

```
SDL_Boolean SDL_Active (
  xSignalIdNode TimerId,
  xPrsNode      P )
```

Note:

Only timers without parameters can be tested. This is a restriction in the Cadvanced/Cbasic SDL to C Compiler.

There is one more place where timers are handled. When a process instance performs a stop action all timers in the timer queue connected to this process instance are removed. This is performed by calling the function xRemoveTimer with the first parameter equal to 0.

Processes

Data Structure Representing Processes

A process instance is represented by two structs, an `xLocalPIdRec` and a struct containing both the general process data and the local variables and formal parameters of the process (`yVDef_`*`ProcessName`*), see also Figure 554. The reason for having both the `xLocalPIdRec` and the `yVDef_`*`ProcessName`* will be discussed under "Create and Stop Operations" on page 3085.

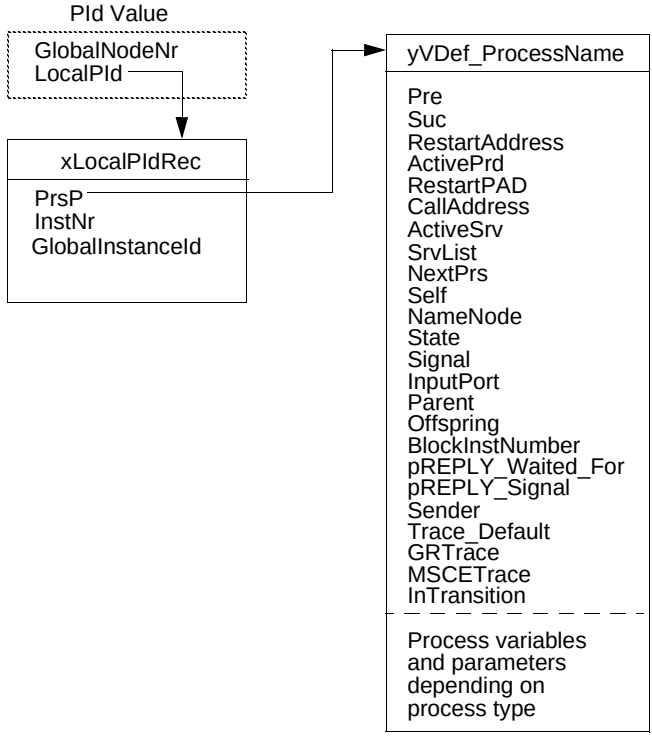

Figure 554: Representation of a process instance

The corresponding type definitions, which can be found in `scttypes.h`, are:

```
#ifdef XPRSSENDER

typedef struct {
   xPrsNode      PrsP;
   int           InstNr;
   int           GlobalInstanceId;
}  xLocalPIdRec;

typedef xLocalPIdRec  *xLocalPIdNode;

typedef struct {
   int            GlobalNodeNr;
   xLocalPIdNode  LocalPId;
}  SDL_PId;

typedef struct xPrsStruct  *xPrsNode;

typedef struct xPrsStruct {
   PROCESS_VARS
} xPrsRec;
```

A `PId` value is thus a struct containing two components:

- The global node number
- A pointer to a `xLocalPIdRec` struct.

The use of the global node number is discussed in the chapter 57, *Building an Application*.

A **`xLocalPIdRec`** contains the following three components:

- **`PrsP`** of type `xPrsNode`. This component is a pointer to the `xPrsRec` struct that is part of the representation of the process instance.
- **`InstNr`** of type `int`. This is the instance number of the current process instance, which is used in the communication with the user in the monitor and in dynamic error messages.
- **`GlobalInstanceId`** is used in MSCE traces to have a unique identification of the process instance.

A **`xPrsRec`** struct contains the following components described below. As each `yVDef_ProcessName` struct contains the `PROCESS_VARS` macro as first item, it is possible to cast pointer values between a pointer to `xPrsRec` and a pointer to a `yVDef_ProcessName` struct.

- **`Pre`** and **`Suc`** of type `xPrsNode`. These components are used to link the process instance in the ready queue (see below).
- **`RestartAddress`** of type `int`. This component is used to find the appropriate SDL symbol to continue execute from.
- **`ActivePrd`** of type `xPrdNode`. This is a pointer to the `xPrdRec` that represents the currently executing procedure called from this process instance. The pointer is 0 if no procedure is currently called.
- **`RestartPAD`**, which is a pointer to a `PAD` function. This component refers to the `PAD` function where to execute the sequence of SDL symbols. `RestartPAD` is used to handle inheritance between process types.
- **`CallAddress`** of type `int`. This component contains the symbol number of the procedure call currently executed by this process.
- **`ActiveSrv`** of type `xSrvNode`. This component contains a reference to the currently active service (or latest active service) in this process.

- **SrvList** of type xSrvNode. This component contains a reference to the first service contained in this process. The component NextSrv in the struct representing a service can be used to find next active service in the process.
- **NextPrs** of type xPrsNode. This component is used to link the process instance either in the active list or in the avail list for this process type. The start of these two lists are the components ActivePrsList and AvailPrsList in the IdNode representing the current process type.
- **Self** of type SDL_PId. This is the PId value of the current process instance.
- **NameNode** of type xPrsIdNode. This is a pointer to the PrsIdNode representing the current process or process instantiation.
- **State** of type int. This component contains the int value used to representing the current state of the process instance.
- **Signal** of type xSignalNode. This is a pointer to a signal instance. The referenced signal is the signal that will cause the next transition by the current process instance, or that caused the transition that is currently executed by the process instance.
- **InputPort** of type xInputPortRec. This is the queue head in the doubly linked list that represents the input port of the process instance. The signals are linked in this list using the Pre and Suc components in the xSignalRec struct.
- **Parent** of type SDL_PId. This is the PId value of the parent process (according to the rules of SDL). A static process instance has parent equal to NULL.
- **Offspring** of type SDL_PId. This is the PId value of the latest created process instance (according to the rules of SDL). A process instance that has not created any processes has offspring equal to NULL.
- **BlockInstNumber** of type int. If the process is part of a block instance set, this component indicates which of the blocks that the process belongs to.

- **pREPLY_Waited_For** of type xSignalIdNode. When a process is waiting in the implicit state for the pREPLY signal in a RPC call, this components is used to store the IdNode for the expected pREPLY signal.
- **pREPLY_Signal** of type xSignalNode. When a process receives a pCALL signal, i.e. accepts a RPC, it immediately creates the return signal, the pREPLY signal. This component is used to refer to this pREPLY signal until it is sent.
- **Sender** of type SDL_PId. This component represents the SDL concept Sender.
- **Trace_Default** of type int. This component contains the current value of the trace defined for the process instance.
- **GRTrace** of type int. This component contains the current value of the GR trace defined for the process instance.
- **MSCETrace** of type int. This component contains the current MSCE trace value for the process instance.
- **InTransition** of type xbool. This component is true while the process is executing a transition and it is false while the process is waiting in a state. The monitor system needs this information to be able to print out relevant information.

The Ready Queue, Scheduling

The ready queue is a doubly linked list with a head. It contains the process instances that can execute an immediate transition, but which has not been allowed to complete that transition. Process instances are inserted into the ready queue during output operations and nextstate operations and are removed from the ready queue when they execute the nextstate or stop operation that ends the current transition. The head in the ready queue, which is an object in the queue that does not represent any process but is inserted only to simplify the queue operations, is referenced by the xSysD component:

```
xPrsNode   xReadyQueue;
```

This component is initiated in the function xInitKernel and used throughout the runtime library to reference the ready queue.

Scheduling of events is performed by the function `xMainLoop`, which is called from the `main` function after the initialization is performed.

```
void xMainLoop()
```

The strategy to have all interesting queues (the ready queue, the timer queue, and the input ports) sorted in the correct order is used in the library. Sorting is thus performed when an object is inserted into a queue, which means that scheduling is a simple task: select the first object in the timer queue or in the ready queue and submit it for execution.

There are several versions of the body of the endless loop in the function `xMainLoop`, which are used for different combinations of compilation switches. When it comes to scheduling of transitions and timer outputs they all have the following outline:

```
while (1) {
  if ( xTimerQueue->Suc->TimerTime <= SDL_Now() )
    SDL_OutputTimerSignal( xTimerQueue->Suc );
  else if ( xReadyQueue->Suc != xReadyQueue) {
    xRemoveFromInputPort(xReadyQueue->Suc->Signal);
    xReadyQueue->Suc->Sender =
       xReadyQueue->Suc->Signal->Sender;
   (*xReadyQueue->Suc->RestartPAD)(xReadyQueue->Suc);
  }
}
```

or, in descriptive terms:

```
while (1) {
  if ( there is a timer that has expired )
    send the corresponding timer signal;
  else if ( there is a process that can execute
            a transition ) {
    remove the signal causing the transition
      from input port;
    set up Sender in the process to Sender of
      the signal;
    execute the PAD function for the process;
  }
}
```

The different versions of the main loop handle different combinations of compilation switches. Other actions necessary in the main loop are dependent of the compilation switches. Example of such actions are:

- Handling of the monitor
- Calling the `xInEnv` function

- Handling real time or simulated time
- Delay execution up to the next scheduled event
- Handling enabling conditions and continuous signals that need to be recalculated.

Create and Stop Operations

A process instance is, while it is active, represented by the two structs:

- `xLocalPIdRec`
- The `yVDef_ProcessName` struct.

These two structs are dynamically allocated. A `PId` value is also a struct (not allocated) containing two components, `GlobalNodeNr` and `LocalPId`, where `LocalPId` is a pointer to the `xLocalPIdRec`. Figure 555 shows how the `xLocalPIdRec` and the `yVDef_ProcessName` structs representing a process instance are connected.

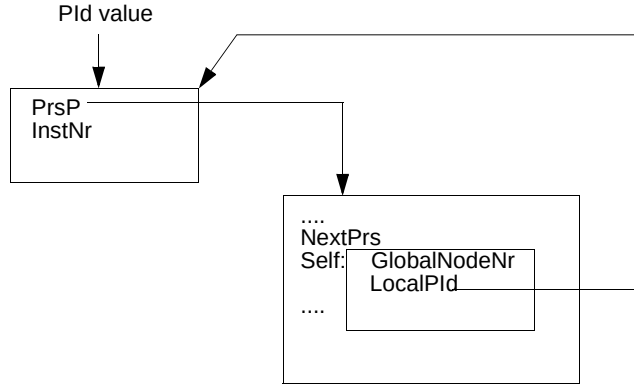

Figure 555: A xLocalPIdRec and a yVDef_ProcessName representing a Process instance

When a process instance performs a stop action, the memory used for the process instance should be reclaimed and it should be possible to reuse in subsequent create actions. After the stop action, old (invalid) `PId` values might however be stored in variables in other process instances.

If a signal is sent to such an old `PId` value, that is, to a stopped process instance, it should be possible to find and perform appropriate actions.

If the complete representation of a process instance is reused then this will not be possible. There must therefore remain some little piece of information and thus some memory for each process instance that has ever existed. This is the purpose of the `xLocalPIdRec`. These structs will never be reused. Instead the following (see Figure 556) will happen when the process instance in Figure 555 performs a stop action.

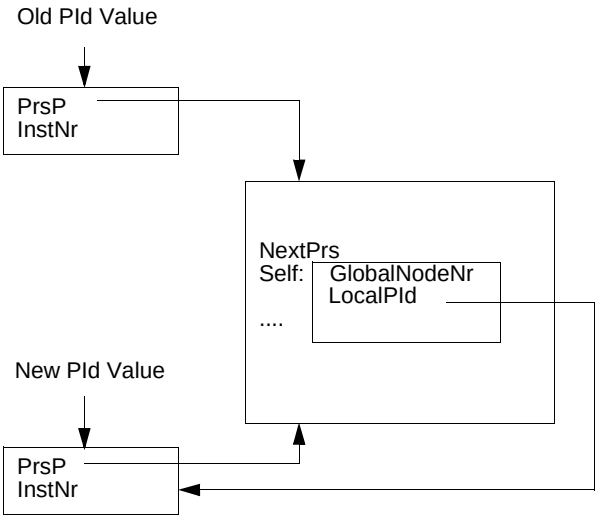

Figure 556: The memory structure after the process in Figure 555 has performed a stop action

A new `xLocalPIdRec` is allocated and its `PrsP` references the `yVDef_ProcessName` (`InstNr` is 0). The `Self` component in the `yVDef_ProcessName` is changed to reference this new `xLocalPIdRec`. The old `xLocalPIdRec` still references the `yVDef_ProcessName`. The `yVDef_ProcessName` is entered into the avail list for this process type.

To reuse the data area for a process instance at a create operation it is only necessary to remove the `yVDef_ProcessName` from the avail list and update the `InstNr` component in the `xLocalPIdRec` referenced by `Self`.

Using this somewhat complicated structure to represent process instances allows a simple test to see if a `PId` value refers to an active or a stopped instance:

If P is a PId variable then the following expression:

```
P.LocalPId == P.LocalPId->PrsP->Self.LocalPId
```

is true if the process instance is active and false if it is stopped.

The basic behavior of the create and stop operations is performed by the functions SDL_Create and SDL_Stop.

```
void SDL_Create(
  xSignalNode  StartUpSig,
  xPrsIdNode   PrsId )

void SDL_Stop( xPrsNode  PrsP )
```

To create a process instance takes three steps performed in generated code:

1. Call xGetSignal to obtain the start-up signal.
2. Assign the actual process parameters to the start up signal parameters.
3. Call SDL_Create with the start-up signal as parameter, together with the PrsIdNode representing the process to be created.

In xGetProcess the process instance is removed from the avail list of the process instance set (the component AvailPrsList in the PrsIdNode representing the process instance set), or if the avail list is empty new memory is allocated.

The process instance is linked into the list of active process instances (the component ActivePrsList in the PrsIdNode representing the process instance set). Both the avail list and the active list are single linked lists (without a head) using the component NextPrs in the yVDef_ProcessName struct as link.

To have an equal treatment of the initial transition and other transitions, the start state is implemented as an ordinary state with the name “start state” It is represented by 0. To execute the initial transition a “startup” signal is sent to the process. The start state can thus be seen as a state with one input of the startup signal and with save for all other signals. This implementation is completely transparent in the monitor, where startup signals are never shown in any way.

Note:

The actual values for FPARs are passed in the startup signal.

Two `IdNodes` that are not part of the symbol table tree are created to represent a start state and a startup signal.

```
xStateIdNode   xStartStateId;
xSignalIdNode  xStartUpSignalId;
```

These `xSysD` components are initialized in the function `xInitSymbolTable`, which is part of `sctsdl.c`.

At a stop operation the function `SDL_Stop` is called. This function will release the signal that caused the current transition and all other signals in the input port. It will also remove all timers in the timer queue that are connected to this process instance by calling `xRemoveTimer` with the first parameter equal to `0`. It then removes the process executing the stop operation from the ready queue and from the active list of the process type and returns the memory to the avail list of the current process instance set.

Output and Input of Signals

There are three actions performed in generated code to send a signal. First `xGetSignal` is called to obtain a data area that represents the signal instance, then the signal parameters are assigned their values and finally the function `SDL_Output` is called to actually send the signal. First in the `SDL_Output` function there are a number of dynamic tests (check if receiver in TO-clause is not `NULL` and not stopped, check if there is a path to the receiver). If the output does not contain any TO-clause and the Cadvanced/Cbasic SDL to C Compiler has not been able to calculate the receiver, the `xFindReceiver` function is called to calculate the receiver according to the rules of SDL.

Next, in `SDL_Output` signals to the environment are handled. Three cases can be identified here:

1. The environment function `xOutEnv` is called.
2. The corresponding function that sends signals via the SDL Suite communication mechanism (`xOutPM`) is called.
3. The signal is inserted into the input port of the process representing the environment (`xEnv`).

Finally, internal signals in the SDL system are treated. Here also three cases can be identified (how this is evaluated is described last in this subsection):

1. The signal can cause an immediate transition by the receiver.
2. The signal should be saved.
3. The signal should be immediately discarded.

If the signal can cause an immediate transition, the signal is inserted into the input port of the receiver, and the receiving process instance is inserted into the ready queue.

If the signal should be saved, the signal is just inserted into the input port of the receiver.

If the signal should be discarded, the function `xReleaseSignal` is called to reused the data area for the signal.

When a signal is identified to be the signal that should cause the next transition by the current process instance (at an Output or Nextstate operation), the component `Signal` in the `yVDef_ProcessName` for the process is set to refer to the signal. The signal is still part of the input port list.

When the transition is to be executed, the signal is removed from the input port in the main loop (see "The Ready Queue, Scheduling" on page 3083) immediately before the `PAD` function for the process is called.

First in the `PAD` function, the parameters of the signal are copied to the local variables according to the input statement. In the ending Nextstate or Stop operation of the transition the signal instance is returned to the avail list.

Evaluating How To Handle a Received Signal

There are two places in the run-time kernel where it is necessary to evaluate how to handle signals (input, save, discard,...):

- At an Output operation to a currently idle process.
- At a Nextstate operation, when the process have signals in the input port.

This calculation is implemented in the run-time kernel function `xFindInputAction`.

```
typedef unsigned char xInputAction;
#define xDiscard         (xInputAction)0
#define xInput           (xInputAction)1
#define xSave            (xInputAction)2
#define xEnablCond       (xInputAction)3
#define xPrioInput       (xInputAction)4

static xInputAction xFindInputAction(
  xSignalNode  SignalId,
  xPrsNode     VarP,
  xbool        CheckPrioInput )
```

The parameters of this function is:

- `SignalId`, which is a pointer to a signal.
- `VarP`, which is a pointer to a process instance.
- `CheckPrioInput`, which is a boolean value indicating is the function should check only for priority inputs or for ordinary inputs.

As a result the function should return:

- The action that should be performed for this signal (input, save,...), taking all information about this process into account, like inheritance between processes, virtual - redefined transitions and so on.
- If the function result is `xInput` or `xPrioInput`, then the `RestartPAD` and `RestartAddr` components in the `VarP` struct should be updated with information about where this input can be found.

After this last update the correct transition can be started by the scheduler by just calling the function referenced by `RestartPAD`, which the as first action performs switch `RestartAddr` and starts execute the input symbol.

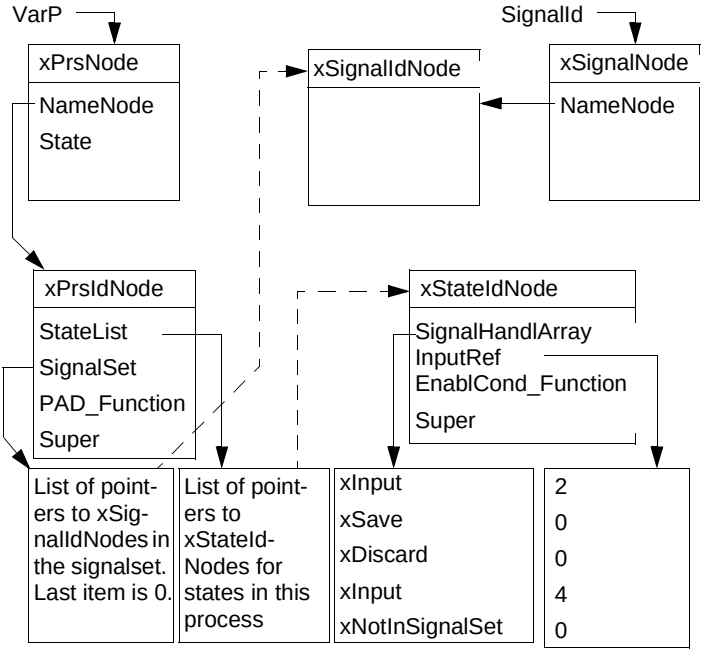

Figure 557: Data structure used to evaluate the xFindInputAction

The algorithm to find the `InputAction`, the `RestartAddr`, and the `RestartPAD` is as follows:

1. Let `ProcessId` become `yVarP->NameNode` and let `StateId` become `ProcessId->StateList[yVarP->State]`.
2. In `ProcessId->SignalSet` find the index (`Index`) where `SignalId->NameNode` is found. If the signal is not found, this signal is not in the signal set of the process, and the algorithm terminates returning the result `xDiscard`.
3. `StateId->SignalHandlArray[Index]` now gives the action to be performed. If this value is `xEnablCond`, then the function `StateId->EnablCond_Function` is called. This function returns either `xInput` or `xSave`.

4. If the result from step 3 is `xInput`, the algorithm terminates returning this value. `yVarP->RestartAddr` is also updated to `StateId->InputRef[Index]`, while `yVarP->RestartPAD` is updated to `ProcessId->PAD_Function`.

   If the result from step 3 is `xSave`, the algorithm terminates returning this value.

   If the result from step 3 is `xDiscard` and `ProcessId->Super` equal to `NULL`, then the algorithm terminates returning this value.

   If the result from step 3 is `xDiscard` and `ProcessId->Super` not equal to `NULL`, then we are in a process type that inherits from another process type. We then have to perform step 2 - 4 again, with `ProcessId` assigned the value `ProcessId->Super` and `StateId` assigned the value `StateId->Super`.

Nextstate Operations

The nextstate operation is implemented by the `SDL_Nextstate` function, where the following actions are performed:

1. The signal that caused the current transition (component `Signal` in the `yVDef_ProcessName`) is released and the state variable (component `State` in the `yVDef_ProcessName`) is updated to the new state.

2. Then the input port of the process is scanned for a signal that can cause a transition. During the scan signals might be saved or discarded until a signal specified in an input is found. Priority inputs are treated according to the rules of SDL.

3. If no signal that can cause a transition is found, a check is made if any continuous signal can cause a transition (see "Enabling Conditions and Continuous Signals" on page 3093). The process is thereafter removed from the ready queue.

4. If any signal (or continuous signal) can cause a transition then the process is re-inserted into the ready queue again at a position determined by its priority, else if the new state contains any continuous signal or enabling condition with an expression that might change its value during the time the process is in the state (view, import...), the process is inserted into the check list (see also "Enabling Conditions and Continuous Signals" on page 3093).

Decision and Task Operations

Decision and Task operations are implemented in generated code, except for the Trace-functions implemented in the `sctutil.c` and `sctmon.c` files and for informal and any decisions that uses some support functions in `sctmon.c`. A Decision is implemented as a C if-statement, while the assignments in a Task are implemented as assignments or function calls in C.

Compound Statements

A compound statement without variable declarations is translated just to the sequence of action it contains, while a compound statement with variable declarations is translated in the same way as an SDL procedure (without parameters). Statements within a compound statement are translated according to the normal rules. The new statement types in compound statements are translated as:

- **if** in SDL is translated to **if** in C
- **decision** in compound statements is translated as ordinary decisions.
- **for** loops, **continue**, and **break** are all translated using **goto** in C.

Enabling Conditions and Continuous Signals

The expressions involved in continuous signals and enabling conditions are implemented in generated code in functions called `yCont_`*`StateName`* and `yEnab_`*`StateName`*. These functions are generated for each state containing continuous signals respectively enabling conditions. The functions are referenced through the components `ContSig_Function` and `EnablCond_Function` in the `StateIdNode` for the state. These components are `0` if no corresponding functions are generated.

The `EnablCond_Functions` are called from the function `xFindInputAction`, which is called from `SDL_Output` and `SDL_Nextstate`. If the enabling condition expression for the current signal is true then `xInput` is returned else `xSave` is returned. This information is then used to determine how to handle the signal in this state.

The `ContSig_Functions` are called from `SDL_Nextstate`, if the component `ContSig_Function` is not `0` and no signal that can cause an immediate transition is found during the input port scan. A `ContSig_Function` has the following prototype:

```
void ContSig_Function_Name (
  void *, int *, xIdNode *, int *);
```

where the first parameter is the pointer to the `yVDef_ProcessName`. The remaining parameters are all out parameters; the second contains the priority of the continuous signal with highest priority (=lowest value) that has an expression with the value true. Otherwise <0 is returned here. The third and fourth is only defined the second parameter >=0; the third is the `IdNode` for the process/procedure where the actual continuous signal can be found and the fourth is the `RestartAddress` connected to this continuous signal.

If a continuous signal expression with value true is found, a signal instance representing the continuous signal is created and inserted in the input port, and is thereafter treated as an ordinary signal. The signal type is continuous signal and is represented by an `SignalIdNode` (referenced by the variable `xContSigId`).

The check list is a list that contains the processes that wait in a state where enabling conditions or continuous signals need to be repeatedly recalculated.

A process is inserted into the check list if:

1. It enters a state containing enabling conditions and/or continuous signals and
2. No signal or continuous signal can cause an immediate transition and
3. One or several of the expressions in the enabling conditions or continuous signals can change its value while the process is in the state (view, import, now, ...)

The component `StateProperties` in the `StateIdNode` reflects if any such expression is present in the state.

The check list is represented by the `xSysD` component:

```
xPrsNode  xCheckList;
```

The behavior of enabling conditions and continuous signals is in SDL modeled by letting the process repeatedly send signals to itself, thereby to repeatedly entering the current state. In the implementation chosen here, nextstate operations are performed “behind the scene” for all pro-

cesses in the check list directly after a call to a PAD function is completed, that is directly after a transition is ended and directly after a timer output. This is performed by calling the function xCheckCheckList in the main loop of the program.

View and Reveal

A view expression is part of an expression in generated code and implemented by calling the function SDL_View.

```
void * SDL_View (
  xViewListRec *VList,
  SDL_PId       P,
  xbool         IsDefP,
  xPrsNode      ViewingPrs,
  char *        Reveal_Var
  int           SortSize);
```

- **VList** is a list of all revealed variables in this block.
- **P** is the PId expression given in the view statement.
- **IsDefP** is 1 is the view expression contained a PId value, 0 otherwise.
- **ViewingPrs** is the process instance performing the view operation.
- **Reveal_Var** is the name of the revealed variable as a string. The Reveal_Var parameter is only used in error messages and is remove under certain conditions.
- **SortSize** is the size of the data type of the viewed variable.

The SDL_View function performs a test that the view expression is not NULL, refers to a process in the environment, or to a stopped process instance. If no errors are found the address of the revealed variable is returned as result from the SDL_View function. Otherwise the address of a variable containing only zeros is returned.

Import, Export, and Remote Variables

For an exported variable there are two components in the yVDef_ProcessName struct. One for the current value of the variable and one for the currently exported value of the variable. For each exported variable there will also be a struct that can be linked into a list in

the corresponding `RemoteVarIdNode`. This list is then used to find a suitable exporter of a variable in an import action.

An export action is a simple operation. The current value of the variable is copied to the component representing the exported value. This is performed in generated code.

An import action is more complicated. It involves mainly a call of the function `xGetExportAddr`:

```
void * xGetExportAddr (
  xRemoteVarIdNode RemoteVarNode,
  SDL_PId          P,
  xbool            IsDefP,
  xPrsNode         Importer )
```

`RemoteVarNode` is a reference to the `RemoteVarIdNode` representing the remote variable (implicit or explicit), `P` is the PId expression given in the import action and `IsDef` is 0 or 1 depending on if any `PId` expression was given in the import action or not, Importer is the importing process instance. The `xGetExportAddr` will check the legality of the import action and will, if no `PId` expression is given, calculate which process it should be imported from.

If no errors are found the function will return the address where the exported value can be found. This address is then casted to the correct type (in generated code) and the value is obtained. If no process possible to import from is found, the address of a variable containing only zeros is returned by the `xGetExportAddr` function.

Note:

The strategy for import actions is in one sense not equal to the model for import given in the SDL recommendation. An import action is in the recommendation modeled as a signal sent from the importing process to the exporting process asking for the exported value, and a signal with this value sent back again. The synchronization effects by this signal communication is lost in the implementation model we have chosen. Instead our model is much easier and faster and the primary part of the import action, to obtain the exported value, is the same.

Services

Data Structure Representing Services

A service is represented by a struct type. The `xSrvRec` struct defined in `scttypes.h`, is, just like `xPrsRec` for processes, a struct containing general information about a service, while the parameters and variables of the service are defined in generated code in the same way as for processes.

In `scttypes.h` the following types concerning procedures can be found:

```
#ifdef XMONITOR
#define XCALL_ADDR   int  CallAddress;
#else
#define XCALL_ADDR
#endif

#define SERVICE_VARS \
   xSrvNode       NextSrv; \
   xPrsNode       ContainerPrs; \
   int            RestartAddress; \
   xPrdNode       ActivePrd; \
   void (*RestartPAD) (xPrsNode  VarP); \
   XCALL_ADDR \
   xSrvIdNode     NameNode; \
   int            State; \
   XSIGTYPE       pREPLY_Waited_For; \
   xSignalNode    pREPLY_Signal; \
   XINTRANSCOMP
#ifndef XNOUSEOFSERVICE
typedef struct xSrvStruct *xSrvNode;
#endif

#ifndef XNOUSEOFSERVICE
typedef struct xSrvStruct {
   SERVICE_VARS
}  xSrvRec;
#endif
```

In generated code yVDef_ProcedureName structs are defined according to the following:

```
typedef struct {
   SERVICE_VARS
   components for FPAR and DCL
}  yVDef_ServiceName;
```

The components in the `xSrvRec` are used as follows:

- **`NextSrv`** of type `xSrvNode`. Reference to next service contained in this process.
- **`ContainerPrs`** of type `xPrsNode`. Reference to the process instance containing this service.
- **`RestartAddress`** of type `int`. This component is used to find the appropriate SDL symbol to continue execution from.
- **`ActivePrd`** of type `xPrdNode`. This is a pointer to the xPrdRec that represents the currently executing procedure called from this service instance. The pointer is 0 if no procedure is currently called.
- **`RestartPAD`**, which is a pointer to a PAD function. This component refers to the PAD function where to execute the sequence of SDL symbols. RestartPAD is used to handle inheritance between service types.
- **`CallAddress`** of type `int`. This component contains the symbol number of the procedure call performed from this procedure (if any).
- **`NameNode`** of type `xSrvIdNode`. This is a pointer to the IdNode representing the service or service instantiation.
- **`State`** of type `int`. This component contains the int value used to represent the current state of the service instance.
- **`pREPLY_Waited_For`** of type `xSignalIdNode`. When a service is waiting in the implicit state for the pREPLY signal in a RPC call, this components is used to store the IdNode for the expected pREPLY signal.

- **pREPLY_Signal** of type xSignalNode. When a service receives a pCALL signal, i.e. accepts a RPC, it immediately creates the return signal, the pREPLY signal. This component is used to refer to this pREPLY signal until it is sent.
- **InTransition** of type xbool. This component is true while the service is executing a transition and it is false while the service is waiting in a state. The monitor system needs this information to be able to print out relevant information.

Executing Transitions in Services

From the scheduler's point view, it is not of interest if a process contains services or not. It is still the process instance that is scheduled in the ready queue and the PAD function of the process that is to be called to execute a transition. The PAD function for a process containing services performs three different actions:

- Assign default value to variables declared at the process level
- Create one service instance for each service or service instantiation in the process.
- Calls the proper PAD function for a service to execute transitions.

The structure for a PAD function for a process with services are as follows:

```
YPAD_FUNCTION(yPAD_z00_P1)
{
  YPAD_YSVARP
  YPAD_YVARP(yVDef_z00_P1)
  YPRSNAME_VAR("P1")
  LOOP_LABEL_SERVICEDECOMP
  CALL_SERVICE

/*-----
* Initialization (no START symbol)
------*/
  BEGIN_START_TRANSITION(yPDef_z00_P1)
  yAssF_SDL_Integer(yVarP->z002_Global,
     SDL_INTEGER_LIT(10), XASS);
  START_SERVICES
}
```

where LOOP_LABEL_SERVICEDECOMP and BEGIN_START_TARNSITION are empty macros, i.e. expanded to no code. The yAss_SDL_Integer statement in an assignment of a default value to a process variable.

The macro CALL_SERVICE is expanded to:

```
if (yVarP->ActiveSrv != (xSrvNode)0) {
  (*yVarP->ActiveSrv->RestartPAD)(VarP);
  return; \
}
```

that is to a call of the PAD function of service reference by ActiveSrv.

The macro START_SERVICE is expanded to a call to the function `xStart_Services`, which can be found in `sctsdl.c`.The function creates the service instances, sets up the ActiveSrv pointer for the process to the first service, and then schedules the process for a new transition. This means that the next action performed by the system will be the start transition by the first service instance. When the first service executes a nextstate or stop action in the end of its start transition, the process will be scheduled again to execute the start transition of the second service, and so on until all services in the process has executed its start transitions.

For ordinary transitions, i.e. reception of a signal, it is obvious from the code above that the ActiveSrv pointer is essential. It should refer to the service instance that is to be executed. When a signal is to be received by a process, it is the function xFindInputAction (in `sctsdl.c`) that determines how to handle the signal and if it is to be received, where is the code for that transition. This function now also determines and sets up the ActiveSrv pointer.

Procedures

Data Structure Representing Procedures

A procedure is represented by a struct type. The `xPrdRec` struct defined in `scttypes.h`, is, just like `xPrsRec` for processes, a struct containing general information about a procedure, while the parameters and variables of the procedure are defined in generated code in the same way as for processes.

In `scttypes.h` the following types concerning procedures can be found:

```
#define PROCEDURE_VARS \
   xPrdIdNode   NameNode; \
   xPrdNode     StaticFather; \
   xPrdNode     DynamicFather; \
   int          RestartAddress; \
   XCALL_ADDR \
   void (*RestartPAD) (xPrsNode  VarP); \
   xSignalNode  pREPLY_Signal; \
   int          State;

typedef struct xPrdStruct  *xPrdNode;

typedef struct xPrdStruct {
   PROCEDURE_VARS
}  xPrdRec;
```

In generated code yVDef_ProcedureName structs are defined according to the following:

```
typedef struct {
   PROCEDURE_VARS
   components for FPAR and DCL
}  yVDef_ProcedureName;
```

The components in the xPrdRec are used as follows:

- **NameNode** of type xPrdIdNode. This is a pointer to the IdNode representing the procedure type.
- **StaticFather** of type xPrdNode. This is a pointer that represents the scope hierarchy of procedures (and the process at the top), which is used when a procedure instance refers to non-local variables. An example is shown in Figure 558 on page 3103. StaticFather == 0 means that the static father is the process.
- **DynamicFather** of type xPrdNode. This is a pointer that represents that this procedure is called by the referenced procedure. DynamicFather == 0 means that this procedure was called from the process. This component is also used to link the xPrdRec in the avail list for the procedure type.
- **RestartAddress** of type int. This component is used to find the appropriate SDL symbol to continue execution from.
- **CallAddress** of type int. This component contains the symbol number of the procedure call performed from this procedure (if any).
- **RestartPRD** is a pointer to a procedure function. This component refers to the PRD function where to execute the next sequence of SDL symbols. RestartPRD is used to handle inheritance between procedures.
- **pREPLY_Signal** of type xSignalNode. When a process receives a pCALL signal, i.e. accepts a RPC, it immediately creates the return signal, the pREPLY signal. This component is used to refer to this pREPLY signal until it is sent.
- **State** of type int. This is the value representing the current state of the procedure instance.

In Figure 558 on page 3103 an example of the structure of yVDef_ProcedureName after four nested procedure calls are presented. Note that procedure Q is declared in the process, procedure R and S in Q and T in S.

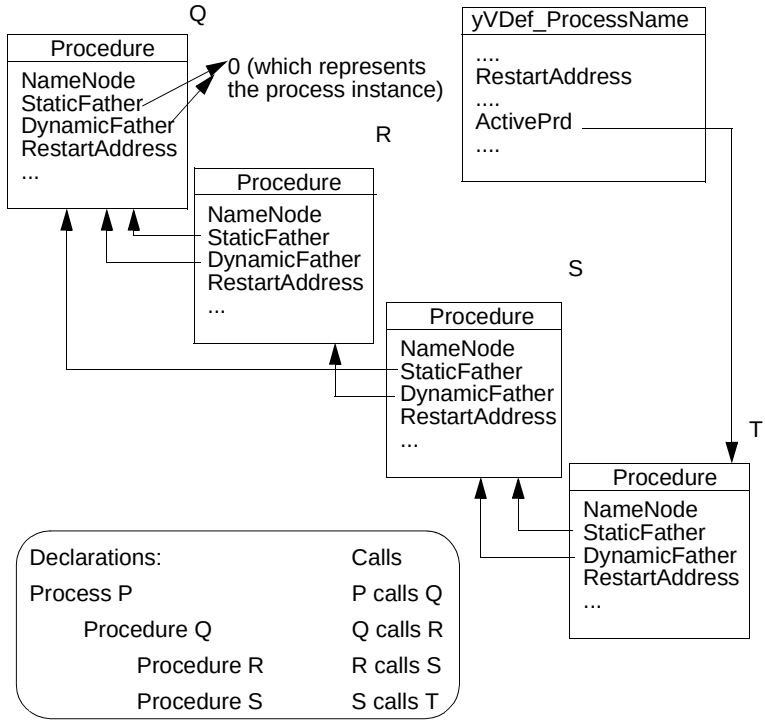

Figure 558: Structure of `yVDef_ProcedureName` *after four nested procedure calls*

The SDL procedures are partly implemented using C functions and partly using the structure shown above. Each SDL procedure is represented by a C function, which is called to execute actions defined in the procedure. This function corresponds to the `PAD` function for processes. The formal parameters and the variables are however implemented using a struct defined in generated code. The procedure stack for nested procedure calls is implemented using the components `StaticFather` and `DynamicFather`, and does not use the C function stack.

Calling and Returning from Procedures

Procedure calls and procedure returns are handled by three functions, one handling allocation of the data areas for procedures:

```
xPrdNode  xGetPrd( xPrdIdNode  PrdId )
```

and two functions called from generated code at a procedure call and a procedure return:

```
void xAddPrdCall(
  xPrdNode  R,
  xPrsNode  VarP,
  int       StaticFatherLevel,
  int       RestartAddress )

void xReleasePrd (xPrsNode  VarP)
```

A procedure call in SDL is in C represented by the following steps:

1. Calling `xGetPrd` to obtain a data area for the procedure.
2. Assigning procedure parameters to the data area.
3. Calling `xAddPrdCall` to link the procedure into the static and dynamic chains.
4. Calling the C function modeling the SDL procedure, i.e. the `yProcedureName` function.

The parameters to `xAddPrdCall` are as follows:

- **`R`**. A reference to the `xPrdNode` obtained from the call of `xGetPrd`.
- **`VarP`**. A reference to the yVDef_ProcessName, i.e. the data area for variables and parameters of the process (even if it is a procedure that performed the procedure call).
- **`StaticFatherLevel`**. This is the difference in declaration levels between the caller and the called procedure. This information is used to set up the `StaticFather` component correctly.
- **`RestartAddress`**. This is the symbol number of the SDL symbol directly after the procedure call. The symbol number is the switch case label generated for all symbols.

The `xGetPrd` returns a pointer to an `xPrdRec`, which can then be used to assign the parameter values directly to the components in the data

area representing the formal parameters and variables of the procedure. Note that IN/OUT parameters are represented as addresses in this struct.

A procedure return is in generated code represented by calling the `xReleasePrd` followed by return 0, whereby the function representing the behavior of the SDL procedure is left.

The function representing the behavior of the SDL procedure is returned in two main situations:

- When an SDL `Return` is reached (the function returns 0)
- When a `Nextstate` is reached (the function returns 1).

If 0 is returned then the execution should continue with the next SDL symbol after the procedure call, while if 1 is returned the execution of the process instance should be terminated and the scheduler (main loop) should take control. This could mean that a number of nested SDL procedure calls should be terminated.

To continue to execute at the correct symbol when a procedure should be resumed after a nextstate operation, the following code is introduced in the `PAD` function for processes containing procedure calls:

```
while ( yVarP->ActivePrd != (xPrdNode)0 )
  if ((*yVarP->ActivePrd->RestartPRD)(VarP))
    return;
```

This means that uncompleted procedures are resumed one after one from the bottom of the procedure stack, until all procedures are completed or until one of them returns 1, i.e. executes a nextstate operation, at which the process is left for the scheduler again.

Channels and Signal Routes

The `ChannelIdNodes` for channels, signal routes, and gates are used in the functions `xFindReceiver` and `xIsPath`, which are both called from `SDL_Output`, to find the receiving process when there is no TO clause in the Output statement, respectively to check that there is a path to the receiver in the case of a TO clause in the Output statement. In both cases the paths built up using the `ToId` components in the `IdNodes` for processes, channels and signal routes are followed. To show the structure of these paths we use the small SDL system given in Figure 559.

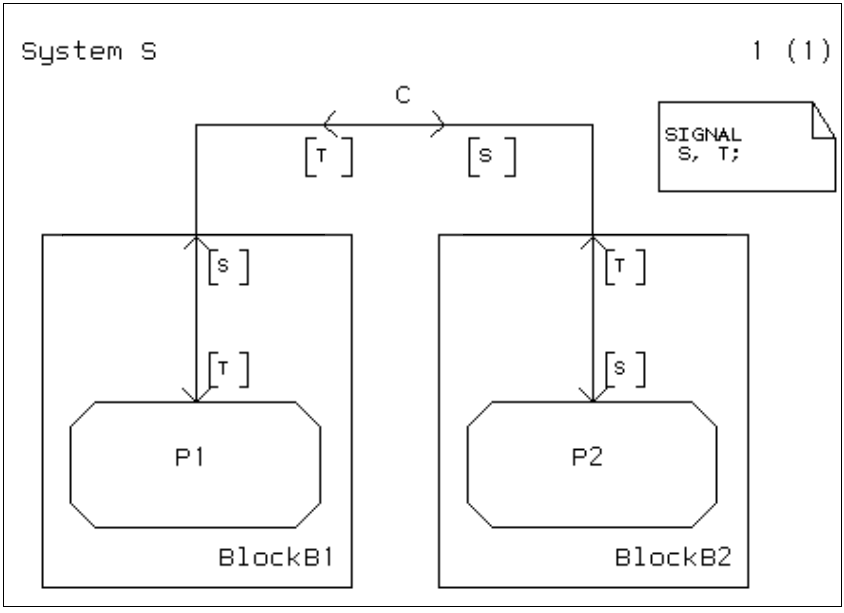

Figure 559: A small SDL system

During the initialization of the system, the symbol table is built up. The part of the symbol table starting with the system will then have the structure outlined in Figure 560. As we can see in this example the declarations in the SDL system are directly reflected by `IdNodes`.

Note:

Each channel and signal route is represented by two `IdNodes`, one for each direction. This is also true for an unidirectional channel or signal route. In this case the signal set will be empty for the unused direction.

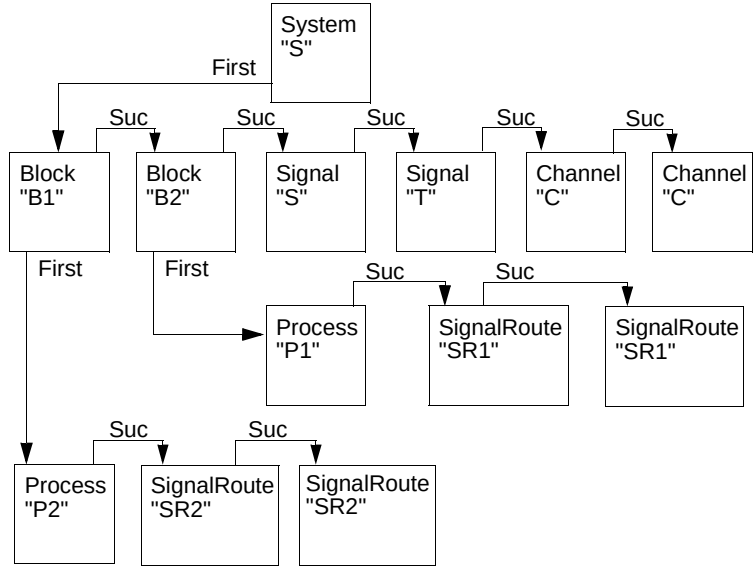

Figure 560: The symbol table tree for the system in Figure 559

Each IdNode representing a process, a signal route, or a channel will have a component `ToId`. A `ToId` component is an address to an array of references to `IdNodes`. The size of this array is dependent on the number of items this object is connected to. A process that has three outgoing signal routes will have a `ToId` array which can represent three pointers plus an ending `0` pointer.

In the example in Figure 559 and Figure 560 there is no branching, so all `ToId` arrays will be of the size necessary for two pointers. Figure 561 shows how the `IdNodes` for the processes, signal routes and channels are connected to form paths, using the components `ToId`. In this case only simple paths are found (one from P1, via SR1, C, SR2, to P2, and

one in the reverse direction). The generalization of this structure to handle branches is straightforward and discussed in the previous paragraph.

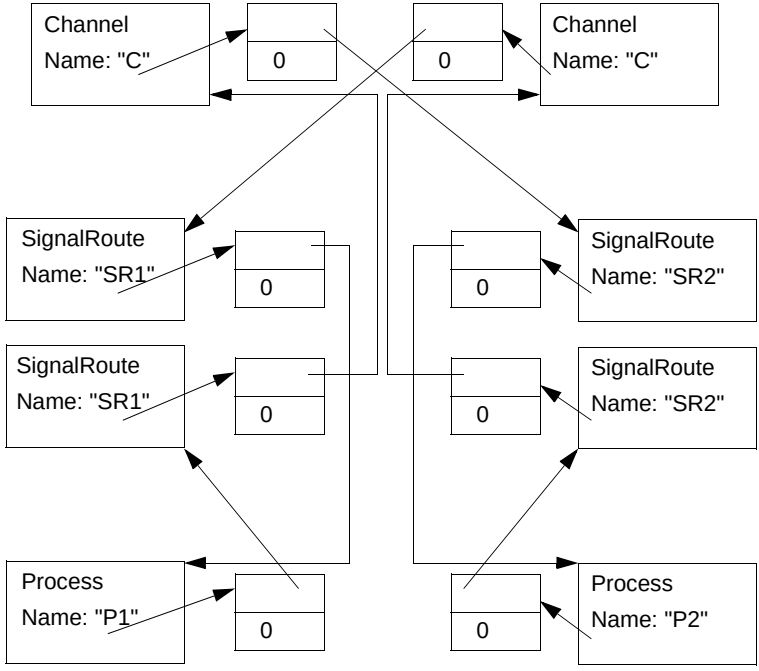

Figure 561: The connection of `ToId` *for the system in Figure 559 and Figure 560*

The Type Concept in SDL-92

The probably most important new feature in SDL-92 is the introduction of the object oriented features, such as TYPE, INHERITS, VIRTUAL, and REDEFINED. Here we start by discussing process types.

For each process type the Cadvanced/Cbasic SDL to C Compiler will generate:

- a `PrsIdNode`
- a `PAD` function
- a `yVDef_ProcessName` struct.

In the `PrsIdNode` there is one component (Super) that will refer to the `PrsIdNode` for the process type inherited by this process type. As sons to a `PrsIdNode`, `IdNodes` for declaration that are common for all instantiation of the process type can be found. Examples of such `IdNodes` are: nodes for variables, formal parameters, signals, timers, procedures, states, newtypes, and syntypes. Any typedefs or help functions for such units are also treated in the process type.

The `PAD` function will be independent of the `PAD` function for a inherited type, each `PAD` function just implementing the action described in its process type.

A `yVDef_ProcessName` struct will on the other hand include all variables and formal parameters from the top of the inheritance chain and downwards. Example:

```
process type P1;
fpar f1 integer;
dcl  d1 integer;
...
endprocess;

process type P2 inherits P1;
fpar f2 integer;
dcl  d2 integer;
...
endprocess;
```

This will generate the following principle yVDef_... structs:

```
typedef struct {
  PROCESS_VARS
  SDL_Integer f1;
  SDL_Integer d1;
} yVDef_P1;
```

```
typedef struct {
  PROCESS_VARS
  SDL_Integer f1;
  SDL_Integer d1;
  SDL_Integer f2;
  SDL_Integer d2;
} yVDef_P2;
```

A pointer to `yVDef_P2` can thus be casted to a pointer to `yVDef_P1`, if only the common component (in `PROCESS_VARS`) or the variables in P1 is to be accessed. This possibility is used every time the `PAD` function for an inherited process type is called.

Each process instantiation will all be implemented as a xPrsIdNode. The `Super` component in such an object refers to the process type that is instantiated. No `PAD` function or yVDef_... struct will be generated. As sons to the `PrsIdNode` for a process instantiation, only such object are inserted that are different in different instantiations. For a process instantiation this is the gates. For other types of information the process instantiation uses the information given for its process type.

A very similar structure when it comes to `IdNodes` generated for block types and block instantiations are used by the code generator. There will be a `BlockIdNode` for both a block type and for a block instantiation. As sons to a block type, nodes that are the same in each block instantiation can be found (example: signal, newtype, syntype, block type, process type, procedure). As sons to a block instantiation, nodes that are needs to be represented in each block instantiation can be found (example: block instantiation, process instantiation, channel, signal route, gate, remote definitions).

Note:

A block or process (according to SDL-88), that is contained in a block type or a system type, is translated as if it was a type and instantiation at the same place.

A way to look at the structure of `IdNodes` in a particular system is to use the command Symboltable in the monitor system. This command prints the `IdNode` structure as an indented list of objects.

Allocating Dynamic Memory

Introduction

This section deals with the allocation and deallocation of dynamic memory.

> **Note:**
>
> This information is only valid when the Master Library is used. The OS integrations might have different strategies for memory allocation.

Information is provided about the following topics:

- Explanation about how dynamic memory is allocated and reused (deallocation and avail lists)
- How to estimate the total need of dynamic memory for an application.

Dynamic memory is used for a number of objects in a run-time model for applications generated by the Cadvanced/Cbasic SDL to C Compiler. These objects are:

- Process instances
- Signal and timer instances
- Procedure instances
- Charstring, Octet_string, Bit_string, and Object_identifer variables and variables of String, Bag, general Array, and general Powerset types.
- Variables of other user-defined data types, where the user has decided to use dynamic memory.

To help to estimate the need for memory for an application we will give information about the size of these objects and about how many of the objects are created. The size information given is true for generated applications, that is, ones that do not, for example, contain the monitor. The type definitions given are stripped of components that will not be part of an application. The full definitions may be found in the file `scttypes.h`.

Processes

Each process instance is represented by two structs that will be allocated on the heap. In `scttypes.h` the type `xLocalPIdRec` is defined and in generated code `yVDef_ProcessName` structs are defined:

```
typedef struct {
   xPrsNode      PrsP;
}  xLocalPIdRec;

typedef struct {
   xPrsNode       Pre;
   xPrsNode       Suc;
   int            RestartAddress;
   xPrdNode       ActivePrd;
   void (*RestartPAD) (xPrsNode  VarP);
#ifndef XNOUSEOFSERVICE
   xSrvNode       ActiveSrv;
   xSrvNode       SrvList;
#endif
   xPrsNode       NextPrs;
   SDL_PId        Self;
   xPrsIdNode     NameNode;
   int            State;
   xSignalNode    Signal;
   xInputPortRec  InputPort;
   SDL_PId        Parent;
   SDL_PId        Offspring;
   int            BlockInstNumber;
   xSignalIdNode  pREPLY_Waited_For;
   xSignalNode    pREPLY_Signal;

   /* variables and formal parameters in the
      process */
} yVDef_ProcessName;
```

To calculate the size of the structs above it is necessary to know more about the components in the structs. The types `xPrsNode`, `xPrdNode`, `xSignalNode`, `xPrsIdNode`, `xStateIdNode`, and `xSignalIdNode` are all pointers, while `SDL_PId` is a struct containing an int and a pointer. The `xInputPortRec` is a struct with two pointers and one int.

This means that it is possible to calculate the size of the `xLocalPIdRec` and the `xPrsRec` struct using the following formulas, if the compiler does not use any strange alignment rules:

$$\text{Size}_{\texttt{xLocalPIdRec}} = \text{Size}_{\text{address}}$$

$$\text{Size}_{\texttt{xPrsRec}} = 16 \cdot \text{Size}_{\text{address}} + 7 \cdot \text{Size}_{\texttt{int}}$$

The size of xPrsRec can be reduced by 2 x sizeof (address) if the code is compiled with the XNOUSEOFSERVICE flag. Then, of course, the SDL concept service cannot be used. The size of `yVDef_ProcessName` is the size of the `xPrsRec` plus the size of the variables and parameters in the process. Any overhead introduced by the C system should also be added. The size of the formal parameter and variables is of course dependent on the declarations in the process. The translation rules for SDL types, both predefined and user defined, can be found in *chapter 56, The Cadvanced/Cbasic SDL to C Compiler*.

For each process instance set in the system the following number of structs of a different kind will be allocated:

- There will be one `xLocalPIdRec` for each process instance created. These structs will not be reused, as they serve as identification of process instances that have existed (see also optimizations below).
- There will be as many `yVDef_ProcessName` structs as the maximum concurrently executing process instances of the process instance set (maximum during the complete execution of the program).

The `yVDef_ProcessName` structs are reused by having an avail list where this struct is placed when the process instance it represents perform a stop action. There is one avail list for each process type. When a process instance should be created, the runtime library first looks at the avail list and reuses an item from the list. Only if the avail list is empty new memory is allocated.

Compilation switch XPRSOPT

If the compilation switch `XPRSOPT` is defined then:

- `xLocalPIdRec`s are reused together with the `xPrsRec`s.
- `xLocalPIdRec`s contain an additional int component.

Services

Services are handled very similar to processes. The following struct type are allocated for each service instance.

```
typedef struct xSrvStruct {
   xSrvNode       NextSrv;
   xPrsNode       ContainerPrs;
   int            RestartAddress;
   xPrdNode       ActivePrd;
   void (*RestartPAD) (xPrsNode  VarP);
   xSrvIdNode     NameNode;
   int            State;
   XSIGTYPE       pREPLY_Waited_For;
   xSignalNode    pREPLY_Signal;
}  xSrvRec;
```

This means that:

$$\text{Size}_{\texttt{xSrvRec}} = 7 \cdot \text{Size}_{\text{address}} + 2 \cdot \text{Size}_{\texttt{int}}$$

The size of `yVDef_ServiceName` is the size of the xSrvRec plus the size of the variables in the service. `yVDef_ServiceName` struct are re-used in the same way as for processes (see previous section).

Signals

Signals are handled in much the same way as processes. A signal instance is represented by one struct (in generated code generated).

```
typedef struct {
   xSignalNode   Pre;
   xSignalNode   Suc;
   int           Prio;
   SDL_PId       Receiver;
   SDL_PId       Sender;
   xIdNode       NameNode;

   /* Signal parameters */
} yPDef_SignalName;
```

This struct type contains one component for each signal parameter. The component types will be the translated version of the SDL types of the parameters.

This means that it is possible can calculate the size of a `xSignalRec`, which is the same as a struct for a signal without parameters, using the following formula:

$$\text{Size}_{\texttt{xSignalRec}} = 5 \cdot \text{Size}_{\text{address}} + 3 \cdot \text{Size}_{\texttt{int}}$$

The size of a `yPDef_SignalName` struct is thus equal to the size of the `xSignalRec` plus the size of the parameters. The translation rules for SDL types, both the predefined and user defined, can be found in *chapter 56, The Cadvanced/Cbasic SDL to C Compiler*.

For each signal type in the system the following number of data areas will be allocated:

- There will be as many `yPDef_SignalName` struct as the maximum number of signals (during the complete execution of the program) of the signal type that are sent but not yet received in an input operation.

The `yPDef_SignalName` struct is reused by having an *avail* list, where the struct is placed when the signal instance they represent is received. The exact point where the signal instance is returned to the avail list is when the transition caused by the signal instance is ended by a nextstate or stop action. There is one avail list for each signal type. When a signal instance should be created, for example during an output operation, the runtime library first looks at the avail list and reuses an item from this list. Only if the avail list is empty new memory is allocated.

Note:

There is one common avail list for all signals without parameters.

Timers

The memory needed for timers can be calculated in the same way as for signals with one exception, each timer contains an extra `SDL_Time` component, i.e. two extra 32-bit integers.

Procedures

Procedures and processes have much in common in terms of memory allocation. A procedure is, during the time it exists from call to return, represented by a struct; the `yVDef_ProcedureName`.

```
typedef struct {
   xPrdIdNode  NameNode;
   xPrdNode    StaticFather;
   xPrdNode    DynamicFather;
   int         RestartAddress;
   int (*RestartPRD) (xPrsNode  VarP);
   xSignalNode pREPLY_Signal;
   int         State;

   /* Formal parameters and variables */
} yVDef_ProcedureName;
```

The struct type contains one component for each formal parameter or variable. The component types will be the translated version of the SDL types of the parameters, except for an IN/OUT parameter which is represented as an address.

The size of the `xPrdRec` struct (which is the same as a procedure without variables and formal parameters) can be calculated using the following formula:

$$\text{Size}_{\texttt{xPrdRec}} = 5 \cdot \text{Size}_{\text{address}} + 2 \cdot \text{Size}_{\texttt{int}}$$

The size of a `yVDef_ProcedureName` struct is the size of the `xPrdRec` plus the size of the formal parameter and variables defined in the procedure. The translation rules for SDL types, both the predefined and user defined can be found in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*.

For each type of procedure in the system the following number of data areas will be allocated:

- There will be as many `yVDef_ProcedureName` structs as the maximum number of concurrent calls (during the complete execution of the program) of the procedure. Concurrent calls occur both when a procedure calls itself recursively within one process instance, and when several process instances of the same process type calls the same procedure during overlapping times.

The `yVDef_ProcedureName` struct is reused by having an avail list, where this two struct is placed when the procedure instance executes a

return action. There is one avail list for each procedure type. When a procedure instance should be created, that is, at a call operation, the runtime library first looks at the avail list and reuses an item in the list. Only if the avail list is empty new memory is allocated.

Data types

The predefined SDL type charstring is implemented as `char *` in C and thus requires dynamic memory allocation. The predefined data types Bit_string, Octet_string, and Object_identifier are also implemented using dynamic memory.

The implementation of the SDL sorts Charstring, Bit_string, Octet_string, and Object_identifier is both flexible in length and all memory can be reused.

The mechanism used to release unused memory is to call the `xFree` function in the file `sctos.c`, which uses the standard function free to release the memory.

Charstrings, Bit_strings, Octet_strings, and Object_identifiers are also handled correctly if they are part of structs or arrays. When, for example, a new value is given to a struct having a charstring component, the old charstring value will be released. For all structured types containing any of these types there will also be a `Free` function that is utilized to release all dynamic memory in the structured variable.

Functions for Allocation and Deallocation

The allocation and deallocation of memory is handled by the functions `xAlloc` and `xFree` in the file `sctos.c`. The functions in this file are used for the adoption of the generated applications to the operating system or hardware. The `sctos.c` file is described in detail in "The sctos.c File" on page 3149.

In generated code and in the run-time library the functions `xAlloc` and `xFree` are used in each situation where memory is needed or can be released. `xAlloc` receives as parameter a requested size in bytes and returns the address to a data area of the requested size. All bytes in the data area are set to zero. `xFree` takes the address of a pointer and returns the data area referenced by the pointer to the pool of free memory. It also sets the pointer to 0.

The xAlloc and xFree functions are usually implemented using some version of the C standard functions for allocation (malloc, calloc) and deallocation (free). Other implementations are of course possible as long as the interface described in the previous section is fulfilled. In a micro controller, for example, it is probably necessary to handle allocation and deallocation directly towards the physical memory.

To prevent memory fragmentation we have used our own avail lists in almost all circumstances. Memory fragmentation is phenomena occurring when a program allocates and de-allocates data areas (of different sizes) in some “random” order. Then small pieces of memory here and there are lost, since their sizes are to small to fit an allocation request. This can lead to a slowly increasing demand for memory for the application.

Note that deallocation of memory is only used for data types. More specific it is used for variables of type:

- Charstring
- Octet_string
- Bit_string
- Object_identifier
- Types created by String (not #STRING) and Bag generator
- Types created by Array generator, if the index type is such that an array in C cannot be used. (General array)
- Types created by Powerset generator, if the component type has the has property as for the index type in general arrays.

This means that if variables of the above mentioned types are not used and the user has not introduced the need for deallocation of memory himself, no memory deallocation will occur. In this case it is of course unnecessary to implement the xFree function.

It is easy to trace the need for dynamic memory. As all memory allocation is carried out through the xAlloc function and this function is available in source code (in sctos.c), it is only necessary to introduce whatever count statements or printout statements that are appropriate.

Compilation Switches

The compilation switches are used to decide the properties of the Master Library and the generated C code. Both in the library and in generated code `#ifdefs` are used to include or exclude parts of the code.

The switches that are used can be divided into four groups.

1. Switches defining properties of the compiler.
2. Switches defining a library version.
3. Switches defining a property of a library version.
4. Switches defining the implementation of a property.

The first group will be discussed in "Adaptation to Compilers" on page 3147.

The following switches define the library version:

Switch	Corresponds to Library
`SCTDEBCOM`	*Simulation*
`SCTDEBCLCOM`	*RealTimeSimulation*
`SCTAPPLCLENV`	*Application*
`SCTDEBCLENVCOM`	*ApplicationDebug* (Simulation with environment)
`SCTPERFSIM`	*PerformanceSimulation* (Library with simulated time, no environment functions, no monitor.)

The definition of the properties of these libraries can be found in `scttypes.h` and will be discussed below. Each library version is specified by the switches in the group property switches that it defines.

New library versions, containing other combinations of property switches, can easily be defined by introducing new library definitions in the `scttypes.h` file.

The property switches discussed below can be used to form library versions. If not stated otherwise for a certain property, all code, variables, struct components, and so on, are either included or excluded using conditional compiling (`#ifdef`), depending on whether the property is used or not.

This means, for example, that all code for the monitor interface will be removed in an application not using the monitor, which makes the application both smaller and faster.

Description of Compilation Switches

XCLOCK

If this compilation switch is not defined then simulated time is used, otherwise the system time is connected to a real clock, via the `sctos.c` function `SDL_Clock`.

XCALENDARCLOCK

This is the same as `XCLOCK` (it will actually define `XCLOCK`), except that if `XCLOCK` is used, time will be zero at system start up, while if `XCALENDARCLOCK` is used, time will be whatever the clock returns at system start up.

XPMCOMM

Define this compilation switch if the application should be able to communicate with signals via the SDL Suite communication mechanism. This facility is used to accomplish communicating simulations and simulations communicating with, for example, user interfaces.

XITEXCOMM

This switch should be defined if a generated simulator should be able to communicate with a TTCN simulator.

XENV

If this compilation switch is defined the environment functions `xInitEnv`, `xCloseEnv`, `xInEnv`, and `xOutEnv` will be called at appropriate places.

XTENV

This is the same as `XENV` (it will actually define `XENV`), except that xInEnv should return a time value which is the next time it should be called (a value of type `SDL_Time`). The main loop will call `xInEnv` at

the first possible occasion after the specified time has expired, or when the SDL system becomes idle.

XENV_CONFORM_2_3

This switch make signals using a compatible data structure as in SDT 2.3. This means that an extra and unnecessary component `yVarP` is inserted in each signal.

XSIGLOG

This facility makes it possible for a user to implement his own log of the major events in the system. This compilation switch is normally not defined. By defining this switch, each output of a signal, i.e. each call of the function `SDL_Output`, will result in a call of the function `xSignalLog`. Each time a transition is started, the function `xProcessLog` will be called.

These functions have the following prototypes:

```
extern void xSignalLog
  (xSignalNode  Signal,
   int          NrOfReceivers,
   xIdNode    * Path,
   int          PathLength);

extern void xProcessLog
  (xPrsNode P);
```

which are included in `scttypes.h` if `XSIGLOG` is defined.

`Signal` will be a pointer to the data area representing the signal instance.

`NrOfReceivers` will indicate the success of the output according to the following table:

NrOfReceivers	Output Statement Contents
-1:	A TO clause, but no path of channels and signal routes were found between the sender and the receiver.
0:	No TO clause, and no possible receivers were found in the search for receivers.

NrOfReceivers	Output Statement Contents
1:	If the output statement contains a TO clause, a path of channels and signal routes was found between the sender and the receiver. If the output statement contains no TO clause, exactly one possible receiver was found in the search for receivers. The output was thus successful. The only error situation that still might be present is if an output with a TO clause is directed to a process instance that is stopped.

The third parameter, `Path`, is an array of pointer to `IdNodes`, where `Path[0]` refers to the `IdNode` for the sending process, `Path[1]` refers to the first signal route (or channel) in the path between the sender and the receiver, and so on, until `Path[PathLength]` which refers to the `IdNode` for the receiving process.

The parameter `P` in the `xProcessLog` function will refer to the process just about to start executing.

The fourth parameter, `PathLength`, represents thus the number of components in the `Path` array that are used to represent the path for the signal sent in the output. If the signal is sent to or from the environment, either `Path[0]` or `Path[PathLength]` will refer to `xEnvId`, that is to the `IdNode` for the environment process.

In the implementation of the `xSignalLog` and `xProcessLog` functions which should be provided by the user, the user has full freedom to use the information provided by the parameters in any suitable way, except that it is not possible to change the contents of the signal instance. The functions are provided to make it possible for a user to implement a simple log facility in environments where standard IO is not provided, or where the monitor system is too slow or too large to fit. A suitable implementation can be found in the file `sctenv.c`

XTRACE

If this compilation switch is defined, traces of the execution can be printed.

This facility is normally used together with the monitor, but can also be used without the monitor. The file `stdout` must of course be available for printing.

Setting trace values must, without the monitor, be performed in included C code, as the monitor interface is excluded. The trace components are called `Trace_Default` and can be found in `IdNodes` representing system, blocks, and processes, and in the struct `xPrsRec` used to represent a process instance. The values stored in these components are the values given in the Set-Trace command in the monitor. The value undefined is represented by -1.

When the monitor is excluded all trace values will be undefined at startup, except for the system which has trace value 0. This means that no trace is active at start up.

Example 512 ––

Suitable statements to set trace values in C code:

```
xSystemId->Trace_Default = value;
   /* System trace */
xPrsN_ProcessName->Trace_Default = value;
   /* Process type trace */
PId_Var.LocalPId->PrsP->NameNode->Trace_Default =
  value
   /* Process type trace */
PId_Var.LocalPId->PrsP->Trace_Default = value;
   /* Process instance trace */
```

`PId_Var` is assumed to be a variable of type `PId`.

> **Note:**
>
> Note that the variable `xPrsN_ProcessName` is declared, and therefore only available, in the file containing the block where the process is defined (and in files representing processes contained in the block).

––

XGRTRACE

If this compilation switch is defined it is possible for a simulation to communicate with the Organizer and the SDL Editor to highlight SDL symbols in the graphical representation.

This feature is used together with the monitor to implement graphical trace and commands like Show-Next-Symbol and Show-Previous-Symbol. It is possible to use graphical trace without the monitor in the same way as the ordinary trace (substitute `Trace_Default` with `GRTrace` in the description above). However the graphical trace is synchronized which means that the speed of the application is dramatically reduced.

XCTRACE

Defining this compilation switch makes information available to the monitor about where in the source C code the execution is currently suspended. This facility, which is used together with the monitor, makes it possible to implement the monitor command Show-C-Line-Number.

XMONITOR

If this compilation switch is defined, the monitor system is included in the generated application.

XCOVERAGE

This compilation switch makes it possible to generate coverage tables. It should be used together with `XMONITOR`.

MAX_READ_LENGTH

This macro controls the length of the `char *` buffers used to read values of SDL sorts. A typical usage is when the monitor commands Assign-Value is entered. If large data types are used, it is possible to redefine the sizes of the buffers from their default size (10000 bytes) to something more appropriate.

XSIMULATORUI

This compilation switch should be defined if the generated simulator is to be executed from the Graphical User Interface to the simulator monitor.

XMSCE

This compilation switch should be defined if the generated simulator should be able to generate Message Sequence Charts.

XSDLENVUI

This compilation switch should be defined if it should be possible to start and communicate with a user interface (or another application) from the simulation. This feature should be used together with the monitor and will define the switch XPMCOMM (see also this switch).

XNOMAIN

When this compilation switch is defined the functions main and xMainLoop are removed using conditional compiling. This feature is intended to be used when a generated SDL application should be part of an already existing application, that is when the SDL system implements a new function in an existing environment. The following functions are available for the user to implement scheduling of SDL actions:

```
extern void xMainInit(
  void (*Init_System) (void)
#ifdef XCONNECTPM
 ,int argc,
  char *argv[]
#endif
  );

#ifdef XNOMAIN
extern void SDL_Execute (void);

extern int SDL_Transition_Prio (void);

extern void SDL_OutputTimer (void);

extern int SDL_Timer_Prio (void);

extern SDL_Time SDL_Timer_Time (void);
#endif
```

The behavior of these functions are as follows:

xMainInit: This function should be called to initialize the SDL system before any other function in the runtime library is called. An appropriate way to call xMainInit is:

```
#ifdef XCONNECTPM
xMainInit(yInit, argc, argv);
#else
xMainInit(yInit);
#endif
```

The compilation switch XCONNECTPM will be defined if the any switch that requires communication via the SDL Suite communication mechanism is defined (XPMCOMM or XGRTRACE).

SDL_Execute: This function will execute one transition by the process instance first in the ready queue.

Before calling this function it must be checked that there really is at least one process instance in the ready queue. This test can be performed using the function SDL_Transition_Prio discussed below.

SDL_Transition_Prio: This function returns the priority of the process first in the ready queue (if signal priorities are used it is the priority of the signal that has caused the transition by the actual process instance). If the ready queue is empty, -1 is returned.

SDL_OutputTimer: This function will execute one timer output and may only be called if there is a timer ready to perform a timer output. This test can be performed with either SDL_Timer_Prio or SDL_Timer_Time described below.

SDL_Timer_Prio: This function returns the priority of the timer first in the timer queue if the timer time has expired for this timer. That is, if Now is greater than or equal to the time given in the Set statement for the timer.

If the timer queue is empty or the timer time for the first timer has not expired, -1 will be returned.

If signal priorities are used, the priority returned is the priority assigned to the timer type (in the timer definition) or the default timer priority; while if process priorities are used the priority returned is the priority of the process that has set the timer.

SDL_Timer_Time: This function returns the time given in the set statement for the first timer in the timer queue. If the timer queue is empty, the largest possible time value (xSysD.xMaxTime) is returned.

Depending on how the SDL system is integrated in an existing environment it might be possible to also use the monitor system. In that case the function xCheckMonitors should be called to execute monitor commands.

```
extern void xCheckMonitors (void);
```

To give some idea of how to use the functions discussed above, an example reflecting the way the internal scheduler in the runtime library works is given below:

Example 513 ----------

```
  while (1) {
#ifdef XMONITOR
    xCheckMonitors();
#endif
    if ( SDL_Timer_Prio() >= 0 )
      SDL_OutputTimer();
    else if ( SDL_Transition_Prio() >= 0 )
      SDL_Execute();
  }
```

XMAIN_NAME

Sometimes when integrating generated application or simulations in larger environments the main function can be useful but cannot have the name `main`. This name can be changed to something else by defining the macro `XMAIN_NAME`. The main function came be found in the file `sctsdl.c`.

XSIGPRIO

The `XSIGPRIO` compilation switch defines that priorities on signals (set in Output statements) should be used. This switch and the three other switches for priorities given below are, of course, mutually exclusive.

A signal priority is specified with a priority directive (see "Assigning Priorities – Directive #PRIO" on page 2739 in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*, that is by a comment with the following outline:

```
/*#PRIO 5 */.
```

A priority can be assigned to a signal instance in an output statement by putting a #PRIO directive **last in the output symbol**. In SDL/PR it is possible to put the #PRIO directive both immediately before and immediately after the semicolon ending the output statement. The Cadvanced/Cbasic SDL to C Compiler will first look for #PRIO directives in the output statement. If no directive is found there it will look in the signal definition for the signal for a priority directive. A #PRIO direc-

tive should be placed directly **before** the comma or semicolon ending the definition of the signal.

Example 514 ----------

```
SIGNAL
  S1 /*#PRIO 3 */,
  S2 (Integer) /*#PRIO 5 */;
```

If no priority directive is found in the output symbol or in the definition of the signal, the default value for signal priority is used. This value is 100. Timers can be assigned priorities in timer definitions in the same way as signals in signal definitions.

The signal priorities will be used to sort the input port of process instances in priority order, so that the signal with highest priority (lowest priority value) is at the first position. Two signals with same priority are placed in the order they arrive. The priority of the signal that can cause the next transition by a process instance is used to sort the ready queue in priority order, so that the process with a signal of highest priority is first. With equal priority, the processes are placed in the order they are inserted into the ready queue. If a continuous signal caused a processes to be inserted into the ready queue, it is the priority of the continuous signal that will be used as signal priority for this “signal”.

Note that a start transition also have a “signal priority”. This is by default also 100 and is set by the macro `xDefaultPrioCreate` described below.

Caution!

Signal priority is not included in SDL according to ITU Recommendation Z.100, and that sorting the signals in the input port of a process instance according to priorities is a direct violation of the SDL standard. This feature is however included for users that need such a behavior to implement their applications.

XPRSPRIO

This compilation switch defines that process priorities should be used. For more information see chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*, section Assigning Priorities - Directive #PRIO.

XSIGPRSPRIO

This compilation switch defines that priorities on signals should be used as first key for sorting in priority order, and process priorities should be used as second key.

XPRSSIGPRIO

This compilation switch defines that process priorities should be used as first key for sorting in priority order, and priorities on signals should be used as second key.

xDefaultPrio...

It is possible to redefine the default priorities for processes, signals, timer signals, continuous signals and start-up signals by defining the symbols below to appropriate values. The default value for these defaults are 100.

```
xDefaultPrioProcess
xDefaultPrioSignal
xDefaultPrioTimerSignal
xDefaultPrioContSignal
xDefaultPrioCreate
```

XOPT

This compilation switch will turn on full optimization (except XOPTCHAN), that is, it will define the following switches:

XOPTSIGPARA	XOPTDCL
XOPTFPAR	XOPTSTRUCT
XOPTLIT	XOPTSORT

For more information, see these switches below. The XOPT switches should not be used together with the monitor.

XOPTSIGPARA

In the symbol table tree (see section "Symbol Table Tree Structure" on page 3028) there will be one node for each parameter to a signal. These nodes are not necessary in an application and can be removed by defining the compilation switch XOPTSIGPARA.

XOPTDCL

There will be a `VarIdNode` in the symbol table tree for each variable declared in processes, procedures, or operator diagram. These nodes are not used in an application (without the monitor) and can be removed by defining the compilation switch `XOPTDCL`.

XOPTFPAR

There will be a `VarIdNode` in the symbol table tree for each formal parameter in a processes, procedures, or operator diagram. These node are not used in an application and may be removed by defining the compilation switch `XOPTFPAR`.

XOPTSTRUCT

For each component in an SDL struct there will be one `VarIdNode` defining the properties of this component. These `VarIdNodes` are not used in an application and can be removed by defining the compilation switch `XOPTSTRUCT`.

XOPTLIT

For each literal in a newtype that will be translated to an enum type, there will be an `LitIdNode` representing the literal. These nodes will not be used in an application and can be removed by defining the compilation switch `XOPTLIT`.

XOPTSORT

Each newtype and syntype, including the SDL standard types, will be represented by an `SortIdNode`. These nodes are not used in an application if all the other `XOPT...` mentioned above are defined.

XNOUSEOFREAL

Defining this compilation switch will remove all occurrences of C `float` and `double` types, and means for example that the SDL type Real is no longer available.

This switch is intended to be used in situations when it is important to save space, to see to that the library functions for floating type operations are not necessary to load. It cannot handle situations when the user includes floating type operations in C code, for example #CODE directives. Another consideration is if BasicCTypes.pr, or other ADTs, are

included in the system. If so, it is required that types dependent on SDL Real be removed from these packages.

XNOUSEOFOBJECTIDENTIFER

Defining this switch will remove all code for the SDL predefined sort Object_identifier.

XNOUSEOFOCTETBITSTRING

Defining this switch will remove all code for the SDL predefined sorts Bit_string, Octet, and Octet_string.

Special consideration needs to be taken if BasicCTypes.pr, or other ADTs, are included in the system. If so, it is required that types dependent on these types be removed from these packages.

XNOUSEOFEXPORT

By defining this switch the user states that he is not going to use the export - import concept in SDL.

> **Caution!**
>
> An attempt to perform an import operation when XNOUSEOFEXPORT is defined will result in a compilation error, as the function `xGetExportAddr` is not defined.

XNOUSEOFSERVICE

This compilation switch can be defined to save space, both in data and in the size of the kernel, if the SDL concept service is not used. If services are used and this switch is defined, there will be compilation errors (probably many!), when the generated code is compiled.

XPRSOPT

Section "Create and Stop Operations" on page 3085 describes how `xLocalPIdRec` structs are allocated for each created process instance, and how these structs are used to represent process instances even after they have performed stop actions. This method for handling `xLocalPIdRecs` is required to be able to detect when a signal is sent to a process instance that has performed a stop operation.

In an application that is going to run for a “long” period of time and that uses dynamic processes instances, this way of handling `xLocalPIdRecs` will eventually lead to no memory being available.

By defining the compilation switch `XPRSOPT`, the memory for the `xLocalPIdRecs` will be reused together the `yVDef_ProcessName` structs. This has two consequences:

1. The need for memory will not increase due to the use of dynamic processes (the memory need depends on the maximum number of concurrent instances).
2. It will no longer be possible to always find the situation when a signal is sent to a process instance that has performed a stop action.

More precisely, if we have a PId variable that refers to a process instance which performs a stop operation and after that a create operation (on the same process instance set) is performed where the same data area is reused, then the PId variable will now refer to the new process instance.

This means, for example, that signals intended for the old instance will be sent to the new instance. Note that it is still possible to detect signal sending to processes in the avail list even if `XPRSOPT` is defined.

XOPTCHAN

This switch can be used to remove all information about the paths of channels and signal routes in the system. The following memory optimization will take place:

- The two `ChannelIdNodes` for each channel, signal route, and gate are removed.
- The `ToId` component in the `xPrsIdNodes` representing processes is removed.
- A number of functions in the library (`sctsdl.c`) are no longer needed and are removed.

When the information about channels, signal routes, and gates is not present two types of calculations can no longer be performed:

1. To check if there is a path of channels and signal routes between the sender and the receiver in an OUTPUT statement with a TO clause.

This is no problem as this is just an error test that we probably do not want to be performed in an application.

2. To calculate the receiver in an OUTPUT without TO clause, if the Cadvanced/Cbasic SDL to C Compiler has not performed this calculation at generate time (see *"Calculation of Receiver in Outputs" on page 2655 in chapter 56, The Cadvanced/Cbasic SDL to C Compiler*). This is more serious, as it means that **OUTPUT without TO cannot always be used. The restrictions are:**

   – No outputs without to in process types, or in process in block or system types.
   – No outputs without to, designated to a process in a SEPARATE unit.

> **Caution!**
>
> If the `XOPTCHAN` switch is defined and still OUTPUT without TO clause are used (which the Cadvanced/Cbasic SDL to C Compiler cannot optimize), there will be a C compilation error saying that the name `xNotDefPId` is not defined.

In an ordinary SDL system OUTPUTs without TO must be used to start up the communication between different parts of the system, as there is no other way in SDL to distribute the PId values needed for OUTPUTs with TO.

This problem is solved if the Cadvanced/Cbasic SDL to C Compiler can calculate the receiver. Otherwise the data type `PIdList` in the library of abstract data types is intended to solve this problem. It is described in chapter 62, *The ADT Library*. When this data type is used, global PId literals my be introduced, implemented as SDL synonyms. These literals can then be used to utilize OUTPUT statements with TO clauses from the very beginning.

X_LONG_INT

The SDL sort Integer is translated to int in C. To translate the Integer sort to long int instead, just define the compilation switch `X_LONG_INT`.

XENVSIGNALLIMIT

If this switch is defined, only a limited number of signals will be stored in the input port of the Env function. The limit is equal to the value defined for `XENVSIGNALLIMIT` and is normally set to 20.

XEALL

This switch will define all error handling switches (XE...) and `XASSERT` given below.

XECREATE

This switch will report if the initial number of instances of a process type is greater than the maximum number.

XECSOP

This switch will report error situations in ADT operator.

XEDECISION

This switch will report if no path out from a Decision is found.

XEEXPORT

This switch will report errors during Import actions.

XEFIXOF

This switch will report overflow when an SDL Real value is converted to an SDL Integer value using the operator Fix.

XEINDEX

This switch will report value out of range for array index.

XEINTDIV

This switch will report division by zero in an integer division.

XEOUTPUT

This switch will report errors during Output operations.

XERANGE

This switch will report range errors when a value is assigned to a variable of a sort containing range conditions.

XEREALDIV

This switch will report division by zero in a real division.

XEVIEW

This switch will report errors in View operations

XECHOICE

This switch will turn on error reports when accessing non-active choice components.

XEOPTIONAL

This switch will turn on error reports when accessing non-present optional struct components.

XEUNION

This switch will turn on error reports when accessing non-active union components.

XEREF, XEOWN

These switches turn on error checking on pointers (generator Ref and Own).

XASSERT

By defining this switch the possibility to define user assertions which is described in "Assertions" on page 2196 in chapter 49, *The SDL Simulator*.

XTRACHANNELSTOENV

When using partitioning of a system a problem during the redirection of channels is that the number of channels going to the environment is not known at code generation time, which means that the size of the data

area used for the connections is not known. This problem is solved in two ways.

Either the function handling redirections allocates more memory, which is the default, or the user specifies how many channels that will be redirected (which could be difficult to compute, but will lead to less need of memory).

In the first case (allocation of more memory) the macros:

```
#define XTRACHANNELSTOENV  0
#define XTRACHANNELLIST
```

should be defined like above. This is the standard in scttypes.h. If the user wants to specify the number of channels himself then

```
#define XTRACHANNELSTOENV  10
#define XTRACHANNELLIST    ,0,0,0,0,0,0,0,0,0,0
```

i.e. XTRACHANNELSTOENV should be the number of channels, while XTRACHANNELLIST should be a list of that many zeros.

XDEBUG_LABEL

It is for debugging purposes sometimes of interest to introduce extra labels. The macro XDEBUG_LABEL is inserted in the code for each input symbol. As macro parameter it has a name which is the name of the state concatenated with an underscore concatenated with the signal name.

Example 515 ––

```
state State1; input Sig1;
state State2; input *;
state *; input Sig2;
```

In the generated code for these input statements the following macros will be found:

```
XDEBUG_LABEL(State1_Sig1)
XDEBUG_LABEL(State2_ASTERISK)
XDEBUG_LABEL(ASTERISK_Sig2)
```

A suitable macro definition to introduce label would be:

```
#define XDEBUG_LABEL(L)  L: ;
```

To use these label the usage of SDL must be restricted in one area. The same state may not receive two different signals with the same name! This is allowed and handled by the SDL Suite. The signal have to be

defined at different block or system level and the outermost signal must be referenced with a qualifier.

XCONST, XCONST_COMP

Using these compilation switches most of the memory used for the `IdStructs` can be moved from RAM to ROM. This depends of course on the compiler and what properties it has.

The following macro definitions can be inserted:

```
#define XCONST const
#define XCONST_COMP const
```

This will introduce **const** in the declaration of most of the `IdStructs`. It is then up to the compiler to handle const.

The XCONST_COMP macro is used to introduce const on components within a struct definition. This is necessary for some compilers to accept const on the struct as such.

If `const` is successfully introduced, there is a lot of RAM memory that will be saved, as probably 90% of the data area for `IdStructs` can be made `const`.

XAVL_TIMER_QUEUE

This compilation switch changes the timer queue data structure from the default sorted double linked list to an AVL tree. Each node in the tree represents a specific TimerTime and holds all timers scheduled to fire at that time. Insertions grow logarithmically with the total number of scheduled timers, instead of linearly as is the case with the ordered list. For models with a large number of timers the AVL tree can offer a significant performance boost. The AVL tree requires slightly more memory and is not recommended for models with few timers.

Compilation Switches – Summary

The property switches are in principle independent, except for the relations given in the descriptions above, and it should always be possible to any combination.

The number of combinations is, however, so huge that it is impossible for us to even compile all combinations. If you happen to form a combination that does not work, please let us know, so that we either can correct the code, or, if that is not possible, publish a warning against that combination.

The switches defining a standard library version will define the following property switches:

SCTDEBCOM	**SCTDEBCLCOM**
XPRSPRIO XPARTITION XEALL XMONITOR XTRACE XCTRACE XMSCE XCOVERAGE XGRTRACE XPMCOMM XSDLENVUI XITEXCOMM XSIMULATORUI	XCLOCK XPRSPRIO XPARTITION XEALL XMONITOR XTRACE XCTRACE XMSCE XCOVERAGE XGRTRACE XPMCOMM XSDLENVUI XSIMULATORUI
SCTAPPLCLENV	**SCTDEBCLENVCOM**
XCALENDARCLOCK XENV XPRSPRIO XOPT XPRSOPT	XCALENDARCLOCK XPRSPRIO XPARTITION XENV XPRSOPT XEALL XMONITOR XTRACE XCTRACE XMSCE XCOVERAGE XGRTRACE XPMCOMM XSDLENVUI XSIMULATORUI
SCTPERFSIM	
XEALL XPRSPRIO	

The lowest layer of switches (that handle the implementation details) are set up using the three layers above. These switches will not be discussed here. Please refer to the source code files `scttypes.h` and `sctsdl.c` for more details.

Creating a New Library

Caution!

If you create new versions of the library, make sure that the library and the generated code are compiled with the same compilation switches. If not, you might experience any type of strange behavior in the generated application!

This section describes how to generate a new library. The following topics are covered:

- The **directory structure** for source and object code.
- The **`sdtsct.knl`** file, which determines what libraries the Analyzer knows about, that is, what libraries that will be shown when Generate-Options is selected.
- The **`comp.opt`** file and the **`makeoptions`** (**`make.opt` in Windows**) file, which determines the properties of an object code library.
- The make file **`Makefile`**, which includes the `makeoptions (make.opt)` file and generates a new object code library with the properties given by the included `makeoptions (make.opt)` file.
- The relations with the generated make files for SDL systems will also be discussed.

Directory Structure

The structure of files and directories used for the Cadvanced/Cbasic SDL to C Compiler libraries is shown in Figure 562 The directory `sdtdir` is in the installation:

```
<installation directory>/sdt/sdtdir/<machine
dependent dir>
```

where <*machine dependent dir*> is for example `sunos5sdtdir` on SunOS 5 and `wini386` in Windows. (**In Windows**, `/` should be replaced by `\` in the path above.)

This directory is here called sdtdir and is in UNIX normally referred to by the environment variable `sdtdir`.

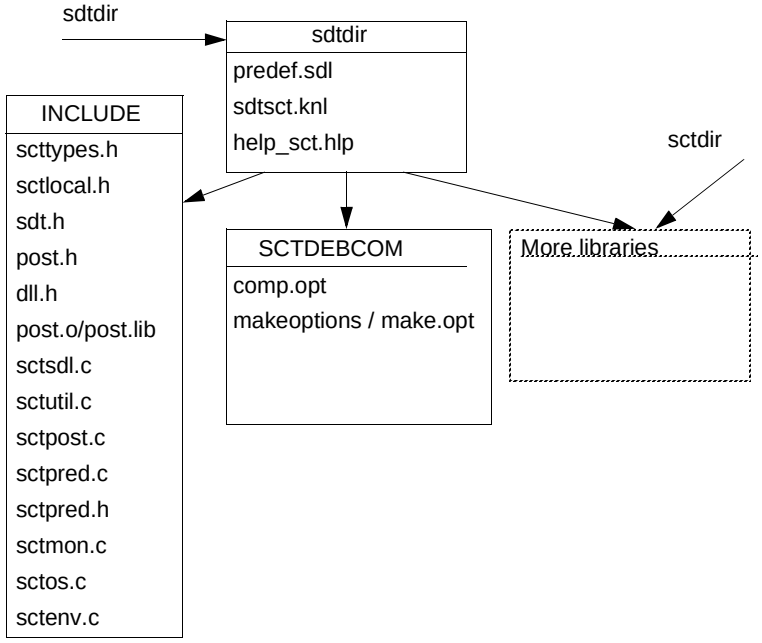

Figure 562: Directory structure

"sctdir" is a reference to an object library and is usually setup as a parameter in the call to make. It can also be an environment variable.

In the `sdtdir` directory three important files are found:

3. `predef.sdl` contains the definition of the predefined sorts in SDL.
4. `sdtsct.knl` contains a list of the available libraries that can be used together with code generated by the Cadvanced/Cbasic SDL to C Compiler.
5. `help_sct.hlp` contains the help information that can be obtained using the monitor command help.

The file `predef.sdl` is read by the SDL Analyzer during analysis, while the file `sdtsct.knl` is used to present the available libraries in the Make dialog in the Organizer (see "Make" on page 120 in chapter 2, *The Organizer*).

In the INCLUDE directory, there are two important groups of files:

1. The source code files for the runtime library:
   scttypes.h, sctlocal.h, sctsdl.c, sctutil.c, sctpost.c, sctpred.h, sctpred.c, sctmon.c, sctos.c and sctenv.c
2. The files necessary to include communication with other SCT applications: post.h, post.o (post64.o for solaris 64-bit, post.lib **in Windows**), sdt.h, itex.h.

In parallel with the INCLUDE directory there are a number of directories for libraries in object form. The SCTDEBCOM directory in Figure 562 is an example of such a directory. Each of these directories will contain three files: comp.opt, makeoptions (make.opt **in Windows**).

The comp.opt file determines the contents of the generated makefile and how make is called. For more details see below.

The makeoptions (make.opt) file describes the properties of the library, such as the compiler used, compiler options, linker options, and so on.

To guarantee the consistency of, for example, compilation flags between the SDL system and the kernel, the makeoptions (make.opt) file is used both by the make file compiling the library (Makefile) and by the generated make files used to compile the generated SDL system. Non-consistency in this sense between the library and the SDL system will make the result unpredictable.

File sdtsct.knl

The sdtsct.knl file describes which libraries that are available. This is presented by the Organizer in the *Make* dialog see "Make" on page 120 in chapter 2, *The Organizer*). The sdtsct.knl file has the following structure. Each available library is described on a line of its own. Such a line should first contain the name of the library (the name presented in the dialog), then the path to the directory containing the library, and last a comment up to end of line.

The path to the library can either be the complete path or a relative path. A relative path is relative to the environment variable sdtdir **(on UNIX)** or SDTDIR **(in Windows)**, if that variable is defined. Otherwise it is relative to the SDL Suite installation.

Example 516 ----------

```
Simulation           SCTDEBCOM
RealTimeSimulation   SCTDEBCLCOM
Application          SCTAPPLCLENV
ApplicationDebug     /util/sct/SCTDEBCLENVCOM

ApplicationDebug     x:\sdt\sdtdir\dbclecom
MyTestLibrary        ..\testlib\dbcom
```

Not that the two last lines is examples for Windows, while the fourth line is for UNIX.

The Organizer will look for an `sdtsct.knl` file first in the directory the SDL Suite is started from, then in the home directory for the user, and then in the directory referenced by the environment variable `sdtdir` (`SDTDIR`) if it is defined, and in the directory where the SDL Suite was installed.

File Makefile

In each directory that contains a library version there is a `Makefile` that can "make" the library. To create a new library after an update of the source code, change directory to the directory for the library and execute the `Makefile`. The `Makefile` uses the `makeoptions (make.opt)` file in the directory to get the correct compilation switches and other relevant information.

Caution!

Do not generate and test libraries in the installation directory structure. Create an appropriate copy.

Note:

The environment variables (if used) `sdtdir (SDTDIR)` and `sctdir (SCTDIR)` need not necessarily refer to directories in the installation directory. Any directory containing the relevant files may be used.

File comp.opt

This file determines the details of the generated make files, and the command issued to execute the makefile. A comp.opt file contains zero,

one or more initial lines starting with a #. These lines are treated as comments. After that it contains five lines of essential data.

- Line 1: How to include the makeoptions (make.opt) file
- Line 2: Compile script
- Line 3: Link script
- Line 4: Command to run make
- Line 5: How to build a library (archive). Used for coders/decoders.

On each of these lines % codes can be used to insert specific information.

On all five lines:

```
%n : newline
%t : tab
%d : target directory
%s : source directory
%k : kernel directory
%f : base name of generated executable (no path, no
     file extension). NOT on line 2 or 5.
```

On line 2, the compile script:

```
%c : c file in compile script
%C : c file in compile script, without extension
%o : resulting object file in compile script
```

On line 3, the link script:

```
%o : list of all object files in link script
%O : list of all object files in link script, with
     \ followed by newline between files
%e : executable file in link script
```

On line 4, the make command:

```
%m : name of generated makefile
```

On line 5, the archive command:

```
%o : list of object files, i.e. $(sctCODER_OBJS).
%a : the archive file, i.e.
     libstcoder$(sctLIBEXTENSION)
```

Example 517: comp.opt file for UNIX ----------

```
# makefile for unix make
include $(sctdir)/makeoptions
%t$(sctCC) $(sctCPPFLAGS) $(sctCCFLAGS) $(sctIFDEF) %c -o %o
%t$(sctLD) $(sctLDFLAGS) %o -o %e
make -f %m sctdir=%k
%t$(sctAR) $(sctARFLAGS) %a %o
```

File makeoptions / make.opt

This file has the following structure:

Example **on UNIX:**

```
# #
sctLIBNAME     = Simulation
sctIFDEF       = -DSCTDEBCOM
sctEXTENSION   = _smd.sct
sctOEXTENSION  = _smd.o
sctLIBEXTENSION=  _smd.a
sctKERNEL      = $(sctdir)/../INCLUDE
sctCODERDIR    = $(sctdir)/../coder

#Compiling, linking
sctCC          = cc
sctCODERFLAGS  = -I$(sctCODERDIR)
sctCPPFLAGS    = -I. -I$(sctKERNEL) $(sctCODERFLAGS)
 $(sctCOMPFLAGS) $(sctUSERDEFS)
sctCCFLAGS     = -c -Xc
sctLD          = cc
sctLDFLAGS     =
sctAR          = ar
sctARFLAGS     = rcu

all : default

# below this point there are a large number of
# compilation rules for compiling the Master Library
# and the Coder library (used for encoding/decoding)
# The following name of any importance are defined:

sctLINKKERNEL  =
sctLINKKERNELDEP =
sctLINKCODERLIB =
sctLINKCODERLIBDEP =
```

The information to the right of the equal signs should be seen as an example. These environment variables set in the `makeoptions` (`make.opt`) file should specify:

- **`sctLIBNAME`**. This is only used by the `Makefile` to report what it is doing.
- **`sctIFDEF`**. This variable should specify what compilation switches, among those defined by the Cadvanced/Cbasic SDL to C Compiler system, that should be used. Usually there is one switch defining the library version.

- **sctEXTENSION**. This is used to determine the file extension of the executable files.
- **sctOEXTENSION**. This is used to determine the file extension of the object files.
- **sctLIBEXTENSION**. The extension of the archive/library
- **sctKERNEL**. Directory of Master Library source code.
- **sctCODERDIR**. The directory for the source code of the coders/decoders.
- **sctCC**. This defines the compiler to be used.
- **sctCODERFLAGS**. Compilation options needed to compile the coder/decoder files
- **sctCPPFLAGS**. This variable should give the compilation flag necessary to specify where the C preprocessor can find the include files `scttypes.h`, `sctlocal.h`, `sctpred.h`, `sdt.h`, and `post.h`.
- **sctCCFLAGS**. This should specify other compiler flags that should be used, as for example -g (Sun cc) or -v (Borland bcc32) for debug information, -O for optimization.
- **sctLD**. This defines the linker to be used.
- **sctLDFLAGS**. This should specify other flags that should be used in the link operation.
- **sctAR**. The archive application
- **sctARFLAGS**. Flags to sctAR.
- **sctLINKKERNEL**. This variable should specify the `.o` files for the Master Library source files. It will be used in the link command in the generated make file.
- **sctLINKKERNELDEP**. Used to implement the dependencies to recompile the kernel when it is needed.
- **sctLINKCODERLIB**. This variable should specify the `.o` files for the Coder Library source files. It will be used in the link command in the generated make file.

- **sctLINKCODERLIBDEP**. Used to implement the dependencies to re-compile the Coder Library when it is needed.

Generated Make Files

The generated make files for an SDL system will as first action include the makeoptions (make.opt) file in the directory referenced by the environment variable sctdir. It will then use the variables sctIFDEF, sctLINKKERNEL, sctCC, sctCPPFLAGS, sctCCFLAGS, sctLD, and sctLDFLAGS to compile and link the SDL system with the selected library.

The make file is generated and executed by the Cadvanced/Cbasic SDL to C Compiler.

Example 518 ----------

Below, a UNIX make file generated for the SDL system *example* is shown.

```
# makefile for System: example

sctAUTOCFGDEP =
sctCOMPFLAGS = -DXUSE_GENERIC_FUNC

include $(sctdir)/makeoptions

default: example$(sctEXTENSION)

example$(sctEXTENSION): \
  example$(sctOEXTENSION) \
  $(sctLINKKERNELDEP)
        $(sctLD) $(sctLDFLAGS) \
  example$(sctOEXTENSION) $(sctLINKKERNEL) \
  -o example$(sctEXTENSION)

example$(sctOEXTENSION): \
  example.c
        $(sctCC) $(sctCPPFLAGS) $(sctCCFLAGS) \
  $(sctIFDEF) example.c -o example$(sctOEXTENSION)
```

Adaptation to Compilers

In this section the necessary changes to the source code to adapt it to a new environment are discussed. Adapting to a new environment could mean moving the code to new hardware or using a new compiler.

There are two parts of the source code that might need changes:

1. In `scttypes.h` there is a section defining the properties of different compilers, where a new compiler can be added.
2. In `sctos.c` the functions that depend on the operating system or hardware are collected. These might need to be changed due to a new compiler, a new OS, or a new hardware.

In "Compiler Definition Section in scttypes.h" on page 3147 the compiler definition section in `scttypes.h` is discussed in detail, while `sctos.c` is treated in "The sctos.c File" on page 3149.

Compiler Definition Section in scttypes.h

Caution!

Do not to use the compiler `/usr/ucb/cc`. Our experience is that the bundled compiler is subject to generating compilation errors.

Instead, we recommend to run the unbundled compiler `/opt/SUNWSpro/bin/cc` or the GNU C compiler.

In `scttypes.h` the properties of the compiler is recognized by the compiler/computer dependent switches set by the compiler:

```
#if defined(__linux)
#define SCT_POSIX

#elif defined(__sun)
#define SCT_POSIX

#elif defined(__hpux)
#define SCT_POSIX

#elif defined(__CYGWIN__)
#define SCT_POSIX

#elif defined(QNX4_CC)
#define SCT_POSIX
```

```
#elif defined(__BORLANDC__)
#define SCT_WINDOWS

#elif defined(_MSC_VER)
#define SCT_WINDOWS

#else
#include "user_cc.h"

#endif
```

Basically this section distinguishes between Unix-like/POSIX compilers and Windows compilers. In the case the compiler is not in the list above, the user must configure it himself by writing a file `user_cc.h`, which is best placed in the target directory.

The compilers above are:

- __linux : gcc on linux
- __sun : different compilers on SUN
- __hpux : different compilers on HP
- __CYGWIN__ : gcc on windows, for more information please see http://sources.redhat.com/cygwin/
- QNX4_CC : QNX
- __BORLANDC__ : Borland compiler on Windows
- _MSC_VER : Microsoft compiler on Windows

After this compiler configuration section a general configuration section follows:

```
#if defined(SCT_POSIX) || defined(SCT_WINDOWS)
#define XMULTIBYTE_SUPPORT
#endif

#include <string.h>
#include <stdlib.h>
#include <limits.h>
#include <stdarg.h>
#ifdef XREADANDWRITEF
#include <stdio.h>
#ifdef XMULTIBYTE_SUPPORT
#include <locale.h>
#endif
#endif

#ifndef GETINTRAND
#define GETINTRAND      rand()
#endif
#ifndef GETINTRAND_MAX
#define GETINTRAND_MAX  RAND_MAX
#endif
```

```
#ifndef xptrint
#if (UINT_MAX < 4294967295)
#define xptrint         unsigned long
#define X_XPTRINT_LONG
#else
#define xptrint         unsigned
#endif
#endif

#ifndef xint32
#if (INT_MAX >= 2147483647)
#define xint32          int
#define X_XINT32_INT
#else
#define xint32          long int
#endif
#endif
```

First, the presence of multi-byte character support is set up. Then a number of standard include files are included, followed by setting up properties for random number generation. Last the two types, `xptrint`, which defines an `unsigned int` type with the same size as an address, and `xint32`, which defines a 32-bits int type, is configured.

The last three parts in this section handle the utility functions needed by `sctos.c` to implement some of the operating system dependent functions. Please see below where `sctos.c` is discussed in detail.

The sctos.c File

The following important functions are defined in `sctos.c`

```
extern void * xAlloc (xptrint Size);

extern void xFree (void **P);

extern void xHalt (void);

#ifdef XCLOCK
extern SDL_Time SDL_Clock (void);
#endif

#if defined(XCLOCK) && !defined(XENV)
extern void xSleepUntil (SDL_Time WakeUpTime);
#endif

#if defined(XPMCOMM) && !defined(XENV)
extern int xGlobalNodeNumber (void);
#endif
```

```
#if defined(XMONITOR) && !defined(XNOSELECT)
extern xbool xCheckForKeyboardInput (
  long xKeyboardTimeout);
#endif
```

Several of these functions have three different implementations, one for SCT_POSIX, one for SCT_WINDOWS and one for other cases. The other cases solution is “an empty implementation” that does not do anything. If the standard solutions in sctos.c do not fit the needs of a certain application, any of the functions above can be supplied by the user instead. By defining some of the switches:

- XUSER_ALLOC_FUNC
- XUSER_FREE_FUNC
- XUSER_HALT_FUNC
- XUSER_CLOCK_FUNC
- XUSER_SLEEP_FUNC
- XUSER_KEYBOARD_FUNC

the corresponding function or functions are removed from sctos.o and have to be supplied by the user instead.

xAlloc

The function `xAlloc` is used to allocate dynamic memory and is used throughout the runtime library and in generated code. The function is given a size in bytes and should return a pointer to a data area of the requested size. All bytes in this data area are set to zero. The standard implementation of this function uses the C function `calloc`.

A user who wants to estimate the need for dynamic memory can introduce statements in `xAlloc` to record the number of calls of `xAlloc` and the total requested size of dynamic memory. Please note two things. A program using the monitor requires more dynamic memory than a program not using the monitor, so estimates should be made with the appropriate compilation switches. A call of `calloc` will actually allocate more memory than is requested to make it possible for the C runtime system to deallocate and reuse memory. The size of this additional memory is compiler-dependent.

A user who wants to handle the case when no more memory is available at an allocation request can implement that in `xAlloc`. In the standard implementation for `xAlloc` a test if calloc returns 0 can be introduced, at which the program can be terminated with an appropriate message.

xFree

The function `xFree` is used to return memory to the list of free memory so it can be reused by subsequent calls of `xAlloc`. The standard implementation of this function uses the C function `free`. In very simple cases, no data types using dynamic memory are used and no other introduction of dynamic data by the user, this function will not be used.

The parameter of the `xFree` function, is the address of the pointer to the allocated memory.

Example 519 Using the `xFree` function ––––––––––––––––––––––––

```
unsigned char *ptr;
ptr = xAlloc(100);
xFree (&ptr);       /* NOTE: Not xFree(ptr); */
```

––

xHalt

The function `xHalt` is used to exit from a program and is in the standard implementation using the C function `exit` to perform its task.

SDL_Clock

The function `SDL_Clock` should return the current time, read from a clock somewhere in the OS or hardware. The return value is of type `SDL_Time`, that is a struct with two 32-bits integer components, representing seconds and nanoseconds in the time value.

```
typedef struct {
  xint32  s;        /* for seconds */
  xint32  ns;       /* for nanoseconds */
} SDL_Time;
```

The standard implementation of `SDL_Clock` uses the C function **`time`**, which returns the number of seconds since some defined date.

Note:

Note that the C function `time` only handles full seconds.

In an embedded system or any other application that requires better time resolution, or when the C function time is not available, `SDL_Clock` should be implemented by the user.

Note:

If an application does not require a connection with real time (for example if it is not using timers and should run as fast as possible), there is no need for a clock function. In such a case it is probably suitable to use simulated time by not defining the compilation switch `XCLOCK`, whereby `SDL_Clock` is never called and does not need to be implemented. An alternative is to let `SDL_Clock` always return the time value 0.

A typical implementation in an embedded system is to have hardware generating interrupts at a predefined rate. At each such interrupt a variable containing the current time is updated. This variable can then be read by `SDL_Clock` to return the current time.

Caution!

The variable must be protected from updates during the period of time that `the SDL_Clock` reads the clock variable.

Calling the interrupt routine while the `SDL_Clock` reads the clock variable would cause a system disaster.

xSleep_Until

The function `xSleep_Until` is given a time value, as a value of type `SDL_Time` (see above) and should suspend the executing until this time is reached, when it should return.

This function is used only when real time is used (the switch `XCLOCK` is defined) and when there is no environment functions (`XENV` is not defined). The `xSleep_Until` function is used to wait until the next event is scheduled when there is no environment that can generate events.

xGlobalNodeNumber

The function `xGlobalNodeNumber` is used to assign unique numbers to each SDL system which is part of an application.

If environment functions are used for an SDL system this function should be implemented there. If, however, we have communicating simulations, there are no `env` functions and the `xGlobalNodeNumber` function is defined in `sctos.c` instead.

So the xGlobalNodeNumber function is only used if XPMCOMM is defined and XENV is not defined. As this function is only used in the case of a communicating simulation, it is only necessary to implement it for computers/compilers that communicate with the SDL Suite, which means that it is not interesting for a user to change the standard implementation of this function. The implementation calls the function getpid, and uses thus the OS process number as global node number.

xCheckForKeyboardInput

The function xCheckForKeyboardInput is used to determine if there is a line typed on the keyboard (stdin) or not. If this is difficult to implement it can instead determine if there are any characters typed on the keyboard or not. This function is only used by the monitor system, (when XMONITOR is defined).

The xCheckForKeyboardInput function is used to implement the possibility to interrupt the execution of SDL transitions by typing <Return> and to handle polling of the environment (xInEnv or its equivalent when communicating simulations is used) when the program is waiting at the "Command :" prompt in the monitor.

List of All Compilation Switches

Introduction

This section is a reference to the macros that are used together with the generated C code from the Cadvanced/Cbasic SDL to C Compiler. Here the macros are just enumerated and explained. The section is divided in a number of subsection, each treating one major aspect of the code. Within the subsections the macros are enumerated in alphabetic order.

Information about some of the macros (Library Version Macros, Compiler Definition Section Macros, and General Properties) can also be found in the section "Compilation Switches" on page 3119.

To fully understand the descriptions of the macros in this section it is also necessary to know the basic data structures used, especially for the static structures, i.e. the xIdNodes. This information can be found in the section "The Symbol Table" on page 3028.

The information about the data types used for the dynamic structure of the system, i.e. about process instances, signal, timers, and so on, are also of interest. This can be found in "The SDL Model" on page 3070.

Library Version Macros

SCTAPPLCLENV

Application.

SCTAPPLENV

Application without clock.

SCTDEB

Stand-alone simulator for any environment. Should be executed from OS.

SCTDEBCL

Stand-alone simulator with real time for any environment. Should be executed from OS.

SCTDEBCLCOM

Simulator with real time for host. Can be executed from the SDL Suite or from OS.

SCTDEBCLENV

Stand-alone simulator, with real time and env functions, for any environment. Should be executed from OS.

SCTDEBCLENVCOM

Simulator, with real time and env functions, for any environment. May be executed from OS or from simulator GUI.

SCTDEBCOM

Simulator for host. Can be executed from the SDL Suite or from OS.

SCTOPT1APPLCLENV

Application with minimal memory requirements. Real cannot be used. No channel information

SCTOPT2APPLCLENV

Application with minimal memory requirements. Real cannot be used. Const for all channel information.

SCTPERFSIM

Suitable for execution of performance simulations.

Compiler Definition Section Macros

SCT_POSIX

Set up for UNIX/POSIX like compilers/systems.

SCT_WINDOWS

Set up for compilers on Windows

Some Configuration Macros

COMMENT(P)

Should be defined as:

```
#define COMMENT(P)
```

The macro is used to insert comments in included C code. See Example 377 on page 2683.

GETINTRAND

A random generation function. Usually `rand()` or `random()`.

GETINTRAND_MAX

The max int value generated by function mentioned in GETINTRAND. Usually RAND_MAX or 2147483647 (32-bit integers).

SCT_VERSION_6_3

Defined in generated code if the Cadvanced/Cbasic SDL to C Compiler version 6.3 was used.

XCAT(P1,P2)

Should concatenate token P1 and P2. Possibilities:

```
#define XCAT(P1,P2) P1##P2
```

or

```
#define XCAT(P1,P2) P1/**/P2
```

or

```
#define XCAT(P1,P2) XCAT2(P1)P2
#define XCAT2(P2) P2
```

XMULTIBYTE_SUPPORT

Should be set if the compiler supports multi byte characters.

XNOSELECT

Should be defined if there is no support for the select function found in UNIX operating systems. This is used to implement “user defined interrupt” by typing the return key while simulating.

XNO_VERSION_CHECK

If this macro is defined there will be no version check between the generated code and the `scttypes.h` file.

XSCT_CBASIC

Defined in generated code if Cbasic was used.

XSCT_CADVANCED

Defined in generated code if Cadvanced was used.

X_SCTTYPES_H

Defined in `scttypes.h` in a way that it possible to include the `scttypes.h` file several times without any problems.

X_XINT32_INT

Should be defined if `xint32` is `int`.

X_XPTRINT_LONG

Should be defined if `xptrint` is `unsigned long`.

General Properties

TARGETSIM

Can be used to connect an application with a monitor on a target system with the SDL Suite running on a host computer.

XASSERT

Detect and report user defined assertions that are not valid.

XCALENDARCLOCK

Use the clock function in `sctos.c` (not simulated time). Time is whatever the clock function returns.

XCLOCK

Use the clock function in `sctos.c` (not simulated time). Time is zero at system start up.

XCOVERAGE

Compile with code to store information about the current coverage of the SDL system. This information can also be printed in the monitor.

XCTRACE

Compile preserving the possibility to report the current C line number during simulations.

XEALL

Defines XEOUTPUT, XEINTDIV, XEREALDIV, XECSOP, XEFIXOF, XERANGE, XEINDEX, XECREATE, XEDECISION, XEEXPORT, XEVIEW, XEERROR, XEUNION, XECHOICE, XEOPTIONAL, XEREF, XEOWN, and XASSERT.

For more information, see these macros.

XECHOICE

Detect and report attempts to access non-active components in Choice variables.

XECREATE

Detect and report if more static instances are created at start up, than the maximum number of concurrent instances.

XECSOP

Detect and report errors in ADT operators.

XEDECISION

Detect and report when there is no possible path out from a decision.

XEERROR

Detect and report the usage of the error term in an SDL expression.

XEEXPORT

Detect and report errors in import actions.

XEFIXOF

Detect and report integer overflow in the operator fix.

XEINDEX

Detect and report index out of bounds in arrays.

XEINTDIV

Detect and report integer division with 0.

XENV

Call the env functions.

XENV_CONFORM_2_3

Insert the `VarP` pointer in the `xSignalNode` so that signals conform with their implementation in SDT 2.3.

XEOPTIONAL

Detect and report attempts to access optional struct components that are not present.

XEOUTPUT

Detect and report warnings in outputs (mainly outputs where signal is immediately discarded).

XEOWN

Detect and report illegal usage of Own and ORef pointers.

XERANGE

Detect and report subrange errors.

XEREALDIV

Detect and report real division with 0.0.

XEREF

Detect and report attempts to dereference null pointer.

XEUNION

Detect and report attempts to access non-active components in a #UNION.

XEVIEW

Detect and report errors in view actions.

XGRTRACE

Compile with the trace in source SDL graphs enabled.

XITEXCOMM

Enable the possibility for an executable to communicate with the TTCN Suite via the Postmaster.

XMAIN_NAME

If this macro is defined the main function in `sctsdl.c` will be renamed to the name given by the macro.

XMONITOR

Compile with the monitor system. This macro will implicitly set up a number of other macros as well.

XMSCE

Compile with the MSC trace enabled.

XNOMAIN

If this macro is defined the main function in `sctsdl.c` will be removed.

XPMCOMM

Enable the possibility for an executable to communicate via the Postmaster.

XPRSPRIO

Use priorities on process instance sets.

XPRSSIGPRIO

Use first priorities on process instance sets and then priorities on signal instances.

XSDLENVUI

Enable the possibility to communicate with a user-defined UI.

XSIGLOG

Call the `xSignalLog` and `xProcessLog` functions.

XSIGPRIO

Use priorities on signal instances.

XSIGPRSPRIO

Use first priorities on signal instances and then priorities on process instance sets.

XSIMULATORUI

Enable the possibility to communicate with the simulator UI.

XTENV

As XENV but call `xInEnv` at specified times (next event time is out parameter from function `xInEnv`).

XTRACE

Compile with the textual trace enabled.

Code Optimization

XCONST

The majority of the `xIdNode` structs can be made const by defining `CONST` as `const`. This is only possible in applications (not simulations).

XCONST_COMP

This should normally be defined as const if XCONST is const. It is used to introduce const in the component declarations within the `xIdNode` structs.

XNOCONTSIGFUNC

Do not include functions to calculate the expressions in continuous signals. This saves also one function pointer in the `xIdNode` for the states. If this switch is defined, continuous signals cannot be used.

XNOENABCONDFUNC

Do not include functions to calculate the expressions in enabling conditions. This saves also one function pointer in the `xIdNode` for the states. If this switch is defined, enabling conditions cannot be used.

XNOEQTIMERFUNC

Do not include function to compare the parameters of two timers. This saves also one function pointer in the `xIdNode` for the signals. If this switch is defined, timers with parameters cannot be used.

XNOREMOTEVARIDNODE

Do not include xIdNodes for remote variable definitions.

XNOSIGNALIDNODE

Do not include `xSignalIdNodes` for signals and timers.

XNOSTARTUPIDNODE

Do not include `xSignalIdNodes` for start up signals.

XNOUSEOFOBJECTIDENTIFIER

The type Object_identifier and all operations on that type are removed.

XNOUSEOFOCTETBITSTRING

The types Bit_string, Octet, Octet_string and all operations on these types are removed.

XNOUSEOFSERVICE

All data and code needed to handle services are removed.

XNOUSEOFREAL

The type real and all operations on real are removed.

XOPT

Defines XOPTSIGPARA, XOPTDCL, XOPTFPAR, XOPTSTRUCT, XOPTLIT, and XOPTSORT.

For more information see these macros.

XOPTCHAN

Do not include xIdNodes for channels, signal routes, and gates. Information in services and processes about connections to signal routes and gates are also removed.

Note:

If this compilation switch is defined all outputs must either be sent TO a process or the receiver must be possible to calculate during code generation.

XOPTDCL

Do not include xIdNodes for variables.

XOPTFPAR

Do not include xIdNodes for formal parameters.

XOPTLIT

Do not include xIdNodes for literals.

XOPTSIGPARA

Do not include xIdNodes for signal parameters.

XOPTSORT

Do not include xIdNodes for newtypes and syntypes.

XOPTSTRUCT

Do not include xIdNodes for struct components.

XPRSOPT

Optimize memory for process instances. All memory for a process instance can be reused, but signal sending to a stopped process, who's memory has been reused by a new process, cannot be detected. The new process will in this case receive the signal.

XSYNTVAR

If this compilation switch is defined, xVarIdNodes are inserted for the Present components for optional struct components. This feature is only needed by the Explorer and by LINK. It should not be defined otherwise.

Definitions of Minor Features

XBREAKBEFORE

Should be used mainly if the MONITOR or GRTRACE switches are defined. It will make the functions and struct components for SDT references available and is also used to expand the macros XAT_FIRST_SYMBOL, XBETWEEN_SYMBOLS, XBETWEEN_SYMBOLS_PRD, XBETWEEN_STMTS, XBETWEEN_STMTS_PRD, XAFTER_VALUE_RET_PRDCALL, and XAT_LAST_SYMBOL to suitable function calls. These functions are used to interrupt a transition between symbols during simulation.

XCASEAFTERPRDLABELS

See XCASELABELS below. The SDL symbols just after an SDL procedure call have to be treated specially, as the symbol number (=case label) for these symbols are used as the restart address for the calling graph. Normally this macro should be defined. If SDL procedure calls are transformed to proper C function calls, and SDL return is translated to a C return, and nextstate in a procedure is NOT translated to a C return (i.e. the process will be hanging in the C function representing the SDL procedure) then it is not necessary to define XCASEAFTERPRDLABELS.

XCASELABELS

The function implementing the behavior of a process, procedure, or service contains one large switch statement with a case label for each SDL symbol in the graph. This switch is used to be able to restart the execution of a process, procedure, or service at any symbol. In an application most of these label can be removed (all except for those symbols that start a transition, i.e. start, input, continuous signal). The macro XCASELABELS should be defined to introduce the case labels for all SDL symbol. This means that XCASELABELS should be defined in a simulation but not in an application.

XCONNECTPM

If XCONNECTPM is defined the SDL simulation will try to connect itself to the postmaster. This is necessary if GR trace (XGRTRACE), communicating simulations (XPMCOMM), or communication with the

TTCN Suite (XITEXCOMM) is to be used. The XCONNECTPM feature is normally only used in simulations.

XCOUNTRESETS

Count the number of timers that are removed at a reset operation. This information is used by the textual trace system (XTRACE) to present this information. The information is really only of interest at a stop action when more then one timer might be (implicitly) reset. XCOUNTRESETS should not be defined in an application.

XENVSIGNALLIMIT

This macro is used to determine the number of signals sent to the environment that, during simulation, should be saved in the input port of the env process instance. Such signals can be inspected with the normal monitor commands for viewing of signals. This macro is only of interest in a simulation and has the default value 20.

XERRORSTATE

Insert the data structure to represent an “error” state that can be used if no path is found out from a decision. This should normally be defined if XEDECISION is defined.

XFREESIGNALFUNCS

Insert free functions for each signal, timer, or startup signal that contains a parameter of a type having a free function. These signal free functions can the be used to free allocated data within a signal. This macro should be defined if Master Library is used.

XFREEVARS

Insert free function calls for all variables of a type with free function, just before stop or return actions. This means that free actions are performed on allocated data referred to from variables is before the object ceases to exist. This macro should be defined.

XIDNAMES

This macro is used to determine if the SDL name of an SDL object should be stored in the `xIdNode` for the object. This character string is used for communication with the user in for example the monitor. Nor-

mally this macro should not be used in an application. Sometime it might be useful for target debugging to define XIDNAMES, as it is then fairly easy to identify objects by just printing the SDL name from a debugger. On average this seems to cost approximately 5% more memory.

XNRINST

This macro should be defined if process instance numbers are to be maintained. The instance number is the number in the monitor printout `Test:2`, identifying the individual instances of the process instance set Test in this case. XNRINST is normally only used in a simulation.

XOPERRORF

Include the function `xSDLOpError` in `sctsdl.c`. This function is used to print run-time errors in ADT operators.

XPRSSENDER

Store the value of sender also in the `xPrsNode`. The normal place is in the latest received signal. This is only needed in a simulation as sender might be accessed from the monitor system after the transition is completed and the signal has been returned to the pool of available memory.

XREADANDWRITEF

Include the functions for basic Read and Write. This is needed mainly in simulations.

XREMOVETIMERSIG

Allow the removal of timer signals for not-executing PIds. This is needed only in simulations to implement the monitor commands set-timer and reset-timer.

XSIGPATH

If this macro is defined then the functions `xIsPath` and `xFindReceiver` will return the path of signal routes, channels, and gates from the sender to the receiver, as out parameters. This information can then be used in the monitor system, for example, to produce signal logs. This macro should normally not be defined in an application.

XSYMBTLINK

The XSYMBTLINK macro is used to determine if a complete tree should be built from the xIdNodes of the system. If XSYMBTLINK is defined then all xIdNodes contains a `Parent`, a `Suc`, and a `First` pointer. The value of the `Parent` pointer is generated directly into the xIdNodes. `Suc` and `First`, however, are calculated in the `yInit` function by calling the `xInsertIdNode` function. The `Suc` and `First` pointers are needed by the monitor system, but not in an application, i.e. XSYMBTLINK should be defined in a simulation but not in an application.

XTESTF

This macro is used to include or remove test functions for syntype (or newtypes) with range conditions. The `yTest` function is used by the monitor system and by the functions to test index out of bounds in arrays and to test subranges. This means that XTESTF should be defined if the monitor is used or if XERANGE or XEINDEX is defined.

XTRACHANNELSTOENV

When using partitioning of a system a problem during the redirection of channels is that the number of channels going to the environment is not known at code generation time, which means that the size of the data area used for the connections is not known. This problem is solved in two ways.

Either the function handling redirections allocates more memory, which is the default, or the user specifies how many channels that will be redirected (which could be difficult to compute, but will lead to less need of memory).

In the first case (allocation of more memory) the macros:

```
#define XTRACHANNELSTOENV  0
#define XTRACHANNELLIST
```

should be defined like above. This is the standard in scttypes.h. If the user wants to specify the number of channels himself then

```
#define XTRACHANNELSTOENV  10
#define XTRACHANNELLIST    ,0,0,0,0,0,0,0,0,0,0
```

i.e. `XTRACHANNELSTOENV` should be the number of channels, while `XTRACHANNELLIST` should be a list of that many zeros.

XTRACHANNELLIST

See `XTRACHANNELSTOENV` just above.

Static Data, Mainly xIdNodes

XBLO_EXTRAS

All generated struct values for block, block type, and block instance structs contain this macro last in the struct. By defining this macro new components can be inserted. Note that the type `xBlockIdStruct` must be updated as well. Normally this macro should be empty.

Example 520 ----------

```
#define XBLO_EXTRAS  ,0
```

XBLS_EXTRAS

All generated struct values for block substructure structs contain this macro last in the struct. By defining this macro new components can be inserted. Note that the type `xBlockSubstIdStruct` must be updated as well. Normally this macro should be empty.

Example 521 ----------

```
#define XBLS_EXTRAS  ,0
```

XCOMMON_EXTRAS

All generated struct values for `xIdNode` structs contain this macro after the common components. This means that it is possible to insert new components in all xIdNodes by defining this macro. Normally this macro should be empty.

Example 522 ----------

To insert a new int component with value 0 the following definition can be used:

```
#define XCOMMON_EXTRAS  ,0
```

XLIT_EXTRAS

All generated struct values for literal structs contain this macro last in the struct. By defining this macro new components can be inserted. Note that the type `xLiteralIdStruct` must be updated as well. Normally this macro should be empty.

Example 523 ----------

```
#define XLIT_EXTRAS  ,0
```

XPAC_EXTRAS

All generated struct values for package structs contain this macro last in the struct. By defining this macro new components can be inserted. Note that the type `xPackageIdStruct` must be updated as well. Normally this macro should be empty.

Example 524 ----------

```
#define XSYS_EXTRAS  ,0
```

XPRD_EXTRAS

All generated struct values for procedure structs contain this macro last in the struct. By defining this macro new components can be inserted. Note that the type `xPrdIdStruct` must be updated as well. Normally this macro should be empty.

Example 525 ----------

```
#define XSYS_EXTRAS  ,0
```

XPRS_EXTRAS

`(PREFIX_PROC_NAME)`

All generated struct values for process, process type, and process instance structs contain this macro last in the struct. By defining this macro new components can be inserted. Note that the type `xPrsIdStruct` must be updated as well.

Example 526 ----------

```
#define XPRS_EXTRAS(PREFIX_PROC_NAME) \
   ,XCAT(PREFIX_PROC_NAME,_STACKSIZE)
```

XSIG_EXTRAS

All generated struct values for signal, timer, RPC_signal, startup signal structs contain this macro last in the struct. By defining this macro new components can be inserted. Note that the type `xSignalIdStruct` must be updated as well. Normally this macro should be empty.

Example 527 ----------

```
#define XSIG_EXTRAS  ,0
```

XSPA_EXTRAS

All generated struct values for signal parameter structs contain this macro last in the struct. By defining this macro new components can be inserted. Note that the type `xVarIdStruct` must be updated as well (Note that variables, formal parameters, signal parameters, and struct components are all handled in `xVarIdStruct`.) Normally this macro should be empty.

Example 528 ----------

```
#define XSPA_EXTRAS  ,0
```

XSRT_EXTRAS

All generated struct values for newtype and syntype structs contain this macro last in the struct. By defining this macro new components can be inserted. Note that the type `xSortIdStruct` must be updated as well. Normally this macro should be empty.

Example 529 ----------

```
#define XSRT_EXTRAS  ,0
```

XSRV_EXTRAS

All generated struct values for service, service type, and service instance structs contain this macro last in the struct. By defining this macro new components can be inserted. Note that the type `xSrvIdStruct` must be updated as well. Normally this macro should be empty.

Example 530

```
#define XSRV_EXTRAS  ,0
```

XSTA_EXTRAS

All generated struct values for state structs contain this macro last in the struct. By defining this macro new components can be inserted. Note that the type `xStateIdStruct` must be updated as well. Normally this macro should be empty.

Example 531

```
#define XSTA_EXTRAS  ,0
```

XSYS_EXTRAS

All generated struct values for system, system type, and system instance structs contain this macro last in the struct. By defining this macro new components can be inserted. Note that the type `xSystemIdStruct` must be updated as well. Normally this macro should be empty.

Example 532

```
#define XSYS_EXTRAS  ,0
```

XSYSTEMVARS

This macro gives the possibility to introduce global variables declared in the beginning of the C file containing the implementation of the SDL system unit.

XSYSTEMVARS_H

If extern definitions are needed for the data declared in XSYSTEMVARS, this is the place to introduce it. These definitions will be present in the `.h` file for the system unit (if separate generation is used).

XVAR_EXTRAS

All generated struct values for variables, formal parameters, and struct components structs contain this macro last in the struct. By defining this macro new components can be inserted. Note that the type `xVarIdStruct` must be updated as well (Note that signal parameters also uses the type `xVarIdStruct`). Normally this macro should be empty.

Example 533

```
#define XVAR_EXTRAS  ,0
```

Data in Processes, Procedures and Services

PROCEDURE_VARS

The struct components that are needed for each procedure instance. Example: state.

PROCESS_VARS

The struct components that are needed for each process instance. Example: state, parent, offspring, self, sender, inputport.

SERVICE_VARS

The struct components that are needed for each service instance. Example: state

YGLOBALPRD_YVARP

This macro is used to declare the `yVarP` pointer (which is a pointer to the `yVDef` struct for the process) in a procedure defined outside of a process. As a global procedure never can access process local data, it is suitable to let `yVarP` be a pointer to a struct only containing the components defined in the macro PROCESS_VARS.

YGLOBALSRV_YVARP

This macro is used to declare the `yVarP` pointer (which is a pointer to the `yVDef` struct for the process) in a service type defined outside of a process. As a global service type never can access process local data, it is suitable to let `yVarP` be a pointer to a struct only containing the components defined in the macro PROCESS_VARS.

YPAD_TEMP_VARS

Local variables in the PAD function for a process or service. Example: temporary variables needed for outputs, create actions.

YPAD_YSVARP

Declaration of the `ySVarP` pointer used to refer to the received signal. Normally `ySVarP` is `void *`.

YPAD_YVARP

(VDEF_TYPE)

This macro is used within a process and in a service defined within a process. It should be expanded to a declaration of yVarP, which is the pointer that is used to access SDL variables in the process. yVarP should be of type VDEF_TYPE *, where VDEF_TYPE is the type of the yVDef struct for the process. If the pointer to the yVDef struct is passed as parameter to the PAD function, yVarP can be assigned its correct value already in the declaration.

YPRD_TEMP_VARS

Local variables in the function implementing the behavior of an SDL procedure.

YPRD_YVARP

(VDEF_TYPE)

This macro is used within a procedure defined in a process. It should be expanded to a declaration of yVarP, which is the pointer that is used to access SDL variables in the process. yVarP should be of type VDEF_TYPE *, where VDEF_TYPE is the type of the yVDef struct for the process. If the pointer to the yVDef struct is passed as parameter to the procedure function, yVarP can be assigned its correct value already in the declaration.

Some Macro Used Within PAD Functions

BEGIN_PAD

```
(VDEF_TYPE)
```

BEGIN_PAD is a macro that can be used to insert code that is executed in the beginning of the PAD functions. `VDEF_TYPE` is the yVDef `type` for the process.

BEGIN_START_TRANSITION

```
(STARTUP_PAR_TYPE)
```

This macro can be used to introduce code that is executed at the beginning of the start transition. `STARTUP_PAR_TYPE` is the `yPDef` struct for the startup signal for this process.

CALL_SERVICE

This macro is used in the PAD function of a process that contains services. It should be expanded to a call to PAD function for the service that should execute the next transition (`ActiveSrv`).

CALL_SUPER_PAD_START

```
(PAD)
```

During the start transition of a process all inherited PAD functions up to and including the PAD function containing the START symbol have to be called. The reason is to initialize all variables defined in the process. This macro is used to perform a call to the inherited PAD function (the macro parameter PAD). Usually this macro is expanded to something like:

```
yVarP->RestartPAD = PAD; PAD(VarP);
```

followed by either a `return` or a `goto NewTransition` depending on execution model.

CALL_SUPER_PRD_START

```
(PRD, THISPRD)
```

This macro is used in the same way as CALL_SUPER_PAD_START (see above) but for the start transition in a procedure. `THISPRD` is the executing procedure function, while `PRD` is the inherited procedure function.

CALL_SUPER_SRV_START

(PAD)

This macro is used in the same way as CALL_SUPER_PAD_START (see above) but for the start transition in a service. PAD is the inherited PAD function.

LOOP_LABEL

The LOOP_LABEL macro should be used to form the loop from a next-state operation to the next input operation necessary in the OS where OS tasks does not perform return at end of transition (most commercial OS). This macro is also suitable to handle free on received signals and the treatment of the save queue. In an OS where SDL nextstate is implemented using a C `return` (the Master Library for example) the LOOP_LABEL macro is usually empty.

LOOP_LABEL_PRD

Similar to LOOP_LABEL but used in procedures with states.

LOOP_LABEL_PRD_NOSTATE

Similar to LOOP_LABEL but used in procedures without states. This macro is in many circumstances expanded to nothing.

LOOP_LABEL_SERVICEDECOMP

Similar to LOOP_LABEL but used in the PAD function for a process containing services.

SDL_OFFSPRING

Should return the value of offspring.

SDL_PARENT

Should return the value of parent.

SDL_SELF

Should return the value of self.

SDL_SENDER

Should return the value of sender.

START_SERVICES

This macro is used in the PAD function of a process that contains services. It should be expanded in such a way that the start transitions for all of the services are executed.

XEND_PRD

This is a macro generated at the end of a function that represents the behavior of a procedure. It needs not to be expanded to anything. To define it as

```
return (xbool)0;
```

might remove a compiler warning that the end of a value returning function might be reached.

XPRSNODE

Should usually be expanded to the type `xPrsNode`.

XNAMENODE

How to reach the `xPrsIdNode` from a PAD function. Normally this is `yVarP->NameNode`.

XNAMENODE_PRD

How to reach the `xPrdIdNode` from a PRD function. Normally this is `yPrdVarP->NameNode`.

XNAMENODE_SRV

How to reach the `xSrvIdNode` from a PAD function. Normally this is `ySrvVarP->NameNode`.

YPAD_FUNCTION

`(PAD)`

The function heading of the PAD function given as parameter.

YPAD_PROTOTYPE

`(PAD)`

The function prototype of the PAD function given as parameter.

YPRD_FUNCTION

```
(PRD)
```

The function heading of the PRD function given as parameter.

YPRD_PROTOTYPE

```
(PRD)
```

The function prototype of the PRD function given as parameter.

yInit Function

BEGIN_YINIT

This macro is placed in the beginning of the `yInit` function in the file containing code for the system. It can be expanded to variable declarations and initialization code.

XPROCESSDEF_C

```
(PROC_NAME, PROC_NAME_STRING, PREFIX_PROC_NAME,
PAD_FUNCTION, VDEF_TYPE)
```

This macro can be used to introduce code for each process instance set in the system.

Parameters:

- `PROC_NAME`
  the name of the process without prefix.
- `PROC_NAME_STRING`
  the name of the process as a character string.
- `PREFIX_PROC_NAME`
  the name of the process with prefix.
- `PAD_FUNCTION`
  the PAD function for this process instance set.
- `VDEF_TYPE`
  the `yVDef` struct for this process.

XPROCESSDEF_H

```
(PROC_NAME, PROC_NAME_STRING, PREFIX_PROC_NAME,
PAD_FUNCTION, VDEF_TYPE)
```

This macro can be used to introduce extern declaration (placed in the proper `.h` file) for each process instance set in the system.

Parameters:

- `PROC_NAME`
  the name of the process without prefix.
- `PROC_NAME_STRING`
  the name of the process as a character string.
- `PREFIX_PROC_NAME`
  the name of the process with prefix.
- `PAD_FUNCTION`
  the PAD function for this process instance set.
- `VDEF_TYPE`
  the `yVDef` struct for this process.

xInsertIdNode

In the `yInit` function the function `xInsertIdNode` is called for each `IdNode`. In an application this is not necessary, and `xInsertIdNode` can be defined as

```
#define xInsertIdNode(Node)
```

The function `xInsertIdNode` is needed if XSYMBTLINK, XCOVERAGE, or XMONITOR is defined.

YINIT_TEMP_VARS

This macro is placed in all yInit functions and can be expanded to local variables needed within the `yInit` function.

Implementation of Signals and Output

ALLOC_SIGNAL

ALLOC_SIGNAL_PAR

```
(SIG_NAME, SIG_IDNODE, RECEIVER, SIG_PAR_TYPE)
```

These macros are used to allocate a data area for a signal to be sent. ALLOC_SIGNAL is used if the signal has no parameters, while ALLOC_SIGNAL_PAR is used if the signal has parameters. The resulting data area should be reference by the variable mentioned by the macro OUTSIGNAL_DATA_PTR (see below).

Parameters:

- `SIG_NAME`
  the name of the signal without prefix.
- `SIG_IDNODE`
  the `xSignalIdNode` of the signal.
- `RECEIVER`
  the receiver given in the TO clause, or calculated. In a NO_TO output, `RECEIVER` is `xNotDefPId`.
- `SIG_PAR_TYPE`
  the yPDef `type` of the signal. If the signal has no parameters this macro parameter is XSIGNALHEADERTYPE (see below).

INSIGNAL_NAME

This macro should be expanded to the identification of the currently received signal. It is used to distinguish between signals when several signal is enumerated in the same input symbol.

OUTSIGNAL_DATA_PTR

This should be the pointer referring to be signal data area while building the signal during an output. It should be assigned its value in ALLOC_SIGNAL or ALLOC_SIGNAL_PAR, and will then be used during assignment of signal parameters and in the SDL_2OUTPUT macro just below.

SDL_2OUTPUT

SDL_2OUTPUT_NO_TO

SDL_2OUTPUT_COMPUTED_TO

SDL_ALT2OUTPUT

SDL_ALT2OUTPUT_NO_TO

SDL_ALT2OUTPUT_COMPUTED_TO

```
(PRIO, VIA, SIG_NAME, SIG_IDNODE, RECEIVER,
SIG_PAR_SIZE, SIG_NAME_STRING)
```

These six macros are used to send the signal created in ALLOC_SIGNAL or ALLOC_SIGNAL_PAR. The SDL_ALT versions of the macros are used if the directive `/*#ALT*/` has been given in the output. The version without suffix is used for an output TO, while the suffix _COMPUTED_TO is used for an output without to but it was possible to compute the receiver during code generation time. The suffix _NO_TO indicates an output without to, where the receiver cannot be calculated during code generation time.

Parameters:

- `PRIO`
  the priority of the signal specified in a #PRIO directive.
- `VIA`
  the via list given in the output.
- `SIG_NAME`
  the name of the signal without prefix
- `SIG_IDNODE`
  the `xSignalIdNode` for the signal.
- `RECEIVER`
  the receiver given in the TO clause, or calculated. In a NO_TO output, `RECEIVER` is `xNotDefPId`.
- `SIG_PAR_SIZE`
  the size of the `yPDef` struct of the signal. If signal without parameters `SIG_PAR_SIZE` is 0.
- `SIG_NAME_STRING`
  the name of the signal as a character string.

SDL_THIS

In an output TO THIS in SDL, the RECEIVER parameter in the ALLOC_SIGNAL and SDL_2OUTPUT macros discussed above will become SDL_THIS.

SIGCODE

```
(P)
```

This macro makes it possible to store a signal code (signal number) in the `xSignalIdNode` for a signal. The macro parameter `P` is the signal name without prefix.

SIGNAL_ALLOC_ERROR

This macro is inserted after the ALLOC_SIGNAL macro and the assignment of parameter values to the signal. It can be used to test if the alloc was successful or not.

SIGNAL_ALLOC_ERROR_END

This macro is inserted after the SDL_2OUTPUT macro.

SIGNAL_NAME

```
(SIG_NAME, SIG_IDNODE)
```

This macro should be expanded to an identification of the signal given as parameter. Normally the identification is either the `xSignalIdNode` for the signal or an `int` value. If the id is an `int` value it is suitable to insert defines of type #define signal_name number. A file containing such defines can be generated using the Generate Signal Numbers feature in Cadvanced/Cbasic.

Parameters:

- `SIG_NAME`
  the name of the signal without parameters
- `SIG_IDNODE`
  the `xSignalIdNode` for the signal.

SIGNAL_VARS

The struct components that are needed for each signal instance. Example: sender, receiver, signal type.

TO_PROCESS

```
(PROC_NAME, PROC_IDNODE)
```

This macro is used as RECEIVER in the ALLOC_SIGNAL and SDL_2OUTPUT macros if the signal is sent to a process instance set in SDL.

Parameters:

- `PROC_NAME`
  the name of the receiving process without prefix.
- `PROC_IDNODE`
  the `xPrsIdNode` of the receiving process.

TRANSFER_SIGNAL

TRANSFER_SIGNAL_PAR

```
(SIG_NAME, SIG_IDNODE, RECEIVER, SIG_PAR_TYPE)
```

These macros are used as alternative for the ALLOC_SIGNAL macros (see these macros above) if the directive `#TRANSFER` if given in the output.

- `SIG_NAME`
  the name of the signal without prefix.
- `SIG_IDNODE`
  the `xSignalIdNode` of the signal.
- `RECEIVER`
  the receiver given in the TO clause, or calculated. In a NO_TO output, `RECEIVER` is `xNotDefPId`.
- `SIG_PAR_TYPE`
  the `yPDef` type of the signal. If the signal has no parameters this macro parameter is XSIGNALHEADERTYPE (see below).

XNONE_SIGNAL

The representation for a none signal.

XSIGNALHEADERTYPE

This macro is used to indicate a `yPDef` struct for a signal without parameters. Such a signal has no generated `yPDef` struct. It is suitable to let

XSIGNALHEADERTYPE be the name of a struct just containing the components in SIGNAL_VARS.

XSIGTYPE

Depending on the representation of the signal type that is used (`xSignalIdNode` or `int`) this macro should either be `xSignalIdNode` or `int`.

Implementation of RPC

ALLOC_REPLY_SIGNAL

ALLOC_REPLY_SIGNAL_PAR

ALLOC_REPLY_SIGNAL_PRD

ALLOC_REPLY_SIGNAL_PRD_PAR

```
(SIG_NAME, SIG_IDNODE, RECEIVER, SIG_PAR_TYPE)
```

These macros are used to allocate the Reply signal in the signal exchange in an RPC. The suffix _PAR is used if the reply signal contains parameters. The suffix _PRD is used if the implicit RPC transition is part of a procedure.

Parameters:

- `SIG_NAME`
  the reply signal name without prefix.
- `SIG_IDNODE`
  the `xSignalIdNode` for the reply signal.
- `RECEIVER`
  the receiver of the reply signal. The macro XRPC_SENDER_IN_ALLOC or XRPC_SENDER_IN_ALLOC_PRD are used as actual parameter. The suffix _PRD is used if the implicit RPC transition is part of a procedure.
- `SIG_PAR_TYPE`
  the `yPDef` type for the reply signal. If the reply signal does not contain any parameters the macro name XSIGNALHEADERTYPE is generated as actual parameter.

REPLYSIGNAL_DATA_PTR

REPLYSIGNAL_DATA_PTR_PRD

This should be a reference to the data area for the reply signal that is allocated in the ALLOC_REPLY_SIGNAL macro. The suffix _PRD is used if the implicit RPC transition is part of a procedure.

SDL_RPCWAIT_NEXTSTATE

SDL_RPCWAIT_NEXTSTATE_PRD

```
(PREPLY_IDNODE, PREPLY_NAME, RESTARTADDR)
```

These macros are used to implement the implicit nextstate operation in the caller of an RPC. The suffix _PRD is used if the implicit RPC transition is part of a procedure.

Parameters:

- `PREPLY_IDNODE`
  the `xSignalIdNode` for the reply signal.
- `PREPLY_NAME`
  the name without prefix for the reply signal.
- `RESTARTADDR`
  the restart address (symbol number) for the implicit input of the reply signal.

SDL_2OUTPUT_RPC_CALL

```
(PRIO, VIA, SIG_NAME, SIG_IDNODE, RECEIVER,
SIG_PAR_SIZE, SIG_NAME_STRING)
```

Send the call signal of an RPC.

Parameters:

- `PRIO`
  priority of signal.
- `VIA`
  the via list, which in this case always is `(xIdNode *)0`, i.e. no via list.
- `SIG_NAME`
  the RPC call signal name without prefix.
- `SIG_IDNODE`
  the `xSignalIdNode` for the RPC call signal.

- RECEIVER
  the receiver of the call signal. This is either expressed as an ordinary TO-expression or using the macro XGETEXPORTINGPRS (see below) in case of no explicit receiver specified in the call.

- SIG_PAR_SIZE
  the size of the yPDef struct for the call signal. If the call signal has no parameters this parameter will be 0.

- SIG_NAME_STRING
  the name of the RPC call signal as a character string.

SDL_2OUTPUT_RPC_REPLY

SDL_2OUTPUT_RPC_REPLY_PRD

```
(PRIO, VIA, SIG_NAME, SIG_IDNODE, RECEIVER,
SIG_PAR_SIZE, SIG_NAME_STRING)
```

These macros are used to send the RPC reply signal. The suffix _PRD is used if the implicit RPC transition is part of a procedure.

Parameters:

- PRIO
  priority of signal.

- VIA
  the via list, which in this case always is `(xIdNode *)0`, i.e. no via list.

- SIG_NAME
  the RPC reply signal name without prefix.

- SIG_IDNODE
  the `xSignalIdNode` for the RPC reply signal.

- RECEIVER
  the receiver of the reply signal. This is expressed using the macro XRPC_SENDER_IN_OUTPUT or XRPC_SENDER_IN_OUTPUT_PRD.

- SIG_PAR_SIZE
  the size of the yPDef struct for the reply signal. If the reply signal has no parameters this parameter will be 0.

- SIG_NAME_STRING
  the name of the RPC reply signal as a character string.

XGETEXPORTINGPRS

```
(REMOTENODE)
```

This macro should be expanded to an expression that given the remote procedure given as actual macro parameter (more exactly the `IdNode` for the remote procedure), returns one possible exporter of this remote procedure. Usually this macro is expanded to a call of the library function `xGetExportingPrs`.

XRPC_REPLY_INPUT

XRPC_REPLY_INPUT_PRD

Macros that can be used for special processing needed to receive an RPC reply signal. The macros are usually expanded to nothing.

XRPC_SAVE_SENDER

XRPC_SAVE_SENDER_PRD

These macros can be used to save the sender of a received RPC call signal, for further use when the reply signal is to be sent. The suffix _PRD is used if the implicit RPC transition is part of a procedure.

XRPC_SENDER_IN_ALLOC

XRPC_SENDER_IN_ALLOC_PRD

These macros are used to obtain the receiver of the reply signal (from the sender of the call signal) in the ALLOC_REPLY_SIGNAL macros. The suffix _PRD is used if the implicit RPC transition is part of a procedure.

XRPC_SENDER_IN_OUTPUT

XRPC_SENDER_IN_OUTPUT_PRD

These macros are used to obtain the receiver of the reply signal (from the sender of the call signal) in the SDL_2OUTPUT_RPC_REPLY macros. The suffix _PRD is used if the implicit RPC transition is part of a procedure.

XRPC_WAIT_STATE

The state number used for a RPC wait state. XRPC_WAIT_STATE is usually defined as -3.

Implementation of View and Import

XGETEXPORTADDR

```
(REMOTENODE, EXPORTER, IS_DEF_EXPORTER)
```

This macro should be expanded to an expression that returns the address of the exported variable. Usually the function `xGetExportAddr` is called.

Parameters:

- `REMOTENODE`
  the IdNode for the remote variable.
- `EXPORTER`
  the value of the optional PId expression. If no PId expression is given this parameter is SDL_NULL.
- `IS_DEF_EXPORTER`
  has the value `(xbool)1` if a PId expression was found in the import statement, otherwise it is `(xbool)0`.

SDL_VIEW

```
(PID_EXPR, HAS_EXPR, VAR_NAME_STRING, REVEALED_LIST,
SORT_SIZE)
```

This macro should be expanded to an expression that returns the address of the viewed variable. Usually the function SDL_View is called.

Parameters:

- `PID_EXPR`
  the value of the optional PId expression. If no PId expression is given this parameter is SDL_NULL.
- `HAS_EXPR`
  has the value `(xbool)1` if a PId expression was found in the view statement, otherwise it is `(xbool)0`.
- `VAR_NAME_STRING`
  the name of the viewed variable as a character string.
- `REVEALED_LIST`
  the list of the revealed variables.
- `SORT_SIZE`
  the size of the sort of the revealed variable.

Implementation of Static and Dynamic Create and Stop

ALLOC_STARTUP

ALLOC_STARTUP_PAR

```
(PROC_NAME, STARTUP_IDNODE, STARTUP_PAR_TYPE)
```

Allocate the data area for a startup signal and let the pointer mentioned in the macro STARTUP_DATA_PTR refer to this data area. The suffix _PAR is used if the startup signal contains parameters.

Parameters:

- `PROC_NAME`
  the name without prefix for the created process.
- `STARTUP_IDNODE`
  the `xSignalIdNode` for the startup signal of the created process.
- `STARTUP_PAR_TYPE`
  the `yPDef` for the startup signal of the created process.

ALLOC_STARTUP_THIS

Allocate the data area for a startup signal and let the pointer mentioned in the macro STARTUP_DATA_PTR refer to this data area. This macro is used in a create THIS operation.

INIT_PROCESS_TYPE

```
(PROC_NAME, PREFIX_PROC_NAME, PROC_IDNODE,
PROC_NAME_STRING, MAX_NO_OF_INST, STATIC_INST,
VDEF_TYPE, PRIO, PAD_FUNCTION)
```

This macro will be call once for each process instance set in the yInit function. It should be used to initiated common features for all instances of a process instance set.

Parameters:

- `PROC_NAME`
  the name without prefix for the process instance set.
- `PREFIX_PROC_NAME`
  the name with prefix for the process instance set.
- `PROC_IDNODE`
  the `xPrsIdNode` for the process instance set.

- PROC_NAME_STRING
  the name as character string for the process instance set.
- MAX_NO_OF_INST
  the maximum number of instances of this process instance set.
- STATIC_INST
  the number of static instances of this process instance set.
- VDEF_TYPE
  the yVDef type for this process instance set.
- PRIO
  the priority for process instance set.
- PAD_FUNCTION
  the PAD for this process instance set.

SDL_CREATE

```
(PROC_NAME, PROC_IDNODE, PROC_NAME_STRING)
```

This macro is used to create (a create action) a process instance.

Parameters:

- PROC_NAME
  the name without prefix for the process instance set.
- PROC_IDNODE
  the xPrsIdNode for the process instance set.
- PROC_NAME_STRING
  he name as character string for the process instance set.

SDL_CREATE_THIS

This macro is used to implement create this.

SDL_STATIC_CREATE

```
(PROC_NAME, PREFIX_PROC_NAME, PROC_IDNODE,
PROC_NAME_STRING, STARTUP_IDNODE, STARTUP_PAR_TYPE,
VDEF_TYPE, PRIO, PAD_FUNCTION, BLOCK_INST_NUMBER)
```

This macro is called in the yInit function once for each static process instances that should be created of a process instance set.

Parameters:

- `PROC_NAME`
  the name without prefix for the process instance set.
- `PREFIX_PROC_NAME`
  the name with prefix for the process instance set.
- `PROC_IDNODE`
  the `xPrsIdNode` for the process instance set.
- `PROC_NAME_STRING`
  the name as character string for the process instance set.
- `STARTUP_IDNODE`
  the `xSignalIdNode` for the startup signal for the process instance set.
- `STARTUP_PAR_TYPE`
  the `yPDef` type for the startup signal for the process instance set.
- `VDEF_TYPE`
  the `yVDef` type for the process instance set.
- `PRIO`
  the priority for the process instance set.
- `PAD_FUNCTION`
  the PAD function for the process instance set.
- `BLOCK_INST_NUMBER`
  if this process instance set is part if a block instance set then this macro is the block instance number for the block instance set that this process belongs to. Otherwise this macro parameter is 1.

SDL_STOP

This macro is used to implement the SDL operation stop (both in processes and in services).

STARTUP_ALLOC_ERROR

This macro is inserted after the ALLOC_STARTUP macro and the assignment of parameter values to the signal. It can be used to test if the alloc was successful or not.

STARTUP_ALLOC_ERROR_END

This macro is inserted after the SDL_CREATE macro.

STARTUP_DATA_PTR

This macro should be expanded to a temporary variable used to store a reference to the startup signal data area. It should be assigned in the ALLOC_STARTUP macro and will be used to assign the actual signal parameters (the fpar values) to the startup signal.

STARTUP_VARS

This macro can be used to insert additional general components in the startup signals. In all startup signal yPDef structs SIGNAL_VARS will be followed by STARTUP_VARS.

Implementation of Timers, Timer Operations and Now

ALLOC_TIMER_SIGNAL_PAR

```
(TIMER_NAME, TIMER_IDNODE, TIMER_PAR_TYPE)
```

Allocate a data area for the timer signal with parameters.

Parameters:

- `TIMER_NAME`
  the name without prefix of the timer.
- `TIMER_IDNODE`
  the `xSignalIdNode` for the timer.
- `TIMER_PAR_TYPE`
  the `yPDef` for the timer.

DEF_TIMER_VAR

DEF_TIMER_VAR_PARA

```
(TIMER_VAR)
```

There will be one application of this macro in the `yVDef` type for the process for each timer declaration the process contains. These declarations can be used to introduce components (timer variables) in the `yVDef` struct to track timers. The parameter `TIMER_VAR` is a suitable name for such a variable. The suffix _PARA is used if the timer has parameters.

INIT_TIMER_VAR

INIT_TIMER_VAR_PARA

```
(TIMER_VAR)
```

These macros will be inserted in start transitions, during initialization of process variables. This makes it possible to initialize the timer variables that might be inserted in the DEF_TIMER_VAR macro. The parameter `TIMER_VAR` is the name for such a variable. The suffix _PARA is used if the timer has parameters.

INPUT_TIMER_VAR

INPUT_TIMER_VAR_PARA

```
(TIMER_VAR)
```

These macros will be inserted at an input operation on a timer signal. This makes it possible to update the timer variables that might be inserted in the DEF_TIMER_VAR macro. The parameter `TIMER_VAR` is the name for such a variable. The suffix _PARA is used if the timer has parameters. Note that if a timer signal is received in an input * statement, no INPUT_TIMER_VAR will be present in this case.

RELEASE_TIMER_VAR

RELEASE_TIMER_VAR_PARA

```
(TIMER_VAR)
```

These macros will be inserted at a stop. This makes it possible to perform cleaning up of the timer variables that might be inserted in the DEF_TIMER_VAR macro. The parameter `TIMER_VAR` is the name for such a variable. The suffix _PARA is used if the timer has parameters.

SDL_ACTIVE

```
(TIMER_NAME, TIMER_IDNODE, TIMER_VAR)
```

This macro is used to implement the SDL operation active on a timer. Note that active on timers with parameters is not implemented in the Cadvanced/Cbasic SDL to C Compiler.

Parameters:

- `TIMER_NAME`
  the name without prefix of the timer.
- `TIMER_IDNODE`
  the xSignalIdNode for the timer.
- `TIMER_VAR`
  the timer variable that might be inserted in the macro DEF_TIMER_VAR.

SDL_NOW

This is the implementation of now in SDL.

SDL_RESET

```
(TIMER_NAME, TIMER_IDNODE, TIMER_VAR,
TIMER_NAME_STRING)
```

This macro is used to implement the SDL operation reset on a timer without parameters.

Parameters:

- `TIMER_NAME`
  the name without prefix of the timer.
- `TIMER_IDNODE`
  the `xSignalIdNode` for the timer.
- `TIMER_VAR`
  the timer variable that might be inserted in the macro DEF_TIMER_VAR.
- `TIMER_NAME_STRING`
  the name of the timer as a character string.

SDL_RESET_WITH_PARA

```
(EQ_FUNC, TIMER_VAR, TIMER_NAME_STRING)
```

This macro is used to implement the SDL operation reset on a timer with parameters. Before this macro a timer signal with the timer parameters in the reset operation is created.

Parameters:

- EQ_FUNC
  the name of the generated equal function that can test if two timer instance are equal or not.

- TIMER_VAR
  the timer variable that might be inserted in the macro DEF_TIMER_VAR.

- TIMER_NAME_STRING
  the name of the timer as a character string.

SDL_SET

```
(TIME_EXPR, TIMER_NAME, TIMER_IDNODE, TIMER_VAR,
TIMER_NAME_STRING)
```

SDL_SET_WITH_PARA

```
(TIME_EXPR, TIMER_NAME, TIMER_IDNODE,
TIMER_PAR_TYPE, EQ_FUNC, TIMER_VAR,
TIMER_NAME_STRING)
```

SDL_SET_DUR

```
(TIME_EXPR, DUR_EXPR, TIMER_NAME, TIMER_IDNODE,
TIMER_VAR, TIMER_NAME_STRING)
```

SDL_SET_DUR_WITH_PARA

```
(TIME_EXPR, DUR_EXPR, TIMER_NAME, TIMER_IDNODE,
TIMER_PAR_TYPE, EQ_FUNC, TIMER_VAR,
TIMER_NAME_STRING)
```

SDL_SET_TICKS

```
(TIME_EXPR, DUR_EXPR, TIMER_NAME, TIMER_IDNODE,
TIMER_VAR, TIMER_NAME_STRING)
```

SDL_SET_TICKS_WITH_PARA

```
(TIME_EXPR, DUR_EXPR, TIMER_NAME, TIMER_IDNODE,
TIMER_PAR_TYPE, EQ_FUNC, TIMER_VAR,
TIMER_NAME_STRING)
```

These six SDL_SET macros are used to implement the SDL operation set on a timer. The suffix _WITH_PARA indicates the set of a timer with parameters. In this case the SDL_SET macro is preceded by an ALLOC_TIMER_SIGNAL_PAR macro call, plus the assignment of the timer parameters. The suffix _DUR is used if the time value in the set operation is expressed as:

```
now + expression
```

In this case both the time value and the duration value (the expression above) is available as macro parameter. The suffix _TICKS is used if the time value in the set operation is expressed as:

```
now + TICKS(...)
```

where TICKS is an operator returning a duration value. In this case both the time value and the duration value (the TICKS expression above) is available as macro parameter.

Parameters:

- `TIME_EXPR`
  the time expression.
- `DUR_EXPR`
  the duration expression (only in _DUR and _TICKS).
- `TIMER_NAME`
  the timer name without prefix.
- `TIMER_IDNODE`
  the `xSignalIdNode` for the timer.
- `TIMER_PAR_TYPE`
  the `yPDef` struct for the timer (only in _WITH_PARA)
- `EQ_FUNC`
  the function that can be used to test if two timers have the same parameter values (only in _WITH_PARA).
- `TIMER_VAR`
  the name of the timer variable that might be introduced in the macro DEF_TIMER_VAR.
- `TIMER_NAME_STRING`
  the name of the timer as a character string.

TIMER_DATA_PTR

This should be the pointer referring to be timer data area while building the timer. It should be assigned its value in ALLOC_TIMER_SIGNAL_PAR, and will then be used during assignment of signal parameters and in the SDL_SET macro

TIMER_SIGNAL_ALLOC_ERROR

This macro is inserted after the ALLOC_TIMER_SIGNAL_PAR macro and the assignment of parameter values to the timer. It can be used to test if the alloc was successful or not.

TIMER_SIGNAL_ALLOC_ERROR_END

This macro is inserted after the SDL_SET macro.

TIMER_VARS

The struct components that are needed for each timer instance. Example: sender, receiver, timer type.

As timers are signals as well, after the timer signal has been sent, TIMER_VARS has to be identical to SIGNAL_VARS, except that new component may be add last in TIMER_VARS.

XTIMERHEADERTYPE

This macro is used to indicate a `yPDef` struct for a timer without parameters. Such a timer has no generated `yPDef` struct. It is suitable to let XTIMERHEADERTYPE be the name of a struct just containing the components in TIMER_VARS.

Implementation of Call and Return

ALLOC_PROCEDURE

```
(PROC_NAME, PROC_IDNODE, VAR_SIZE)
```

Allocate a data area (`yVDef`) for the called procedure.

Parameters:

- `PROC_NAME`
  the name of procedure with prefix.
- `PROC_IDNODE`
  the `xPrdIdNode` of the called procedure
- `VAR_SIZE`
  the size of the `yVDef` struct for the procedure.

ALLOC_THIS_PROCEDURE

Allocate a data area (`yVDef`) for a procedure when call THIS is used.

ALLOC_VIRT_PROCEDURE

```
(PROC_IDNODE)
```

Allocate a data area (`yVDef`) for the called procedure when calling a virtual procedure. The `PROC_IDNODE` parameter is the `xPrdIdNode` for the call procedure.

CALL_PROCEDURE

CALL_PROCEDURE_IN_PRD

```
(PROC_NAME, PROC_IDNODE, LEVELS, RESTARTADDR)
```

These macros are used to implement a call operation in SDL. The `yVDef` struct has been allocated earlier (in ALLOC_PROCEDURE) and the actual parameters have been assigned to components in this struct. The suffix _IN_PRD indicates that the procedure call is made in a procedure.

Parameters:

- `PROC_NAME`
  the name of procedure with prefix, which is the same as the name of the C function representing the behavior of the procedure.
- `PROC_IDNODE`
  the `xPrdIdNode` of the called procedure.
- `LEVELS`
  the scope level between the caller and the called procedure.
- `RESTARTADDR`
  the restart address the symbol number for the symbol after the procedure call.

CALL_PROCEDURE_STARTUP

CALL_PROCEDURE_STARTUP_SRV

These two macros are only of interest if the PAD functions are left via a return at the end of transitions. In that case any outstanding procedure must be restarted when the process becomes active again.

CALL_THIS_PROCEDURE

```
(RESTARTADDR)
```

This macro is used to implement a call THIS operation in SDL. `RESTARTADDR` is the restart address the symbol number for the symbol after the procedure call.

CALL_VIRT_PROCEDURE

CALL_VIRT_PROCEDURE_IN_PRD

```
(PROC_IDNODE, LEVELS, RESTARTADDR)
```

These macros are used to implement a call operation on a virtual procedure in SDL. The `yVDef` struct has been allocated earlier (in ALLOC_VIRT_PROCEDURE) and the actual parameters have been assigned to components in this struct. The suffix _IN_PRD indicates that the procedure call is made in a procedure.

Parameters:

- `PROC_IDNODE`
  the xPrdIdNode of the called procedure.
- `LEVELS`
  the scope level between the caller and the called procedure.
- `RESTARTADDR`
  the restart address the symbol number for the symbol after the procedure call.

PROCEDURE_ALLOC_ERROR

This macro is inserted after the ALLOC_PROCEDURE macro and the assignment of parameter values to the procedure parameters. It can be used to test if the alloc was successful or not.

PROCEDURE_ALLOC_ERROR_END

This macro is inserted after the CALL_PROCEDURE macro.

PROC_DATA_PTR

This macro should be expanded to a temporary variable used to store a reference to the procedure data area. It should be assigned in the ALLOC_PROCEDURE macro and will be used to assign the actual procedure parameters (the fpar values).

SDL_RETURN

The implementation of return in SDL.

XNOPROCATSTARTUP

If this macro is defined then all the code discussed for the macro CALL_PROCEDURE_STARTUP (just above) is removed.

Implementation of Join

Joins in SDL are normally implemented as goto:s in C, but in one case a more complex implementation is needed. This is when the label, mentioned in the join, is in a super type.

XJOIN_SUPER_PRS

`(RESTARTADDR,RESTARTPAD)`

XJOIN_SUPER_PRD

`(RESTARTADDR,RESTARTPRD)`

XJOIN_SUPER_SRV

`(RESTARTADDR,RESTARTSRV)`

These macros represent join to super type in processes, procedures, and services, in that order.

Parameters:

- `RESTARTADDR`
  The restart address in the super type.
- `RESTARTPAD, RESTARTPRD, RESTARTSRV`
  The PAD function for the super type.

Implementation of State and Nextstate

> **Note:**
>
> Implicit nextstate operations in RPC calls are treated in the RPC section.

ASTERISK_STATE

The state number for an asterisk state. ASTERISK_STATE is usually defined as -1.

ERROR_STATE

The state number used for the error state. ERROR_STATE is usually defined as -2.

START_STATE

The state number for the start state. START_STATE should be defined as 0.

START_STATE_PRD

The state number for the start state in a procedure. START_STATE_PRD should be defined as 0.

SDL_NEXTSTATE

```
(STATE_NAME, PREFIX_STATE_NAME, STATE_NAME_STRING)
```

Nextstate operation (in process or service) of the given state.

Parameters:

- `STATE_NAME`
  the name without prefix of the state.
- `PREFIX_STATE_NAME`
  the name with prefix for the state. This identifier is defined as a suitable state number in generated code and is usually used as the representation of the state.
- `STATE_NAME_STRING`
  the name of the state as a character string.

SDL_DASH_NEXTSTATE

Dash nextstate operation in a process.

SDL_DASH_NEXTSTATE_SRV

Dash nextstate operation in a service.

SDL_NEXTSTATE_PRD

```
(STATE_NAME, PREFIX_STATE_NAME, STATE_NAME_STRING)
```

Nextstate operation (in procedure) of the given state.

Parameters:

- STATE_NAME
  the representation of the state.
- PREFIX_STATE_NAME
  the name with prefix for the state. This identifier is defined as a suitable state number in generated code and is usually used as the representation of the state.
- STATE_NAME_STRING
  the name of the state as a character string.

SDL_DASH_NEXTSTATE_PRD

Dash nextstate operation in a procedure.

Implementation of Any Decisions

An any decision with two paths are generated according to the following structure:

```
BEGIN_ANY_DECISION(2)
DEF_ANY_PATH(1, 2)
DEF_ANY_PATH(2, 0)
END_DEFS_ANY_PATH(2)
BEGIN_FIRST_ANY_PATH(1)
  statements
END_ANY_PATH
BEGIN_ANY_PATH(2)
  statements
END_ANY_PATH
END_ANY_DECISION
```

BEGIN_ANY_DECISION

```
(NO_OF_PATHS)
```

Start of the any decision. NO_OF_PATHS is the number of paths in the decision.

BEGIN_ANY_PATH

```
(PATH_NO)
```

A path (not the first) in implementation part of the any decision. PATH_NO is the path number.

BEGIN_FIRST_ANY_PATH

```
(PATH_NO)
```

The first possible path in implementation part of the any decision. PATH_NO is the path number.

DEF_ANY_PATH

(PATH_NO, SYMBOLNUMBER)

Definition of a path in the decision.

Parameters:

- PATH_NO
  the path number.
- SYMBOLNUMBER
  the symbol number for the first symbol in this path.

END_ANY_DECISION

The end of the any decision.

END_ANY_PATH

End of one of the paths in the implementation section.

END_DEFS_ANY_PATH

(NO_OF_PATHS)

End of the definition part of the any decision. NO_OF_PATHS is the number of paths in the decision.

Implementation of Informal Decisions

The implementation of informal decisions are similar to any decisions.

BEGIN_FIRST_INFORMAL_PATH

(PATH_NO)

The first possible path in implementation part of the informal decision. PATH_NO is the path number.

BEGIN_INFORMAL_DECISION

(NO_OF_PATHS, QUESTION)

Start of the any decision.

Parameters:

- NO_OF_PATHS
  the number of paths in the decision.
- QUESTION
  the question charstring.

BEGIN_INFORMAL_ELSE_PATH

(PATH_NO)

The else path in implementation part of the any decision. PATH_NO is the path number.

BEGIN_INFORMAL_PATH

(PATH_NO)

A path in implementation part of the any decision. PATH_NO is the path number.

DEF_INFORMAL_PATH

(PATH_NO, ANSWER, SYMBOLNUMBER)

Definition of a path in the decision.

Parameters:

- PATH_NO
  the path number.
- ANSWER
  the answer string.
- SYMBOLNUMBER
  the symbol number for the first symbol in this path.

DEF_INFORMAL_ELSE_PATH

(PATH_NO, SYMBOLNUMBER)

Definition of the else path in the decision.

Parameters:

- PATH_NO
  the path number.
- SYMBOLNUMBER
  the symbol number for the first symbol in this path.

END_DEFS_INFORMAL_PATH

```
(NO_OF_PATHS)
```

End of the definition part of the informal decision. `NO_OF_PATHS` is the number of paths in the decision.

END_INFORMAL_ELSE_PATH

End of the else paths in the implementation section.

END_INFORMAL_DECISION

The end of the informal decision.

END_INFORMAL_PATH

End of one of the paths in the implementation section.

Macros for Component Selection Tests

The macros in this section handles testing the validity of for example a component selection of a choice or #UNION variable. Also tests for optional components in structs and for de-referencing of pointers is treated here.

XCHECK_CHOICE_USAGE

```
(TAG,VALUE,NEQTAG,COMPNAME,CURR_VALUE,TYPEINFO)
```

XSET_CHOICE_TAG

```
(TAG,VALUE,ASSTAG,NEQTAG,COMPNAME,CURR_VALUE,
 TYPEINFO)
```

XSET_CHOICE_TAG_FREE

```
(TAG,VALUE,ASSTAG,NEQTAG,FREEFUNC,COMPNAME,
 CURR_VALUE,TYPEINFO)
```

The CHOICE macros are used to test and to set the implicit tag in a choice variable. The XSET_CHOICE_TAG and XSET_CHOICE_TAG_FREE set the tag when some component of the choice is assigned a value. The FREE version of the macro is used if the choice contains some component that has a Free function. The XCHECK_CHOICE_USAGE is used to test if an accessed component is active or not.

Parameters:

- TAG
  The implicit tag component
- VALUE
  The new or expected tag value
- ASSTAG
  The assignment function for the tag type
- NEQTAG
  The equal test function for the tag type
- FREEFUNC
  The Free function for the Choice type
- COMPNAME
  The name of the selected component as a char string
- CURR_VALUE
  The current value of the tag type
- TYPEINFO
  The type info node for the tag type.

XCHECK_OPTIONAL_USAGE

```
(PRESENT_VAR,COMPNAME)
```

This macro is used to check that a selected optional component is present. The PRESENT_VAR parameter is the present variable for this component, while COMPNAME is the selected components name as a char string.

XCHECK_UNION_TAG_USAGE

```
(TAG,VALUE,NEQTAG,COMPNAME,CURR_VALUE,TYPEINFO)
```

XCHECK_UNION_TAG

```
(TAG,VALUE,ASSTAG,NEQTAG,COMPNAME,CURR_VALUE,
 TYPEINFO)
```

XCHECK_UNION_TAG_FREE

```
(TAG,VALUE,ASSTAG,NEQTAG,FREEFUNC,COMPNAME,
 CURR_VALUE,TYPEINFO)
```

The UNION macros are used to test tag in a union variable. The XCHECK_UNION_TAG and XCHECK_UNION_TAG_FREE check the tag when some component of the union is assigned a value. The

FREE version of the macro is used if the union contains some component that has a Free function. The XCHECK_UNION_USAGE is used to test if an accessed component is active or not.

Parameters:

- TAG
  The tag component
- VALUE
  The expected tag value
- ASSTAG
  The assignment function for the tag type
- NEQTAG
  The equal test function for the tag type
- FREEFUNC
  The Free function for the UNION type
- COMPNAME
  The name of the selected component as a char string
- CURR_VALUE
  The current value of the tag type
- TYPEINFO
  The type info node for the tag type.

XCHECK_REF

XCHECK_OWN

XCHECK_OREF

```
(VALUE,REF_TYPEINFO,REF_SORT)
```

These macros are used to implement a test that Null pointers (using the Ref, Own, or ORef generator) are not de-referenced. These macros are inserted before each statement containing a Ref/Own/ORef pointer de-referencing. In case of an ORef pointer it is also checked that the ORef is valid, i.e. that it refers to an object owned by the current process.

Parameters:

- VALUE
  This is the value of the pointer.

- REF_TYPEINFO
  The typeinfo node for the Ref sort.
- REF_SORT
  The C type that corresponds to the Ref instantiation newtype.

XCHECK_OREF2

```
(VALUE)
```

Checks that a ORef pointer is a valid pointer, i.e. NULL, or that it refers to an object owned by the current process.

Debug and Simulation Macros

XAFTER_VALUE_RET_PRDCALL

```
(SYMB_NO)
```

A macro generated between the implementation of a value returning procedure call (implicit call symbol) and the symbol containing the value returning procedure call. `SYMB_NO` is the symbol number of the symbol containing the value returning procedure call.

XAT_FIRST_SYMBOL

```
(SYMB_NO)
```

A macro generated between an input or start symbol and the first symbol in the transition. `SYMB_NO` is the symbol number of the first symbol in the transition.

XAT_LAST_SYMBOL

A macro generated immediately before a nextstate or stop operation.

XBETWEEN_STMTS

XBETWEEN_STMTS_PRD

```
(SYMB_NO, C_LINE_NO)
```

A macro generated between statements in a task. The suffix _PRD indicates that these statements are part of a procedure.

Parameters:

- `SYMB_NO`
  the symbol number of the next statement.

- C_LINE_NO
  line number in C of this statement.

XBETWEEN_SYMBOLS

XBETWEEN_SYMBOLS_PRD

(SYMB_NO, C_LINE_NO)

A macro generated between symbols in a transition. The suffix _PRD indicates that these symbols are part of a procedure.

Parameters:

- SYMB_NO
  the symbol number of the next symbol.

- C_LINE_NO
  line number in C of this statement.

XDEBUG_LABEL

(LABEL_NAME)

This macro gives the possibility to insert label at the beginning of transitions. Such labels can be useful during debugging. The LABEL_NAME parameter is a concatenation of state name and the signal name. The * in state *; and input *; will cause the name ASTERISK to appear.

XOS_TRACE_INPUT

(SIG_NAME_STRING)

This macro is generated at input statements and can, for example, be used to generated trace information about inputs. The SIG_NAME_STRING parameter is the name of the signal in the input.

YPRSNAME_VAR

(PRS_NAME_STRING)

This macro is generated among the declarations of variables in the PAD function for a process. It can, for example, be used to declare a `char *` variable containing the name of the process. Such a variable can be useful during debugging. The PRS_NAME_STRING parameter is the name of the process as a character string.

YPRDNAME_VAR

(PRD_NAME_STRING)

This macro is generated among the declarations of variables in the PRD function for a procedure. It can, for example, be used to declare a `char*` variable containing the name of the procedure. Such a variable can be useful during debugging. The `PRD_NAME_STRING` parameter is the name of the procedure as a character string.

Utility Macros to Be Inserted

The following sequence of macros should be inserted. Most of them concern removal of struct components (in IdNodes) that are not used due to the combination of other switches used.

```
#define NIL 0
#define XXFREE xFree
#define XSYSD xSysD.

#if defined(XPRSPRIO) || defined(XSIGPRSPRIO) ||
    defined(XPRSSIGPRIO)
#define xPrsPrioPar(p)  , p
#else
#define xPrsPrioPar(p)
#endif

#if defined(XSIGPRIO) || defined(XSIGPRSPRIO) ||
    defined(XPRSSIGPRIO)
#define xSigPrioPar(p)  , p
#define xSigPrioParS(p)  p;
#else
#define xSigPrioPar(p)
#define xSigPrioParS(p)
#endif

#ifdef XTESTF
#define xTestF(p)  , p
#else
#define xTestF(p)
#endif

#ifdef XREADANDWRITEF
#define xRaWF(p)  , p
#else
#define xRaWF(p)
#endif

#ifdef XFREEFUNCS
#define xFreF(p)  , p
#else
#define xFreF(p)
#endif

#ifdef XFREESIGNALFUNCS
#define xFreS(p)  , p
```

```
#else
#define xFreS(p)
#endif

#define xAssF(p)
#define xEqF(p)

#ifdef XIDNAMES
#define xIdNames(p)  , p
#else
#define xIdNames(p)
#endif

#ifndef XOPTCHAN
#define xOptChan(p)  , p
#else
#define xOptChan(p)
#endif

#ifdef XBREAKBEFORE
#define xBreakB(p)  , p
#else
#define xBreakB(p)
#endif

#ifdef XGRTRACE
#define xGRTrace(p)  , p
#else
#define xGRTrace(p)
#endif

#ifdef XMSCE
#define xMSCETrace(p)  , p
#else
#define xMSCETrace(p)
#endif

#ifdef XTRACE
#define xTrace(p)  , p
#else
#define xTrace(p)
#endif

#ifdef XCOVERAGE
#define xCoverage(p)  , p
#else
#define xCoverage(p)
#endif

#ifdef XNRINST
#define xNrInst(p)  , p
#else
#define xNrInst(p)
```

```
#endif

#ifdef XSYMBTLINK
#define xSymbTLink(p1, p2) , p1, p2
#else
#define xSymbTLink(p1, p2)
#endif

#ifdef XEVIEW
#define xeView(p)  p,
#define xeViewS(p)  p;
#else
#define xeView(p)
#define xeViewS(p)
#endif

#ifdef XCTRACE
#define xCTrace(p)  p,
#define xCTraceS(p)  p;
#else
#define xCTrace(p)
#define xCTraceS(p)
#endif

#ifndef XNOUSEOFSERVICE
#define xService(p)  , p
#else
#define xService(p)
#endif

#if !defined(XPMCOMM) && !defined(XENV)
#define xGlobalNodeNumber() 1
#endif

#define xSizeOfPathStack 50

#ifndef xOffsetOf
#define xOffsetOf(type, field) \
        ((xptrint) &((type *) 0)->field)
#endif
#define xToLower(C) \
        ((C >= 'A' && C <= 'Z') ? \
        (char)((int)C - (int)'A' + (int)'a') : C)

#ifndef xDefaultPrioProcess
#define xDefaultPrioProcess      100
#endif

#ifndef xDefaultPrioSignal
#define xDefaultPrioSignal       100
#endif

#ifndef xDefaultPrioTimerSignal
#define xDefaultPrioTimerSignal  100
#endif
```

```
#ifndef xDefaultPrioContSignal
#define xDefaultPrioContSignal   100
#endif

#ifndef xDefaultPrioCreate
#define xDefaultPrioCreate       100
#endif

#define xbool int

#ifndef MAX_READ_LENGTH
#define MAX_READ_LENGTH 5000
                        /* max length of input line */
#endif
```

The xDefaultPrio macros above should, of course, be defined to the suitable default values.

Other macros that should be defined are.

SDL_NULL

a null value for the type PId.

xNotDefPId

which is used as RECEIVER parameter in the SDL_2OUTPUT macros. Please see also the section were signals are treated.

Chapter

62 *The ADT Library*

This chapter provides information about the library of Abstract Data Types (ADT) that comes with the SDL Suite. The data types provide services that are often needed in SDL systems.

The ADT library is mainly intended for usage together with the Cadvanced/Cbasic SDL to C Compiler and the ordinary simulation, validation, and applications kernels. Some of the ADTs are, however, also possible to use together with OS integrations (Cadvanced) and with Cmicro. If this is the case it is indicated in the description of the ADT.

General

The ADT library currently contains the following:

- A package, `ctypes`, that contains a number of sorts and generators to simplify an integration with C data types
- A data type that provides handling of text files and I/O operations as SDL operator calls
- A data type to generate random numbers from a number of distributions
- A data type that implements linked lists
- Data types for byte, unsigned, long int and so on (provided only for backward compatibility; use package `ctypes` instead)
- A data type that makes it possible to define PId literals for static process instances as synonyms
- A data type that provides a number of general purpose operators that may be used to reduce the complexity of an SDL system

These data types are delivered in source code. Feel free to change and adapt these data types for your own needs.

Important!

There is no commitment from IBM Rational to support the ADTs described in this chapter. IBM Rational has used the ADTs in internal projects with successful results.

The files that are contained in the ADT library are located in the subdirectory `<installation directory>/include/ADT`. (**In Windows**, replace `/` in the path above with `\`)

Note: Conformance with earlier releases

The ADTs in SDL Suite are backward compatible with the ADTs in earlier releases, in the sense that you only need to include the new versions of the ADTs to obtain the same behavior.

However, it is important to remember that the ADTs and the code generators you use, must be from the same version of SDL Suite.

Integration with C Data Types

The package `ctypes` presented below contains a number of types and generators that is intended to directly support C data types in SDL. The package `ctypes` can also be used in OS integrations and with Cmicro. However, usage of C pointers (generator Ref) might cause problems, due to potential memory leaks and potential memory access protection between OS tasks.

The file `ctypes.sdl` is a SDL/PR version of this package suitable to use in an include statement in an SDL/PR system, while `ctypes.sun` is a SDL/GR version of the package.

In an SDL/GR system it is only necessary to insert a use clause, i.e.

```
use ctypes;
```

at a proper place. The Organizer will then by itself include the `ctypes` package, for example when the system is to be analyzed. To use the `ctypes` package in an SDL/PR system the following structure should be used.

```
/*#include 'ctypes.sdl'*/

use ctypes;
system example;
  ...
endsystem;
```

The `ctypes` package consists of the following newtypes, syntypes, and generators:

SDL	C
`syntype ShortInt`	`short int, short`
`syntype LongInt`	`long int, long`
`syntype UnsignedShortInt`	`unsigned short int, unsigned short`
`syntype UnsignedInt`	`unsigned int, unsigned`
`syntype UnsignedLongInt`	`unsigned long int, unsigned long`
`syntype Float`	`float`
`newtype Charstar`	`char *`

SDL	C
newtype Voidstar	void *
newtype Voidstarstar	void **
generator Carray	array type
generator Ref	pointer type

All the newtypes and syntypes introduce type names for “standard types” in C.

Some of the types and generators are briefly described below.

Charstar

In Charstar there is a literal and some operators included:

```
LITERALS
  Null;
OPERATORS
  cstar2cstring : Charstar   -> Charstring;
  cstring2cstar : Charstring -> Charstar;
  cstar2vstar   : Charstar   -> Voidstar;
  vstar2cstar   : Voidstar   -> Charstar;
  cstar2vstarstar : Charstar -> Voidstarstar;
```

Note that the operators `cstar2cstring` and `cstring2cstar` are not available when using Cmicro.

The operators are all conversion routines to convert a value from one type to another. Note that Charstar and Charstring are **not** the same types even if they both corresponds to char * in C. Note also that freeing allocated memory for Charstar is the responsibility of the user, as there is not enough information to handle this automatically (as for Charstring). For more information about how to free memory, see the Ref generator below.

Voidstarstar

The Voidstarstar type has all the properties of the Ref generator (see below). This means that `*>`, `&`, `+`, and `-` can be used and that the following literal and operators are defined:

```
LITERALS
  Null,
  Alloc;
OPERATORS
  vstarstar2vstar : Voidstarstar -> Voidstar;
  vstar2vstarstar : Voidstar -> Voidstarstar;
```

Carray

The generator Carray has the following parameters:

```
GENERATOR Carray (CONSTANT Length, TYPE Itemsort)
```

where Length is an integer giving the number of elements of the array (index from 0 to Length-1), and Itemsort gives the type of each element in the array. A Carray in SDL is translated to an array in C. Indexing a Carray variable in SDL follows the same rules as for ordinary SDL Arrays.

Ref

The generator Ref has the following definition:

```
GENERATOR Ref (TYPE Itemsort)
  LITERALS
    Null,
    Alloc;
  OPERATORS
    "*>"       : Ref, Itemsort -> Ref;
    "*>"       : Ref -> Itemsort;
    "&"        : Itemsort -> Ref;
    make!      : Itemsort -> Ref;
    free       : in/out Ref;
    "+"        : Ref, Integer -> Ref;
    "-"        : Ref, Integer -> Ref;
    Ref2VStar  : Ref -> Voidstar;
    VStar2Ref  : Voidstar -> Ref;
    Ref2VStarStar : Ref /*#REF*/ -> Voidstarstar;
  DEFAULT Null;
ENDGENERATOR Ref;

procedure Free; fpar p Voidstarstar;
external;
```

Instantiating the Ref generator creates a pointer type on the type given as generator parameter. The literals and operators have the following behavior:

- **Null**: The NULL value (= 0) for the pointer type. This is also the default value for a pointer variable.

- **Alloc**: An operator without parameters that returns a new allocated data area with the size of the Itemsort.
- ***>**: This is the extract! and modify! operator and can be used to reference the value referenced by a pointer. If p is a pointer type, `p*>` is the value the pointer refers to. Comparing with C, `p*>` is the same as `*p`. If p is a pointer to a struct, then `p*>!a` is the same as `(*p).a`.
- **&**: The & operator corresponds to the C operator with the same name. It can be used to take the address of a variable. Comparing with C, &p and &(p) in SDL is the same as &p in C.
- **make!**: The make! operator, which as usual in SDL has the syntax (. .), is a short hand for creating memory and initializing it to a given value. The statement:

  ```
  a := (. 2 .);
  ```

  has the same meaning as

  ```
  a := Alloc, a*> := 2;
  ```

- **free**: The Free operator is used to deallocate memory referenced by a Ref pointer. If the component type contains automatically handled pointers (Charstring, Octet_string, Bit_string, Bags, Own pointers, and so on) the memory for these components is also deallocated.
- **+, -**: These operator have the meaning of pointer arithmetics in exactly the same way as in C. For example, p+1 (if p is of a pointer type) will add the Itemsort size to the value p. The + and - operators are mostly used to step through an array in C.
- **ref2vstar**, **vstar2ref**, **ref2vstarstar**: These operators are conversion operators, that can be used to cast between pointers and void * and void **.
- procedure **Free**: NOTE: Old feature provided for backward compatibility. Use operator free above instead.

  This external procedure is closely connected to the Ref generator. It should be used to deallocate memory allocated by the Alloc operator. Free should be passed the pointer variable that references the data area to be released. The variable should be casted to Voidstarstar. After calling Free the pointer variable will have the value Null.

  Example: `Free(Ref2VStarStar(variable_name))`

  Apart from the difficult syntax for calling the Free procedure it has another problem, it does not free components inside the referenced data area as the free operator above does.

The SDL Analyzer can allow implicit type conversion of pointer data types created by the Ref generator; see "Implicit Type Conversions" on page 134 in chapter 3, *Using SDL Extensions, in the SDL Suite 6.2 Methodology Guidelines*.

Abstract Data Type for File Manipulations and I/O

The ADT TextFile

In this section an SDL abstract data type, `TextFile`, is discussed where file manipulations and I/O operations are implemented as operations on the abstract data type. This ADT can be used also in OS integrations and in Cmicro if the target system has support for files in C.

This data type, which you may include in any SDL system, makes it possible to access, at the SDL level, a subset of the file and I/O operations provided by C.

The implementation of the operators are harmonized with the I/O in the monitor, including the Simulator Graphical User interface. All terminal I/O, for example, will be logged on the interaction log file if the monitor command Log-On is given.

The data type defines a "file" type and contains three groups of operations:

1. Operations to open and close files
2. Operations to write information onto a file
3. Operations to read information from a file.

The operations may handle I/O operations both on files and on the terminal (file `stdin` and `stdout` in C).

Note:

This data type is not intended to be used in the SDL Explorer!

Purpose

The `TextFile` data type supplies basic file and I/O operations as abstract data type operations in SDL, whereby I/O may be performed within the SDL language. The operations may handle I/O both on the

terminal and on files and are harmonized with the I/O from the monitor, from the trace functions, and from the functions handling dynamic errors.

To make the data type available you include the file containing the definition with an analyzer include in an appropriate text symbol:

Example 534: Including an ADT File ––––––––––––––––––––––––––

```
/*#include 'file.pr' */
```

––

Remember that all file systems are operating system specific. Any rules in your file system apply.

Summary of Operators

The following literals are available in the data type FileName:

```
SYNTYPE FileName = Charstring
ENDSYNTYPE;

SYNONYM NULL    FileName = 'NULL';
SYNONYM stdin   FileName = 'stdin';
SYNONYM stdout  FileName = 'stdout';
SYNONYM stderr  FileName = 'stderr';
```

The following literals and operators are available in the data type `TextFile`:

```
NEWTYPE TextFile
  LITERALS
    NULL, stdin, stdout, stderr;

  OPERATORS
    GetAndOpenR   : FileName -> TextFile;
    GetAndOpenW   : FileName -> TextFile;
    OpenR         : FileName -> TextFile;
    OpenW         : FileName -> TextFile;
    OpenA         : FileName -> TextFile;
    Close         : TextFile -> TextFile;
    Flush         : TextFile -> TextFile;
    IsOpened      : TextFile -> Boolean;
    AtEOF         : TextFile -> Boolean;
    AtLastChar    : TextFile -> Boolean;

    PutReal       : TextFile, Real -> TextFile;
    PutTime       : TextFile, Time -> TextFile;
    PutDuration   : TextFile, Duration -> TextFile;
    PutPId        : TextFile, PId -> TextFile;
    PutInteger    : TextFile, Integer -> TextFile;
    PutBoolean    : TextFile, Boolean -> TextFile;
```

```
    PutCharacter  : TextFile, Character -> TextFile;
    PutCharstring : TextFile, Charstring -> TextFile;
    PutString     : TextFile, Charstring -> TextFile;
    PutLine       : TextFile, Charstring -> TextFile;
    PutNewLine    : TextFile -> TextFile;
    "//"          : TextFile, Real -> TextFile;
    "//"          : TextFile, Time -> TextFile;
    "//"          : TextFile, Duration -> TextFile;
    "//"          : TextFile, Integer -> TextFile;
    "//"          : TextFile, Charstring -> TextFile;
    "//"          : TextFile, Boolean -> TextFile;
    "//"          : TextFile, PId -> TextFile;
    "+"           : TextFile, Character -> TextFile;

    GetReal       : TextFile, Charstring -> Real;
    GetTime       : TextFile, Charstring -> Time;
    GetDuration   : TextFile, Charstring -> Duration;
    GetPId        : TextFile, Charstring -> PId;
    GetInteger    : TextFile, Charstring -> Integer;
    GetBoolean    : TextFile, Charstring -> Boolean;
    GetCharacter  : TextFile, Charstring -> Character;
    GetCharstring : TextFile, Charstring -> Charstring;
    GetString     : TextFile, Charstring -> Charstring;
    GetLine       : TextFile, Charstring -> Charstring;
    GetSeed       : TextFile, Charstring -> Integer;

    GetReal       : TextFile -> Real;
    GetTime       : TextFile -> Time;
    GetDuration   : TextFile -> Duration;
    GetPId        : TextFile -> PId;
    GetInteger    : TextFile -> Integer;
    GetBoolean    : TextFile -> Boolean;
    GetCharacter  : TextFile -> Character;
    GetCharstring : TextFile -> Charstring;
    GetString     : TextFile -> Charstring;
    GetLine       : TextFile -> Charstring;
    GetSeed       : TextFile -> Integer;
ENDNEWTYPE TextFile;
```

The operators may be divided into three groups with different purpose:

1. Operators that, together with the literals, are used for handling files.
2. Operators suited for writing information to files.
3. Operators intended for reading information from files.

The next three subsections provide the necessary information for using these operators. The data type itself will be discussed together with the operators for handling files.

File Handling Operators

First in this subsection each operator and literal will be discussed in detail and then some typical applications of the operators will be presented.

> **Caution!**
>
> The operators GetAndOpenR and GetAndOpenW **do not work** with the Application library. The operators GetPId and PutPId (and the // operator to write PIds) can be used with the Application library, but they will use a different output format.

Operator Behavior

The type `TextFile` is implemented using the ordinary C file type `FILE`. A `TextFile` is a pointer to a `FILE`.

```
typedef FILE * TextFile;
```

The literal `NULL` represents a null value for files. This literal is translated to `TextFileNull()` in the generated C code by an appropriate `#NAME` directive and is then implemented using the macro:

```
#define TextFileNull() (TextFile)0
```

All variables of the type `TextFile` will have this value as default value.

The literals `stdin` and `stdout` represent the standard files `stdin` and `stdout` in C, which are the files used in C for I/O to the terminal. The file `stdin` is used for reading information from the keyboard, while `stdout` is used for writing information on the screen.

The standard operators assignment and test for equality is implemented in such a way that `A:=B` means that now A refers to the same file as B, while `A=B` tests if A and B refer to the same file.

FileName

The data type `FileName` is used to represent file names in the operators `GetAndOpenR`, `GetAndOpenW`, `OpenR`, `OpenW`, and `OpenA`. It has all Charstring literals and the special synonyms `NULL`, `stdin` (input from the keyboard), `stdout` (output to the screen), and `stderr` (output to the screen from which the SDL Suite was started). As `FileName` is a syn-

type of Charstring, the usual Charstring operators are defined for this type.

Caution!

The synonyms `stdin`, `stdout`, `stderr` in some circumstances hide the literals with the same names according to SDL scope rules. If that is the case, please insert a qualifier `<<type textfile>>` before the literal name.

GetAndOpenR – GetAndOpenW

The operators `GetAndOpenR` and `GetAndOpenW` are used to open a file with a name prompted for on the terminal. `GetAndOpenR` opens the file for read, while `GetAndOpenW` opens the file for write. The operators take the prompt as parameter (type charstring), print the prompt on the screen (on `stdout`), and read a file name from the keyboard (from `stdin`). An attempt is then made to open a file with that name. If the open operation was successful, a reference to the file is returned by the `GetAndOpenR` or `GetAndOpenW` operator, otherwise `NULL` is returned. After a successful open operation you may use the file for reading or writing.

If you type `<Return>`, `-` or the file name `stdin` at the prompt in `GetAndOpenR` a reference to `stdin` is returned by the operator. `GetAndOpenW` will, in the same way, return a reference to `stdout` if the prompt is answered by `<Return>`, `-` or the file name `stdout`.

Note:

To work properly in the *Simulator Graphical User Interface*, the prompt string should be terminated with: ": ", i.e. colon space.

OpenR – OpenW – OpenA

The operators `OpenR`, `OpenW`, and `OpenA` are used to open a file with a file name passed as parameter. `OpenR` opens the file for read, while `OpenW` opens the file for write and `OpenA` opens the file for append. An attempt is made to open a file with the name given as a parameter. If the open operation was successful, a reference to the file is returned by the `OpenR`, `OpenW`, or `OpenA` operator, otherwise `NULL` is returned. After a successful open operation you may read, write or append on the file.

Close

The operator `Close` is used to close the file passed as parameter. `Close` always returns the value `NULL`. This operator should be used on each file opened for write after all information is written to the file to ensure that any possibly buffered data is flushed.

> **Note:**
>
> Always close a file variable before assigning it to a new file, otherwise data may be lost.

Flush

Output to files is usually buffered, and is therefore not immediately written on the physical output device. The operator `Flush` forces the output buffer of the file that is passed as parameter to be written on the physical output device. It is equivalent to C function `fflush`.

IsOpened

The operator `IsOpened` may be used to determine if a `TextFile` is open or not. It may, for example, be used to test the result of the `Open` operation discussed above. The test `IsOpened(F)` is equivalent to `F /= NULL`.

AtEOF

The operator `AtEof` may be used to determine if a `TextFile` has reached the end of file or not. This operator could be used in order to determine when to stop reading input from a file. The test `AtEof(F)` is equivalent to `feof(F)`.

> **Note:**
>
> `AtEof` first becomes true when attempts are made to read behind the end-of-file. Operator `AtLastChar` becomes true when the last character of the file has been read, and is usually more useful than `AtEof`.

AtLastChar

The operator `AtLastChar` may be used to determine if a `TextFile` has reached the end of file or not. This operator is useful in order to determine when to stop reading input from a file. The test `AtLastChar(F)` returns `true` if there are no more characters to be read from the file.

Examples of Use

Three typical situations when you want to write information are easily identified:

1. The information is to be printed on the screen.
2. The information is to be printed on a file with a given name.
3. You want to determine at run-time where the information is to be printed.

Example 535: ADT for File I/O, Print to Screen ––––––––––––––––––

If the information is to be **printed on the screen**, you may use the following structure:

```
DCL F TextFile;
TASK F := stdout // 'example';
```

Declare a variable of type `TextFile` and assign it the value `stdout`. You may then use it in the write operators discussed under "Write Operators" on page 3229.

––

Example 536: ADT for File I/O, Print to File ––––––––––––––––––––

If the information is to be **printed on a file** with a given name, you may use the following structure:

```
DCL F TextFile;
TASK F := OpenW('filename');
TASK F := F // 'example';
```

The difference from the above is that the operator `OpenW` is used to open a file with the specified name. This outline may be complemented with a test if the `OpenW` operation was successful or not.

––

Example 537: ADT for File I/O, Accessing Text File ––––––––––––––––

If you **want to be able to determine at run-time where the information should be printed**, you should define a `TextFile` as in the examples above, and then use the following structure.

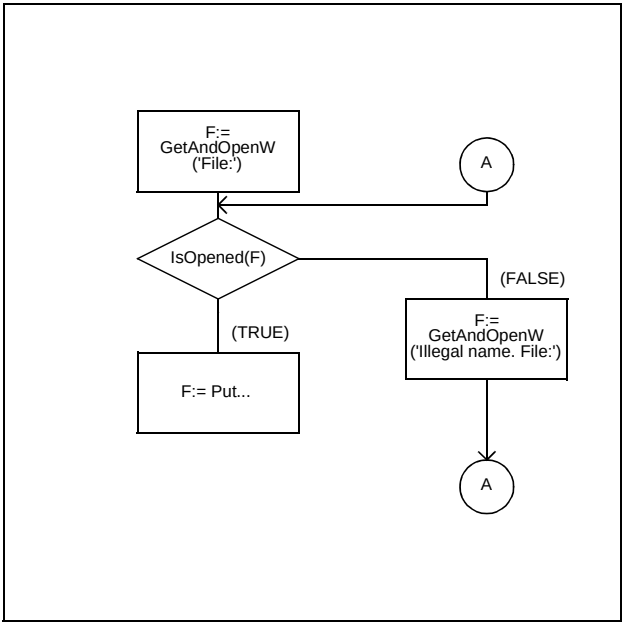

Figure 563: Accessing a TextFile

If you answer the question by hitting `<Return>` or by typing `stdout`, the information will be printed on screen (`stdout`). If you type the name of a file, the information will be printed on that file.

––

If you want to open the file for read instead of write, you may use almost identical structures.

Write Operators

Operator Behavior

The write operators `PutReal`, `PutTime`, `PutDuration`, `PutInteger`, `PutBoolean`, `PutCharacter`, and `PutCharstring` all take a `TextFile` and a value of the appropriate type as parameters. The operators print the value passed as parameter on the file referenced by the `TextFile` parameter and then return the `TextFile`. The *Put** operators will print the values in the same format as the monitor uses for the command Examine-Variable, and will append a space after each printed value.

The operator `PutString` takes a `TextFile` and a `Charstring` parameter and prints the string on the `TextFile`. `PutString` prints the string as a C string, not using the format for SDL Charstring. This means that no ' is printed. `PutString` returns the `TextFile` given as parameter as result.

The infix write operator `"//"` takes as parameters a `TextFile` and a value of type `Boolean, Charstring, Integer, PId, Real, Time,` or `Duration`. `TextF // Val` prints the value `'Val'` to the `TextFile` referenced by `'TextF'`, and returns value `'TextF'`. `Character` strings are printed without enclosing `''`. All // operators except the one for `Charstring` append a space to the file, after the value is written.

The infix write operator `"+"` takes as parameters a `TextFile` and a `Character`. `"+"` behaves just as `"//"`, but it has its special name in order to avoid type conflicts with `Charstring`.

The operator `PutNewLine` takes a `TextFile` as parameter, prints a carriage return (actually a `"\n"`) on this file, and returns the `TextFile` as operator result.

The different `Put` operators are equivalent to the `//` operators, and they are mainly present for backward compatibility reasons.

There is a function named `xPutValue` in the implementation of the data type `TextFile`. This function may print a value of any type that may be handled by the monitor system, but may only be accessed from in-line C code and not from SDL. A detailed description of the `xPutValue` function may be found under "Accessing the Operators from C" on page 3231.

Example 538: ADT for File I/O, Print to File ––––––––––––––––––––

To print a line according to the following example, where 137 is the value of the variable `NoOfJobs`:

```
Number of jobs: 137 Current time: 137.0000
```

You could use the following statements, assuming that the `TextFile F` is already opened:

```
TASK
  F := F // 'Number of jobs: ' // NoOfJobs;
TASK
  F := F // 'current time: ' // Now;
TASK
  F := PutNewLine(F);
```

––

Read Operators

Operator Behavior

The read operators `GetReal`, `GetTime`, `GetDuration`, `GetInteger`, `GetBoolean`, `GetCharacter`, `GetCharstring`, and `GetSeed` are used to read values of the various sorts.

The operator `GetSeed` is used to read appropriate values to initialize random number generators (odd integers in the range 1 to 32767).

There are two versions of each `Get` operator: one that only takes as parameters a `TextFile`, and the other that takes as parameters a `TextFile` and a `Charstring` which is used as prompt. All `Get` operators behave differently depending on if the value should be read from the terminal (`stdin`) or from a file.

If the value should be **read from the terminal**, the `Get` operators with the prompt parameter may be used. This prompt is printed on the screen, and then an attempt to read a value of the current type is made. If a `Get` operator with only the `TextFile` parameter is used, a default prompt is used, that depends on the type that is to be input. If the operation is successful, the read value is returned as a result, otherwise the message `"Illegal value"` is printed and the user is given a new chance to type a value.

Note:

To work properly in the *Simulator Graphical User Interface*, the prompt string should be terminated with: ": ", i.e. colon space.

If the value should be **read from a file**, it is recommended to use the `Get` operators without the prompt parameter, as it is not used. It is assumed that a value of the correct type will be found.

There are several `Get` operators for reading character strings:

`GetString` reads a sequence of characters until the first white space character, and is equivalent to `fscanf (f, "%s")`.

`GetLine` reads a sequence of characters until the end of line is reached. It is equivalent to `fgets`, but the end-of-line character will not be part of the string.

`GetCharstring` reads a sequence of characters on a single line that is enclosed by single quotes `(')`. This operator is mainly present for backward compatibility reasons.

There is a function named `xGetValue` in the implementation of the data type `TextFile`, which may read a value of any type that may be handled by the monitor system. This function can only be accessed from in-line C code and not from SDL. A detailed description of the `xGetValue` function may be found under "Accessing the Operators from C" on page 3231.

Example 539: ADT for File I/O, Read from File

```
TASK
  Mean := GetReal (F),
  A(1) := GetReal (F),
  A(2) := GetReal (F),
  A(3) := GetReal (F);
```

Accessing the Operators from C

In some circumstances it may be easier to use C code (in `#CODE` directives) rather than SDL to implement an algorithm. SDL implementations for linear algorithms sometimes become unnecessarily large and complex, as SDL for example lacks a loop concept. Consider the SDL

graph in Figure 563 on page 3228. This graph could be replaced by a TASK with the following contents:

```
'Open file F' /*#CODE
#(F) = GetAndOpenW("LFile : ");
while ( ! IsOpened(#(F)) )
  #(F) = GetAndOpenW("LIllegal name. File : "); */
```

which is more compact and gives a better overview at the SDL level.

#(F) is an SDL directive telling the SDL to C compiler to translate the SDL variable F to the name it will receive in the generated C code.

To simplify the use of in-line C code, #NAME directives are introduced on all identifiers defined in this data type. The same names are used in C as in SDL.

Note:

Upper and lower case letters are significant in C (but not in SDL).

Note also the additional L in the Charstring literals, for example "LIllegal name. File : ". This first character is used in the implementation of the SDL sort Charstring and should **always** be L in a charstring literal.

From in-line C, two functions xGetValue and xPutValue are also available to read and write values of any type. These functions have the following prototypes:

```
extern void xGetValue(
  TextFile       F,
  SDL_Charstring Prompt,
  xSortIdNode    SortId,
  void         * Result,
  char         * FunctionName );

extern void xPutValue(
  TextFile    F,
  xSortIdNode SortId,
  void      * Value,
  char      * FunctionName );
```

Parameter	Interpretation
TextFile F	The file to read from or to print to.
In xGetValue: SDL_Charstring Prompt	Is used as prompt in exactly the same way as for the ordinary Get operators.

Parameter	Interpretation
`xSortIdNode SortId`	A reference to the `xIdNode` that represents the SDL sort to be read or printed For the **predefined SDL sorts** you may use variables named `xSrtN_SDL_Real`, `xSrtN_SDL_Integer`, and so on, as parameter. For **user-defined sorts**, you may use similar variables named `ySrtN_#(SortName)`, where `SortName` should be replaced by the sort name.
`void * Result` `void * Value`	The address to the variable where the result should be stored, or the address to the variable that should be printed.
`char * FunctionName`	A string specifying the name of an appropriate function. This name will be given if an error is detected during reading or printing.

Note:

xGetValue and xPutValue **will not work** together with the Application library.

To handle, for example, I/O of an SDL struct, the ideas presented below may be used.

Example 540: ADT for File I/O of an SDL Struct

```
NEWTYPE SName STRUCT
  a, b Integer;
ENDNEWTYPE;

DCL
  FIn, FOut TextFile,
  SVar SName;

TASK 'Put SVar on FOut' /*#CODE
  xPutValue( #(FOut), ySrtN_#(SName),
  &(#(SVar)), "PutSName" ); */;

TASK 'Get SVar from FIn' /*#CODE
  xGetValue( #(FIn), "Value : ",
  ySrtN_#(SName),&(#(SVar)), "LGetSName"); */;
```

Abstract Data Type for Random Numbers

One important feature, especially in performance simulations, is the possibility to generate random numbers according to a number of distributions, like for example the negative exponential distribution and the Erlang distribution. It is also important that the random number sequences are reproducible, to be able to run a slightly modified version of a simulation with the same sequence of random numbers.

In this section an SDL abstract data type according to the previous discussion is presented. This data type may be included in any SDL system. This ADT can also be used in OS integrations and in Cmicro. It is, however, necessary to check that the typedef for the RandomControl, see below, refers to an unsigned 32-bit type.

Purpose

The SDL `RandomControl` data type allows you to generate pseudo-random numbers. A number of distributions are supported, including the negative exponential distribution and the Erlang distribution. In performance simulations, which is the main application area for this data type, the most important need for random numbers is in connection with `Time` and `Duration` values. It is, for example, interesting to draw inter- arrival times in job generators, and service lengths in servers. Distributions returning positive real numbers are thus most meaningful.

The basic mechanism behind pseudo-random number generation is as follows. A sequence of bit-patterns is defined using a formula of type:

$$Seq_{n+1} = f(Seq_n)$$

The function f should be such that the sequence of elements seen as numbers should be “random”, and the number of element in the sequence, before it starts to repeat itself, should be as large as possible.

To obtain a new random number is thus a two step process:

1. Compute and store a new bit-pattern from the old bit-pattern
2. Interpret the new bit-pattern as a number, which is returned as the new random number.

In this data type, 32 bit patterns, implemented in C using the type unsigned long, are used together with the formula:

$$Seq_{n+1} = ((2^{16} + 3) \cdot Seq_n) \bmod 2^{32}$$

The result returned by the operator `Random`, which is the basic random number generator, is this bit-pattern seen as a number between 0 and 1, and expressed as a float.

The data type `RandomControl` may be included in any SDL system using an analyzer include statement, where the file containing the definition of the data type is included. Example:

```
/*#include 'random.pr' */
```

As the C standard functions `log` and `exp` are used in the `random.pr` file, it is necessary to link the application together with the library for math functions, i.e. to have `-lm` in the link operation in the makefile. See "Makefile Options" on page 123 in chapter 2, *The Organizer*. To use the entry `-lm` in the link list seems to be a fairly standard way to find the library for math functions. If this does not work, or you want more details, please see the documentation for your C compiler.

Available Operators

The type `RandomControl`, introduced by this data type, is in C implemented as the address of an unsigned long.

```
typedef unsigned long * RandomControl;
```

Note that you have check that `unsigned long` is a 32 bit type, otherwise you have to change the typedef.

The reason for passing the address to the bit-pattern (that is to the unsigned long), is that this bit-pattern has to be updated by the random functions.

Below the operators provided in this data type are listed. There are, for many of the operators, several versions with different sets of parameters and/or result types to support different usage of the operator.

```
Random : RandomControl -> Real;
Random : RandomControl -> Duration;
Random : RandomControl -> Time;

Erlang : Real, Integer, RandomControl -> Real;
Erlang : Real, Integer, RandomControl -> Duration;
Erlang : Real, Integer, RandomControl -> Time;
Erlang : Duration, Integer, RandomControl -> Real;
Erlang : Duration, Integer, RandomControl -> Duration;
Erlang : Duration, Integer, RandomControl -> Time;
Erlang : Time, Integer, RandomControl -> Real;
Erlang : Time, Integer, RandomControl -> Duration;
Erlang : Time, Integer, RandomControl -> Time;
```

```
HyperExp2 :
  Real, Real, Real, RandomControl -> Real;
HyperExp2 :
  Real, Real, Real, RandomControl -> Duration;
HyperExp2 :
  Real, Real, Real, RandomControl -> Time;
HyperExp2 :
  Duration, Duration, Real, RandomControl -> Real;
HyperExp2 :
  Duration, Duration, Real, RandomControl -> Duration;
HyperExp2 :
  Duration, Duration, Real, RandomControl -> Time;
HyperExp2 :
  Time, Time, Real, RandomControl -> Real;
HyperExp2 :
  Time, Time, Real, RandomControl -> Duration;
HyperExp2 :
  Time, Time, Real, RandomControl -> Time;

NegExp : Real, RandomControl -> Real;
NegExp : Real, RandomControl -> Duration;
NegExp : Real, RandomControl -> Time;
NegExp : Duration, RandomControl -> Real;
NegExp : Duration, Rando mControl -> Duration;
NegExp : Duration, RandomControl -> Time;
NegExp : Time, RandomControl -> Real;
NegExp : Time, RandomControl -> Duration;
NegExp : Time, RandomControl -> Time;

Uniform : Real, Real, RandomControl -> Real;
Uniform : Real, Real, RandomControl -> Duration;
Uniform : Real, Real, RandomControl -> Time;
Uniform : Duration, Duration, RandomControl -> Real;
Uniform :
  Duration, Duration, RandomControl -> Duration;
Uniform : Duration, Duration, RandomControl -> Time;
Uniform : Time, Time, RandomControl -> Real;
Uniform : Time, Time, RandomControl -> Duration;
Uniform : Time, Time, RandomControl -> Time;

Draw    : Real, RandomControl -> Boolean;

Geometric : Real, RandomControl -> Integer;
Geometric : Real, RandomControl -> Duration;
Geometric : Real, RandomControl -> Time;
Geometric : Duration, RandomControl -> Integer;
Geometric : Duration, RandomControl -> Duration;
Geometric : Duration, RandomControl -> Time;
Geometric : Time, RandomControl -> Integer;
Geometric : Time, RandomControl -> Duration;
Geometric : Time, RandomControl -> Time;

Poisson : Real, RandomControl -> Integer;
Poisson : Real, RandomControl -> Duration;
```

```
Poisson : Real, RandomControl -> Time;
Poisson : Duration, RandomControl -> Integer;
Poisson : Duration, RandomControl -> Duration;
Poisson : Duration, RandomControl -> Time;
Poisson : Time, RandomControl -> Integer;
Poisson : Time, RandomControl -> Duration;
Poisson : Time, RandomControl -> Time;

RandInt : Integer, Integer, RandomControl -> Integer;
RandInt : Integer, Integer, RandomControl -> Duration;
RandInt : Integer, Integer, RandomControl -> Time;

DefineSeed : Integer -> RandomControl;
GetSeed    : Charstring -> Integer;
Seed       : RandomControl -> Integer;
```

Random (RandomControl)

The operator `Random` is the basic random generator and is called by all the other operators. `Random` uses the formula

$$Seq_{n+1} = ((2^{16} + 3) \cdot Seq_n) \bmod 2^{32}$$

to compute the next value stored in the parameter of type `RandomControl`. The result from `Random` is a real random number in the interval 0.0 < Value < 1.0.

Erlang (Mean, N, RandomControl)

The operator Erlang provides random numbers from the Erlang-N distribution with mean `Mean`. The first parameter Mean should be > 0.0, and the second parameter N should be > 0.

HyperExp2 (Mean1, Mean2, Alpha, RandomControl)

The `HyperExp2` operator provides random numbers from the hyperexponential distribution. With probability `Alpha` it return a random number from the negative exponential distribution with mean `Mean1`, and with the probability `1-Alpha` it returns a random number from the negative exponential distribution with mean `Mean2`. `Mean1` and `Mean2` should be > 0.0, and `Alpha` should be in the range 0.0 <= `Alpha` <= 1.0.

NegExp (Mean, RandomControl)

The operator `NegExp` provides random numbers from the negative exponential distribution with mean `Mean`. `Mean` should be > 0.0.

Uniform (Low, High, RandomControl)

The operator `Uniform` is given a range `Low` to `High` and returns a uniformly distributed random number in this range.
`Low` should be <= `High`.

Draw (Alpha, RandomControl)

The `Draw` operator returns true with the probability `Alpha` and false with the probability `1-Alpha`. `Alpha` should be in the range 0.0 <= `Alpha` <= 1.0.

Geometric (p, RandomControl)

The operator `Geometric` returns an integer random number according to the geometric distribution with the mean p/(1-p). The parameter `p` should be 0.0 <= `p` < 1.0.

Caution!

Since the range of feasible samples from the distribution is infinite and the result type is integer, integer overflow may occur.

Poisson (m, RandomControl)

The operator `Poisson` returns an integer random number according to the Poisson distribution with mean `m`. The parameter `m` should be >= 0.0.

Caution!

Since the range of feasible samples from the distribution is infinite and the result type is integer, integer overflow may occur.

RandInt (Low, High, RandomControl)

This operator `RandInt` returns one of the values `Low`, `Low+1`, . . . , `High-1`, `High`, with equal probability. `Low` should be <= `High`.

DefineSeed (Integer) -> RandomControl

Each `RandomControl` variable, which is used as a control variable for a random generator, has to be initialized correctly so the first bit-pattern used by the basic random function is a legal pattern. This `DefineSeed`

operator takes an integer parameter, which should be an odd value in the range 1 to 32767, and creates a legal bit-pattern. This first value is usually referred to as the seed for the random generator. Using the same seed value, the same random number sequence is generated, which means that the random number sequences are reproducible.

Seed (RandomControl) -> Integer

The `Seed` operator returns random numbers that are acceptable as parameters to the operator `DefineSeed`. If many `RandomControl` variables are to be initialized, the `Seed` operator may be useful.

GetSeed (Prompt) -> Integer

The `GetSeed` operator, which is implemented in the data type `TextFile` (see "The ADT TextFile" on page 3221), may be used to read an integer value that is acceptable as parameter to the `DefineSeed` operator.

Using the Data Type

To use the abstract data type for random number generation you must:

- Include the definition of the data type using an analyzer include. Usually it is appropriate to include the data type in a text symbol in the system diagram.
- Define a suitable number of `RandomControl` variables, one for each random number sequence that is to be used.
- Initialize the `RandomControl` variables, either in the variable declaration or in a `TASK` often placed in the start transition of the process. The operator `DefineSeed` should be used to initialize a `RandomControl` variable.
- Use the `RandomControl` variables in appropriate random number operators.

> **Note:**
>
> SDL variables can only be declared in processes and will be local to the process instances.

To have global RandomControl variables you may, however, define synonyms of type RandomControl and use them in random generator operators.

Example 541: Using RandomControl, DefineSeed

```
SYNONYM Seed1 RandomControl =
  DefineSeed(GetSeed(stdin, 'Seed1 : '));

TASK Delay := NegExp(Mean1, Seed1);
```

This is correct according to SDL as operators only have IN parameters and therefore expressions are allowed as actual parameters. In C it is also an IN parameter and cannot be changed. But as a RandomControl value is an address it is possible to change the contents in that address.

The SDL to C Compiler will, for synonyms that cannot be computed at generation time, allocate a variable and initialize it according to the synonym definition at start-up time. Note that this will be performed before any transitions have been executed.

A typical application of RandomControl synonyms are together with the Seed operator. The Seed operator is used to generate values suitable to initialize RandomControl variables with.

Example 542: Using RandomControl, Seed

```
SYNONYM BasicSeed RandomControl =
  DefineSeed(GetSeed(stdin, 'Seed : '));

DCL S1 RandomControl :=
  DefineSeed(Seed(BasicSeed));
DCL S2 RandomControl :=
  DefineSeed(Seed(BasicSeed));
```

The variety of operators with the same name makes it possible to directly use operators in many more situations. This is called overloading of operators. If, for example, there were only the NegExp version:

```
NegExp : Real, RandomControl -> Real;
```

then explicit conversion operators would have been necessary to draw, for example, a Duration value from the negative exponential distribution. The code to draw a Duration value would then be something like:

```
RealToDuration(NegExp(Mean, Seq))
```

We have instead introduced several operators with the same name and purpose, but with different combinations of parameter types and result type. So for the `NegExp` operator discussed above, there is also a version:

```
NegExp : Real, RandomControl -> Duration;
```

which is exactly what we wanted.

There is, however, a price to be paid for having overloaded operators. It must be possible for the SDL Analyzer to tell which operator that is used in a particular situation. It then uses all available information about the parameters and what the result is used for. Consider Example 543 below.

Example 543: Overloaded Operator ––––––––––––––––––––––––––

```
TIMER T;
DCL
  Mean, Rand Real,
  D Duration,
  Seq RandomControl :=
    DefineSeed(GetSeed('Seed : '));

TASK Rand := NegExp(Mean, Seq);
TASK D := NegExp(Mean, Seq);
TASK D := NegExp(TYPE Real 1.5, Seq);

DECISION NegExp(Mean, Seq) >
         TYPE Duration 10.0;
  (true) : ....
  ELSE :
ENDDECISION;
SET (Now + NegExp(Mean, Seq), T);
```

- The first two applications of `NegExp` are no problem, as the parameter type is given by the type of the `Mean` variable, and the result type is given by the variable that result is assigned to.
- In the third `NegExp` call, the value 1.5 has to be given a qualifier, that is, `TYPE Real`, as the literal 1.5 may be of type `Real`, `Duration`, or `Time`.
- In the fourth example it is the result type that cannot be determined if the literal 10.0 was not given with a qualifier.
- In the fifth example the only + operator that takes `Time` as left parameter and returns `Time` (`SET` should have a `Time` value as first parameter) is:

```
"+" : Time, Duration -> Time;
```

defined in the sort `Time`. So, both the type for the parameter and the result are possible to determine for the `NegExp` operator in this example.

Most of these problems can be avoided by using `SYNONYMS` or variables instead of literal values. This is in most cases a better solution than to introduce qualifiers.

Example 544: Using SYNONYMS

If, for example, the synonyms:

```
SYNONYM MeanValue Real = 1.5;
SYNONYM Limit Duration = 10.0;
```

were defined, the third and fourth `NegExp` call would cause no problem:

```
TASK D := NegExp(MeanValue, Seq);
DECISION NegExp(Mean, Seq) > Limit;
  (true) : ....
  ELSE :
ENDDECISION;
```

Trace Printouts

Trace printouts are available for the functions in this abstract data type. By assigning a trace value greater or equal to nine (9) using the monitor command Set-Trace, each call to an operator in this data type causes a printout of the name of the operator.

> **Note:**
>
> Each operator returning a random number will call the basic operator `Random` at least once.

Accessing the Operators from C

The operator for random number generation may be used directly in C by using the name given in the appropriate `#NAME` directive. Please look at the `random.pr` file for the `#NAME` directives.

Abstract Data Types for List Processing

The abstract data types defined in this “package” are intended for processing of linked lists. Linked lists are commonly appearing in applications and are one of the basic data structures in computer science. With these data types, you can concentrate on using the lists and do not have to worry about the implementation details, as all list manipulations are hidden in operators in the data types.

> **Note:**
>
> This data type is **not** implemented in a way that makes it possible to be used in the SDL Explorer. It can be used in OS integrations, but it is **not** recommended, due to the risk for memory leaks.

Purpose

Definitions

A *queue* is a list in which the members are ordered. The ordering is entirely performed by the user. The available operations make it possible to access members of the queue and insert members into or remove members from any position. Furthermore, the operators suppress the implementation aspects. That is, the fact that the queue is implemented as a doubly linked list with a queue head. The operators also prevent the unwary user from trying to access, for instance, the successor of the last member or the predecessor of the first member.

The entities which may be members of a queue are called *object instances*. An object instance is a passive entity containing user defined information. This information is described in the *object description*.

In SDL these definitions are implemented using sorts called `Queue`, `ObjectInstance`, and `ObjectDescr`, where `ObjectDescr` should be defined by the user. `ObjectDescr` should have the structure given in the example below (Example 545).

The data types for list processing may be included in any SDL system using Analyzer `#include` statements, where the files containing the definitions of the data types are included. The definitions should be placed in the order given in the example below:

Example 545: Including ADT for List Processing ––––––––––––––––

```
/*#include 'list1.pr'*/
NEWTYPE ObjectDescr /*#NAME 'ObjectDescr'*/
  STRUCT
    SysVar SysTypeObject;
    /* other user defined components */
ENDNEWTYPE;
/*#include 'list2.pr'*/
```

––

The file `list1.pr` contains the definition of the sort `Queue` (and the help sorts `ObjectType` and `SysTypeObject`), while the file `list2.pr` contains the definition of the type `ObjectInstance`.

Available Sorts

When the data types for list processing are included, two new sorts, `Queue` and `ObjectInstance`, are mainly defined, together with the type `ObjectDescr` defined by the user. The user can declare variables of type `Queue` and type `ObjectInstance`, but should never declare a variable of type `ObjectDescr`.

Variables of the sorts `Queue` and `ObjectInstance` are references (pointers) to the representation of the queue or the object instance. In both sorts there is a null value, the literal `NULL`, which indicates that a variable refers to no queue or no object instance. The default value for `Queue` and `ObjectInstance` variables is `NULL`.

A variable of sort `ObjectInstance` can refer to a data area containing the components defined in the struct `ObjectDescr`. The example below shows how to manipulate these components.

Example 546: ADT for List Processing, Struct ObjectDescr––––––––

```
/*#include 'list1.pr'*/
NEWTYPE ObjectDescr /*#NAME 'ObjectDescr'*/
  STRUCT
    SysVar SysTypeObject;
    Component1  Integer;
    Component2  Boolean;
ENDNEWTYPE;
/*#include 'list2.pr'*/

DCL O1 ObjectInstance;

TASK
  O1 := NewObject;  /* see next section */
```

```
TASK
  O1!ref!Component1 := 23,
  O1!ref!Component2 := false;

TASK
  IntVar := O1!ref!Component1,
  BoolVar := O1!ref!Component2;
```

A component is thus referenced by the syntax:

```
ObjectInstanceVariable ! ref ! ComponentName
```

Caution!

You should never directly manipulate the component `SysVar` in the struct `ObjectDescr`. It contains information about if and how the object instance is inserted into a queue and should only be used by the queue handling operators.

Assignments and test for equality may be performed for queues and for object instances. The assignments:

```
Q1 := Q2;  O1 := O2;
```

mean that `Q1` now refers to the same queue as `Q2` and that `O1` now refers to the same object instance as `O2`. Assignment is thus implemented as copying of the reference to the queue (and not as copying of the contents of the queue). The same is true for object instances.

The test for equality is in the same way implemented as a test if the left and right hand expression reference the same queue or the same object instance (and not if two queue or object instances have the same contents).

Due to the order in which the sorts are defined, a component of sort `Queue` can be a part of the `ObjectDescr` struct, while components of type `ObjectInstance` cannot be part of `ObjectDescr`.

If you want several different types of objects in a queue, with different contents, the `#UNION` directive (see *"Union" on page 2668 in chapter 56, The Cadvanced/Cbasic SDL to C Compiler*) may be used according to the following example:

Example 547: Unions and Queues ----------

```
NEWTYPE Ob1 STRUCT
  Comp1Ob1 integer;
  Comp2Ob1 boolean;
ENDNEWTYPE;

NEWTYPE Ob2 STRUCT
  Comp1Ob2 character;
  Comp2Ob2 charstring;
ENDNEWTYPE;

NEWTYPE Ob /*#UNION*/ STRUCT
  Tag integer;
  C1  Ob1;
  C2  Ob2;
ENDNEWTYPE;

NEWTYPE ObjectDescr /*#NAME 'ObjectDescr'*/
  STRUCT
    SysVar SysTypeObject;
    U      Ob;
/*#ADT (X)*/
ENDNEWTYPE;
```

The components may now be reached using:

```
O1 ! ref ! U ! Tag
O1 ! ref ! U ! C1 ! Comp1Ob1
O1 ! ref ! U ! C2 ! Comp2Ob1
```

Available Operators

Operators in the Sort Queue

In the sort `Queue`, the following literals and operators are available:

```
null
NewQueue

Cardinal     : Queue -> Integer;
DisposeQueue : Queue -> Queue;
Empty        : Queue -> Boolean;
FirstInQueue : Queue -> ObjectInstance;
Follow       :
     Queue, ObjectInstance, ObjectInstance -> Queue;
IntoAsFirst  : Queue, ObjectInstance -> Queue;
IntoAsLast   : Queue, ObjectInstance -> Queue;
LastInQueue  : Queue -> ObjectInstance;
Member       : Queue, ObjectInstance ->  Boolean;
```

```
Precede      :
     Queue, ObjectInstance, ObjectInstance -> Queue;
Predecessor  : ObjectInstance -> ObjectInstance;
Remove       : ObjectInstance -> ObjectInstance;
Successor    : ObjectInstance -> ObjectInstance;
```

Operators in the Sort ObjectInstance

In the sort `ObjectInstance`, the following literals and operators are available:

```
null
NewObject

DisposeObject: ObjectInstance -> ObjectInstance;
```

The operators defined in the sorts `Queue` and `ObjectInstance` have the behavior described below. All operators will check the consistency of the parameters. Each queue and object instance parameter should, for example, be `/= null`. If an error is detected the operator will cause an SDL dynamic error that will be treated as any other dynamic error found in an SDL system.

NewQueue: -> Queue

The literal `NewQueue` is used as an operator with no parameters and returns a reference to a new empty queue. The data area used to represent the queue is taken from an avail stack maintained by the list processing sorts. Only if the avail stack is empty new dynamic memory is allocated.

Cardinal: Queue -> Integer

This operator takes a reference to a queue as parameter and returns the number of components in the queue.

DisposeQueue: Queue -> Queue

This operator take a reference to a queue as parameter and returns all object instances and the data area used to represent the queue to the avail stack mentioned in the presentation of `NewQueue`. `DisposeQueue` always returns the value `null`.

> **Note:**
>
> Any references to an object instance or to a queue that is returned to the avail stack is now invalid and any use of such a reference is erroneous and has an unpredictable result.

Empty: Queue -> Boolean

This operator takes a reference to a queue as parameter and returns `false` if the queue contains any object instances. Otherwise the operator returns `true`.

FirstInQueue: Queue -> ObjectInstance

This operator takes a reference to a queue as parameter and returns a reference to the first object instance in the queue. If the queue is empty, `null` is returned.

Follow: Queue, ObjectInstance, ObjectInstance -> Queue

Follow takes a reference to a queue and to two object instances and inserts the first object instance directly after the second object instance. It is assumed and checked that the second object instance is a member of the queue given as parameter, and that the first object instance is not a member of any queue prior to the call.

Note:

The operator `Member` is used to check that the second object instance is member of the queue.

IntoAsFirst: Queue, ObjectInstance -> Queue

This operator takes a reference to a queue and to an object instance and inserts the object instance as the first object in the queue. The queue given as parameter is returned as result from the operator. It is assumed and checked that the object instance is not a member of any queue prior to the call.

IntoAsLast: Queue, ObjectInstance -> Queue

This operator takes a reference to a queue and to an object instance and inserts the object instance as last object in the queue. The queue given as parameter is returned as result from the operator. It is assumed and checked that the object instance is not a member of any queue prior to the call.

LastInQueue: Queue -> ObjectInstance

This operator takes a reference to a queue as parameter and returns a reference to the last object instance in the queue. If the queue is empty, `null` is returned.

Member: Queue, ObjectInstance -> Boolean

This operator takes a reference to a queue and to an object instance and returns `true` if the object instance is member of the queue, otherwise it returns `false`.

Precede: Queue, ObjectInstance, ObjectInstance-> Queue

Precede takes a reference to a queue and to two object instances and inserts the first object instance directly before the second object instance. It is assumed and checked that the second object instance is a member of the queue given as parameter, and that the first object instance is not a member of any queue prior to the call.

Note:

The operator `Member` is used to check that the second object instance is member of the queue.

Predecessor: ObjectInstance -> ObjectInstance

This operator takes a reference to an object instance and returns a reference to the object instance immediately before the current object instance. If the object instance given as parameter is the first object in the queue, `null` is returned. It is assumed and checked that the object instance given as parameter is a member of a queue.

Remove: ObjectInstance -> ObjectInstance

Remove takes a reference to an object instance and removes it from the queue it is currently a member of. A reference to the object instance is returned as result from the operator. It is assumed and checked that the object instance given as parameter is a member of a queue.

Successor: ObjectInstance -> ObjectInstance

This operator takes a reference to an object instance and returns a reference to the object instance immediately after the current object instance. If the object instance given as parameter is the last object in the queue,

`null` is returned. It is assumed and checked that the object instance given as parameter is a member of a queue.

NewObject: -> ObjectInstance

The literal `NewObject` is used as an operator with no parameters and returns a reference to a new object instance, which is not member of any queue. The data area used to represent the object instance is taken from an avail stack maintained by the list processing sorts. Only if the avail stack is empty new dynamic memory is allocated.

DisposeObject: ObjectInstance -> ObjectInstance

This operator take a reference to an object instance as parameter and returns it to the avail stack mentioned above. `DisposeObject` always returns the value `null`.

> **Note:**
>
> Any references to an object instance that is returned to the available stack are now invalid and any use of such a reference is erroneous and has an unpredictable result.

Examples of Use

In this section a number of examples will be given to give some indications of how to use the list processing "package". The following sort definitions are assumed to be included in the system diagram:

```
/*#include 'list1.pr' */

NEWTYPE ObjectDescr /*#NAME 'ObjectDescr'*/
  STRUCT
    SysVar SysTypeObject;
    Number Integer;
    Name   Charstring;
ENDNEWTYPE;

/*#include 'list2.pr' */
```

Example 548: Creating a Queue ––––––––––––––––––––––––––––––

To create a new queue and insert two objects in the queue, so that the first object has `Number = 23` and `Name = 'xyz'` and the second object has `Number = 139` and `Name = 'Telelogic'`, you could use the following code (assuming appropriate variable declarations):

```
TASK
  Q := NewQueue,
  O1 := NewObject,
  O1!ref!Number := 23,
  O1!ref!Name := 'xyz',
  Q := IntoAsFirst(Q, O1),
  O1 := NewObject,
  O1!ref!Number := 139,
  O1!ref!Name := 'Telelogic',
  Q := IntoAsLast(Q, O1);
```

Example 549: Removing from Queue

To remove the last object instance from a queue, assuming the queue is not empty, you could use the following code:

```
TASK
  O1 := Remove(LastInQueue(Q));
```

Example 550: Looking in Queue

You may look at the component `Name` in the first object instance in the queue in the following way:

```
TASK
  O1 := FirstInQueue(Q),
  StringVar := O1!ref!Name;
```

or if the reference to `O1` is not going to be used any further

```
TASK
  StringVar := FirstInQueue(Q)!ref!Name;
```

Example 551: Searching in Queue

The result of the following algorithm is that `O1` will be a reference to the first object instance that has the value `IntVar` in the component `Number`. If no such object is found `O1` is assigned the value `null`.

```
TASK O1 := FirstInQueue(Q);
NextObject:
DECISION O1 /= null;
  (true) :
    DECISION O1!ref!Number /= IntVar;
      (true):
        TASK O1 := Successor(O1);
        JOIN NextObject;
      (false):
    ENDDECISION;
  (false):
ENDDECISION;
```

Example 552: Removing Duplicates from Queue

The algorithm below removes all duplicates from a queue (and returns them to the avail stack). A duplicate is here defined as an object instance with the same `Number` as a previous object in the queue.

```
TASK O1 := FirstInQueue(Q);
NextObject:
DECISION O1 /= null;
  (true) :
    TASK O2 := Successor(O1);
    NextTry:
    DECISION O2 /= null;
      (true):
        DECISION O1!ref!Number = O2!ref!Number;
          (true):
            TASK Temp := O2,
                 O2 := Successor(O2),
                 Temp := DisposeObject (
                           Remove(Temp));
          (false):
            TASK O2 := Successor(O2);
        ENDDECISION;
        JOIN NextTry;
      (false):
        TASK O1 := Successor(O1);
        JOIN NextObject;
    ENDDECISION;
  (false) :
ENDDECISION;
```

Connection to the Monitor

Trace printouts are available for the operators in this abstract data type. By assigning a trace value greater or equal to eight (8) using the monitor command Set-Trace, each call to an operator in this data type causes a printout of the name of the current operator. Note that some of the operators may call some other operator to perform its task.

You may use the monitor command Examine-Variable to examine the values stored in a variable of type `ObjectInstance`. By typing an additional index number after the variable `Queue` the value of the `ObjectInstance` at that position of the queue is printed.

Accessing List Operators from C

The sorts `Queue`, `ObjectInstance`, and `ObjectDescr`, and all the operators and the literals `NewQueue` and `NewObject` have the same name in C as in SDL, as `#NAME` directives are used. The literal `null` is the sort `Queue` and is translated to `QueueNull()`, while the literal `null` in sort `ObjectInstance` is translated to `ObjectInstanceNull()`.

In C you access a component in an `ObjectInstance` using the -> operator:

```
OI_Var -> Component
```

As an example of an algorithm in C, consider the algorithm in Example 551 on page 3252. A reference to the first object instance that has the value `IntVar` in the component `Number` is computed:

```
#(O1) = FirstInQueue(#(Q));
while ( #(O1) != ObjectInstanceNull () ) {
  if ( #(O1)->Number == #(IntVar) ) break;
  #(O1) = Successor(#(O1));
}
```

Abstract Data Type for Byte

In this section an abstract data type for byte, i.e. `unsigned char` in C, is presented. This ADT can be used also in OS integrations and with Cmicro. However, please see the note below.

> **Note:**
>
> This ADT is only provided for backward compatibility, as the new predefined data type Octet should be used instead of Byte.

Purpose

The purpose of this data type is of course to have the type byte and the byte operations available directly in SDL.

The data type becomes available by including the file containing the definition with an analyzer included in an appropriate text symbol.

Example 553: ––

```
   /*#include 'byte.pr' */
 ––––––––––––––––––––––––––––––––––––––––––––––––––––––––––
```

Available Operators

The following operators are available in this data type:

BAND: byte, byte -> byte

Bitwise and. Corresponds to C operator &

BOR: byte, byte -> byte

Bitwise or. Corresponds to C operator |

BXOR: byte, byte -> byte

Bitwise exclusive or. Corresponds to C operator ^

BNOT: byte -> byte

Unary not. Corresponds to C operator ~

BSHL: byte, integer -> byte

Left shift of the byte parameter the number of steps specified by the integer parameter. Corresponds to C operator <<

Implementation:

```
(byte)( (b << i) & 0xFF )
```

BSHR: byte, integer -> byte

Right shift of the byte parameter the number of steps specified by the integer parameter. Corresponds to C operator >>

```
Implementation: ( b >> i)
```

BPLUS: byte, byte -> byte

Byte plus (modulus 0xFF). Corresponds to C operator +

BSUB: byte, byte -> byte

Byte minus (modulus 0xFF). Corresponds to C operator -

BMUL: byte, byte -> byte

Byte multiplication (modulus 0xFF). Corresponds to C operator *

BDIV: byte, byte -> byte

Byte division. Corresponds to C operator /

BMOD: byte, byte -> byte

Byte modulus. Corresponds to C operator %

BHEX: charstring -> byte

This operator transforms a charstring (’00’ - ’ff’ or ’FF’) into a byte. The string may be prefixed with an optional ’0x’.

I2B: integer -> byte

I2B transforms an integer in range 0 - 255 into a byte.

B2I: byte -> integer

B2I transforms a byte into an integer.

Unsigned (and Similar) Types

There are three files called:

```
unsigned.pr
unsigned_long.pr
longint.pr
```

where three SDL sorts implemented in C as unsigned, unsigned long, and long int may be found. All these types are in SDL implemented as syntypes of integer. For more information please see the definitions of the data types.

Note:

These ADTs are only provided for backward compatibility, as is recommended to use the types in the package `ctypes` instead. The package `ctypes` is discussed first in this chapter.

How to Obtain PId Literals

This section describes a way to obtain `PId` literals for static process instances. `PId` literals will make it possible to simplify the start-up phase of an SDL system, as direct communication (*OUTPUT TO*) may be used from the very beginning. It is otherwise necessary to start sending signals without *TO*, as the only `PId` values known at the beginning are the *Parent* - *Offspring* relations.

Note:

This ADT **cannot** be used in OS integrations or with Cmicro. There are, however, a special version for OS integrations that can be found in the directory for the OS integration, and a special version for Cmicro that can be found in the Cmicro installation directory.

Note:

`PId` literals cannot be created for processes within block types or system types.

Purpose

In SDL the only way to obtain a `PId` value is to use one of the basic functions *Self*, *Parent*, *Offspring*, or *Sender*. Such values may then, of course, be passed as parameters in signals, in procedure calls and in create operations.

During system start-up there is no way to obtain the `PId` value for a static process instance at the output that starts a communication session. The receiver of the first signal must therefore be implicit, by using an output without *TO*.

To be able to handle outputs without TO, in SDL-92 types and in separate generated units, complete knowledge about the structure of channels and signal routes must be known at run-time. The same knowledge is also necessary if we want to check that there is a path from the sender to the receiver in an output with TO. As the information needed about channels and signal routes requires substantial amounts of memory, it would be nice, in applications with severe memory requirements, to be able to optimize this.

To remove all information about channels and signal routes from a generated application means two things:

1. Output without TO cannot be used in SDL-92 types or in separate generated units.
2. It is not possible to check that there is a path between the sender and the receiver at an output with TO.

The second limitation is no problem as this is the way we probably want it in a running application (during debugging the test ought to be used, but not in the application).

The first limitation, that output without TO cannot be used, is however more difficult. In an SDL system not using the OO concepts (block type, process type, and so on) and not using separate generation there are no problems, but otherwise such outputs are necessary at the system start-up phase to establish communication between processes in different blocks. The purpose of this abstract data type is to provide a way to establish `PId` literals and thereby to be able to avoid outputs without TO.

The Data Type PIdLit

Caution!

The PIdLit data type should only be used in the way described here to introduce synonyms referring to static process instances. Other usage may not work!

If you are using this data type in a system that is to be validated using the SDL Explorer there are two additional requirements:

- Only process types with the number of instances equal to (N,N) for N>0, may be referenced in PId_Lit operators.
- No process type with the number of instances equal to (N,N) for N>0, may contain a Stop symbol, independently if a PId_Lit operator is used for the process type or not.

The data type PIdLit contains the following operators:

```
PId_Lit : xPrsIdNode -> PId;
PId_Lit : xPrsIdNode -> PIdList;
PId_Lit : xPrsIdNode, Integer -> PId;
```

In the file containing the data type (`pidlist.pr`) there is also a synonym that you may use to access the environment:

```
SYNONYM EnvPId PId = ...;
```

The type `xPrsIdNode` corresponds to the C type `xPrsIdNode`, which is used to refer to the process nodes in the symbol table tree built up by a generated application.

Use the **first** version of `PId_Lit` to obtain a synonym referring to the process instance of a process instance set with one initial instance.

Use the **second** version of `PId_Lit` to obtain a synonym of array type referring to the process instances of a process instance set with several initial instances.

Use the **third** version of `PId_Lit` to obtain a synonym referring to one of the process instances of a process instance set with several initial instances.

To introduce PId literals implemented as SDL synonyms, follow the steps below:

1. Include the file pidlist.pr, which contains the implementation of the PIdList type, among the declarations in the system:

   ```
   /*#include 'pidlist.pr' */
   ```

2. Identify which process instance sets that should have PId literals.

3. Introduce #NAME directives for these process instance sets.

4. Insert a #CODE directive among the declarations in the system. If. however, separate generation is not used, this #CODE directive need **not** be included.

   ```
   /*#CODE
   #HEADING
   extern XCONST struct xPrsIdStruct
          yPrsR_ProcessName1;
   extern XCONST struct xPrsIdStruct
          yPrsR_ProcessName2;
   extern XCONST struct xPrsIdStruct
          yPrsR_ProcessName3;
   */
   ```

   There should be an external definition for each process instance set identified in step 2. ProcessNameX should be replaced by the name introduced in the #NAME directives for the processes.

5. For each process instance set that should have PId literals, introduce the following synonym definition in the system diagram.

   If the process type has **one initial instance**:

   ```
   SYNONYM Name1 PId =
     PId_Lit(#CODE('&yPrsR_ProcessName1'));
   ```

   If the process type has **several initial instances**:

   ```
   SYNONYM Name2 PIdList =
     PId_Lit(#CODE('&yPrsR_ProcessName2'));
   ```

   If the process type has **several initial instances, but only one of them should be possible to refer to by a synonym**:

   ```
   SYNONYM Name3 PId =
     PId_Lit(#CODE('&yPrsR_ProcessName3'), No);
   ```

where No should be the instance number, that is, if No is 2, then the synonym Name3 should refer to the second instance of the process type.

Of course, you may choose the names of the synonyms, but the string in the #CODE directive should be the xPrsIdNode variables in the extern definitions discussed in step 4 above.

6. You may now use the synonyms of type PId that you defined in step 5 in expressions of PId type, for example as a receiver in the TO clause in an output. The synonym EnvPId, which refers to an environment process instance, can be used in the same way.

   Synonyms of type PIdList may be indexed (as an array) by an integer expression to obtain a PId value and may then be used in the same way as the synonyms of type PId. Indexes should be in the range 1 to the number of initial instances.

Example 554: PIdList Data Type ----------

```
OUTPUT Sig1 TO Name1;
OUTPUT Sig2 TO Name2(2);
OUTPUT Sig3 TO Name2(InstNo);
OUTPUT Sig4 TO EnvPId;
DECISION (Name3 = Sender);
TASK PId_Variable := Name2(1);
```

where InstNo is an integer variable or synonym and PId_Variable is a variable of type PId.

Note:

Note that no index check will be performed when indexing a PIdList synonym.

General Purpose Operators

Introduction

The abstract data type `IdNode` described in this section introduces a number of operators that may be used to simplify an SDL system. The simplifications will give both reduced code size and higher speed of execution for your application, as well as make debugging easier. This ADT **cannot** be used in OS integrations or with Cmicro.

The operators may be grouped into two groups:

- "Almost SDL operations", that is, operators that are easy to understand in an SDL context, but which are not available in SDL. Examples are the possibility to enumerate all active instances of a certain process instance set, or to count the number of signals in an input port.
- Operators that handle implementation aspects. An example is an operator to reuse memory in avail lists.

Caution!

Be very careful using these operators, as you will then not be designing true SDL systems.

If the SDL description is a goal in itself you should not use the operators. If the SDL system is just a means to obtain something else, an application for example, the operators may be very useful.

Type IdNode

This abstract data type becomes available by inserting the analyzer include:

```
/*#include 'idnode.pr'*/
```

This abstract data type file introduces three SDL sorts called `PrsIdNode, PrdIdNode,` and `SignalIdNode` in SDL. These sort correspond to the types `xPrsIdNode, xPrdIdNode,` and `xSignalIdNode` in C, which are used to represent the symbol table in the generated application. The symbol table, which is a tree, will contain the static information about the SDL system during the execution of the generated program.

Is is possible to refer to processes, procedures, and signals (among others) using the following the names:

```
yPrsN_ProcessName     or &yPrsR_ProcessName
yPrdN_ProcedureName   or &yPrdR_ProcedureName
ySigN_SignalName      or &ySigR_SignalName
```

where *ProcessName*, *ProcedureName*, and *SignalName* should be replaced by the name of the process, procedure, or signal with prefix, or by the name given to the unit in a `#NAME` directive. To obtain a name of a unit with prefix the directive `#SDL` may be used:

```
yPrsN_#(ProcessName)   or &yPrsR_#(ProcessName)
```

To avoid problems when separate generation is to be used, the `&yPrsR_...` syntax is recommended.

The `#SDL` directive is not always possible to use. It will look for an entity with the specified name in the current scope unit (where the `#SDL` directive is used) and outwards in the scope hierarchy. So, for example, if the reference for a process is to be used in a process defined in another block, a `#SDL` directive cannot be used for the referenced process. The name of the referenced process ought then to be given in a `#NAME` directive.

If separate generation is used there may be more problems to access these references. The variables will be defined in the compilation unit where the entity they represent is defined.

- The `xPrsIdNode` for a process will be defined in the file containing the code for the block enclosing the process.
- The `xPrdIdNode` for a procedure will be defined in the file containing code for the enclosing unit.
- The `xSignalIdNode` for a signal will be defined in the file containing code for the enclosing system, block, or process.

A reference is visible in the compilation unit (file) where it is defined and in all subunits to the unit, as a compilation unit will include the `.h` file of all its parent units.

Problems occur when we want to use a reference in a place where it is not visible, for example using an `xPrsIdNode` for a process defined in a separate block, in a process in another block. All references are, however, extern, which makes it possible for a user to introduce an appro-

priate `extern` definition (in a `#CODE` directive) himself in the compilation units where it is needed.

Example 555 ----------

```
/*#CODE
#HEADING
extern XCONST struct xPrsIdStruct yPrsR_ProcessName;
*/
```

To know the name of the referenced process, a `#NAME` directive ought to be used.

> **Note:**
> Such `extern` definitions introduce dependencies between otherwise independent compilation units. It is your responsibility completely to maintain these dependencies.

Available Operators

GetIdNode: PId -> PrsIdNode;

This operator takes a `PId` value and returns a reference to the `PrsIdNode` that represents the process type. `PrsIdNode` values are not useful for anything except as parameters to the operators discussed here.

Kill: PId -> PId;

The `Kill` operator can be used to stop another process instance. In SDL a process instance may only stop itself. This operator has exactly the same effect as if the process instance given as parameter executed a stop operation. The `Kill` operator always returns the value `null`.

KillAll: PrsIdNode -> Integer;

This operator takes a reference to an `PrsIdNode` representing a process type and will kill all the instances of the specified process type. The effect is the same as if all the instances executed stop operations. The operator returns the number of “killed” process instances.

FirstPId: PrsdNode -> PId;

See “SucPId: PId -> PId;” on page 3264 (next).

SucPId: PId -> PId;

This operator, together with FirstPId, are intended to be used to enumerate all process instances of the process type referenced by the `PrsIdNode` given as parameter to `FirstPId`. `FirstPId` should be given a reference to an `PrsIdNode` for a process type and returns the first (last created) process instance. `SucPId` should be given a `PId` value and will return the next `PId` for the given process type.

> **Note:**
>
> During the enumeration of the process instances, no action that stops any instance of the enumerated process type may be executed.
>
> This means, for example, that the complete enumeration should take place in one transition and that `Kill` operations should not be used in the enumeration.

InputPortLength: PId -> Integer;

This operator returns the number of signals in the input port of the given process instance.

InputPortLength: PId, SignalIdNode -> Integer;

This operator returns the number of signals, of the signal type given as `IdNode` parameter, that are present in the input port of the given process instance. The `SignalIdNode` parameter should refer to a `SignalIdNode` that represents a signal or a timer.

NoOfProcesses: PrsIdNode -> Integer;

This operator should be given a reference to an `PrsIdNode` representing a process instance set and will return the number of active instances of this instance set.

IsStopped: PId -> Boolean;

The operator may be used to determine if a `PId` value refers to a process instance that is active or has executed a stop operation.

Broadcast: PrsIdNode, SignalIdNode, PId -> Integer;

This operator may be used to send one signal (without parameters) to each active process instance of a specified process instance set. The value of the third parameter, of type `PId`, will be used as sender in the signals. The result of the operator is the number of signals that are sent dur-

ing this operation, i.e. the number of active process instances of the specified type.

> **Note:**
>
> When you use this operator you hide signal sending in an expression in, for example, a task. This will decrease the readability of your SDL description, and should be well documented, at least with a comment.

FreeAvailList: PrsIdNode -> Integer and PrdIdNode -> Integer and SignalIdNode -> Integer

> **Note:**
>
> The FreeAvailList operator has no meaning in the SDL Explorer. It can be used but will in the Explorer be a null action.

The operator takes a reference to an `IdNode` (of one of the three type above) that represents a process, a procedure, or a signal and returns the memory in the avail list for the specified `IdNode` to the free memory by calling the `sctOS` function `xFree`. The function `xFree` uses the C standard function 'free' to release the memory. The `FreeAvailList` operator requires thus that free really releases the memory in such a way that it can be reused in subsequent memory allocations. Otherwise the operator is meaningless.

`FreeAvailList` is intended to be applied for reusing memory allocated for processes, procedures, and signals used only during a start-up phase. If the system, for example, contains a process used only during start-up, that is, all instances of this process perform stop actions early during the execution and no more processes will be created later, then the memory for these instances can be reused.

> **Caution!**
>
> This operator should only be used as one of the last resorts in the process of minimizing the memory requirements of an application.

Connection to Monitor

In the trace output, operators like `Kill` and `Broadcast` will produce trace messages exactly in the same way as the equivalent `Stop` operation and the sequence of `Output` operations.

Summary of Restrictions

The table below summarizes the restrictions concerning the usability of the various Abstract Data Types that are delivered with the SDL Suite.

	Sim.	Real-Time Sim.	Perf. Sim.	Sim. with env.	Appl. with Cadv.	Valid.
`list1, list2`	✓	✓	✓	✓	✓	✝
`file`	✓	✓	✓	✓	☛	☛
`random`	✓	✓	✓	✓	✓	☛
`pidlist`	✓	✓	✓	✓	✓	☛
`idnode`	✓	✓	✓	✓	✓	✓
`byte`	✓	✓	✓	✓	✓	✓

Chapter

63 *The Performance Library*

This chapter presents an overview of a method for performance simulation projects using the Performance Library. The Performance Library is available as an optional product.

The method is in no way complete or described in all details. The intention is not to describe the method itself in depth, but rather to present an application area for the SDL Suite. For more details about performance simulations in general, please refer to the literature in that field.

A Performance Simulation Project

To develop a performance simulation and use it to obtain estimates about a particular system involves a number of steps. The SDL Suite may be helpful in many, but not all, of these steps.

The major activities in a performance simulation project are:

1. Collect information about the behavior of the system to be simulated and define the purpose of the simulation, that is, what estimates should be the result of the project?

2. Create a performance model for the system. This is often expressed as a queuing network. As the behavior of a system is usually too complex to be simulated in all details, simplifications have to be made.

   This modeling phase is the most critical phase in the complete project. A good performance model leads to relevant results, while a bad model leads to nonsense. The key question is what simplifications and abstractions you may make and still obtain relevant results from simulations of the model.

3. Describe the performance model in detail in SDL and simulate it, using the library *Simulation*, until the SDL model behaves satisfactorily.

4. Execute the generated simulation a number of times to collect statistical data from the model.

   You will normally need 10,000 to 50,000 samples (of for example a queue length or a waiting time) to obtain any significance in the data. This means that program executions will be fairly long. There are two ways to execute the performance simulation:

   – Use the library *Simulation* and start by performing the monitor commands “Set-Trace 0" and “Go”, or

   – Use the library *PerformanceSimulation*. It is specially designed to execute performance simulations and does not include the monitor system. It will execute the performance simulation in the order **10 to 15** times faster than executing it using the library *Simulation*.

5. During the execution of the performance simulation, the best way to handle data measured in the system is to write the data on file. You may then analyze the data files using packages or programs for statistical analysis to obtain, for example, mean value, variance and confidence intervals for these estimates. (The SDL Suite does not provide means for statistical analysis.)

6. To validate these estimates it is common practice to compare the simulation results with results from mathematical methods applied on the system (simplified versions of the system). Queuing theory and the theory for queuing networks are the most relevant mathematical methods for such activities.

Some of these steps will discussed in more detail in the following subsections. For other aspects please see literature about performance simulations.

The Performance Model

Let us first state that a description of the functional behavior of a system and a performance model of the same system are (usually) not the same, even if both models can be expressed in SDL. The two models describe two different aspects of the same system. This is why there is a modeling phase in the development of the performance simulation.

Queuing Models

Most performance models can be viewed as queuing models or queuing networks, where a queuing network is an interconnected system of queuing models. A typical model for a queue would look like:

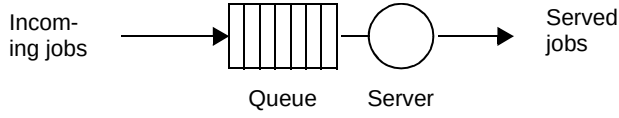

Figure 564: A queue model

The model contains jobs that need some service from the server. The jobs may have to wait in a queue for the service. The basic properties of this model are:

- The service time for a job. This can be modeled as a property of the job or of the server, depending on the system to be simulated.
- The queue discipline, that is, the order in which jobs are inserted into the queue and removed from the queue to get service. Typical disciplines are, to mention a few:
  - FCFS (First Come - First Served)
  - Priority order according to the priority of the jobs
  - Priority order with pre-emption.
- The inter-arrival time for jobs, or more generally: when new jobs are entered into the queue. The creation of new jobs is usually modeled in job-generators described as separate objects.

The queue model is a general model that may be used as an abstraction in many situations, for example to model programs (jobs) that are to be executed by the CPU in a computer (server). The queue is then the scheduled list of jobs that are in a “ready to execute” state. The queuing discipline is usually complex, involving for example priorities, pre-emption and cyclic execution of jobs.

Another quite different example would be a port, where ships (jobs) are coming for loading or unloading (the service). To perform loading or unloading the ship needs a crane (the server).

The systems that we want to simulate are usually not simple enough to be modeled by just one queue. However, models using interconnected queues-servers, connected in such a way that jobs leaving one server are inserted into the queue of another, have the power to describe many interesting real systems. An example of a simple queuing network model is given in Figure 565.

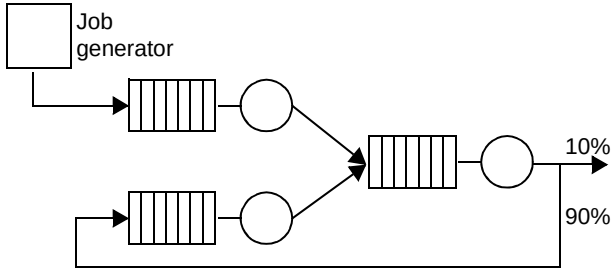

Figure 565. Simple queuing network

Each node in the network consists of one or several servers. The network also contains places where jobs are entered into the system and places where jobs are leaving the system.

Measurements

In a queue model or a queuing network model it is of interest to estimate for example:

- For jobs: total time in system, total waiting time
- For servers: load
- For queues: average and maximum queue length.

Such estimates can be obtained in two ways, using mathematical theories like queuing theory, or by measurements in simulations. With the mathematical theories, rather complicated models can be analyzed, usually more complicated than a nonspecialist thinks is possible. You should investigate this possibility before taking the decision to implement a simulation program.

Implementation of the Model

Mapping of Queue Models to SDL

A queuing network model may easily be described in SDL. Appropriate mapping rules are, for example:

- A server is implemented as a process and the queue as a variable in the server process.
- Jobs are described as data objects, that is, as passive entities that can be inserted into queues.
- Job generators are implemented as processes.
- Signals, with jobs as parameters, are used to send the jobs from job generators to servers and from servers to other servers.

Abstract Data Types for Queues and Random Numbers

In the implementation of the model there will be extensive use of queues and jobs and of queue manipulations, for example inserting a job into a queue. The chapter 62, *The ADT Library* provides an abstract data type specially designed for this purpose. See "Abstract Data Types for List Processing" on page 3243.

The ADT library also contains an abstract data type that can be used to generate random numbers. This data type can, for example, be used to draw job lengths and inter-arrival times according to a given distribution. See "Abstract Data Type for Random Numbers" on page 3234.

Random numbers are, in most situations in a performance simulation, used to model time intervals (for example service time required for a job) or to model a number of something (the number of jobs to be generated by a job generator at a certain time). The abstract data type for random numbers therefore contains the possibility to generate random numbers according to distributions returning non-negative values, for example:

- Negative exponential distribution
- Erlang distribution
- Hyperexponential distribution
- Uniform distribution
- Poisson distribution.

Implementation of Job Generators and Servers

To give a better understanding of job generators and servers, two process graphs are presented in Figure 566 and Figure 567, showing simple but typical processes.

A job generator sets a timer, and when the timer time expires, it generates a new job, sends it into the queuing system and sets the timer again. The time value in the set statements is usually Now + some random time interval. Note that the data types `Queue` and `ObjectInstance` are defined in the abstract data types for queue handling that are included in the ADT library (see "Abstract Data Types for List Processing" on page 3243 in chapter 62, *The ADT Library*).

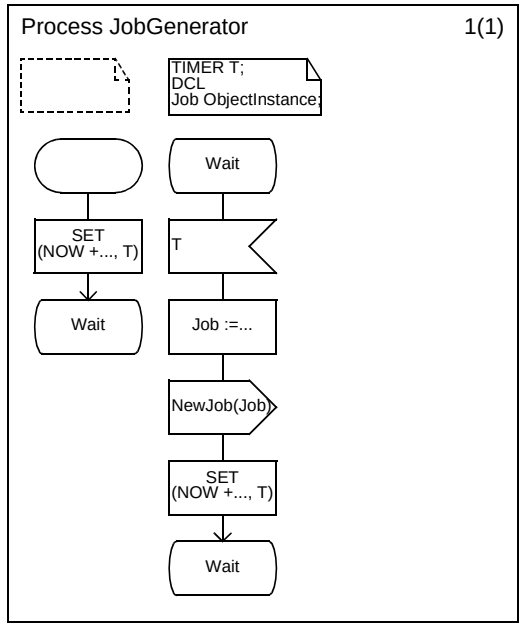

Figure 566: A job generator

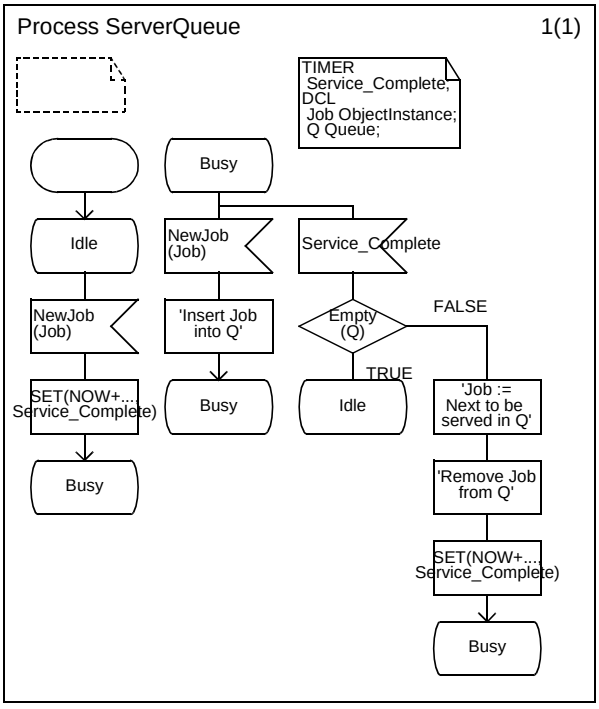

Figure 567: A server with a queue

The most important observation concerning the server process, is that the act of giving service is modeled by letting the server process wait in the state Busy. It is thus only the time needed for the service that is modeled. Otherwise the process is rather straight forward. The variable Job is used to refer to the job that is currently given service and the variable Q is used to store other jobs waiting for service. The queuing discipline will be implemented in the details in the tasks “Next to be served in Q”, “Insert Job in Q” and “Remove Job from Q”.

I/O and Performance Simulations

A performance simulation uses I/O mainly for two things:

1. Writing measurements on file
2. Prompting for parameters to the simulation.

A specially designed abstract data type for the purpose of simplifying I/O is included in the ADT library (see "Abstract Data Type for File Manipulations and I/O" on page 3221 in chapter 62, *The ADT Library*). With this data type it is possible to open files and to perform read and write operations in SDL.

It is, of course, interesting to parameterize a performance simulation on, for example, seed values for random generators, mean values for inter-arrival times and service times.

These values should be read at simulation start-up time. In SDL the concept of external synonyms can be used for such a purpose. As synonyms can only be defined in processes, not in instances, it is difficult to handle cases when the process instances should have different values for a certain simulation parameter. In such cases the abstract data type for I/O operations can be useful.

The second category of I/O mentioned above is printing of measurement data. There are basically two different types of measurements that have to be handled in a performance simulation.

1. Data concerning jobs such as waiting times.
   It is usually best to store this type of data in the job itself, until the job leaves the system, when the appropriate values are printed on a file.
2. Queue lengths and other related data.
   Such data is easiest to handle by introducing measurement processes that with regular time intervals print the queue lengths on file.

The best way to obtain the queue lengths is, in most situations, to let the measurement process view (or import) the appropriate queue variables. Otherwise a signal interface must be implemented only for measurement purposes.

The reason for printing all measurement data on file is that it is difficult to compute the relevant statistical entities at simulation time. If only the

mean values are of interest, these are simple to compute, but if variances and confidence intervals are to be computed it is better to let a professional statistical tool perform the job.

Note that data series produced from a simulation contains dependent data. If, for example, a job has been subject to a long waiting time, then the probability is high that the next job will also have a long waiting time.

Exit from a Simulation

The appropriate way to terminate the execution of a performance simulation is to call the function SDL_Halt(). It is best performed by introducing the call in a #CODE directive in a task symbol (see *"Including C Code in Task – Directive #CODE" on page 2728 in chapter 56, The Cadvanced/Cbasic SDL to C Compiler*). SDL_Halt is a function in the run-time library with the following prototype:

```
void SDL_Halt (void);
```

Execution with the Library Performance Simulation

As mentioned earlier, you may use the library *PerformanceSimulation* to speed up the execution of a performance simulation. This library has the same properties as the library *Simulation*, except that it does not contain the monitor system, which may increase the execution speed by a factor of 10 to 15.

Use the library *Simulation* to debug and verify the simulation model. Then select the library *PerformanceSimulation* in the make dialog in the Organizer (see "Make" on page 120 in chapter 2, *The Organizer*) and press the button *Make*. The thereby generated performance simulation may be executed from the OS as an ordinary program.

Chapter

64

Integration with Operating Systems

This chapter describes how to integrate code generated by the Cadvanced SDL to C Compiler with operating systems.

The different integration models (Light Integration, Threaded Integration and Tight Integration) are explained in the introduction.

There is a separate annex for each supported RTOS where the OS specific parts are described.

Important!

You are free to reuse the integrations supplied by IBM Rational or modify them to your needs. The OS integrations are tested by IBM Rational but IBM Rational does not guarantee that they will perform in your specific target environment (hardware, CPU, RTOS version etc.). Please refer to "RTOS integrations" on page 8 in chapter 1, *Platforms and Products, in the Installation Guide* for information about host and target environments where the integration types have been developed and tested.

Light and Threaded integrations

The Light and Threaded integrations are included in the delivery.

The standard product support and maintenance agreement **only** includes support for the Light and Threaded integrations available from IBM Rational if **no changes** have been made to the integrations.

Tight Integration

The Tight integration is meant to serve as a **template**, to be adapted to your needs. It is available for you as a free download from the IBM Rational Support web site.

The standard product support and maintenance agreement **does not** assist in adapting to your target environment.

Customer specific OS integrations

All OS integration models can be supported, enhanced and customized by using IBM Rational's Professional Services.

Other integrations

IBM Rational has developed a large number of integrations based on the company's vast experience of integrating with all operating systems on the market.

Introduction

The code that is generated by the Cadvanced SDL to C compiler is designed to run on different platforms. This is done by letting all platform dependent concepts be represented by C macros that can be expanded appropriately for each environment. There are also types used in the generated code that have to be defined. Integration, as referred to in this chapter, is the process of adapting the generated code to a certain platform.

This chapter describes the different models that are supported in SDL Suite.

> **Note:**
> Throughout this chapter, annexes excluded, VxWorks terminology has been used whenever there are differences between operating systems. Particularly, this means that the term *task* has been used on several occasions. The corresponding term would be *thread* for Win32 and Solaris, *process* for OSE Delta, and *task* for Nucleus.

Different Integration Models

With Cadvanced, there are three different run-time models, called Light Integration, Threaded Integration and Tight Integration. Tight integrations are then divided into two submodels, the Standard model and the Instance-Set model. All models use the same generated code.

You will find descriptions of the different models below, as well as guidelines for choosing between them.

Light integration

The simplest case is called a Light integration because only a minimum of interaction with the operating system is required; a Light integration could even run on a target system without any OS at all.

The complete SDL system runs as a single OS task. Scheduling of SDL processes is handled by the standard kernel, running a complete state transition at a time (no preemption). Worst case scheduling latency is thus the duration of the longest transition.

Communication between SDL processes is handled by the kernel; communication between the SDL system and the environment is handled in

the two user supplied functions `xInEnv`() and `xOutEnv`(). These functions are platform dependent. See Figure 568.

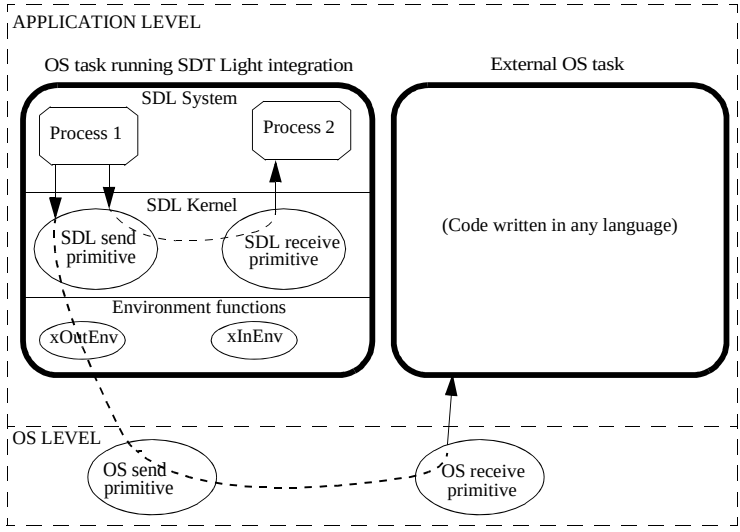

Figure 568: Signalling in the Light Integration Model.

An SDL process sends one internal and one external signal. `xOutEnv`*() must be written to call the OS send primitive. Thick borders denote OS tasks.*

Other properties of a Light Integration:

- The scheduling order can be controlled by process priorities and/or signal priorities as set by the `#PRIO` directive.
- An SDL system can be partitioned, i.e. split into several executables. Each partition has its own kernel/scheduler and set of environment functions. Partitioning is explained in *"Partitioning" on page 2641 in chapter 56, The Cadvanced/Cbasic SDL to C Compiler*.
- It is easy to "go to target": Write the environment functions and recompile the standard kernel with a cross compiler.

Threaded Integration

The main difference between a Light integration and a Threaded integration is that any part of the SDL system can execute in its own thread in a Threaded integration. A thread in a Threaded integration can exe-

cute one or several SDL processes or even blocks. How the different SDL objects should be mapped to threads is specified in the Deployment Editor. The user can specify thread-specific parameters like: STACKSIZE, PRIORITY, MAXMESSAGEQUEUESIZE and MAXMESSAGESIZE in the Deployment Editor. The Deployment Editor works together with the Targeting Expert to generate a Threaded integration.

Note:

A Threaded integration can only be generated using the Deployment Editor and the Targeting Expert, i.e. the make feature in the Organizer CANNOT be used.

Communication and execution control in one thread is handled by the SDL kernel and not the OS kernel. See Figure 569. This model shows the default Threaded integration where OS semaphores are the only OS primitives used in the signal sending. The `xMainLoop()` function is the entry point for each thread.

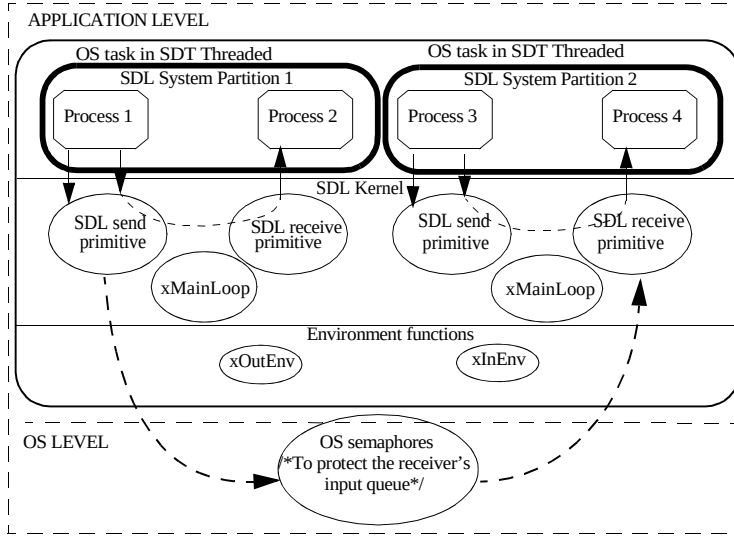

Figure 569: Signalling in Threaded Integration.

SDL Kernel functions are used for sending signals within or between threads. Thick borders denote threads.

Semaphores are used frequently in Threaded to protect globally accessible data like input queues and export queues. Semaphores are also used in the start-up to synchronize the execution of newly created threads. We must ensure that no thread is allowed to start executing until ALL threads have been created in the start-up phase.

Communication with external threads (Threads not made from SDL specifications) is handled by the environment functions in the same way as for a Light integration. There is though one major difference and that is that it is possible in a Threaded to send signals directly to an SDL process with the `SDL_Output()` function. The `SDL_Output()` function is "thread-safe" because of the use of OS semaphores.

Variations of Threaded Integration

There are two different implementation of signal sending between threads in Threaded. The default model send signals in the same way as in a Light integration but the input queues are protected by OS semaphores. In the alternative model, the signals are sent/received by OS_Send and OS_Received. In the alternative model there is no use for OS semaphores. Which model to use can be decided at compilation time by setting the compilation switch `THREADED_ALTERNATIVE_SIGNAL_SENDING`.

Threaded Default

The sender of an SDL signal "takes" a semaphore before accessing the receivers input queue. The signal is then linked into the input queue and the semaphore is "given" back.

The receiver is normally "waiting" for a semaphore. When a signal is sent, the semaphore is "released" by the sender. To send a signal, two semaphores are normally needed. One semaphore is protecting the input queue and the other is used for synchronizing the sender and the receiver. In Solaris, where we use POSIX threads and semaphores they are called: xInputPortMutex and xInputPortCond.

One OS feature that is needed in Threaded is a "Conditional Wait". We are only allowed to wait for a signal until the first internal timer expires. In POSIX, there is a primitive called `pthread_cond_wait()` and in Windows there is a similar concept called `WaitForSingleObject()` where a time-out can be specified. In VxWorks and OSE, the only concept where you can specify a time-out is OS_Receive. For synchroniza-

tion between the sender and receiver we are sending a small OS_Message (the character ‘c’) in these two RTOS.

Threaded using OS Send and OS Receive

In this alternative implementation we are sending the signals using OS_Send and OS_Receive. Signals are now sent to OS_Message queues. The sender sends the pointer to the SDL signal in an OS_Message to the receiver’s OS_Queue. When the signal is received, the SDL signal is unpacked and linked in to the receivers input queue. The advantage with this implementation is that there is now synchronization between the sender and the receiver. Any number of threads can send signals at the same time to a specific receiver without having to wait for a semaphore.

Tight integration

We also provide an alternate run-time model, which is called a Tight integration because the generated code interacts directly with the underlying operating system when creating processes, sending signals, etc.

The SDL processes run as separate OS tasks as explained below. Scheduling is handled by the OS and is normally time-sliced, priority based and preemptive.

Communication takes place using the inter-process communications mechanisms offered by the OS, normally message queues. This applies to signals sent between SDL processes as well as signals sent to or received from the environment. There are no environment functions, as illustrated in Figure 570.

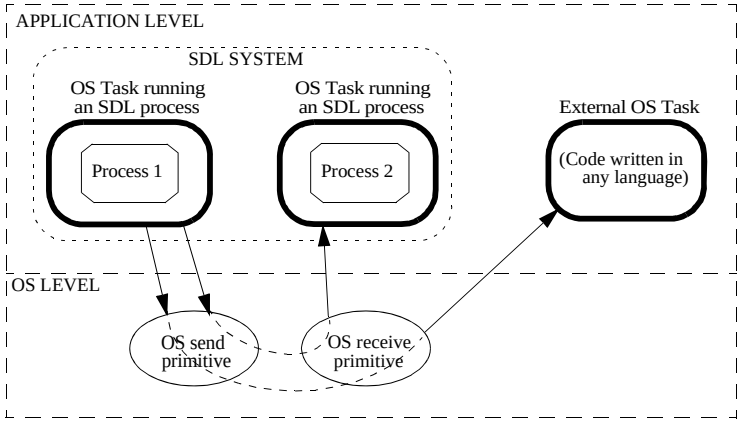

Figure 570: Signalling in the Tight Integration Model.

An SDL process sends one internal and one external signal. OS primitives are always used. The SDL system is not an entity of its own. Thick borders denote OS tasks.

Other properties of a Tight Integration:

- There is a single timer task which handles all SDL timers.
- SDL Simulators cannot be tightly integrated with an RTOS.
- Execution trace is available in textual or MSC format.[1]

Variations on Tight integration

Tight integrations come in two varieties, the Standard model and the Instance-Set model. Consider an SDL system with processes as outlined in Figure 571.

1. The MSC trace will be printed on standard output. To see the trace in an MSC diagram, copy the text into a file and read it into the MSC Editor.

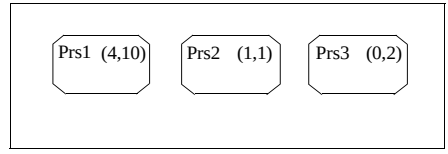

Figure 571: A partial SDL system

This system will be used for explaining the different models of Tight Integration.

Tight Standard

In the standard model of a Tight integration every SDL process instance is mapped to its own OS task. Tasks are created and destroyed dynamically as SDL process instances are created and terminated.

The example system will initially run as five OS tasks (four for Prs1, and one for Prs2). Up to 13 tasks may be created as needed.

Tight Instance-Set

In the Instance-Set model of a Tight integration every SDL process instance set is mapped to its own OS task. Tasks are created statically when the SDL system is initialized and are never destroyed. Thus there may be OS tasks that have no SDL process instances to run.

The example system will run as three OS tasks regardless of the number of process instances (one task each for Prs1, Prs2 and Prs3).

Choosing between Light, Threaded and Tight Integration

Choosing between the three integration models depends on many factors. Some of them are related to properties of the SDL system, others relate to the target environment. Important factors to consider are:

- The trade-off between performance and scheduling latency.
- How complex interaction the system has with the environment.
- Whether an operating system will be used or not.
- Memory management

Performance vs. scheduling latency

Generally, the Light integration model provides better performance than a Tight integration, but worst-case scheduling latency is the duration of the longest state transition.

A Tight integration is normally preferable when low scheduling latency is important. On the other hand, performance suffers from the overhead associated with OS scheduling and inter-process communications.

Another consideration is that blocking calls (either inlined in SDL code or as part of environment functions) will completely stop execution of a Light integration for the duration of the call. Making blocking calls in a Tight integration will only stop the thread making the call.

The Threaded integration is in a sense a combination of the other two integration models. An application part that makes blocking calls can be mapped to a separate OS thread. Other parts, where fast inter-process communication is important, can be mapped to another OS thread. Internally in this thread, signal exchange will be handled in the same way as in a Light integration.

Environment interaction

If interaction with the environment is simple then a Light integration is the best choice, especially if the system sends many signals and receives few. You can generate templates for the environment functions from the SDL Suite and just add code for converting between the signal representation and the actual environment hardware or software.

If interaction with the environment is complex then a Tight integration is probably the easiest to use, since you only need to interface to the operating system queues. This is the case if you need process behavior in the interaction (for example, to establish a communications session before sending the signal).

Other cases where a Tight integration might be the best choice are

- when the environment consists of many OS tasks written in other languages than SDL
- when external processes send signals directly to SDL processes rather than to the SDL system in general
- when there are many signals passing to and from the environment

In a Threaded integration, the integration with the environment should normally be handled in the environment functions in the same way as for a Light integration. It is possible though in Threaded to send signals directly to an SDL process with the `SDL_Output()` function without involving the `xInEnv()` function.

Operating system issues

If you will not use an OS at all then you have to select a Light integration. In addition, you will have to provide some simple functions for getting system time and handling memory allocation (depending on compiler and libraries, standard C library functions can often be used).

If you use an OS that takes care of load balancing between CPUs then you should select a Tight integration, because load balancing normally uses threads as the load unit to distribute.

If you want to distribute your SDL System over several nodes (CPUs) you should use the Threaded integration together with the TCP/IP feature.

Considerations when choosing between Tight and Threaded

Overall, IBM Rational recommends using the Threaded integration mode, unless there are specific technical reasons to prefer one of the other integration models.

The two most important reasons for choosing the Threaded model are:

1. The Threaded integration out-perform a Tight Integration in most situations, e g implementation of Timers and creation of tasks is about 100% faster in Threaded.
2. In Threaded you are not limited to two partitioning models. Any mapping between SDL objects and threads can be specified in the Deployment editor.

For a more comprehensive list of the differences between Threaded and Tight see the following sections.

Advantages of Threaded

- The default model is very simple to implement for a new OS. A working prototype should normally take 2-3 days.

- The Threaded model can be used together with the TCP/IP feature.
- The Threaded model is supporting all partitioning models (1 process instance/1 or many process instance-set/1 or many blocks/1 entire system mapped to one Thread.
- The user can easily specify Thread specific parameters like: stack size, Thread priority, Thread message queue size and maximum message size for each Thread.
- The Thread specific code for all supported OS is placed in one file.

Advantages of Tight

- Simple mapping od SDL concepts to OS primitives.
- Simple interactions with environment (at least in the default model), by direct call to the OS message passing primitives.
- Support textual and MSC-pr textual trace in console window when executing.

Disadvantages of Threaded

- Slightly more difficult to interact with the environment. An external function/thread must use the SDL_Output function when sending signals to an SDL process.

Disadvantages of Tight

- Very difficult and time consuming to support a new OS.
- Can only support two partitioning models.
- Very inefficient Timer model.

Common Features

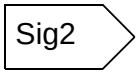
This section describes the parts of the integration that are common to the different models, but also some important differences.

> **Note:**
> Many of the data structures and macros described in this section are described in more detail in chapter 61, *The Master Library*. That chapter is, however, focused on a Light Integration. Some things, especially the listings of data structures, are not correct in every detail for Tight Integrations but should still be very useful.

The Use of Macros

A source file generated by an SDL to C compiler is independent from the choice of integration model and operating system. Instead of system calls, it uses macros that have to be defined elsewhere when the system is built. Each SDL concept is represented by one or more C macros. These macros will have different definitions for different integration models and operating systems. The SDL Suite provides a number of integration packages for this purpose. In a Light Integration, many macros are expanded into functions of the standard kernel. A Tight Integration has lower level macros that are defined in separate files for each operating system, and finally expanded into OS primitives or certain OS dependent constructions.

Below is an example of generated code for signal sending. Code in capital letters are the SDL Suite macros. The bracketed numbers indicate corresponding lines of code. For a description of the different macros, see chapter 61, *The Master Library*.



SDL symbol: Output

Generated code before macro expansion:

```
[1]   ALLOC_SIGNAL(sig2, ySigN_z3_sig2,
        TO_PROCESS(Env, &yEnvR_env),
        XSIGNALHEADERTYPE)
      SIGNAL_ALLOC_ERROR
[2]   SDL_2OUTPUT_COMPUTED_TO(
        xDefaultPrioSignal,
        (xIdNode *)0, sig2,
        ySigN_z3_sig2,
        TO_PROCESS(Env, &yEnvR_env),
        0, "Sig2")
      SIGNAL_ALLOC_ERROR_END
```

Generated code after macro expansion for a Light Integration:

```
[1]   yOutputSignal = xGetSignal
        ((&ySigR_z3_sig2),
        (*(&yEnvR_env)->
        ActivePrsList !=
        (xPrsNode) 0 ?
        (*(&yEnvR_env)->
        ActivePrsList)->Self :
        xSysD.SDL_NULL_Var),
        yVarP->Self);
[2]   SDL_Output (yOutputSignal,
        (xIdNode *) 0);
```

File Structure

> **Note:**
>
> The source file and examples for Tight Integration are not included in the standard delivery. They are available as free downloads from IBM Rational Support web site.

The Generated Files

An integration uses one or more of four files that can be generated by the Code Generator. All integrations require the C source file `<systemname>.c`, whereas the interface file `<systemname>.ifc` is optional. For a Tight Integration the signal number file `<systemname>.hs` may be used, and for a Light Integration the file `sctenv.c`, representing the environment, can be used.

The source file uses the highest level set of macros, that are defined in the different integration packages.

The Integration Packages

The files containing the necessary macro definitions and support functions are organized as shown in Figure 572. For each operating system there is one package for the Light Integration, and one for the Tight Integration. Although the files in different packages may have the same name they do not necessarily contain the same code. The principles for Tight Integration packages are described more thoroughly in "Tight Integration" on page 3340. Details about each operating system can be found in the annexes.

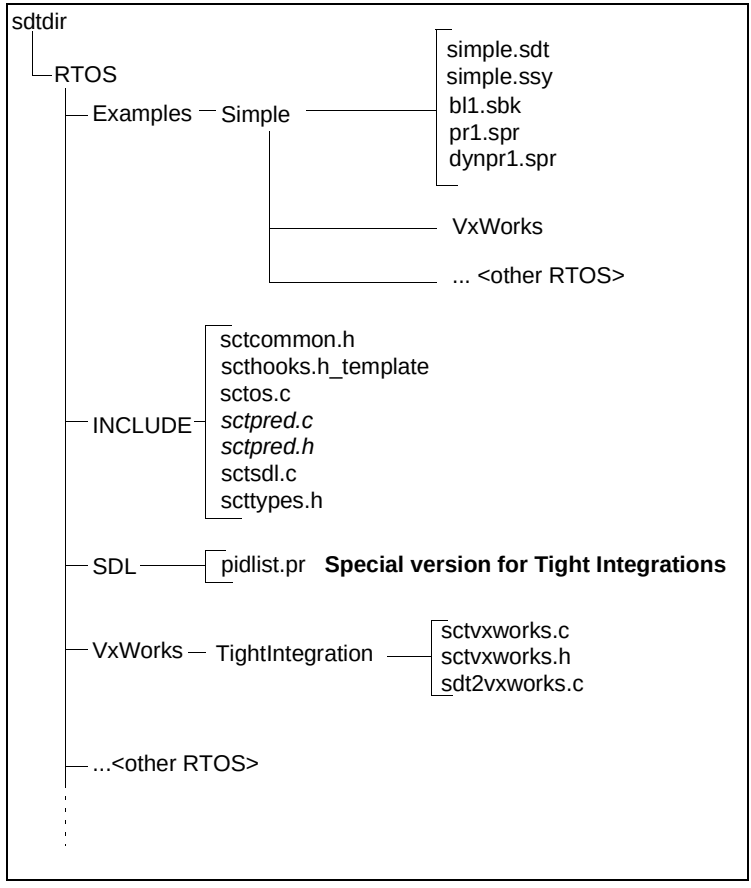


Figure 572: File structure for the RTOS integrations

There is also an INCLUDE directory containing source files common to all supported operating systems. These files are described in "File Structure" on page 3025 in chapter 61, *The Master Library*. Below are some additional comments on these files:

- scthooks.h:

  This file contains macro hooks into the system. These hooks are used for customizing a Tight Integration, for example by adding external tasks. See the examples to find out how this is done.

  All the hook macros are initially empty.

- sctcommon.h:

  This file contains general macros for all Tight Integrations

- sctos.c:

  This file contains functions that are operating system and/or compiler dependent, like allocation and free of dynamic memory.

- sctpred.h and sctpred.c:

  This is the header and source file where all the SDL predefined datatypes are implemented.

- sctsdl.c:

  This file contains SDL support functions, the timer task and the timer support functions. It is non-OS-specific and calls many second level OS-specific macros defined in sct<RTOS>.h.

- scttypes.h:

  This file contains the general datatype definitions for signals, IdNodes, etc. It also contains the macro definitions found in generated code. Note that this file is non-OS-specific. This means that if a call to an OS-specific primitive is needed, then a second level of macro is defined, according to the following model.

  In the generated code:

  ```
  ALLOC_SIGNAL_PAR(ok, ySigN_z3_ok, TO_PROCESS(Env,
  &yEnvR_env), yPDef_z3_ok)
  ```

  In scttypes.h:

```
#define ALLOC_SIGNAL_PAR(SIG_NAME, SIG_IDNODE, \
   RECEIVER, SIG_PAR_TYPE) \
   RTOSALLOC_SIGNAL_PAR(SIG_NAME, SIG_IDNODE, \
   RECEIVER, SIG_PAR_TYPE)
```

In `sct<RTOS>.h`:

```
#define RTOSALLOC_SIGNAL_PAR(SIG_NAME,SIG_IDNODE,\
   RECEIVER, SIG_PAR_TYPE) \
   yOutputSignalPtr = \
    xAlloc(sizeof(xSignalHeaderRec)+ \
    sizeof(SIG_PAR_TYPE)); \
   yOutputSignalPtr->SigP = yOutputSignalPtr+1; \
   yOutputSignalPtr->SignalCode = SIG_NAME; \
   yOutputSignalPtr->Sender = SDL_SELF;
```

The `Examples` directory contains a simple SDL system that also uses an external process (a separate OS task). For each supported operating system there is an implementation of this, demonstrating how to hook into the integration package. Further description of the example can be found in "A Simple Example" on page 3355.

Naming Conventions

Names of variables, datatypes and support functions in generated code and package files often start with one of the letters x, y and z.

The general rules (there are some exceptions) are:

- Names and objects starting with an 'x' represent general datatypes and support functions in the kernel.

  Examples: `extern XCONST struct xVarIdStruct, xInputSignal, xFindReceiver`

- Names starting with a 'y' are names of IdNodes representing SDL variables, process states, channels, blocks, datatypes for signals, PAD functions, etc. in generated code.

  Examples: `extern XCONST struct xVarIdStruct yVarR_z012_okmess, ySigR_z3_ok, yPAD_z01_pr1`

- Names and objects starting with a 'z' are SDL variables, SDL names, process state names, etc. in generated code.

  Examples: `#define z010_idle 1, z012_okmess`

The Symbol Table

All signals, blocks, processes, channels, etc. in an SDL system have a corresponding representation in the symbol table described in chapter 61, *The Master Library*. This symbol table consists of nodes (`IdNodes`) each representing one entity of the system. The `IdNodes` are pointers to structs. See the following example:

```
extern XCONST struct xPrsIdStruct yPrsR_z02_dynpr1;
#define yPrsN_z02_dynpr1  (&yPrsR_z02_dynpr1)
```

The `N_` and the `R_` just before `z02_dynpr1` indicate if it is a node (`N_`) or a record (`R_`).

Memory Allocation

The `xAlloc` function is always used when allocating dynamic memory. The function is placed in the `sctos.c` file, but in the Tight Integrations the body of the function is found in the `sct<RTOS>.h` file.

Start-up

The `yInit` function is called during start-up of the SDL system. It is responsible for creating all static processes and for initializing SDL synonyms.

Implementation of SDL Concepts

SDL Processes

An SDL process consists of three parts in generated code: Instance set common data, instance specific data and dynamic behavior.

Instance set common data

Variables and structures that are common to all instances of a process are stored in a record of the type `xPrsIdStruct`, defined in `scttypes.h`. This record is referenced by a node in the symbol table.

Instance specific data

Variables and structures of the process instance are declared via the macro `PROCESS_VARS`. This macro is defined in different ways in the Light and the two models of Tight Integration. It contains state informa-

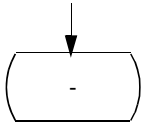
tion, local variables, pointers to parent and offspring, etc. One important entry is the `RestartAddress`, pointing out which transition to execute when the PAD function runs (see below).

Dynamic behavior

The dynamic behavior of an SDL process is implemented in a PAD function (Process Activity Definition). The PAD function is used somewhat differently in the different integration models:

- In the Light Integration the scheduler calls the PAD function of the process. The PAD function then returns to the scheduler when the transition is finished.
- In the Standard Model Tight Integration the PAD function is called when the process is started and does not return until process termination. It then contains a main loop where one iteration corresponds to one transition.
- The Instance Set Model Tight Integration contains a mix of the two.

Below is the code for ending a transition, before and after macro expansion for a Light Integration.



SDL symbol: Nextstate
Generated code before macro expansion:

```
      /*-----
      * NEXTSTATE -
      * #SDTREF(SDL,/ti/RTOS/MANUAL/SDL/simple.spr(1),
                143(55,100),1)
      ------*/
      #ifdef XCASELABELS
[1]     case 6:
      #endif
[2]     XAT_LAST_SYMBOL
[3]     SDL_DASH_NEXTSTATE
```

Generated code after macro expansion for a Light Integration:

```
      /*-----
      * NEXTSTATE -
      * #SDTREF(SDL,/ti/RTOS/MANUAL/SDL/simple.spr(1),
                143(55,100),1)
      ------*/

[1]     case 6:

[2]       xGRSetSymbol (-1);
[3]       SDL_NextState (VarP, yVarP->State);
          return;
```

Signal Queues

Basically, every process has at least one signal queue.

- In a Light Integration each process instance has an input queue.
- In the Standard Model Tight Integration there is an input queue and a save queue for each instance.
- In the Instance Set Model Tight Integration there is an input queue and a save queue for every instance set. These two queues are shared by all the instances.

All signals that are sent to a process arrive in the input queue. The save queue is used to keep signals that cannot be handled in the current state but should be saved for future use. This is tightly connected to the SDL Save concept, but is also used in the implementation of timers. For a Light Integration there are no save queues. Instead, all signals that should be saved will remain in the input queue until they can be received.

Process Priorities

The use of process priorities requires some caution. Priorities can be set with the `#PRIO` directive in the SDL Suite, but there is no mapping of priorities for different platforms. The generated code will use exactly the values specified in the SDL system. This will not be a problem in a Light Integration, but for Tight Integrations the result may not be the expected.

Example 556: Process priority problems ––––––––––––––––––––––

Assume that Process1 has its priority set to 100 using the `#PRIO 100` directive and Process2 has `#PRIO 50`. These priority values will be used as-is by the underlying scheduler.

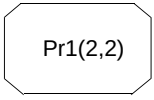
In the SDL Suite simulators and Light integrations, the highest priority is 0. In VxWorks, 0 is the highest priority, whereas in pSOS the highest priority is 255.

Thus the simulated system, a Light integration for any operating system and a Tight integration for VxWorks will all run Process2 at a higher priority than Process1. In contrast, a Tight integration for pSOS will run Process1 at a higher priority than Process2!

––

Process Creation

Regardless of the integration model there are a number of things that have to be done when an SDL process instance is created. The structs that represent the instance have to be created. It needs a representation in the symbol tree and a signal queue, except in the Instance Set Model of Tight Integration where the signal queue belongs to the instance set. A start-up signal is also always allocated and sent to the process.



SDL symbol: SDL Static Create

Generated code before macro expansion:

```
      /*********************************************************
                    SECTION      Initialization
      *********************************************************/

      extern void yInit XPP((void))
      {
        int  Temp;
      ........
        INIT_PROCESS_TYPE(pr1,z01_pr1,yPrsN_z01_pr1,"z01_pr1",
                          SDL_INTEGER_LIT(2),SDL_INTEGER_LIT(2),
                          yVDef_z01_pr1, xDefaultPrioProcess,
                          yPAD_z01_pr1)
      #ifdef SDL_STATIC_CREATE
[1]     for (Temp=1; Temp<=SDL_INTEGER_LIT(2); Temp++) {
[2]        SDL_STATIC_CREATE(pr1,z01_pr1,yPrsN_z01_pr1,
                             "pr1",ySigN_z01_pr1,
                             yPDef_z01_pr1,yVDef_z01_pr1,
                             xDefaultPrioProcess,yPAD_z01_pr1,1)
        }
      #endif
```

Generated Code after macro expansion for a Light Integration:

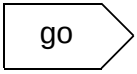
```
      /*********************************************************
                       SECTION      Initialization
      *********************************************************/
      extern void
      yInit ()
      {
        int  Temp;
      ..........
[1]     for (Temp = 1; Temp <= 2; Temp++) {

[2]       SDL_Create (xGetSignal ((&ySigR_z01_pr1),
                      xSysD.SDL_NULL_Var, xSysD.SDL_NULL_Var),
                     (&yPrsR_z01_pr1), 1);
        }
```

SDL Signals

Signal Sending

In generated code a signal sending is handled by two macros: `ALLOC_SIGNAL` (or `ALLOC_SIGNAL_PAR` for a signal with parameters) and `SDL_2OUTPUT_xxxx` (there are different macros depending on how the SDL output was defined, e.g. with or without an explicit TO).



SDL symbol: Output

Generated code before macro expansion:

```
[1]   ALLOC_SIGNAL(go,ySigN_z03_go,TO_PROCESS(p,yPrsN_z09_p),
                   XSIGNALHEADERTYPE)
      SIGNAL_ALLOC_ERROR
[2]   SDL_2OUTPUT_COMPUTED_TO(xDefaultPrioSignal,(xIdNode*)0, go,
                ySigN_z03_go,TO_PROCESS(p, yPrsN_z09_p), 0, "Go")
      SIGNAL_ALLOC_ERROR_END
      XBETWEEN_SYMBOLS(4, 579)
```

Generated code after macro expansion for a VxWorks Tight Integration:

```
[1]   yOutputSignalPtr = xAlloc(sizeof(xSignalHeaderRec));
[1]   yOutputSignalPtr->SignalCode = 2;
[1]   yOutputSignalPtr->Sender = yVarP->Self;
[2]   Err = msgQSend (xTo_Process ((&yPrsR_z09_p)),
[2]                   (char*)*&yOutputSignalPtr,
[2]                   sizeof(xSignalHeaderRec) + 0, 0, 0);
[2]   xFree ((void **) &yOutputSignalPtr);
[2]   if (Err == (-1)) {
[2]     taskLock ();
[2]     printf ("Error during %s found in VXWORKS
[2]     function %s. Error code %s\n", "OUTPUT",
[2]     "msgQSend", strerror ((*__errno ())));
[2]     taskUnlock ();
[2]   }
```

In this example the signal is called go and has no parameters. The `SDL_2OUTPUT_COMPUTED_TO` macro indicates that it was sent without an explicit TO.

SDL Procedures

An SDL procedure is represented by a function similar to a PAD function. Before a procedure is called there are two support functions that need to be called: `xGetPrd` and `xAddPrdCall`.

The `xGetPrd` function allocates an `xPrdStruct` for the called procedure and returns an `xPrdNode` pointing to the struct.

The `xAddPrdCall` function adds the new procedure call in the calling process' `ActivePrd` list (an element in the `xPrsStruct`).

The procedure is called with a pointer to the instance data of the calling SDL process. This is because the procedure must be able to use internal variables in the calling process.

Before a procedure returns to the caller it performs an `xReleasePrd` call. This function removes the call from the `ActivePrd` list.

SDL Timers

SDL timers are represented by signals. All active timer signals are kept in a sorted list, either within the single task of a Light Integration or in a certain timer task in a Tight Integration. When a timer expires, the signal representing it is sent to the SDL process that set it.

SET
(Now+5,T1)

SDL symbol: SET Timer

Generated code before macro expansion:

```
      /*-----
      * SET T1
      * #SDTREF(SDL,/ti/RTOS/MANUAL/SDL/dynpr1.spr(1),
                119(55,25),1)
      ------*/
      #ifdef XCASELABELS
[1]     case 2:
      #endif
[2]       SDL_SET_DUR(xPlus_SDL_Time(SDL_NOW,
[3]        SDL_DURATION_LIT(5.0, 5, 0)),
[4]        SDL_DURATION_LIT(5.0, 5, 0), t1, ySigN_z021_t1,
             yTim_t1, "T1")
```

Generated code after macro expansion for a Light Integration:

```
      /*-----
      * SET T1
      * #SDTREF(SDL,/ti/RTOS/MANUAL/SDL/dynpr1.spr(1),
                119(55,25),1)
      ------*/

[1]     case 2:

[2]       SDL_Set (xPlus_SDL_Duration (SDL_Now (),
[3]         SDL_Duration_Lit (5, 0)), xGetSignal
[4]         ((&ySigR_z021_t1), yVarP->Self,
            yVarP->Self));
```

Light Integration

A Light Integration is a stand-alone executable which can be generated with or without a simulator. An executable that should run under UNIX can use the precompiled kernels. Only the environment functions need to be written by the user.

PAD Functions

The PAD function is called by the scheduler when its process is in turn to execute a transition. The scheduler calls the PAD function with a symbol table node of the type `xPrsNode`, pointing to the instance specific data of the instance that is scheduled.

Start-Up

A Light Integration starts when the generated main function is called. The start-up phase works like this (pseudocode shown in *italics*):

```
void main( void )
{
   xMainInit();
   Code from #MAIN
   xMainLoop();
}

void xMainInit( void )
{
   xInitEnv();
   Init of internal structures
}
```

You must supply the `xInitEnv()` function to initialize external code and hardware, etc. (this is of course application dependent). This function is placed in the same program module (environment module) as the `xInEnv()` and `xOutEnv()` functions. The `xMainLoop()` function contains an eternal loop, which constitutes the scheduler itself. See below:

```
void xMainLoop (void)
{
   while (1)
   {
     xInEnv(...)
     if (a timer has expired)
       send the corresponding timer signal
     else if (a process can execute a transition)
      {
       remove the signal from the input port
       set up Sender in the process to Sender of the signal
       call the PAD function for the process
      }
   }
}
```

Connection to the Environment

Signals going in and out of the SDL system are handled in the two user written functions `xInEnv` and `xOutEnv`. There is a template file for writing these two function in the standard distribution. This file can be found at `<installation directory>/sdt/sdtdir/<your platform os version>sdtdir/INCLUDE/sctenv.c`.

Running a Light Integration under an External RTOS

Since there are some fundamental differences between different RTOS we can only give a general idea of how to generate a Light Integration under an external RTOS here. Typical things that may be different in different RTOS:

- If you are allowed to have a main function in your application.
- If your start-up function must be specified in a configuration file.
- If the cross compiler requires additional OS-specific header files to be included.
- If it is possible to run the application in a simulated target environment.
- Syntax for the makefile.

General Steps

The normal steps to create a Light Integration under an external RTOS can be summarized as follows:

1. Copy the source and header files for an application kernel from the installation of the SDL Suite. The files are residing in the following directory:

   `<installation directory>/sdt/sdtdir/<your host and os version>sdtdir/INCLUDE`.

2. Generate an `<application>.c` file with the SDL to C Compiler.

Note:

The code generator option *Cadvanced* **must** be used.

3. Generate an environment header file (an option in the Organizer *Make* dialog).
4. Edit the `sctenv.c` template file to handle your in and out environment signals. Include the generated `<application>.ifc` file (the environment header file).
5. Create a makefile or edit the generated makefile. Write entries for the kernel source files, the environment file and the application file.
6. Set the appropriate compilation switches for your RTOS and your compiler.
7. Compile the application and the kernel file to create a relocatable object file.
8. Download.

Threaded Integration

Introduction

The first part of this section is about the Threaded integration. The second part is about the TCP/IP feature. With the Threaded and TCP/IP features you can partition an SDL system into several threads that can execute in a distributed environment.

The "New threaded integrations" on page 3326 described last has been developed by IBM Rational in the IBM Rational Tau product. Our intention, however, is that the integrations should be possible to use both in SDL Suite (Cadvanced) and Tau/Developer (AgileC and C Code Generator) products.

Implementation Details for Threaded

The main areas where a Threaded differs from a Light integration are:

- Symbol table structures and global variables
- Process creation
- Signal sending

Symbol Table Structures and Global Variables

Each thread has a global variable of type `xSystemData` in Threaded. In Light, there is only one global variable of this type for the entire system. In Threaded this variable is initialized in `yInit()` and is one of the parameters in the macro for creating a new thread.

The data structure `xSystemData` has a couple of new entries:

```
...
#ifdef THREADED
   xInputPortRec  xNewSignals;
   THREADED_THREAD_VARS
#endif
...
```

The entry `xNewSignals` is used when a new signal is received. The signal is first linked into the receiver's `xNewSignals` queue before it is handled in the receiver's `xMainLoop()`.

The entry THREADED_THREAD_VARS is a macro that contains different thread variables like the semaphore handles xInputPort.

Global variables are declared in the macro THREADED_GLOBAL_VARS:

```
#elif THREADSOLARIS
.....
#define THREADED_GLOBAL_VARS \
  pthread_mutex_t xListMutex; \
  pthread_mutex_t xExportMutex; \
  sem_t xInitSem; \
  int xNumberOfThreads; \
  int QueueCounter; \
  int xInitPhase;  \
  pthread_attr_t Attributes ;
#endif /* THREADED_ALTERNATIVE_SIGNAL_SENDING */
#endif
```

Process Creation

There are three macros related to the creation of threads in a Threaded:

- THREADED_START_THREAD(F, SYSD, THREAD_STACKSIZE, THREAD_PRIO, THREAD_MAXQUEUESIZE, THREAD_MAXMESSIZE)

  This macro is used if there is only one thread to be created for all instances (Instance Set) of an SDL process (or another SDL object). The parameters are:

Parameters	Explanation
F	The entry point of the thread, i.e. the SDL kernel function xMainLoop()
SYSD	A variable of type xSystemData
THREAD_STACKSIZE	The stacksize for the thread is specified in the Deployment Editor
THREAD_PRIO	The thread priority specified in the Deployment Editor

Parameters	Explanation
THREAD_MAXQUEUESIZE	The maximum number of messages/signals in the input queue of the thread, as specified in the Deployment Editor. This parameter is only used if the alternate signal sending model is used.
THREAD_MAXMESSIZE	The maximum size of a message/signal. This parameter is ignored at the moment in both implementation models. The maximum size of a message/signal in the alternate signal sending model is always the size of the pointer to an SDL signal (sizeof(xSignalNode).

Note:

Thread parameters for individual threads can be specified in the Deployment Editor. If no values are specified, default values will be used.

- SDL_CREATE(PROC_NAME, PROC_IDNODE, PROC_NAME_STRING)

  This macro is used for creation of dynamic processes (processes created during run-time).

  It is defined exactly the same way in Threaded as in Light. It will call the SDL kernel function SDL_Create().

  SDL_Create() will create a new thread if, for instance, there should be one thread for each instance of an SDL process. See the following extract from the SDL_Create() function:

```
.....................
#ifdef THREADED
 if (PrsId->SysD == 0) {
    THREADED_START_THREAD(xMainLoop, StartUpSig-
>Receiver.LocalPId->PrsP->SysD, PrsId->ThreadParam-
>ThreadStackSize, PrsId->ThreadParam->ThreadPrio,
PrsId->ThreadParam->MaxQueueLength, PrsId-
>ThreadParam->MaxMesSize);
}
#endif
```

```
.....................
```

Please note that the thread parameters are taken from the `xPrsIdNode` for the process.

```
SDL_STATIC_CREATE(PROC_NAME, PREFIX_PROC_NAME,
PROC_IDNODE, PROC_NAME_STRING, STARTUP_IDNODE,
STARTUP_PAR_TYPE, PRIV_DATA_TYPE, PRIO,
PAD_FUNCTION, BLOCK_INST_NUMBER)
```

This macro is used for creating static processes (processes that are created at system start-up). It will be called from the `yInit()` function and is mapped to the SDL kernel function `SDL_Create()` in the same way as in the `SDL_CREATE` macro.

The `xMainLoop()` function is the entry point for the thread. First in this function is the macro

```
THREADED_THREAD_BEGINNING(SYSD)
```

The main purpose of this macro is to wait for the start-up semaphore `xInitSem`. No thread is allowed to start executing until ALL static processes/threads have been created.

Sending Signals

In the default model, signals are sent in the same way as for a Light integration except that they are first linked into the `xNewSignals` queue.

In the `xMainLoop()` function, the `xNewSignals` queue is checked for new entries. If a new signal is available, it is sent to the process itself with the `SDL_Output()` function. See the following extract from the `xMainLoop()` function:

```
........
THREADED_LOCK_INPUTPORT(((xSystemData *)SysD))
while (((xSystemData *)SysD)->xNewSignals.Suc != (xSig-
nalNode)&((xSystemData *)SysD)->xNewSignals)
SDL_Output(((xSystemData *)SysD)->xNewSignals.Suc
xSigPrioPar(((xSystemData *)SysD)->xNewSignals.Suc-
>Prio), 0);
THREADED_UNLOCK_INPUTPORT(((xSystemData *)SysD))

.........
```

The Alternative Signal Sending Model.

In the alternative signal sending model, an OS message/signal is sent containing a pointer to the SDL signal. For this, a message queue must

be created for each thread at thread creation. How this is done differs from OS to OS. See : Signalling in Threaded Integration.

The sender sends the pointer to the SDL signal with the OS_Send primitive. The receiver receives the message, extracts the pointer to the SDL signal and links it into the xNewSignal queue. After this, the signal is handled in the same way as in the default model.

New Macros

The same source files are used in a Threaded integration as in a Light. The only SDL kernel source files that are affected by the Threaded integration are `scttypes.h`, `sctsdl.c` and `sctos.c`.

Most of the OS specific code is found in the `scttypes.h` file. The following macros are new for Threaded:

MACRO NAME	Explanation
`THREADWIN32`	Main macro for Threaded Windows integration
`THREADSOLARIS`	Main macro for Threaded Solaris integration
`THREADVXWORKS`	Main macro for Threaded VxWorks integration
`THRAEDOSE`	Main macro for Threaded OSE integration
`THREADED_ALTERNATIVE_SIGNAL_SENDING`	Main macro for using the alternative signal sending model.
`THREADED_POSIX_THREADS`	Main macro for the Threaded integration model defining the kernel specifics
`THREADED`	Internal macro used only in the kernel source files
`THREADED_TRACE`	Enabling textual execution trace
`THREADED_OSTRACE`	This macro is mapped to a printf statement.

MACRO NAME	Explanation
THREADED_ERROR	Enabling textual error printout when calling OS primitives.
THREADED_ERROR_VAR	Defines a variable used in THREADED_ERROR_RESULTS.
THREADED_ERROR_RESULT	Stores the return result after calling an OS primitive.
THREADED_ERROR_REPORT	Checks the value of the return variable and if ERROR makes a printout.
THREADED_ERROR_REPORT_NULL	Checks the value of the return variable and if ERROR makes a printout.
THREADED_ERROR_REPORT_NEG	Checks the value of the return variable and if ERROR makes a printout.
THREADED_ERROR_REPORT_OPEN_NEG	Checks the value of the return variable and if ERROR makes a printout.
THREADED_ERROR_REPORT_WAIT_NEG	Checks the value of the return variable and if ERROR makes a printout.
THREADED_GLOBAL_VARS	Global variable defines.
THREADED_GLOBAL_INIT	Initialization of global variables like semaphores.
THREADED_THREAD_VARS	Definitions of thread variables.
THREADED_THREAD_INIT	Initialization of thread variables.
THREADED_THREAD_BEGINNING	Wait for xInitSem to be released.
THREADED_LOCK_INPUTPORT	Protect the input queue by taking the semaphore.
THREADED_UNLOCK_INPUTPORT	Releasing the semaphore for the input queue.

MACRO NAME	Explanation
THREADED_WAIT_AND_UNLOCK_INPUTPORT	Wait for next message/signal to arrive or the next internal timer to expire.
THREADED_SIGNAL_AND_UNLOCK_INPUTPORT	Send a signal and release the semaphore for the input queue.
THREADED_LISTREAD_START	Protect global active and available lists with a semaphore before reading it.
THREADED_LISTWRITE_START	Protect global active and available lists with a semaphore before writing to it.
THREADED_LISTACCESS_END	Release the semaphore protecting a global active or available list.
THREADED_EXPORT_START	Protect export and import actions by taking a semaphore
THREADED_EXPORT_END	Release the semaphore after export and import actions.
THREADED_START_THREAD	Start a new thread.
THREADED_STOP_THREAD	Terminate a thread.
THREADED_AFTER_THREAD_START	Synchronize the start-up of newly created threads.
THREADED_SEND_OUTPUT	Send messages/signals. Used in both models.

Textual and MSC Trace in Threaded

Textual SDL Trace, similar to the Textual Trace in the SDL Suite Simulator, can be turned on by selecting the flag *SDL trace* (will set the flag THREADED_XTRACE) in the Target Library/Kernel window in Targeting Expert.

On-line MSC trace is possible when running an application under a soft-kernel on Windows or UNIX. Select the flag *MSC trace* (will set the flag THREADED_MSCTRACE) in the Target Library/Kernel window in Targeting Expert.

API for interfacing a Threaded Integration

An API is available with a number of useful functions/MACROS that will facilitate the work of sending/receiving signals between external processes/threads and an SDL Threaded Application.

The following functions and MACROS are available:

SDL_PId xThreadedRegExtTask()

This function will return an SDL PId representing the calling External process/thread. It works in the following way:

1. Get a ThreadId for the calling process/thread.
2. Allocate and assign an SDL struct (`xPrsIdRec`) representing the external process/thread.
3. Call the SDL kernel function `xGetPId()` to get an `SDL_PId`.
4. If MSC trace is on it will generate an entry for the process/thread in the MSC diagram.
5. Allocate and initialize an SDL "system data record" for the external process/thread.
6. Create a queue for the calling process/thread.
7. Assign the "system data record" entry in the `SDL_PId`.
8. Return the `SDL_PId`.

xSignalNode xThreadedReceiveSDLSig(SDL_PId)

This function will wait for an SDL signal indefinitely. When a signal arrives the signal will be taken out of the queue and return the signal. If MSC trace is on the signal will also be traced in the MSC diagram.

xSignalNode xThreadedReceiveSDLSig_WithTimeOut(SDL_PId, SDL_Duration)

This function will work in the same way as `xThreadedReceiveSDLSig()` except that it will only wait for the specified time.

THREADED_ASSIGN_SDL_SIG_PARAMS(sigptr,signame,paramno,param)

This macro will use the macro token operator ## to concatenate the sigptr, signame, paramno into a simple assignment of the signal parameter with the specified number.

> **Note:**
> This macro should only be used with simple datatypes where assignments can be done using the simple assignment operator "="

THREADED_GET_SDL_SIG_PARAM(sigptr,signame,paramno,param)

This macro will assign the user's param the value of the signal parameter with the specified number.

> **Note:**
> This macro should only be used with simple datatypes where assignments can be done using the simple assignment operator "="

SDL_Output()

This is the standard SDL kernel function that should be used when sending signal into a Threaded Application. The following must be done before a signal can be sent from an external process/thread into a Threaded Application.

1. Use the `xThreadedRegExtTask/xThreadedRegExtTask_WithQueue` function to get an `SDL_PId`.
2. Call the SDL kernel function `xGetSignal` with the following parameters: `signalId`, `Receiver`, `Sender`.
3. Assign signal parameters using the API macro `THREADED_ASSIGN_SDL_SIG_PARAMS()`
4. Call the SDL_Output function with the SDL signal.

For an example see Annex 6: Building a Threaded Integration

THREADED_START_EXTTASK

This macro is normally empty. It is called after all static SDL threads are created in the `THREADED_AFTER_THREAD_START` macro (last in generated c file for application).

By defining this macro to user can make the application start external tasks.

THREADED_SIMPLE_EXAMPLE

If this flag is defined the external tasks in the simple example will be started.

Implementation Details for Different RTOS

VxWorks

The Threaded integration for VxWorks is developed and tested using a Windows Softkernel.

The following VxWorks header files are used:

```
#ifdef THREADVXWORKS

#include "errno.h"
#include "vxWorks.h"
#include "semLib.h"
#include "msgQLib.h"        /* msgQCreate msgQDelete ms-
gQSend msgQReceive *//* msgQNumMsgs */
#include "taskLib.h"         /* taskSpawn */
#include "semaphore.h"       /* POSIX semaphores */
#endif
```

The following VxWorks primitives have been used:

VxWorks primitives	Explanation
`sem_init(..),` `sem_wait(..),` `sem_post(..),` `sem_destroy(..),`	POSIX semaphores are frequently used, e.g. to protect the input queue, to synchronize start-up...
`msgQCreate(..),` `msgQReceive(..),` `msgQSend(..),` `msgQDelete(..)`	Message queues are used in both models in VxWorks. The message queue is created in the `THREADED_START_THREAD` MACRO.

VxWorks primitives	Explanation
`taskSpawn(..), taskDelete(..), taskSuspend(..)`	taskSpawn is used for creating a thread. The name entry is not used. taskSuspend is only used by the "Main" thread. It is called from the macro `THREADED_AFTER_THREAD_START`.
`taskIdSelf()`	Used in taskDelete() and taskSuspend()

Thread Parameters	Default values
`DEFAULT_STACKSIZE`	800
`DEFAULT_PRIO`	100
`DEFAULT_MAXQUEUESIZE`	250
`DEFAULT_MAXMESSIZE`	sizeof(xSignalNode)

Solaris

The Threaded integration for Solaris is developed and tested in the following environment:

Sun Solaris 2.6 with Sun WorkShop compiler cc version 5.0.

Included header files for Solaris:

```
#elif THREADSOLARIS
#include <pthread.h>
#include <semaphore.h>
#ifdef THREADED_ALTERNATIVE_SIGNAL_SENDING
#include <mqueue.h>
#include <signal.h>
#include <time.h>
#endif /* THREADED_ALTERNATIVE_SIGNAL_SENDING */
#endif
```

The following Solaris primitives have been used:

Solaris primitives	Explanation
`sem_init(..),` `sem_wait(..),` `sem_post(..),` `pthread_mutex_init(..),` `pthread_mutex_lock(..),` `pthread_mutex_unlock(..),` `pthread_mutex_destroy(..)` `pthread_cond_init(..),` `pthread_cond_wait(..),` `pthread_cond_timedwait(..),` `pthread_cond_signal(..),` `pthread_cond_destroy(..)`	The sem_.. primitives are only used in the start-up to synchronize static processes/threads. The pthread_mutex_.. primitives are used to protect the input queues and other queues. The pthread_cond_... primitives are used to synchronize sender and receiver in the default model.
`pthread_attr_init(..),` `pthread_attr_setstacksize(..),` `pthread_attr_setschedpolicy(..),` `thread_attr_setdetachstate(..),` `pthread_attr_setscope(..)`	The pthread_attr_.. primitives are used to set the attributes of a thread before it is created.
`mq_open(..),` `mq_close(..),` `mq_receive(..),` `mq_unlink(..),` `mq_send(..)`	These primitive are only used in the alternative signal sending model.
`pthread_create(..),` `pthread_exit(..),`	These primitives are used when a thread is created and when it terminates.
`timer_settime(..),` `timer_delete(..)`	These primitives are used for setting a timer before the mq_receive() is called in the alternative signal sending model. The time-out for the timer is the duration for the next internal SDL timer to expire. When the timer expires the signal_handler function sets the error message to EINTR.

Thread Parameters	Default values
DEFAULT_STACKSIZE	15000
DEFAULT_PRIO	10
DEFAULT_MAXQUEUESIZE	128
DEFAULT_MAXMESSIZE	sizeof(xSignalNode)

OSE

The Threaded integration for OSE have been developed and tested with an OSE Softkernel (version 4.3) on Solaris 2.6 using the gcc compiler (version 2.95).

The following OSE header file is include:

```
#ifdef THREADOSE
#include "ose.h"
#endif /* THREADOSE */
```

The following OSE primitives have been used:

OSE Primitives	Explanation
create_sem(..), wait_sem(..), signal_sem(..),	These primitives are used for protecting input queues, other queues and for synchronizing start-up
receive(..), receive_w_tmo(..), send(..)	These primitive are used for receiving/sending signals in both models. Receive/send is also used to pass the start-up parameter xSysD to a new thread, since OSE does not support start-up parameters in the create_process primitive.
alloc(..), free_buf(..)	These primitives are used for allocating and returning OSE signals.

OSE Primitives	Explanation
`start(..)`	This primitive is used for starting a newly created thread.
`kill_proc(..)`	This primitive terminates a thread
`stop(..)`	This primitive stop the execution of a thread. Used in the `THREADED_AFTER_THREAD_START` macro.
`current_process()`	Used in the kill_proc() and stop() calls.
`create_process(..)`	This primitive is used for creating Threads.

Thread Parameters	Default values
`DEFAULT_STACKSIZE`	1024
`DEFAULT_PRIO`	8
`DEFAULT_MAXQUEUESIZE`	1024
`DEFAULT_MAXMESSIZE`	sizeof(xSignalNode)

Declaration of xMainLoop().

The declaration and definition of the thread's entry point (xMain-Loop()) is special in OSE:

Declaration in scttypes.h;

```
.......
#elif THREADOSE
extern OSENTRYPOINT xMainLoop;
#else
extern void xMainLoop XPP((xSystemData *));
#endif
```

Definition in sctsdl.c:

```
......
#elif THREADOSE
```

```
OS_PROCESS(xMainLoop)
#else
#ifndef XNOPROTO
void xMainLoop (xSystemData * SysD)
#else
void xMainLoop (SysD)
                                xSystemData * SysD;
#endif
#endif
..............
```

Definition of NIL.

NIL is defined in the OSE kernel and must not be redefined in the SDL kernel.

```
#ifndef THREADOSE
#define NIL 0
#endif /* THREADOSE */
```

Forward declaration of xSignalNode.

The xSignalNode must have forward declaration very early in the scttypes.h file since it is used in the union SIGNAL definition.

```
.............
typedef struct xSignalStruct *xSignalNode;
union SIGNAL
{
  SIGSELECT      sigNo;
  xSignalNode    SDLSig;
  xSystemDataPtr SysD;
};

.....
```

Further down in the scttypes.h file.

```
.....
#ifndef THREADOSE
typedef struct xSignalStruct       *xSignalNode;
#endif /* THREADOSE */
.....
```

Windows

The Threaded integration for Windows is developed and tested on Windows XP with the Microsoft C++ compiler.

The following header files for Windows are included:

```
#ifdef THREADWIN32
#include "limits.h"
#include "windows.h"
#include "dos.h"
......
```

The following Windows primitives are used in the Threaded integration:

Windows primitives	Explanation
`CreateSemaphore(..)`, `ReleaseSemaphore(..)`, `WaitForSingleObject(..)`, `CloseHandle(..)`	These primitives are used for protecting input queues, other queues and synchronization in start-up. One extra semaphore, xInitQueue, is used when a newly created thread is creating his own input queue.
`PeekMessage(..)`	This primitive is used in the `THREADED_THREAD_BEGINNING` macro in the alternative signal sending model. This primitive force the thread to create a message queue. It is used together with the xInitQueue semaphore.
`GetMessage(..)`, `PostThreadMessage(..)`,	These primitives are used for receiving/sending messages in the alternative signal sending model.
`SetTimer(..)`, `KillTimer(..)`	These primitives are used to set an OS timer that will signal the thread when it expires. The timeout of this timer is the duration until the next internal SDL timer expires for this thread. The window message will be set to `WM_TIMER` if the OS timer expires.

Windows primitives	Explanation
`CreateThread(..), ExitThread(..)`	These primitives are used for creating and terminating threads.
`SetThreadPriority(..)`	This primitive is used for setting the priority of the thread.
`SuspendThread(..)`	Called by the “main” thread in the macro `THREADED_AFTER_THREAD_START`
`GetCurrentThread()`	Used in the SuspendThread macro.

Thread Parameters	Default values
`DEFAULT_STACKSIZE`	0 (Automatically resized by OS)
`DEFAULT_PRIO`	`THREAD_PRIORITY_NORMAL`
`DEFAULT_MAXQUEUESIZE`	1024
`DEFAULT_MAXMESSIZE`	sizeof(xSignalNode)

Signal Sending over TCP/IP

Introduction

For applications using the Threaded integration model, a plug-in module for TCP/IP communication is available. The module supports signal sending between distributed SDL applications via a TCP/IP connection. ASCII Encoding/Decoding is used for the conversion between signal and transport format. The module is delivered as C source code which is integrated and built together with code generated by the CAdvanced SDL to C Compiler.

The TCP/IP adapter supports the four operating systems for which Threaded integrations are available. These are Windows, Solaris, VxWorks and OSE.

Architecture

The TCP/IP functions are called from the environment functions `xInitEnv` and `xOutEnv`. The functions are included by setting the `XENV_INC` flag to `"tcpipcomm.h"`. The `tcpipcomm.h` file contains `#define` directives that translates macros in the environment file to function calls in the TCP/IP adapter.

When a signal is sent to the environment using the `xOutEnv` function, `xSendSignal` is called. A connection is set up with a remote server. The signal destination is specified using a user-implemented function. When the connection is accepted, the signal is encoded into ASCII format and sent via a TCP/IP socket. The session is then closed.

From `xInitEnv`, a thread is started which polls a socket for incoming connections. When a connection from a remote client is accepted, a new thread is started, which receives and decodes data for one signal. When the signal is decoded, it is inserted in the signal queue of the SDL system. The thread finishes its execution after the connection is closed.

An executing SDL system thus acts as a server when signals are received from the environment and as a client when a signal should be sent to the environment.

The environment file of an SDL application may not be modified if the TCP/IP adapter is to be used. Making modifications may override the TCP/IP signal sending functionality. If you want to use the TCP/IP adapter together with other external code from an environment file, please consult "Configuration" on page 3324.

File Structure

The TCP/IP adapter consists of four files, located in `$sdtdir/tcpip/`.

- `tcpipcomm.c` should be compiled and linked with the generated C code
- `tcpipcomm.h` is a C header file which is included from the generated environment file
- `tcpipthr.h` and `tcpipsock.h` are header files that are included from `tcpipcomm.c` and `tcpipcomm.h`.

The tcpip directory is referenced relative to the $sdtdir variable.

Hint: Using TCP/IP with a new $sdtdir

If you use an $sdtdir that is different from the default $sdtdir (in the SDL Suite installation directory), be sure to copy the **tcpip** directory to the new location. Otherwise, you may encounter problems in finding the TCP/IP files at compilation.

Note: Pointers as Signal Parameters

Distributed components execute in separate memory spaces. Care must be taken so that pointers are not sent as signal parameters over TCP/IP and used in a remote component.

Routing of Signals

For each signal that is sent from your SDL application, you must specify a destination in the form of an IP address (or host name) and a TCP port number. This information should be accessed from a routing function which is called when a signal is sent from the SDL application.

The routing function is made accessible from the TCP/IP adapter by setting the flag XROUTING_INC to the name of a routing header file. This is a plain C header file where the macro XFINDDEST(OUTSIG, SIGNAME, IP, PORT) is defined as a function. OUTSIG and SIGNAME are **in** parameters. IP and PORT are **out** parameters.

OUTSIG should be declared as xSignalNode*. From this parameter, signal data such as parameters can be accessed. SIGNAME holds the name of the signal and is declared as char*. In many cases, the signal name is sufficient routing information. The IP and PORT variables should be set to the host address and port number. IP should be declared as char* and PORT as int*.

The routing function should be implemented in a C file which is compiled and linked together with the application. The server IP address should be given as char*, e.g. "255.255.255.255" (dotted decimal notation) or "server.the_company.com" (hostname notation). The server port number should be given as int, e.g. 8888.

On the server side, the IP address is inherent to the host that the application resides on. The port number on which a server should listen for incoming connections should be specified using the flag XSERVPORT.

Note: Usage of Port Numbers

Generally, TCP port numbers below 1024 are reserved by operating system services or internet applications. For instance, the port numbers 21 and 23 are used by FTP and port number 80 is used by HTTP. If a port number is occupied, you will get an error message at start-up and the server thread will not start. It is recommended that you select port numbers larger than 1024 for your SDL application.

Example 557: TCP/IP Adapter Routing Settings ––––––––––––––––––

This example shows a situation where different signals should be directed to different recipients. An SDL system is partitioned into three components (i.e. executable files) using the Threaded integration model. From component 1, two different signals can be sent. Sig1 should be sent to component 2 and Sig2 should be sent to component 3.

Component 2 resides on a host called "host2". It uses port number 7001 for listening for incoming connections, which means that XSERVPORT is set to 7001 (XSERVPORT=7001). Component 3 resides on "host3" and listens on port number 7001 (XSERVPORT=7001). Please note that the ports are not in conflict since the hosts are different.

For component 1, a routing function is implemented. The flag XROUTING_INC is set to "router.h". The routing header file has the following contents:

```
#define XFINDDEST(OUTSIG, SIGNAME, IP, PORT)\
xGetDestination(OUTSIG, SIGNAME, IP, PORT)
```

The routing C file, router.c, contains the implemented function:

```
#include "stdlib.h"

void xGetDestination(xSignalNode *sig, char
*sigName, char *IPAddr, int *Port)
{
  if (strcmp(sigName, "Sig1") == 0)
  {
    strcpy(IPAddr, "host2\0");
    (*Port)= 7001; /* Dereferencing */
  }
  else if (strcmp(sigName, "Sig2") == 0)
  {
    strcpy(IPAddr, "host3\0");
```

```
      (*Port)= 7001;
    }

    return;
  }
```

`router.c` is then compiled and linked together with the generated code, the coder library and the TCP/IP adapter. This example shows a fairly trivial routing scenario. The routing is based only on the name of the signal. The xSignalNode pointer is not used.

Error Handling

The TCP/IP adapter contains basic error handling. Error checks are performed when encoding/decoding, socket and thread functions are invoked. If `THREADED_ERROR` is defined, an error message is printed on stdout with the name of the function where the error occurred. A platform-dependent error code is included in the error message. For a description of the error code, consult the User's Manual of your target operating system.

An error implies that the function where the error occurred exits. Clean-up is performed, which means that the application can continue its execution.

A special case to consider is when an error occurs in the server thread function, which runs statically during the execution. The thread exits and must be restarted manually.

If `THREADED_TRACE` is defined, the execution of the TCP/IP adapter is logged onto stdout when signals are encoded, sent, received and decoded.

Example 558: TCP/IP Adapter Error Message ––––––––––––––––––

An error occurs when a signal should be sent via the TCP/IP adapter. The following is logged on stdout:

```
ERROR xSendSignal/SCM_CONNECT: 146
```

The target platform is Solaris. The error code indicates that the connection was refused, probably because a server can not be found at the specified address. `xSendSignal` exits and the application continues its execution.

Configuration

The TCP/IP adapter is configured using compilation flags. The basic configuration can be done using the TCP/IP Connection Wizard in the Targeting Expert.

Including the TCP/IP adapter

The TCP/IP adapter requires environment files, environment header files and ASCII encoding/decoding for correct operation. These options are activated when the TCP/IP Signal Sending check box is enabled in the Targeting Expert's TCP/IP Connection Wizard.

Server Port Number

For a component that receives signals, a TCP port number must be specified. The server thread uses this port number to listen for incoming connections.

The port number is set in a text box in the TCP/IP Connection Wizard. You can also set the port manually by setting the flag `XSERVPORT` to the desired value. If no port number is specified, the port number is set to 5000 by default.

Routing

You must manually implement a routing function, so that a destination is specified for every SDL signal that is sent to the environment. The function must be declared in a C header file. The file is specified in a text box in the TCP/IP Connection Wizard or by setting the flag `XROUTING_INC` to the header file name.

The routing function implementation should be placed in a C file that is compiled and linked with the other code. It is specified using either the text box in the TCP/IP Connection Wizard or by including it in the compiler settings manually. See Example 557 for an example of how a routing function is implemented.

Using the TCP/IP Adapter with Other Environment Functionality

The TCP/IP adapter header file (`tcpipcomm.h`) is included from the environment file of a component. The file `tcpipcomm.h` contains `#define` statements for macros in the environment functions that invoke TCP/IP functions.

If you want to use other functionality in parallel with the TCP/IP adapter, these macros can be defined outside `tcpipcomm.h`. By setting the flag `XEXTENV_INC` to the header file you wish to use, your header file is included from `tcpipcomm.h`. This enables you to insert your code without modifying `tcpipcomm.h`. Please note that the `XEXTENV` flag can not be set in the TCP/IP Connection Wizard. It must be set manually.

Before using the `XEXTENV_INC` flag, look carefully at the #define statements in `tcpipcomm.h`. These must be valid for proper operation of the TCP/IP adapter.

Hint: Using External env Code with the TCP/IP Adapter

When combining the TCP/IP adapter with other environment functions, always preprocess the environment file to verify that the code is expanded as expected.

Example 559: External Code in Combination with the TCP/IP Adapter

A file called `mycomm.h` contains declarations of functions that should be used in parallel with the TCP/IP adapter. From the xInitEnv function, an initialization function should be called (`InitComm()`). From the `xInEnv` function, a function for polling communication (`ReadComm()`) should be invoked.

In `mycomm.h`, the following is inserted:

```
#define XENV_INIT Initcomm();\
                  xInitSignalSender();\
                  xInitSignalReceiver();
#define XENV_IN_START ReadComm();
```

`xInitsignalSender` and `xInitSignalReceiver` are taken from `tcpipcomm.h`, which contains the following:

```
#ifndef XENV_INIT
#define XENV_INIT xInitSignalSender();\
                  xInitSignalReceiver();
#endif
#ifndef XENV_IN_START
#define XENV_IN_START
#endif
```

The #defines in `tcpipcomm.h` are overridden. Still, the original calls are invoked, which ensures that the TCP/IP adapter executes properly.

Using Thread Parameters

Some thread parameters in the TCP/IP adapter can be set to fine-tune performance of your Threaded SDL application. The TCP/IP adapter threads do not use OS queues. Two parameters can be set: Thread Priority and Thread Stack Size. These are set manually using flags. They can not be set using the TCP/IP Communication Wizard.

The server wait thread uses the following flags:

```
XSERVTHRPRIO
XSERVTHRSTACK
```

The signal receiver threads use the following flags:

```
XRECVTHRPRIO
XRECVTHRSTACK
```

Set the flags to values that are specific to the target platform used.

New threaded integrations

Overview

The threaded integrations with Real-time operating systems described in this document has been developed by IBM Rational in the IBM Rational Tau product. Our intention, however, is that the integrations should be possible to use both in SDL Suite (Cadvanced) and Tau/Developer (AgileC and C Code Generator) products.

The difference between the currently existing threaded integrations and new ones presented here is not that large. The integration principles are almost exactly the same. The major difference is that the current integrations are expressed using macros, while the new ones uses a functional interface. Another difference is that all the current integrations provided by IBM Rational are mixed into one .h file, while in the new integration, each RTOS integration is implemented using one .h and one .c file. Both these changes are made to increase the readability and to simplify debugging. The change in file structure makes it also easier to implement new integrations and for a customer to modify an integration.

The currently available integrations are listed below.

Current integrations:

- SUN Solaris (This is a POSIX pthread integration that probably can be used on most UNIX-like operation system.)
- Win32
- VxWorks
- OSE

The new integrations:

- POSIX pthreads (tested on SUN Solaris and Linux but can probably be used on most UNIX-like operation system.)
- Win32
- VxWorks
- Nucleus Plus

Each RTOS integration consists of two files with the names rtapidef.h and rtapidef.c. The rtapidef.h file is included in the scttypes.h file, while the rtapidef.c file is included in the sctsdl.c file. As rtapidef.c is included in sctsdl.c there are no new files to compile and the make files are not effected, except for some compilation options discussed below.

When it comes to compilation none of the compilation switches used for the current threaded integrations should be defined. To use the new integrations the following should be given:

- a switch selecting an application kernel, for example SCTAPPLCLENV
- the switch THREADED
- a compiler option to tell the compiler where to find the rtapidef.h and the rtapidef.c file.

Example 560 ----------

```
cc -DSCTAPPLCLENV -DTHREADED -I/some/suitable/path
```

In the remaining part of this document the new threaded integrations are described in detail. This documentation is provided for customer who want to understand and possibly modify the integrations or to make new integrations themselves. The documentation was initially written for the

AgileC code generator in Tau/Developer and has been somewhat adopted to Cadvanced in SDL Suite.

Threaded integrations

To implement a new integration or to understand an existing one it is recommended to use this manual together with the code for some existing integration(s). There are some major aspects that have to be handled to implement an integration with real-time operating system.

- It is necessary to implement a clock function.
- There is need for a number of mutexes or binary semaphores to protect some shared data.
- Some startup code, for creating threads with relevant properties and synchronizing them are needed.
- A thread must be able to suspend its execution when it has nothing to do. It must then be possible to wake it up again when a signal is sent to a part in the thread.

To explain the details in these integration aspects the POSIX integration will be used as an example. Apart from the code mentioned below the rtapidef.h should include the necessary system include files to be able to access the concepts needed.

Example 561: Includes in rtapidef.h for POSIX ––––––––––––––––––

```
#include <pthread.h>
#include <sched.h>
#include <semaphore.h>
#include <time.h>
#include <sys/time.h>
```

––

If the RTOS has any requirements on the main function, which might be the case, it is possible to rename the main function included in uml_kern.c by defining XMAIN_NAME to for example:

```
#define XMAIN_NAME agilec_main
```

Then the user has to implement a proper main function that calls the `agilec_main` function.

The clock function

To support the SDL concept of timers, a clock function is necessary. The generated code and the kernel assumes that there is a clock function called `xNow` that returns the current time. Time values are represented by values of type `SDL_Time` which is defined as:

```
typedef struct
  s, ns xint32;
} SDL_Time;
```

`xint32` is implemented as a 32-bit int. The components `s` and `ns` represent the number of seconds and nanoseconds passed from some time in the past depending on the implementation of the clock function.

There are two standard implementations of the clock function, one for UNIX like systems and one for Windows. In Windows the standard function `_ftime` is used to read the system clock, while on UNIX like systems the standard function `clock_gettime` is used.

To implement a clock function you should include code in your own `rtapidef.h` and `rtapidef.c` files according to the details below.

If timers are not used and the clock is not explicitly accessed in SDL or C, there is no need for a clock implementation. Just include the macro definition:

```
#define xInitSystime()
```

in `rtapidef.h`.

If a clock implementation is needed then include the following prototypes in `rtapidef.h`:

```
extern void xInitSystime(void);
extern SDL_Time xNow (void);
```

If no initialization function is needed then the `xInitSystime` function can be replaced by the macro.

```
#define xInitSystime()
```

In the file `rtapidef.c` the implementation of these functions should be provided. The implementations will depend a lot on the support in software and hardware for the underlying architecture.

Protection of shared data

It is necessary to protect the list of available signals, the list of available timers, and a few other things. For this four global mutexes or binary semaphores are needed. These variables should be defined `extern` in `rtapidef.h` and declared in `rtapidef.c`. The names of the variables should be the same as in the example given below.

Example 562: In rtapidef.h:

```
extern pthread_mutex_t xFreeSignalMutex;
extern pthread_mutex_t xFreeTimerMutex;
extern pthread_mutex_t xCreateMutex;
#ifdef USER_CFG_USE_MEMORY_PACK
  extern pthread_mutex_t xMemoryMutex;
#endif
```

Example 563: In rtapidef.c:

```
pthread_mutex_t xFreeSignalMutex;
pthread_mutex_t xFreeTimerMutex;
pthread_mutex_t xCreateMutex;
#ifdef USER_CFG_USE_MEMORY_PACK
  pthread_mutex_t xMemoryMutex;
#endif
```

These four variables should be initialized during the startup of the application to an unlocked state. The function `xThreadInit` is a proper place for this initialization. Note that the names of the variables are chosen for AgileC in Tau/Developer, and do not fully reflect their usage in Cadvanced.

Example 564: xThreadInit

```
void xThreadInit (void)
{
  (void)pthread_mutex_init(&xFreeSignalMutex, 0);
  (void)pthread_mutex_init(&xFreeTimerMutex, 0);
  (void)pthread_mutex_init(&xCreateMutex, 0);
  #ifdef USER_CFG_USE_MEMORY_PACK
    (void)pthread_mutex_init(&xMemoryMutex, 0);
  #endif
  ....
}
```

The lock and unlock operation must also be implemented for mutexes or binary semaphores. The following two functions should be implemented.

Example 565 ----------

In **rtapidef.h:**

```
extern void xThreadLock (pthread_mutex_t *);
extern void xThreadUnlock (pthread_mutex_t *);
```

In rtapidef.c:

```
void xThreadLock (pthread_mutex_t *M)
{
  (void)pthread_mutex_lock(M);
}

void xThreadUnlock (pthread_mutex_t *M)
{
  (void)pthread_mutex_unlock(M);
}
```

Startup phase - creating the threads

After some basic initialization the kernel will in the main function start the specified threads. For each thread the functions xThreadInitOneThread and xThreadStartThread will be called, where xThreadInitOneThread should perform some thread specific initialization and xThreadStartThread should start the thread. Each thread should run the function xMainLoop declared in the kernel. This is performed by using a wrapper function, xThreadEntryFunc, which is defined in the integration and is the function really started in the thread.

After all the threads have been started the function xThreadGo is called in the function main. Some more information on these functions are given below.

It is important that the started threads do not execute any SDL transitions before all threads are created. Therefore the xThreadEntryFunc will as first action wait on a semaphore. The xThreadGo function will when all threads are created release this semaphore.

Many functions has a pointer to type xSystemData as parameter. This contains the local information for the thread. Among other things it con-

tains a field of type `xThreadVars`, which should be defined in the RTOS integration.

Example 566 ----------

`xThreadVars` type in `rtapidef.h`

```
typedef struct {
  pthread_mutex_t SignalQueueMutex;
  pthread_cond_t  SignalQueueCond;
  pthread_t       ThreadId;
} xThreadVars;
```

where the two first fields will be discussed in the next section, and the ThreadId will be used during the startup phase to store the identity of the threads.

The code for the behavior described in this section should look something like the following example.

Example 567 ----------

In `rtapidef.h`:

```
extern sem_t xInitSem;
#if !defined(USER_CFG_USE_xInEnv) && !defined(XENV)
  extern sem_t xMainThreadSem;
#endif

extern void xThreadInitOneThread (
   struct _xSystemData *);
extern void xThreadStartThread (
   struct _xSystemData *,
   unsigned int, unsigned int,
   unsigned int, unsigned int);
```

In `rtapidef.c`:

```
sem_t xInitSem;
#if !defined(USER_CFG_USE_xInEnv) && !defined(XENV)
  sem_t xMainThreadSem;
#endif

void xThreadInit (void)
{
  ....
  (void)sem_init(&xInitSem, 0, 0);
}

void xThreadInitOneThread(struct _xSystemData *xSysDP)
```

```
{
  (void)pthread_mutex_init(
    &xSysDP->ThreadVars.SignalQueueMutex, 0);
  (void)pthread_cond_init(
    &xSysDP->ThreadVars.SignalQueueCond, 0);
}

static void *xThreadEntryFunc (void *xSysDP)
{
  (void)sem_wait(&xInitSem);
  (void)sem_post(&xInitSem);
  xMainLoop((xSystemData *)xSysDP);
}

void xThreadStartThread(struct _xSystemData *xSysDP,
                        unsigned int StackSize,
                        unsigned int Prio,
                        unsigned int User1,
                        unsigned int User2)
{
  pthread_attr_t Attributes;
  ....
  (void)pthread_create(&xSysDP->ThreadVars.ThreadId,
                       &Attributes, xThreadEntryFunc,
                       (void *)xSysDP);
  ....
}

void xThreadGo(void)
{
  (void)sem_post(&xInitSem);

  #if defined(USER_CFG_USE_xInEnv)
    xInEnv();  /* AgileC */
  #elif defined(XENV)
    xInEnv(xNow());  /* Cadvanced */
  #else
    (void)sem_init(&xMainThreadSem, 0, 0);
    (void)sem_wait(&xMainThreadSem);
  #endif
}
```

The `xInitSem` semaphore is used for synchronization of the threads. It is initialized in the beginning of `xThreadInit` to 0, that is to a blocking state. After that the `xThreadStartThread` once for each thread that is to be started. The function `pthread_create` will call the function given as third parameter (`xThreadEntryFunc`) with the void * parameter given as fourth parameter (the `xSysD` pointer) as parameter. `pthread_create` will also store the identity of the thread in the variable passed as first parameter. The second parameter is the properties of the thread. This will be discussed later in this section.

If any of the threads get a chance to execute before all the threads are created, these threads will hang on the `sem_wait` call in `xThreadEntryFunc`, until the main thread calls `xThreadGo` that will post the semaphore `xInitSem` once. One of the threads waiting on this semaphore will then be able to execute and will immediately post the semaphore again. This will continue until all threads are free to execute.

After that all threads are running and depending on the OS and the application properties, the main thread can perform different things. Our recommendation is to call the `xInEnv` function and let that function run in this thread. For more details see the discussion on `xInEnv`. Another alternative is to hang the main thread on a semaphore, as shown above using the semaphore `xMainThreadSem` (if `xInEnv` is not used). In this case you can post the `xMainThreadSem` semaphore anywhere to restart the execution of the main thread.

When the main thread returns from the function `xThreadStart`, the program will continue to execute in the main function and will perform a call to exit. The behavior of a threaded program when the main thread performs exit, is OS dependent. In POSIX pthreads all threads are stopped at such an action. That is the reason it is important to hang the main thread at the end of the `xThreadStart` function.

Now to the properties of the threads. In most RTOS, properties like stack size and priority can be set for individual threads. Four integer values can be specified.

- The first value is interpreted as the stack size.
- The second value is interpreted as the priority.
- The third and fourth values can be used for other properties, defined by the RTOS integration or defined by you.

The currently predefined integrations only makes use of the first and second values. These values are passed as parameters to the `xTreadStartThread` function.

How the properties are set up in detail depend on the RTOS. Please see the available integrations, in the function `xThreadStartThread`, for examples.

In `rtapidef.h` proper default values for the four `xThreadData` fields should be set up. These default values are used if no value is specified in the thread definition.

Example 568 ----------

```
#define DEFAULT_STACKSIZE     1024
#define DEFAULT_PRIO             0
#define DEFAULT_USER1            0
#define DEFAULT_USER2            0
```

Suspending and waking up threads

When a thread finds out that it has nothing more to do, at least just for the moment, it should suspend itself to make the processor available for other threads. The thread should then wake up again either when a timer has expired and needs to be handled, or when some other thread (including `xInEnv`) sends a signal that should be treated by the suspended thread.

To implement these features one mutex or binary semaphore is used together with some sort of conditional variable. We need the possibility to perform a condition wait, with or without a timeout. We need also a way to signal to a thread to wake up again. These two entities are needed for each thread and is therefore included in the `xThreadVars` struct mentioned earlier:

```
typedef struct {
  pthread_mutex_t SignalQueueMutex;
  pthread_cond_t  SignalQueueCond;
  pthread_t       ThreadId;
} xThreadVars;
```

The purpose of the `SignalQueueMutex` is to protect the signal queue where signals from the outside of the thread are inserted. The `SignalQueueCond` should facilitate the conditional wait.

The `SignalQueueMutex` should be initialized in `xThreadInitOneThread`. If `SignalQueueCond` needs to be initialized it could be performed at the same place.

Example 569 ----------

```
void xThreadInitOneThread(struct _xSystemData *xSysDP)
{
 (void)pthread_mutex_init(&xSysDP-
>ThreadVars.SignalQueueMutex, 0);
 (void)pthread_cond_init(&xSysDP->ThreadVars.SignalQueueCond,
0);
}
```

The SignalQueueMutex is locked by using the function xThreadLock, discussed above. It is then unlocked in three different ways:

- xThreadUnlock (discussed above)
- xThreadWaitUnlock
- xThreadSignalUnlock

The xThreadWaitUnlock is called by the thread itself when it has come to the conclusion that it should suspend itself, while xThreadSignalUnlock is called by another thread that wants to wake up the current thread. Both functions are passed the xSysD pointer for the thread that the operation should be performed on.

Example: In rtapidef.h:

```
extern void xThreadWaitUnlock (struct _xSystemData *);
extern void xThreadSignalUnlock (struct _xSystemData
*);
```

Example: In rtapidef.c:

```
void xThreadWaitUnlock (struct _xSystemData *xSysDP)
{
  #if defined(CFG_USED_TIMER) || defined(THREADED)
  #ifdef THREADED
      /* Cadvanced */
    if (xSysDP->xTimerQueue->Suc==xSysDP->xTimerQueue)
{
  #else
      /* AgileC */
    if (! xSysDP->TimerQueue) {
  #endif
      (void)pthread_cond_wait(
        &xSysDP->ThreadVars.SignalQueueCond,
        &xSysDP->ThreadVars.SignalQueueMutex);
    } else {
      struct timespec timeout;
      #ifdef THREADED
          /* Cadvanced */
        timeout.tv_sec =
          ((xTimerNode)xSysDP->xTimerQueue->Suc)->
            TimerTime.s;
        timeout.tv_nsec =
          ((xTimerNode)xSysDP->xTimerQueue->Suc)->
            TimerTime.ns;
      #else
          /* AgileC */
        timeout.tv_sec = xSysDP->TimerQueue->Time.s;
        timeout.tv_nsec = xSysDP->TimerQueue->Time.ns;
      #endif
      (void)pthread_cond_timedwait(
```

```
            &xSysDP->ThreadVars.SignalQueueCond,
            &xSysDP->ThreadVars.SignalQueueMutex,
            &timeout);

      }
    #else
      (void)pthread_cond_wait(
        &xSysDP->ThreadVars.SignalQueueCond,
        &xSysDP->ThreadVars.SignalQueueMutex);
    #endif
    (void)pthread_mutex_unlock(
      &xSysDP->ThreadVars.SignalQueueMutex);
}

void xThreadSignalUnlock (struct _xSystemData *xSysDP)
{
  (void)pthread_cond_signal(
    &xSysDP->ThreadVars.SignalQueueCond);
  (void)pthread_mutex_unlock(
    &xSysDP->ThreadVars.SignalQueueMutex);
}
```

At the time when `xThreadWaitUnlock` or `xThreadSignalUnlock` is called the `SignalQueueMutex` will be locked and must therefore be unlocked at the end of both functions.

In `xThreadWaitUnlock` the thread wants to suspend itself. If timers are used and there is a timer active in the timer queue, it should wait until the timer expires or until some other thread tells it to wake up. In POSIX pthreads the function `pthread_cond_wait` performs exactly this. If timers are not used or there is no timer active, the thread should be suspended until someone else wakes it up. In POSIX pthreads this can be achieved with the function `pthread_cond_wait`.

In `xThreadSignalUnlock` the thread given by the parameter should be waken up. Here the `pthread` function `pthread_cond_signal` can be used.

The integrations described here are also used when the Cadvanced is used to generate threaded applications. This adds a few requirements in the implementation of a threaded integration. First a function that can stop a thread is needed.

In rtapidef.h:

```
#if defined(THREADED) || defined(CFG_USED_DYNAMIC_THREADS)
extern void xThreadStopThread(struct _xSystemData *);
#endif
```

In rtapidef.c:

```
#if defined(THREADED) || defined(CFG_USED_DYNAMIC_THREADS)
void xThreadStopThread(struct _xSystemData *xSysDP)
{
  pthread_mutex_destroy(&xSysDP->ThreadVars.SignalQueueMutex);
  pthread_cond_destroy(&xSysDP->ThreadVars.SignalQueueCond);
  pthread_exit(0);
}
#endif
```

The `xThreadStopThread` function should clean up the thread specific semaphores and stop the thread. It is always the thread that should be stopped that will call this function to stop itself.

Another difference is the way timers are accessed for the two code generators. This effects the details in the `xThreadWaitUnlock` function. Please see this function above and especially the sections under #ifdef THREADED.

In the case of the Cadvanced the RTOS integrations are accessed through a macro layer. The macros in this layer is used in the Cadvanced kernel files and in the generated code.

Example 570: Defines in scttypes.h ––––––––––––––––––––––––––

The following defines are relevant (from scttypes.h):

```
#define THREADED_GLOBAL_VARS
#define THREADED_GLOBAL_INIT \
     xThreadInit();
#define THREADED_THREAD_VARS \
     xThreadVars ThreadVars;
#define THREADED_THREAD_INIT(SYSD) \
     xThreadInitOneThread(SYSD);
#define THREADED_THREAD_BEGINNING(SYSD)
#define THREADED_AFTER_THREAD_START \
     xThreadGo();
#define THREADED_START_THREAD(F, SYSD, STACKSIZE,
PRIO, USER1, USER2) \
xThreadStartThread(SYSD, STACKSIZE, PRIO, USER1,
USER2);
#define THREADED_STOP_THREAD(SYSD) \
     xThreadStopThread(SYSD);
#define THREADED_LOCK_INPUTPORT(SYSD) \
     xThreadLock(&SYSD-
>ThreadVars.SignalQueueMutex);
#define THREADED_UNLOCK_INPUTPORT(SYSD) \
     xThreadUnlock(&SYSD-
>ThreadVars.SignalQueueMutex);
#define THREADED_WAIT_AND_UNLOCK_INPUTPORT(SYSD) \
     xThreadWaitUnlock(SYSD);
#define THREADED_SIGNAL_AND_UNLOCK_INPUTPORT(SYSD) \
     xThreadSignalUnlock(SYSD);
#define THREADED_LISTREAD_START
```

```
xThreadLock(&xFreeSignalMutex);
#define THREADED_LISTWRITE_START
xThreadLock(&xFreeSignalMutex);
#define THREADED_LISTACCESS_END
xThreadUnlock(&xFreeSignalMutex);
#define THREADED_EXPORT_START
xThreadLock(&xCreateMutex);
#define THREADED_EXPORT_END
xThreadUnlock(&xCreateMutex);
```

Tight Integration

Note:

The source file and examples for Tight Integrations are not included in the standard delivery. They are available as free downloads from IBM Rational Support web site.

Note:

This presentation is focused on the general principles and models used in a Tight Integration. When specific RTOS primitives are needed in the presentation, examples from the VxWorks implementation are used. The implementation and RTOS calls used in other integrations are covered in separate annexes to this chapter, one for each supported RTOS.

There are two models of Tight Integration. In the Standard Model one SDL process instance is mapped to one OS task. In the Instance Set Model an entire instance set (all instances of a process) is mapped to one OS task. Scheduling between OS tasks is managed by the RTOS scheduler; this means that preemption is normally used, though only on an instance set level in the Instance Set Model. SDL semantics are preserved in a Tight Integration, for example setting a timer implies an automatic reset first.

The start-up of a system, i.e. creation of static processes, initialization of synonyms and creation of an environment task and a timer task, is handled by a generated initialization function called `yInit`. Normally this function is called from another initialization function, where some additional initializations take place before the `yInit` function is called.

Timers in the system are handled by one central timer task. This task receives messages[1], each containing a request to set a timer, and will send messages back as the timers expire.

Common Features

File Structure

The files related to the tight integration concept are placed in the following directory in the installation: `<installation directo-`

1. SDL signals will be implemented as messages in VxWorks.

ry>/sdt/sdtdir/RTOS/<operating system>/TightIntegration/. The same files are used for both the Standard Model and the Instance Set Model.

Each RTOS directory contains the following files:

- sct<RTOS>.h:

  This file contains the second level of macros (see the comments for scttypes.h in "The Integration Packages" on page 3291). All macros are using OS-specific calls or types.

- sct<RTOS>.c:

  This file contains OS-specific support functions.

- sdt2<RTOS>.c:

  Most RTOS require that signals/messages are represented with an integer value. This is the source file for a utility program for generating signal identities. Each signal will be assigned an integer value. The output will be a file with the suffix .hs. This file is automatically included in the application.

  In the SDL Suite, the .hs file can also be generated by the SDL to C Compiler by turning on the option *Generate signal number file* in the *Make* dialog. The .hs file is included in the application if the compilation switch XINCLUDE_HS_FILE is set.

The SDL_PId Type

The SDL_PId (SDL Process ID) type has different meanings in the Standard and the Instance Set Models. In the Standard Model it represents the message queue, while it represents the process instance in the Instance Set Model. This is because the entire instance set will have the same message queue in the last case.

```
#ifdef X_ONE_TASK_PER_INSTANCE_SET
typedef xEPrsNode SDL_PId;
#else
typedef MSG_Q_ID  SDL_PId;
#endif
```

Signals

The signal header consists of a struct with information needed to handle the signal inside an SDL system. The signal header struct is defined in the RTOS-specific file `sct<RTOS>.h`.

```
typedef struct xSignalHeaderStruct *xSignalHeader;
typedef struct xSignalHeaderStruct {
  int            SignalCode;
  xSignalHeader  Pre, Suc;
  SDL_PId        Sender;
  void          *SigP;
  #ifdef X_ONE_TASK_PER_INSTANCE_SET
    SDL_PId        Receiver;
  #endif
  #ifdef XMSC_TRACE
    int            SignalId;
    int            IsTimer;
  #endif
} xSignalHeaderRec;
```

The signal header stores `SignalCode`, in this case an integer, two pointers `Pre` and `Suc` used when saving the signal in the save queue, and `Sender`, holding the `SDL_PId` of the sending SDL process. In the Instance Set Model there is an extra parameter `Receiver`, necessary to make a distinction between the SDL processes in an instance set task.

If the signal contains parameters they are allocated in the same function call. Example:

```
OutputSignalPtr = xAlloc (sizeof (xSignalHeaderRec)
+ sizeof(yPDef_z05_s2));
```

The second parameter to the `xAlloc` function is a struct representing the signal parameters of the signal. In this case, with one integer, it is defined in the following way:

```
typedef struct {
  SIGNAL_VARS
  SDL_Integer     Param1;
} yPDef_z05_s2;
```

The macro `SIGNAL_VARS` is in most RTOS empty.

There is an extra element in the `SignalHeader` defined as a `void` pointer. This pointer `SigP` is set to point to the parameter area.

```
OutputSignalPtr->SigP = OutputSignalPtr+1;
```

This pointer is used in the Signal-Free-Function to address the parameter-part of either a signal-structure as also a timer-signal-structure.

Note:

The SDL signal parameters are always named `Param1`, `Param2`, etc.

Assignment of the signal parameter is done in generated code and not in a macro. Example:

```
SIGNAL_ALLOC_ERROR
yAssF_SDL_Integer(((yPDef_z05_s2*)
  OUTSIGNAL_DATA_PTR)->Param1 ,yVarP->z023_param1,
  XASS);
```

The macro `OUTSIGNAL_DATA_PTR` macro is defined:

```
#define OUTSIGNAL_DATA_PTR (yOutputSignalPtr->SigP)
```

After expansion of the whole expression the code will be:

```
((yPDef_z05_s2 *) ((xSignalHeader) yOutputSignalPtr
+ 1))->Param1 = yVarP->z023_param1;
```

Signal reception

The support function `xInputSignal` is used for receiving signals in both models of Tight Integration. The implementation and the parameters are different though.

Timer Signals

A timer signal is defined similarly to an ordinary signal but will contain some additional elements representing time-out time, etc. The timer header struct looks like this:

```
typedef struct xTimerHeaderStruct *xTimerHeader;
typedef struct xTimerHeaderStruct {
      int             SignalCode;
      xTimerHeader    Pre, Suc;
      SDL_PId         Sender;
      void           *SigP;
#ifdef X_ONE_TASK_PER_INSTANCE_SET
      SDL_PId         Receiver;
#endif
#ifdef XMSC_TRACE
      int             SignalId;
      int             IsTimer;
#endif
      SDL_Time        TimerTime;
```

```
        int             TimerToSetOrReset;
        xbool           (* yEq)();
        xbool           TestParams;
        xTimerHeader    Param;
} xTimerHeaderRec;
```

Note:

An ordinary signal is identical to the first part of a timer signal. This makes it possible to type-cast between the two types as long as only elements in the common part of the headers are used.

Time

When the System time is required, for example when using NOW, the macro `SDL_NOW` is used. The macro is in turn mapped to the function `SDL_Clock()` (in `sctos.c`). This function is implemented differently depending on the RTOS representation of time. In VxWorks it returns the result of calling the RTOS function `tickGet`. `SDL_Time` is normally implemented as `int` or `unsigned long int`.

Mapping Between SDL Time and RTOS Time

The macro `SDL_DURATION_LIT` specifies the mapping between the SDL time in seconds and the local RTOS representation of time. In VxWorks the system time is given in ticks and the translation is defined as follows:

```
#define SDL_DURATION_LIT(R,I,D) \
  ((I)*1000 + (D)/1000000)
```

`R` is the real type representation of the time in seconds. `I` and `D` are the integer and decimal parts of an integer type representation of the time. `I` is in seconds and `D` in nanoseconds. The code generator will generate all three numbers but either `R`, or `I` and `D` will be used depending on the RTOS.

Timers

All timer activity in the SDL system is handled by a dedicated timer task. The timer task accepts requests in the form of messages (in VxWorks). It then keeps the requests for setting a timer sorted in a timer queue and uses some OS mechanism to wait for the first request to time out. The mechanism used can be either an OS timer, or a timeout in the waiting for new requests. When a request times out, the timer task sends a signal back to the task that first sent the request. The function calls and

OS signaling involved in setting and waiting for an SDL timer can be viewed in Figure 573.

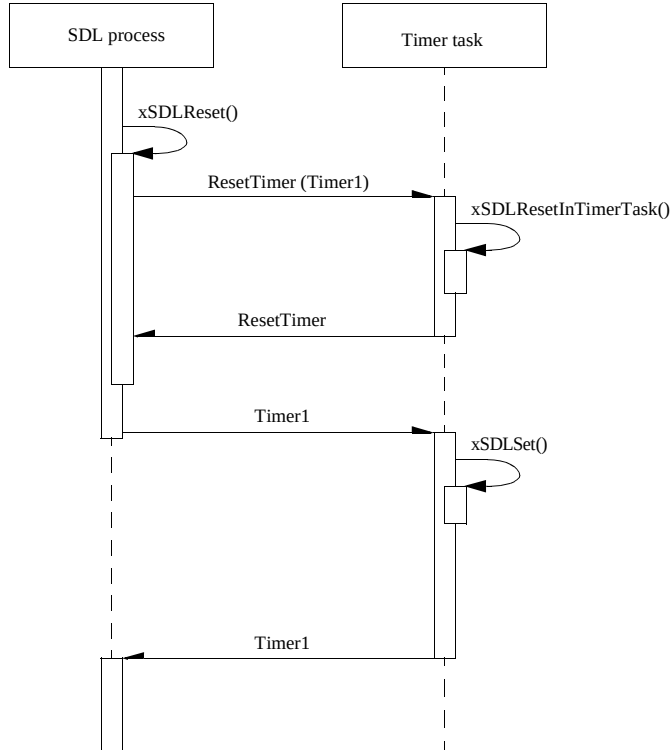


Figure 573: Function calls and OS signaling when setting and waiting for a timer.

UML notation is being used, thus the full arrowheads represent function calls and the half arrowheads represent messages. Parameters have been left out, except for the name of the timer in the ResetTimer request. Note that a reset is performed first, as required in the SDL specification.

To be able to implement the full semantics of SDL timers a number of support functions have been implemented:

- `xSDLActive`

  Checks whether an SDL timer is active and returns true or false. The function passes the question on to the timer task in the form of a request.

- `xSDLActiveInTimerTask`

  Called by the timer task upon request. Checks if an SDL timer is active and returns true or false.

- `xSDLReset`

  Resets an SDL timer by sending a request to the timer task. While waiting for a reply all new signals to the calling task are saved in the save queue. In the case of an Instance Set Model Tight Integration this means that no instance of the process can execute a transition until a reply is received. If the reply states that the timer couldn't be found it might be in the save queue or the input queue of the task because it has recently expired. If so, it is simply removed. SDL semantics require that a reset is always performed implicitly prior to setting a timer.

- `xSDLResetInTimerTask`

  Called by the timer task when a request has been made for resetting a timer. Checks the timer queue to see if the timer to reset is there. If the timer is found, it is removed and the data area it holds is freed. A message is sent back to the task that made the request, telling whether the timer was found or not.

- `xSDLSet`

  Called by the timer task when a request has been made for setting a timer. This function sorts the request into the timer queue.

Addressing SDL Processes

There are two ways to address SDL processes from an external task. Either the `xFindReceiver` function can be called to find an arbitrary receiver, or the file `pidlist.pr` can be used to provide a list of the SDL processes and then address the receiver explicitly via the input queue ID of its OS task.

The xFindReceiver Function

When sending a signal into the SDL system where the receiver is not known a support function called `xFindReceiver` can be used. This function takes the following parameters:

- The ID of the signal

- The sender ID (in this case an SDL_PId representing the environment)
- An optional VIA-list.

The following files are needed to get access to SDL types, signal numbers and signal parameter types: `scttypes.h`, `<system_name>.hs` and `<system_name>.ifc`.

Example of how to use the `xFindReceiver` function:

```
#include "scttypes.h"
#include "<system_name>.ifc"
#include "<system_name>.hs"

void MyExtTask(void) {

   xSignalHeader yOutputSignalPtr;
   int Err;

   /*Allocate signal header and signal parameter
     buffer */
   yOutputSignalPtr =
      (xSignalHeader)xAlloc(sizeof(xSignalHeaderRec)
       + sizeof(yPDef_go);

   /*Setup signal header */
   yOutputSignalPtr->SignalCode = go;
   yOutputSignalPtr->Sender = xEnvPId;

   /*Give value 100 to integer parameter */
   ((yPDef_go *)(yOutputSignalPtr+1))->Param1 = 100;

   /*Send signal from environment */
   Err = msgQSend(xFindReceiver(go, xEnvPrs, 0),
           (char*) yOutputSignalPtr,
           sizeof(xSignalHederRec)+sizeof(yPDef_go),
           0 ,0);
}
```

The following types, signal definitions and global variables are used in the example:

- `xEnvPId`: An SDL PId representing the environment, from `scttypes.h`
- `xEnvPrs`: A PrsNode representing the environment, from `scttypes.h`
- `xSignalHeader`: A datatype representing an SDL signal, from `scttypes.h`

- `yPDef_go`: A datatype representing the signal parameter types, from `<system_name>.ifc`
- `go`: An SDL signal, from `<system_name>.ifc`

The File pidlist.pr

An alternative way to get the PId for the Receiver is to use an ADT defined in the ADT library called `pidlist.pr`. This file defines an ADT called PidList and an operator called PId_Lit. With this ADT it is possible to directly address any static process instance in the system, both from internal SDL processes and from external OS-tasks. You can find more information about this feature in "How to Obtain PId Literals" on page 3256 in chapter 62, *The ADT Library*.

> **Note:**
>
> If you need the `pidlist.pr` ADT in a Tight Integration then you must use the version in the `<installation directory>/sdt/sdtdir/RTOS/SDL/` directory.

The Standard Model

In the Standard Model of the Tight Integration each SDL process is implemented as an OS task. Preemption and the use of process priorities is only limited to what the OS supports.

Processes

Process Creation

An SDL process is created in the following way (in the VxWorks integration):

1. A start-up signal is allocated.
2. A message queue is created. Some operating systems create the message queue automatically when the task is created. This is explained for each operating system in the annexes to this chapter.
3. The task is created with the message queue ID as a start-up parameter. In the case of VxWorks, the task will have a name starting with `VXWORKSPAD_`. This is a function which will first initialize some internal variables and then call the PAD function.

4. A function (`xAllocPrs`) is called to create a representation of the new instance in the global symbol tree.
5. The start-up signal is sent. When this signal is received in the task the start transition of the process is executed.

Process Termination

The following actions are carried out when a process terminates:

1. The save queue and the message queue are emptied.
2. The save queue is deleted.
3. A message is sent to the `xTimerTask` with a request to remove all active timers of the process.
4. `xFreePrs` is called to free the `PrsNode`.
5. The message queue is deleted. In some operating systems this is done automatically when the task is deleted.
6. The task is deleted.

PAD functions

Each PAD (Process Activity Definition) function will contain an eternal loop with an OS receive statement. When a process instance is created it is the PAD function that is called in the OS Create primitive.

The start-up and execution of a PAD function works like this:

1. The support function `xInputSignal` is called. This function will wait for the start-up signal, that is always received first, and then return to the PAD function.
2. The PAD function goes to the label `Label_Execute_Transition`. This label is the start of a code block containing a switch statement that evaluates the process variable `RestartAddress`. The code under each different case then represents a transition. At the end of this block the process variable `State` is updated and execution continues at `Label_New_Transition`.
3. In `Label_New_Transition` a new call is made to `xInputSignal` and execution then continues at `Label_Execute_Transition`.

The structure of a PAD function is described below (with pseudo-code shown in *italics*):

```
void yPAD_z01_pr1 (void *VarP)
{
  Variable declarations
  xInputSignal is called to receive the start-up signal
  ...........
  goto Label_Execute_Transition;
  ...........
  Label_New_Transition:
  xInputSignal is called to receive a signal

  Label_Execute_Transition:
  Local declarations
  switch (yVarP->RestartAddress) {
  case 0:
    Execute the start transition
    Update the process state variable
    goto Label_New_Transition;
  case 1:
    Execute the transition
    Update the process state variable
    goto Label_New_Transition;
  ...........
  }
  ...........
}
```

Scheduling

Since each SDL process is implemented as an OS task, scheduling between processes will be handled completely by the OS.

Start-up

Start-up of a Standard Model Tight Integration can be described as follows (pseudocode is shown in *italics*):

```
MyMain() {
/* initialization of semaphores etc */
 yInit();
 Give startup semaphores
 taskSuspend(Mymain);
}

yInit() {
 Create the timer task
 Create an environment task or only an environment queue
 for(i=1;i<=NoOfStaticProcessTypes;i++){
  for(j=1;j<=NoOfStaticInstancesOfEachProcesstype;
      j++){
    Allocate a startup signal
    Create a message queue
```

```
        Create a task
        Call xAllocPrs
        Send the startup signal
      }
    }
    Assign SDL synonyms
  }
```

The semaphore is used for synchronizing start-up of static processes. No static process is allowed to execute its start transition before all static processes are created, because a start transition can have signal sending to other static instances.

The `MyMain` function is placed among other support functions in the file `sctsdl.c`.

The `yInit` function is generated by the code generator and placed last in the generated file for the system.

The Instance Set Model

The Instance Set Model is based on the same principles as the Standard Model with the difference that the instance set is the basic unit rather than the process instance.

Processes

Both the instances and the instance sets are represented in the symbol table. In addition to the three parts that always make up an SDL process there is also an extra struct for the instance set, defining for example the input queue which is common to all the instances. Further, there is a PAD function for each instance, but also for the instance set.

Process Representation

An SDL_PId is represented by an `xEPrsNode`, pointing to an `xEPrsStruct`. An `xEPrsNode` also represents a process instance in the symbol table both in the Standard Model and the Instance Set Model.

```
typedef struct xEPrsStruct {
  xEPrsNode       NextPrs;
  SDL_PId         Self;
  xPrsIdNode      NameNode;
  int             BlockInstNumber;
  xPrsNode        VarP;
} xEPrsRec;
```

Instance Set Data

The datatype `xPrsInstanceSetVars` is only used in the Instance Set Model. It defines common data for all instances of the set, like the save queue and the size of the instance data.

```
typedef struct {
  xSignalHeader   SaveQ;
  xSignalHeader   CurrentInSaveQ;
  xSignalHeader   yInSignalPtr;
  char            name[100];
  unsigned        PrsDataSize;
} xPrsInstanceSetVars.
```

PAD functions

In the Instance Set Model there is a PAD function for each process instance but also for each instance set. The instance set PAD functions will be called at system start-up and contain an eternal loop in the same fashion as PAD functions in the Standard Model. Instance PAD functions are only called to execute transitions.

Process Creation

All instance sets, even for dynamic processes, are created at system start-up. Since the OS task and the signal queues are created with the instance set, the creation of an instance requires less labor than in the Standard Model. For the instance set creation the macro `INIT_PROCESS_TYPE` is used.

Process Termination

The instance set task is never terminated. Termination of a process instance will not remove the save queue, the input queue and the task. This is done at system termination. All queues, including the active timer queue, are emptied of messages to the terminated process though.

Signal queues

The message queue id of the receiver's instance set is accessed through `NameNode` in the receiver's `xEPrsStruct` and the variable `PROCID`.

Example from `xSDLResetInTimerProcess`:

```
Err=msgQSend ((MSG_Q_ID) (yInSignalPointer->Sender)
  ->NameNode->PROCID, (char *) yInSignalPointer,
  sizeof (xTimerHeaderRec), 0, 0);
```

In this case the receiver is the same as the original sender.

Signal sending

A support function `xHandle_Sig` is used when sending signals, instead of the macro `RTOSSEND` as in the Standard Model. This difference is shown in **bold** in the code below:

```
#ifdef X_ONE_TASK_PER_INSTANCE_SET
#define SDL_2OUTPUT(PRIO, VIA, SIG_NAME, SIG_IDNODE,\
   RECEIVER, SIG_PAR_SIZE, SIG_NAME_STRING)\
   XOS_TRACE_OUTPUT(SIG_NAME_STRING) \
   XMSC_TRACE_OUTPUT(RECEIVER, yOutputSignalPtr, \
     SIG_NAME_STRING) \
   xHandle_Sig(yOutputSignalPtr,SDL_SELF,SIG_PAR_SIZE,\
    RECEIVER,(RTOSTASK_TYPE)RECEIVER-> \
    NameNode->PROCID RTOSHANDLESIG_PAR);
#else
#define SDL_2OUTPUT(PRIO, VIA, SIG_NAME, SIG_IDNODE, \
   RECEIVER, SIG_PAR_SIZE, SIG_NAME_STRING)\
   XOS_TRACE_OUTPUT(SIG_NAME_STRING) \
   XMSC_TRACE_OUTPUT(RECEIVER, yOutputSignalPtr,\
     SIG_NAME_STRING) \
   RTOSSEND(&yOutputSignalPtr, RECEIVER,SIG_PAR_SIZE)
#endif
```

Scheduling

Scheduling between instance sets is handled by the operating system. Within the instance sets, however, scheduling is based on the signal queue. When the instance set PAD function is executing, it takes the first signal in the input queue and calls the PAD function of the addressed SDL process. The instance PAD function then executes one transition and returns control to the scheduling loop of the instance set PAD function.

Integrating with external code

You can easily integrate the SDL system with external code, for example written in C. Just use the hooks described below for inserting C statements in the `main()` function of the SDL system.

The hooks are in the form of `#define` macros located in a file called `scthooks.h`. A file called `scthooks.h_template` with empty macros can be found in the `INCLUDE` directory. Use this file as a template for your own application. You will find usage examples in the `Examples` directory.

`HOOK_GLOBAL_DECLARATIONS`

This hook lets you declare function prototypes etc. at file scope.

HOOK_MAIN_DECLARATIONS

This hook lets you declare variables for use in the `main()` function.

HOOK_MAIN_START_OF_CODE

Any code inserted here will execute first in the `main()` function.

HOOK_MAIN_AFTER_PROCESS_RELEASE

Any code inserted here will execute as soon as all static processes have been created and are allowed to run.

HOOK_MAIN_AFTER_SIGNAL_RECEPTION

The `main()` function of the SDL system enters an infinite loop after having created all static processes. This loop is used to receive signals sent to the environment queue.

Use the `HOOK_MAIN_AFTER_SIGNAL_RECEPTION` to insert code for processing these signals.

Limitations for Integrations

In general, the same restrictions as for the SDL to C Compiler apply, but Tight integrations have some further restrictions. The detailed limitations for Light and Tight integrations are listed in the Release Guide.

A Simple Example

This section describes an example system named Simple. The annexes show how to integrate the example with different operating systems.

The example demonstrates the following techniques:

- How to integrate an SDL system with an operating system
- How to make the environment communicate with the SDL system in a Light integration
- How to make an external process written in C communicate with the SDL system in a Tight integration
- How to use the special Tight Integration version of the ADT `pidlist.pr` .

The Simple System

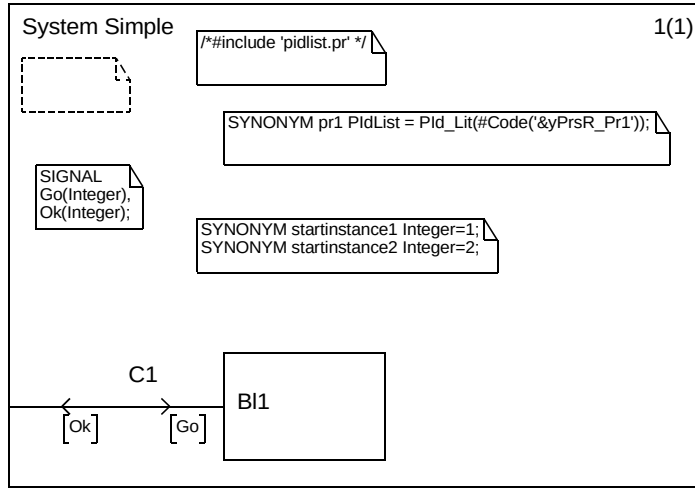

Figure 574: System Simple

The SDL representation of Simple consists of a single block Bl1. Seen from the outside, the system accepts the signal Go and responds after about five seconds by sending the signal Ok. The signal Go may be sent twice to the system.

Block Bl1

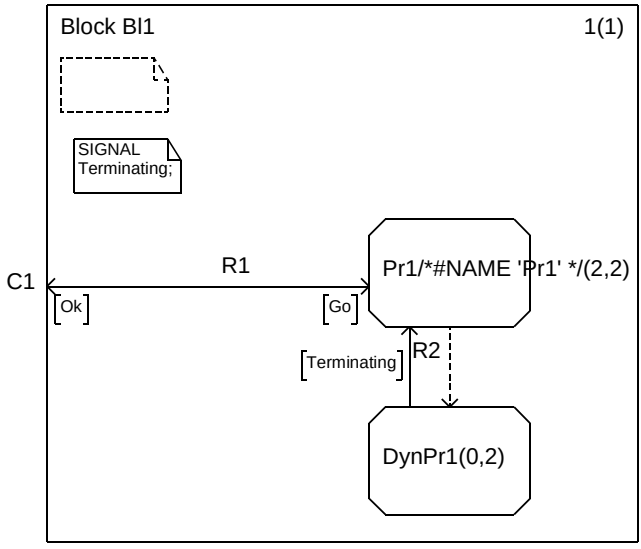

Figure 575: Block Bl1

Block Bl1 has two processes. The static process Pr1 and the dynamic process DynPr1. DynPr1 is created by Pr1 and can send the signal Terminating back to its parent. Pr1 handles all the interaction with the environment, through the signals Go and Ok.

Process Pr1

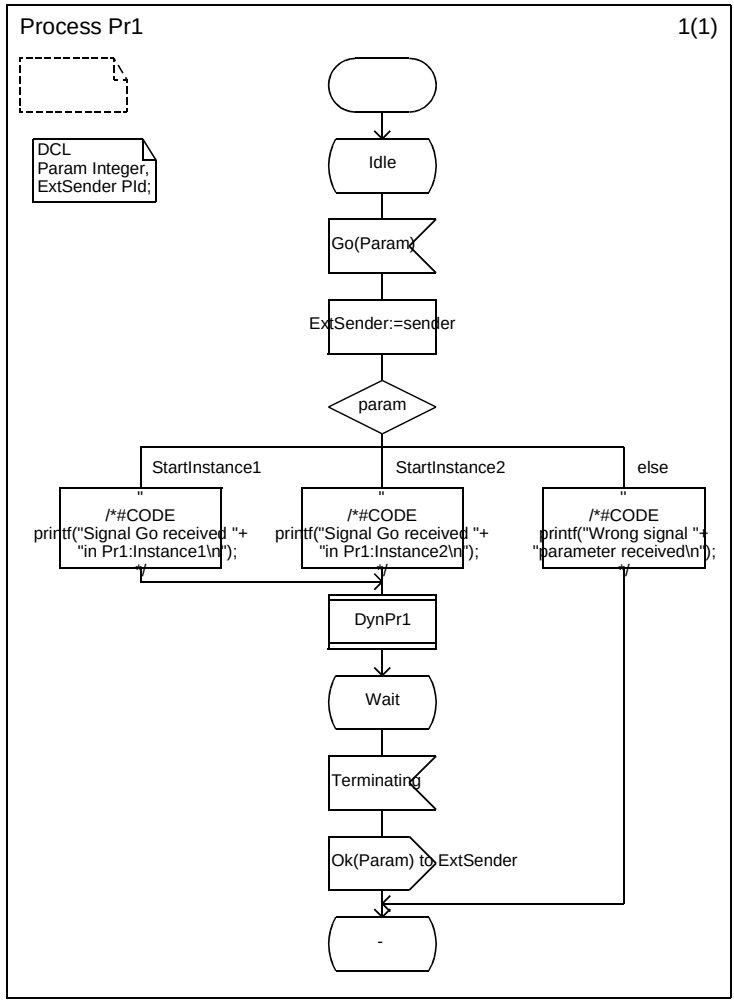

Figure 576: Process Pr1

Process Pr1 is a static process with two instances. It has two states, Idle and Wait. In the Idle state the process waits for the signal Go with an integer parameter representing the instance number of this instance. It then prints the instance number to the standard output, creates one in-

stance of DynPr1 and enters the Wait state. In the Wait state it waits for the signal Terminating from the created instance of DynPr1, sends Ok back to the environment and goes back into the Wait state. Since the Terminating signal will only be received once, the process is going to remain in the Wait state forever.

Process DynPr1

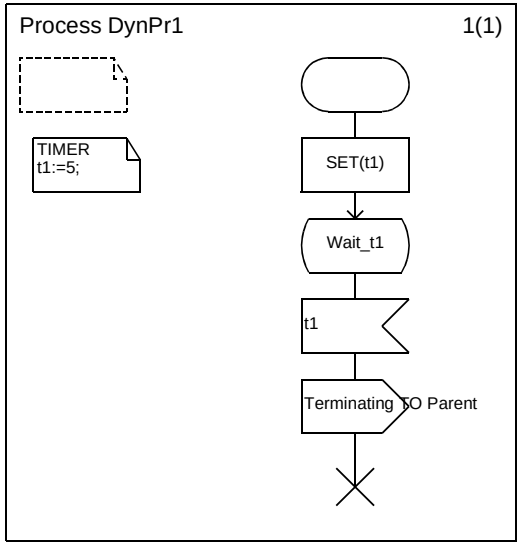

Figure 577: Process DynPr1

The dynamic process DynPr1 has no instances at system start and a maximum of two instances. Each instance of Pr1 creates one instance of DynPr1. DynPr1 sets the timer t1 to five seconds, waits for a timeout, sends the signal Terminating to its creator and finally terminates.

Connection to the Environment

The environment is handled in different ways depending on the integration model. See below for details.

Building and Running a Light Integration

This section will take you through the general steps required to build a Light Integration for the Simple example. The procedure works the same for most operating systems. Please also check the annexes for important information about your operating system.

General Steps for a Light Integration

1. Create a working directory and an INCLUDE directory below it.

> **Note:**
> `$(sdtdir) = <installation directory>/sdt/sdtdir/<machine dependent dir>`
>
> where `<machine dependent dir>` is `sunos5sdtdir` on SunOS 5 and `wini386` in Windows.

2. Copy all files from `$(sdtdir)/RTOS/Examples/Simple/<selected RTOS>/LightIntegration` to the working directory.
3. Copy the following files to the `INCLUDE` directory:

   ```
   $(sdtdir)/INCLUDE/sctlocal.h
   $(sdtdir)/INCLUDE/sctpred.c
   $(sdtdir)/INCLUDE/sctsdl.c
   $(sdtdir)/INCLUDE/sctos.c
   $(sdtdir)/INCLUDE/sctpred.h
   $(sdtdir)/INCLUDE/scttypes.h
   ```

4. Open the system file
   `$(sdtdir)/RTOS/Examples/Simple/simple.sdt`
5. Change the destination directory to your working directory
6. Set the options *Lower Case* and *Generate environment header file.*
7. Select the Cadvanced SDL to C Compiler and generate an application.
8. Edit the `makefile` supplied with the example to fit your environment. Normally you will only have to point out the directory where the RTOS is installed.
9. Use the makefile to build an executable.
10. Download the executable to target or run it under a kernel simulator (“soft kernel”).

Result From Running the System

The output when running the example should be:

```
Signal Go received in Pr1:Instance1
Signal Go received in Pr1:Instance2
Signal Ok received with the following parameter:1
Signal Ok received with the following parameter:2
```

The xInEnv Function

This is where the start-up signal Go is sent. In a real system `xInEnv` may be used for polling hardware devices for data. The code looks like this:

```
xSignalNode S;
static int SendGo = 0;

if(SendGo<=1){
  if(SendGo==0) {
    S = xGetSignal(go,  pr1[1],   xEnv );
    ((yPDef_go *)(S))->Param1 = startinstance1;
  }
  else {
    S = xGetSignal(go,  pr1[2],   xEnv );
    ((yPDef_go *)(S))->Param1 = startinstance2;
  }
  SDL_Output( S, xSigPrioPar(xDefaultPrioSignal)
                 (xIdNode *)0 );
  SendGo++;
```

The signal Go is sent the first and the second time `xInEnv` is called. The parameters `startinstance1 and startinstance2` are integer constants defined in the SDL system, as integer `SYNONYM`'s. They are made available by generating and including the file `simple.ifc`.

The xOutEnv Function

The code in `xOutEnv` for receiving the signal Ok looks like this:

```
if ( ((*S)->NameNode) == ok ) {
  printf("Signal Ok received with the following
          parameter:%lu\n",
          ((yPDef_ok *)(*S))->Param1);
  xReleaseSignal( S );
  return;
```

The signal Ok also has an integer parameter, the value of this should be 1 if it is sent by Pr1 instance one and 2 if it is sent by instance two.

Building and Running a Tight Integration

This section will take you through the general steps required to build a Tight Integration for the Simple example. The procedure works the same for most operating systems. Please also check the annexes for important information about your operating system.

Note:

The source file and examples for Tight Integrations are not included in the standard delivery. They are available as free downloads from IBM Rational Support web site.

General Steps for a Tight Integration

1. Create a working directory and an INCLUDE directory below it.

Note:

`$(sdtdir) = <installation directory>/sdt/sdtdir/<machine dependent dir>`

where `<machine dependent dir>` is `sunos5sdtdir` on SunOS 5 and `wini386` in Windows.

2. Copy all files from `$(sdtdir)/RTOS/Examples/Simple/<selected RTOS>/TightIntegration` to the working directory.
3. Copy all files from `$(sdtdir)/RTOS/Examples/Simple/<selected RTOS>/TightIntegration`/INCLUDE to the INCLUDE directory.
4. Open the system file `$(sdtdir)/RTOS/Examples/Simple/simle.sdt`
5. Change the destination directory to your working directory.
6. Set the options *Lower Case*, *Generate environment header file* and *Generate signal number file*.
7. Select the Cadvanced SDL to C Compiler and generate an application.
8. Edit the `makefile` supplied with the example to fit your environment. Normally you will only have to point out the directory where the RTOS is installed.

9. Use the makefile to build an executable.
10. Download the executable to target or run it under a kernel simulator ("soft kernel").

Result From Running the System

The output when running the example depends on what kind of trace has been enabled. If you set XMSC_TRACE it should be similar to the following:

```
System_Init_Proc: instancehead process Environment;
msc RTOS_Trace;
Pr11: instancehead process Pr1;
Pr12: instancehead process Pr1;
Pr11: condition Idle;
Pr12: condition Idle;
Pr11: in Go,0 from MyExtTask3;
Signal Go received in Pr1:Instance1
dynpr14: instancehead process dynpr1;
Pr11 : create dynpr14;
Pr11: condition Wait;
Pr12: in Go,1 from MyExtTask3;
Signal Go received in Pr1:Instance2
dynpr15: instancehead process dynpr1;
Pr12 : create dynpr15;
Pr12: condition Wait;
dynpr14: set T1,2 (5000); /* #SDTNOW(269) */
dynpr14: condition wait;
dynpr15: set T1,3 (5000); /* #SDTNOW(276) */
dynpr15: condition wait;
dynpr14: timeout  T1,2; /* #SDTNOW(5284) */
dynpr14: out Terminating,4 to Pr11;
dynpr14: endinstance;
Pr11: in Terminating,4 from dynpr14;
Pr11: out Ok,5 to MyExtTask3;
Ok received in MyExtTask with paramer = 1
dynpr15: timeout  T1,3; /* #SDTNOW(5463) */
dynpr15: out Terminating,6 to Pr12;
dynpr15: endinstance;
Pr12: in Terminating,6 from dynpr15;
Pr12: out Ok,7 to MyExtTask3;
Ok received in MyExtTask with paramer = 2
```

Setting the XOS_TRACE flag should result in the following output:

```
** Process Pr1:9901455 created **

** Process Pr1:9901456 created **

** Process instance 9901455 **
Pr1: nextstate Idle
```

```
** Process instance 9901456 **
Pr1: nextstate Idle

** Process instance 9901455 **
Pr1: input signal Go
Signal Go received in Pr1:Instance1
Pr1: process dynpr1:9901458 created
Pr1: nextstate Wait

** Process instance 9901456 **
Pr1: input signal Go
Signal Go received in Pr1:Instance2

** Process instance 9901458 **

DynPr1: Set timer T1
Process instance 9901459
DynPr1: nextstate wait

** Process instance 9901458 **
DynPr1: input signal T1
DynPr1: signal Terminating sent
DynPr1: stopped

** Process instance 9901455 **
Pr1: input signal Terminating
Pr1: signal Ok sent
Pr1: dash nextstate
Ok received in MyExtTask with parameter = 1

** Process instance 99014516 **
DynPr1: input signal T1
DynPr1: signal Terminating sent
DynPr1: stopped

** Process instance 99014513 **
Pr1: input signal Terminating
Pr1: signal Ok sent
Pr1: dash nextstate
Ok received in MyExtTask with parameter = 2
```

Standard Model

In the standard model each instance of the Pr1 and the DynPr1 processes will be represented by an OS task (in all four tasks). The environment is represented by a task called `MyExtTask`. This task is external to the SDL system.

Instance Set Model

In the instance set model there will be two OS tasks, one each for Pr1 and DynPr1. The environment is represented by a task called `MyExTask`, just as in the standard model. This task is external to the SDL system.

How Signals are Sent to and from the Environment

There is an external task called `MyExtTask` which is written in C. It sends the signal Go into the SDL system and receives the signal Ok back by using services in the operating system.

The `HOOK_MAIN_AFTER_PROCESS_RELEASE` macro in `scttypes.h` is used to create `MyExtTask` as soon as the SDL system allowed to run.

The source code for the external task is placed in the file `MyExtTask.c`. This file is specific to the selected operating system because it calls the operating system directly.

Tight Integration Code Reference

This section explains data types, procedures and macros used in a Tight Integration (Light Integrations are explained in the Master Library).

General Macros

XPP(x)

The macro `XPP` is used in function declarations to specify the function parameters. It is defined like this:

```
#define XPP(x)  x
```

if function prototypes according to ANSI C can be used.

xptrint

The following type is also always defined:

```
#define xptrint unsigned
```

where `xptrint` should be an `int` type with the same size as a pointer.

xPrsNode and xPrdNode

```
typedef struct xPrsStruct  *xPrsNode;
typedef struct xPrdStruct  *xPrdNode;
```

`xPrsNode` and `xPrdNode` are pointers to structs holding instance data for an instance of a process or a procedure. Note that some parts of the structs are OS-dependent.

xInputAction, xNotInSignalSet ...

These defines specify the different ways of handling a signal.

Macros to Exclude Unnecessary Code

The following macros are defined to exclude unnecessary code for `IdNode` variables etc.:

```
#define XNOSTARTUPIDNODE
#define XOPTSIGPARA
#define XOPTDC
#define XOPTFPAR
#define XOPTSTRUCT
#define XOPTLIT
```

```
#define XOPTSORT
#define XNOUSEOFSERVICE
......
```

Macros to activate Signal-Free-Functions

The following macro must be defined to activate the Signal-Free-Functions. This is necessary if signals and timers with string parameter (dynamic allocated) are used - to avoid memory leaks.

```
#define XFREESIGNALFUNCS
```

If strings not are used as parameters in signals this flag should not be set cause it does lead to some performance deterioration. (Normally this define is set in the make-file).

For timer string parameters the define

```
#define XTIMERSWITHSTRINGPARAMS
```

must be set.

The following macro must be defined to activate the Signal-Free-Functions. This is necessary if signals and timers with string parameter (dynamic allocated) are used - to avoid memory leaks.

```
#define XFREESIGNALFUNCS
```

Default Priorities

One group of macros defines default priorities for processes and signals:

```
#ifndef xDefaultPrioProcess
#define xDefaultPrioProcess      RTOSPRIODEFAULT
#endif

#ifndef xDefaultPrioSignal
#define xDefaultPrioSignal       RTOSPRIODEFAULT
#endif
...
```

Macros to Implement SDL

First in this section is a macro defining the symbol table root:

```
xIdNode         xSymbolTableRoot;
```

XPROCESSDEF_C and XPROCESSDEF_H

These macros define the start-up function for a PAD function. It is this function that is called in the task creation. As mentioned before this function will after some variable initializations call the PAD function. The definition of the start-up function varies in different RTOS, that is why there is a second OS-specific macro here.

STARTUPSIGNAL, ALLOCPRSSIGNAL, etc.

Each signal in an application is assigned a unique integer value. The values 31992 through 32000 are reserved for internal signals like the start-up signal.

Variables in the PAD Function

PROCESS_VARS, PROCEDURE_VARS

These macros define the elements in the `xPrsStruct` and `xPrdStruct` respectively.

YPAD_YSVARP

This macro defines a variable representing a pointer to a signal's parameter area.

YPAD_YVARP

This macro defines the variable `yVarP` which represents the process instance data.

LOOP_LABEL, LOOP_LABEL_PRD, LOOP_LABEL_PRD_NOSTATE

These three macros define the eternal loop inside processes, procedures and procedures without a state.

START_STATE

Each state in a process and procedure is represented as an integer. The Start state will always have the value 0.

Using OSE Trace Features

Note:

IBM Rational has noticed that the OSE-trace feature can make the application crash in some situations. This seems to happen when a SDL process (OSE-task) sends a signal immediately before terminating. If you come across this problem, first check if the application works correctly when generated without OSE-trace.

Annex 1: Integration for OSE Delta

Introduction

This annex briefly describes the OSE Delta models and primitives used in the SDL Suite OSE tight integration. The presentation is focused on the differences from the OSE classic model described in the previous annex.

One section describes how to set up and run a simple test example in both a light and tight integration.

> **Note:**
> Third-party products referred to in this manual may have limitations that have impact on the usability of the SDL Suite. Please consult the supplier's support organization or the third-party product's technical reference documentation for up-to-date information about such limitations.

Principles

This integration is developed with OSE Delta Soft Kernel 3.2 and tested on a Sun workstation with SunOS Release 5.6.

The main differences between the OSE Delta and the OSE Classic model are:

- The OSE Delta model uses three semaphores to avoid synchronization problems in SDL start transitions.
- The timer is implemented in `systimer.c`, which is supplied by ENEA. This is not accurate and is only for demonstration purposes. You will have to supply a suitable timer implementation for the target environment.

Running the Test Example: Simple

Note:

The source file and examples for Tight Integrations are not included in the standard delivery. They are available as free downloads from IBM Rational Support web site.

Prerequisites

This test example is developed as an OSE Delta application on a Sun workstation. The makefile and compilation switches are set up for the application to run under an OSE Simulator for OS68. If you are using another configuration of OSE you probably need to edit the provided makefile.

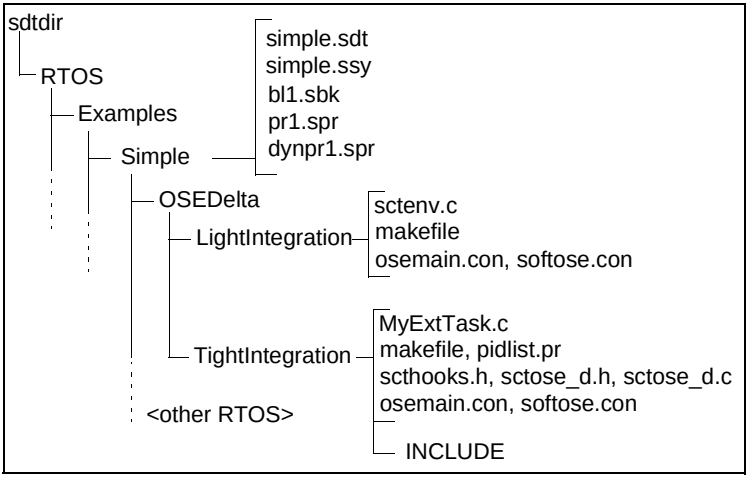

Figure 578: File structure for the Simple example

Light Integration

Limitations for the Light Integration

Please see the Release Guide.

Building a Light Integration

Please see the "Building and Running a Light Integration" on page 3359 for instructions.

Tight Integration

Limitations for the Tight Integration

Please read the Release Guide for details about limitations that apply to all systems using Tight Integration.

Building a Tight Integration

Please see the "Building and Running a Tight Integration" on page 3361 for instructions.

How Signals are Sent to and from the Environment.

The signal Go is sent from an external task `MyExtTask`. The code for this task is placed in the program file `MyExtTask.c`. This is the same as used for OSE Classic.

Annex 2: Integration for VxWorks

Introduction

This annex describes briefly the VxWorks models and primitives used in the SDL Suite VxWorks tight integration. The presentation is focused on the differences from the general model described earlier in this chapter.

One section describes how to set up and run a simple test example in both a light and tight integration.

> **Note:**
>
> Third-party products referred to in this manual may have limitations that have impact on the usability of the SDL Suite. Please consult the supplier's support organization or the third-party product's technical reference documentation for up-to-date information about such limitations.

Principles

This integration is developed with VxWorks Tornado 1.0 version and tested under VxSim version 5.3 on a Sun workstation with SunOS 4.1.4.

The main differences between VxWorks and the general model are:

- The VxWorks `msgQReceive` copies the Signal into a buffer when it is received. The sender makes free of the signal immediately after it has been sent and the receiver allocates a buffer (signal) before a receive statement.
- An extra optimization flag `XOPTSIGNALALLOC` has been introduced for the VxWorks tight integration. When freeing a signal’s memory, we place it in an availlist so that subsequent signal memory allocation calls can check to see if suitable sized memory already exists which may be reused. Otherwise memory is allocated as normal.

Running the Test Example: Simple

Note:

The source file and examples for Tight Integrations are not included in the standard delivery. They are available as free downloads from IBM Rational Support web site.

Prerequisites

This test example is developed as a VxWorks Tornado application on a Sun workstation. The makefile and compilation switches are set up for the application to run under an VxSim target simulator. If you are using another configuration of VxWorks you probably need to edit the provided makefile.

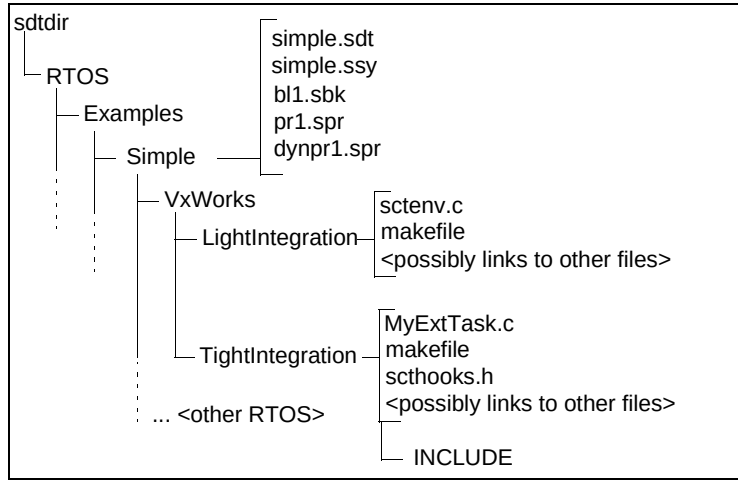

Figure 579: File structure for the Simple example

Note:

A VxWorks application is not allowed to contain a main function. The name of the generated main is changed to “root” with the compilation switch `-DXMAIN_NAME=root`.

Light Integration

Limitations for the Light Integration

Please see the Release Guide.

Building a Light Integration

Please see the "Building and Running a Light Integration" on page 3359 for instructions.

Tight Integration

Limitations for the Tight Integration

Please read the Release Guide for details about limitations that apply to all systems using Tight Integration.

Building a Tight Integration

Please see the "Building and Running a Tight Integration" on page 3361 for instructions.

Annex 3: Integration for Win32

This annex briefly describes integration with Win32. The presentation is focused on the differences from the general model described earlier in this chapter.

> **Note:**
>
> Third-party products referred to in this manual may have limitations that have impact on the usability of the SDL Suite. Please consult the supplier's support organization or the third-party product's technical reference documentation for up-to-date information about such limitations.

Principles

This integration is developed using the Microsoft 32-bit C/C++ Compiler Version 11.00.7022 and tested on NT 4.0, NT 3.51 and Windows 95 platforms.

The main differences between integration with Win32 and the general model are:

- Threads are created with the Win32 primitive CreateThread(). The thread is then automatically given an input queue the first time it calls a USER or GDI function
- xAlloc is implemented with Win32 function `HeapAlloc()`.
- xFree is implemented with Win32 function `HeapFree()`.
- The timer implementation uses the Win32 `GetTickCount()` function.

Running the Test Example: Simple

> **Note:**
>
> The source file and examples for Tight Integrations are not included in the standard delivery. They are available as free downloads from IBM Rational Support web site.

Prerequisites

This test example is developed as a Win32 console application on a PC. The makefiles and compilation switches are set up for the application to compile using the Microsoft compiler listed above.

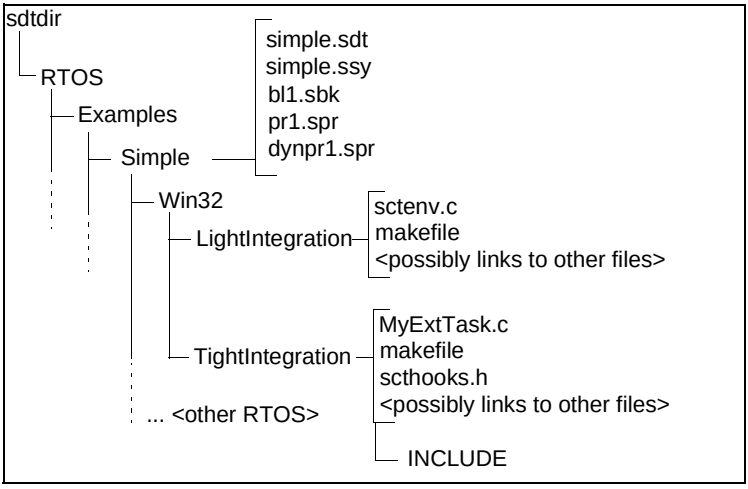

Figure 580: File structure for the Simple example

Light Integration

Limitations for the Light Integration

Please see the Release Guide.

Building a Light Integration

Please see the "Building and Running a Light Integration" on page 3359 for instructions.

Tight Integration

Limitations for the Tight Integration

Please read the Release Guide for details about limitations that apply to all systems using Tight Integration.

Building a Tight Integration

Please see the "Building and Running a Tight Integration" on page 3361 for instructions.

> **Note:**
> The command line length limitation for the Borland compiler can sometimes be exceeded. If this happens, you should define the `DEFINE MACROS` at the beginning of the `sctwin32.h` file.

Compiler Flags

The following defines (`#ifdef`) are used in this integration:

- `WIN32_INTEGRATION`: Ensures that the `sctwin32.h` file is included in each C file. Must be set in all cases.
- `XOS_TRACE`: Gives a textual trace for most of the SDL events by using printf to some device. This flag should not be used together with `XMSC_TRACE`.
- `XMSC_TRACE`: Will give a textual trace in the format of MSC/PR Z.120 by using printf. This trace is possible to view in the MSC Editor. This flag should not be used together with `XOS_TRACE`.
- `XMSC_EDITOR`: Used together with the `XMSC_TRACE` flag, the MSC trace is automatically displayed in the MSC Editor. Note that you must have the Organizer open on your machine.
- `X_ONE_TASK_PER_INSTANCE_SET`: States that the Instance Set Model is used. The Standard Model is otherwise chosen by default.
- `XERR`: When this flag is defined, the return status of all Win32 function calls will be printed.
- `XINCLUDE_HS_FILE`: Includes the system signal header file which is required for tight integrations. This file maps signal names to integers.

- XRTOSTIME: Should always be set for all tight integrations.
- XUSING_SCCD: This should be set when using the preprocessor SCCD to ensure that the windows header files are not included on the preprocessor pass. The files are included though on the compiler pass and this ensures that the preprocessed C files only contain the expanded the SDL Suite macros. It also helps greatly to speed up the process. Note that this flag only works with the Microsoft compiler and should not be used with any other compiler.
- XWINCE: This flag allows you to compile the integration for Microsoft WinCE target systems. This flag should not be used together with the MSC trace flags.

Annex 4: Integration for Solaris 2.6

Introduction

This annex describes briefly the Solaris 2.6 model and primitives used in the SDL Suite Solaris 2.6 tight integration. The presentation is focused on the differences from the general model described earlier in this chapter.

One section describes how to set up and run a simple test example for a tight integration.

Note:

The Solaris 2.6 tight integration is fully POSIX compliant. For this reason it will not work with earlier versions of Solaris.

Note:

Third-party products referred to in this manual may have limitations that have impact on the usability of the SDL Suite. Please consult the supplier's support organization or the third-party product's technical reference documentation for up-to-date information about such limitations.

Principles

This integration is developed using cc:WorkShop Compilers 4.2 with Solaris 2.6 running on a workstation.

The main differences between the Solaris 2.6 integration and the general model are:

- In the file `sctsolaris.h`, the macros which contain the Solaris 2.6 specific function calls are implemented. The file `sctsolaris.c` contains the Solaris 2.6 integration specific functions.
- The Solaris 2.6 integration is fully POSIX compliant. SDL processes are mapped to POSIX threads using the `pthread_create()` function and POSIX queues are created for each thread using `mq_open()`. The threads are suspended when its corresponding queue is empty.

Running the Test Example: Simple

Note:

The source file and examples for Tight Integrations are not included in the standard delivery. They are available as free downloads from IBM Rational Support web site.

Prerequisites

This test example is developed as a Solaris 2.6 application on a workstation. The makefile and compilation switches are set up for the application to run under Solaris 2.6 using the cc:WorkShop Compilers 4.2 compiler.

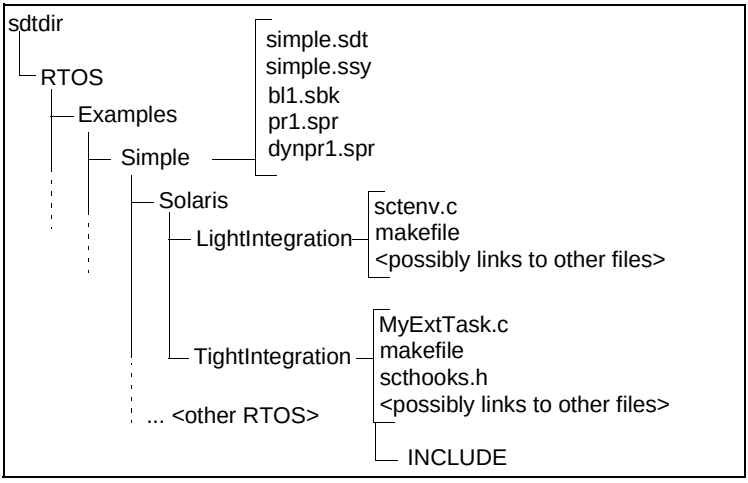

Figure 581: File Structure for the Simple example.

Light Integration

Limitations for the Light Integration

Please see the Release Guide.

Building a Light Integration

Please see the "Building and Running a Light Integration" on page 3359 for instructions.

Tight Integration

Limitations for the Tight Integration

Please read the Release Guide for details about limitations that apply to all systems using Tight Integration.

Building a Tight Integration

Please see the "Building and Running a Tight Integration" on page 3361 for instructions.

Compiler Flags

The following defines (`#ifdef`) are used in this integration:

- `SOLARIS_INTEGRATION`: Ensures that the `sctsolaris.h` file is included in each C file. Must be set in all cases.
- `XOS_TRACE`: Gives a textual trace for most of the SDL events by using printf to some device. This flag should not be used together with `XMSC_TRACE`.
- `XMSC_TRACE`: Will give a textual trace in the format of MSC/PR Z.120 by using printf. This trace is possible to view in the MSC Editor. This flag should not be used together with `XOS_TRACE`.
- `XMSC_EDITOR`: Used together with the `XMSC_TRACE` flag, the MSC trace is automatically displayed in the MSC Editor. Note that you must have the Organizer open on your machine.
- `X_ONE_TASK_PER_INSTANCE_SET`: Should be defined when the alternative runtime model is to be used.
- `XINCLUDE_HS_FILE`: Includes the system signal header file which is required for tight integrations. This file maps signal names to integers.
- `XRTOSTIME`: Should always be set for all tight integrations.

Annex 5: Generic POSIX Tight Integration

Introduction.

Note:

The Generic POSIX integration is based on the Solaris integration. For a description and instructions on how to generate and run the example see “Annex 4: Integration for Solaris 2.6” on page 3379.

Annex 6: Building a Threaded Integration

Introduction

This Tutorial, on how to create a Threaded integration, is developed on a Windows machine and is intended to be run under a Windows OS. If you want to use this example on another machine and for another OS, please remember to choose the appropriate integration and compiler for your OS in the Targeting Expert.

Preparations

The same SDL source files for the example Simple, that is used in the Light integration example will be used in this tutorial.

Copy the Source files for the Example: Simple

1. Create your own test directory and enter it.
2. Copy the SDL source files for the example Simple:

   ```
   cp <installation>/sdt/sdtdir/RTOS/Example/Sim-
   ple/*.s*
   ```

3. Copy the environment file from the Win32/ThreadedIntegration directory:

   ```
   cp <your Installation>/sdt/sdtdir/RTOS/Examples/Sim-
   ple/Win32/ThreadedIntegration/MyExtTask.c
   ```

4. Start the SDL Suite and open the system file for the Simple example.

Partition the system using the Deployment Editor

1. Create a new deployment diagram and call it Simple.
2. Edit the deployment diagram according to the figure below, see : Signalling in Threaded Integration.

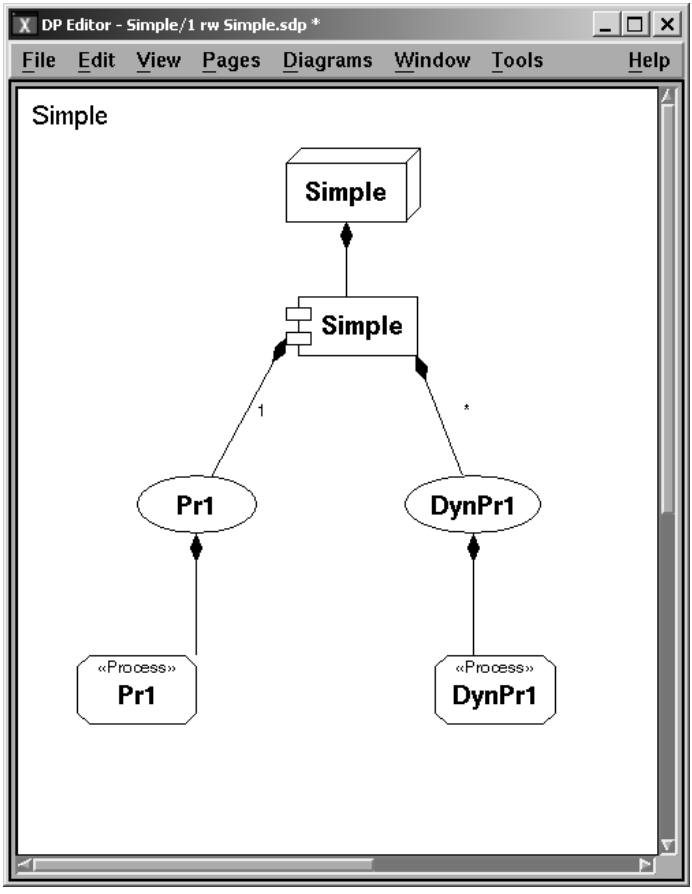

Figure 582 Deployment Diagram for the example Simple

3. Make sure that you got the multiplicity right on the aggregation line from the component to thread.

   To check this you can double click on the line. The right value should be:

   – 1 - On aggregation line from component to thread Pr1.

   – * - On aggregation line from component to thread DynPr1.

The multiplicity on the aggregation lines specifies how the component should be mapped to threads.

– A '*' means that each instance of the component should be mapped to an individual thread.

– A name means that the entire component should be mapped to a thread.

In our example this means that there should be one thread for **all** instances of Pr1 and one thread for **each** instance of DynPr1.

4. Double-click the component symbol. In the Symbol Details window specify that the integration model should be Threaded, see : Signalling in Threaded Integration.

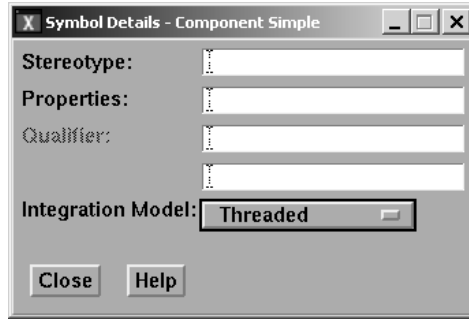

Figure 583 Symbol Details for the Component Simple

5. Double-click the thread symbol for Pr1. Specify the following Thread Parameters for the Thread P1:

   Thread Stack Size = 2048
   Thread Priority = 8
   Queue Size = 128
   Max Signal Size = 1024

6. Double-click the object symbol and specify that the stereotype should be Process and that the qualifier (for Pr1) should be:

   – Simple/Bl1/Pr1.

   Make the appropriate specifications for the object Symbol for DynPr1(Qualifier = Simple/Bl1/DynPr1).

7. Save the deployment diagram.
8. Select the deployment diagram in the Organizer and open the Targeting Expert from the Generate menu.
9. Choose the integration: Threaded Integrations->Win32 threaded.
10. You will be prompted if you want to generate the sdl_cfg.h file. Select No!
11. Disable the Generation of Environment Function by deselecting Environment Functions in the Environment section of the window.
12. Click on the Compiler/Linker/Make line in the Partitioning Diagram Model. You should now see the following in the Targeting Expert window, see:: The Compile/Linker/Make Window in Targeting Expert.

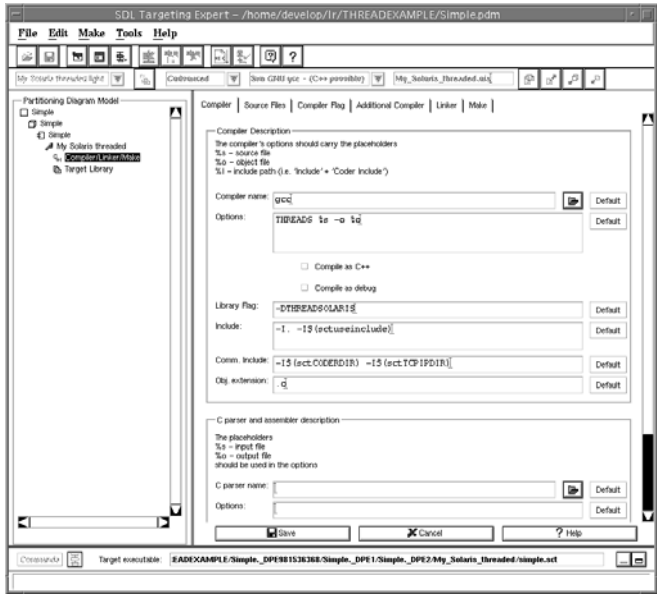

Figure 584: The Compile/Linker/Make Window in Targeting Expert.

13. Define the following flag: THREADED_SIMPLE_EXAMPLE in the Compiler description/Options window. This flag will start the External threads in the simple example.

14. Define the following Compilation flags:

    – THREADED_XTRACE,

    – THREADED_MSCTRACE

    by selecting the flags: *SDL trace and MSC* trace in the *Target library/Kernel window*

15. Add the `MyExtTask.c` file as a new source file.

    Click on the Source Files entry in the window and add the `MyExtTask.c` file in the source file list.

    Save the settings. You are now prompted again to generate configuration file, this time select Yes.

16. You should now be back in the Analyze/Generate code window and be ready to generate the application.

    Do a full Make and if you have followed the instructions the Targeting Expert will now analyze, generate code, generate makefile, compile and link the application.

17. Run the application simple.sct. Please note that you have to traverse down in the generated directory structure to find the application.

    You will find the application in a subdirectory similar to this path:

    – `<your test directory>/Simple._DPE981536368/Simple._DPE1/Simple._DPE2/Win32_threaded/....`

The output you should see when you run the application should be as follows:

```
Connected with the Postmaster.
*   OUTPUT of go to Pr1:1
*      Parameter(s) : 1
*** NEXTSTATE  Idle
*   OUTPUT of go to Pr1:2
*      Parameter(s) : 2
*** NEXTSTATE  Idle
Signal Go received in Pr1:Instance1
*   CREATE DynPr1:1
*** NEXTSTATE  Wait
Signal Go received in Pr1:Instance2
*   CREATE DynPr1:2
*   SET on timer t1 at 17.5580
*** NEXTSTATE  Wait_t1
*** NEXTSTATE  Wait
*   SET on timer t1 at 17.5880
*** NEXTSTATE  Wait_t1

*** TIMER signal was sent
*   Timer    : t1
*   Receiver : DynPr1:1
*** Now      : 17.5650
*   OUTPUT of t1 to DynPr1:1
*   PROCEDURE START Prd
Not doing much
*   PROCEDURE RETURN Prd
*   OUTPUT of terminating to Pr1:1

*** TIMER signal was sent
*   Timer    : t1
*   Receiver : DynPr1:2
*** Now      : 17.6050
*   OUTPUT of t1 to DynPr1:2
*** STOP   (no signals were discarded)
*   PROCEDURE START Prd
*   OUTPUT of ok to env:1
*      Parameter(s) : 1
Signal Ok received with the following parameter:1
*** NEXTSTATE  Wait
Not doing much
*   PROCEDURE RETURN Prd
*   OUTPUT of terminating to Pr1:2
*** STOP   (no signals were discarded)
*   OUTPUT of ok to env:1
*      Parameter(s) : 2
Signal Ok received with the following parameter:2
*** NEXTSTATE  Wait
```

Chapter 64 Integration with Operating Systems

Chapter

65

The Cmicro SDL to C Compiler

The Cmicro SDL to C Compiler translates your SDL system into a C program that you can compile together with the Cmicro Library and the SDL Target Tester target library. The Cmicro Library and the SDL Target Tester target library is not available as a pre-linked library but is delivered as source to enable scaling of the kernel. The scaling is dependent upon the SDL system characteristics. This chapter is a reference manual for the Cmicro SDL to C Compiler.

- **In chapter 66, *The Cmicro Library*, you will find information about how to customize your own libraries for specific purpose, such as application generation for target computers. The chapter also describes the structure of the generated C code and the internal data structures in the generated C code. The Cmicro Library is only of use when compiled with the code which is generated by the Cmicro SDL to C Compiler.**
- **In chapter 67, *The SDL Target Tester*, you will find a reference to the features, which enables testing in a host-target environment. The SDL Target Tester is applicable for the Cmicro SDL to C Compiler and the Cmicro Library only.**

Application Area for the Cmicro SDL to C Compiler

The application area for the Cmicro SDL to C Compiler is:

- Generation of applications, including embedded system applications with real time characteristics (Configuration: Cmicro Library and generated C code running on target).
- Generation of target debug applications, including embedded system applications with real time characteristics (Configuration: Cmicro Library, generated C code and SDL Target Tester running on target).

In this part of the chapter, the general behavior of the Cmicro SDL to C Compiler, as seen from the users point of view, is discussed.

Highly Optimized Code for Target

The generated code in combination with the Cmicro Library is highly optimized, which is unavoidable for microcontrollers and real-time applications. Some optimizations have been possible only by introducing restrictions in the use of SDL. Other optimizations have been possible by generating more compact code. For the restrictions in the use of SDL please see "SDL Restrictions" on page 3450. Details regarding the output of the Cmicro code generation can be found in "Output of Code Generation" on page 3418.

Target Debug

With the generated code it is possible to debug the application on the target using the Cmicro Library and the SDL Target Tester library. The parts of the Cmicro code generation which are used for the SDL Target Tester are also highly optimized. Please see chapter 67, *The SDL Target Tester*.

Overview of the Cmicro SDL to C Compiler

The SDL Analyzer, which can be invoked from the Organizer, contains an SDL parser, an SDL semantic checker, and – among other code generators – the Cmicro SDL to C Compiler.

Many options can be chosen from the user which affect the analysis of the SDL system. Furthermore, a lot of error checks are performed automatically before code generation starts. This makes it possible to improve written SDL specifications before any run-time testing must be done.

The options that the user may choose for analysis and the error checks that are performed by the analyzer are described in chapter 54, *The SDL Analyzer*.

At some places the Cmicro SDL to C Compiler can be used in exactly the same way as the Cadvanced/Cbasic SDL to C Compiler can be used. At some other places the use of this C Code Generator, or what this C Code Generator produce, is different.

The Cmicro SDL to C Compiler generally can process the same input as the Cadvanced/Cbasic SDL to C Compiler can. The differences are explained within this chapter.

The differences in the output of the both code generators are described within the subsection "Output of Code Generation" on page 3418.

The overall differences of the both code generators are described in the section "Differences between Cmicro and Cadvanced" on page 3456 in chapter 66, *The Cmicro Library*.

The following subsections describe how the Cmicro SDL to C Compiler might be used.

Generated Files

The C files, which are generated by the Cmicro SDL to C Compiler, can only be used in connection with the Cmicro Library and the SDL Target Tester. It is not possible to validate and simulate the SDL system with the C code generated by Cmicro as this code is only suitable for target applications. To simulate and validate the SDL system within the SDL Suite, the user has to choose the Cbasic SDL to C Compiler. In order to view the process of generating C applications see the Organizer's *Make* dialog in chapter 2, *The Organizer*.

The SDL Analyzer, which contains the Cmicro SDL to C Compiler can also be started as a stand-alone tool. For more information about this possibility please see *chapter 54, The SDL Analyzer*.

There are several steps that must be carried out before the generated C files can be compiled and linked together with the Cmicro Library. The user should follow the procedures that are documented in the section "Targeting using the Cmicro Package" on page 3481 in chapter 66, *The Cmicro Library*.

In the following subsections the different files that are generated are explained.

Generated Configuration File

The first file that is generated from the Cmicro SDL to C Compiler is called `sdl_cfg.h`. It is used to scale the Cmicro Kernel depending on what characteristics the SDL system has. This is called automatic scaling and automatic dimensioning facility.

The file contains a header, process ID declarations, and then a `#define` or a `/*NOT define ... */` for each of the flags that the Cmicro SDL to C Compiler can generate automatically.

Example 571: The Header of an sdl_cfg.h ----------

```
/* Program generated by SDL Suite.Cmicro <version> <date> */

#ifndef XSCT_CMICRO
#define XSCT_CMICRO
#endif

/* "sdl_cfg.h" file generated for system <systemname> */

#define XMK_CFG_TIME <GenerationTime>
```

The XMK_CFG_TIME macro is used internally when compiling and executing with the SDL Target Tester takes place. With this macro, a rough consistency check for the generated files is done. The <GenerationTime> of the different files that are generated is compared in the Library and by the SDL Target Tester. If there is an inconsistency, compilation errors will occur.

The rest of the file sdl_cfg.h is about the automatic scaling and automatic dimensioning of the SDL system. It may look for example like:

Example 572: The Tail of an sdl_cfg.h ----------

```
#define MAX_SDL_PROCESS_TYPES <N>
#define XMK_USED_ONLY_X_1
#define MAX_SDL_TIMER_TYPES <X>
#define MAX_SDL_TIMER_INSTS <Z>
#define XMK_HIGHEST_SIGNAL_NR 4
/* NOT #define XMK_USED_TIMER */
/* NOT #define XMK_USED_DYNAMIC_CREATE */
/* NOT #define XMK_USED_DYNAMIC_STOP */
/* NOT #define XMK_USED_SAVE */
#define XMK_USED_SIGNAL_WITH_PARAMS
/* NOT #define XMK_USED_TIMER_WITH_PARAMS */
/* NOT #define XMK_USED_SENDER */
/* NOT #define XMK_USED_OFFSPRING */
/* NOT #define XMK_USED_PARENT */
/* NOT #define XMK_USED_SELF */
/* NOT #define XMK_USED_PWOS */
/* NOT #define XMK_USED_INITFUNC */
```

For a first rough understanding of the meaning of the different flags: The SDL system from above contains <N> process types (using SDL'88 terminology), all the processes are declared in the form (0,1) or (1,1). There are <X> timers declared (in this case, <X> must be 0, because XMK_USED_TIMER is undefined, and the system uses an amount of <Z> signals. The system does not use any create or stop (XMK_USED_DYNAMIC_CREATE and XMK_USED_DYNAMIC_STOP are undefined). In this way all the other flags have special meaning.

For explanations about the different flags the user should refer to "Automatic Scaling Included in Cmicro" on page 3519 in chapter 66, *The Cmicro Library*.

Generated C File

Assumed, that the user selected *"No separation"* in the Organizer's Make Dialog, and no partitioning is used, then the Cmicro SDL to C Compiler will generate one C file per SDL system. This file contains all the characteristics of the SDL system including all the declarations that

the SDL system itself needs. For an explanation of this file see "Output of Code Generation" on page 3418.

Generated Environment Header File

There is one file generated from the Cmicro SDL to C Compiler that contains all the definitions and declarations that are necessary to implement the environment functions `xInEnv` and `xOutEnv`.

The file is generated only if the option *Environment header file* in the Targeting Experts is switched on.

The file is called `<systemname>.ifc` and it contains a header, the type definitions used on system level (newtypes, syntypes, synonyms), the signal IDs and the structure type definitions for the parameters of the signals.

The `IFC_FILENAME` macro is defined when generating code from the Make dialog, i.e. when using the comp.opt and make.opt files. The macro is not automatically defined when using Targeting Expert. The macro contains the full path to the ifc file, even if that file has been chosen not to be generated.

Typical usage of this macro is to include the ifc file when implementing the environment functions or whenever you would like to include the ifc file in external code.

Example 573: Compiler options macro when using Targeting Expert–

```
-DIFC_FILENAME=
"'C:\MyProject\MySys._0\Application_CA\MySys.ifc'"
```

If Targeting Expert is used and you would like to use the `IFC_FILENAME`, you must define the macro by yourself in the compiler options.

Example 574: The Header of an <systemname>.ifc file–

```
#ifndef X_IFC_z_env01
#define X_IFC_z_env01
#define XMK_IFC_TIME <GenerationTime>
```

The `XMK_IFC_TIME` macro is used internally when compiling and executing with the SDL Target Tester takes place. With this macro, a rough consistency check for the generated files is done. The

<GenerationTime> of the different files that are generated is compared in the Library and by the SDL Target Tester. If there is an inconsistency, compilation errors will occur.

Caution!

As there are defines generated that contain no prefixes, there might be compiler warnings like `Illegal redefinition of macro`. Such redefinitions should never be ignored because fatal errors during run-time may occur. The user should introduce a prefix for signals or sorts with different meaning on SDL level, in order to map these names to unambiguous identifiers in C.

More explanation about the environment header file is given in chapter 66, *The Cmicro Library*.

Sorts

Followed by the header the section about sorts follows. The sorts are generated according to the documentation in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*.

Signal IDs and Parameter Structures

Next, the definitions for signals follows, which consists of:

- A C comment with a comment explaining if the signal is `IN` or `OUT` as seen from SDL
- An optional declaration of a C structure type definition (if the signal carries parameters)
- The definition of the signal ID

For easy interpretation: For an SDL signal **without** parameters, going from the environment to SDL, like:

```
signal SIn;
```

the following is generated into the `.ifc` file:

```
/* SIn IN */
#define SIn  <X>
```

For an SDL signal **with** parameters, going from SDL to the environment, like

```
signal SOut (integer, mystruct, boolean);
```

the following is generated into the `.ifc` file:

```
/* SOut OUT */
typedef struct {
    SIGNAL_VARS
    SDL_Integer  Param1;
    mystruct     Param2;
              /* mystruct declared in the section */
              /* declaring sorts                  */
    SDL_Boolean  Param3;
} yPDef_<UniquePrefix>_SOut;

typedef yPDef_<UniquePrefix>_SOut  *yPDP_<UniquePrefix>_SOut;
#define yPDP_SOut                  yPDP_<UniquePrefix>_SOut
#define yPDef_SOut                  yPDef_<UniquePrefix>_SOut
#define SOut                       <X>
```

At least the signal ID (here: `SOut`) and the name of the structure (here: `yPDef_SOut`) must be used in the `xOutEnv` C function in this case.

The code generation of structure types and signal IDs is (except the C comment about `IN` or `OUT`) independent from the direction the signal goes.

Process IDs

At last the process ID declarations are generated as `#define` values in C, like:

```
#define XPTID_<auto-prefix>_MyProcess 0
```

where the first process in the system is the value of 0 assigned, the second process gets the value 1, and so on. Due to the implementation of SDL'92 object orientation in the Cmicro SDL to C Compiler, there is also an automatic prefix generated. Using this prefix in the user's environment functions, it is possible to distinguish between several processes with the same name. Please refer to "Generation of Identifiers" on page 3446 for more information.

Generated Make File

The Cmicro SDL to C Compiler generates a file that contains production rules for the C program. This file can be used together with "make" facility only. The file is called `<systemname>.m`.

Additionally there is an ASCII file called `<systemname>_gen.m` which gives a list of all the generated files. This files is used by the Targeting Expert to generate a makefile. Please see "Generated Makefile" on page 2997 in chapter 59, *The Targeting Expert*.

Generated Symbol File

The generated symbol file is used to store symbolic information about the SDL system. The file has meaning for the host part of the SDL Target Tester only and is called `<systemname>.sym`. It is used for SDL Target Tester purposes only and is described within "The Host Symbol Table" on page 3731 in chapter 67, *The SDL Target Tester*.

Generated Kernel Group File

The generated kernel group file contains information about process names. This file is especially used in integrations, when OO is used and processes are instantiated. Using the information from this file, it is possible to distinguish between several process instantiations with the same name.

Implementation

In this section the implementation details are discussed. These details are meaningful for understanding how a generated Cmicro application does work.

Time

For host simulation, with the predefined integration settings, a time unit represents one second. In target applications, time is to be implemented by the user (see subsection "Defining the SDL System Time Functions in mk_stim.c" on page 3528 in chapter 66, *The Cmicro Library*).

Real Time

If real time is used, then there will be a connection between the clock in the executing program and the wall clock. For applications the user must provide the connection with the wall clock, normally the hardware timer.

> **Note:**
>
> The C standard function `time` used as the real time clock returns the time in seconds. The implementation of the clock can be changed by re-implementing the function `xmk_NOW` in `mk_stim.c`.

Scheduling

The Cmicro Kernel does not use a process ready queue. It processes the signals in the order of their appearance. To do this, there is a signal queue which stores the signals sent to any process (either internally or externally). There are different ways to influence the scheduling when using the Cmicro SDL to C Compiler:

- assigning priorities to processes
- assigning priorities to signals
- any combination of process and signal priorities

Assigning Priorities to Processes – Preemptive Scheduling

It is possible to assign priorities to process types (using SDL'88 terminology). The processes' priorities are assigned when designing the SDL system. They are assigned using the #PRIO directive.

There are some things to be kept in mind when using process priorities:

- Priorities have to begin with zero.
- Priorities have to be consecutive.
- All instances of a type have the same priority (SDL'88 terminology).
- Priority decreases with increasing numbers (zero is the highest priority level).
- The default priority is to be in the range of zero to the lowest priority number.

The Cmicro Kernel handles process priorities by collecting all signals sent to processes of the same priority in a separate queue. Thus, there is a queue for each priority level.

While the SDL system is running the kernel checks for signals in the queues with decreasing priority. This check takes place whenever an SDL output appears or a process performs an SDL nextstate operation. Because of the kernel checking for signals whenever an output takes place, it is possible to have preemptive scheduling.

Assume, there are two process types lowprio and highprio. Let process type lowprio have the priority one and process type highprio have the priority zero.

If an instance of process type lowprio performs an output to process type highprio, there appears a signal in a queue of a higher priority level (zero is the highest priority level available, process lowprio has priority one) which leads to the kernel immediately working on the signal sent to the process highprio. The transition of process lowprio will not end until process highprio has finished its transition invoked by the signal.

This way of scheduling is implemented using recursion.

Note:

Process priorities are available only when using a compiler which can handle recursion.

There is basically no restriction on the number of priority levels, but the target and compiler used will of course limit the depth of recursion.

As a general recommendation process priorities should not be assigned one per process type, but the process types should be grouped according to their purposes and these groups should then be assigned a priority level.

Assigning Priorities to Signals

The signals in the queue(s) are normally ordered according to their appearance (FIFO-strategy). By assigning priorities to signals this ordering is user definable. The directive #PRIO is used to assign a priority to signals.

Priority increases with decreasing numbers, but there is no restriction to use consecutive numbering.

Whenever a signal is sent, it is inserted into the signal queue(s) according to its priority.

Assume, there is a process performing two signal outputs, first_sig and second_sig. Using the standard FIFO-strategy signal first_sig would be worked on before signal second_sig. But with signal priorities and signal first_sig assigned priority fifty and signal second_sig assigned priority twenty, signal second_sig would be in front of signal first_sig in the queue and thus would be worked on before signal first_sig.

For more details please refer to "Assigning Priorities – Directive #PRIO" on page 3415.

Combinations of Signal/Process Priority

Every combination of signal and process priorities may be used. In this way it is possible to adapt the scheduling to the users' needs.

Note:

Without process priorities a transition once started will have to be finished before the next transition can be dealt with. This is valid regardless of the time it will need to finish a transition.

Synonyms

External Synonyms

External synonyms can be used to parameterize an SDL system and thereby also a generated program. The values that should be used for the external synonyms must be included as macro definitions into the generated code, for instance by including another header file.

Using a Macro Definition

To use a macro definition in C to specify the value of an external synonym, the user should perform the following steps:

1. Write the actual macro definitions on a file.

   Example 575: Macro Definition

   ```
   #define synonym1 value1
   #define synonym2 value2
   ```

   The synonym names are the SDL names (without any prefixes).

2. Introduce the following `#CODE` directive at the system level among the SDL definitions of synonyms, sorts, and signals, for example, but before any use of the synonyms.

   Example 576: #CODE Directive

   ```
   /*#CODE
   #TYPE
   #include "filename"
   */
   ```

If this structure is used, the value of an external synonym can be changed merely by changing the corresponding macro definition and recompiling the system.

Procedure Calls and Operator Calls

In SDL-92, value returning procedures and operator calls are introduced. This means, that an SDL procedure can be called within an expression. As the Cmicro SDL to C Compiler cannot handle procedures with states, it is not necessary to map such calls to a different scheme.

Example 577: Procedure Call

```
TASK i := (call p(1)) + (call Q(i,k));
```

is translated to something like:

```
i = p(1) + Q(i,k);
```

Note:

The value returning procedure calls are transformed to C functions which return values.

Operators which are defined using operator diagrams, are as in the models in the SDL recommendation, treated exactly as value returning procedures.

Generation of PAD function

The code generation for the PAD function is different compared with Cadvanced, in the way that code that is common in process types is copied into the PAD function for instantiated processes. This is implemented in contrast to Cadvanced, where for each process type definition there is a C function generated once, that is called by the instantiated PAD function, for common code. This makes a difference when system partitioning and/or file separation is used.

Any

‘Any’ should not be used in applications using the Cmicro SDL to C Compiler, as it leads to an error message.

Calculation of Receiver in Outputs

The Cmicro SDL to C Compiler is a code generator using the semantics of SDL-92 with some restrictions. The behavior for output is according to the rules described in the following:

- For an output without TO and without VIA in SDL, the Cmicro SDL to C Compiler calculates the receiver of the signal during code generation. If there is more than one possible receiving process type, then an error message will be printed out.
- For an output without TO and without VIA in SDL, it is also possible to have one process type, but more than one receiving instance of the signal. The response is that any of the living possible receivers may be selected during execution time. If no receiver is found, the C function `ErrorHandler` will be called.
- For an output with the VIA clause, the behavior of the Cmicro SDL to C Compiler is in principle the same as for an output without TO It computes the possible receivers in an output with the VIA clause and if there are several possible receivers, an error message is produced. The only difference between output with VIA and output without TO is that VIA can restrict the amount of possible processes.
- If output with TO is used in the above cases, no ambiguity can occur. The addressing of the process is then performed by a run-time variable.
- The possibility of specifying the name of a process when using OUTPUT TO is implemented. This is an SDL-92 feature. The Cmicro SDL to C Compiler behaves in the same way as when using implicit addressing (output without to).
- The broadcast feature of SDL-92 (VIA ALL) is not implemented, because it is not a real broadcast and not very useful for Cmicro Applications.

Abstract Data Types

In this section the specialities and exceptions about abstract data types for Cmicro are discussed only. A complete documentation about the abstract data types is given in chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*.

General C Definitions

All the macros and external definitions for functions can be found in the file `sctpred.h` except for the PId sort which is handled in the file `ml_typ.h`.

The C functions for the handling of predefined sorts are defined in the file `sctpred.c`.

On UNIX these files can be found in `$sdtdir/cmicro/kernel`.

In Windows these files can be found in the installation under `%SDTDIR%\cmicro\kernel`.

Exceptions for SDL Predefined Types

A general exception existing for all the predefined types is that the user must configure which predefined types are to be compiled into the target C program. This is necessary to hold the target C program as small as possible. The configuration is to be performed with the help of the Targeting Expert, please view "Configure and Scale the Target Library" on page 2946 in chapter 59, *The Targeting Expert*.

Caution!

Problems will occur during compilation when the configuration is not according to what the SDL system needs. The user should refer to the explanations about manual scaling in chapter 66, *The Cmicro Library*.

External Synonyms

External synonyms are to be defined by the user in the following way.

For a synonym like

```
synonym xternal integer = EXTERNAL;
```

Cmicro expects to see `xternal` as a `#define` value that is to be defined by the user. This can be done for example in the following way:

```
synonym xternal integer = EXTERNAL;
/*#CODE
#TYPE
#ifdef XSCT_CMICRO
#define xternal 7
#endif
*/
```

This also means, that if `xternal` is not defined from the user, it will lead to compilation errors.

Charstring

Charstrings can be used either in the usual way as they are when using Cadvanced, or they can be used in a restricted way. The decision is up to the user and is a question of configuration. The user should be aware that some of the predefined sorts from ASN.1 are based on the implementation of SDL charstrings. This is discussed in subsection "Support of SDL Constructs" on page 3510 in chapter 66, *The Cmicro Library*.

Time/Duration

The predefined data types Time and Duration are implemented in a more or less restrictive way. It is possible to specify a real value for Time and Duration on SDL level, like 23.45. The Cmicro Library uses only the integer part in front of the dot, 23 in this example. The mapping of SDL time units to time units in a target application is – in any case – up to the user.

UnionC

The #UNIONC directive is not recommended when using the Cmicro SDL to C Compiler because there is no support for checking the validity of the component selection. Both the #UNION directive and the CHOICE concept are a better alternative.

Predefined Generators Array, String, Powerset, Bag, Ref

These generators are implemented in Cmicro, but the user should be aware that the use of any of them requires that dynamic memory allocation is used in the target system. Generally, Cmicro tries to prevent the use of dynamic memory allocation whenever possible. The reasons for this are explained in chapter 66, *The Cmicro Library*.

ctypes.sdl

This package can be used together with Cmicro with the following restriction.

There are two operators that are excluded when Cmicro C code is compiled. The operators are "`CStar2CString`" and "`CharStar`".

The reason for this is that with Cmicro it is possible to define an array of char in C instead of the predefined solution of Cadvanced (to use dynamic memory allocation). This is discussed in subsection "Support of SDL Constructs" on page 3510 in chapter 66, *The Cmicro Library*.

byte.pr

This ADT can be used together with Cmicro in the same way as described for Cadvanced.

file.pr

This ADT is not useful for typical Cmicro applications (embedded systems usually do not provide a hard disk in Cmicro applications) and for that reason never has been tested. The ADT may however work with Cmicro.

idnode.pr

This ADT **cannot** be used together with Cmicro because it refers to Cadvanced code.

list1/list2.pr

This ADT **cannot** be used together with Cmicro because it refers to Cadvanced code.

long_int.pr

This ADT can be used together with Cmicro.

pidlist.pr

This ADT **cannot** be used together with Cmicro, generally.

Instead of `pidlist.pr`, the user may include the `cm_pidlist.pr` file. The use of this ADT is however restricted, because Cmicro implements a different scheduling algorithm. This means, that systems that

are successfully simulated first, may contain problems when a Cmicro target application is build and executed.

It is therefore recommended **not** to use neither `pidlist.pr` nor `cm_pidlist.pr`, in order to achieve the best possible SDL conformity.

random.pr

This ADT **cannot** be used together with Cmicro because it refers to Cadvanced code.

unsigned.pr

This ADT can be used together with Cmicro.

unsigned_long.pr

This ADT can be used together with Cmicro.

Default Values

Default values are in principle generated in the same way as with the Cadvanced SDL to C Compiler. It is however possible to configure the default value setting, which is explained in chapter 66, *The Cmicro Library*. The right configuration is essential to prevent illegal behavior.

Exceptions for Implementations of Operators

Read and Write Functions

The Cmicro SDL to C Compiler does not provide read and write functions. The reason is, that the Cmicro SDL to C Compiler mainly is used to build target applications, and not simulations. This is also a consequence of optimizing the target program. If the user uses the Q (question) operator, the Cmicro SDL to C Compiler ignores this.

Error Situations in Operators

In the C function used to implement operators (and literals), it is possible to define error situations and handle them as ordinary SDL run-time errors. The C library function `ErrorHandler`, with the following prototype

```
extern void ErrorHandler( xmk_OPT_INT errnum )
```

can be used for this purpose. `xmk_OPT_INT` is defined in `ml_typ.h`, normally as an ordinary C `int`. `errnum` may be one of the free values of error numbers. Please inspect `ml_err.h` in order to get a list of reserved values.

Example 578: Error Handler in Operator

```
  if ( strlen(C) <= 1 ) {
#ifdef XMK_USE_ERR_CHECK
    ErrorHandler (ERR_N_InvalidStringLength);
#endif
    return SDL_NUL;
  } else
    return C[1];
```

This is a simplified version of the test in the function for the operator First in the sort Charstring. Here the error situation is when we try to access the first character in a charstring of length 0. In this case the C function `ErrorHandler` is called and a default value is returned (NULL). By including the call to `ErrorHandler` between `#ifdef XMK_USE_ERR_CHECK - #endif` the function is only called to report the error, if error checks are turned on. The one parameter to the C function `ErrorHandler` should identify the error. The number must be given by the user.

Another possibility to route error messages to the host system is to use the C function `xmk_PrintString` of the SDL Target Tester, defined as:

```
extern void xmk_PrintString( char * )
```

Example 579: Error Handler in Operator

```
  if ( strlen(C) <= 1 ) {
#ifdef XMK_ADD_MICRO_TESTER
    xmk_PrintString ("ERR:Invalid Stringlength");
#endif
    return SDL_NUL;
  } else
    return C[1];
```

Access to Predefined Sorts based on Charstring

As already mentioned in earlier subsections, the user should be aware that some of the ASN.1 predefined sorts are based on the implementation of SDL charstrings. The user should also refer to subsection "Sup-

port of SDL Constructs" on page 3510 in chapter 66, *The Cmicro Library*.

To avoid problems one should be aware that Charstring is implemented as char * in C and take the consequences thereof. There are a number of help functions (that implement the operators for the Charstring sort) supplied in the run-time library that might be helpful when handling Charstrings.

It is usually necessary to allocate dynamic memory when an operator returning a charstring value is implemented. There are two help functions that should be used in connection with allocation and de-allocation of dynamic memory. These are documented in "Dynamic Memory Allocation" on page 3543 in chapter 66, *The Cmicro Library*.

Caution!

Do not use Charstring in SDL if you want to get a correct trace output with the SDL Target Tester, or if you want to use the Cmicro Recorder. In the last case, the use of charstring may lead to a fatal error when an SDL session is replayed.

Exceptions for Directives

Selecting File Structure for Generated Code – Directive #SEPARATE

The purpose of the separate generation feature is to specify the file structure of the generated program. Both the division of the system into a number of files and the actual file names can be specified. There are two ways this information can be given.

- Normally this information is set up in the Organizer, using the command in chapter 2, *The Organizer*. Here file names for the generated files can also be specified. In the *Make* dialog in the Organizer (see "Generated Files" on page 3394) it is possible to select full separate generation, user-defined separate generation, or no separate generation.
- For an SDL/PR file that is generated by running the SDL Analyzer as a stand-alone tool, the same information can be entered by

#SEPARATE directives directly introduced in the SDL program. Full separate file generation, user-defined separate file generation, or no separate file generation can be set up in the command interface of a stand-alone Analyzer, see *"Set-Modularity" on page 2491 in chapter 54, The SDL Analyzer*.

The Cmicro SDL to C Compiler can generate a separate file for:

- System (always separate)
- Block
- Process
- Procedure

Note:

Instantiations cannot be separated. If #SEPARATE directives are used, they should be placed directly after the first semicolon in the system, block, process, or procedure heading; see the following example.

Example 580: #SEPARATE Directive ––––––––––––––––––––––––

```
system S; /*#SEPARATE 'filename' */
block B; /*#SEPARATE */
process type P1 inherits PType; /*#SEPARATE */
process P2 (1, ); /*#SEPARATE */
procedure Q; /*#SEPARATE */
```

––

In the example above the two versions of separate directive, with or without file name, are shown. As can be seen a file name should be enclosed between quotes. The Cmicro SDL to C Compiler will append appropriate extensions to this name when it generates code.

If no file name is given in the directive, the name of the system, block, process, or procedure will be used to obtain a file name. In such a case the file name becomes the name of the unit with the appropriate extension (`.c .h`) depending on contents. The file name is stripped of characters that are not letters, digits or underscores.

The possibility to set up full, user-defined, or no separation in the Organizer's *Make* dialog and in the user-interface of a stand-alone Analyzer (see "Generated Files" on page 3394), can be used in a simple manner

to select certain default separation schemes. This setting will be interpreted in the following way:

- *No* separation.
  The whole system will be generated into one file.
- *User defined* separation.
  The system, each package, and each unit that the user has specified as separate will become a separate file.
- *Full* separation.
  The system, each package, each block, block type, and process, and process type will become a separate file. Note that even in this case a procedure is separate only if the user has specified it as separate.

Independently if *No*, *User defined*, or *Full* separation has been selected, the Cmicro SDL to C Compiler will use the file name specified in the *Edit Separation* dialog or the #SEPARATE directive, for a file that is to be generated.

An Example of the Usage of the Separate Feature

In the following example a system structure and the #SEPARATE directives are given. The same information can easily be set up in the Organizer as well. This example is then used to show the generated file structure depending on selected generation options.

Example 581: #SEPARATE Directive ––––––––––––––––––––––––

```
system S; /*#SEPARATE 'Sfile' */
  block B1; /*#SEPARATE */
    process P11; /*#SEPARATE 'P11file' */
    process P12;
  block B2;
    process P21;
    process P22; /*#SEPARATE */
```

––

Applying Full Separate Generation

If *Full* separate generation is selected then the following files will be generated:

Sfile.c	Sfile.h
B1.c	B1.h

P11file.c	
P12.c	
B2.c	B2.h
P21.c	
P22.c	

The .c files contain the C code for the corresponding SDL unit and the .h files contain the module interfaces.

Applying Separate Generation

If *User defined* separate generation is selected then the following files will be generated:

Sfile.c	Sfile.h	Contains code for units S, B2, P21
B1.c	B1.h	Contains code for units B1, P12
P11file.c		Contains code for unit P11
P22.c		Contains code for unit P22

The user defined separate generation option thus makes it possible for a user to completely decide the file structure for the generated code. The comments on files and extensions given above are, of course, also valid in this case.

Applying No Separate Generation

If the separation option *No* is selected, only the following file will be generated:

Sfile.c		Contains code for all units

The comments on files and extensions earlier are valid even here.

Guidelines

Generally a system should be divided into manageable pieces of code That is, for a **large system**, *full separate generation* should be used, while for a **small system**, *no separate generation* ought to be used. The possibility to regenerate and re-compile only parts of a system usually

compensate for the overhead in generating and compiling several files for a large system.

> **Note:**
> A file name has to be specified, using the Organizer *Edit Separation* command or the #SEPARATE directive, if two units in the system have the same name in SDL and should both be generated on separate files. Otherwise the same file name will be used for both units.

Assigning Priorities – Directive #PRIO

#PRIO for Processes

Priorities can be assigned to processes using the directive #PRIO. The process priorities will affect the scheduling of processes, see "Scheduling" on page 3469. A priority is a positive integer, where low value means high priority. #PRIO directives should be placed directly after the process heading in the definition of the current process.

Example 582: #PRIO Directive

```
Process P1; /*#PRIO 0 */
Process P2(1,1); /*#PRIO 1 */

Process P3 : P3Type; /*#PRIO 0 */
Process P4(1,1) : P4Type; /*#PRIO 1 */
```

Processes that do not contain any priority directive will have a user defined default priority with the name `xDefaultPrioProcess`.

There are some things to be kept in mind when using process priorities:

- Priorities have to begin with zero.
- Priorities have to be consecutive (0,1,2,3,4,5).
- All instances of a type have the same priority.
- Priority decreases with increasing numbers (zero is the highest priority level).
- The default priority is to be in the range of zero to the highest priority number, that is 0 or 1 in the example above.

#PRIO for Signals

Priorities can be assigned to signals using the directive #PRIO. The signal priorities will also effect the scheduling of processes, see "Scheduling" on page 3469.

Signal priorities can be specified, either:

- in the declaration of the signal
- in SDL output

It is impossible to specify #PRIO in a SDL input. Cmicro will ignore any occurrence of #PRIO in SDL input.

Signal priorities do affect the SDL output and the SDL create actions only.

The following rules are to be considered here:

- Signal priorities have to be in the range from 0 to 255.
- Signal priorities do not have to be consecutive, as process priorities have to be.
- If not specified otherwise (in SDL output) all instances of a signal have the same priority.
- Signal priority decreases with increasing numbers (zero is the highest priority level).
- The signal default priority is to be specified by the user (`xDefaultPrioSignal`), and must in the range of 0 to 255. As a recommendation, this value should be set to 100, so that both higher, as well as lower priorities can be declared with #PRIO.
- Signal priorities come after process priorities.
- If no #PRIO is specified for a signal, neither in its declaration, nor in any output, Cmicro uses `xDefaultPrioSignal` for each occurrence of that signal in an output.
- If #PRIO is specified only in the declaration of a signal, Cmicro uses this specified priority in each occurrence of that signal in an output.
- If #PRIO is specified in a specific output of a signal, but not in its declaration, then the specified #PRIO value is taken from the out-

put. If the signal is output without #PRIO, in that case `xDefaultPrioSignal` will be used.

- For dynamic process creation, an internal create signal is used. This signal carries the priority defined by `XMK_CREATE_PRIO`. As a general recommendation, this priority should be higher than any other signal priority.

The following example will give more explanations (note, that the values PA, PB are of sort pid):

Example 583: #PRIO Directive

```
Signal
S1, /*#PRIO 11 */
S2, /*#PRIO 22 */
S3,
S4; /*#PRIO 44 */

....
output S1 to PA
output S1 to PB; /*#PRIO 55*/
....
output S3 to PC;
output S3 to PD; /*#PRIO 66*/
```

Assuming the following C definition:

```
#define xDefaultPrioSignal 100
```

the following priorities will then be generated:

```
output S1 to PA--->use of prio 11
output S1 to PB--->use of prio 55
....
output S3 to PC--->use of prio 100
output S3 to PD--->use of prio 66
```

Modifying Outputs – Directive #EXTSIG, #ALT, #TRANSFER

There is no difference for the #EXTSIG, #ALT and #TRANSFER directives for Cmicro compared with Cadvanced, except that the use of it will sometime lead to a better performance. This is because if #EXTSIG for example is used in the case of an output to the environment, the user can prevent the Cmicro Kernel to be called (and the `xOutEnv` function to be executed).

Output of Code Generation

This section gives an overview of the code generated by the Cmicro SDL to C Compiler. This is useful, to make it possible to interpret the generated code. To know how the code is generated makes it quite easy to understand the program which is necessary and useful when testing and debugging erroneous executable programs.

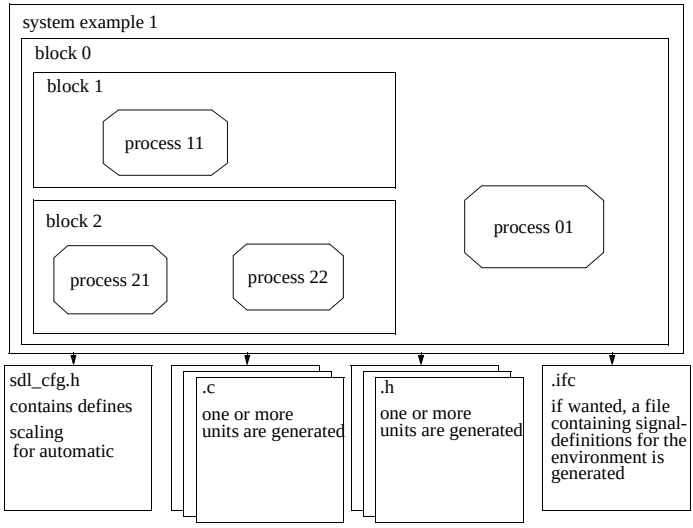

Figure 587: Structure of the generated C code

Not all the intricate details of the generated code are described here. The depth of description is sufficient to give the reader a reasonable understanding of the code generation algorithms. Explanations will illustrate what the code looks like, but not why.

The generated code contains several places where prefixes are generated, which consists of a prefix and unique numbering. The following prefix is generated for all objects: "`z<nnn>_`", where nnn is an incremental number.

Allowance for conditional compilation occurs in several places throughout the generated code. The generated C code is conditionally compiled, for example, for dynamic process creation (create symbol). A differentiation is made between conditional compilations generated by

the Cmicro SDL to C Compiler (called automatic scaling, prefix XMK_USED_) and conditional compilations which are dependent on header files, which are to be modified by the user (called manual scaling, prefix XMK_USE_).

> **Note:**
>
> Generally speaking, the ordering of the following subsections corresponds to the ordering in which the code is generated.

Each compilation unit is compiled either in one a.c file or into two files, a.c and a.h.

Only the differences are shown, when comparing the output of SDL to C Compiler with the Cmicro SDL to C Compiler. The overall differences of the both code generators are described in the section "Differences between Cmicro and Cadvanced" on page 3456 in chapter 66, *The Cmicro Library*.

Header of Generated C File

Code generation on the .c file for the current unit is started by generating the following header:

Example 584: The Head of a Generated C File

```
/* Program generated by the SDL Suite.Cmicro,
version x.y */
#define XSCT_CMICRO

#define C_MICRO_x_y
#define XMK_C_TIME <GenerationTime>
#include "ml_typ.h"
```

The XSCT_CMICRO macro can be used by the user to distinguish between the different Code generators, for example within ADT bodies.

The C_MICRO_x_y macro can be used by the user to distinguish between different versions of the Cmicro SDL to C Compiler. This is usually not but might become necessary if the output of the Cmicro SDL to C Compiler is different.

The XMK_C_TIME macro is used internally when compiling and linking and executing with the SDL Target Tester takes place. With this macro, a rough consistency check for the generated files is done. The

<GenerationTime> of the different files that are generated is compared in the Library and by the SDL Target Tester. If there is an inconsistency, compilation errors will occur.

The `#include "ml_typ.h"` is used to include all necessary declarations that the generated C code may use, including automatic scaling from `sdl_cfg.h` and predefined sorts.

SECTION Types and Forward References

As a difference to SDL to C compiler, this section contains the definitions for the process IDs and the forward declarations used in the generated C code.

Process IDs are generated as `#define` values in C, like:

```
#define XPTID_<UniquePrefix>_MyProcess 0
```

where the first process in the system is the value of 0 assigned, the second process gets the value 1, and so on. Please refer to "Generation of Identifiers" on page 3446 for more information.

The following forward references are generated:

```
extern XCONST XPDTBL yPDTBL_<UniquePrefix>_MyProcess;
```

Following this, the usual declarations are generated as described in *chapter 56, The Cadvanced/Cbasic SDL to C Compiler*.

No synonym variables are generated when using Cmicro.

Symbol Tables

Symbol tables are only generated for the SDL Target Tester, and not into the generated C code. The symbol tables generated for the SDL Target Tester are described within chapter 67, *The SDL Target Tester*.

Tables for Processes

Tables are used to represent the behavior of SDL objects, like processes and timers. It is not absolutely necessary to understand how these tables are generated and how the Cmicro Kernel works with them. The following subsections are only for those readers interested in the nature of the table structure.

Root Process Table

The root process table contains, for each of the defined SDL process types, a reference (i.e. a pointer) to the Process Description Table. The Cmicro Kernel is the main user of the root process table. Via this table, it can access all SDL process types and all SDL process instance data. The location of the generated root process table is directly before the yPAD-functions in the generated C file. The type definitions used in this table are located in the `ml_typ.h` module.

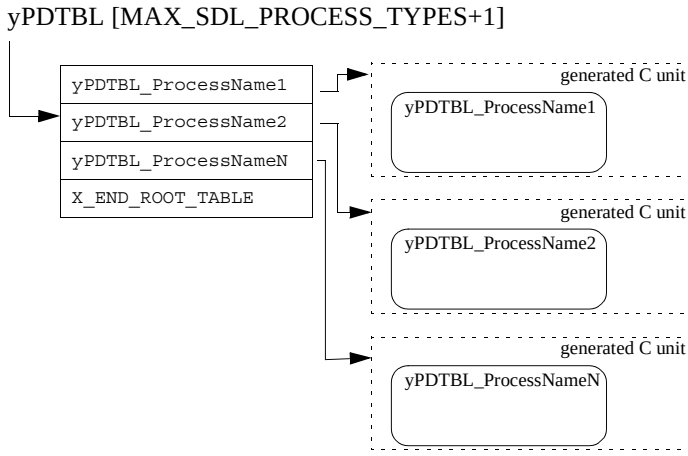

Figure 588: Root process table

Example 585: Code of Root Process Table ––––––––––––––––––––

C-Type definition (`ml_typ.h`):

```
extern xPDTBL yPDTBL [];/* for the Cmicro Kernel */
#define X_END_ROOT_TABLE/* Table-End Marker of yPDTBL*/
```

C constants (`sdl_cfg.h`):

```
#define MAX_SDL_PROCESS_TYPES <N>

   /* <Process-type-id´s>  Process Types are numbered */
   /* from 0 to N-1(see chapter "Generating PID") */
   #define XPTID_Process1Name 0
   #define XPTID_Process2Name 1
   #define XPTID_ProcessnName N-1
```

C code generation for the whole system:

```
XPDTBL yPDTBL [MAX_SDL_PROCESS_TYPES+1] =
{
  yPDTBL_ Process1Name,
  yPDTBL_ Process2Name,
  ......
  yPDTBL_ ProcessnName,
  X_END_ROOT_TABLE
}
```

Symbol Trace Table

In order to reduce the use of dynamic memory allocation, there is a table generated in the code which is used by the SDL Target Tester to store and retrieve test options, like switches, which define the trace.

The table is conditionally compiled and only included if the SDL Target Tester is contained in the target- executable.

The symbol trace table looks like:

Example 586: Code for Symbol Trace Table

```
/************************************************************
**  Symbol trace table
************************************************************/
#ifdef XMK_ADD_TEST_OPTIONS
XSYMTRACETBL *xSYMTRACETBL[MAX_SDL_PROCESS_TYPES+1] =
{
  (XSYMTRACETBL_ENTRY *)  NULL, /* for first Processtype */
  (XSYMTRACETBL_ENTRY *)  NULL, /* for second Processtype */
  ........
  ........
  (XSYMTRACETBL_ENTRY *)  NULL, /* for last Processtype */
  X_END_SYMTRACE_TABLE /* table end marker */
};
#endif
```

More information can be obtained by reading chapter 67, *The SDL Target Tester*.

Optimized Decision Trace information

An option to reduce the trace information for SDL decisions by showing only the first ten characters of the decision expression during trace. Setting the environment variable CMICRO_SHORT_DECISION_TRACE to any value prior to the Cmicro code generation is started, will have the effect on the generated C code that all xTraceDecision<parameter> statements will contain a parameter that is the first ten characters of the

decision expression instead of the complete expression. This will reduce the trace information for systems that contain a lot of decisions.

Instance-Data-Struct

The struct is generated in the header-section of the generated C file.

Example 587: Code Generation of type definition for each SDL process

```
typedef struct {
  PROCESS_VARS
  TypeName1  FPAR_var1;
  TypeName2  FPAR_var1;
  TypeName3  DCL_var1;
  TypeName4  DCL_var2;
  TypeName4  yExp_DCL_var2;
  TypeName5  FPAR_var1;
} yVDef_ProcessName;
```

Instances of a given type are represented as a C array. The code generation of variables for each SDL process looks like:

Example 588

```
#define X_MAX_INST_ProcessName upperlimitofprocessinstances1

static yVDef_ ProcessName

yINSTD_ProcessName[X_MAX_INST_ProcessName];
```

A reference to this array is generated in the Process Description Table which is discussed in the subsection "Process Description Table" on page 3427.

Process State Table

This table is generated for each process in the header-section of the generated C file. It contains information about the state of each process instance. The table contains ordinary SDL state values as well as the values `XSTARTUP` and `XDORMANT`. `XSTARTUP` is generated for each instance which is to be statically created (in (x, N) declarations, where x is > 0), `XDORMANT` is the value which is used to tag a process instance as sleeping. In the case of creation this instance can be reused.

Example 589: Code for Process State Table ----------

C typedef for the process state table (located in `ml_typ.h`):

```
typedef u_char xSTATE; /* see defines below */
#define XSTARTUP 0xff  /* valid only if xSTATE is */
                       /* u_char else 0xffff */
#define XDORMANT 0xfe  /* valid only if xSTATE is */
                       /* u_char, else 0xfffe */
```

C code generation for each process:

```
static xSTATE yPSTATETBL_znn_ProcessName
                                [X_MAX_INST_znn_ProcessName] =
{
  <creation-tag>  /* Instance 0 */
  <creation-tag>  /* Instance 1 */

  <creation-tag>  /* Instance M-1 */
};
```

where `<creation-tag>` is either `XSTARTUP` or `XDORMANT`.

Example 590: ----------

Code for a process type with 4 instances, 2 of which are to be created at SDL system start:

```
static xSTATE yPSTATETBL_znn_ProcessName [4] =
{
  XSTARTUP, /* Create at SDL-system-start */
  XSTARTUP, /* Create at SDL-system-start */
  XDORMANT, /* Create later               */
  XDORMANT  /* Create later               */
};
```

A reference to this table is created in the Process Description Table, which is discussed in the subsection "Process Description Table" on page 3427.

Transition Table

This is generated in the header-section of the generated C file. It contains all transitions of a process, including asterisk states, asterisk inputs and asterisk save.

The C `typedef` for the transition table (located in `ml_typ.h`) is as follows:

Example 591: Code for Transition Table ––––––––––––––––––––––

```
typedef struct {
  xINPUT    SignalID; /* Input, Asterisk-Input. */
                      /* Input is Timer */

                      /* and/or ordinary Signal */
  xSYMBOLNR SymbolNr; /* Symbolnumber to be used */
                      /* in yPAD-function */
} xTR_TABLE_ENTRY;
```

C code generation:

```
static XCONST xTR_TABLE_ENTRY   yTRTBL_znn_ProcessName
                                [XMAX_TRANS_znn_ProcessName]=
{
  /* state_0-table */
  input_1, SymbolNr,
  input_2, SymbolNr,
  XASTERISK,XSAVEID /* asterisk save */

  input_N, SymbolNr,

  /* state_1-table */
  ..............
  ..............
  /* state_j-table */
  input_1, SymbolNr,
  input_2, SymbolNr,

  input_N, trans_jN,
  XASTERISK,XSAVEID /* asterisk save */
};
```

The `SymbolNr` shown above is used to select the right transition in the switch generated in the yPAD function.

Where the C define

`XASTERISK` is an ID defining all possible SDL Inputs (asterisk Inputs),

`XSAVEID` is a simple ID defined in `ml_typ.h` which can be compared by the SDL Kernel to detect signal-save.

And where:

```
#define XASTERISK   -1
#define XSAVEID     xSave
```

––

A reference to this table is created in the Process Description Table.

State Index Table

This is generated in the header section of the generated C file.

Example 592: Code for State Index Table

C typedef (`ml_typ.h`):

```
typedef   u_char xSTATE_INDEX;
```

C code generation (header of generated C file):

```
static xCONST xSITBL   xSTATE_INDEX_znn_ProcessName
                         [<count_transitions_of_ProcessName] =
{
  0, /* i.e.a process with 3 states, but no asterisk states */
     /* state_0 has 2 transitions */
  2, /* state_1 has 5 transitions */
  7, /* state_2 has 3 transitions */
  10 /* table-end-index XI_TABLE_END */
};
```

The first value in the above table indicates the beginning of the first state in the Transition Table. If asterisk state definitions are not found in the process, this value is 0.

A reference to this table is created in the Process Description Table.

PID Table

These tables are used to store the values parent and offspring for each process. The reason an extra table is used to store this information is to simplify initialization. The Cmicro Kernel updates the values in the table according to the SDL rules.

Example 593: Code for PID Table

C-type definition (`ml_typ.h`):

```
#ifdef XMK_USE_PID_ADDRESSING
  typedef struct
  {
    #ifdef XMK_USE_SDL_PARENT
      xPID            Parent;
    #endif

    #ifdef XMK_USE_SDL_OFFSPRING
      xPID            Offspring;
    #endif

  } xPIDTable;
#endif
```

C code generation for each process:

```
/*-----------Process-PID-Values-------------*/
#ifdef XMK_USE_PID_ADDRESSING
  static xPIDTable yPID_TBL_z00_P1[X_MAX_INST_z00_P1];
#endif
```

A reference to this table is created in the Process Description Table, which is discussed in the subsection "Process Description Table" on page 3427.

Process Description Table

For each SDL process, an automatically initialized C structure is generated called process description table. This table is used in the Root Process Table to enable the Cmicro Kernel to access process type information as well as process instance data.

Inspect the following diagram to see which information is contained in the process description table:

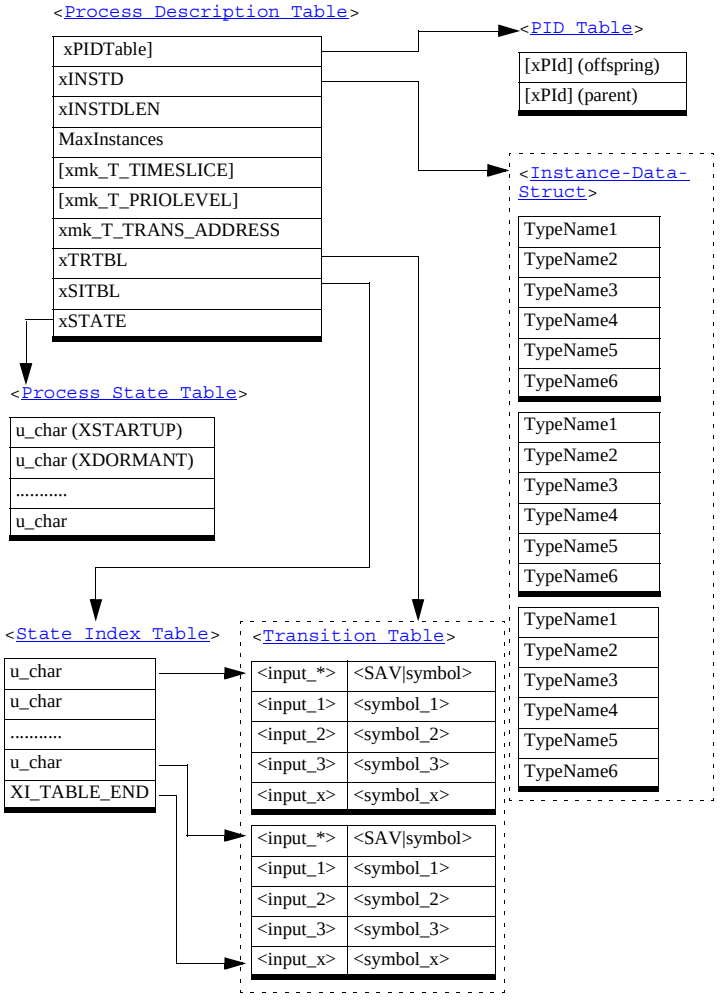

Figure 589: Process description table

Allocated to each SDL process type is one table `yPDTBL_ProcessName`.

The type definitions of this table are located in the `ml_typ.h` module.

Example 594: Code for Process Description Table

C typedef for the process description table (`ml_typ.h`):

```
typedef struct {
  #ifdef XMK_USE_PID_ADDRESSING
    xPIDTable  *pPIDTable; /* Table with */
                           /* Parent/OffspringValues */
  #endif

  xINSTD      *pInstanceData ; /* Pointer to Instancedata*/
                               /* Vector                 */
  xINSTDLEN    DataLength ;  /* Length of Instancedata  */
                             /* for 1 Instance          */
                             /* (used by SDL-BS)        */
  unsigned char MaxInstances ; /* Max.Number of Instances*/

  #ifdef XMK_USE_TIMESLICE
    /* Time-Slices can be individually specified by the user*/
    /* The value stored in TimeSlice is measured in ticks   */
    /* The Cmicro Kernel has to be scaled to handle     */
    /* timeslicing */
    xmk_T_TIMESLICE TimeSlice;
  #endif

  #ifdef XMK_USE_PREEMPTIVE
    /* Process-Priority can be specified with #PRIO on the */
    /* SDL-Level. It is available only, if the Cmicro    */
    /* Kernel is scaled to handle preemption. */
    xmk_T_PRIOLEVEL PrioLevel;/*Priority of this processtype*/
  #endif

  xmk_T_TRANS_ADDRESS yPAD_Function ; /* Address of the */
                                      /* yPADFunction */
  xTRTBL TransitionTable ;  /* Pointer to transition table */
  xSITBL *StateIndexTable ; /* Pointer to state index table */
  xSTATE *ProcessStateTable;/* Pointer to process state table
*/
} XPDTBL;
```

C code generation for each process:

```
#define X_MAX_INST_ProcessName 1

xPDTBL yPDTBL_ProcessName =
{
  yPID_TBL_znn_<process:N>,
  (xINSTD*) yINSTD_znn_ProcessName,
  X_MAX_INST_znn_ProcessName,
  (xmk_T_TRANS_ADDRESS) yPAD_znn_ProcessName,
  yTRTBL_znn_ProcessName;
  xSTATE_INDEX_znn_ProcessName,
  yPSTATETBL_znn_ProcessName;
};
```

For each generated process description table, a new entry in the Root Process Table is generated.

Actions by Processes and Procedures

GR References

No code is generated to evaluate the graphical references during runtime of the SDL system. A large amount of memory is required to store and handle such information which normally proves too large for any real target system.

Alternatively, C comments are generated which make it possible to verify and debug the generated code as illustrated in the following example. The PR <position> indicates in which line number of the SDL/PR file the symbol can be found.

```
For processes :
/*************************************************************
**  PROCESS <process-name>
**  <<SYSTEM <system-name>/BLOCK <block-name>>
**  #SDTREF(<reference>)
*************************************************************/

For signals :
/*************************************************************
**  SIGNAL S1
**  <<SYSTEM <system-name>/BLOCK <block-name>>
**  #SDTREF(<reference>)
*************************************************************/

For yPAD-function
/*+++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
** Function for process <process-name>
** #SDTREF(<reference>)
+++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++*/

For output :
/*-----
** OUTPUT <signal-name>
** #SDTREF(<reference>)
------*/

For nextstate :
/*-----
** NEXTSTATE <state-name>
** #SDTREF(<reference>)
------*/
```

Structure of Process and Procedure Functions

The basic structure of the generated C code for process and procedure definitions remains the same as for the SDL to C compiler although some modifications are evident.

The code generation for the PAD function is different compared with Cadvanced, in the way that code that is common in process types is copied into the PAD function for instantiated processes.

Procedures follow the same code generation as processes, with some small exceptions in macro naming conventions for variable declarations.

Each SDL process is represented in C by a C function called `yPAD_ProcessName`.

Example 595: `yPAD_ProcessName` ----------

```
/* Function for process ProcessName */
#ifndef XNOPROTO
extern YPAD_RESULT_TYPE yPAD_ProcessName ( YPAD_ANSI_PARAM )
#else
extern YPAD_RESULT_TYPE yPAD_ProcessName ( YPAD_KR_PARAM )
  YPAD_KR_DEF
#endif
{
  local variable section
  State-input-selection
  {
    start-transition including nextstate
    transition-1 including nextstate
    transition-2 including nextstate
    .......
    transition-n including nextstate
  }
  pad-end-section
}

/* Function for procedure ProcedureName */
#ifndef XNOPROTO
extern YPRD_RESULT_TYPE yPAD_ProcedureName ( YPRD_ANSI_PARAM )
#else
extern YPRD_RESULT_TYPE yPAD_ProcedureName ( YPRD_KR_PARAM )
  YPRD_KR_DEF
#endif
{
  local variable section
  section representing procedure body
}
```

Local Variables Section

The following defines are generated in the local variables section for processes.

Example 596 ----------

```
YPAD_YSVARP             /* used for signal variable pointers
*/
YPAD_YVARP(yVDef_z00_P1)/* used for process variables */
YPAD_TEMP_VARS          /* used for temporary variables */
YPRSNAME_VAR("P1")      /* can be used for printf */
BEGIN_PAD               /* used for some preparations */
                        /* to handle signals, or Integration*/
                        /* of any Realtime operating system */
```

After expansion by the C preprocessor:

```
yVDef_z00_ProcessName *yVarP
                          =(yVDef_z00_ProcessName *)pRunData;
unsigned char *yOutputSignal;
unsigned char *ySVarP;

(void) printf(("PROCESS:%s\n", "ProcessName"));

if((P_MESSAGE != ((void *) 0))
    && (P_MESSAGE->mess_length > 4))
{
  ySVarP = (unsigned char *) P_MESSAGE->mess_ud.pt_ud;
}
else
{
  ySVarP = (unsigned char *) P_MESSAGE->mess_ud.ud;
}
```

The following defines are generated in the local variables section for procedures:

```
YPRD_YVARP(yVDef_znnn_ProcedureName)
/* used for procedure variables */

YPRD_TEMP_VARS
/* used for temporary variables */

YPRDNAME_VAR("ProcedureName")
/* can be used for printf */
```

State – Input Selection

The selection of the appropriate SDL transition which is to be executed in the current state with the current signal in the input port goes in principle over the transition table, described in previous chapters. With this table, the Cmicro Kernel can evaluate a symbol number, which is local to a process, a unique numbering of the different possible transitions. This numbering algorithm begins at 0 (which corresponds to the start symbol) and continues until all symbols for this particular process type have been numbered.

The appropriate transition is selected by the following switch:

```
switch (XSYMBOLNUMBER) {
{
  case 0:. start-transition
  nextstate;

  case 1: transition-1
  nextstate;
}
```

After pre-compiling it:

```
switch (_xSymbolNumber_ )
{
  .....
}
```

Start Transition

The start transition is included into the body of the generated yPAD function and has the same layout as transitions, with the following exceptions:

Assignment of initialization values to all local variables in the processes and procedures (if any) is executed. All DCL variables are filled with their default-values.

The start transition is selected by the special case-value zero in the switch-statement of the yPAD function.

> **Note:**
>
> FPARS in dynamic process creation are not contained in this version of the Cmicro Package.

Transitions

The transitions are translated in the order they are found and are only translated to the sequence of actions they consist of. The translation of actions are discussed in the subsection "Translation of Actions" on page 3434 following a few lines below.

PAD-End-Section

Each yPAD function is finished with:

```
END_PAD (yPAD_ProcessName);
```

The main reason for this is to make it possible to integrate other real-time operating systems.

> **Note:**
>
> Some compilers produce a warning if there is no return at the end of the yPAD function. Other compilers produce a warning "unreachable code", if there is a return at the end of the yPAD function. For this reason, a function returning macro `END_PAD` exists which can be expanded in accordance with the particular compiler used.

Translation of Actions

Translation of Output

SDL output statements are translated to the following basic structure:

- allocate the data area for the parameters of the signal to be output
- assign signal parameters
- send the signal, parameters will be copied
- release the data area for the parameters of the signal.

There are a lot of different output macros generated. The main reason for this is that for each output situation an optimized code is to be generated.

One differentiation is made for signals without parameters and signals with parameters. For a signal without parameters, suffix `_NPAR` is used for the macro generated and for a signal with parameters, suffix `_PAR` is used. The relevant output macro can then be expanded to a simpler output C function called `xmk_SendSimple`, if no signal priority is used.

Another differentiation is made for signals which are sent to the system's environment or which are sent internally in the SDL system. The suffix `_ENV` is appended to the macros which are shown here, if the signal should go to the system environment.

The different directives which can be used within the SDL Suite to modify outputs are discussed in subsection "Modifying Outputs – Directive #EXTSIG, #ALT, #TRANSFER" on page 3417.

The other different output situations which are handled, will be described in the next subsections.

Output without TO and without VIA

If the user specifies output SignalName without TO and VIA in SDL, the Cmicro SDL to C Compiler calculates the receiver of the signal. It is also possible to have more than one receiver for the signal. During execution time, any possible receiver that are alive may be selected otherwise if no receiver can be found, the C function `ErrorHandler` will be called. The following code is generated:

```
ALLOC_SIGNAL_ppp(SignalNamewithoutPrefix,
                 SignalNamewithPrefix,
                 SignalParameterTypeStructureName)
```

ordinary assignment of Signal Parameters, if there are some...

```
SDL_OUTP_ppp(Priority,
             SignalNamewithoutPrefix,
             SignalNamewithPrefix,
             TO_PROCESS(ProcessNamewithoutPrefix,
                        ProcessNamewithPrefix),
             SignalParameterTypeStructureName,
             "SignalNamewithoutPrefix")
```

Note:

The `ppp` above stands for either `PAR` or `NPAR` for a Signal with or without parameters.

After expansion, the user will find a C function call to the `xmk_SendSimple` function or the `xmk_Send` function.

Priority is generated as `xDefaultPrioSignal` if no priority is specified for the signal with `#PRIO`.

`TO_PROCESS` is expanded to a function call if there is at minimum one (x, N) declaration in the system, where N is > 1. This function returns one of the possible receivers of the signal.

`TO_PROCESS` selects an active instance of the given process type It does not check for different types as receivers.

`TO_PROCESS` is expanded so that the pid is passed directly to one of the C functions `xmk_Send*`, if there are only (x,1) declarations in the system.

If the environment is the receiver of the signal, then the following code is generated:

```
ALLOC_SIGNAL_ppp(SignalNamewithoutPrefix,
                 SignalNamewithPrefix,
                 SignalParameterTypeStructureName)
```

ordinary assignment of Signal Parameters, if there are any...

```
SDL_OUTP_ppp_ENV(Priority,
                 SignalNamewithoutPrefix,
                 SignalNamewithPrefix,
                 ENV,
                 SignalParameterTypeStructureName,
       "SignalNamewithoutPrefix")
```

Note:

The `ppp` above stands for either `PAR` or `NPAR` for a Signal with or without parameters.

After expansion, the user will find that `ENV` is passed to one of the C functions `xmk_SendSimple` or `xmk_Send`. `ENV` is a special value used

inside the Cmicro Kernel to detect which signals are to be passed to the C function `xOutEnv`.

Output with TO clause

If the user specifies the output SignalName to pid in SDL, the Cmicro SDL to C Compiler generates the following code:

```
ALLOC_SIGNAL_ppp(SignalNamewithoutPrefix,
                 SignalNamewithPrefix,
                 SignalParameterTypeStructureName)
```

ordinary assignment of Signal Parameters, if there are some...

```
SDL_OUTP_ppp(Priority,
             SignalNamewithoutPrefix,
             SignalNamewithPrefix,
             pid-variable,
             SignalParameterTypeStructureName,
             "SignalNamewithoutPrefix")
```

Note:

The `ppp` above either stands for `PAR` or `NPAR` for a Signal with or without parameters.

Expansion reveals a C function call to the `xmk_SendSimple` function or the `xmk_Send` function.

Priority is generated as `xDefaultPrioSignal`, if no priority is specified for the signal with #PRIO.

Possible generated values for pid variable are `SDL_SENDER`, `SDL_PARENT`, `SDL_OFFSPRING` and `SDL_SELF` or an SDL pid variable. These values are passed to the `xmk_Send*` functions. The name of a process as specified in SDL may also be given.

Output with VIA clause

The Cmicro SDL to C Compiler computes the possible receivers in an output with the **VIA** clause. If there are several possible receivers, an error message is produced.

If there is exactly one receiver, the same code is generated as for SDL output without **to**.

List of Generated Output Macros

- `ALLOC_SIGNAL_NPAR`
  Allocating memory for signal without parameters
- `ALLOC_SIGNAL_PAR`
  same for signals with parameters
- `TO_PROCESS`
  Macro used to evaluate a receiver process instance, if necessary in the case of (x, N) declarations, where N > 1.
- `SDL_OUTP_NPAR`
  Output internally in the SDL system for signal without parameters
- `SDL_OUTP_PAR`
  same for signal with parameters
- `SDL_OUTP_NPAR_ENV`
  Output to the system environment for signal without parameters
- `SDL_OUTP_PAR_ENV`
  same for signal with parameters
- `SDL_ALTOUTP_NPAR`
  #ALT for an output internally in the SDL system for signal without parameters
- `SDL_ALTOUTP_PAR`
  same for signal with parameters
- `SDL_ALTOUTP_NPAR_ENV`
  #ALT for an output to the system environment for signal without parameters
- `SDL_ALTOUTP_PAR_ENV`
  same for signal with parameters
- `EXT_SignalName`
  if #EXTSIG is used in output
- `TRANSFER_SIGNAL`
  #TRANSFER is used in output

Translation of Create

The create action in SDL is translated to the following C code:

```
ALLOC_STARTUP_ppp(ProcessNamewithoutPrefix,
                  ProcessNamewithPrefix,
                  "ProcessNamewithoutPrefix, 0);
```

....assignment of start-up values (cannot be used in this version of the Cmicro Package)

```
SDL_CREATE(ProcessNamewithoutPrefix,
           ProcessNamewithPrefix,
           "ProcessNamewithoutPrefix, 0,
           VariableofCreatedProcess,
           PriorityofCreatedProcess,
           yPAD-functionNameofCreatedProcess);
```

`PriorityofCreatedProcess` is generated as `xDefaultPrioProcess`, if no priority is specified with #PRIO.

Translation of Set

The translation of set is restricted in a few areas in order to produce efficient code for a micro controller. For example, the SDL duration expressed by a real value in the context of timers is not implemented. The reason for this is that controllers do not have floating point operations or floating point operations are not used in order to increase the performance. For timers, such a high resolution is not necessary in most applications. The Cmicro Package uses a long value in its standard implementation to represent absolute time.

In order to make the examples below more readable, it is assumed that at least one timer with parameter is used in the system (macro `XMK_USED_TIMER_WITH_PARAMS` is defined in the generated file `sdl_cfg.h`). If the macro is not defined, then the handling for timers with parameters is not included.

Example 597 ----------

If the following is specified in SDL/PR:

```
Timer TimerName;
        ......
Set (now + durationvalue, TimerName) ;
```

or

```
Set (now + 22222, TimerName) ;
```

then the following code is generated:

```
SDL_SET_DUR  \
(xPlus_SDL_Time(SDL_NOW,SDL_DURATION_LIT(22222.0,22222,0)),
           SDL_DURATION_LIT(22222.0, 22222, 0),
           TimerName,
           TimerNamewithPrefix,
           yTim_timer2,
           "TimerNamewithoutPrefix")
```

Example 598 ----------

If the following is specified in SDL/PR:

```
Timer TimerName := TimerGroundValue ;---> see Note: on page 3440!
```

then the following code is generated:

```
SDL_SET_TICKS
(xPlus_SDL_Time(SDL_NOW, TICKS(SDL_INTEGER_LIT(22222))),
              TICKS(SDL_INTEGER_LIT(22222)),
              TimerName,
              TimerNamewithPrefix,
              yTim_timer2,
              "TimerNamewithoutPrefix")
```

The code after expansion then contains a function call to

```
xmk_TimerSet (TIMEEXPR,TimerNamewithPrefix,0).
```

`TIMEEXPR` is the result of the evaluation of **now** plus duration value.

```
#define SDL_SET_DUR(TIME_EXPR, DUR_EXPR, TIMER_NAME,
        TIMER_IDNODE, TIMER_VAR, TIMER_NAME_STRING) \
xmk_TimerSet(TIME_EXPR, TIMER_IDNODE,0);

#define SDL_SET_TICKS(TIME_EXPR, DUR_EXPR, TIMER_NAME,
        TIMER_IDNODE, TIMER_VAR, TIMER_NAME_STRING) \
xmk_TimerSet(TIME_EXPR,TIMER_IDNODE,0);
```

Example 599 ----------

If a timer with parameter is defined in SDL/PR:

```
Timer TimerName (integer);
...
set (now+1, TimerName (4711));
```

then the following code is generated:

```
SDL_SET_DUR_WITH_1IPARA(xPlus_SDL_Time(SDL_NOW,
                       SDL_DURATION_LIT(1.0, 1, 0)),
                       SDL_DURATION_LIT(1.0, 1, 0), TimerName,
                       TimerNamewithPrefix,
                       yPDef_z262_twp1,
                       yTim_TimerName,
                       "TimerName",
                       SDL_INTEGER_LIT(4711))
```

The code after expansion then contains a function call to

```
xmk_TimerSet (TIMEEXPR,TimerNamewithPrefix,4711).
```

Restrictions in the Use of Timers

- Timers with parameters are restrictively supported in Cmicro. There might be only one parameter of sort “integer”. This implementation has been chosen to achieve the highest efficiency.
- Duration values as real values are not supported in this version of the Cmicro Package, i.e. this:

```
set (now + 5.5, TimerName)
```

  is **not allowed** (the real part is discarded i.e. 5.5 (= 5).

Translation of Reset

If the user specifies in SDL/PR:

```
Reset (TimerName) ;
```

then the following code is generated:

```
SDL_RESET(TimerNamewithoutPrefix,
          TimerNamewithPrefix,
          yTim_TimerName)
```

The code after expansion contains a function call to `xmk_TimerReset` (TimerNamewithPrefix).

For a timer with one integer parameter, the following macro call is generated:

```
SDL_RESET_WITH_1IPARA(TimerNamewithoutPrefix,
                      TimerNamewithPrefix,
                      TimerParStruct,
                      yTim_TimerName,
                      TimerValue)
```

Note:

Timers with parameters are supported with the restriction that only one integer parameter is allowed.

Translation of Call

As SDL procedures are implemented with the restrictions explained within subsection “SDL Restrictions” on page 3450, the following explanatory C code (to a procedure called `ex_proc`) is generated:

```
ex_proc (....C parameters ...);
```

All necessary parameters are routed via the C function call stack.

Translation of Call to a Procedure Returning Value / Operator Diagram

Operator diagrams and procedures returning values are – considering the call – handled in the same way please see the following explanatory example:

Example 600: Procedure Call ––––––––––––––––––––––––––––––

```
TASK i := (call p(1)) + (call Q(i,k));
```

is translated to something like:

```
i = p(1) + Q(i,k);
```

––

> **Note:**
> The value of returning procedure calls are transformed to C functions returning values.

Translation of Nextstate

The nextstate operation is generated at the end of each transition contained in the yPAD function, as follows:

- If the process performs simple nextstate operation:

  ```
  SDL_NEXTSTATE(State1, z000_State1, "State1")
  ```

  after preprocessing:

  ```
  return (z000_State1);
  ```

- If it performs a nextstate, which is defined as a dash state:

  ```
  SDL_DASH_NEXTSTATE
  ```

  which is defined as:

  ```
  return (XDASHSTATE);
  ```

Translation of Stop

A stop action is translated to:

```
SDL_STOP
```

which is defined as

```
return (XDORMANT);
```

which is good code saving. The Cmicro Kernel then enters the new state value into the Process State Table.

> **Note:**
>
> This table contains ordinary SDL state values as well as the values `XSTARTUP` and `XDORMANT`. `XSTARTUP` is generated for each instance which is to be statically created (in (x, N) declarations, where x is > 0). `XDORMANT` is the value which is used to tag a process instance as sleeping. In the case of creation this instance can be reused.

Translation of Return

```
#ifdef XFREEVARS
  FREE_PROCESS_VARS ()
#endif

SDL_RETURN
```

The macro definitions are:

```
#define SDL_RETURN \
        if (_xxptr != (unsigned char*) NULL) \
        { \
          XMK_MEM_FREE ((unsigned char *)_xxptr); \
        } \
        return ;
```

where xxptr is the pointer to the procedure instance data, as given via the C function call parameter list. Note, that the memory previously allocated directly before the procedure call is freed at the end of the procedure, not outside of the procedure.

Translation of SDL Expressions

In this section some of the translation rules for expressions are described. For more information see *"Translation of Sorts" on page 2665 in chapter 56, The Cadvanced/Cbasic SDL to C Compiler* where for example the translation rules for literals and operators in the predefined abstract data types are given.

Now

SDL now is translated to the macro `SDL_NOW` which is expanded to the C function `xmk_NOW`. This function is exported by the module `mk_stim.c`.

Self, Parent, Offspring, Sender

The definitions for **self**, **parent**, **offspring**, **sender** are:

```
#ifdef  XMK_USED_SELF
#define SDL_SELF               xRunPID
#endif

#ifdef  XMK_USED_PARENT
#define SDL_PARENT             pRunPIDTable->Parent
#endif

#ifdef  XMK_USED_OFFSPRING
#define SDL_OFFSPRING          pRunPIDTable->Offspring
#endif

#ifdef  XMK_USED_SENDER
#define SDL_SENDER             P_MESSAGE->send
#endif
```

All the variables above are of type `xPID`. All variables are maintained by the Cmicro Kernel. `xRunPID` is a global variable which contains the pid of the SDL process which is currently running. `P_MESSAGE` is a pointer to the signal instance which is currently worked on.

Timer Active

An SDL timer active expression is translated to:

```
SDL_ACTIVE(TimerName, TimerName,
  yTim_TimerName)
```

which is expanded to:

```
xmk_TimerActive(TimerName)
```

A conditional expression in SDL is translated to a conditional expression in C.

Init Function

An explicit initialization function is not generated by the Cmicro SDL to C Compiler in any case.

The structure of the SDL system is not generated into the C code. What is seen in the generated code, is the behavior of the SDL system. Vari-

ables of processes are initialized during the start transition of a process and no information about the structure of the SDL system is available during run-time in the generated code.

An initialization function is generated only in that case if synonyms are used within SDL, which require an initialized C variable.

All this results in a more compact executable.

For example, the following use of an SDL synonym results in a generated initialization function:

```
synonym a integer := /*#CODE anyUserFunction () */
```

The following C code is then generated within the C function `yInit`:

```
yAssF_SDL_Integer(a, anyUserFunction (), XASS);
```

`yInit` is called by the Cmicro Kernel if the define

```
XMK_USED_INITFUNC
```

is generated into the file `sdl_cfg.h`, which is done in the case above.

Initialization of Synonyms

The Cmicro SDL to C Compiler allows SDL synonyms to be implemented as C macros and C variables.

Initialization is implemented within the C function `yInit` which is conditionally compiled.

Function main

The C function `main` is not automatically generated by the Cmicro SDL to C Compiler. This is unnecessary because the `main` function usually is provided from the user or the predefined `main` function can be used. Instead of an automatically generated `main` function, the user must supply the function body of `main`, for target applications. Guidelines can be found in the subsection "Implementation of Main Function" on page 3530 in chapter 66, *The Cmicro Library*.

Symbol Table File

The structure of an SDL system can be represented by a tree diagram. In SDL the root of the tree is represented by the SDL system followed by blocks, block substructures, processes and procedures[1]. Channels, channel substructures and signal routes are also represented in the tree. This tree is static, which means it cannot be modified during the run-time of an SDL system.

The SDL to C Compiler generates code so that this static structure is present in the generated code. This is good for debugging purposes.

The Cmicro SDL to C Compiler generates code so that this static structure is **not** present in the generated code, in order to spare memory. To enable debugging of the generated code, C comments are generated. Please consult the subsection "GR References" on page 3430.

A symbol table is necessary for the SDL Target Tester running on the host or the development system.

For more information consult chapter 67, *The SDL Target Tester*.

1. In SDL-92 several SDL systems can exist in parallel.

Generation of Identifiers

Processes and Process IDs (PID)

In order to implement the environment functions, it is important to notice that process IDs in Cmicro are generated into the `sdl_cfg.h` file, which must be included by the user's environment C module. These IDs are coded like it is described in "Generated Configuration File" on page 3394. More explanations are given in the following.

Since process IDs might become ambiguous, especially in block type and process type instantiations in SDL'92, the names of process IDs that are to be used in the environment functions are to be given a prefix. Using this prefix within the environment functions (`xInEnv`), it can be guaranteed that different process IDs (equates to "instance sets" in SDL'92) with the same name can be distinguished, which is necessary in order to send signals to the right process instance within the SDL system. On the other hand, prefixes are not necessary when all the process instance sets within the system have a different name. The Cmicro SDL to C Compiler uses an algorithm to calculate the prefixes in the most convenient way.

For example, if a process named "myprocess" exists only once within the SDL system, there will be no automatic prefix generated, e.g. the full process ID is

```
#define XPTID_myprocess 0
```

If, as another example, the process "myprocess" exists twice, for example once within a block called "myfirstblock" and once more within a block called "mysecondblock", the Cmicro SDL to C Compiler then creates two definitions which guarantee that the processes can be distinguished:

```
#define XPTID_myfirstblock_myprocess  0
#define XPTID_mysecondblock_myprocess 1
```

In this way, by adding scope names (block names), prefixes are always generated in a way so that no naming conflicts occur. Of course, for process and block type instantiations, the name of the instance is being used to generate this unambiguous prefix.

SDL process types (process instance sets in SDL'92), as well as SDL process instances are numbered consecutively beginning with zero. The

ordering of these numbers is the same as the ordering of the processes in the SDL/PR file.

The values 250 to 255 are reserved for internal purposes and must not be used for process type numbering. The Targeting Expert checks this rule automatically. For small systems this does not create any problems.

The Cmicro Kernel assumes the above definitions.

In the generated C code, the SDL values self, sender, parent and offspring, and variables of this type are represented by the `typedef xPID`. The intention is to have unique numbering of processes and their instances in the whole SDL system. This becomes necessary because of the Cmicro Code no longer containing the structure of the SDL system (system, block...). The `typedef xPID` is defined as

- `unsigned char` or `unsigned int`
  if there are only (x,1) declarations in the system no distinction between instances is necessary. This is automatically detected. See the flag `XMK_USED_ONLY_X_1` in the section "Automatic Scaling Included in Cmicro" on page 3519 in chapter 66, *The Cmicro Library*.

- `unsigned int` or `unsigned long`
  if there is at minimum one (x, N) declaration in the system, where N > 1, instances need to be distinguishable from each other.

There are a few macros defined to extract the process type number or the process instance number from a variable of the type `xPID` and to build an `xPID` variable from a process type number and a process instance number, the users do not have to think about the internal representation:

Example 601: Macros to extract process type or instance number ––

```
processtype     = EPIDTYPE(xPID_variable)
processinstance = EPIDINST(xPID_variable)
xPID_variable   = GLOBALPID(processtype, processinstance)
```

––

Signals and Timers

SDL signals and timers are numbered automatically by the Cmicro SDL to C Compiler so that they have a unique number over the complete system. Timers are represented by the values 1, 2, 3.... MT to the last timer of the MT timers in the system. After that follow ordinary SDL signal numbers beginning with MT+1, MT+2, MT+3... MT + MS.

When using the standard Cmicro Package, as delivered, then the values 0 and 251 to 255 are reserved for internal purposes. If the upper limit of 250 signals and timers is being reached, then the signal ID type has to be changed from `unsigned char` to `unsigned int`, thus allowing more than 60000 signals/timers to be handled. All these changes will be done if the flag XMK_USE_MORE_THAN_250_SIGNALS is set.

Caution!

The Cmicro SDL to C Compiler does not check for the upper limit of 250 signals being reached for a generated SDL system. Instead the Targeting Expert will check the amount of signals and timers in the SDL system and will inform the user.

Example 602: ----------

C code generated for signals and timers:

```
#define znnn_SignalName 1
#define znnn_SignalName 2
```

Where `znnn_` is the automatically generated prefix which is required to cope with the SDL scope rules. Remember, that processes in SDL can have the same name as signals, states etc. Prefixing, however, ensures uniquely named SDL objects in the generated C Code.

Example 603: ----------

A system with 2 signals S1 and S2, and a timer TIMER1:

```
#define z049_TIMER1     1
#define z050_S1         2
#define z051_S2         3
```

When it comes to connecting the environment to the SDL system, the automatic numbering of signal IDs and timer IDs may not be required. If the user wants to prevent the automatic numbering of signals, then it is possible to #include a file containing all the signal and timer numbers. The file may contain something like:

```
#undef  SignalOrTimerName
#define SignalOrTimerName AnyValueAccordingToKernelRules
```

States

SDL states are consecutively numbered from 1 through to N for each process type. The values 0, and 250 to 255 are reserved for internal purposes in the Cmicro Package. This restriction incurs no foreseeable difficulty as processes should never have more than 50 States as a recommendation.

If there are even more states per process the flag XMK_USE_HUGE_TRANSITIONTABLES must be set.

The following C code generation is supplied for the header-section of the generated C file(s).

For each SDL process:

```
#define znnn_State1Name 1
#define znnn_State2Name 2
....
#define znnn_State3Name 3
```

Example 604: ----------

For a process with 2 states S1 and S2:

```
#define z020_S1
#define z021_S2
```

These values are used in the state-index-table and in the generated C functions, wherever a nextstate is referenced.

SDL Restrictions

General

The Cmicro SDL to C Compiler handles SDL concepts according to the definition of SDL-92. In addition to the restrictions of all the SDL to C Compilers, the following additional restrictions are introduced for the Cmicro SDL to C Compiler:

- Inheritance of procedures
- Procedures with states
- Remote Procedure Calls
- Nested procedure call data scope
- Export / Import
- View / Reveal
- Enabling condition / Continuous signal
- Service and priority input and output
- Channel substructure
- Declaring an infinite number of process instances (x,) or (,)
- FPARS when creating a process
- Omission of parameters in a signal input
- Output via all
- Timers duration values cannot be real
- Timers with more than one parameter
- Timers with another parameter than sort integer
- The any expression
- Only the list of ADT and packages that are explained in the subsection "Exceptions for SDL Predefined Types" on page 3406 and the subsection "Exceptions for Implementations of Operators" on page 3409 are handled correctly with Cmicro.

The following restrictions are additional regarding the packages that are delivered together with the SDL Suite.

sdth2sdl

It is impossible to read in header files created with Cadvanced and use them in Cmicro and the other way around. The reason is that it is impossible to mix up C code between Cadvanced/Cbasic and Cmicro.

Combining Cadvanced / Cmicro C Code

Mixing C code from different C Code Generators is not possible as the different code generators use their own run-time model and run-time data structures. Trying to mix up the C code will lead to compilation errors.

Light and Tight Target Integrations

The light and tight target integrations delivered with the SDL Suite are only available for Cadvanced but not applicable to Cmicro. There are light and tight target integrations for Cmicro but these are not part of the product.

Restrictions in Combination with SDL Target Tester

Scope Rules / Qualifiers

If the SDL Target Tester is to be used, then the **scope rules** of SDL are handled in a restrictive fashion. No information is generated for the system, block, block substructure, channel and signalroute. After applying the Cmicro SDL to C Compiler, all the structuring information is lost.

This means that it is impossible to address two different processes with the same name in different blocks. In order to avoid problems, give all processes, signals and timers in the system a different (unique) name.

Predefined Sorts

The predefined sort charstring and all the predefined sort that are based on the implementation of charstring (like predefined sorts from ASN.1) cannot be handled, if the SDL Target Tester is to be used. All predefined sorts which are generated into pointers in C cannot be used. In order to get a detailed description, please see in chapter 67, *The SDL Target Tester*.

Analyzer Restrictions

The restrictions in the SDL Analyzer, which also affects the Cmicro SDL to C Compiler, are summarized in *chapter 54, The SDL Analyzer*.

Declaration of signals

There is a restriction in the Cmicro code generator which causes a compilation error. The error is related to declaration of signals under the three following conditions:

- The signal must be declared inside a block. If the signal is declared on system or package level, this restriction will not occur.
- The signal must have parameters that are deallocated by the receiving process. For signals containing simple types or no parameters, this restriction will not occur.
- When generating code “Full separation” must be switched on. If no separation is used, this restriction will not occur.

If all three conditions are met there will be a compilation error from compilation of the <system>.c file. The function cm_Free_Signal requires all signal declarations to be able to free the parameters for the signals. When signals are declared on block level the header file for such blocks are not included in the compilation of the <system>.c file.

If these three conditions apply you must include the needed header files manually on system level, this can for example be done by adding a text symbol on system level:

```
/*#CODE
#HEADING
#include "x.h"
#include "y.h"
*/
```

Chapter

66 *The Cmicro Library*

The Cmicro Library consists of a configurable SDL kernel together with all the necessary SDL data handling functions. The collection of C functions and C modules make up the so called SDL machine.

The Cmicro Library is used in combination with the C code generated by the Cmicro SDL to C Compiler. For information on the generator see chapter 65, *The Cmicro SDL to C Compiler*.

The scaling facilities in Cmicro mean that it is useful for both micro controller and real-time applications. The Targeting Expert will help to scale and configure the generated code and the library. Please view chapter 59, *The Targeting Expert*.

The SDL Target Tester offers the ability to target tests and debug Cmicro code. Please see chapter 67, *The SDL Target Tester*.

Introduction

The Cmicro Library is required for handling the SDL objects that have been generated from SDL into C with the Cmicro SDL to C Compiler. This means that the C code which was generated with the Cmicro SDL to C Compiler cannot be used without the Cmicro Library. It also means that the C code generated with Cadvanced cannot be used together with the Cmicro Library and vice versa.

The Cmicro Library is a collection of C functions and C modules which consists of:

- The non preemptive Cmicro Kernel
- The preemptive Cmicro Kernel
- All functions which are necessary to handle SDL data
- Utility functions

Note:

The Cmicro preemptive kernel is only available if the according license is available.

Furthermore the Cmicro Library can be instrumented with SDL Target Tester functionality.

Before the Cmicro Library can be used, some adaptations and configurations must be made. The Targeting Expert is a tool which helps in configuring the application, node, component and the SDL Target Tester.

In this chapter, the C source code of the Cmicro Library and the generated C code of an application are described. Although a separate chapter is dedicated to the SDL Target Tester (see chapter 67, *The SDL Target Tester*), a few features are outlined here. The following topics are discussed:

1. The section "Differences between Cmicro and Cadvanced" on page 3456 helps in taking care of compatibility between different C code generators. There are things which must be observed in SDL diagrams.
2. The section "The SDL Scheduler Concepts" on page 3460 gives information about how the SDL scheduler works. This is also of interest for creating SDL specifications with the most highest conformity because the different SDL schedulers work differently.

3. The section "Targeting using the Cmicro Package" on page 3481 presents all the steps that must be carried out for doing targeting with Cmicro.

4. The section "Compilation Flags" on page 3486 presents a complete list of all the flags that the Targeting Expert recognizes. The different flags are explained in detail.

5. The section "Adaptation to Compilers" on page 3523 must usually be read before the C code generated by the Cmicro SDL to C Compiler and Cmicro Library can be compiled to form an executable. This section outlines the steps that must be carried out for introducing a C compiler which is not in the available list. The Targeting Expert offers an easy to use feature to add a new compiler. Please view "Compiler Definition for Compilation" on page 2910 in chapter 59, *The Targeting Expert*.

6. The section "Bare Integration" on page 3530 gives detailed information on how to adapt the generated SDL system to the environment. Communication with handwritten C code, as well as communication between SDL and the operating system or a naked machine, is described here.

7. The section "File Structure" on page 3565 explains the functionality of the different C files delivered with Cmicro.

8. The section "Functions of the Basic Cmicro Kernel" on page 3570 contains a list of C functions that are usually included in a target executable plus a short description.

9. The section "Functions of the Expanded Cmicro Kernel" on page 3592 contains a list of C functions that are usually not included in a target executable. The functions listed in this section can usually be left out because they have meaning for special forms of integration in target systems only. The functions include a short description.

10. The section "Technical Details for Memory Estimations" on page 3598 presents some information to the user which enables him to roughly estimate the consumption of memory in the target system. A self defined benchmark test is included, too.

Pay extra attention to the subsection "Automatic Scaling Included in Cmicro" on page 3519, which contains important information on the differences to the Cadvanced Library.

If examples of generated code are given, they are always shown in ANSI style. In addition, only the important parts of the code are shown to increase readability in the examples.

Differences between Cmicro and Cadvanced

General

This description deals with the differences between the generated C code of the Cadvanced SDL to C Compiler and the Cmicro SDL to C Compiler and the run-time libraries. There are differences because the main application area for the code generators differ.

Some of the differences discussed in the following are of interest for SDL users, while others are not.

SDL Restrictions

The Cmicro SDL to C Compiler has more SDL restrictions than the Cadvanced SDL to C Compiler. The additional restrictions are described in the subsection "SDL Restrictions" on page 3450 in chapter 65, *The Cmicro SDL to C Compiler*.

Furthermore, there are restrictions within the Cmicro Library that may affect the user's SDL system design. These restrictions are listed in the following. More technical information can be found in the section "Generation of Identifiers" on page 3446 in chapter 65, *The Cmicro SDL to C Compiler*.

- The run time model in Cmicro is such that there are global variables used in the generated C code and the Cmicro Library. The code generation uses "Auto initialization in C" quite extensively because the C compiler then can produce code that is more efficient than if initialization would take place within a generated C function (like `yInit`).
- The run-time model of the preemptive kernel requires function recursion from the C compiler.

Scheduling

First, it must be emphasized that both schedulers conform fully with SDL, although the schedulers introduce a different behavior.

Cadvanced uses a process ready queue together with signal queues in order to schedule processes. Cmicro does not use a process ready queue but all scheduling is derived from one physical queue. This physical queue represents all SDL process input ports. Logically, or seen from SDL, each SDL process has its own input port.

Another difference is the preemptive scheduler of Cmicro, if it is used.

Thus, different execution of processes will occur.

It is also a question of SDL design whether the differences between Cadvanced and Cmicro can be externally recognized.

If no SDL process assumes a particular real-time behavior from its communicating partner process then the behavior – as seen from a black box view – is always the required one.

Generation of Files

The Cmicro SDL to C Compiler generates some more files. This is of interest when implementing build scripts, makefiles and so on.

It is important that after each change in the SDL system the Cmicro Library is re-compiled. The reason for this is the automatic scaling facility. Please view "Automatic Scaling Included in Cmicro" on page 3519.

Environment Handling Functions

The main differences arise when considering the environment handling functions. However, this only has consequences if the SDL environment is the same in both cases (if Cadvanced is used for simulation only and Cmicro for targeting, then the environment functions are to be implemented twice in any case).

Instead of including `scttypes.h` as in Cadvanced, for Cmicro the following include statements are to be introduced in the header of the environment module:

```
#include "ml_typ.h"
#include "<systemname>.ifc"
```

In general (for Cmicro as well as Cadvanced) four C functions are used to represent the SDL environment, namely

- `xInitEnv`,
- `xInEnv`,
- `xOutEnv`,
- `xCloseEnv`.

The functions have the same general meaning for Cadvanced and Cmicro, but there are a few differences so that it is necessary to implement the environment twice.

For Cmicro, each of the above C functions is compiled only if it is required (selected by `XMK_USE_xInitEnv, XMK_USE_xInEnv`...)

Differences occur in the declaration of the C functions `xInEnv()` and `xOutEnv()`.

The `xInEnv()` function of Cmicro carries no parameters.

The `xOutEnv`() function of Cmicro carries a few parameters which represent the signal which is to be output to the environment, including the signal parameters. It is recommended that the definition of the C function `xOutEnv()` should be written twice, once for Cadvanced and once for Cmicro.

The environment functions can also be generated with the help of the Targeting Expert.

Another difference is that signals and processes are identified in different ways. Cmicro does not use identifications like `xIdNode`. Instead, it uses fixed C defines to identify signals and processes. This is beneficial in reducing the amount of memory but has the consequence that each access to any signal and any process is to be implemented differently. Process type IDs are generated into the file `sdl_cfg.h`, signal IDs and type definitions are generated into the `<systemname>.ifc` file. The chapter about the Cmicro SDL to C Compiler gives more details on how identifiers are generated and can be used.

Including C Code in SDL by User

C code may be included in SDL by the user in the following cases:

- In order to connect SDL to the environment in a way other than via the C functions `xInEnv() / xOutEnv()`

- To use C constructs, which do not exist in SDL
- To use existing C code (e.g. C library functions)
- To implement the body of ADTs
- In an SDL task.

If any C code or C identifiers are used, then users must use the right identifiers and functions.

Generated C Code

Of course, the generated C code is different when comparing Cmicro with Cadvanced. It would take too much room to list all the details in this subsection. In any case these differences are of interest for certain technical reasons only and not for pure SDL users.

To compare the different code generator outputs, the user should refer to the subsection "Output of Code Generation" on page 3418 in chapter 65, *The Cmicro SDL to C Compiler*.

General Recommendations Regarding Compatibility

In order to reach full compatibility between Cadvanced and Cmicro, the following general recommendations should be followed:

- In general, C code should not be used in SDL diagrams.
- If there is no option other than to use C code, the C code should be written as compatible as possible, i.e. the C code should be written without using any C code generator or compiler specific commands. Also the C code should be placed at dedicated locations, and should not be distributed over the SDL diagrams.
- If it is not possible to reach full compatibility, then the C code must be written twice. A switch, which is used when invoking the C compiler, selects C code either for Cadvanced or for Cmicro. The macro `XSCT_CMICRO` will help to distinguish automatically.

The SDL Scheduler Concepts

In this section, the concepts of the Cmicro SDL scheduler are outlined, with particular emphasis on basic SDL, the handling of the queue, scheduling, signals, timers, states etc. To obtain information about data in SDL, especially ADTs, please consult chapter 56, *The Cadvanced/Cbasic SDL to C Compiler*. Here both predefined and user defined ADTs are outlined.

Signals, Timers and Start-Up Signals

Data Structure for Signals and Timers

Each signal that is either an ordinary SDL signal, a timer or the start-up signal used for the dynamic process creation, is represented by three structures:

- A C structure defining the entries in the queue
- A C structure defining the header of each signal
- A generated C structure representing the parameters of the signal

The first and the second is defined in `ml_typ.h`, the third is defined in the generated code as `yPDef_SignalName`. Some structure components are conditionally compiled, which is used to scale the system. Please view the following C structure:

```
typedef struct
{
   #ifdef XMK_USE_RECEIVER_PID_IN_SIGNAL
       xPID          rec;   /* Receiver process */
   #endif

   xmk_T_SIGNAL  signal;    /* Signalcode       */

   #ifdef XMK_USE_SIGNAL_PRIORITIES
      xmk_T_PRIO  prio;     /* Priority         */
   #endif

   #ifdef XMK_USE_SIGNAL_TIME_STAMP
      xmk_T_TIME time_stamp;/* Timestamp        */
   #endif

   #ifdef XMK_USE_SENDER_PID_IN_SIGNAL
       xPID         send    /* Sender process   */
   #endif
```

```
    #ifdef XMK_USED_SIGNAL_WITH_PARAMS
      xmk_T_MESS_LENGTH mess_length;
      union
      {
         void          *ParPtr;
         #if (XMK_MSG_BORDER_LEN > 0)
           unsigned char ParCopy[XMK_MSG_BORDER_LEN];
         #endif
      } ParUnion;
    #endif

} xmk_T_MESSAGE;
```

- `signal:`
  represents a C constant which uniquely identifies the signal or timer across the complete system.

- `rec and send:`
  represents the PID values of the receiver and sender of the signal. See the subsection "Processes and Process IDs (PID)" on page 3446 in chapter 65, *The Cmicro SDL to C Compiler* for details. These are conditionally compiled.

- `prio`:
  is used to store the priority of the signal. This is specified by using the directive `#PRIO` in the SDL diagram. It is compiled only, if signals with priority are stipulated by the user.

- `timestamp:`
  is used to store a timestamp, which is set when the SDL signal is put into the queue (output time). This component is also conditionally compiled.

- `mess_length:`
  represents the amount of parameter bytes in the signal.

Three different cases are to be considered concerning signals with parameters:

- If the signal has no parameters, then `mess_length` is set to 0 and `ParPtr` is a `NULL` pointer.

- If the signal parameters are larger than XMK_MSG_BORDER_LEN (*) bytes, then `mess_length` is set to the number of bytes and `ParPtr` is undefined.

- If more than XMK_MSG_BORDER_LEN (*) bytes of parameters are to be transferred, then `mess_length` defines the amount of bytes used for the parameters and `ParPtr` points to a dynamically allocated area.

Note:

This margin of XMK_MSG_BORDER_LEN bytes can of course be modified by the user to prevent dynamic memory allocation for any signal in the queue, or in contrast, to always use dynamic memory allocation. See the file `ml_mcf.h` to modify this.

The second structure, which encapsulates the above one, is used to administrate the signals in the queue, as required by the FIFO handling and SDL save construct:

```
typedef struct _T_E_SIGNAL
{
  xmk_T_MESSAGE       Signal;
  struct _T_E_SIGNAL *next;

#ifdef XMK_USED_SAVE
  xmk_T_STATE         SaveState;
#endif /* XMK_USED_SAVE */
} T_E_SIGNAL ;
```

- `next:`
  is a pointer which refers to the next entry of the queue. This is used by the Cmicro Kernel to get the next signal after the current one has been worked on.

- `SaveState:`
  contains either a dummy state value XEMPTYSTATEID or the state in which the process saved the signal. This is necessary to compare when the signal is to be consumed after state changes in the receiver process. It is used only if save is used anywhere in the SDL system.

As already mentioned, the above structure is used for ordinary SDL signals, timers and the start-up signal for the dynamic process creation.

No differentiation is made between signals and timers, except that signals and timers have a different identification (signal in the `xmk_T_SIGNAL` structure).

When a process is to be created, a start-up signal is sent. The start-up signal is tagged by a special priority value and a special id.

Dynamic Memory Allocation

Dynamic memory allocation is in principle not necessary with Cmicro. There are SDL systems which can live without any dynamic memory allocation and there are SDL systems that require dynamic memory allocation from the user's point of view. The users should in general try to prevent any dynamic memory allocation due to the problems this introduces. Soon or later memory leaks will occur.

Cmicro offers its own dynamic memory allocator. Please view "Dynamic Memory Allocation" on page 3543 for getting more information on this.

In the following subsections, the exceptions for when Cmicro uses dynamic memory allocation are listed.

Signals and Signal Parameters

In order to cope with efficiency, dynamic memory allocation should not be done, whenever possible. Cmicro offers two principles of memory allocation for signal instances, namely:

1. Signal instances are allocated from a static memory pool only.

   The static memory is allocated during compilation. The pool's size is predefined with the `XMK_MAX_SIGNALS` macro. To enable this configuration, the macro `XMK_USE_STATIC_QUEUE_ONLY` is to be set. This principle has the disadvantage that if there is no free memory in the static memory pool, a fatal error occurs. The user is however given the possibility to react on this error situation because the `ErrorHandler` C function is called.

2. As another principle, it is possible to first take memory from the static memory pool. If no more memory is available in that pool, further signal instances are created from the dynamic memory pool.

> **Caution!**
>
> This configuration is not available when the preemptive scheduling mechanism is used.

To enable the configuration, the macro XMK_USE_STATIC_AND_DYNAMIC_QUEUE must be set. The static memory pool's size is still predefined with the XMK_MAX_SIGNALS macro.

When signal instances are allocated from the static memory pool, the allocation procedure is the most efficient.

When the second principle is used, the execution speed will of course dramatically slow down because dynamic memory allocation happens. This change in the behavior of the Cmicro Kernel may cause problems in a real-time environment and the user should keep this in mind.

The static memory pool above is implemented as a predefined array in C. The array is dimensioned with the XMK_MAX_SIGNALS macro.

Dynamic memory is requested with the xAlloc C function and released again with the xFree C function. The body of both these C functions must in any case be filled out appropriately by the user in all cases.

Signal parameters are to be allocated dynamically, if the amount of parameter bytes exceeds a predefined constant. If the amount of signal parameters is below or equal this predefined constant, the parameter bytes are put into the signal's header.

The default value for this predefined constant XMK_MSG_BORDER_LEN is 4 bytes. Dynamic memory allocation only occurs if a signal carries more than XMK_MSG_BORDER_LEN bytes, where the latter is defined as 4.

If the user defines XMK_MSG_BORDER_LEN as 0, then for each signal, which has parameters, the C function xAlloc() is called.

If the user defines XMK_MSG_BORDER_LEN to 127, then

- for signals which have 127 parameter bytes or less, the parameters are copied into the xmk_T_SIGNAL structure.
- for signals which have more than 127 parameter bytes, the parameters are copied into an allocated area (using the C function xAlloc()).

Due to this mechanism, the allocation of signal parameters is also very fast. Releasing the memory is performed automatically by calling the xFree C function.

Predefined Sorts

Some of the predefined sorts require dynamic memory allocation. The sorts are

- charstring
- any ASN.1 sort that is based on charstring
- predefined Generators like Array (without a specified upper limit), String, Powerset, Bag, Ref

SDL Target Tester

If the SDL Target Tester is used, there are some more allocations from the dynamic memory pool. The SDL Target Tester allocates one block of dynamic memory in the start phase. This block is never de-allocated again. The size of the block depends on the amount of process types in the system. Another dynamic memory allocation takes place when a binary frame is to be sent to the host machine. The blocks that are allocated here are de-allocated again after the frame is put into the physical transmitter buffer.

Overview for Output and Input of Signals

Output and input of signals is performed according to the rules of SDL. To get detailed information about the implementation of output and input, please consult the subsection "Output and Input of Signals" on page 3476.

Signal instances are sent using the C function `xmk_Send()` or `xmk_SendSimple()`. The function takes a signal and puts it into the input port of the receiving process instance.

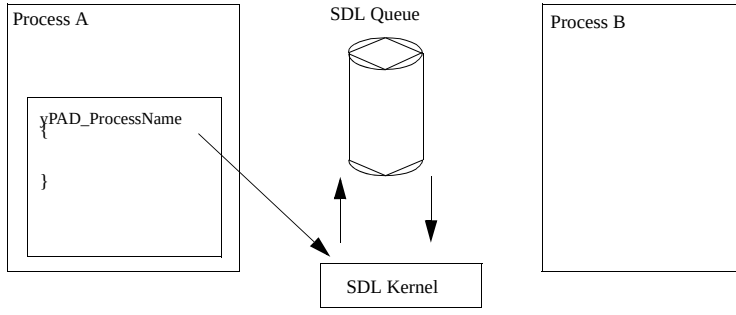

Figure 590: Queueing - sending side

There is no process ready queue. Physically, the queues of the different processes of the system are represented by just one queue. There are different principals to create signal instances which the user can choose between. The principals are explained within the subsection "Signals and Signal Parameters" on page 3463.

From an abstract point of view, it does not matter, if there is one physical queue for all the signal instances in the system, or if there is one physical queue for all the signal instances sent to one process instance. The fact that Cmicro uses one physical queue for all signals in the system only, has no effect on SDL users and conforms to the semantic rules of SDL. The scheduling simply depends on the ordering of signals in the queue. In the case of a preemptive Cmicro Kernel scaled this way, there is one linked list of signals per priority level all using the array mentioned above. See the subsection "Scheduling" on page 3469 for details.

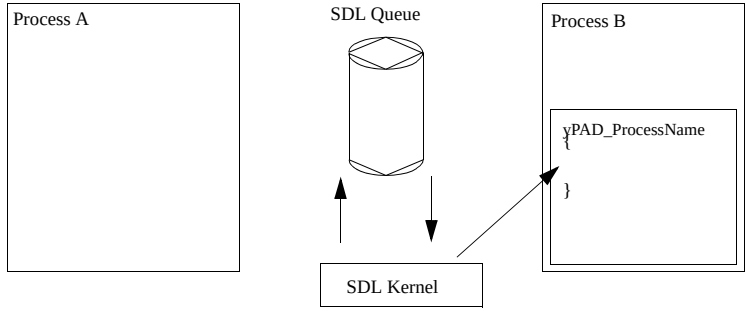

Figure 591: Queueing - receiving side

When working on a signal, the Cmicro Kernel decides between four different constellations:

- The receiving process instance is active. In its current state the signal is to be saved. The Cmicro Kernel tags the signal as "saved" and works on the next signal.
- The receiving process instance is active and there is a transition to be executed receiving the current signal. The Cmicro Kernel fires the transition.
- The receiving process instance is active but there is no transition to be executed for that signal in the current process state. The signal is in accordance with SDL rules implicitly consumed by the process.

- The receiving process instance is not active, i.e. either not yet created or already stopped. The signal will be discarded and the C function `ErrorHandler()`, discussed within the subsection "User Defined Actions for System Errors – the ErrorHandler" on page 3548, will be called.

In any case, except when being saved, the signal will be removed from the queue and returned to the list of free signals.

After performing the nextstate operation, the input port is scanned in accordance with the rules of SDL to find the next signal which would cause an implicit or explicit transition.

There is no specific input function. This functionality is contained in the Cmicro Kernel.

Timers and Operations on Timers

With the delivered timer model, all timer management entities fully conform to SDL. This means that more memory is required to implement this timer.

For each timer, there is a C structure defined in `ml_typ.h`.

```
typedef struct _TIMER
{
  struct _TIMER *next ;

  xmk_T_SIGNAL   Signal    ;
  xmk_T_TIME     time      ;
  xPID           OwnerProcessPID ;

} TIMER ;
```

`xmk_T_TIME` is defined as a long value.

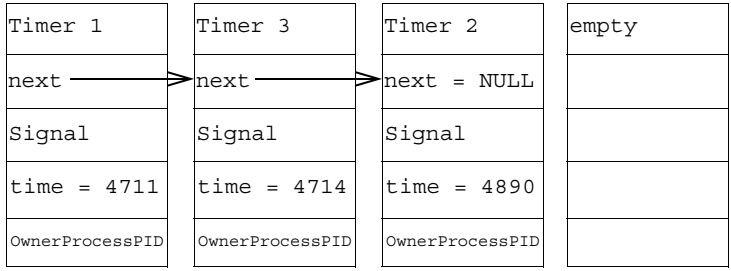

Figure 592: Handling of timers (timer model 1)

The component

- `next` is used to refer to the next entry;
- `signal` is the timer identification;
- `time` is used to store the absolute time when the timer should expire;
- `OwnerProcessPID` is used to refer to the process PID for which the timer was set.

As can be seen above, timers are implemented as a forward linked list.

- An array of timers is allocated during compile time
- The size of the array is calculated by the Cmicro SDL to C Compiler as the required maximum. It is defined by the macro MAX_SDL_TIMER_INSTS. This is also valid for multiple process instances, so that there is always enough memory to handle all timer instances which are possible. (If the user wishes to reduce the occupied RAM memory for timers, he must evaluate the maximum amount of timer instances required during run-time and modify the above define by hand).
- The timer which expires first is always put to the front of the linked list (increasing performance).
- The time value is stored as absolute time from the start of the SDL system.

Processes

Data Structure for Processes

Each process is represented by structures and tables containing SDL information, for example, tables containing transition definitions and a structure representing the variables of the process. The typedef for variables is generated in the generated code and named `yVDef_ProcessName`. For each process instance, there is one array element defined statically during compile time.

The structures and tables for processes are described in detail in the subsection "Tables for Processes" on page 3420 in chapter 65, *The Cmicro SDL to C Compiler*.

Scheduling

The Cmicro Kernel supports in principle the following scheduling policies:

- Non Preemptive Scheduling:
  Transitions in SDL cannot be interrupted.
- Preemptive Scheduling with Process Priorities:
  Transitions in SDL can be interrupted by any external or internal output. This could be a signal coming from the environment, i.e. an interface driver.
- In addition, signal priorities can be used to specify the ordering of signals in the signal queue. Signal priorities are discussed in each of the subsections mentioned above.

General Scheduling Rules

- All of the above policies basically operate on the SDL queue. Physically, the Cmicro Kernel uses one array for all process queues in the system. From the SDL point of view, the implementation conforms to SDL because each SDL process virtually has its own queue in the implementation.
- signal priorities can be used in all cases.
- process priorities are given priority treatment.

- If no signal priorities are assigned, then the ordering of signals depends on their arrival (FIFO strategy).
- In order to increase the performance, there is no process ready queue implemented. The scheduling of processes is fully derived from the SDL queue.

Further explanation of the scheduling is in the next subsection.

Non Preemptive Scheduling

The Cmicro Kernel takes the first signal from the queue and if the signal is not to be saved the appropriate SDL transition is executed until a nextstate operation is encountered. Outputs in SDL transitions as well as SDL create operations are represented by signals, where create signals are given priority treatment no matter whether signal priorities are used or not. This guarantees that there will not be any problems when a signal is sent to a process just before the process has been dynamically created.

The ordering of signals in the queue can be affected by using signal priorities (#PRIO directive for signals).

Whenever an output takes place, the Cmicro Kernel inserts the signal into the queue according to its priority. High priority signals are inserted at the queue's head, low priority signals at the queue's end. Create signals are still given priority treatment.

Note:

The priority of a create signal in the standard delivery is set to one.

This, as well as all the default signal priorities, is user-definable in the file `ml_mcf.h` (generated by the Targeting Expert). In this way it is possible to define signals with a higher priority then the create signal. The user should remember not to do so!

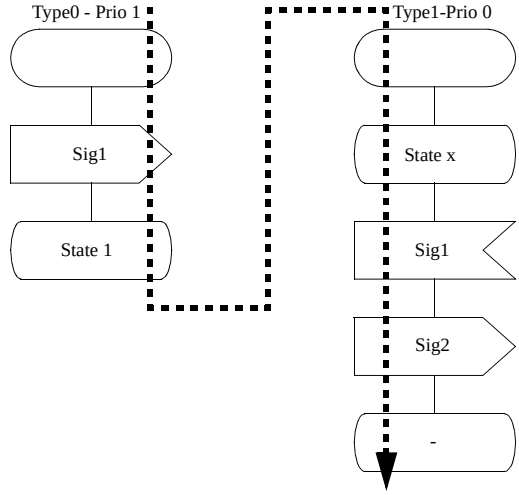

Figure 593: Non preemptive scheduling

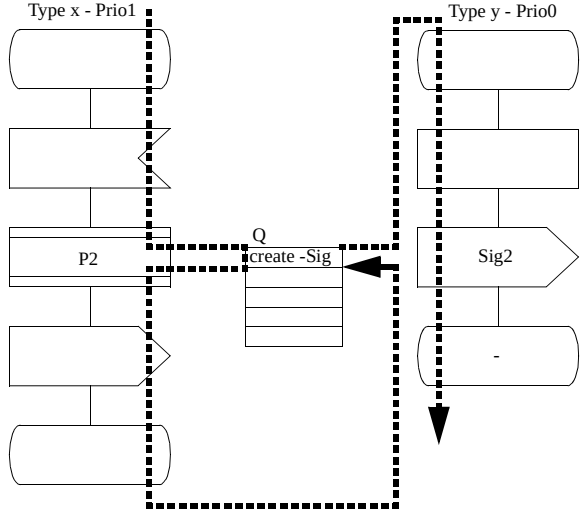

Figure 594: Scheduling for Create

A signal (this is either an ordinary SDL signal, a timer signal or the internal start-up signal in the event of SDL create) with the highest prior-

ity is always put in front of the SDL queue, a signal with the lowest priority is always put at the end of the SDL queue.

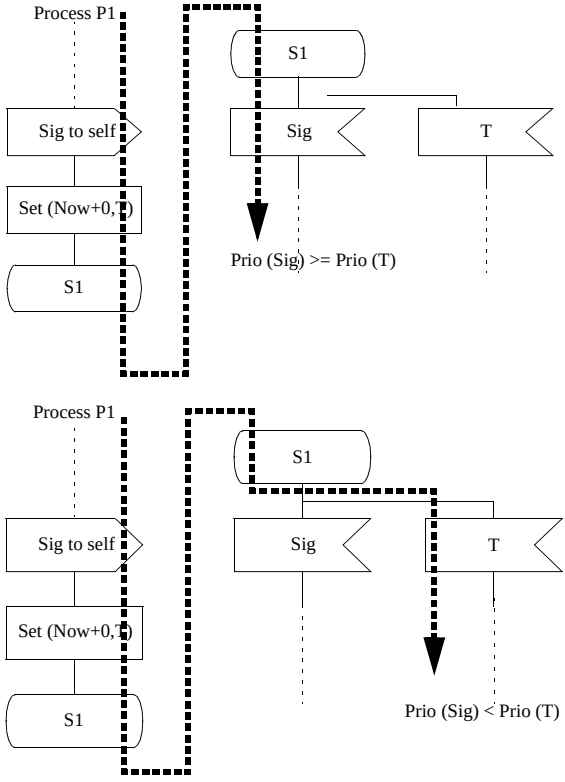

Figure 595: Signal priorities

For applications, which do not have time critical requirements, the non preemptive scheduling policy is the correct one to implement. The Cmicro Kernel memory requirements are also reduced when the non-preemptive scheduling policy is implemented. For example, for an interface with a very high transmission rate, the preemptive scheduling policy is better suited in order to increase the reaction time on external signals coming from the environment.

On starting the SDL system, processes are statically created according to their order of priority.

Preemptive Scheduling with Process Priorities

Note:

The Cmicro preemptive kernel is only available if the according license is available.

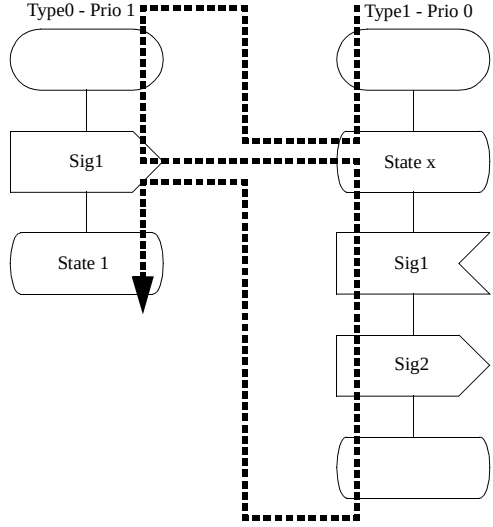

Figure 596: Preemptive scheduling

SDL assumes the start transitions of all statically created processes are already finished at system start-up (a transition takes no time according to SDL semantics). To simulate this, the Cmicro Kernel starts all statically created processes in the order of their priority before working on any signal. Preemption is disabled during the start-up phase of the system. There are two C functions namely `xmk_DisablePreemption` and `xmk_EnablePreemption` which can be used to prevent the Cmicro Kernel from performing a context switch. In this way it is possible to affect the scheduling from within the SDL system (using the #CODE directive).

The preemptive scheduling policy is absolutely necessary if an application consists of a mixture of processes, of which some have to react very quickly to external events, while others require enough time for pro-

cessing. The Cmicro Kernel does all things necessary to schedule such a mixture of processes.

Users only have to specify a high priority for processes which have to react after a short time. This can be done with the #PRIO directive for processes. If no `#PRIO` directive is specified, then a process is given the default value, which is specified by the user in the file `ml_mcf.h` (please view the subsection "Compilation Flags" on page 3486).

The highest priority is represented by the value zero. The numbering has to be consecutive with the priority decreasing with increasing numbers. Processes with the same priority are on the same priority level. The default process priority must be in the range of zero to the lowest priority value used in the system. Assume the following priority levels:

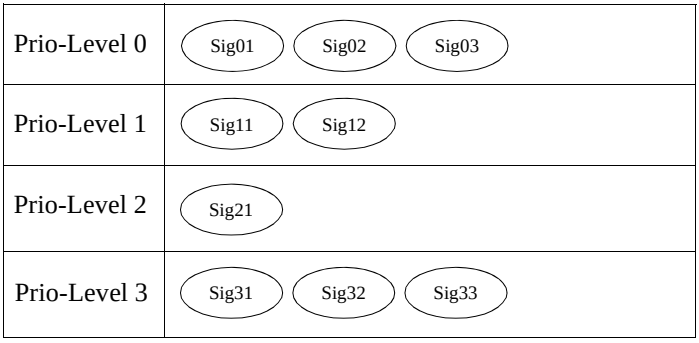

Figure 597: Priority levels

In the figure above there are signals queued for processes on four different priority levels. These would be worked on in this order:

According to their priorities the signals on priority level zero are consumed first, afterwards those of level one, two and last three. This is relevant only, if no signals are sent during the transitions executed because of the signals.

Rules

- At system start, SDL processes are statically created in accordance with their defined priority. During their start transitions it is possible for processes to send signals or create other processes but no preemption will take place until the start-up phase is completed, i.e. all

static processes have completed the transition from start state to first state.

- Processes running on a priority level never interrupt other processes running on the same priority level, thus two instances of the same type never run at one time.
- A higher priority level is entered, if a signal results in a process with a higher priority running.
- A lower priority level is entered, if all signals on the currently active priority level are consumed so that still no process is running on this priority level.
- Global variables are used to store some information concerning processes. The Cmicro Kernel is responsible for the storing and reloading of these, if a preemptive kernel is implemented.

Note:

If C variables are to be used in the SDL application, i.e. (x, N) declarations are used where N > 1 these variables are only available once and not once per process instance.

Restrictions

In order to produce portable C code, this version of the Cmicro Kernel uses recursive C function calls. A few C compilers available on the market do not support recursion. If such a C compiler is required, the user cannot use preemptive scheduling with process priorities.

Create and Stop Operations

No dynamic memory allocation occurs if an SDL create operation is performed. No freeing of memory occurs if an SDL stop operation is performed.

Data of a process instance is represented by the following typedef structs:

- A typedef struct representing PID values (parent and offspring) stored for an instance
- A typedef struct representing SDL states of an instance
- A typedef struct representing SDL data of an instance

The reason for using such a structure is to make it possible for the Cmicro Kernel to operate on the PID structure and the table with SDL states, so that no code needs to be generated in the application to update such variables.

An array of N elements for each of these typedef structs is generated, where N is the maximum number of process instances. The maximum number is to be specified in the process declaration header in the SDL diagram.

After performing a stop action, old PID values might exist in variables of other processes. The synchronization between processes to prevent situations where signals are sent to dead processes is left to the discretion of the user. If a process sends a signal to a non existent process, where nonexistent means either “never created” or “is dead”, the `ErrorHandler` is called and the signal is discarded (SDL conform).

When the Cmicro Kernel stops a process, the input queue assigned to the process stopped will be removed. No interpretation error occurs for the signals which existed in the queue before the process was stopped.

Note:

It is also possible for the user to implement dynamic memory allocation for process instance data. Some C defines are to be redefined in this case.

Output and Input of Signals

The actions to perform an output in the generated code are as follows:

- A struct variable is initialized with the type of the signal parameters, not using memory allocation.
- The struct variable is then filled, parameter per parameter in generated code.
- One of the `xmk_Send*` functions is called with a pointer to the location of the struct variable. There are several `xmk_Send*` functions in order to use the most effective one in SDL output.

Within the `xmk_Send*`- functions there are a few checks performed. For example, if the receiver is a NULL-PID, then the ErrorHandler is called.

Next, the environment C function `xOutEnv` is called. This function is to be filled out by the user. The function decides if the signal should be sent to the environment. The information necessary can be extracted from the signal ID, the priority or the receiver of the signal. If `xOutEnv` has "consumed" the signal, `xmk_Send*` returns immediately. `xOutEnv` has to copy the parameters of the signal to the receiver of the signal in the environment because after returning, the parameters will no longer exist.

If the signal is not environment bound, then the signal is sent to an internal SDL system process and `xmk_Send*` inserts the signal into the queue. This is done according to the priority of the signal (see subsection "Assigning Priorities – Directive #PRIO" on page 3415 in chapter 65, *The Cmicro SDL to C Compiler*.

If the signal carries no parameters, or if the signal parameters are represented by less than or equal to `XMK_MSG_BORDER_LEN` bytes, no dynamic memory allocation occurs and possible parameters are transferred directly by copying them into the signal header.

If more than `XMK_MSG_BORDER_LEN` bytes parameters are to be transferred dynamic memory allocation occurs. A pointer in the signal header then points to this allocated memory area. Freeing is done after consumption of the signal at the receiver process after executing the next-state operation or after the signal was consumed by the environment.

In order to implement this strategy, each signal carries a field "data length" in its header, to detect if a pointer is transferred or a copy of the parameters.

Note:

There are several possibilities to send signals to the environment by not using `xOutEnv`. The user should have a look at the `#EXTSIG`, `#ALT` and `#TRANSFER` directives which can be used in SDL Output. The one most similar to SDL, however, is the one which simply uses the C function `xOutEnv`.

At the receiver's side, when the input operation is to be performed, it is checked if the signal is to be saved or discarded. In the case of save, the next signal contained in the queue is checked and worked on. If on the other hand the signal is to be discarded, in the case of an "implicit transition", i.e. no definition is present to handle that signal in the current

state, the signal is then deleted from the input port of the process and, using the SDL Target Tester, the user is notified.

Otherwise, the signal leads to the execution of the transition. After performing the nextstate operation, the signal is deleted from the input port of the process and scheduling continues according to the rules of the scheduler again.

In the case of a so scaled preemptive Cmicro Kernel, the signal remains active in the input port until the nextstate operation is executed, although other processes can interrupt the running one (preemption).

Nextstate Operation

The nextstate operation is implemented by a return (return value) statement in the generated code. Several return values are possible to control the action to be taken by the Cmicro Kernel. The PAD function representing the SDL process can return any of the following (PAD means "Process Activity Description").

The return-value either expresses

- An ordinary SDL state change, the value is a C constant representing the SDL state as a simple integer (generated as #define),
- no SDL state change, indicated by the value `SDL_DASH_STATE`,
- SDL process stop operation, indicated by the value `SDL_STOP`.

After recognizing the action to be taken, the Cmicro Kernel either writes the process state variable or stops the SDL process.

The signal which was just being worked on is deleted from the input port. This includes the freeing of the memory area allocated for the signal, if memory was previously allocated.

Decision and Task Operations

No action is to be performed by the Cmicro Kernel for decisions and tasks, except those to trace these actions for the SDL Target Tester.

For SDL decisions and SDL tasks, C assignments and C function calls are implemented. Function calls are used in the case of an ADT or where simple C data operations (i.e. =, >, >=, ==) cannot represent the SDL operation wanted.

Note:

Function calls, however, are not necessarily generated, i.e. if the user defines C macros/defines instead of C functions for an ADT. Please consult the subsection "Abstract Data Types" on page 3406 in chapter 65, *The Cmicro SDL to C Compiler*.

Procedures

There are some special topics regarding procedures in SDL. The most important are:

- The location of data and how to access data
- Scope and visibility rules
- Procedures with states
- Recursivity
- Who can call a procedure

Note that procedures with states and remote procedure calls are **not supported** within the Cmicro Package.

It is possible to use global procedures (SDL'92) which makes it possible to specify a procedure once, by allowing several processes to call it.

Recursion is allowed, but should be introduced only if an algorithm cannot be designed alternatively. In most cases, algorithms and recursivity are subjects for an ADT.

Procedures returning values are also implemented. The return value in SDL is mapped to a return value in C. Procedures not returning values are mapped to C functions returning void.

The remaining part is the location of procedure data and the access to procedure data. Here another restriction exists, namely that it is not possible to access data of the father procedure of a procedure without declaring this explicitly.

Data, which belongs to a process is always located as a global array in C (for x, N process declarations, where N is >1). Data which belongs to a procedure is always allocated on a C stack for the called procedure.

Procedure Calls

An SDL procedure call is implemented as a direct function call in C. Each formal parameter is passed as a C parameter to the function. Ac-

cess to global data of the calling process is possible only if the procedure is not a global procedure. The C code generated for a local procedure uses global C variables of the surrounding process.

Data which is declared locally within a procedure is also allocated on the C stack.

No dynamic memory allocation is performed as procedures with states are not handled.

The following example shows the mapping for procedures returning values.

Example 605: Procedure Call

```
TASK i := (call p(1)) + (call Q(i,k));
```

is translated to something like:

```
i = p(1) + Q(i,k);
```

Note:

The value returning procedure calls are transformed to C functions returning values.

An SDL procedure can be called more than once. No conflicts occur if using a preemptive Cmicro Kernel.

Procedure Body

For each SDL procedure, there is one C function generated. The Procedure body can contain the same SDL actions as the process body. The same code generation is performed with the exception of a few statements declaring temporary variables.

Within global procedures, no objects of the calling process can be used without declaring them via formal parameters. Another restriction is that each output in a global procedure must be specified with **to PID**.

Blocks, Channels and Signal Routes

No C code is generated for blocks, channels and signal routes, except the C comment, which tells the user the location of processes and procedures.

Targeting using the Cmicro Package

Directory Structure

At first it is necessary to know the directory structure the Cmicro Package is stored in.

On UNIX, the Cmicro Package is contained in `$sdtdir/cmicro`.

In Windows, the Cmicro Package is contained in `%SDTDIR%\cmicro`.

```
cmicro
   +-- include
   +-- kernel
   +-- mcod
   +-- template
         +-- commlink
   +-- tester
```

Furthermore all files, which are used when targeting Cmicro, are definitely stored in this directory tree. Otherwise the files are generated by the Cmicro SDL to C Compiler or by the Targeting Expert.

Prerequisites

Before starting the targeting with Cmicro it is necessary to have an SDL system designed and already tested with the help of the Simulator.

This means targeting begins when the first testing phase is finished.

All steps of targeting will be discussed in the following sub-sections.

Different Steps in the Work Flow

All the different operation steps listed here will completely supported by the Targeting Expert (see chapter 59, *The Targeting Expert*).

1. To start the Targeting Expert, select the entry *Targeting Expert* in the Organizer's *Generate* menu.
2. Select pre-defined integration settings or <*user defined*> for a new integration. See "Pre-defined Integration Settings" on page 2977 in chapter 59, *The Targeting Expert*.
   - select the Code Generator Cmicro (if not automatically done)
   - select the compiler (if not automatically done)

   The Cmicro SDL to C Compiler will automatically be invoked and generates the following files (assumed that separation is not selected):

sdl_cfg.h	the automatic configuration
<systemname>.c	the SDL system
<systemname>.ifc	the environment header file
<systemname>_gen.m	the sub-makefile (Targeting Expert)
<systemname>.xrf	the X-References (not used)
<systemname>.sym	the symbol file (SDL Target Tester)

3. Specify the compiler, linker and make settings (if not automatically done).

   Please view "Configure Compiler, Linker and Make" on page 2930 in chapter 59, *The Targeting Expert*.
4. Configure and scale the generated C code and the Cmicro Library.
   - For information about the compilation flags and their interdependencies please view "Compilation Flags" on page 3486.
   - For more details how to use the Targeting Expert please view "Configure and Scale the Target Library" on page 2946 in chapter 59, *The Targeting Expert*.
5. Copy template files.

Several files of the Cmicro Package are delivered as template files. This is done because lots of things can only be done by the user as they must fit to the user's SDL system. The template files give easy to use C functions including help to adapt them to the user's needs.

All the files `mk_stim.c`, `mk_user.c` and `mk_cpu.c` should be copied into the project's directory tree (generated by the Targeting Expert). All these files are stored in the `template` directory.

If the SDL Target Tester should also be used it is necessary to copy the files `mg_dl.c` and the files describing the preferred communications link (e.g. the file `8051_v24.[ch]` if an 8051 micro controller and a V.24 interface should be used) into the project directory, too. The file `mg_dl.c` is stored in the `template` directory and the communications link files are stored in `template/commlink` if contained in the Cmicro Package delivery. Please view the sub-section "The Communications Link's Target Site" on page 3712 to get information about how to create an own communication link.

Please view also "Source Files" on page 2935 in chapter 59, *The Targeting Expert* to get information on how to add more files to the list of files to be compiled. The Targeting Expert will automatically add these files to the makefile.

6. Full make the complete system.

   It is probably necessary to do an environment connection first (see "Connecting the SDL Environment" on page 3483).

7. Download and execute the executable.

   The following sections in the Targeting Expert's manual (chapter 59, *The Targeting Expert*) should be checked to find out how these steps can be eased:

   – "Download Application" on page 2955

   – "Test Application" on page 2955 (which is probably the target executable itself)

Connecting the SDL Environment

From the Cmicro Package's point of view the SDL environment is represented in template C functions. A short overview of this C functions

is given here. For further information please view "Bare Integration" on page 3530.

- xInitEnv():
  This function is given as a template in the file `env.c`. It needs to be filled any time it is necessary to initialize specific hardware components on the target.

- xCloseEnv():
  `xCloseEnv()` is given as a template in `env.c`, too. It is only necessary to fill this function if the SDL system can perform a system stop.

- xInEnv():
  `xInEnv()` is basically generated by the Targeting Expert into the file `env.c`. This means that all the signals coming from the environment are already inserted into the C code of this function.

Note:

All the modifications of `env.c` should only be done between the comments `/* BEGIN User Code */` and `/* END User Code */`. All the other modifications will be lost when re-generating the `env.c` file.

- xOutEnv():
  For all the signals to the environment the Targeting Expert generates the C function `xOutEnv()` into the file `env.c`. All the signals to the environment are included into the C code.

Note:

All the modifications of `env.c` should only be done between the comments `/* BEGIN User Code */` and `/* END User Code */`. All the other modifications will be lost when re-generating the `env.c` file.

- User Defined Actions for System Errors – the ErrorHandler:
  The Cmicro Package supports the handling of detected errors by calling the C function `ErrorHandler()` in the module `mk_user.c`. The user needs to redirect the error messages to his target hardware. I.e. display the errors on the hardware.

The compilation and linkage of the environment functions can be prevented by using the flags given in "Compilation Flags" on page 3486.

Different Forms of Target Integration

Different forms of target integration, that is, integrating generated C code, are distinguished:

- Bare Integration: There is no operating system available on the target machine. The `main()` function of Cmicro can be used.
- Light Integration: An operating system is used and the complete SDL system executes in one operating system task. The SDL task communicates with the environment by using the communication resources of the operating system.
- System partitioning: An operating system is used, the SDL system may execute in different CPUs, or the processes of the SDL system execute in different OS tasks.
- Tight Integration: An operating system is used, the SDL system executes in one CPU, and the processes of the SDL system execute in different tasks.

Bare and Light integration represent the most easiest form of integration.

Bare integration is described in "Bare Integration" on page 3530.

Light integration is described in "Light Integration" on page 3559.

Tight integration can be performed with Cmicro, but the complexity makes it difficult to describe the integration in this section. It is a generic solution available, which guides thought the integration.

Please contact IBM Rational local sales office/Professional Services for further information.

Compilation Flags

Compilation flags are used to decide the properties of the Cmicro Library and the generated C code. Both in the Cmicro Library and in the generated code `#ifdef`'s are used to include or exclude parts of the code.

The switches used can be grouped:

1. Flags defining the compiler
2. Flags defining the properties of a compiler
3. Flags defining the properties of the Cmicro Library
4. Flags defining the implementation of a property

The first two groups are discussed in "Adaptation to Compilers" on page 3523.

The remaining two groups are discussed under "Manual Scaling" on page 3486 and "Automatic Scaling Included in Cmicro" on page 3519.

Flag naming conventions:

- `XMK_ADD_`: include optional parts
- `XMK_USED_`: automatically include parts of the Cmicro SDL to C Compiler. Note: Do not switch off by hand.
- `XMK_USE_`: manual scalings
- `XMK_MAX_`: manual scalings

Use the default settings of these flags in order to reduce potential problems.

Manual Scaling

Users are able to scale some features of the Cmicro Library and the Cmicro Kernel in order to optimize the generated code. All the flags discussed in this section are used throughout the complete SDL system, therefore it is not possible to define flags for processes separately.

> **Note:**
> The whole SDL system must always be generated.

The manual scalings have to be done in the file `ml_mcf.h`. They are divided into the following groups:

1. Cmicro Kernel/Library
   - Kernel
   - Signals
   - Timers
   - Error checks
2. Support of SDL Constructs
   - Predefined sorts
   - Size of variables
   - Use of memory
3. SDL Environment
4. SDL Coder
5. SDL Target Tester
   - Initialization
   - Trace
   - Record and Play
6. Communication Link and Compiler

In the following subsections, the way to configure the Cmicro Package by hand and all the available flags are described.

The user is asked to use the Targeting Expert to configure the Cmicro Package. A description of how to use the targeting Expert can be found in "Targeting Work Flow" on page 2926 in chapter 59, *The Targeting Expert*.

To configure the Cmicro Package by hand, the user has to modify the file `ml_mcf.h`.

To use a Cmicro Package feature just define it in `ml_mcf.h` like

```
#define FLAG_NAME_AS_DESCRIBED_BELOW
```

Sometimes a flag just carries a value. In this case the user has to modify the value in `ml_mcf.h`

```
#define FLAG_CARRYING_VALUE  VALUE
```

Cmicro Kernel/Library

Kernel

General

- XMK_USE_KERNEL_INIT

  When this flag is defined, the Cmicro Kernel `memsets` all variables of the SDL processes to 0 before the process is created. This is useful to spare some ROM memory but has the disadvantage of a longer process creation phase. The ROM used by the `yDef_SDL_*` functions can be spared in this case where the initialization with 0 is appropriate.

Initial setting	set

- XMK_USE_SDL_SYSTEM_STOP

  Normally, it is unnecessary to have an SDL system stop in micro controller applications. An SDL system stop occurs if no living process in the SDL system exists and all queues are empty. This occurs if all process instances have executed an SDL stop and no create process action is open (create signal in any queue).
  Defining `XMK_USE_SDL_SYSTEM_STOP` means that the C function `main` returns correctly with exit(...). To avoid this overhead in the Cmicro Kernel, the user should not define the above flag.

Default setting	unset

- XMK_SYSTEM_INFO

  If this flag is set, some functions available to get information about the SDL system during runtime. See "Functions to get System Information" on page 3593

Initial setting	unset

- XMK_USE_NO_AUTO_SCALING

  When this flag is defined, automatic scaling of SDL features is prevented. An example of flag usage is implementing a change to the SDL system which does not require re-compilation of the Cmicro Library. Note that if the number of processes, signals or timers is changed, the Cmicro Library must be re-compiled. The definitions contained in `sdl_cfg.h` are overwritten in `ml_typ.h`.

Initial setting	unset

- XMK_USE_KERNEL_WDTRIGGER

  If this flag is defined, the Cmicro Kernel calls the C function `WatchdogTrigger` before executing a transition. This function is present as a template in the Cmicro Library source files.

Initial setting	unset

- XMK_USE_INTERRUPT_SERVICE_ROUTINE

  If this flag is defined, the Cmicro Kernel will enable more critical paths in functions xmk_InsertSignal, xmk_AllocSignal and xmk_FreeSignal. This flag needs to be manually set if Interrupt Service Routine (ISR) is used and can lead to signal sending.

Initial setting	unset

Kernel Limits

- XMK_USE_HUGE_TRANSITIONTABLES

  Per default the Cmicro Package can handle up to 252 different transitions per process. If the SDL system exceeds this size, it is necessary to set this flag. See "Transition Table" on page 3424 for further information.

Initial setting	unset

- XMK_USE_MORE_THAN_250_SIGNALS

Per default the Cmicro Package is designed to handle up to 250 user defined signals. When using larger SDL systems it is necessary to define this flag. This results in larger RAM and ROM occupation and should only be done if necessary (see `xmk_T_SIGNAL`).

Initial setting	unset

- XMK_USE_MORE_THAN_256_INSTANCES

  Per default the Cmicro Package handle up to 256 instances per process type. If the system uses more than 256 instances per type it is necessary to set this flag.

Initial setting	unset

- XMK_USE_PAR_GREATER_THAN_250

  Per default the Cmicro Package is able to handle signal parameters up to a length of 250 octets. If greater signal parameters are used (at least once) this flag needs to be set. Please view `xmk_T_MESS_LENGTH` in `ml_typ.h` for further information.

Initial setting	unset

Signal Structure

- XMK_USE_SENDER_PID_IN_SIGNAL

  When this flag is defined a sender pid is included in each signal instance. It is possible to omit the sender pid if the system contains no to SENDER or to PARENT addressing.

Initial setting	set

- XMK_USE_RECEIVER_PID_IN_SIGNAL

  When this flag is defined a receiver pid is included in each signal instance. It is possible to omit the receiver pid if the user writes a C function `xRouteSignal()` which is given as a template in `mk_user.c`. Each signal type is then mapped to a unique receiver. It is recommended to define this flag in small systems where unique receivers exist for each signal type. It is important to note that in the case of dynamically created processes an internal create signal is used. If there are any (x, N) where N > 1, declarations in the system, the create signal cannot contain the receiver pid. The receiver pid is necessary for correct creation of processes. Never leave it out when using dynamic process creation.

Initial setting	set

- XMK_MSG_BORDER_LEN

  The value of this macro gives the length of signal parameters carried inside the signal. Note: If the parameter length exceeds this value a memory allocation is performed and the signal parameters are copied into this buffer. The pointer to the allocated buffer is carried inside the signal's structure (see `ml_typ.h` for the typedef `xmk_T_SIGNAL`).

Initial value	4

Signal Handling

- XMK_USE_xmk_SendSimple

  This flag enables the output C function `xmk_SendSimple()` defined in the Cmicro Kernel. If the SDL system contains several signals without parameters and priorities, it is useful to set this flag in order to select the more optimal output C function, `xmk_SendSimple()`, in the Cmicro Kernel.

Initial setting	set
Reset	XMK_USE_SIGNAL_PRIORITIES

- XMK_USE_SAFE_ADDRESSING

  Setting this flag includes a special entry in the signal queue which ensures the handling of sender and offspring in the start transition.

Initial setting	unset

Signal Queue

- XMK_USE_STATIC_QUEUE_ONLY

  Create signals only from the static memory. The static memory is predefined with XMK_MAX_SIGNALS.

Initial setting	set

Reset	XMK_USE_STATIC_AND_DYNAMIC_QUEUE

- XMK_USE_STATIC_AND_DYNAMIC_QUEUE

  Create signals from the static memory which is predefined with XMK_MAX_SIGNALS. If more signals have to be inserted memory is allocated from the dynamic memory pool.

Initial setting	unset
Reset	XMK_USE_STATIC_QUEUE_ONLY

- XMK_MAX_SIGNALS

  In the Cmicro Package, the SDL queue is physically implemented as one queue for all processes. The define discussed in this section represents the maximum amount of signals in the static signal instance memory pool (see "Dynamic Memory Allocation" on page 3543 for more information). It may be difficult to evaluate the maximum entries required during run-time because this totally depends on how the SDL system is specified, and target hardware performance. It is for example, impossible to state how much time hardware requires to process an SDL signal.
  By examining the SDL system it can be determined which processes have a long transition time and which processes send or receive more than one signal. Estimate by trying out worst case situations.
  A first estimation is also possible by calculating:
  maximum amount of process instances * 3
  For a more exact estimation the user should use the profiler contained in the SDL Target Tester to obtain the necessary information on how many entries are used during run time.
  Another method of helping to determine the maximum amount of signals required by the system is to use the exception handling mechanism offered by the `ErrorHandler`, i.e. when the queue is full and another signal is to be inserted then the `ErrorHandler` function is called.

Initial value	20

Note:

Using dynamic memory allocation does not prevent the user from estimating the required memory for the queue. Sooner or later problems arise (e.g. memory fragmentation) if dynamic memory management is used frequently. For this reason the Cmicro Package avoids where possible the use of dynamic memory management.

Light Integration

- XLI_LIGHT_INTEGRATION

  If this flag is set, some functionality is included to make a light integration easier.

Initial setting	unset
Automatic set	XMK_USE_INTERNAL_QUEUE_HANDLING XLI_LIGHT_INTEGRATION

- XMK_USE_INTERNAL_QUEUE_HANDLING

  This flag make additional functions for queues the handling available which are needed for light integrations.

Initial setting	unset
Reset	XLI_LIGHT_INTEGRATION

- XLI_INCLUDE

  The value of this is the name of the header file which is included in ml_typ.h when XLI_LIGHT_INTEGRATION is set. This file contains the definitions of the light integration macros. See "Define the macros which are needed in the task function." on page 3561

Initial setting	"li_os_def.h"

Tight Integration

The complexity of a tight integration is very high. But there is a generic solution available, which guides you through the integration.

Please contact IBM Rational local sales office/Professional Services for further information about this solution.

- XTI_USE_INTERNAL_OUTPUT

  For more information about this contact local Professional Services

Initial setting	unset

- XTI_USE_LOCK_IN_CREATE

  For more information about this contact local Professional Services

Initial setting	unset

Error Handler

- XMK_USE_MAX_ERR_CHECK

  When this flag is defined, additional error checks are included in the generated code of the Cmicro Library. For further details, see the appropriate section on “errors and warnings”. For example the Cmicro Kernel calls the ErrorHandler if a signal is sent to an undefined process (i.e. undefined pid value).

Initial setting	set
Reset	XMK_USE_MIN_ERR_CHECK XMK_USE_NO_ERR_CHECK

- XMK_USE_MIN_ERR_CHECK

  In comparison to `XMK_USE_MAX_ERR_CHECK` this flag only includes a basic set of error checks.

Initial setting	unset
Reset	XMK_USE_MAX_ERR_CHECK XMK_USE_NO_ERR_CHECK

- XMK_USE_NO_ERR_CHECK

  When this flag is defined, all error checks are excluded. It is recommended not to use this flag until the post testing phase of the implementation, where it can be reasonably assumed that no errors remain. For further details see the appropriate section on “errors and warnings”.

Initial setting	unset
Reset by	XMK_USE_MAX_ERR_CHECK XMK_USE_MIN_ERR_CHECK

- XMK_USE_MON

  If the target executable runs on an environment with monitor functions, the module `ml_mon.c` can be included to have access to functions like `xxmonhexasc()` etc.

Initial setting	unset

- XMK_ADD_PRINTF

  When this flag is defined some additional `printf` C function calls are compiled giving users more information about the internal work of the system. The `printf` function can be switched on separately for Cmicro Kernel, SDL Target Tester and SDL application. At a lower level, it can be switched on separately for each C module. Look at the defines in `ml_typ.h`, which are all named as `XMK_ADD_PRINTF_*`.
  This flag must be undefined when compiling for the target, except in the case where there is a `stdio` implemented on the target. For correct compilation, the user must also set XMK_ADD_STDIO. If the user wishes to implement user specific `printf` functionality then this flag need not be set.

Initial setting	unset
Automatic set	XMK_ADD_STDIO

Reactions on Warnings

- XMK_WARN_ACTION_HANG_UP

If this flag is defined, the default behavior, if a warning is detected during SDL execution, is defined as “program hang up”.

The user might choose this reaction when there is no output device (like `printf`) available in the SDL program environment.

The user should notice that a warning can lead to an illegal system behavior. As an example, this might come true for an implicit signal consumption. The system then hangs but the user might perhaps not be able to see the reason why this occurs. As a result, it is recommended to trace for warnings also.

Initial setting	set
Reset	XMK_WARN_ACTION_PRINTF XMK_WARN_ACTION_USER

- XMK_WARN_ACTION_PRINTF

  By defining this flag, the user chooses that in the case of a warning, a `printf` function call with an appropriate error text should occur. Please see `XMK_WARN_ACTION_HANGUP` also.

Initial setting	unset
Reset	XMK_WARN_ACTION_HANG_UP XMK_WARN_ACTION_USER

- XMK_WARN_ACTION_USER

  By defining this flag, the user chooses that in the case of a warning, a user defined function should be called. The user’s function name must then be specified with `XMK_WARN_USER_FUNCTION`. Please see `XMK_WARN_ACTION_HANGUP` also.

Initial setting	unset
Reset	XMK_WARN_ACTION_HANG_UP XMK_WARN_ACTION_PRINTF

- XMK_WARN_USER_FUNCTION

If the flag XMK_WARN_ACTION_USER is defined, then the user must define the name of a C function with this macro. Please see XMK_WARN_ACTION_HANGUP also.

Initial setting	user_function()

Reaction on Errors

- XMK_ERR_ACTION_HANG_UP

  If this flag is defined, the default behavior, if a fatal system error is detected during SDL execution, is defined as “program hang up”.

  The user might choose this reaction when there is no output device (like printf) available in the SDL program environment.

  The user should notice that if a fatal system error is ignored, this usually leads to an illegal system behavior. As an example, this might come true for any use of null pointer values, for which there is an error check. It is strongly recommended to trace for system errors and warnings.

Initial setting	set
Reset	XMK_ERR_ACTION_PRINTF XMK_ERR_ACTION_USER

- XMK_ERR_ACTION_PRINTF

  By defining this flag, the user chooses that in the case of a system error, a printf function call with an appropriate error text should occur. Please see XMK_ERR_ACTION_HANGUP also.

Initial setting	unset
Reset	XMK_ERR_ACTION_HANG_UP XMK_ERR_ACTION_USER

- XMK_ERR_ACTION_USER

  By defining this flag, the user chooses that in the case of an system error, a user defined function should be called. The user’s function name must then be specified with XMK_ERR_USER_FUNCTION. Please see XMK_ERR_ACTION_HANGUP also.

Initial setting	unset
Reset	XMK_ERR_ACTION_HANG_UP XMK_ERR_ACTION_PRINTF

- XMK_ERR_USER_FUNCTION

  If the flag `XMK_ERR_ACTION_USER` is defined, then the user must define the name of a C function with this macro. Please see `XMK_ERR_ACTION_HANGUP` also.

Initial setting	user_function()

Timer Scaling

If there are timers used within the SDL system, the timers have to be scaled.

- XMK_USE_TIMER_SCALE

  The timer units can be scaled within the Cmicro Kernel. This means that the factor given with XMK_USE_TIMER_SCALE_FACTOR is used.

Initial setting	unset

- XMK_USE_TIMER_SCALE_FACTOR

  The factor modifies the expiration of timers. Is a value of 1 given here, it means that the expiration time is un-modified. A value of 100 increase the expiration time with a factor of 100 with other words the timer needs 100 times longer.

Initial value	100

- XMK_TIMERPRIO

  An expired timer is handled like a signal inside the Cmicro Kernel and inserted into the signal queue. In this way there has to be a priority level if signal priorities are used. The XMK_TIMERPRIO gives the priority for all expired timers. This default value can lay between 0 and 250.

Initial value	100

Timer queue

- XMK_USE_GENERATED_AMOUNT_TIMER

  The code generator evaluates the amount of timers that are declared in the system. The result of this evaluation is then, after code generation, defined with `XMK_MAX_TIMER_INST` in the file `sdl_cfg.h`. Timer instances are, usually, implemented as a C array with Cmicro. If the `XMK_USE_GENERATED_AMOUNT_TIMER` flag is set, then the timer array is dimensioned with the evaluated amount (`XMK_MAX_TIMER_INST`).

  When timers with parameters are in the system, the automatically generated value `XMK_MAX_TIMER_INST` can be used to pre-define one timer instance of a timer declaration. If there are then more timers to be instantiated, dynamic memory allocation must take place. This cannot be evaluated by the code generator.

  As a result, if there are timers with parameters in the system, the user should think about how many timer instances there could be during execution and should decide upon the maximum amount by himself. In this way, memory consumption and performance can be balanced.

Initial value	set

- XMK_MAX_TIMER_USER

  This macro is used for internal purposes. The meaning of it is the opposite of `XMK_USE_GENERATED_AMOUNT_TIMER`.

  The flag is set when `XMK_USE_GENERATED_AMOUNT_TIMER` is not set. The flag `XMK_MAX_TIMER_USER` is unset if `XMK_USE_GENERATED_AMOUNT_TIMER` is set.

Initial value	unset

- XMK_MAX_TIMER_USER_VALUE

  If `XMK_MAX_TIMER_USER` is set, the value `XMK_MAX_TIMER_USER_VALUE` becomes meaningful. With this val-

ue, the user may specify how many timer instances should be predefined during compilation time. The predefined timer instances offer the advantage that no dynamic memory allocation is to be done for them. If the predefined amount of timer instances is exceeded, then dynamic memory allocation will occur. As a result, it is up to the user how he balances static and dynamic memory for timer instances by changing this value.

Initial value	20

Execution Time

- XMK_USE_CHECK_TRANS_TIME

  When this flag is defined the time duration for each executed transition is checked against a predefined duration. If the executed duration is longer than the predefined duration set by the `XMK_TRANS_TIME` flag, the `ErrorHandler()` is called. The flag is only available when using a non preemptive Cmicro Kernel. No additional hardware is necessary as the evaluation is based on the SDL time value `NOW` which is provided by the same hardware source as for the system clock.

Initial setting	unset
Automatic set	XMK_TRANS_TIME

- XMK_TRANS_TIME

  This macro specifies the time duration that a transition execution time is compared with. The value must be in the target system time units, e.g. if the target's system step is 0,002 sec, the value 100 specifies a duration of 0.2 sec.

Initial value	20
Depend on	XMK_USE_CHECK_TRANS_TIME

Signal Priorities

In the standard configuration of the Cmicro Kernel no signal priorities are used. So each signal sent is inserted at the end of the signal queue.

- XMK_USE_SIGNAL_PRIORITIES

When this flag is defined, the header of each signal which is sent via the SDL queue has an additional entry, namely “priority”. This is used to modify the ordering of signals in the queue.
This flag should be used in combination with using the #PRIO directive. It works for all the different scheduling methods.
If signal priorities are enabled, signal handling `xmk_SendSimple` has to be switched of.

Initial setting	unset
Automatic set	xDefaultPrioSignal XMK_CREATE_PRIO
Reset	XMK_USE_xmk_SendSimple

- xDefaultPrioSignal

  If a signal has not got a priority assignment within the SDL system, it is handled with the default value `xDefaultPrioSignal`. A value between 0 (highest priority!) and 250 should be entered.

Initial value	100
Depend on	XMK_USE_SIGNAL_PRIORITIES

- XMK_CREATE_PRIO

  Create signals can not be assigned a signal priority within the SDL system. As these signals are also handled over the signal queue, a default priority is necessary when signal priorities are selected (i.e. `XMK_USE_SIGNAL_PRIORITIES` is defined). A value between 0 (highest priority!) and 250 should be entered.

Initial value	1
Depend on	XMK_USE_SIGNAL_PRIORITIES

Preemption

Normally, the Cmicro Kernel is configured so that the simple scheduling policy is used, i.e. transitions of SDL processes are non interruptible.

Note:

The Cmicro preemptive kernel is only available if an according license is available.

- XMK_USE_PREEMPTIVE

  Usually the Cmicro Kernel is configured to “non preemptive”. This means, that each transition must execute to its end, before the next transition can be processed.
  This means, that the nextstate symbol of a process is executed, before the next SDL input can be handled. On the other hand, “preemptive scheduling” is useful, if an SDL process must directly execute when an external event from an interrupt source is detected and sent to the SDL system. In this case, an executing transition is possibly suspended, and another transition can be executed.
  The kernel makes decisions based on the defined priority of processes when to schedule to another process. If the receiver of a signal which has been received from the environment (or a process inside the SDL system) has a higher priority than the currently executing process, the new signal is treated immediately.

Initial setting	unset
Automatic set	MAX_PRIO_LEVELS xDefaultPrioProcess XMK_USE_RECEIVER_PID_IN_SIGNAL
Reset	XMK_USE_CHECK_TRANS_TIME

- MAX_PRIO_LEVELS

  This defines the amount of process priority levels in the SDL system. It is of relevance only, if preemption is selected and must be equal to the lowest process priority plus 1. The lowest priority has the highest value.

Initial value	1
Depend on	XMK_USE_PREEMPTIVE

Caution!

A run-time error occurs if this definition is wrong. If the error checks are enabled, a check is made by the Cmicro Kernel and the C function `ErrorHandler()` is called if the check fails.

- xDefaultPrioProcess

  If there is an SDL process with no process priority assigned to it, this process will be handled with the `xDefaultPrioProcess`. It is mandatory that the `xDefaultPrioProcess` is in the range of 0 to (`MAX_PRIO_LEVELS` -1).

Initial value	0
Depend on	XMK_USE_PREEMPTIVE

SDL Target Tester

Initialization

- XMK_ADD_MICRO_TESTER

  This is the main flag to enable or disable the SDL Target Tester. Use this flag if the addition of the SDL Target Tester features is wanted. The following features are selected by this flag:

  – Trace into a file.
  – Trace into a buffer on target side.
  – Trace via a serial interface.
  – the Cmicro Recorder

Initial setting	unset
Automatic set	XMK_USE_MAX_ERR_CHECK

Reset when unset	XMK_ADD_MICRO_COMMAND, XMK_USE_DEBUGGING, XMK_ADD_PROFILE, XMK_ADD_MICRO_ENVIRONMENT, XMK_WAIT_ON_HOST, XMK_ADD_SDLE_TRACE, XMK_ADD_SIGNAL_FILTER, XMK_USE_COMMLINK, XMK_ADD_MICRO_TRACER, XMK_ADD_TEST_OPTIONS, XMK_USE_SIGNAL_TIME_STAMP, XMK_ADD_MICRO_RECORDER

- XMK_WAIT_ON_HOST

  During the start up of the target executable (see `xmk_MicroTesterInit()` in the module `mk_main.c`), the target can wait for the host's run-time configuration. If this is not needed, the `XMK_WAIT_ON_HOST` flag has to be undefined.

Initial setting	unset
Depend on	XMK_ADD_MICRO_TESTER

- XMK_ADD_PROFILE

  This flag is to be defined if the profiler is to be used. With the profiler, it is possible:

  – to trace the SDL queue concerning it's traffic load,
  – to trace the number of timers which exist in parallel (not included in this version of the Cmicro Package).
  – to trace the execution time process transitions

  The profiler can be used independently from the SDL Target Tester functions. By using a debugger the following values may be inspected:

  `int xmk_max_q_cnt,`

  representing queue-dimensioning, and

  `int xmk_act_q_cnt,`

  representing the maximum traffic load of the queue at any time during the execution.

Initial setting	unset
Depend on	XMK_ADD_MICRO_TESTER

- XMK_USE_DEBUGGING

  If the debugging functions should be included to the target executable, this flag needs to be defined.

Initial setting	unset
Depend on	XMK_ADD_MICRO_TESTER

- XMK_ADD_MICRO_COMMAND

  This flag adds the command interface of the SDL Target Tester (please view chapter 67, *The SDL Target Tester*).

Initial setting	unset
Depend on	XMK_ADD_MICRO_TESTER

- XMK_ADD_MICRO_ENVIRONMENT

  To allow the signal exchange with the external environment connected to the SDL Target Tester, this flag needs to be defined.

  The external environment can be a GUI application or a cmdtool for example.

Initial setting	unset
Depend on	XMK_ADD_MICRO_TESTER

Trace

Trace Scaling

- XMK_ADD_MICRO_TRACER

  This flag enables the trace of the SDL execution and trace of system events to any device.

Initial setting	unset
Depend on	XMK_ADD_MICRO_TESTER
Reset when unset	XMK_USE_SIGNAL_TIME_STAMP

- XMK_ADD_SDLE_TRACE

  This flag enables the trace of SDL symbols in the SDL Editor.

Initial setting	unset
Depend on	XMK_ADD_MICRO_TESTER

- XMK_USE_COMMLINK

  If this flag is defined the trace via the specified communications link is enabled. The trace is handled with the SDL Target Tester's data link layer. See the module `mg_dl.c` for further information.

Initial setting	unset
Depend on	XMK_ADD_MICRO_TESTER

- XMK_USE_AUTO_MCOD

  Is this flag defined, the host get a further message for the message coder. Depending on this flag the Targeting Expert insert the entry 'USE_AUTO_MCOD yes' into the sdtmt.opt file. The entrys LENGTH_, ENDIAN_, and ALIGN_ are ignored. For more information view chapter 67, *The SDL Target Tester*.

Initial setting	set

- XMK_ADD_SIGNAL_FILTER

  This flag conditionally compiles the signal filtering mechanism of the SDL Target Tester (please view chapter 67, *The SDL Target Tester*). With the signal filter, it is possible to specify that some signals should be traced while others are not.

Initial setting	unset

Depend on	XMK_ADD_MICRO_TESTER

- XMK_ADD_TEST_OPTIONS

  By defining this flag the symbol trace of the target can be configured. See function `main()` in module `mk_user.c`.

Initial setting	unset
Depend on	XMK_ADD_MICRO_TESTER

- XMK_USE_SIGNAL_TIME_STAMP

  Defining this flag means that in the header of each signal which is sent via the SDL queue, there is an additional entry “time-stamp”. When using the standard Cmicro Library, the Cmicro Kernel sets the time-stamp to `NOW`, if an SDL signal is inserted into the queue.

  This time-stamp is especially used by the Cmicro Recorder (XMK_ADD_MICRO_RECORDER) in order to enable the replay of an SDL session in simulated real-time.

  In other cases, the user is free to modify the type of time-stamp implementation.

Initial setting	unset
Depend on	XMK_ADD_MICRO_TESTER
Reset when unset	XMK_ADD_REALTIME_PLAY

- XMK_MAX_PRINT_STRING

  The user can add his own trace messages to the standard trace of the SDL Target Tester. This message will be handled like a string. The maximum size of these strings are defined with `XMK_MAX_PRINT_STRING`.

Initial value	40

Buffers

- XMK_MAX_RECEIVE_ENTRIES

If the ring buffer is used this flag gives the amount of entries for the receiver buffer.

Initial value	20

- XMK_MAX_RECEIVE_ONE_ENTRY

  This flag gives the size of one entry of the receiver buffer. The message received here are SDL Target Tester commands or the Cmicro Recorder's play data. I.e. as a rule over the thumb a value of 12 + maximum signal parameter size must be given here.

Initial value	100

- XMK_MAX_SEND_ENTRIES

  When the Cmicro Tracer is used the target executable writes the trace data into a ring buffer (view `ml_buf.c`). The recommended amount of entries given here depends of the used communications link. I.e. if using a slow communications link like V.24 this amount should be increased.

Initial value	20

- XMK_MAX_SEND_ONE_ENTRY

  When the Cmicro Tracer is used the target executable writes the trace data into a ring buffer (view `ml_buf.c`). The size of one entry depends on the SDL system. As a rule over the thumb a value of 12 + maximum signal parameter size must be given here.

Initial value	100

Recorder and Play

Note:

The SDL Target Tester's Record and Play functions are only available if a Cmicro Recorder license is available.

- XMK_ADD_MICRO_RECORDER

This flag adds the functions of the record mode of the Cmicro Recorder (please view chapter 67, *The SDL Target Tester*).

Initial setting	unset
Depend on	XMK_ADD_MICRO_TRACER
Reset when unset	XMK_ADD_REALTIME_PLAY

- XMK_ADD_REALTIME_PLAY

  When defining this flag, the replay of a recorded session can be performed in simulated real-time.

Initial setting	unset
Automatic set	XMK_USE_SIGNAL_TIME_STAMP
Depend on	XMK_ADD_MICRO_RECORDER

Support of SDL Constructs

Predefined Sorts

Character Strings

- XRESTUSEOFCHARSTRING

  This flag must be seen in combination with XNOUSEOFCHARSTRING, which forbids the use of SDL charstrings. If this flag is set, SDL charstrings are only supported in a restricted way. I.e. constant character buffers are used in this implementation.

  As a third possible way XRESTUSEOFCHARSTRING and XNOUSEOFCHARSTRING should both be undefined to enable a full support of SDL charstrings.

Initial setting	set
Reset by	XNOUSEOFCHARSTRING

Caution!

The Cmicro Recorder is not able to handle SDL charstrings within signal parameters.

- XNOUSEOFCHARSTRING

  The use of SDL charstrings is not possible. This can be selected for systems witch do not use SDL charstrings.

Initial setting	set
Reset by	XRESTUSEOFCHARSTRING

Predefined Sorts

- XNO_LONG_MACROS

  The setting of this flag prevents the use of predefined generators (please view "sctpredg.h, sctpred.h and sctpred.c" on page 3566). This can be done to reduce the target's memory size. But must be done for some specific compilers as these are not able to handle long macro definitions. Please view the appropriate compiler section in `ml_typ.h` ("Adaptation to Compilers" on page 3523)

Initial setting	set

- XNOUSEOFREAL

  This flag allows using real values in SDL if it is undefined.

Initial setting	set

Note:

Every multiplication of an integer value with an integer value is mapped to a multiplication of a real value with a real value. This is done because an overflow cannot be detected when using integer values.

ASN.1 Sorts

- XNOUSEOFASN1

If this flag is undefined it is allowed to use ASN.1 data types. It is recommended not to use ASN.1 data types if possible, because the functions that are necessary to handle these types occupy much memory.

Initial setting	set
Depend on	XNOUSEOFCHARSTRING

- XNOUSEOFOCTETBITSTRING

  If this flag is undefined it is allowed the use of ASN.1 data type octetbitstring. It is recommended not to use ASN.1 data types if possible, because the functions that are necessary to handle these types occupy much memory.

Initial setting	set
Depend on	XNOUSEOFASN1

- XNOUSEOFOBJECTIDENTIFIER

  If this flag is undefined it is allowed the use of ASN.1 data type objectidentifier. It is recommended not to use ASN.1 data types if possible, because the functions that are necessary to handle these types occupy much memory.

Initial setting	set
Depend on	XNOUSEOFASN1

Error Checks

- XEREALDIV

  If this flag is defined, then a C function is used to perform division of real values, otherwise a C macro is used. The flag should be set for allowing better error checks, but may be unset for optimizing the target program code, as the checks occupy a lot of memory.

Initial setting	set

- XEINTDIV

If this flag is defined, then a C function is used to perform division of integer and octet values, otherwise a C macro is used. The flag should be set for allowing better error checks, but may be unset for optimizing the target program code, as the checks occupy a lot of memory.

Initial setting	set

- XEINDEX

  If this flag is defined, then additional error checks are introduced that check the index of array at each position an array element is accessed. The flag should be set for allowing better error checks, but may be unset for optimizing the target program code, as the checks occupy a lot of memory.

Initial setting	set

- XEFIXOF

  If this flag is defined, then additional error checks are introduced that check the conversion from real to integer. The flag should be set for allowing better error checks, but may be unset for optimizing the target program code, as the checks occupy a lot of memory.

Initial setting	set

- XECSOP

  Setting this flag includes an error check for predefined ADT operators, as the checks occupy a lot of memory.

Note:

This flag should be used for testing purposes but uses lots of code size within the target.

Initial setting	set

- XERANGE
  XTESTF

These flags define that an SDL syntype is to be checked against its defined range. If the flags are not set, the code to perform this check is left out. The flag should be set for allowing better error checks, but may be unset for optimizing the target program code, as the checks occupy a lot of memory.

Initial setting	set

Size of Variables

- X_COMPACT_BOOL

  This flag defines that an SDL boolean is translated to unsigned char, when it is set. Otherwise each SDL boolean is translated to integer. Usually this flag should be left set, as it is in the default setting. An exception might become true when a C compiler can handle integer values more efficient than char values.

Initial setting	set

- X_SHORT_REAL

  When this flag is defined, then each SDL real value is translated to a float in C. If it is not defined, Cmicro assumes SDL real values are C double values. The user must take care that at no place in the SDL system there is a real value used that exceeds the maximum range of the appropriate C type.

Initial setting	set

- X_LONG_INT

  By defining this switch, the SDL predefined sorts, integer and natural are translated to long, otherwise these are translated to integer. The user must take care that at no place in the SDL system there is a real value used that exceeds the maximum range of the appropriate C type.

Initial setting	unset

Use of Memory

Memory Management

- XMK_USE_SDL_MEM

  If this flag is defined, then the Cmicro Kernel can use the dynamic memory management functions contained in the `ml_mem` module (`xmk_Malloc()`, `xmk_Calloc()` and `xmk_Free()`). This is necessary if the compiler in use has no `malloc/free` or if the user wishes to modify the standard behavior of these functions, i.e. using a best fit, instead of first fit searching algorithm. The user should refer to "Dynamic Memory Allocation Functions – Cmicro" on page 3544 also.

Initial setting	unset
Reset when unset	XMK_USE_memshrink

- XMK_USE_MIN_BLKSIZE

  By setting this define it is possible to organize the dynamic memory allocation in a similar way as arrays in C. If all the allocated blocks in the memory occupy the same space then no fragmentation problems occur.

Initial setting	unset

- XMK_USE_memshrink

  If this flag is defined, then the `xmk_Memshrink()` function of the `ml_mem` module can be used. This function delivers the opportunity to free the unused space of a memory block that was requested previously with `xmk_Malloc()` or `xmk_Calloc()`.

Initial setting	unset
Depend on	XMK_USE_SDL_MEM

- XMK_USE_memset

  If this flag is defined, then the `memset()` function of the `ml_mem` module is compiled.

Initial setting	unset

- XMK_USE_memcpy

  If this flag is defined, then the `memcpy()` function of the `ml_mem` module is compiled.

Initial setting	unset

- XMK_CPU_WORD_SIZE

  For allocating memory the pointer to the end of the allocated memory must be dividable by XMK_CPU_WORD_SIZE. This value is set to 8 as default, but should be decreased to 4, 2 or even 1 if the CPU's layout allows it.

Initial value	8
Depend on	XMK_USE_SDL_MEM

- XMK_MEM_MIN_BLKSIZE

  The requested block size is rounded to a value of XMK_MEM_MIN_BLKSIZE, if the XMK_MEM_MIN_BLKSIZE is greater than the requested block size.

Initial value	64
Depend on	XMK_USE_MIN_BLKSIZE

- XMK_MAX_MALLOC_SIZE

  If the Cmicro memory functions (`xmk_Malloc()`, `xmk_Calloc()` and `xmk_Free()`) are used, the buffer that is used for dynamic memory allocation is to be initialized with `xmk_MemInit()`. The size of the buffer can be given here.

Initial value	1024
Depend on	XMK_USE_SDL_MEM

String Functions

- XMK_USE_strcpy

  If this flag is defined, then the `strcpy()` function of the `ml_mem` module is compiled.

Initial setting	unset

- XMK_USE_strncpy

  If this flag is defined, then the `strncpy()` function of the `ml_mem` module is compiled.

Initial setting	unset

- XMK_USE_strcmp

  If this flag is defined, then the `strcmp()` function of the `ml_mem` module is compiled.

Initial setting	unset

- XMK_USE_strlen

  If this flag is defined, then the `strlen()` function of the `ml_mem` module is compiled.

Initial setting	unset

SDL environment

- XMK_USE_xInitEnv

  This flag enables the C function xInitEnv() which is generated as a template in file env.c by the Targeting Expert.

Initial setting	set

- XMK_USE_xInEnv

  This flag enables the C function xInEnv() which is generated as a template in file env.c by the Targeting Expert.

Initial setting	set

- XMK_USE_xOutEnv

  This flag enables the C function xOutEnv() which is generated as a template in file env.c by the Targeting Expert.

Initial setting	set

- XMK_USE_xCloseEnv

  This flag enables the C function which is generated as a template in file env.c by the Targeting Expert.

Initial setting	set

- XMK_USE_SEND_ENV_FUNCTION

  This flag make it possible to use an alternative function to send signals to the environment. This is needed if the used compiler does not support re-entrant functions. The disadvantage of this implementation exists in the missing error checks. See "Alternative Function for sending to the Environment" on page 3595

Initial setting	unset

- XMK_ADD_STDIO

  The Cmicro Package is mainly intended for target implementation. However on some occasions the user may wish to use OS features. Normally this flag is undefined when compiling for the target system but may be defined if `stdio` is available and required on the target system.
  Defining `XMK_ADD_STDIO` without setting `XMK_ADD_PRINTF` allows the user to exclude the default `printf`s of the Cmicro Library and instead implement user defined `printf`s.

Initial setting	unset
Reset when unset	XMK_ADD_PRINTF

Automatic Scaling Included in Cmicro

The flags described in this section are automatically generated into the file `sdl_cfg.h` by the Cmicro SDL to C Compiler. The purpose is to exclude parts of the C code in order to reduce the generated code. Features or functions which are not required in the SDL description produce no (or only a small) overhead in the generated code.

If the user does not wish to employ automatic scaling facilities, for example if test and debugging proves too difficult, then simply define the flags XMK_USE_NO_AUTO_SCALING.

All the flags discussed in this section are used on the whole SDL system i.e. it is not possible to define flags for processes separately.

The Targeting Expert will use these flags, too, to optimize and ease the manual scaling.

- XMK_USED_ONLY_X_1

  If this flag is generated as defined, then there is no process defined in the system, where N is > 1 in the process declaration (x, N). This allows memory to be saved as the overhead for process addressing in the system is reduced. The need for numbering of process instances is also eliminated.

- XMK_USED_DYNAMIC_CREATE

If this flag is generated as defined, the SDL system uses the dynamically created process feature of SDL. (It only requires one create-symbol in the SDL system to enable this flag to be set). This of course constitutes a bigger Cmicro Kernel.

- XMK_USED_DYNAMIC_STOP

  If this flag is generated as defined, the SDL system uses the dynamic process stop feature of SDL. (It only requires one stop-symbol in the SDL system to enable this flag to be set). This of course constitutes a bigger Cmicro Kernel.

- XMK_USED_SAVE

  If this flag is generated as defined, the SDL system uses the save feature of SDL. Using save means that there has to be additional overhead in each signal stored in the SDL queue (each signal is tagged as save or not save).
  The save construct, although a useful construct for manipulation of the SDL FIFO queue mechanism, unfortunately imposes a large code overhead. The user should avoid the utilization of this construct where possible.

- XMK_USED_TIMER

  If there is a minimum of one timer declaration in the system, then this flag is generated as defined. If no timer declarations exist in the SDL system, the timer handling functions are excluded.

Note:

It is possible to implement a user defined timer model by un-defining these flags and defining some other macros.

- XMK_HIGHEST_SIGNAL_NR

  This define gives the amount of signals and timers used in the SDL system in sum. It is used to scale internal buffers of the Cmicro Package.

- XMK_USED_SIGNAL_WITH_PARAMS

  If no signals with parameters are defined in the SDL system, then this flag is generated as defined which reduces the overall code size.

Note:

It is not recommended in each case (because it is not SDL conform), but is possible to send parameters via global parameters by using C code in SDL.

- XMK_USED_TIMER_WITH_PARAMS

  This define is generated if there is at least on timer with parameter used in the system. If this is the case, additional functionality for this construct is added when the kernel is compiled. The timer operations will result in producing more overhead, both symbol by symbol and overhead in the kernel compared with the case if there are no timers with parameters defined.

- XMK_USED_SENDER, XMK_USED_PARENT, XMK_USED_OFFSPRING, XMK_USED_SELF

  The above flags are generated as defined if the user uses the appropriate addressing construct within SDL, that is sender, parent, offspring or self.
  If “to” in output actions is not used, none of the above flags is generated as defined.
  The define `XMK_USE_PID_ADDRESSING` depends on the above flags.

- XMK_USED_PWOS

  If procedures without states are contained in the SDL system, this flag is defined. Procedures with states are not supported by the Cmicro Package.

Automatic Dimensioning in Cmicro

Some resources of the Cmicro Library are automatically dimensioned. These are described in the following subsections.

- MAX_SDL_PROCESS_TYPES

  The Cmicro SDL to C Compiler counts the amount of process types in the system and generates this define. This is used to dimension some tables used in the generated code, the Cmicro Kernel and the SDL Target Tester.

- MAX_SDL_TIMER_TYPES

The Cmicro SDL to C Compiler counts the amount of timer types in the system and generates this define. This is used to dimension some tables used in the generated code, the Cmicro Kernel and the SDL Target Tester.

- MAX_SDL_TIMER_INSTS

  The Cmicro SDL to C Compiler counts the amount of instances of timers in the system and generates this define. This is used to dimension some tables used in the generated code, the Cmicro Kernel and the SDL Target Tester.

Adaptation to Compilers

In this section the steps are explained that must be carried out in order to deal with a new C compiler which is not yet in the list of available compilers.

The following parts may be modified manually:

- In `mk_stim.c`, there are template functions as templates which have to be modified to adapt another hardware/compiler to the SDL system time (Now).
- In `mk_cpu.c`, there are templates for functions which represent hardware access. Those are required if the preemptive Cmicro Kernel is used.

The following parts can be added by using the Targeting Expert:

- A compiler specific header file `user_cc.h` which will automatically be included in `ml_typ.h`. Please view "Compiler Definition for Compilation" on page 2910 in chapter 59, *The Targeting Expert*.
- An entry in the Targeting Expert's configuration files. Please view "Compiler Definition for Compilation" on page 2910 in chapter 59, *The Targeting Expert*.

List of Available C Compilers in ml_typ.h

C compilers are to be selected by the user by choosing from an available list with the help of the Targeting Expert.

The Targeting Expert will generate a C define into the `ml_mcf.h` file. When compiling Cmicro sources, the right C compiler section in `ml_typ.h` is selected by using a `#ifdef <compilername>` construct.

The following `<compilername>` defines are currently defined in `ml_typ.h`:

Compilation switch	Meaning
GCC	The GNU C++ compiler for workstations
GNU80166	The GNU UNIX C compiler for Siemens 80C166 microcontrollers
TCC80166	The BSO/Tasking DOS C compiler for Siemens 80C166 microcontrollers
TCC80C196	The BSO/Tasking DOS C compiler for INTEL 80196 microcontrollers
IARC51	The Archimedes/IAR UNIX C compiler for INTEL 8051 microcontrollers
IARC6301	The Archimedes/IAR DOS C compiler for Hitachi 6301 microcontrollers
KEIL_C51	The Franklin/Keil DOS C compiler for INTEL 8051 microcontrollers
KEIL_C166	The Franklin/Keil DOS C compiler for Siemens 80166 microcontrollers
TMS320 MSP58C80	The Texas Instruments DOS C compiler for TMS 320C2x/C5x microcontrollers
IARC7700	The Archimedes/IAR DOS C compiler for Melps 7700 microcontrollers
HYPERSTONE	Hyperstone 5.07 C compiler with HyRTK real-time kernel
MCC68K	The MicroTech DOS C compiler for Motorola 68k microprocessors
MICROSOFT_C	The Microsoft C++ compiler
ARM_THUMB	The Thumb compiler for ARM microcontrollers
ICC_HC12	The ICC12 5.0 Compiler for HC12 microcontrollers

If none of these compiler flags is defined during compilation the file `user_cc.h` (generated by the Targeting Expert) will be included in `ml_typ.h`.

The remaining part of the code of the Cmicro Library should be compilable without performing any modifications. If there are problems with adapting a new compiler or hardware please contact Cmicro technical support.

The user may however decide to define his own C compiler. This is explained in the following subsection.

Introducing a new C Compiler

Adding a new C Compiler to the Project

The first alternative to add a new user defined C compiler, is to add that compiler to a user's project. This can be achieved with the Targeting Expert.

- Give the C compiler a name for using it within Cmicro. The name should as a recommendation be in the notation of C macros, that is, it should be 8 to approximately 16 characters long in uppercase letters.
- Below the Targeting Expert's *Edit* menu there is a choice called "Add a new C Compiler" by which the new C compiler can be defined.
- It is also possible to remove the user defined C compiler later on by using this menu.

These changes are not stored within the installation, but within the user's project directory (which is the target directory that was chosen when the Targeting Expert was started).

Do the C Compiler Adaptations

- Create a new file with the name `user_cc.h`. If a C compiler is selected, which is not in the list of available C compilers in the Cmicro product, the `user_cc.h` is included automatically. This can easily be done by using the Targeting Expert's *Edit* menu "Edit compiler section".
- Take care that the right path names are specified when the C compiler is invoked. There usually should be something like a "`-I.`" option which must point to the path in which `user_cc.h` is stored.

Description of user_cc.h

The things that are to be defined by the user are:

- Is the compiler able to handle function prototypes, as defined in ANSI-C?

Yes	`#undef  XNOPROTO` `#define XPP(x)     x` `#define PROTO(x)   x`
No	`#define XNOPROTO` `#define XPP(x)` `#define PROTO(x)`

- Is the controller faster in accessing character values or integer values?

char	`#define xmk_OPT_INT char`
integer	`#define xmk_OPT_INT integer`

- Does the compiler support variables stored in registers?

Yes	`#undef  X_REGISTER` `#define X_REGISTER >register<`
No	`/* Nothing to do for X_REGISTER */`

`>register<` is the compiler specific command to store variables in registers.

- Default setting:
  `#define xptrint unsigned long`
  This setting should work for the very most compilers In a few cases it is necessary to define `xptrint` as `unsigned int`.

- Default setting:
  `#define xint32 long`
  This setting should work for the very most compilers. In a few cases it is necessary to define `xint32` as `int`.

- Is the compiler able to handle the C keyword `const` in the correct way?

Yes	`#define XCONST const`

No	`#undef XCONST`

In general, the compilers which are able to produce ROM-able code, can handle the keyword `const`. Compilers may generate false object code, if using `const`.

- Is it a UNIX system for which code is to be compiled for?

Yes	`#define XMK_UNIX`
No	

- Is it an MS Windows system for which code is to be compiled for?

Yes	`#define XMK_WINDOWS`
No	

- Critical paths must be enabled and disabled:

```
#undef  XMK_END_CRITICAL_PATH
#define XMK_END_CRITICAL_PATH  \
               if (xmk_InterruptsDisabled) \
               {\
                 xmk_InterruptsDisabled--;\
                 if (!xmk_InterruptsDisabled) \
                 { ENABLE; }}

#undef  XMK_BEGIN_CRITICAL_PATH
#define XMK_BEGIN_CRITICAL_PATH \
                 DISABLE;\
                 xmk_InterruptsDisabled++;
```

`ENABLE` and `DISABLE` are the compiler specific command to allow/prevent interrupts and must be filled.

- A #include of <stdio.h>, if supported by the compiler (not all the target compilers do). Write:

```
#ifdef XMK_ADD_STDIO
  #include <stdio.h>
#endif
```

- Which include header files must be added?

  For example, for the IARC51:

```
#define "io51.h"
```

is used. For the GNU80166:

```
#include <string.h>
#include <stdlib.h>
#include <stdarg.h>
#include <c166.h>
```

is used.

- The include header files containing the prototypes for dynamic memory allocation and string and memory functions must be added. This subsection should look like this for allowing the user to select either the memory functions from the C compiler or from Cmicro:

```
#ifdef XMK_USE_SDL_MEM
  #include "ml_mem.h"
#else
  #include "string.h"
#endif /* XMK_USE_SDL_MEM */
```

It must be checked if `malloc(), free(), calloc()` etc. are really prototyped in `string.h`, on other compilers it might be `stdlib.h`. Cmicro always calls `xAlloc()` and `xFree()` which are given as examples in the `mk_cpu.c` file below the template directory. For more information on dynamic memory allocation please view the subsection "Dynamic Memory Allocation" on page 3543.

Defining the SDL System Time Functions in mk_stim.c

The following functions exist in the module `mk_stim.c`:

- `void xmk_InitSystime(void)`
  Initialize the hardware registers to support the system time
- `void xmk_DeinitSystime(void)`
  Give up to use the system time. This normally cannot happen, but in some applications, where the SDL system is stopped and restarted again during run-time, it may prove useful.
- `void xmk_SetTime(xmk_T_TIME)`
  This function sets the system-time to the given value. Called by Cmicro Kernel in the case when an overrun in the time value is detected.

- `xmk_T_TIME xmk_NOW(void)`
  This is the most important C function to handle SDL system-time. This function returns the absolute time, which is by default defined as a `long` value (`xmk_T_TIME`).

Usually, the above functions are conditionally compiled. To make the functions available in the target system, at least one timer in SDL must be declared. The functions are not included if there is no timer declared but duration, time or now is used in SDL. This will lead to compilation errors.

To make timers in SDL operable, absolute time must be implemented. This can be reached by using a hardware free running counter or by using a timer interrupt service routine, which clocks a global variable containing the absolute time.

Bare Integration

This section deals with functions that must be adapted by the user in order to connect the SDL system to the environment i.e. connection to target hardware, and the environment.

Implementation of Main Function

The user may decide to implement his own `main()` function body when it comes to target application in a bare integration. A default `main()` function is included in the template file `mk_user.c`.

The implementation of a first `main` function looks like this:

Example 606 ----------

```
main ()
{
  xmk_InitQueue();
  xmk_InitSDL ();
  xmk_RunSDL ();
}
```

Of course this example does nothing in order to start the SDL Target Tester. The only possible way to get a very simple trace output is to define:

```
#define XMK_ADD_PRINTF
```

in `ml_mcf.h` with the help of the Targeting Expert. This will include calls to the C function `xmk_printf()` at several places in the generated C code and the Cmicro Library. The `xmk_printf()` function is available as an example in the file `mk_cpu.c`.

The user can use the `main()` functions delivered with the Cmicro Kernel to have full access to all Cmicro features. This delivered `main()` function is a template and can be modified to add or remove functionality.

Integrating Hardware Drivers, Functions and Interrupts

There is no extra handling for hardware drivers, hardware functions and interrupt service routines. It is necessary to implement an interface in the user's application. Hardware drivers, hardware functions and interrupt service routines are seen from the SDL system as the environment. The user has to implement the interface between the SDL system and the environment as it is described in the following subsections.

Critical Paths in the Cmicro Library

As with every real time application the Cmicro Library has to deal with critical paths.

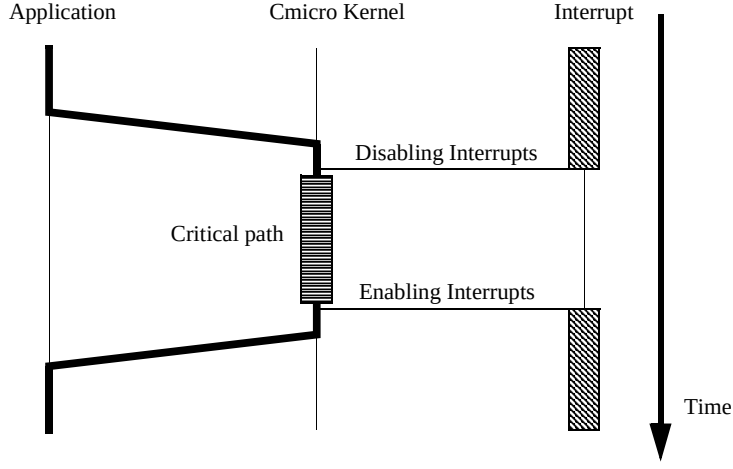

Figure 598: Critical paths

These are well defined in the source code using two macros namely `XMK_BEGIN_CRITICAL_PATH` and `XMK_END_CRITICAL_PATH` (see file `ml_typ.h`/compilersections).

The macros are expanded to compiler specific calls which disable/enables interrupts. The calls are counted using an internal variable, thus after having called `XMK_BEGIN_CRITICAL_PATH` n times `XMK_END_CRITICAL_PATH` has also to be called n times, to enable the interrupts again.

In the Cmicro Library these macros are used to disable/enable interrupts only. The application should take care not to handle interrupts without using these macros or at least evaluating the internal counter.

Caution!

When it comes to implementing the interrupt handling routines it is of the greatest importance to know about the Cmicro Library's handling of critical paths. Unpredictable results may result from a careless implementation!

Initializing the Environment / Interface to the Environment

xInitEnv()

There is one C function called `xInitEnv()` available as a template in the generated file `env.c`. The user should fill this module out appropriately, thus implementing connection to the environment (drivers, interrupt service routines and so on).

Receiving Signals from the Environment

There are two possibilities to send signals into the SDL system. In all cases, the user has to specify an SDL input symbol in the process which has to consume the signal. The possibilities are:

1. Polling external events.
   This is done by the C function `xInEnv()`, which is called by the Cmicro Kernel after each transition.

2. Directly sending signals into the SDL system.
   For example directly in an interrupt service routine. This is possible by using the `XMK_SEND_ENV()` function. This function directly operates on the SDL queue. If interrupt service routine is used and can result in signal sending the user need to manually define flag XMK_USE_INTERRUPT_SERVICE_ROUTINE to enable additional needed critical paths in kernel.

Caution!

For each signal sent into the system, the user must ensure that the addressed receiver process instance exists. Each pid value is checked for consistency by the Cmicro Kernel. In the case of an inconsistency the `ErrorHandler()` is called with an error message.

xInEnv()

Parameters:

```
In/Out: -no-
Return: -no-
```

In the case when no interrupt service routine is available to handle an external event, the Cmicro Kernel can poll external events. The user must use the C function `xInEnv()` in the file `env.c` generated by the Targeting Expert.

For example, a hardware register can then be checked in order to establish if its value has changed since the last call.

If an external signal is detected, then one of the `xmk_Send*()` functions is to be called thus enabling the signal to be put into the SDL queue.

Note:

There is a file called `<systemname>.ifc`, which is generated by the Cmicro SDL to C Compiler. It is necessary to include this file together with `ml_typ.h` before defining `xInEnv()`. This is necessary to have access to all the objects that are generated by the Cmicro SDL to C Compiler. The user should also make sure that this file is generated, because the analyzer's make menu contains an option for this.

Example 607: `xInEnv()` ----------

Assume, a hardware register where the value 0 is the start-value and where any other value means: data received. Two signals, namely `REGISTER_TO_HIGH`, and `REGISTER_TO_LOW` are to be defined in the SDL system, with a process receiving these. Then the user supplied C code should look like this (the `<p>` below stands for the automatically generated prefix, see the file `sdl_cfg.h`):

```
void xInEnv (void)
{
  XMK_SEND_TMP_VARS
  static state = 0;
              /* state, to detect changes in the */
              /* hardwareregister               */

 /* BEGIN User Code */
 if ((state==0) && (hw_register != 0))
 /*   END User Code */
 {
   XMK_SEND_ENV (REGISTER_TO_HIGH,
                 xDefaultPrioSignal,
                 0,
                 NULL,
 /* BEGIN User Code */
   GLOBALPID(XPTID_<p>_ReceiverName,0));
   state = 1;
 /*   END User Code */
   return;
 }

 /* BEGIN User Code */
 if ((state==1) && (hw_register == 0))
 /*   END User Code */
 {
   XMK_SEND_ENV (REGISTER_TO_LOW,
                 xDefaultPrioSignal,
                 0,
                 NULL,
/* BEGIN User Code */
   GLOBALPID(XPTID_<p>_ReceiverName,0));
   state = 0;
/*   END User Code */
    return;
  }

  return;
} /* END OF SAMPLE */
```

Caution!

The function `xInEnv()` contained in the file `env.c` is generated by the Targeting Expert. To make sure that changes done by the user will not be lost when generating again it is allowed to modify this file only between the comments `/* BEGIN User Code */` and `/* END User Code */`.

Furthermore it is not allowed to remove these comments or to add similar at other places which could especially happen when copy and paste is used during editing.

XMK_SEND_ENV()

Parameters:

```
In/Out: xPID Env_ID

        xmk_T_SIGNAL sig

        #ifdef XMK_USE_SIGNAL_PRIORITIES
          xmk_T_PRIO prio
        #endif

        #ifdef XMK_USED_SIGNAL_WITH_PARAMS
          xmk_T_MESS_LENGTH data_len,
          void xmk_RAM_ptr  p_data
        #endif

        #ifdef XMK_USE_RECEIVER_PID_IN_SIGNAL
          xPID Receiver
        #endif

Return: -no-
```

It is possible to send signals directly into the SDL system by calling the C function `XMK_SEND_ENV()`, no matter whether preemption is used or not. No conflict occurs, if an interrupt service routine uses a `XMK_SEND_ENV()` function parallel to the C function `xInEnv()`.

This function is to be called when a signal is to be sent into the SDL system, e.g. within the users `xOutEnv` function. It must be called with one more parameter than the `xmk_Send` function, which is the first parameter `Env_ID`. This parameter must be set to `ENV` by the user.

The macro internally uses some variables which are to be declared before the macro can be used. For example in the xOutEnv function the `XMK_SEND_TMP_VARS` macro must be introduced for declaring these variables.

The function is implemented as a macro in C.

Use the template in the previous subsection to see details how to use the `XMK_SEND_ENV()` functions.

Sending Signals to the Environment

There are several possibilities to send signals to the environment:

1. Using simple SDL output.
   The Cmicro Kernel is involved in the output operation.

2. Using the `#EXTSIG` directive in the SDL output.
   The user can define his own output operation, like writing to a register in a single in-line-assembler command.

3. Using the `#ALT` directive in the SDL output.
   A variant of alternative 2.

Alternative 1 is the most SDL like alternative because it does not use non SDL constructs, like directives. This alternative should be selected, where possible because it makes the diagrams more SDL like and MSCs more readable.

Alternative 2 and 3 are probably the alternatives with higher performance.

Alternative 1 is described below. Alternative 2 and 3 are already well described in chapter 65, *The Cmicro SDL to C Compiler*.

xOutEnv()

Parameters:

```
   In/Out:
            xmk_T_SIGNAL         xmk_TmpSignalID

            #ifdef XMK_USE_SIGNAL_PRIORITIES
            xmk_T_PRIO           xmk_TmpPrio
            #endif

            #ifdef XMK_USED_SIGNAL_WITH_PARAMS
              xmk_T_MESS_LENGTH xmk_TmpDataLength,
              void xmk_RAM_ptr  xmk_TmpDataPtr
            #endif

            #ifdef XMK_USE_RECEIVER_PID_IN_SIGNAL
              xPID xmk_TmpReceiverPID
            #endif

   Return: xmk_OPT_INT
```

The function `xOutEnv()` exists as a template in the generated module `env.c`.

Each time an SDL output occurs, the generated C code calls the C function xmk_Send or xmk_SendSimple. After performing some checks, and if the signal is to be sent to the environment, the C function xOutEnv() is called with all the parameters necessary to represent the signal. The parameters are explained in the following.

With the parameter xmk_TmpSignalID, the signal ID is to be specified.

With the xmk_TmpPrio parameter, the signal's priority is to be specified (if conditionally compiled). If the XMK_USE_SIGNAL_PRIORITIES is not defined, the signal priorities which are specified with #PRIO in the diagrams is just ignored. The use of signal priorities is not recommended because this violates SDL. A few bytes can be spared if signal priority is not used. See also XMK_USE_SIGNAL_PRIORITIES.

With the parameter xmk_TmpDataLength, the number of bytes of signal parameters is to be specified. The number of bytes is evaluated by using a sizeof (C struct) construct. If the signal carries no parameters, this value is set to 0.

With the xmk_TmpDataPtr parameter, a pointer to the memory area containing the parameter bytes of the signal is given. The memory area is not treated as dynamically allocated within this function. Because the function copies the parameter bytes, the caller may use any temporary memory (for example memory allocated from the C stack by declaring a C variable). This parameter should be set to NULL if no parameter bytes are to be transferred (if conditionally compiled).

The parameters xmk_TmpDataLength and xmk_TmpDataPtr are compiled conditionally. The XMK_USED_SIGNAL_WITH_PARAMS is automatically generated into the sdl_cfg.h file, from the Cmicro SDL to C Compiler. For tiny systems, if there are no SDL signals with parameters specified, this is undefined. It will reduce the amount of information which is to be transferred for each signal, with a few bytes. See also XMK_USED_SIGNAL_WITH_PARAMS.

With the last parameter xmk_TmpReceiverPID, the PID of the receiving process is to be specified (if conditionally compiled). The parameters xmk_TmpDataLength and xmk_TmpDataPtr are compiled conditionally, see also XMK_USE_RECEIVER_PID_IN_SIGNAL.

If XMK_USE_RECEIVER_PID_IN_SIGNAL is not defined, the user must implement the C function xRouteSignal which is responsible to derive the receiver from the signal ID in that case. Using xRouteSignal

is recommended only if the last few bytes must be spared for transferring of signals.

> **Note:**
>
> There is a file called `<systemname>.ifc`, which is generated by the Cmicro SDL to C Compiler. It is necessary to include this file together with `ml_typ.h` before defining `xOutEnv()`. This is necessary to have access to all the objects that are generated by the Cmicro SDL to C Compiler. The user should also make sure that this file is generated, because the analyzer's make menu contains an option for this.

Evaluate the Signals's Sender

The sender of the signal can be retrieved by the global variable `xRunPID` of type `xPID`. Users should remember, that in a system with only (x,1) process declarations, this pid represents the process type of the sender. In a system in which multiple process instances of the same process type appear, this pid represents the process type plus the process instance of the sender. Probably it is required to make decisions depending on the sender of the signal. The user can evaluate the process type of the sender by using the C expression `EPIDTYPE(xRunPID)`, i.e.:

Example 608: Evaluating the Process Type ––––––––––––––––––––

```
unsigned char ptype;
ptype = EPIDTYPE(xRunPID);
```

––

Remember also, if it is required to signal to a specific pid in the environment, this requires dynamic signalling where a process in the environment establishes communication to a process in the system or the other way around.

Checking the Signal's Receiver

Under normal circumstances it is not necessary to check the receiver in `xOutEnv()` as the Cmicro Kernel calls `xOutEnv()` only, if the environment is recognized as the signal's receiver.

Caution!

The users have to ensure that signals to the environment are consumed in the environment by returning `XMK_TRUE` in `xOutEnv()`.

Signal Parameters

If the signal to be sent to the environment contains parameters, it is necessary to copy these parameters to the data area of the environment as the signal and its parameters are deleted after signal consumption.

For each signal carrying parameters, there is a typedef struct generated into the `<systemname>.ifc` file. Please view Example 609.

Return Values of xOutEnv()

The user must ensure that signals which are to be sent to the environment are consumed by the environment. In `xOutEnv()` this is done by returning the values `XMK_TRUE` or `XMK_FALSE`.

- `XMK_TRUE`
  The signal has been consumed by the environment.
- `XMK_FALSE`
  The signal is NOT consumed by the environment.

An Easy Example

Assume, for example, a process which has to send a signal with parameters to the environment. The code the user has to write into the `xOutEnv()`-function, looks as follows:

Example 609: `xOutEnv()`

```
xmk_OPT_INT xOutEnv (xmk_T_SIGNAL      xmk_TmpSignalID,
                     xmk_T_PRIO        xmk_TmpPrio,
                     xmk_T_MESS_LENGTH xmk_TmpDataLength,
                     void *            xmk_TmpDataPtr,
                     xPID              xmk_TmpReceiverPID )

{
  xmk_OPT_INT xmk_TmpResult = XMK_FALSE;

  switch (xmk_TmpSignalID)
  {
    case SDL_Signal1 :
      {
        /* BEGIN User Code */
        int temp;
        temp = (yPDef_z4_SDL_Signal1*)xmk_TmpDataPtr->Param1
        UserFunction(temp);
        /*   END User Code */
        xmk_TmpResult = XMK_TRUE; /* signal is */
                                  /* consumed  */
      }
      break ;

   case SDL_Signal2 :
      {
        /* BEGIN User Code */
        char g;
        int  k;
        g = (yPDef_z5_SDL_Signal2*)xmk_TmpDataPtr->Param1;
        k = (yPDef_z5_SDL_Signal2*)xmk_TmpDataPtr->Param2;
        UserFunction2( g, k );
        /*   END User Code */
        xmk_TmpResult = XMK_TRUE; /* signal is */
                                  /* consumed  */
      }
      break ;

   default :
        xmk_TmpResult = XMK_FALSE;/* signal is NOT */
                                  /* consumed   */
                                  /* and to be handled */
                                  /* by the Cmicro Kernel */
        break ;
  }
  return( xmk_TmpResult );
}
```

Caution!

The function `xInEnv()` contained in the file `env.c` is generated by the Targeting Expert. To secure that changes done by the user will not be lost when generating again it is allowed only to modify this file between the comments `/* BEGIN User Code */` and `/* END User Code */`.
Furthermore it is not allowed to remove these comments or to add similar ones at other places.

Inter-Processor-Communication

> **Note:**
>
> If inter-processor-communication is to be performed, the user has to define a unique protocol between the communicating processors. In small applications with a restricted range, it might be enough to copy C structures, but usually this causes problems when it comes to redesigning the hardware.

Closing the Environment / the Interface to the Environment

xCloseEnv()

Parameters:

```
In/Out: -no-
Return: -no-
```

There is one C function called `xCloseEnv`() available as a template in the generated C module `env.c`.

The user should fill this function out appropriately thus realizing disconnection from the environment (drivers, interrupt service routines and so on). Disconnection can make sense if a re-initialization or a software reset is to be implemented.

The `SDL_Halt` function is mapped to `xCloseEnv()` in Cmicro.

SDL System Time Implementation

Included in the Cmicro Kernel, there are some template functions for the implementation of SDL system time. All these functions are contained in the module `mk_stim`. The functions `xmk_NOW()` or `xmk_SetTime()` must be implemented newly if a new method for accessing the hardware system time is to be implemented. In many cases, the standard C library function `time()` is available, which is used in most of the C compiler adaptations that are already been made.

It is necessary though to implement a function which makes the variable `SystemTime` topical. This will be an interrupt service routine in most cases.

Please view "Defining the SDL System Time Functions in mk_stim.c" on page 3528.

Getting the Receiver of a Signal – Using xRouteSignal

Parameters:

```
In/Out: xmk_T_SIGNAL sig
Return: xPID
```

The user can remove the receiver's xPID from the signal structure by resetting the flag "XMK_USE_RECEIVER_PID_IN_SIGNAL" on page 3491. In this case, the function `xRouteSignal()` has to be filled as the Cmicro Kernel needs to know which process likes to receive the current signal.

Example 610: Function `xRouteSignal()`

```
/*
** the <p> below stands for the automatically generated prefix
*/

xPID xRouteSignal  ( xmk_T_SIGNAL sig )
{
   /*
   ** Please insert appropriate code here to map
   ** Signal ID's to Process - Type - ID's
   ** (XPTID_ProcessName in generated code).
   ** Keep in mind that this function might be
   ** called from within a critical path.
   ** Include <systemname>.ifc to get signal names
   ** and process' XPTID
   */
   switch (sig)
   {
    /*
    **  S D L   T i m e r s ...
    */
    case SDL_Timer1: return (XPTID_<p>_ProcessName_A)
                     break;
    case SDL_Timer2: return (XPTID_<p>_ProcessName_B)
                     break;
    case SDL_Timer3: return (XPTID_<p>_ProcessName_A)
                     break;
    case SDL_TimerN: return (XPTID_<p>_ProcessName_C)
                     break;

    /*
    **  O r d i n a r y  S D L  S i g n a l s ...
    */
    case SDL_Signal1: return (XPTID_<p>_ProcessName_B)
                      break;
    case SDL_Signal2: return (XPTID_<p>_ProcessName_A)
                      break;
    case SDL_Signal3: return (XPTID_<p>_ProcessName_A)
                      break;
             ......

    case SDL_SignalN : return (XPTID_<p>_ProcessName_C)
                      break;

    default: ErrorHandler (ERR_N_NO_RCV);
             return (xNULLPID)
             break;
   }
}
```

Dynamic Memory Allocation

General

Dynamic memory allocation in real life always introduces problems, which are:

- The memory occupation cannot be evaluated by the user, so that it is impossible to configure the dynamic memory. If all objects are allocated statically and if the memory occupation exceeds the available memory, this results in errors during compilation/linking, or at least a memory map file can be viewed.
- If dynamic memory allocation is used, then, after the program has executed for a time, usually memory leaks are the result. Memory leaks are fatal because there might be enough memory, but it is even impossible to allocate one more block.
- If there is no more free dynamic memory available, then it is up to the user to decide how to continue in the program. In any case, the program should be terminated, started again or any similar reaction is to be programmed.

Normally, Cmicro tries to prevent any use of dynamic memory allocation, but there are the following exceptions, in which this is impossible:

- When a signal with too many parameters is to be sent to another process. See "Signals, Timers and Start-Up Signals" on page 3460.
- When an SDL sort is used requiring dynamic memory management, like the charstring sort.
- If the SDL Target Tester is used, because there is dynamic memory allocation in the start-up phase and for each transmit buffer.

There are at least two possibilities to implement dynamic memory allocation namely:

- The dynamic memory management from the C Compiler or operating system can be used.
- The dynamic memory management from Cmicro can be used.

When it comes to targeting, the user decides upon the dynamic memory allocation manager. In the following, the both possibilities are explained.

Dynamic Memory Allocation Functions – Compiler or Operating System

If the C compiler, that the user is using in the target environment, provides dynamic memory allocation functions, it is possible to use these functions. A few steps must be carried out to include the dynamic memory allocation functions of the C compiler or operating system, which are:

- The user must introduce his own C compiler section, please refer to the subsection "Introducing a new C Compiler" on page 3525.
- In the new C compiler section, the correct header files must be introduced with `#include`. The user should refer to the manuals of the C compiler or operating system.
- The SDL Target Tester, Cmicro Library and Cmicro Kernel always allocate dynamic memory by using the functions in the file `mk_cpu.c`.
- The file `mk_cpu.c` below the Cmicro template directory must be copied into the user's project directory. Any modifications should be performed on the private copy of `mk_cpu.c`.
- The `mk_cpu.c` file contains two C functions called `xAlloc()` and `xFree()`. Within these functions, the user should call the appropriate dynamic memory allocation functions of the C compiler or operating system.

Dynamic Memory Allocation Functions – Cmicro

Below the Cmicro kernel directory there is a C module `ml_mem.c` that implements a dynamic memory allocator. The C module `ml_mem.c` can be used for managing memory dynamically for SDL systems, but it is not forbidden to use this module within handwritten C code also.

The module cannot be used if partitioning is to be used. In that case compilation errors will occur. Please refer to "Dynamic Memory Allocation" on page 3543 for an explanation which parts in SDL are to be dynamically allocated. The module provides C functions for initialization, allocation, de-allocation, and getting some information about the current memory status.

There is only one memory pool. The memory pool is to be declared by the user and initialized with the C function `xmk_MemInit` before the

memory pool can be used. Allocations may be performed by calling `xmk_Malloc()` or `xmk_Calloc()`. An allocated block is de-allocated again by calling `xmk_Free()`. So far, the principle behavior is the same as the usual `malloc()`, `calloc()` and `free()` functions from compilers. But the memory pool can probably be cleaned with a Cmicro specific function. There are additional functions which can be used to query the amount of free or occupied space.

Before the memory management functions of Cmicro can be used, a few adaptations are to be made which are explained in the following.

Adaptations That Are to Be Made

Some adaptations are to be made by the user, which are necessary to include the right functions, scale buffers and memory management and take care for general adjusting like alignment of the CPU.

- For general use of the Cmicro memory management functions the user should set the flag `XMK_USE_SDL_MEM` in `ml_mcf.h` with the help of the Targeting Expert. This will make the basic memory allocation functions available. The `ml_mem.c` module must of course be compiled an linked together with the application.
- Adjust the alignment that the CPU is using. There is a macro definition in `ml_mem.c` called `CPU_WORD_SIZE`. The right setting of this macro is basically important for making the dynamic memory allocation functions do work. With this flag, it is possible to define the word size of the target CPU. The value is predefined in `ml_mem.c` but it could be the case that the predefined value is inappropriate for the target system. If the `CPU_WORD_SIZE` value must be redefined, this could be done in `ml_mcf.h` in the user's section. The predefined value for UNIX compilers is 8, the predefined value for `ARM_THUMB` C compiler 4, otherwise a default value of 1 (no alignment) is used.
- Here is a recommendation: The user should use an alignment of 4 (32 Bit) if it is not sure what type of alignment the C compiler / CPU produces. This will work for most cases, but of course probably not if the CPU is 64 Bit CPU. For small systems, this might not be appropriate, because there is an extra overhead of 3 bytes per allocated block. For a CPU like `8051` and derivatives a `CPU_WORD_SIZE` of 1 is appropriate.

- It is possible to introduce a minimum block size per each allocated block. This decreases the risk of getting memory leaks after a while because blocks of the same size can be put together again. If the mechanism of a minimum block size is to be used, then the define XMK_USE_MIN_BLKSIZE is to be used. With the define XMK_MEM_MIN_BLKSIZE the user may define the minimum block size per each allocated block. If the XMK_MEM_MIN_BLKSIZE is not defined from the user, a minimum block size of 64 is predefined.
- The ml_mem.c module contains profiler that keeps track on how many blocks are allocated, how much memory is free and furthermore. The user must define XMK_ADD_PROFILE in order to get the complete functionality. If the SDL Target Tester is used, the flag is automatically predefined.

xmk_CleanPool()
Parameters:
```
In/Out: -no-
Return: size_t
```
This C function returns the amount of occupied memory. It is available only if XMK_USE_SDL_MEM and XMK_SYSTEM_INFO are set.

xmk_GetOccupiedMem()
Parameters:
```
In/Out: -no-
Return: size_t
```
This C function returns the net amount of occupied memory. It is available only if XMK_USE_SDL_MEM and XMK_SYSTEM_INFO are set.

xmk_GetFreeMem()
Parameters:
```
In/Out: -no-
Return: size_t
```
Returns the amount of free memory in sum, which means that the overhead from each block is included. It is available only if XMK_USE_SDL_MEM and XMK_SYSTEM_INFO are set.

xmk_EvaluateExp2Size()
Parameters:
```
In/Out: size_t
Return: size_t
```

This function is either used from Cmicro's dynamic memory allocation functions `xmk_Malloc()` and `xmk_Calloc()` or it may be used directly from the user.

It is available only if `XMK_USE_MIN_BLKSIZE` is set.

The function is declared as:

```
size_t xmk_EvaluateExp2Size ( size_t GivenLength )
```

The function evaluates from the given length a length value, which is in any case a 2 exp N value. This is used to reduce the risk of memory leaks that occur in dynamic memory management systems. It may be used for the memory functions of this module but also for the memory functions of an operating system or C compiler. If the minimum block size is in any case greater than the greatest block that is requested in the target system, then there is no risk for memory leaks. The return result is either the minimum specified with `XMK_MEM_MIN_BLKSIZE`, but might be also one of the following values:

```
64,128,256,512,1024,2048,4096,8192,16384,32768,65536
```

The ?Memory Command

The SDL Target Tester offers a command that allows the user to inspect the status of the dynamic memory. Unfortunately this command can be used only, if the dynamic memory management from Cmicro is used (by setting the `XMK_USE_SDL_MEM` flag in the Targeting Expert).

The command allows the user to check the following:

- Is the dynamic memory correctly initialized after system start-up?
- How is the dynamic memory pool configured?
- At any time during SDL target system execution:
  - what was the greatest block that was allocated?
  - how many blocks are currently in the pool?
  - what is the maximum amount of blocks that have ever been in the pool?
  - physical address of the memory pool (the address of the
  - first block of structure `xmk_T_MBLOCK` (see `ml_mem.c`)

The command presents the following output to the user:

```
M-STATE:Memory pool size incl.overhead     =4096
M-STATE:Current memory fill                =136
M-STATE:Current amount of blocks in pool   =2
M-STATE:Peak hold: Amount of blocks        =29
M-STATE:Peak hold: Largest block           =2048
M-STATE:Overhead per block (in bytes)      =20
```

```
M-STATE:Minimum block size                =0
M-STATE:Memory pool address (hex)         =28478
M-STATE:(Probably there are memory leaks)
```

The command is available only if XMK_USE_SDL_MEM and XMK_ADD_PROFILE are set.

User Defined Actions for System Errors – the ErrorHandler

Parameters:

```
In/Out: int ErrorNo
Return: void
```

Errors, warnings and information can be generated and detected in many places and situations during the lifetime of an SDL system. By fully utilizing the Analyzer, several dynamic error sources can be eliminated at the design stage of development.

Some errors or warnings go undetected by the Analyzer, for example resource errors or real time errors such as memory, performance, or illogical use of SDL.

These errors and warnings are detectable by the Cmicro Kernel and the SDL Target Tester. For a complete list of errors, warnings and information, please view the following subsection "List of Dynamic Errors and Warnings" on page 3550.

As a general rule, for each error and warning there should be an appropriate reaction in the function ErrorHandler() in the mk_user module.

The ErrorHandler() is, as a default implementation, implemented like this:

In the case of a warning message, either:

- The actions defined via the flag XMK_WARN_ACTION_HANG_UP are carried out (see "Reactions on Warnings" on page 3496).
- The actions defined via the flag XMK_WARN_ACTION_PRINTF are carried out.
- The actions defined via the flag XMK_WARN_ACTION_USER and XMK_WARN_USER_FUNCTION are carried out.

In the case of an error message, either:

- The actions defined via the flag XMK_ERR_ACTION_HANG_UP are carried out (see "Reaction on Errors" on page 3498)

- The actions defined via the flag `XMK_ERR_ACTION_PRINTF` are carried out.
- The actions defined via the flag `XMK_ERR_ACTION_USER` and `XMK_ERR_USER_FUNCTION` are carried out.

For more explanations on these flags, please view "Reactions on Warnings" on page 3496 and "Reaction on Errors" on page 3498. If `printf` is used, the C module `ml_mon.c` below the `cmicro/kernel` directory must be compiled also.

Errors are numbered easily by an integer value. If the user's target allows the use of `printf`, then use the C function `xmk_err_text` contained in the `ml_err` module. It is easier to specify error handling in this module rather than directly modifying the `ErrorHandler` function.

Example 611: `Default implementation of ErrorHandler()` **———**

```
void ErrorHandler ( int ErrorNo )
{
  ...
  ...
  ...

 ErrorClass = xmk_GetErrorClass (xmk_TmpErrorNumber);
  #ifdef XMK_WARN_ACTION_HANGUP
    if (ErrorClass==XMK_WARNING_CLASS)
      while (1);
  #endif /* ... XMK_WARN_ACTION_HANGUP */

  #ifdef XMK_ERR_ACTION_HANGUP
    if (ErrorClass==XMK_FATAL_CLASS)
      while (1);
  #endif /* ... XMK_ERR_ACTION_HANGUP */

  #ifdef XMK_WARN_ACTION_PRINTF
    if (ErrorClass==XMK_WARNING_CLASS)
      xmk_MonError (stderr, xmk_TmpErrorNumber);
  #endif /* ... XMK_WARN_ACTION_HANGUP */

  #ifdef XMK_ERR_ACTION_PRINTF
    if (ErrorClass==XMK_FATAL_CLASS)
      xmk_MonError (stderr, xmk_TmpErrorNumber);
  #endif /* ... XMK_ERR_ACTION_HANGUP */

  #ifdef XMK_WARN_ACTION_USER
    if (ErrorClass==XMK_WARNING_CLASS)
      XMK_WARN_USER_FUNCTION( xmk_TmpErrorNumber );
  #endif /* ... XMK_WARN_ACTION_USER */

  #ifdef XMK_ERR_ACTION_USER
    if (ErrorClass==XMK_FATAL_CLASS)
      XMK_ERR_USER_FUNCTION( xmk_TmpErrorNumber );
  #endif /* ... XMK_ERR_ACTION_USER */

  ...
  ...
  ...
```

```
} /* END OF SAMPLE */
```

Example 612: `ErrorHandler()`

```
void ErrorHandler ( int ErrorNo )
{
  /* The user could implement the 3 functions
  ** fatalerror, warning, and information
  */
  switch (ErrNo)
  {
    case  ERR_N_UNKNOWN
          fatalerror(ErrNo);
          break;

    case  .....
          .....
          break;

    default: warning(ERR_N_UNKNOWN); break;
  }
} /* END OF SAMPLE */
```

List of Dynamic Errors and Warnings

Cmicro Kernel Errors

- ERR_N_CREATE_NO_MEM

  This error can happen in the case of using dynamic process creation. When a parent process tries to create another process, the Cmicro Kernel tries to allocate an entry in the queue for the insertion of an internal create signal.

  The error occurs when full queue capacity has been reached.

  Help: Change the size of the signal queue by modifying the macro XMK_MAX_SIGNALS in `ml_mcf.h`.

- ERR_N_CREATE_INSTANCE

  This error happens if there is no dormant instance of a process type which can be (re)used. The Cmicro Package uses fixed upper process instance limits (x, N), where N is to be specified as an integer value. In the C code, all the data of one process instance is represented by one element of an array of the size N.

The error occurs if all instances (i.e. all array elements), of this process type are currently active and the parent tries to create another instance of that type.

- ERR_N_SDL_DISCARD

  A signal was sent to a process not existing (either not yet created or already stopped). The signal is therefore discarded.

- ERR_N_DIVIDE_BY_ZERO

  A division by zero has been detected in the generated SDL code, which is an SDL user error. Possibly, it is helpful to produce an execution trace to localize the error. Normally, it is possible to find such problems within the simulation.

- ERR_N_NO_FREE_SIGNAL

  It is impossible to allocate one more signal instance from the static memory pool. Depending on how the user has defined the signal handling (`XMK_USE_STATIC_QUEUE_ONLY` and `XMK_USE_STATIC_AND_DYNAMIC_QUEUE`), this must be treated either as a warning or as a fatal error.

  It has to be treated as a fatal error, when the macro `XMK_USE_STATIC_QUEUE_ONLY` is set.

  It can be treated as a minor warning, when the macro `XMK_USE_STATIC_AND_DYNAMIC_QUEUE` is set.

  The output operation fails, if it is impossible to allocate one more signal.

  Help: Change the size of the signal queue by modifying the macro XMK_MAX_SIGNALS in `ml_mcf.h` or change the size of predefined dynamic memory pool (the memory pool, that is used when the xAlloc C function is called).

- ERR_N_PARAMETER_MEM_ALLOC

  The output operation fails as a signal with parameters is to be sent but not enough free memory is available for allocation of the signal parameters.

  If the signal parameter's length is greater than the value of XMK_MSG_BORDER_LEN (see "Compilation Flags" on page 3486) the parameters are inserted in a memory area which has to be

allocated. This allocation fails because there is no more memory available.

Help: If using the Cmicro Library's memory functions (flag XMK_USE_SDL_MEM): The size of the memory for allocation can be increased by incrementing the value XMK_MAX_MALLOC_SIZE.

- ERR_N_SYSTEM_SIGNAL

  This error can only happen, if a non specified system signal is sent. Internally, some signals are predefined as system signals. System signals are given priority treatment. For example, for the dynamic process creation, there is a system signal called `XMK_CREATE_SIGNALID` which is automatically defined in `ml_mcf.h` according to the setting of XMK_USE_MORE_THAN_250_SIGNALS.

  To prevent this error situation happening it is strongly recommended not to send an SDL signal with equal or higher priority than that of a system signal (please see the subsection "Scheduling" on page 3469).

- ERR_N_NO_CONT_PRIO

  This error occurs when process priorities are not numbered according to the rules of the preemptive Cmicro Kernel. The numbering must begin from zero incremented consecutively to an upper limit. All numbers between zero and the upper limit-1 are to be used within a #PRIO directive, no number may be omitted. (See MAX_PRIO_LEVELS and `xDefaultPrioProcess` in section "Preemption" on page 3502.

- ERR_N_NO_COR_PRIO

  When the preemptive Cmicro Kernel is selected, the macro MAX_PRIO_LEVELS has to be set correct. As described in MAX_PRIO_LEVELS in section "Preemption" on page 3502, this macro has to contain the amount of process priority levels.

- ERR_N_xRouteSignal

  The function `xRouteSignal`, which is to be filled by the user when signals do not contain a receiver pid, detects an error or was not able

to handle the current signal which is to be routed. See "Bare Integration" on page 3530.

- ERR_N_NO_REC_AVAIL

  If the user is using implicit addressing (output without to) and there are several possible receivers of one type, the Cmicro Kernel tries to assign one of them to this signal. This assignment may fail if there is no possible receiver. If there is more than one, then the first one found will be used in the output of the C function `xmk_Send*`.

- ERR_N_NO_FREE_TIMER

  The error occurs when an SDL process tries to start an instance of a timer and either the timer is unknown or there is no memory available to start a timer instance. To eliminate the first source of error check the SDL compilation. For the second case increase the memory assigned to timers by increasing the value of XMK_TIMERPRIO.

- ERR_N_PID_INDEX

  The Cmicro Kernel uses PIds as index values. Each SDL process in the generated system is numbered by a system-wide unique number. There is an error detected when the index is out of range. This problem most probably lies in the environment which tries to send a signal to a non existing process.

- ERR_N_SEND_TO_NULLPID

  An SDL application tries to send to a NULL - PID. This case normally cannot arise as the Analyzer performs appropriate checks in the dynamic analyses pass. If it occurs, it is most probably that either something is wrong with the environment signalling or possibly with initialization of pid variables.

- ERR_N_TRANS_TIME

  The maximum execution time for one SDL transition was exceeded. This error can only happen if no preemption is used and if the administration of the transition-execution-time is switched on. See "XMK_USE_CHECK_TRANS_TIME" on page 3501.

- ERR_N_xOutEnv

The C function `xOutEnv()` does not handle all necessary signals. It should handle all signals which are sent to the environment. Please view "Return Values of xOutEnv()" on page 3539.

- ERR_N_INIT_SDL_MEM

  If the Cmicro Library's memory functions are used, (XMK_USE_SDL_MEM is defined) the memory for `alloc()` and `malloc()` has to be initialized. This error occurs if a `malloc()` takes place before the memory is initialized. See "ml_mem.c" on page 3566

- ERR_N_SDL_DECISION_ELSE

  An SDL decision without any ELSE branch leads to a fatal error.

- ERR_N_SDL_RANGE

  The index of an SDL array has crossed the range of the SDL array. The definition of the array has to be checked within SDL.

- ERR_N_NO_RCV

  If the flag XMK_USE_RECEIVER_PID_IN_SIGNAL is undefined the function `xRouteSignal()` has to be filled by the user. See "Getting the Receiver of a Signal – Using xRouteSignal" on page 3542. This error code means that there is no receiver defined for the current signal.

- ERR_N_SDL_IMPLICIT_CONSUMPTION

  The receiver process is not expecting the current signal in his current state, so the signal was implicitly consumed.

- ERR_N_PREDEFINED_OPERATOR_CALL

  An error occurred in the call to one of the predefined operators. Unfortunately it is not possible to find out what the reason for this error is without either simulating the system or using the SDL Target Tester or any trace possibility introduced by the user. The error message occurs if a range in the memory is crossed.

- ERR_N_INIT_QUEUE

  The SDL signal queue is not correctly initialized. The error occurs if the user has forgotten to call the C function `xmk_InitQueue()`. This function must be called before `xmk_InitSDL()` may be called.

Please view the section "Implementation of Main Function" on page 3530.

- ERR_N_MEM_PARAM

  This error occurs if the user tries to call to the `xmk_Malloc()` C function with a wrong parameter. It is not allowed to request a memory block of the size 0.

- ERR_N_MEM_NO_FREE

  There is no free block in the memory pool of the Cmicro Memory Management (see "Exported from ml_mem.c" on page 3587). This error can only be detected if the Cmicro Memory Management is used (see the flag "XMK_USE_SDL_MEM" on page 3515).

  The size of the dynamic memory, i.e. the amount of blocks available can be modified by modifying the flag XMK_MAX_MALLOC_SIZE

- ERR_N_MEM_ILLMBLOCK

  A call to the `xmk_Free()` function of the Cmicro Memory Management (see the file "Exported from ml_mem.c" on page 3587) occurred and the given block is an invalid block.

  This error can only be detected if the Cmicro Memory Management is used (see the flag "XMK_USE_SDL_MEM" on page 3515).

- ERR_N_NO_FREE_SIGNAL_DYN

  This error is detected when a new signal is to be allocated dynamically and there is no more free memory available. The Cmicro Kernel starts to create signal instances by using memory allocation in the case that the define XMK_USE_STATIC_AND_DYNAMIC_QUEUE is defined and there is no available signal instance in the predefined pool of static signal instances (see XMK_MAX_SIGNALS).

- ERR_N_NO_FREE_TIMER_DYN

  This error is detected when memory for a new timer instance is to be allocated dynamically and there is no more free memory available. The error only occurs if timers with parameters are used. The Cmicro Kernel starts to create timer instances by using memory allocation in the case that timers with parameters are used in SDL

(XMK_USED_TIMER_WITH_PARAMS is defined in `sdl_cfg.h`) and the amount of statically predefined timer instances (XMK_MAX_TIMER_USER defined with Targeting Expert) is being reached.

- ERR_N_NULL_POINTER_VALUE_USED

  This error occurs within the macros that are generated in order to check null pointer access. These error checks are generated for variables of sort ref, own and oref. If the error occurs, the further behavior of the SDL system is unpredictable.

- ERR_N_UNDEFINED_ERROR

  This error message is implemented to serve the C `switch` statement in use with a default branch. It should not occur during system execution.

SDL Target Tester Errors

- ERR_N_INDEX_SIGNAL

  Under normal circumstances this error should not occur. It is an error detected by the SDL Target Tester when a signal id is out of range. This is only used if signal trace options are modified or asked for.

- ERR_N_ILLEGAL_CMD

  An illegal command was sent to the SDL Target Tester command interface module. This error situation arises due to careless implementation of the function interface and should not occur under normal circumstances.

- ERR_N_TESTER_MESSAGE

  An illegal message was sent to the SDL Target Tester and it is not able to decode the message. A possible error source is an inconsistency in the underlaying protocol on the communications interface.

- ERR_N_LINK_SYNC

  It was not possible to receive the sync byte of the data link frame of the Cmicro Protocol.

- ERR_N_LINK_DEST_BUFFER

A message which is to be decoded is too large for the destination buffer. Possible error sources are an inconsistency in the data definition or the length of information received is wrong.

- ERR_N_LINK_ENC_LENGTH

  An attempt was made to send more than the allowed maximum amount of bytes.

- ERR_N_LINK_ENC_MEMORY

  There is not enough, or no free memory to encode a data link frame of the Cmicro Protocol.

- ERR_N_LINK_NOT_IMPL

  A feature of the data link which is not implemented has been used, for example an attempt to send more than the maximum amount of allowed bytes.

- ERR_N_DATA_LINK

  There is an error on the data link detected.

- ERR_N_DECODE_METHOD

  There is no decoding method defined for a given frame of the Cmicro Protocol.

- ERR_N_RING_WRITE_LENGTH

  There is a ring buffer overflow detected in the data link module.

- ERR_N_TRACE_OUTPUT

  The signal parameter length is greater than the size which can be transmitted.

- ERR_N_RECORD_OUTPUT

  The signal parameter length is greater than the size which can be transmitted.

- ERR_N_RECORD_MAX_EXCEEDED

  The debit counter used for the SDL Target Tester’s record is overflown.

- ERR_N_RECORD_STATE

  The received message cannot be handled in the current recorder state.

- ERR_N_RECORD_CANNOT_CONT

  Because a fatal system error is detected the record session cannot be continued.

Light Integration

A light integration is to be performed if the SDL system including the Cmicro Library should execute within just one operating system task.

The SDL system usually communicates with the environment by using a mailbox or message queue or something similar, which is provided from the operating system. Within the SDL system, the Cmicro scheduler is used. This means that signals that are sent internally in the SDL system are not sent via the mailbox/message queue from the operating system.

Model

The execution model for an SDL system in a light integration can be sketched with the following meta code:

1.

```
/* In the user's initialization task do : */
Initialize memory
Initialize time
Initialize mailbox(es) or message queue(s)
Initialize other resources
Make the SDLTask an operating system task
Wait until the SDLTask has finished initialization
Continue with creating other operating system tasks
```

The model for what the SDL task does in a light integration can be sketched with something like:

2.

```
Initialize SDL Target Tester
Initialize Cmicro SDL queue
Initialize Cmicro Trace options (if wanted)
Initialize SDL and execute start transitions of the
process instances which are to be created statically

Forever do
{
  if there is a signal to be consumed
  {
    Get the next message from the OS queue,
    without suspending the SDL Task
  }
  else, if there are only saved signals
  {
    evaluate the remaining duration for the
```

```
      timer that will expire next

      if there is at least one active timer
      {
        listen on the operating system queue for the
        remaining duration, by using a blocking
        function call
      }
      else
      {
        listen forever to the operating system queue
        by using a blocking function call
      }
      If a message was received, format the message
      and send it as an SDL signal to the SDL system
    }
    If a timeout occured (remaining duration),
    then check all the timers. For each timer that
    has been expired there will be one signal
    put into the SDL queue

    process SDL signal
  }
```

Procedure to Implement the Model

This subsection gives the user the details that he must know for the implementation of the given model. He has to deal with some special macros which must be defined and used. Their names have the prefix `XLI_`.

The user must execute the following steps:

1. Create the module with the C `main()` function.

This module has to contain the C `main()` function, corresponding to the first meta code in the section before. The module should include `ml_typ.h` and the interface file (e.g `component.ifc)`. In this module the definitions of other external tasks can take place. The main function should handle the following steps:

- initialize the memory if required
- initialize the hardware timer
- initialize OS resources (semaphore, message queues,...)
- start the necessary OS tasks, this means also to start the task which represents the SDL state machine.
- wait until all tasks are started

2. Set XLI_LIGHT_INTEGRATION

To set this flag the Targeting Expert can be used. Choose your integration and choose “Support light integration” below Target Library and kernel tab. When the box is chosen three things will happen.

- the compiler flag XLI_LIGHT_INTEGRATION will be set
- the compiler flag XMK_USE_INTERNAL_QUEUE_HANDLING is automatically set
- The macro XLI_INCLUDE is set with the name in the edit line (default is ’li_os_def.h’)

This header file is included in ml_typ.h and must contain a definition of XLI_SDL_TASK_FUNCTION. With the help of this macro, the main function known from the standard Cmicro kernel will be mapped to the OS task function. The body of this function is located in mk_user.c.

3. Define the macros which are needed in the task function.

The task function is corresponding to the second meta code of the model. The following macros can be defined in the header file:

- XLI_TEMP_TASK_VARS

If temporary variables are needed in the task function, they can be declared at this place. It is inserted at the top of the task function.

- XLI_TEMP_QUEUE_VARS

If temporary variables for the communication resources are needed, they can be defined within this macro. It is expanded at the top of the function which queries the queue.

- XLI_OS_TASK_INIT

Any preparations in the task function can be done with this. It follows XLI_TEMP_TASK_VARS at the start of the task function.

- XLI_CREATE_OS_QUEUE

Here the communication resources for the OS task can be created (which ones that will be used depends on the user and the used OS). In the further part of the document the term queue will be used instead of communication resources.

- XLI_START_OS_TASK_SYNC

If a synchronization between the OS tasks is needed, this should be defined with XLI_START_OS_TASK_SYNC.

- XLI_GET_NEXT_MESSAGE_FROM_OS_QUEUE

The function xmk_RunSDL() represents the continuous repeating part of the meta model. Inside of it xmk_QueryOSQueue() is called and it is responsible for the query of the OS queue. If the SDL queue contains signals, XLI_GET_NEXT_MESSAGE_FROM_OS_QUEUE is used to read non-blocking from the OS queue. The task function should not be suspended.

- XLI_LISTEN_ON_OS_QUEUE_WITH_TIMEOUT(TIMEOUT)

If the SDL queue is empty, but at least one timer is active, XLI_LISTEN_ON_OS_QUEUE_WITH_TIMEOUT(TIMEOUT) is used to read from the OS queue with a time-out. The OS queue should be queried as long as the next timer expire. The duration is given with the parameter TIMEOUT.

- XLI_LISTEN_ON_OS_QUEUE_NO_TIMEOUT

If there is no signal in the SDL queue and there is no timer active XLI_LISTEN_ON_OS_QUEUE_NO_TIMEOUT is used to query the OS queue while the next OS message arrives. The SDL task should be suspended.

- XLI_CALL_xInEnv

The content of XLI_CALL_xInEnv is executed after an OS message arrives. It should pass on the content of the received OS message (a signal with parameter) to the SDL system. Normally xInEnv is called to send the signal to the SDL system. The user has to define a data structure which transports the signals from the OS to the SDL system. The name for the data structure can be assigned with XMK_xInEnv_PARTYPE. The name for the parameter of xInEnv can be assigned with XMK_xInEnv_PARNAME.

- XLI_END_OS_TASK_SYNC

This can be defined with something that sign up the other non-SDL tasks about ending of the SDL task.

4. Initialize the environment.

This is usually done in `xInitEnv()`, but probably outside SDL, depending on the needs of the user.

5. Adaptions for sending signals from the SDL task to any other OS task.

Usually, users must fill out the function `xOutEnv()` for sending signals to the environment (another operating system task). It is up to the user what kind of communication is to be used in this direction.

Note:

All necessary resources, e.g. the receivers queue, must have been created before they are used.

6. Adaptions for receiving signals from any other OS task and translation of the signal parameters.

In the SDL task, it is necessary to format the incoming parameters after the message was read from the message queue. Afterwards the signal can be sent to the SDL system with `XMK_SEND_ENV`.

Note:

All necessary resources must have been created before they are used.

7. Implement timers in SDL.

It should be possible to implement hardware timers, like it is described in "Defining the SDL System Time Functions in mk_stim.c" on page 3528. A usual way is to increment a global variable (of type `xmk_T_TIME`) by using an operating system task or similar. A time overrun is automatically detected by the Cmicro Kernel.

8. System shutdown.

There is no default way to shutdown, but usually it is enough to implement the `xCloseEnv` function and call it at an appropriate place.

9. Cmicro Target Tester

The next thing that is remaining is the SDL Target Tester. The instructions which have been given for bare integration, are still valid. The easiest way to use the SDL Target Tester in a light integration is to dedicate a communication interface exclusively for the SDL Target Tester.

Note:

The Target Tester can only used for tracing.

10. Compile and link

The added files must be registered as source files in the Targeting Expert. Please view "Source Files" on page 2935 in chapter 59, *The Targeting Expert* to get information on how to add more files to the list of files to be compiled. The Targeting Expert will automatically add these files to the makefile.

11. Save the settings and press Full Make.

File Structure

Description of Files

The Cmicro Library Functions and Definitions

sdl_cfg.h

This file is automatically generated by the Cmicro SDL to C Compiler into the directory which is currently active. It contains compilation flags used for the automatic scaling of the Cmicro Library and the generated C code. The file must not be edited by the user.

Caution!

The file `sdl_cfg.h` always carries the same name, for each SDL system generated and is stored in the currently active directory (project or working directory). Inconsistencies arise if several systems are to be generated in the same directory. To avoid this situation, it is recommended to use different working directories for each SDL system. Otherwise, unpredictable results at run-time could result, as some required automatic scalable features may/may not have been compiled.

ml_typ.h

This file is the central header file in the Cmicro Package. It contains

- more #includes
- defines, which are of global interest and Cmicro Library internal defines
- typedefs which are of global interest and Cmicro Library internal typedefs
- external declarations which are of global interest and Cmicro Library internal external declarations

sctpredg.h, sctpred.h and sctpred.c

These files contain all definitions necessary to handle SDL data, for example predefined sorts. `sctpred.h` is included in `ml_typ.h`.

ml_err.h

This header file defines all error numbers used by the Cmicro Kernel, the Cmicro Library and the SDL Target Tester.

ml_mem.c

This file contains the dynamic memory management functions from Cmicro. It contains among other functions the C functions `xmk_Malloc()`, `xmk_Calloc()` and `xmk_Free()`. Possible reasons to use this module are:

- Compiler does not support dynamic memory management.
- Dynamic memory management of the compiler does not meet the requirements of the application. This may be the case, if the user wants to use “best fit” instead of “first fit”, the first of which is normally not supported. It is possible to adapt the memory management to ones needs.
- User wants to use other mechanisms of `ml_mem.c`, like profiling. Please view “Dynamic Memory Allocation” on page 3543.

ml_mon.inc

This file is included by the `ml_mon.c` file. It exists only for internal purposes and in order to maintain all the defined errors in the system in a better way.

ml_mon.c

This file contains some help functions which are useful in producing screen outputs. It contains C functions for buffer printouts, SDL PId printouts, displaying error messages, and the display of the current scalings used in the executable. The file should usually be included when compiling the kernel.

ml_*.h

Other header files which contain extern declarations of modules of the Cmicro Library.

The Cmicro Kernel

mk_main.c

This file represents the main-interface to the SDL user. It contains functions which are to be called by the SDL user to integrate the Cmicro Kernel in his application.

- an SDL initialization function `xmk_InitSDL()`
- an SDL system execution function `xmk_RunSDL()`

For SDL Target Tester, there are some more functions to be called during initialization. Please view chapter 67, *The SDL Target Tester*.

> **Note:**
> The SDL queue must in any case be initialized before the SDL system is going to execute. The initialization function is called `xmk_InitQueue()` and is exported from the `mk_queu.c` module.

mk_user.c

This module is not in the Kernel directory, but in the Template directory. It contains function templates or examples which are to be filled out by the user:

`main()`

The C main function contains by default the full access to all Cmicro features.

`ErrorHandler()`

Central error handling routine is called each time an errors occurs.

`WatchdogTrigger()`

Handling of a hardware watchdog.

In earlier versions of the Cmicro Package the functions `xInitEnv()`, `xInEnv()`, `xOutEnv()` and `xCloseEnv()` were include in `mk_user.c`, too. These functions will now be generated by the Targeting Expert and stored in the file `env.c`.

mk_sche.c

This file is the heart of the Cmicro Kernel. It exports those functions which are used in the `mk_main` module and it uses those functions of

other modules which represent the SDL model. The module serves with all the different scheduling policies described later in the subsection "Scheduling" on page 3457.

mk_outp.c

This file contains the SDL operation OUTPUT which is represented by a few functions. There is a C function `xmk_Send()` representing the SDL output operation. In addition, there is a C function `xmk_SendSimple()` which is used when a signal contains no parameters and has no explicitly defined priority. This results in a more compact argument list thus reducing the generated C Code.

mk_queu.c

This module contains the data type "SDL queue" and defines all operations on the SDL queue. The queue handling covers all the aspects of the SDL semantics as far as signals are concerned. There is one function `xmk_InitQueue()` which must be called in the user's `main()` function before the SDL system is going to execute.

mk_tim1.c

This file contains the SDL operations on timers such as set, reset, active, and some help functions used by the Cmicro Kernel. The timer model is described within the subsection "Timers and Operations on Timers" on page 3467. The Cmicro Kernel has to initialize all timers, test for expired timers and reset all timers of a process, when a process instance stops.

mk_stim.c

This file contains some functions which are to be filled up by the user. This is the reason why it is in the Template directory. The functions are used by the Cmicro Kernel to get the system time used in SDL. The contents of this file should be seen as a template. No provision for the connection to hardware timers is provided in the delivered source, as the timer used is application dependent. The user is required to fill out the appropriate functions for the provision of SDL system time. Please view "Defining the SDL System Time Functions in mk_stim.c" on page 3528

mk_cpu.c

This file also contains some hardware specific functions which should be seen as templates. It is also in the Template directory.

mk_*.h

Other header files contain extern declarations of modules of the Cmicro Library. The contents and details of the various header files only need to be known if the user wishes to modify parts of the Cmicro Library.

Functions of the Basic Cmicro Kernel

The list in the following section gives an overview of the functions exported by each module of the Cmicro Library in order to understand the module structure. The functions declared as static are not considered here.

If there is a reference to `xmk_RAM_ptr`, this can be replaced with a * (star) usually. This means that for example the declaration

```
xmk_T_CMD_QUERY_QUEUE_CNF xmk_RAM_ptr qinfo
```

can be replaced with

```
xmk_T_CMD_QUERY_QUEUE_CNF *qinfo
```

which means to refer to a pointer to an object of the type `xmk_T_CMD_QUERY_QUEUE_CNF`.

Exported from env.c

xInitEnv

Parameters:

```
In/Out: -no-
Return: -no-
```

This function is called by the Cmicro Kernel during initialization of the SDL system. The user may include initialization of the environment here.

xInEnv

Parameters:

```
In/Out: -no-
Return: -no-
```

This function is called by the Cmicro Kernel continuously to retrieve signals polled from the environment. Use the Cmicro Kernel function `xmk_Send`* to put signals into the system. The use of this function is not absolutely necessary in the case where the Cmicro Kernel is scaled to preemption and all external Events are put into the SDL system via an Interrupt Service Routines.

xOutEnv

Parameters:

```
In/Out: xmk_T_SIGNAL             sig,
        xmk_T_PRIO               prio,
        unsigned char            data_len,
        void                    *p_data,
        xPID                     Receiver

Return: xmk_OPT_INT
```

This function is called by the Cmicro Kernel if an SDL signal is to be sent to the environment.

> **Note:**
>
> The user has several possibilities to send signals to the environment. Please refer to the subsection about the "Functions of the Expanded Cmicro Kernel" on page 3592.

The function must return with XMK_TRUE, if the Signal was sent to the environment, otherwise it must return with XMK_FALSE.

xCloseEnv

Parameters:

```
In/Out: -no-
Return: -no-
```

This function is called by the Cmicro Kernel during the exit phase of the SDL system. The user may include de-initialization of the environment here.

Exported from mk_user.c

xSDLOpError

Parameters:

```
In/Out: char *xmk_String1 - SDL ADT operators name
        char *xmk_String2 - The reason for failure
Return: -no-
```

This is a function which is to filled up by the user. The function is an central error handling function for ADTs. It is compiled only if XEC-SOP was defined in ml_mcf.h.

ErrorHandler

Parameters:

```
In/Out: int ErrorNo - the given error number
Return: -no-
```

This is a function which is to be filled out by the user. The Cmicro Kernel as well as the SDL application are the main clients of this function.

The user may distinguish between the different errors and define a specific reaction.

The different errors defined in the file `ml_err.h` below the Cmicro Kernel directory.

WatchdogTrigger

Parameters:

```
In/Out: -no-
Return: -no-
```

Description:
If selected this function is called by the Cmicro Kernel each time an SDL transition is executed

> **Caution!**
>
> Be sure, that the time-out used for the Watchdog is longer than the longest SDL Transition (in the case of non preemptive Cmicro Kernel). If the preemptive Cmicro Kernel configuration is used, then the Watchdog Trigger should not be used because the execution time of transitions cannot be calculated.

xRouteSignal

Parameters:

```
In/Out: xmk_T_SIGNAL xmk_TmpSignalID - Signal ID
Return: xPID  Process - PID or xNULLPID
        if no receiver is defined for the given
        signal.
```

Description:
This function is called by the Cmicro Kernel, if SDL signals have no receiver. (undef XMK_USE_RECEIVER_PID_IN_SIGNAL) This might be useful in very small systems in order to spare some RAM memory.The following restrictions apply:

- The SDL System must not contain anything other than the following process declaration. (x,1)
- For each Signal in the SDL System, there is to be only one Receiver process (no signal may be sent to more than one process type).
- no dynamic process creation is used (Create-Symbol is not used)

Note:

Timers are represented as signals, that's because `xRouteSignal` also has to map timers to the receiver process

Hint:

Each signal and timer is represented by a system wide unique integer number.

Exported from mk_main.c

xmk_InitSDL

Parameters:

```
In/Out: -no-
Return: -no-
```

This C function is called by the user before calling the C function `xmk_RunSDL()` and implements the initialization of the whole SDL system, namely Timer, Queue, Processes.

xmk_RunSDL

Parameters:

```
In/Out: -no-
Return: -no-
```

This function operates endlessly unless `XMK_USE_SDL_SYSTEM_STOP` is activated. Then the function is returned if the signal queue is empty or no process is alive. Before processing signals, SDL time-outs are checked and the C function `xInEnv` is called.

xmk_MicroTesterInit

Parameters:

```
In/Out: -no-
Return: -no-
```

This function is used to tell the target configuration to the SDL Target Tester. First the communication interface is initialized, then the startup message is sent to the host. After that the target waits for a "go forever" message from the host.

xmk_MicroTesterDeinit

Parameters:

```
In/Out: -no-
Return: -no-
```

This function is responsible for closing the communication interface to the host after the system has ended.

Exported from mk_sche.c

xmk_StartProcesses

Parameters:

```
In/Out: -no-
Return: -no-
```

This function implements the start-up phase of the SDL system. All static process-instances are created. This means executing the start-transition of all process-instances to be created. For each created process-instance, the first state is set. If configured right, the values SDL_SELF, SDL_PARENT and SDL_OFFSPRING are correctly initialized (only necessary if no semantic check was performed, i.e. if the Analyzer is not used).

xmk_ProcessSignal

Parameters:

```
In/Out: -no-
Return: -no-
```

This function processes an SDL signal and remains in an internal loop, until a signal has been processed or until no signal remains in any input-port in the SDL system.

xmk_CreateProcess

Parameters:

```
In/Out: ProcessID       - ID of the process type
Return: xmk_T_INSTANCE  - created Instance number ID
```

This function tries to create an instance of the given process-type. This can fail, either if the create signal cannot be allocated (no more memory) or if there is no free process instance of that type. E.g. if there is no instance in the `DORMANT` state.

The return value contains the process instance number ID, if one more process instance could be allocated. The return value is set to `xNULLINST` if the creation failed for some reason.

The process instance number is not the same as the process ID. The process ID is calculated from the process ID type plus the process ID instance number.

The generated C code does not use the return value, because the SDL offspring and the parent pid value are stored in the pid tables of the process instance.

xmk_IsAnyProcessAlive

Parameters:

```
In/Out: -no-
Return: xmk_T_BOOL
```

This function checks for any active instance of a process type by searching for instances not in the state XDORMANT.

The function returns with `XMK_TRUE`, if there is an active instance. It returns with `XMK_FALSE` if there is no instance active within the system.

xmk_IfExist

Parameters:

```
In/Out: xPID - Process ID of the process to be
checked
Return: xmk_T_BOOL
```

This function checks if the given PID is valid or not. The return value is `XMK_TRUE` if the given PID is valid. If an instance with this PID does not exist, it returns with `XMK_FALSE`.

xmk_CheckNullPointerValue

Parameters:

```
In/Out: void*
Return: -no-
```

This function checks whether there is a pointer value in the SDL system that is used but has no value. The ErrorHandler is called with the right error message then. The error must be caught in the user's ErrorHandler in order to implement the right reaction on this fatal situation.

xmk_InitPreemptionVars

Parameters:

```
In/Out: -no-
Return: -no-
```

The variables used in preemption are initialized.

xmk_DisablePreemption

Parameters:

```
In/Out: -no-
Return: -no-
```

The variable which stores the preemption status is incremented. A value greater than zero means it is not allowed to perform a context-switch at the moment.

xmk_EnablePreemption

Parameters:

```
In/Out: -no-
Return: -no-
```

The variable which stores the preemption status is decremented if preemption was disabled. If the variable's value is zero after it is decremented, the function `xmk_CheckIfSchedule()` is called.

xmk_FetchHighestPrioLevel

Parameters:

```
In/Out: -no-
Return: xmk_T_PRIOLEVEL
```

This function searches for signals in the priority queue levels. This is done with decreasing priority in order to find the highest priority level at which signals exist. The return value is the highest priority level that contains a signal to process.

xmk_CheckIfSchedule

Parameters:

```
In/Out: -no-
Return: -no-
```

It is checked whether a context switch is admissible. If this is the case the current priority-level is compared with the highest priority-level where a signal exists. Supposing the highest level is higher than the current, a context-switch is performed using `xmk_SwitchPrioLevel()`. This is repeated until the current priority-level is the highest level.

xmk_SwitchPrioLevel

Parameters:

```
In/Out: xmk_T_PRIOLEVEL NewPrioLevel
Return: -no-
```

The global variables for the current priority-level are stored. Afterwards, the function `xmk_ProcessSignal()` is called in order to deal

with the signals on the higher priority level. After returning from this function call the variables for the current priority-level are restored.

With the `NewPrioLevel` the next prio-level to deal with is specified.

xmk_KillProcess

Parameters:

```
In/Out: xPID Process ID
Return: xmk_T_BOOL
```

This function sets a process instance into the state `XDORMANT`, removes all signals directed to it from the queue and resets the local instance data. The return values are `XMK_TRUE` if the call was successfully and `XMK_FALSE` if the process was non-existent, currently running or already in the `XDORMANT` state.

Exported from mk_outp.c

xmk_SendSimple

Parameters:

```
In/Out:
  #ifdef XMK_USE_RECEIVER_PID_IN_SIGNAL
    xmk_T_SIGNAL  sig
    xPID          Receiver
  #else
   xmk_T_SIGNAL   sig
  #endif

Return: -no-
```

This is a simple SDL output function which needs a maximum of only 2 Parameters. Most SDL systems consist of a lot of “normal” Signals without any parameters and no priority. It makes sense to use this simple function whenever possible to spare program code. The signal is put into the linked list of signals by using a default priority.

With the first parameter `sig`, the signal ID of the signal that is to be sent is specified. With the (optional) second parameter, the receiver process ID is specified. If XMK_USE_RECEIVER_PID_IN_SIGNAL is not defined, the user must implement the C function `xRouteSignal()` which is responsible to derive the receiver from the signal ID in that case. Using `xRouteSignal()` is recommended only if the last few bytes must be spared for transferring of signals.

xmk_Send

Parameters:

```
In/Out:
        xmk_T_SIGNAL sig

        #ifdef XMK_USE_SIGNAL_PRIORITIES
          xmk_T_PRIO prio
        #endif

        #ifdef XMK_USED_SIGNAL_WITH_PARAMS
          xmk_T_MESS_LENGTH data_len
          void xmk_RAM_ptr  p_data
        #endif

        #ifdef XMK_USE_RECEIVER_PID_IN_SIGNAL
          xPID Receiver
        #endif

Return: -no-
```

This is, compared to the `xmk_SendSimple` function, a complete SDL output function which needs all possible signal parameters.

With the parameter `sig`, the signal ID is to be specified.

With the `prio` parameter, the signal's priority is to be specified (if conditionally compiled).

With the `data_len`, the number of bytes as the signal's parameters is to be specified. The number of bytes is evaluated by using a `sizeof (C struct)` construct. If the signal carries no parameters, this value must be set to 0 (if conditionally compiled).

With the `p_data` parameter, a pointer to the memory area containing the parameter bytes of the signal is given. The memory area is not treated as dynamically allocated within this function. Because the function copies the parameter bytes, the caller may use any temporary memory (for example memory allocated from the C stack by declaring a C variable). This parameter should be set to `NULL` if no parameter bytes are to be transferred (if conditionally compiled).

With the last parameter `Receiver`, the PID of the receiving process is to be specified (if conditionally compiled).

If the XMK_USE_SIGNAL_PRIORITIES is not defined, the signal priorities which are specified with #PRIO in the diagrams is just ignored. The use of signal priorities is not recommended because the violation of SDL. A few bytes can be spared if signal priority is not used.

The XMK_USED_SIGNAL_WITH_PARAMS is automatically generated into the `sdl_cfg.h` file, from the Cmicro SDL to C Compiler. For tiny systems, if there are no SDL signals with parameters specified, this is undefined. It will reduce the amount of information which is to be transferred for each signal with a few bytes.

If XMK_USE_RECEIVER_PID_IN_SIGNAL is not defined, the user must implement the C function `xRouteSignal()` which is responsible to derive the receiver from the signal ID in that case. Using `xRouteSignal()` is recommended only if the last few bytes must be spared for transferring of signals.

XMK_SEND_ENV

Parameters:

```
In/Out: xPID Env_ID

        xmk_T_SIGNAL sig

        #ifdef XMK_USE_SIGNAL_PRIORITIES
          xmk_T_PRIO prio
        #endif

        #ifdef XMK_USED_SIGNAL_WITH_PARAMS
          xmk_T_MESS_LENGTH data_len,
          void xmk_RAM_ptr  p_data
        #endif

        #ifdef XMK_USE_RECEIVER_PID_IN_SIGNAL
          xPID Receiver
        #endif

Return: -no-
```

This function is to be called when a signal is to be sent into the SDL system, e.g. within the users `xOutEnv()` function. It must be called with one more parameter than the `xmk_Send()` function, which is the first parameter `Env_ID`.

The macro internally uses some variables which are to be declared before the macro can be used. For example in the xOutEnv function the `XMK_SEND_TMP_VARS` macro must be introduced for declaring these variables.

The function is implemented as a macro in C.

xmk_Determine_Receiver

Parameters:

```
In/Out: xmk_T_PROCESS proc_type - process type ID
```

```
Return: xPID                        - process PID
```

This function is used in the context of SDL output in generated C code. The function determines if any instance with the given process type-ID is available to receive the signal. If no instance can be found, `xNULLPID` is returned.

Exported from mk_queu.c

xmk_InitQueue

Parameters:

```
In/Out: -no-
Return: -no-
```

This function initializes the signal queue. It must be called before any other Cmicro Kernel function, e.g. before `xmk_InitSDL()`. All relevant pointers are initialized. All signal-elements are put into the free-list. The SAVE-state of all signals is set to false.

xmk_FirstSignal

Parameters:

```
In/Out: -no-
Return: xmk_T_MESSAGE*
```

The first signal in the current queue which is the one with the highest priority, is copied to the pointer of the currently treated signal and returned to the caller.

The function returns a pointer to the first signal in the queue or `NULL`, if there are no signals in the queue.

xmk_NextSignal

Parameters:

```
In/Out: -no-
Return: xmk_T_MESSAGE*
```

The signal following the current signal is copied to the current signal. If there are no more signals, NULL is returned.

xmk_InsertSignal

Parameters:

```
In/Out: xmk_T_MESSAGE xmk_RAM_ptr p_Message
Return: -no-
```

This function puts a signal into the queue. The position depends on only the signal priority, if specified.

With the parameter `p_Message` a pointer to the signal which is to be inserted is given.

xmk_RemoveCurrentSignal

Parameters:

```
In/Out: -no-
Return: -no-
```

The signal which was currently processed is removed from the queue and inserted into the list of free signals.

xmk_RemoveSignalBySignalID

Parameters:

```
In/Out: xmk_T_SIGNAL SignalId
Return: -no-
```

This function is not used if timers with parameters are in the system (`XMK_USED_TIMER_WITH_PARAMS` macro is defined).

Signals of a given signal-code sent to the current process are removed from the queue and inserted in the list of free signals. The signal currently being processed must not be removed, as it is necessary for the current actions. It is only removed after processing is complete.

With the parameter `SignalID`, the signal ID of the signals which are to be removed for the currently active process instance is specified.

xmk_RemoveTimerWithParameter

Parameters:

```
In/Out: xmk_T_SIGNAL SignalId
In    : SDL_Integer  TimerParValue
Return: -no-
```

This function is only compiled if timers with parameters are in the system (`XMK_USED_TIMER_WITH_PARAMS` macro is defined).

This function has the same purpose as the above `xmk_RemoveSignalBySignalID` but, in addition, must look to the timer's parameter.

xmk_IsTimerInQueue

Parameters:

```
In/Out: xmk_T_SIGNAL TimerID
#ifdef XMK_USED_TIMER_WITH_PARAMS
In    : SDL_Integer  TimerParValue
#endif
Return: -no-
```

This function checks if the given timer is in the signal queue. If timers with parameters are used, the `TimerParValue`, which is conditionally compiled, is checked also.

xmk_RemoveSignalsByProcessID

Parameters:

```
In/Out: xPID ProcessID - PID of Process
Return: XMK_TRUE   - Signal removed
        XMK_FALSE  - no Signal removed
```

All signals addressed to a specific process are removed by calling this Function.

With the parameter `ProcessId`, the PID of the process for which all the signals are to be removed from the queue is specified.

xmk_AllocSignal

Parameters:

```
In/Out: -no-
Return: xmk_T_MESSAGE xmk_RAM_ptr
```

According to the principle chosen by the user (the user has to choose between `XMK_USE_STATIC_QUEUE_ONLY` and `XMK_USE_STATIC_AND_DYNAMIC_QUEUE`), and if possible, an initialized signal instance is returned. The signal instance is then either taken from the static memory pool or from the dynamic memory pool.

Allocation from the dynamic memory pool takes place by calling the `xAlloc` C function.

If `XMK_USE_STATIC_QUEUE_ONLY` is set, the `ErrorHandler` is called with the error "`ERR_N_NO_FREE_SIGNAL`". This indicates that no more memory is available to create one more signal instance, and the user may react appropriately in the `ErrorHandler` C function.

Otherwise, if `XMK_USE_STATIC_AND_DYNAMIC_QUEUE` is set, and if it is impossible to allocate one more instance from the predefined static memory pool, the `ErrorHandler` is called with the error "`ERR_N_NO_FREE_SIGNAL`". This indicates that dynamic memory allocation is started now, and the user may react appropriately in the `ErrorHandler` C function (for example, he might want to print out a warning message). If it is impossible to allocate one more signal from the dynamic memory pool, the `ErrorHandler` is called with the error "`ERR_N_NO_FREE_SIGNAL_DYN`". The user may then also decide what to do in the `ErrorHandler` C function.

A pointer to the signal that was allocated is returned usually, or `NULL`, if there is no space left to allocate one more signal.

xmk_FreeSignal

Parameters:

```
In/Out: xmk_T_MESSAGE xmk_RAM_ptr p_Message
Return: -no-
```

The given signal is de-allocated again.

If the signal was allocated from the static memory pool, it is returned to that pool by initializing it and inserting it into the free list at the first position.

Otherwise, if the signal was allocated from the dynamic memory pool, it will be returned to that pool (by calling the `xFree` C function).

The parameter `p_Message` must point to the signal that is to be initialized.

xmk_TestAndSetSaveState

Parameters:

```
In/Out: xmk_T_STATE State
Return: xmk_T_BOOL
```

This function checks whether a signal's SAVE-state is set or not. In testing, the SAVE-state is set to `TRUE` or `FALSE`.

With the parameter `State`, the value of the process' current state is to be specified.

The function returns with `XMK_TRUE`, if the given state equals the signal's SAVE-state, but returns with `XMK_FALSE` if the given state differs from the signal's save state.

xmk_QueueEmpty

Parameters:

```
In/Out: -no-
Return: -no-
```

This function tests whether there is at least one signal remaining in the queue(s) or not.

The function returns `XMK_TRUE`, if there are no signals in the queue, but returns `XMK_FALSE` if there is at least one signal in the queue. It does not matter if the signal is a saved signal or not.

When the Cmicro Kernel is configured for preemption, all the queues of the different priority levels are checked.

Exported from mk_tim1.c

xmk_InitTimer

Parameters:

```
In/Out: -no-
Return: -no-
```

All initialization of timers is performed within this function, which is called during SDL system start. It initializes some pointers and the free list of timers.

xmk_TimerSet

Parameters:

```
In/Out: xmk_T_TIME   time
        xmk_T_SIGNAL sid
#ifdef XMK_USED_TIMER_WITH_PARAMS
In    : SDL_Integer  TimerParValue
#endif
Return: -no-
```

This function activates an instance of a timer with the given “signal ID” value and the given time. If timers with parameters are used, the `TimerParValue`, which is conditionally compiled, is used also (the value is set to 0 outside this function call if it is not a timer with parameter).

Working principles:

- If a timer instance of this type is already running, this will be deactivated i.e. reset and then set.
- If no free timer is available, the `ErrorHandler()` is called.
- If all is satisfactory, a timer instance is created for the currently running process.

The first parameter `time` specifies the time at which the timer should expire. The call to SDL now is performed in generated C code.

The second parameter `sid` specifies the ID of the timer that is to be started.

If a timer instance of this type is already running, this will be deactivated. If no free timer is available, the ErrorHandler is called. After all these checks a timer instance is created for the currently running process.

xmk_TimerReset

Parameters:

```
In/Out: xmk_T_SIGNAL sid
#ifdef XMK_USED_TIMER_WITH_PARAMS
In    : SDL_Integer  TimerParValue
#endif
Return: -no-
```

This function resets the timer with the given “signal ID” value, if it is active and set by the currently running process. If an active timer instance is found, then the timer is inserted into the free-list. If timers with parameters are used, the `TimerParValue`, which is conditionally compiled, is used also (the value is set to 0 outside this function call if it is not a timer with parameter).

The parameter `sid` specifies the ID of the timer which is to be reset.

xmk_TimerActive

Parameters:

```
In/Out: xmk_T_SIGNAL sid
#ifdef XMK_USED_TIMER_WITH_PARAMS
In    : SDL_Integer  TimerParValue
#endif
Return: xmk_T_BOOL
```

This function checks if a timer with the given ’Signal-ID’ value is active in the current running process. If timers with parameters are used, the TimerParValue, which is conditionally compiled, is used also (the value is set to 0 outside this function call if it is not a timer with parameter).

The parameter `sid` specifies the ID of the timer which is to be checked if it is active.

The function returns with `XMK_TRUE` if the timer is active in the process that is currently running, it returns `XMK_FALSE` otherwise.

xmk_ChkTimer

Parameters:

```
In/Out: -no-
Return: -no-
```

The main intention of this function is to check, if any of the timers which are in the list of active timers is expired. There is a list of active timers in which the active timers are stored in the order of their expiry.

This means that the timer that expires first stands in front of the list.

If a timer was recognized as expired, a timer signal is sent to the owning process instance, the timer is removed from the list of active timers and restored into the list of free timers.

If there is no timer that can expire, the function returns immediately.

Another task for this function is to check if the global system time is overrun. If this case occurs, the `xmk_ChkTimer()` function will readjust the global system time (by calling `xmk_SetTime()` from `mk_cpu.c`) and will readjust all the timers in the active list.

xmk_ResetAllTimer

Parameters:

```
In/Out: xPID pid
Return: -no-
```

All active timers of the given process instance are reset. This will occur if a process instance stops.

With the `pid` parameter the process instance is addressed.

Exported from mk_stim.c

xmk_InitSystime

Parameters:

```
In/Out: -no-
Return: -no-
```

This function initializes the hardware timer and is to be filled out by the user.

xmk_DeinitSystime

Parameters:

```
In/Out: -no-
Return: -no-
```

This function de-initializes the hardware Timer and is to be filled out by the user.

xmk_SetTime

Parameters:

```
In/Out: xmk_T_TIME time
Return: -no-
```

This function sets the system time to the given value `time` and is to be filled out by the user.

xmk_NOW

Parameters:

```
In/Out: -no-
Return: xmk_T_TIME
```

This function is used by

- the Cmicro Kernel to calculate if a timer has expired and this is only the case if absolute time is used by the selected timer model.
- SDL applications to retrieve the current time

The current SDL system time is returned.

The function is to be filled out by the user.

Exported from ml_mem.c

xmk_MemInit

Parameters:

```
In/Out: char* _mem_begin
        char* _mem_end
Return: -no-
```

This function is to be called by the user, before dynamic memory management can be used. The user has to specify the beginning and the end of the area to be used for dynamic memory management. The function should be called before the first call to `xAlloc()`, e.g. as the first statement in the user's `main()` function.

xmk_Malloc

Parameters:

```
In/Out: unsigned long rsize
Return: void *
```

This function allocates one block of memory from the dynamic memory pool. It uses a first fit policy.

xmk_Calloc

Parameters:

```
In/Out: unsigned long RequestedSize
Return: void*
```

This function allocates one block of memory from the dynamic memory pool. It is the same as `xmk_Malloc()` but sets the allocated block to zero.

xmk_Free

Parameters:

```
In/Out: void *mem
Return: void
```

This function is the counterpart of `xmk_Malloc()`. A memory block is de-allocated again.

xmk_Memshrink

Parameters:

```
In/Out: void  *pMemBlock
        unsigned long NewSize
Return: -no-
```

This function is an extension of the compared with the standard of dynamic memory management supported by usual C compilers. It allows the user to shrink down a memory area which was previously requested with `xmk_Malloc()`.

memset

Parameters:

```
In/Out: char *p
        char val
        int length-
Return: -no-
```

This function is a template for the `memset()` implementation.

Caution!

Take care when the preemption policy is utilized.

memcpy

Parameters:

```
In/Out: char *dest
        char *source
        int length
Return: -no-
```

This function is a template for the `memcpy()` implementation.

Caution!

Take care when the preemption policy is utilized.

Exported from ml_mon.c

xmk_GetErrorClass

Parameters:

```
In/Out: xmk_T_ERR_NUM EightBitNumber
Return: int
```

This function returns the error class assigned to the given error number given by the caller. The error class can be one of `XMK_FATAL_CLASS` or `XMK_WARNING_CLASS`. This can be used to classify the predefined error and warning messages and to react properly if such a message occurs.

xmk_MonError

Parameters:

```
In/Out: FILE *fp
        int nr
Return: -no-
```

This function is used to evaluate an ASCII error text from an errornumber given by the caller. The first parameter `fp` must contain a pointer to a valid (i.e. file is opened) file descriptor, for example it could be `stdin`, `stdout`, or a file which was opened with `fopen`. The second parameter `nr` contains one of the possible error numbers defined in `ml_err.h`.

xmk_MonPID

Parameters:

```
In/Out: char *ostring
        xPID pid
Return: -no-
```

Used for test purposes, free use.

xmk_MonHexSingle

Parameters:

```
In/Out: char *p_text
        unsigned char *p_adress
        int length
Return: -no-
```

Used for test purposes, free use.

xmk_MonHex

Parameters:

```
In/Out: char *p_text
        unsigned char *p_adress
        int length
Return: -no-
```

Used for test purposes, free use.

xmk_MonHexAsc

Parameters:

```
In/Out: -no-
Return: -no-
```

Function for test purposes, free use.

xmk_MonConfig

Parameters:

```
In/Out: -no-
Return: -no-
```

Function for test purposes, free use.

Exported from mk_cpu.c

xmk_PutString

Parameters:

```
In/Out: char * Param1
Return: -no-
```

A template for how to print out a character string. The character string must be terminated with "`\0`".

The function must return immediately, i.e. may not be blocking on the output device. If the user does not care about this restriction, the correct function of other program parts cannot be guaranteed.

xmk_GetChar

Parameters:

```
In/Out: -no-
Return: int
```

This function checks if the user has pressed a key on the keyboard (unblocked). The function must return immediately, i.e. may not be blocking on the input device. If the user does not care about this restriction, the correct function of other program parts cannot be guaranteed.

xmk_printf

Parameters:

```
In/Out: char* format
        format string
        other parameters
Return: -no-
```

This function is called from any place in the Cmicro Library, Cmicro Kernel or generated C code, if the `printf` functionality is compiled with at least one of the `XMK_ADD_PRINTF*` defines.

The function must return immediately, i.e. may not be blocking on the output device. If the user does not care about this restriction, the correct function of other program parts cannot be guaranteed.

The function can be used for ANSI C compilers only, because optional argument lists are used like in the `printf` function of the standard C library.

The return value has no meaning and is introduced just for compatibility with `printf`.

xAlloc

Parameters:

```
In/Out: xptrint  Size
Return: void *
```

This function is called from any place in the Cmicro Library, Cmicro Kernel, SDL Target Tester or generated C code, if memory is to be allocated dynamically. The user may choose between the dynamic memory allocation functions from the C compiler or operating system or the dynamic memory allocation functions from Cmicro.

The return value points to the allocated buffer or is `NULL` if the operation was unsuccessful.

xFree

Parameters:

```
In/Out: void **
Return: -no-
```

This is the counterpart of `xAlloc()`. The function is called when a memory block that has been allocated with `xAlloc()` can be de-allocated again. The parameter is the address of the pointer to the allocated buffer.

Example 613 Using the `xFree` function ––––––––––––––––––––––

```
unsigned char *ptr;
ptr = xAlloc(100);
xFree (&ptr);      /* NOTE: Not xFree(ptr); */
```

––

Functions of the Expanded Cmicro Kernel

The expanded Cmicro Kernel offers additional functionality that is usually not necessary for target applications. Extended functionality is for example required by the SDL Target Tester, but may also be required from the user if it comes to target integration.

It is not absolutely necessary to have knowledge of these functions but knowledge of the functions proves useful when it comes to debugging and testing an application.

Functions for Internal Queue Handling

Exported from mk_queu.c

xmk_SaveSignalsOnly

Parameters:

```
In/Out: -no-
Return: xmk_T_BOOL
```

This function tests whether there only are SAVE signals contained in the queue. This can be used in integrations with operating systems.

The function returns `XMK_TRUE`, if there are SAVE signals only in the queue, otherwise it returns `XMK_FALSE`.

Exported from mk_tim1.c

xmk_NextTimerExpiry

Parameters:

```
In/Out: xmk_T_TIME * RemainingTime
Return: xmk_T_BOOL
```

This function looks for the remaining time of the timer that expires next. This is useful for operating system integration. If there is no active timer, the function returns `XMK_FALSE` and the returned parameter `RemainingTime` is set to 0.

If there is an active timer, the function returns with `XMK_TRUE` and the returned parameter `RemainingTime` contains the time at which the timer expires next. `XMK_TRUE` means there is a timer active and the remaining time is returned in the parameter. `XMK_FALSE` means that there is no timer active and returned parameter is set to 0.

Functions to get System Information

Exported from mk_sche.c

xmk_GetProcessState

Parameters:

```
In/Out  xPID pid
Return: xmk_T_STATE
```

The function evaluates the current SDL state of the SDL process `pid` with the given process PID and returns it to the caller. During the SDL system start-up, one possible return value might be `XSTARTUP`. This means that a process will be started during system start-up. During normal execution and system start-up, the return value `XDORMANT` may be returned. This means that an SDL process instance is either stopped or has never been created dynamically (created).

xmk_SetProcessState

Parameters:

```
In/Out: xPID pid,
        xmk_T_STATE state
Return: xmk_OPT_INT
```

The function sets the SDL-state of the process `pid` that is addressed with the first parameter to the given value `state` within the second parameter. Note, that the value is not checked, because Cmicro does not store any information about this in the generated transition tables.

xmk_GetProcessInstanceData

Parameters:

```
In/Out: xPID pid
Return: void *
```

The function returns the address of the process instance data of the given process-PID, or XNOTEXISTENT, if the pid is not existent.

xmk_QueryQueue

Parameters:

```
In/Out: xmk_T_CMD_QUERY_QUEUE_CNF * qinfo
Return: -no-
```

This function evaluates the current SDL-Queue-State and returns some information to the caller:

- information about the size of the Q (maximum amount of entries)

- information about traffic load, measured until now. (Users can directly use this to scale the queue. This information is valuable in the case, where the maximum traffic load is reached during execution.)
- Information about the number of entries that are currently in the queue.
- A pointer to the physical address of the queue.

Exported from mk_tim1.c

xmk_QueryTimer

Parameters:

```
In/Out: xmk_T_CMD_QUERY_TIMER_CNF *tinfo
Return: -no-
```

This function evaluates the current state of the SDL-Timer handling and returns it to the caller. The following information is contained in the C structure that is returned:

- Information about the size of the timer list entries.
- Information about traffic load, measured until now. (Users can directly use this to scale the timer list. This is valuable in the case, when the maximum traffic load is reached during execution)
- The current number of entries in the timer list.
- A pointer to the physical address of the timer list.

xmk_FirstTimer

Parameters:

```
In/Out: -no-
Return: xmk_T_TIMER *
```

The function returns a pointer to the first active timer. If there is no active timer in the queue, `NULL` will be returned.

xmk_NextTimer

Parameters:

```
In/Out: -no-
Return: xmk_T_TIMER *
```

The function returns a pointer to the next active timer in the list of active timers. If there is no or one active timer in the queue, `NULL` will be returned.

Exported from ml_mem.c

xmk_GetOccupiedMem

Parameters:

```
In/Out: -no-
Return: size_t
```

This function returns the currently occupied amount of memory from the pool. The pool size is defined with `XMK_MAX_MALLOC_SIZE`.

xmk_GetFreeMem

Parameters:

```
In/Out: -no-
Return: size_t
```

This function returns the amount of available memory from the pool. This means that it returns the difference between the size of the pool (`XMK_MAX_MALLOC_SIZE`) and the currently occupied memory.

xmk_CleanPool

Parameters:

```
In/Out: -no-
Return: int
```

This function reinitialize the memory pool to free memory leaks. The memory pool can only be cleaned if there are no allocated blocks left.

Alternative Function for sending to the Environment

Exported from mk_outp.c

xmk_EnvSend

Parameters:

```
In/Out:
        xmk_T_SIGNAL sig

        #ifdef XMK_USE_SIGNAL_PRIORITIES
          xmk_T_PRIO prio
        #endif

        #ifdef XMK_USED_SIGNAL_WITH_PARAMS
          xmk_T_MESS_LENGTH data_len
          void xmk_RAM_ptr  p_data
        #endif

        #ifdef XMK_USE_RECEIVER_PID_IN_SIGNAL
```

```
              xPID Receiver
            #endif

   Return: -no-
```

This function is an alternative to the standard function XMK_SEND_ENV for putting signals into the SDL system in external C code. The function is useful when signals are to be sent in interrupt service routines directly. If interrupt service routine is used and can result in signal sending the user need to manually define flag XMK_USE_INTERRUPT_SERVICE_ROUTINE to enable more critical paths in kernel. The function is shorter than XMK_SEND_ENV, but performs not so many error checks. It is especially not checked, if the receiver process ID exist. Usually there is also no call to functions which produce trace output because this would lead to problems in interrupt service routines. But for some error situations like either

- no free signal available
- no more memory available

the ErrorHandler() C function, which is to be implemented by the user, is called.

With the parameter sig, the signal ID is to be specified.

With the prio parameter, the signal's priority is to be specified (if conditionally compiled).

With the data_len, the number of bytes as the signal's parameters is to be specified. The number of bytes is evaluated by using a sizeof (C struct) construct. If the signal carries no parameters, this value must be set to 0 (if conditionally compiled).

With the p_data parameter, a pointer to the memory area containing the parameter bytes of the signal is given. The memory area is not treated as dynamically allocated within this function. Because the function copies the parameter bytes, the caller may use any temporary memory (for example memory allocated from the C stack by declaring a C variable). This parameter should be set to NULL if no parameter bytes are to be transferred (if conditionally compiled).

With the last parameter Receiver, the PID of the receiving process is to be specified (if conditionally compiled).

If XMK_USE_SIGNAL_PRIORITIES is not defined, the signal priorities which are specified with #PRIO in the diagrams is just ignored. The use of signal priorities is not recommended because the violation of SDL. A few bytes can be spared if signal priority is not used.

The XMK_USED_SIGNAL_WITH_PARAMS is automatically generated into the `sdl_cfg.h` file, from the Cmicro SDL to C Compiler. For tiny systems, if there are no SDL signals with parameters specified, this is undefined. It will reduce the amount of information which is to be transferred for each signal with a few bytes.

If XMK_USE_RECEIVER_PID_IN_SIGNAL is not defined, the user must implement the C function `xRouteSignal()` which is responsible to derive the receiver from the signal ID in that case. Using `xRouteSignal()` is recommended only if the last few bytes must be spared for transferring of signals.

Technical Details for Memory Estimations

Allocating Dynamic Memory

Introduction

This section shows when and how dynamic memory allocation is used in the Cmicro Package. It shows,

- how dynamic memory is allocated
- how to estimate the memory requirements for an application

The Cmicro Package uses a form of dynamic memory management for the following objects:

- processes
- signals
- timer
- some of the predefined sorts like charstring, ASN.1 sorts and generators

However, real dynamic memory management is used only in one case, namely for SDL signals, if a signal carries parameters with more than a few bytes.

This means that the Cmicro Kernel has its own memory management to handle processes, signals, and timers. This is done in such a way that each of these 3 objects are managed separately. For each of these 3 objects, a separate fixed memory area is reserved during compilation time, i.e. the area that handles processes cannot be reused to handle timers. This seems to be a restriction but in many micro controller applications users have to fix an upper limit of processes, signals and timers which can be handled in parallel during run time.

Processes

Processes are handled without dynamic memory allocation functions. The user has to specify an upper limit of process instances in the SDL diagram separately for each SDL process. For each process instance, there is a variable which is statically allocated.

Signals with and without Parameters

Cmicro signals are both ordinary SDL signals as well as timer signals. Where timers are implemented without parameters and can therefore be regarded as signals without parameters.

- No `malloc`/`free` for timers
- No `malloc`/`free` for signals without parameters
- No `malloc`/`free` for signals with parameters if less than or equal to `XMK_MSG_BORDER_LEN` bytes parameters are to be transferred.
- malloc and free are used for signals with parameters if more than `XMK_MSG_BORDER_LEN` bytes parameters are to be transferred.
- `XMK_MSG_BORDER_LEN` bytes is a macro defined in the manual configuration file `ml_mcf.h`. It can be set to any value, i.e. zero or the maximum number of signal parameters to be handled in the system.

Timers

For timers, no malloc and free functions are used. The Cmicro SDL to C Compiler evaluates the amount of timers in the system and generates a C constant, which is then used in the Cmicro Kernel to define an array for timers.

Chapter 66 The Cmicro Library

Chapter

67 *The SDL Target Tester*

The SDL Target Tester is a tool which can be used to find errors and illegal or unwanted behavior within a target system. It allows the programmer to follow and to reproduce the execution flow of the SDL system (running on the target) on the host.

The strength of the SDL Target Tester is the minimum amount of storage it occupies on the target. With the exception of certain traces, the SDL Target Tester's memory requirements do not increase proportionally with system size. That means, that the memory amount is a compiler specific constant. If the memory is scarce it is also possible to reduce the memory by reducing the functionality.

In order to use the SDL Target Tester, the system must be developed with the Cmicro SDL to C Compiler (see chapter 65, *The Cmicro SDL to C Compiler*) and the Cmicro Library (see chapter 66, *The Cmicro Library*).

The host and target systems can be connected by any type of communications link, as any kind of communications drivers can easily be connected to the SDL Target Tester system.

Introduction

The SDL Target Tester offers the following features:

- Tracing of internal and external SDL events with the Tracer
- Generating MSC Traces with the Tracer
- Trace of system errors
- Debugging facilities
- Profiling
- Open interface to connect other tools
- Scalable functionality
- Error reproduction using the Recorder

Note:

The SDL Target Tester's Record and Play functions are only available if a Cmicro Recorder license is available.

The SDL Target Tester will be executed in a distributed fashion, i.e. some parts of the SDL Target Tester run on a host machine, while other parts run together with the Cmicro Kernel and the SDL application on the target machine, for example a micro controller. A prerequisite is a communications link between the host and target systems.

The SDL Target Tester – An Overview

Prerequisites

The SDL Target Tester is an optional part of the Cmicro Package and is delivered when specifically ordered. It is an addition to the Cmicro Library and contains the following parts:

- the host tool chain (see "Using the SDL Target Tester's Host" on page 3610)
- the target library (see "The Target Library" on page 3676)

The SDL Target Tester's host executable is a tool chain which consists of the executables sdtmt, sdtmtui, sdtmpm and sdtgate and sockgate. The sdtgate module contains the V.24 and sockgate the TCP/IP implementation for connecting host and target. All open interface functionality is utilized here.

The target library is mandatory when the SDL Target Tester is ordered. It must be used together with the Cmicro Library on the target. By using the open interface, it is possible to connect user specific tools to the SDL Target Tester's target library.

This diagram gives an overview of the SDL Target Tester functionality:

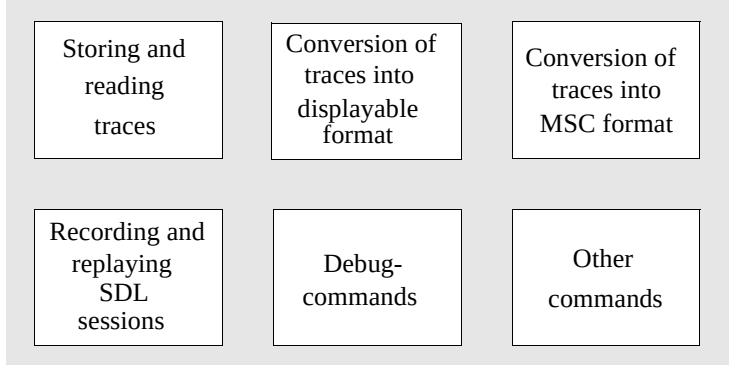

Figure 599: Functionality of the SDL Target Tester

The following components, as seen from the user's point of view, represent the SDL Target Tester:

- The Cmicro Tracer - trace of SDL and system events.
- The Cmicro Recorder - recording and replaying SDL sessions.
- The command and debug interface.

The Cmicro Tracer is introduced in the subsection "Following the Execution Flow – The Cmicro Tracer" on page 3604.

The Cmicro Recorder is introduced following the subsection "Reproduction of Errors – The Cmicro Recorder" on page 3606.

The command and debug interface is introduced in the subsection "Commands for the Host and Debugging Facilities" on page 3609.

The following subsections give an overview of how to use the SDL Target Tester. A detailed description of the necessary preparations and adaptations will be given in the sections itself.

- "Using the SDL Target Tester's Host" on page 3610"
- "Graphical User Interface" on page 3656
- "The Target Library" on page 3676
- "Connection of Host and Target" on page 3688
- "More Technical Descriptions" on page 3730.

These sections follow after the introduction subsections.

Following the Execution Flow – The Cmicro Tracer

General

The Cmicro Tracer transmits information about the execution flow of the SDL system on the target. Information traced includes the signals sent and received by processes and the SDL states and symbols entered in execution flow. A filter can be defined so that only partial trace information is created for particular process instances or for particular SDL constructs. The tracer can be connected with the MSC Editor on the host, thus allowing observation of dynamic signal trace between processes in the system or from the environment to the system on the target.

Tracing SDL Events

The following SDL events can be traced.

State	The SDL nextstate operation
Input	The SDL input operation
Save	The SDL save operation
Output	The SDL output operation
Create	The SDL create operation
Stop	The SDL stop operation
Static Create	Used at system start, appears for each statically created process
Dynamic Create	Used at start of a dynamically created process
Decision	Trace of SDL action decision
Task	Trace of SDL action task
Procedure	Trace of SDL procedure call
Set	Trace of SDL action: Set timer
Reset	Trace of SDL action: Reset timer
Signalparams	Used to switch on/off trace of signal parameters
Implicit consumption	Trace of SDL implicit transition
Discard	Trace of SDL discard

For each symbol in each process in the system the trace can be separately switched on or off.

Please consult the subsection "The API on Target" on page 3679 for information about how to set the different options.

Tracing Other Events

The following system events can be traced.

Schedule	Used to trace scheduling events.
Error	Used to trace System errors, which are detected either within the generated code, within the Cmicro Kernel or within the SDL Target Tester.
Showprio	Used to trace the event, when the scheduling changes to a different priority level.

Each system event can be separately switched on or off.

Please consult the subsection "The API on Target" on page 3679 for information about how to set the different options.

Display of Traces in the MSC Editor

By using the SDL Target Tester, it is possible to create Message Sequence Charts with the MSC Editor. Two modes are of special interest:

- Generating an MSC trace during an SDL session.
- Conversion of a binary file into the MSC format.

The first case, however, only makes sense if the host has enough time to handle and display all the traces created during the run-time of the SDL system. Alternatively there might be SDL systems which do not have these timing constraints. For example, the SDL system may wait until the MSC trace is completed.

The second possibility does not need that much processor power on the host site. In practice, this method is more useful.

The method with using the Cmicro Recorder is the one with the best real-time properties. In comparison to the trace, the Cmicro Recorder stores only a reduced subset of information in a compact format.

Reproduction of Errors – The Cmicro Recorder

Note:

The SDL Target Tester's Record and Play functions are only available if a Cmicro Recorder license is available.

General

Using the Cmicro Recorder, the user can “record” the actions taken within an SDL system running on the target and save these to a file on the host machine. This file can later be “played” in order to run the system through the same state changes, so that the same actions are performed. In this way error situations, perhaps recorded by a client or a developer at another location, can be reproduced. In the following, a general description is given. A more detailed description of the internal procedures can be found in the subsection ““Type and Amount of Stored Information” on page 3733”. The subsection ““General Restrictions on Record and Play” on page 3737”may also provide more information about how it works.

Recording an SDL Session

Use of the Cmicro Recorder makes sense whenever an SDL system is executed in real-time on the target in combination with a host.

The amount of information transferred via the communications link and stored into a file on the hard disk is kept small and compact, so that the real-time properties are not influenced. Only information is stored, which is necessary in order to replay an SDL session later. It is the communication of the environment to the SDL system, and the expiration of timers, which is recorded.

Caution!

The real-time properties, and correspondingly the behavior of the SDL system may be affected when recording. The user has to ensure that there is enough time to process the functions of the Cmicro Recorder, and to transfer all the information via the communications link. In general, it is a good idea to use a high performance communications link with a large transmit buffer and a host machine, which is able to handle all recorded events at any time during the SDL execution.

It is not possible to receive information about the inner events of the recorded SDL system, by using the recorder only. The purpose of the Cmicro Recorder has nothing to do with the purpose of the Cmicro Tracer. The user also has to use the Cmicro Tracer if he wants to get information about internal events. Additional information is then transmitted via the communications link and stored into a file which can be

displayed dynamically or later on. The performance of the communications link dictates whether real-time trace is possible. The more information traced via the link, the higher the performance should be.

The record mode must be switched on within the target (by using the C function interface on target), and on the host - see subsection "Record a Session" on page 3626).

Re-Playing an SDL Session

After producing a file with the record mode, the file can be replayed in order to run the SDL system in the same order through the same system states.

When the end of file is reached which is indicated with <Play mode off> to the target, the SDL system is able to react on ordinary environment signals coming from the real environment (if programmed by the user).

The play mode must be switched on within the target by using the SDL Target Tester Command Recorder-Play. No environment signals may be handled by the user in the C function `xInEnv` during the play.

Reaching the Erroneous System State

Sometimes, when a file is replayed, the erroneous situation can directly be viewed at another device, i.e. if the SDL system runs in an emulator with breakpoints set, or if there is, for instance, an LC display connected to the SDL environment.

In this case, it is not necessary to compare output files. In other cases, it might be of interest to do so as described later.

Comparing the Results

A comparison of two executions is possible, when two files containing the same type and amount of information are compared.

The procedure goes as follows:

- Change the format from binary into ASCII for both files (command "Convert-File" on page 3635).
- Use UNIX diff or an ASCII editor with options in order to evaluate the differences.

Commands for the Host and Debugging Facilities

The command interface and the debugging facilities are very helpful in finding errors produced within the target.

For instance, after an SDL interpretation error has occurred, it is possible to suspend the SDL system and to inspect the global state by viewing the signal queue(s). After the queue size has been re-dimensioned, the queue can be inspected again on the host site during a target execution.

There are several commands to check that timers are correctly processed.

The ability to set breakpoints during real-time execution and to execute a single step also helps to find an error situation.

The amount of trace information can dynamically be defined via commands. A differentiation is made between the information on the communications link and the information displayed.

Using the SDL Target Tester's Host

Introduction

The SDL Target Tester on host site is a tool chain consisting of the parts: GUI (sdtmtui), the logical part (sdtmt), the communications link gateway (sdtgate or sockgate) and the glue between these components the Cmicro Postmaster (sdtmpm). Sometimes, e.g. when the SDL Target Tester uses the MSC Editor, a further tool is executed called Cmicro Link (sdtmlnk).

The SDL Target Tester's host site is the tool, which allows communication with the target via a communications interface (see "The Communications Link's Host Site" on page 3718) to read or write to files (sdtmt), display information on the screen (sdtmtui) and/or the MSC Editor. It allows tracing of SDL and system events and has the ability to record and replay events to reproduce error situations.

Host features:

- Trace of SDL and system events
- Symbols and processes can be selected and filtered in order to reduce the amount of information
- Record and replay of SDL executions (error reproduction)
- Execution trace into file, to screen and to MSC Editor
- Files can be read in later and displayed either on screen or on the MSC Editor
- Small SDL Debugger

It is important to know that the host works independently from the target. The communication between both is built up automatically by the host if you start to communicate with the target. Thus, the host part of the SDL Target Tester remains the same executable when changing the target hardware! Only some adaptations in the configuration file `sdtmt.opt` have to be made, see "Preparing the Host to Target Communication" on page 3614.

The graphical user interface is described in "Graphical User Interface" on page 3656.

Different Ways of Using the SDL Target Tester

The standard method for using the SDL Target Tester is to connect a host with a target machine. A communications link implemented by the user must exist between host and target. The target can be seen as a remote system, where the SDL Target Tester running on the host machine can be considered a controlling unit. This is described in Figure 600.

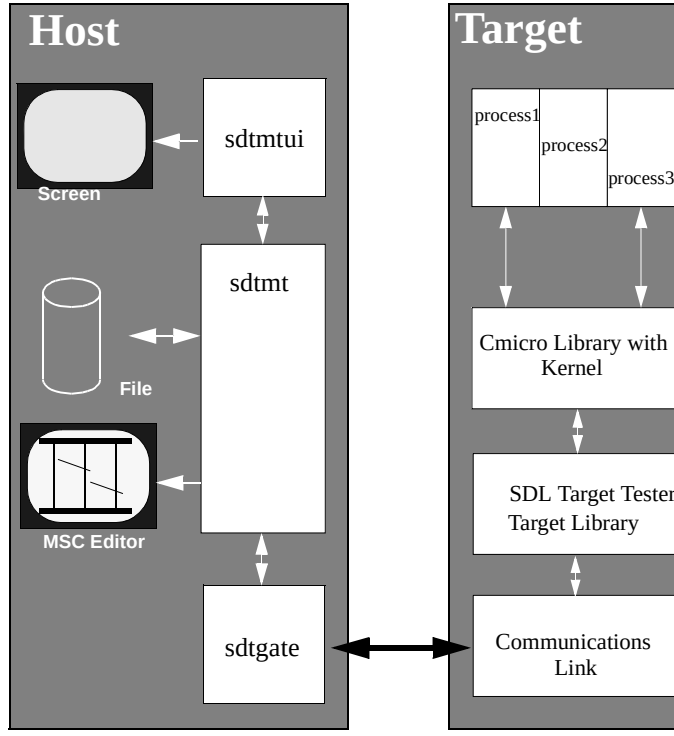

Figure 600: SDL Target Tester used for target control

The second way to use the SDL Target Tester is as a front-end for a host simulation. Therefore, a host simulation for the SDL System is built with the Targeting Expert. As described in Figure 601 the Gateway used for connection to the target is replaced by the host simulation.

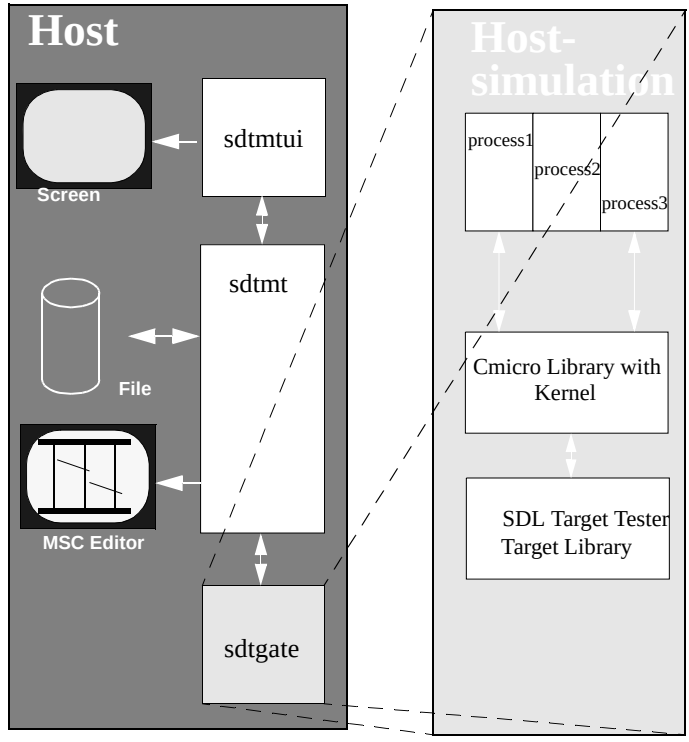

Figure 601: SDL Target Tester used for host simulation

Another way to use the host software is to use it purely as a conversion tool. This is of interest if a binary file has been written during earlier sessions with the target. The following picture shows the SDL Target Tester as a conversion tool:

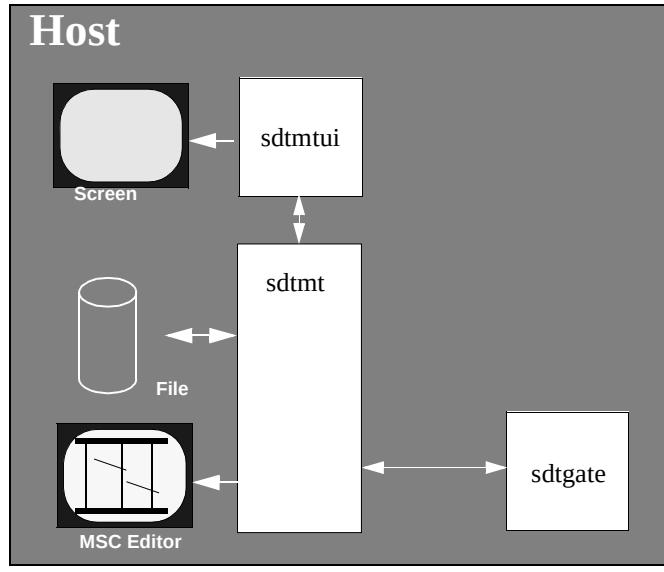

Figure 602: Sdtmt used for file conversion

Furthermore, by using the commands Output-NPAR and Output-PAR the SDL environment of the target or host simulation can be simulated with the host site.

Preparing the Host to Target Communication

After implementing the parts in the target, which are necessary to have a communication between host and target, the appropriate device on the host site is to be selected. This can be done in the file named

`sdtmt.opt`.

The Targeting Expert should be used to generate or modify `sdtmt.opt` (see "Configure the Host (Cmicro only)" on page 2948 in chapter 59, *The Targeting Expert*).

The Default Communications Link of Sdtmt

There is a V.24 interface implementation to transfer data between target and host. This is delivered as an additional executable called `sdtgate`.

The sdtgate default implementation uses the following protocol:

- XON/XOFF protocol possible
- 8 Bit data
- One start bit
- One stop bit
- No parity
- All data is transmitted as binary.
- Control characters are masked and de-masked.
- Binary protocol: Cmicro Protocol.

There is also a socket interface implementation to transfer data between target and host. This is delivered as an additional executable called `sockgate`.

The sockgate default implementation uses the following protocol:

- All data is transmitted as binary.
- Control characters are masked and de-masked.
- Binary protocol: Cmicro Protocol.

Communication Setup on the Host System

If sdtmt is invoked, it searches for the configuration file `sdtmt.opt`. This file is mandatory!

Each line beginning with a '#' is treated as a comment.

It contains information on target options such as:

- Target timer's scale and unit.
  These entries affect only the text trace.
- Target data types' endian, alignment and size

> **Caution!**
>
> The file needs to be updated if another target system is connected, or if you change from a host simulation to your real target.

The file `sdtmt.opt` should have the following entries in order to configure the communications link:

- USE_GATE:

  The path and the name of the used gate executable has to be specified here. In the delivered version of the SDL Target Tester, two executables called sdtgate and sockgate are included. They handle the V.24 and the socket interface on the host system.
  In case of a host simulation, the name of the executable which contains the simulated SDL system is inserted instead of the gateway.

- GATE_CHAR_PARAM_, GATE_INT_PARAM_

  When the gate is forked by sdtmt these values are handed over to the gateway to configure the interface.

  – V.24

    Select the device: `GATE_CHAR_PARAM_1 <devicename>`

    On UNIX `<devicename>` might be `/dev/ttya` or `/dev/ttyb` (Please ask your system administrator).

    In Windows `<devicename>` might be `COM1` or `COM2`

    Select the appropriate baud rate: `GATE_INT_PARAM_1 19200`

All other GATE_. . . entries are not used with V.24 implementation.

– Socket

Select the device: GATE_CHAR_PARAM_1 <IP-address>

<IP-address> has to be given in the standard format 192.168.1.4 or localhost.

Select the socket port number: GATE_INT_PARAM_1 12345

All other GATE_. . . entries are not used with Socket implementation.

- UNIT-NAME, UNIT-SCALE

  The target's timer scale is multiplied with the value of UNIT-SCALE and displayed in units UNIT_NAME in the SDL Target Tester. The default values are "sec" and "1".

- USE_AUTO_MCOD

  Switch on or of the use of the automatic message coder configuration on the host. Valid values are "yes" and "no".

  If the value is "no" you have to use the values described in the following to configure the message coder.

  If the value is "yes" the message coder will be configured by the target itself. Therefore it sends its configuration in a message at start-up.The following values will be ignored in that case.

Note:

The target has to be compiled with the flag XMK_USE_AUTO_MCOD defined

- LENGTH_

  The length (in octets) of the C basic types within the target must be given here. See the compiler manual for further information (header file limits.h).

- ALIGN_

  The alignment for each C basic type must be given here.

  Alignment is the distance (counted in bits) from the first bit of a character to the named basic type. The Character is stored at an address dividable by four. See Figure 603.

  Allowed values are 8, 16, 32

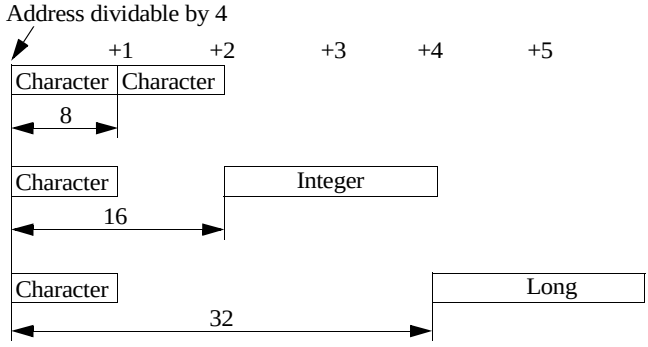

Figure 603: Target's alignment types

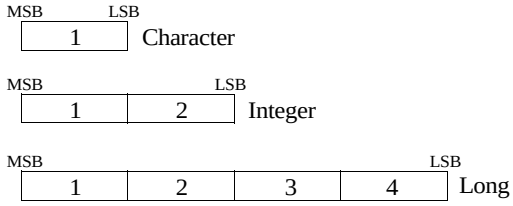
- ENDIAN_

  The order of the C basic types within the target's memory must be given here. See the microcontroller data sheets and Figure 604 to get further information.

  Allowed values are: 1, 12, 21, 14, 41, 23, 32, 18, 81

The octets of some C basic types are numbered as follows:



According to the type sizes above, the following Endians are possible within the target's memory:

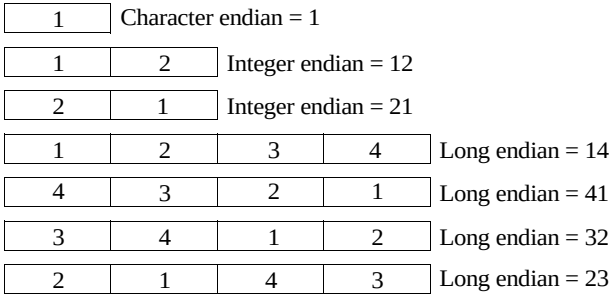


Figure 604: Definitions of the target's endian

Example 614: sdtmt.opt ––––––––––––––––––––––––––––––––––––

```
USE_GATE      $(sdtdir)/sdtgate   (on UNIX)
USE_GATE      $(sdtdir)\sdtgate.exe (in Windows)
GATE_CHAR_PARAM_1     COM2
GATE_CHAR_PARAM_2     0
GATE_CHAR_PARAM_3     0
GATE_INT_PARAM_1      9600
GATE_INT_PARAM_2      0
GATE_INT_PARAM_3      0

UNIT-NAME             sec
UNIT-SCALE            0.001

USE_AUTO_MCOD         no

LENGTH_CHAR           1
LENGTH_SHORT          2
LENGTH_INT            4
LENGTH_LONG           4
LENGTH_POINTER        4
LENGTH_FLOAT          4
LENGTH_DOUBLE         8
ALIGN_CHAR            8
```

```
ALIGN_SHORT          16
ALIGN_INT            32
ALIGN_LONG           32
ALIGN_POINTER        32
ALIGN_FLOAT          32
ALIGN_DOUBLE         32
ENDIAN_CHAR           1
ENDIAN_SHORT         12
ENDIAN_INT           14
ENDIAN_LONG          14
ENDIAN_POINTER       14
ENDIAN_FLOAT         14
ENDIAN_DOUBLE        18
```

Invoking the SDL Target Tester's Host

Command Line Options of the SDL Target Tester

Option	Description
`-h`	Show a short help on the command line options.
`-v`	Show the version of the SDL Target Tester without opening it.
`-t <targetdir>`	Change the working directory to <targetdir>.

Invocation from the Organizer

There are two ways to invoke the SDL Target Tester from the Organizer with the actual project.
First you can use the menu *Tools > SDL >Target Tester UI*.
The other way is to add the following lines into the file `org-menus.ini`. For more information, see *chapter 11, The Public Interface*.

```
[MENU]
Name=&Cmicro
[MENUITEM]
ItemName=&Tester
Separator=0
StatusbarText=Start Target Tester
ProprietaryKey=1
AttributeKey=0
Scope=ALWAYS
ConfirmText=
ActionInterpretation=OS_COMMAND
BlockCommand=0
FormattedCommand=sdtmtui -t%v
```

Note:

Since code generation and compilation for Cmicro is only possible with the Targeting Expert, and the Organizer does not know about the directory where the Targeting Expert generates all files, you will be prompted automatically to enter the right directory.

In host simulation mode, internally, the -s flag is used additionally. The output of the Tester then contains some more helpful information that cannot be given in target debug mode.

Invocation from the Command Line or Desktop

Before using the SDL Target Tester described in the sections below, it is assumed, that a communications link between host and target exists (see "Connection of Host and Target" on page 3688), that the target executable has included the SDL Target Tester and that the trace is switched on within the target.

Several files have to be read from the user's current working directory.

On UNIX, the SDL Target Tester's host simply needs to be started from the working (project) directory.

1. Change the current directory to the project directory (assuming that this directory is `~/cmicro_project`).
   `cd ~/cmicro_project`
2. Now, type
   `sdtmtui`

Note:

If the command `sdtmtui` is not found, the `$path` variable needs to be set up correctly. The user should ask his system administrator or the person that is responsible for the SDL Suite environment.

In Windows it is recommended that you create a new shortcut to the SDL Target Tester in the Window's Start menu or on the desktop. The shortcut must contain the following entries in its properties sheet:

- Target:
  `<instdir>\bin\wini386\sdtmtui.exe -t<targetdirectory> -`

- Entry Start in:
  `<instdir>\bin\wini386\`

Note:

The user should ask his system administrator about adding new links to the Start menu or the desktop.

The SDL Target Tester's host site is started when you double-click the SDL Target Tester icon.

The SDL Target Tester's host tool chain responds by showing the SDL Target Tester window:

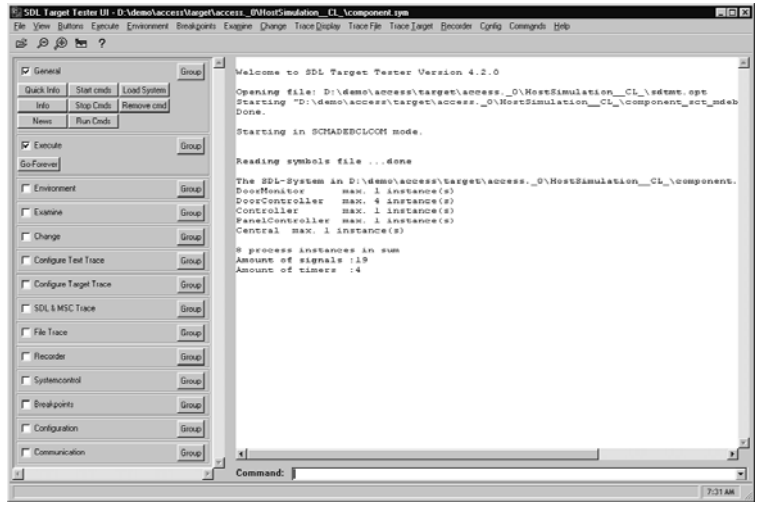

Figure 605: SDL Target Tester window

In the text area of the UI the following is displayed at startup:

```
Welcome to SDL Target Tester Version 6.3.0

Opening file: D:\...\sdtmt.opt
Starting "D:\...\component_sct_mdebcom.exe" ...
Done.

Starting in SCMADEBCOM mode.
```

```
Reading symbols file ...done

The SDL-System in D:\...\component.sym contains these processes:
DoorMonitor max. 1 instance(s)
DoorController max. 4 instance(s)
Controller max. 1 instance(s)
PanelController max. 1 instance(s)
Central  max. 1 instance(s)

8 process instances in sum
Amount of signals :19
Amount of timers  :4
```

After the target is reset its whole configuration is shown:

Example 615: Target's Start-up / Configuration Message ----------

```
The current target configuration is:

Compiled Cmicro KERNEL Features:
  Preemption is                          not active
  Signal Priorities are                  used
  Receiver PId in signals are            used
  Sender PId in signals are              used
  Sending Signals the simple way is      not used
  Pid addressing is                      possible
  SDL System Stop can                    not be used
  Additional errorchecks are switched    ON
  Timer handling is                      implemented
  Timers with parameters are             not used
  Dynamic create is                      implemented
  Save is                                not implemented
  Dynamic stop is                        not implemented
  Only single instance processes         NO

Compiled SDL Target Tester Features:
  Host commands can                      be used
  Profiling can                          be used
  Debugging can                          be used
  Trace is                               implemented
  Signalfilter can                       be set
  Time stamps are                        implemented
  Recorder can                           not be used
  Realtime play can                      not be used
  Trace is currently switched            ON
  Auto MessageCoder is                   ON

Selected TARGET Modes:
  Recorder is currently switched         OFF
  Player is currently switched           OFF

Message Coder configuration: (size in octetts)
-------------------------------------------------------
  SDL process ID's (xPID)               :  4
  SDL state ID's   (xmk_T_STATE)        :  1
  SDL signal ID's  (xmk_T_SIGNAL)       :  1
  SDL time values  (xmk_T_TIME)         :  4
  Message length  (xmk_T_MESS_LENGTH )  :  1
-------------------------------------------------------

SDL Data Type sizes (octetts):
-------------------------------------------------------
  Boolean    :  1 | Bit        :  1 | Character  :  1
  Charstring :Ptr | Integer    :  4 | Natural    :  4
  Real       :  8 | PId        :  4 | Duration   :  4
  Time       :  4 | Null       :  4 | Octet      :  1
  Octetstring: 12 | ObjId      : 16
-------------------------------------------------------

  Target was generated at: Mon Jan 01 12:00:00 2001

SDL System ready for configuration.

Start with "Go-Forever".
```

Note:

Within the target's configuration message the timestamp (seconds since the 1st of January 1970) of the generated C file is sent to the host, too.

If this timestamp is not equal to the one in the symbols file (`.sym`) a message box is displayed giving hints as to what has to be done.

Getting a Target Trace

After the start-up message is received the target is ready to be traced.

The command `Go-Forever` starts the SDL system in the target and the static create trace messages will be sent.

When a process instance executes actions within a transition, trace information describing the different actions is either printed on the screen, on the MSC Editor or written into a file specified by the user. The amount of information printed can be selected using the trace commands in the monitor system. All trace information is self explanatory. This trace example was created from the AccessControl:

Example 616: Trace for the AccessControl ––––––––––––––––––––

```
*** STATIC CREATE
*     PId       : DoorMonitor:0
*   TASK  LastOffspring :=
*** NEXTSTATE Idle

*** STATIC CREATE
*     PId       : Controller:0
*   TASK  NextDoor :=
*   OUTPUT of  Allocate to DoorMonitor:0
*     Prio      : 100
*     Now       : 0.000000 sec
*     Param(s)  : 1
*   SET  MyTimer
*     Time      : 10.000000 sec
*     Value     : 0
*** NEXTSTATE WaitAllocated

*** STATIC CREATE
*     PId       : PanelController:0
*   OUTPUT of  Display to ENVIRONMENT
*     Prio      : 100
*     Now       : 0.000000 sec
*     Param(s)  : 1
*** NEXTSTATE Idle
```

```
*** STATIC CREATE
*     PId      : Central:0
*   TASK  NextFree :=
*** NEXTSTATE Idle
```

Debugging – A Few Guidelines

The following few guidelines may help to understand the different possibilities when searching for a specific command.

Breakpoints

A lot of error situations may occur when the system is downloaded for the first time. Possibly the basic functions needed to allow the SDL system to run the target do not work. Possibly the compiler adaptations are wrong. The initialization of the environment may be incomplete. The compiler may generate faulty object code. The memory of the target may be exceeded, i.e. either variables, constants, program code, stack or dynamic allocated memory. Also, real-time requirements may not be fulfilled.

Breakpoints can greatly help to discover such situations. The breakpoint logic is especially useful as it has only a negligible impact on the systems real-time performance.

Setting Breakpoints

Does a specific process instance (pid) receive a specific signal?

```
BPI processname nr signalname
```

Does a specific process instance (pid) go into a specific state (does it end any transition, which leads to that state)?

```
BPS processname nr statename
```

Trace Scaling

The target's trace can be scaled. Sometimes it is necessary to omit trace altogether.

This may be necessary to reduce the amount of trace messages via the communications link, but can also be used to expand the view of some details.

Switch off the trace of signal parameters

```
Tr-Params 0
```

or switch it on again.

```
Tr-Params 1
```

The main interest may be lay on the work of one special process. This process can be explicitly defined with

```
Tr-Process processname nr
```

The trace for all other processes will be switched off.

Corresponding to this command the scope view can be set to a specific signal

```
Tr-Signal signalname
```

If the trace of the whole SDL system should be reduced, e.g. the trace of TASKs and DECISIONs is of no interest

```
Tr-Detail 4
```

switches the trace of these symbols off.

The command Tr-Detail can be used with five levels, for further information see "Tr-Detail" on page 3652.

Record a Session

> **Note:**
>
> The SDL Target Tester's Record and Play functions are only available if a Cmicro Recorder license is available.

See "Invoking the SDL Target Tester's Host" on page 3619 to start-up the SDL Target Tester. When the target's start-up message is displayed in the text area, the target must be configured to record a session, i.e. the Recorder must be switched on in the target.

If the user wants to replay a recorded session in real-time mode he must be sure that the target executable is compiled with signals including time stamps (see "XMK_USE_SIGNAL_TIME_STAMP" on page 3508).

The user has to do several things

1. Open an output file by using the command
   `Output-File filename`
2. Switch the Cmicro Recorder on by using
   `Recorder-On`
3. Start the SDL system with
   `Go-Forever`

As with a standard trace the target's messages are displayed in the text area. The user can now use the target as if the SDL Target Tester is not involved. All traces and recorded messages are stored into the output file.

4. To end the session the Cmicro Recorder should be stopped:
   Recorder-Off
5. And the output file has to be closed:
   Close-File

Re-Play a Recorded Session

Before replaying a session it is required to record a session by following the steps listed in "Record a Session" on page 3626.

First the target has to be reset. The start-up message reappears.

Now the user can start the replay with the commands

1. `Input-File filename`
   where `filename` is the name of the file written during a recording session (this file must contain Cmicro Tracer messages as well as Cmicro Recorder information).
2. Switch the play mode on:
   `Recorder-Play`
3. If desired switch the real-time play mode on:
   `Recorder-Realtime`
   Remember: the target has to be compiled using this feature.
4. Start the target:
   `Go-Forever`

The target now starts by tracing the static creates and in accordance with the design of the SDL system the first transitions are executed and traced.

Now the SDL Target Tester's host inserts all the signals coming from the environment so that the recorded session will be replayed in the same order.

Note:

The real environment is not being polled during the replay session.

Restrictions of the SDL Target Tester

The SDL Target Tester has a few restrictions:

- Only values of the following SDL data types are displayed in readable form: Bit, Boolean, Char, Charstring, Integer, Natural, Octet, Real, PId, Duration and Time.
  Syntypes, Structures, Enumeration Types and Arrays which contain only SDL-data types can be decoded correctly.
- Complex data types, e.g. Array of Structures indexed by syntype may be decoded wrong due to alignment.
- If the SDL Target Tester encounters a unknown data type, decoding is interrupted. The first unknown data type is printed to the screen and the rest of the parameters is displayed as a hexadecimal buffer.
- Record and play mode may not be entered together.
- During the play mode only certain commands are allowed. The available commands are marked with an asterisk.
- Any SDL sort that is implemented as pointer in C (like Charstring, Object_Identifier, Ref, Own, etc.), cannot be handled in trace, record or play mode. This comes as a result of the implementation of trace (explained in chapter 66, *The Cmicro Library*). The trace does not distinguish if there is a buffer containing a pointer to be traced or not, because there is no symbol information generated into the target system for efficiency.

SDL Target Tester Commands

Syntax of SDL Target Tester Commands

Command Names

Command names are entered character by character on the keyboard. Each command consists of ASCII characters, terminated by a carriage return. A command is interpreted, after the carriage return is given. Commands may have parameters. Command names may be abbreviated by giving sufficient characters to distinguish it from other command names. The command names are interpreted from left to right. There is no distinction between upper and lower case letters.

Consider, as an example, the command ?Breaklist. The command may be entered as “?b”. However, if only ‘?’ is typed, sdtmt will respond with the error message:

```
Command was ambigous, choose one from:
< list of commands >
```

since the command cannot be distinguished from, for example, the ?Queue command. As additional information a list of all commands which would fit to the entered command and which are allowed in the current context is given.

Command Parameters

A parameter is separated from the command name by one or more spaces. The same is applicable to the separation of two parameters. There is no distinction between upper and lower case letters.

Each parameter is mandatory from a syntactical point of view and must be specified. No parameters may be left out.

If the parameter list following a command name is not complete, a dialog window is opened to enter the missing parameter(s).

Specifying more parameters than the command can handle, sdtmt prompts

```
**ERR:Extra parameters specified in command.
```

If the type of any parameter, which was entered, does not match the expected one, then sdtmt responds with an appropriate error message according to the expected type. Type

```
help commandname
```

or refer to the manual.

Abbreviation of SDL Names

Command parameters that are SDL names, may also be abbreviated, as long as the abbreviation is unique. If a name is equal to the first part of another name, as for example Wait and Wait_For_Me, then any abbreviation of Wait is ambiguous. However, if all characters of the shorter name are given (Wait in this example), this is considered as an exact match and the short name will be selected.

Errors in Commands

If an error is detected in a command name or in one of its parameters, an appropriate, self explanatory error message is displayed on the screen. The command will be ignored.

Input and Output of Data Types

<Processtype Instance>

Process type is an ASCII string identifying the SDL name of the process. Process names must be unique for all processes within the system. It is also possible to use the decimal value of the process type. The decimal value can be found by looking into the symbol file, which is also automatically generated.

The separator for process type and instance is a blank.

Instance

The value of the instance number is a decimal value beginning from 0 for the first instance of a process type. If the SDL System contains only (x, 1) declarations on SDL level, then the user has to specify “0” in any case.

Note:

There is a difference between the notation in the simulator and in the SDL Target Tester concerning instance numbering. The simulator always uses the value one as the first instance number whereas the SDL Target Tester begins numbering these at zero!

Caution!

If no symbol file was specified, then neither process type nor instance is checked within sdtmt! If the target is compiled without error checks, that might lead to a fatal error in the target system.

Symbols

Symbols are read in from a file called `<systemname>.sym`. There are a lot of error checks within the SDL Target Tester's host site which only work if a symbol file has been loaded.

Help

SDL Target Tester gives the user some quick help when entering:

```
help
```

A complete list of commands will be displayed on the screen. Commands, which are available in the current mode, are marked with an asterisk. If a command is entered which is not available in the current context the SDL Target Tester responds with:

```
Sorry. The current mode of sdtmt does not allow you
to enter that command.
The command has been ignored.
```

To get a short explanation, type:

```
help <commandname>
```

for instance type:

```
help help
```

To get a complete list of commands, type:

```
help *
```

Most of the commands marked with the type “Remote” can only be executed (in the target) if the flag XMK_ADD_MICRO_COMMAND is defined in the file `ml_mcf.h`. See “Manual Scaling” on page 3486.

??

Parameters:

```
(None)
```

Type: Local

Open a dialog with a list of all allowed commands. By pressing the OK-Button the selected command is copied to the Input line.

Active-Timer

Parameters:

```
<Processtype Instance> <Timername> <Timerparameter>
```

Type: Remote

Check, if a specific timer is set by a process, and has not been expired.

> **Note:**
>
> The input of a timer parameter is mandatory. The type of the parameter has to be an integer value. For a timer without parameter enter a 0 in the parameter dialog.

?All-Processes

Parameters:

```
(None)
```

Type: Remote

> **Note:**
>
> This command is obsolete. Use ?Process-State * * instead.

BA

Parameters:

```
(None)
```

Type: Remote

This command requests to clear all the breakpoints in the break list.

BC

Parameters:

```
<breakpoint number>
```

Type: Remote

This command requests to clear the given breakpoint number from the breakpoint list. The breakpoint number depends on the total number of defined breakpoints.

BP

Parameters:

```
<Processtype Instance> <SignalName> <StateName>
```

Type: Remote

This command sets a breakpoint on the input and the state of a process. Execution is halted only if the given input in the given state is detected.

No parameter is optional. These combinations are allowed:

```
processname nr * statename     ->Use command BPS
processname nr signalname *    ->Use command BPI
processname nr * *
processname nr signalname statename
```

BPI

Parameters:

```
<Processtype Instance> <SignalName>
```

Type: Remote

This command sets a breakpoint on the input of a given process. Execution is halted on any input of the signal in this process.

It is not mandatory to provide a parameter. These combinations are allowed:

```
processname nr *
processname nr signalname
processname *
processname signalname
```

BPS

Parameters:

```
<Processtype Instance> <StateName>
```

Type: Remote

This command sets a breakpoint on the state of a given process. Execution is halted if the given state is reached.

No parameter is optional. These combinations are allowed:

```
processname nr statename
processname *
processname statename
processname nr *
```

?Breaklist

Parameters:

```
(None)
```

Type: Remote

This command requests the current breaklist from the target and displays it on the screen as it was entered. If a symbol file has been specified during the invocation of sdtmt, then process IDs, signal IDs and state IDs are displayed with their symbolic value.

Change-Directory

Parameters:

```
<directoryname>
```

Type: Local

The working directory of the current SDL Target Tester session is switched to `<directoryname>`.

Close-File

Parameters:

```
<filename>
```

Type: Local

The current output/input file (including binary trace) with the name `<filename>` will be closed when using this command. (See “Output-File” on page 3640 and “Input-File” on page 3639)

?Coder

Parameters:

```
(None)
```

Type: Local

After invoking this command the current settings of the Target Message Coder TMCOD are display in the text area. The settings given here have to be previously made in the configuration file `sdtmt.opt` or have been sent by the target itself. See "Preparing the Host to Target Communication" on page 3614.

Continue

Parameters:

```
(None)
```

Type: Remote

This command can be used to continue processing, i.e. after a breakpoint was h. Notification is given when the command cannot be processed within the target system.

Convert-File

Parameters:

```
<input filename> <output filename>
```

Type: Local

This command converts the trace messages of the target (stored in the `<input filename>`) into readable ASCII trace. This ASCII trace is stored into the `<output filename>`.

Create

Parameters:

```
<Parent-Processtype Instance> <Child-Processtype>
```

Type: Remote

This command creates an SDL process of the given type `<Child-Processtype>`. The creating process must be specified in `<Parent-Processtype Instance>`. If there is a free process instance, which is currently dormant, it will be created and the start transition will be executed. This can be seen in the trace.

If the system is under a break condition, the command will be ignored as it is not possible to send signals (dynamic creation uses signal mechanism).

> **Note:**
>
> Please specify the `<Parent-Processtype Instance>` according to the SDL system. There is no check if the parent is specified correctly from the semantic point of view.

Disable-Timer

Parameters:

`(None)`

Type: Remote

This command disables the processing of timers.

The command affects the SDL timers only! However, timers which are already expired and are in the queue will be input as normal. Keep in mind that the disabling of timers changes the system behavior.

Display-Off

Parameters:

`(None)`

Type: Local

The ASCII trace into the text area is switched off.

Display-On

Parameters:

`(None)`

Type: Local

The ASCII trace into the text area is switched on.

Enable-Timer

Parameters:

`(None)`

Type: Remote

This command enables the processing of timers again, if it was previously disabled with the command Disable-Timer. Due to the fact that time (and so the system time) cannot be stopped, it might happen that

all the timers set earlier may expire at the same time this command is entered. This may cause illegal system behavior, i.e. a queue overflow and the call of the ErrorHandler or another illegal behavior.

?Errors

Parameters:

`<const>`

Type: Remote

Query last occurred error. The target system traces the last error within the SDL execution and stores it. The result will be displayed on the screen, both as a decimal value and as ASCII text with an explanation of the error situation.

If the value `<const>` is not equal to zero, further information about the error is given from this manual (the on-line Help Viewer is started).

Especially, when the SDL system is executed for the first time in a new hardware environment, the command may help in finding problems. It is also useful after a long execution of the SDL system, as any error situation arising may be detected. All the errors, warnings and information, which are handled by the ErrorHandler are explained in the section "User Defined Actions for System Errors – the ErrorHandler" on page 3548 in chapter 66, *The Cmicro Library*.

Exit-Single-Step

Parameters:

`(None)`

Type: Local

The single step mode (which has been entered with Single-Step) is finished.

Get-Configuration

Parameters:

`(None)`

Type: Remote

The target responds with its configuration. Compiled features are displayed in the text area as well as the current settings (e.g. trace on/off).

Go-Forever

Parameters:

```
(None)
```

Type: Remote

After initializing the target (for example switching the recorder mode on) the target is started with this command. It is necessary that the target is compiled with the flag XMK_WAIT_ON_HOST.

Help

Parameters:

```
[<commandname>  or  *]
```

Type: Local

A complete list of commands will be displayed on the screen. Commands available in the current mode of the SDL Target Tester are marked with an asterisk.

Example 617 ----------

Type

```
Command>help <commandname> ,
```

to get a short explanation of one or several commands, e.g.

```
help help
```

which is the same as

```
he he
```

Example 618 ----------

A list of all commands beginning with **b** can be requested by typing:

```
help b
```

A complete list of commands can be requested by typing:

```
help *
```

Input-File

Parameters:

`<filename>`

Type: Local

The file named `<filename>` is opened to get the stored trace information (binary format). This command must be used if, for example, a recorded session should be replayed. The file `<filename>` must contain trace information in binary format.

Line

Parameters:

`(None)`

Type: Local

The command displays the line status of the communications interface. It can be used for checking if characters, frames and XONs / XOFFs have been received/transmitted and the kind of device that is actually connected.

?Memory

Parameters:

`(None)`

Type: Local

If the Cmicro Memory Management is selected (the flag XMK_USE_SDL_MEM must be defined, please view "Use of Memory" on page 3515 in chapter 66, *The Cmicro Library*) this command offers the advantage of checking currently allocated memory.

News

Parameters:

`(None)`

Type: Local

The SDL Target Tester Release's news are displayed in the text area.

Next-Step

Parameters:

`(None)`

Type: Remote

This command performs one step (one transition) if single step is active. The Single-Step command must be given prior to this.

Nextstate

Parameters:

```
<Processtype Instance> <Statename>
```

Type: Remote

This command sets the state of the given process instance to the value of `<Statename>`. `<Statename>` must be one of the states which are defined for the corresponding process type in SDL. Normally, that only makes sense if the system is under break condition or is idle.

Output-File

Parameters:

```
<filename>
```

Type: Local

All the target's trace information is stored as binary data into the file `<filename>`. This command can be used to store the information of a recording session in binary format.

Output-NPAR

Parameters:

```
<Receiver-Processtype Instance> <Signalname>
```

Type: Remote

An Output from the environment without any parameters is sent into the SDL system.

Output-PAR

Parameters:

```
<Receiver-Processtype Instance> <Signalname> <Signal
Parameter>
```

Type: Remote

An output from the environment into the SDL system with a signal including parameters is sent into the SDL system. The `<Signal Parameter>` has to be given as a buffer of hexadecimal values. See Example 619.

Example 619: Output with parameters ––––––––––––––––––––––––

```
Output-PAR Process_A 0 Signal_1 "00-12-a3"
```

Signal 'Signal_1' is sent to the instance 0 of process type 'Process_A'. 'Signal_1' contains parameters with the length of three octets and the values 0x00, 0x12 and oxa3. The ordering of the parameter octets must fit into the signal's parameter structure and the target's memory layout (alignment, endian etc.).

––

Options-File

Parameters:

`<filename>`

Type: Local

The options file `<filename>` is read in so that the message coder can be initialized. By default the options file `sdtmt.opt` (see "Preparing the Host to Target Communication" on page 3614) is read in when the SDL Target Tester is started.

Page-File

Parameters:

`<filename> <EventsPerPage>`

Type: Local

The file `<filename>` containing trace information (in binary format) is read in and displayed as ASCII trace in the text area. The constant decimal value `<EventsPerPage>` gives the amount of trace information to be displayed until the user confirms the next page.

Print-Conf

Parameters:

`(None)`

Type: Local

This command gives all configuration information together, see the commands ?Coder and Line.

?Process-Profile

Parameters:

```
<Processtype Instance>
```

Type: Remote

The profiling of one process instance can be requested with this command. The result is the transition execution time of the longest transition and the last transition of the specified process instance. The flag XMK_ADD_PROFILE must be set when compiling the target executable to have access to this command in the target.

Please view the section "Initialization" on page 3504 in chapter 66, *The Cmicro Library*.

?Process-State

Parameters:

```
<Processtype Instance>
```

Type: Remote

Query the state of the given process(es).

The amount of queried process instances can be configured:

- If you specify a valid process instance (?Process-State P1 0), the current state of this instance is printed.
- If you enter a process type and * (?Process-State P1 *) you get the states of all instances of this type.
- If you enter ?Process-State * * all possible Process instances of the system are queried.

Depending on the traffic load on the communications interface the responses may be delayed.

Caution!

The results printed on the screen may be inconsistent. That depends on what the SDL system is doing during the query procedure. The results will be correct, however, if the whole SDL system is idle.

?Queue

Parameters:

(None)

Type: Remote

Some characteristics of the queue will be displayed. The command is very useful for determining the queue's dimensions. There is a peak hold, which shows the maximum number of entries in the queue since the system's start.

Example 620 ----------

After typing the command, information is printed on the screen, which may look like:

```
Current Queue state:
Queue size dimensioned to:Max.20 entries
Peak hold                 :1 entry/entries
Currently                 :0 entry/entries in queue
Queue memory located at   :36a40010,x
```

The explanation for this is: a maximum of 20 entries in the queue can be handled by the system. Since system start, there was never more than one entry being used. Currently, no signal instance has been detected in any process input port. The last value displays the physical memory allocation of the queue, which helps in debugging.

Recorder-Delay

Parameters:

<duration>

Type: Local

If a recorded session should be replayed it is possible to insert each environment signal with a delay of <duration> seconds. This feature can be used instead of the real-time play (Recorder-Realtime).

Recorder-Off

Parameters:

(None)

Type: Remote

Switches the Cmicro Recorder off. This command may be specified any time during a recording session. It can be used in order to reduce the amount of information sent via the communication interface.

Recorder-On

Parameters:

(None)

Type: Remote

Switch Cmicro Recorder to record mode. It is not a good idea to enter this command when the SDL system is not idle. (Furthermore, the question is, whether it makes sense to start a record session in the middle of an SDL execution or from the start-up of the SDL system.) It may not be relevant to start a recording session after the system has started.

> **Note:**
>
> The SDL Target Tester's Record and Play functions are only available if a Cmicro Recorder license is available.

Recorder-Play

Parameters:

(None)

Type: Remote

The Cmicro Recorder's play mode will be set. This command can be entered in a few states of the Cmicro Kernel only. Notification is given if necessary. The same explanation as for Recorder-on apply.

> **Note:**
>
> The SDL Target Tester's Record and Play functions are only available if a Cmicro Recorder license is available.

Recorder-Realtime

Parameters:

(None)

Type: Local

The play mode of the SDL Target Tester is started as real-time play. It is necessary to compile the target with signals including time stamps.

The SDL Target Tester's host sends all environment signals with the recorded time stamp into the target while replaying. Without using this

command all signals are inserted with time 0 which leads to an immediate execution in the target.

Reinitialize

Parameters:

```
(None)
```

Type: Remote

This command tries to reinitialize the system. The reinitialization may fail, if the hardware drivers cannot be reinitialized again. Furthermore, all global auto variables in the user's C program parts cannot be reinitialized. However, if there is a clean implementation of driver initialization and de-initialization, and initialization of global variables, the command will work well.

Remove-All-Signals

Parameters:

```
<Processtype Instance>
```

Type: Remote

Remove all signals of the given receiver from the signal queue.

Remove-Command

Parameters:

```
(None)
```

Type: Local

For each command, which is sent to the target, the host waits for an explicit acknowledgment. The last command can be removed, so that the host does not wait for that acknowledgment. That can be used when the communication is hanging for any reason, for example, when the command could not be sent to the target, or was not received by the target, or the acknowledgment could not be received by the host.

Remove-Queue

Parameters:

```
(None)
```

Type: Remote

All signal instances in the queue will be removed. The signal queue will be empty.

Remove-Signal

Parameters:

```
<Processtype Instance> <Signalname>
```

Type: Remote

Remove a specific signal of the given receiver from the queue.

> **Note:**
>
> E.g. when a breakpoint is hit the signal which led to the current transition still remains in the signal queue. This means the first signal in the queue cannot be removed.

Reset-All-Timers

Parameters:

```
<Processtype Instance>
```

Type: Remote

This command resets all SDL timers of the given process instance.

Reset-Timer

Parameters:

```
<Processtype> <Instance> <Timername>
<Timerparameter>
```

Type: Remote

This command resets a specific SDL timer of the given process instance and with a specific timer value.

> **Note:**
>
> The input of a timer parameter is mandatory. The type of the parameter has to be an integer value. For a timer without parameter enter a 0 in the parameter dialog.

Resume

Parameters:

```
(None)
```

Type: Remote

Resume Cmicro Kernel, after a suspend has been accepted. The same explanations as for the Suspend command apply.

Run-Cmd-Log

Parameters:

`<filename>`

Type: Local

The initialization commands in the log file `<filename>` will be executed.

> **Caution!**
>
> In principle it is possible to use all kinds of commands in this command log file. But the correct execution cannot be guaranteed because there are to many interactions between the SDL Target Tester, the Gateway (`sdtgate.exe`), the target and the Organizer.
>
> E.g. the MSC Editor can only be started from a command log file if the requested performance of the host machine is supported.

> **Caution!**
>
> It is still possible to use debugging commands in this log file, too. But the user has to think about the usefulness as all commands will be executed directly after one another without getting the correct timestamp of execution.

Scale-Timers

Parameters:

`<factor>`

Type: Remote

Scale time when setting a timer.

Often there is a need to simulate time during an SDL execution. By specifying this command, it is possible to make SDL timers run faster or slower. The command is applied on newly set timers only, i.e. if a timer is already running then it remains unaffected from the time scale. Due to this fact, the command should only be given at the start of the SDL system.

In record mode the scaled time will be stored. This results in time being scaled in play mode. It is impossible to scale time manually in play mode!

Set-Timer

Parameters:

```
<Processtype Instance> <Time value> <Timername>
<Timerparameter>
```

Type: Remote

Set an SDL Timer for the given process instance with the given time value in units. The time value is a float value re-calculated to the target's timer ticks. Please view "UNIT-NAME, UNIT-SCALE" on page 3616.

> **Note:**
>
> The input of a timer parameter is mandatory. The type of the parameter has to be an integer value. For a timer without parameter enter a 0 in the parameter dialog.

Example 621 Setting a timer without parameters

```
set   <Processtype> <Instance> 4711 < timername> 0

set   <Processtype> <Instance> 1.456 <timername> 0
```

Shutdown

Parameters:

```
(None)
```

Type: Remote

The command tries to shutdown the system, which means normally to exit the main program. The user can define the actions on `exit` within the target. The same explanations as for the reinitialization command apply.

Single-Step

Parameters:

```
(None)
```

Type: Remote

This command switches the single step mode on. Either Next-Step or Continue may follow.

Note:

Timers are checked normally during single step and may expire, as documented for the Disable-Timer and Enable-Timer commands. It may be better to disable the timers (with Disable-Timer) before going into single step.

Start-Cmd-Log

Parameters:

`<filename>`

Type: Local

All the initialization commands will be written to the log file `<filename>`. Please view the command "Run-Cmd-Log" on page 3647, too.

Start-Gateway

Parameters:

`(None)`

Type: Local

This command is used to start the communication in the default implementation of the sdtgate or a host simulation.

Start-MSC-Log

Parameters:

`<level> <"Diagramname">`

Type: Local

The MSC Editor is started and the target's trace messages will be displayed in the MSC Editor. The `<level>` specifies the amount of MSC symbols:

0 - Basic Message Sequence Chart
1 - like level 0 but with the trace of states
2 - like level 1 plus the trace of actions
4 - Basic Message Sequence Chart to file
5 - like level 0 but with the trace of states to file
6 - like level 1 plus the trace of actions to file

Start-SDLE-Trace

Parameters:

```
<Processtype>  or
*
```

Type: Remote

The trace on SDL symbol level is started for the specified process. The Organizer has to be running and the target needs to be compiled with the flag XMK_ADD_SDLE_TRACE (see "Trace" on page 3506 in chapter 66, *The Cmicro Library*).

Start-Trace-Log

Parameters:

```
<filename>
```

Type: Local

A log file containing the whole ASCII trace of the SDL Target Tester will be written.

Stop

Parameters:

```
<Processtype Instance>
```

Type: Remote

This command stops an SDL Process according to the SDL semantics, no matter if the system is suspended or under break condition. The command is, after it is received, directly executed within the target. All signals which are in the queue for this process are removed, including create signals.

Stop-Cmd-Log

Parameters:

```
<None>
```

Type: Local

The write of initialization commands will be stopped. Please view the command "Run-Cmd-Log" on page 3647, too.

Stop-Gateway

Parameters:

```
(None)
```

Type: Local

This command is used to stop the XON communication in the default implementation of the sdtgate.

Stop-MSC-Log

Parameters:

(None)

Type: Local

The trace on the MSC Editor is stopped.

Stop-SDLE-Trace

Parameters:

<None>

Type: Local

The trace on SDL symbol level is stopped.

Stop-Trace-Log

Parameters:

<None>

Type: Local

The trace to the trace log file is stopped. The file is closed.

Suspend

Parameters:

(None)

Type: Remote

Disables the Cmicro Kernel from scheduling. The transition currently running will not be affected and will be ended first, before the command is accepted. The suspended SDL system cannot process any signals, neither internal signals nor signals coming from the environment. This may lead to a queue overflow. It is recommended to disable the timers to prevent this.

System

Parameters:

<systemname>.sym

Type: Local

The automatically generated symbol file `<systemname>.sym` is loaded. The symbolic names for process types and Signal IDs can only be used if this file is read in.

Additional error checks can be performed within the SDL Target Tester's host if this file is read in.

?Timer-Table

Parameters:

`(None)`

Type: Remote

Some characteristics of the current timer tables are displayed. The command is useful in order to inspect the state of the SDL system, or to see if it is hanging.

Example 622 ----------

After typing the command, information is printed on screen which may look like:

```
Current Timer states:
SDL NOW                    :9147,d
Timer dimensioned to       :6
Currently                  :0 timer(s) active
Timer memory location at   :36bf0014,
```

Where SDL NOW represents the amount of units since system start. The value of 6 shows the maximum number of timer instances in the system. The third line is self explanatory. The last line gives the physical memory allocation of the timer linked lists which may ease debugging.

Tr-Detail

Parameters:

`<level>`

Type: Local

Define Trace detail. The command is applied locally within the SDL Target Tester's host and it works on ASCII traces to the text area only.

Output to either a file or to the MSC Editor will not be affected by this command. Thus if the target is configured correctly no inconsistency can occur and no information stored in a file or in the MSC Editor will be incomplete.

Five levels are defined (0–5). The higher the level, the more SDL events are traced. Different events are assigned the levels depicted in the following table:

Trace subject	L.1	L.2	L.3	L.4	L.5
PRINT STRING	*	*	*	*	*
TASK	-	-	-	-	*
DECISION	-	-	-	-	*
PROCEDURE	-	-	-	-	*
SET	-	-	-	*	*
RESET	-	-	-	*	*
ACTUAL RESET	-	-	-	-	-
STOP	-	-	-	*	*
STATE	-	*	*	*	*
STATIC CREATE	-	-	-	*	*
DYNAMIC CREATE	-	-	-	*	*
CREATE	-	-	-	*	*
SAVE	*	*	*	*	*
TIMER	*	*	*	*	*
INPUT	*	*	*	*	*
OUTPUT	-	-	*	*	*
DISCARD	*	*	*	*	*
IMPLICIT CONSUMPTION	*	*	*	*	*

Tr-Params

Parameters:

`<const>`

Type: Local

The trace of signal parameters can be switched on or off. This command has an influence on the display in the text area only.

<const> can take the values:

0 - to switch trace off or
1 - to switch the trace of signal parameters on

Tr-Process

Parameters:

```
<Processtype Instance> <Bitmask>  or
ENV <Bitmask>  or
* <Bitmask>
```

Type: Remote

This command defines which processes in the system are traced. It is applied in the target (remote command), so that the traffic load on the communications interface can be reduced interactively.

This trace command works for all instances of the given process type. No differentiation is possible between different instances of one type.

Tr-Signal

Parameters:

```
<signalname> <flag>
```

Type: Remote

This command defines the trace for one or all signals in the system. It is applied in the target (remote command), so that the communications interface's traffic load can be reduced interactively.

The signal name is the one from the SDL system. No qualifiers are possible, which means, that signal names have to be unique for the whole SDL system. The flag may be 0 (trace off) or any other value (trace on). If an asterisk is specified for signal name, then flag is applied to all signal types. The command works for SDL output only.

Tr-Off

Parameters:

```
(None)
```

Type: Remote

The command switches the SDL Target Tester's tracer off within the target. The current option settings stored in the target will not be affected. After this command is received within the target, the trace is imme-

diately suspended and can only be resumed with the command Tr-On. The output trace that has been written is interrupted.

> **Note:**
>
> The user has to consider misinterpretation of the trace because of missing traces after resuming the trace via Tr-On.

Tr-On

Parameters:

```
(None)
```

Type: Remote

This command switches the Cmicro Tracer on, if it is compiled within the target. None of the current option settings concerning trace within the target will be affected.

Unit-Name

Parameters:

```
<unitname>
```

Type: Local

The timer unit's name can be assigned with this command, e.g. if the target's system time is 'milliseconds' and the Unit-Scale is dimensioned to 1000, the <unit> should be named as 'sec'.

Unit-Scale

Parameters:

```
(realvalue)
```

Type: Local

The target's system time, which is received with the trace data, is multiplied by this constant factor to get a "readable" system time. See Unit-Name too.

Graphical User Interface

This section describes the appearance and functionality of the graphical user interface of the SDL Target Tester (sdtmtui). Some user interface descriptions common to all tools can be found in chapter 1, *User Interface and Basic Operations*. These general descriptions are not repeated in this chapter.

Starting the SDL Target Tester UI

The SDL Target Tester UI is automatically started from the Cmicro Postmaster. When the UI is started the definition file for the button groups (see "The Button Area" on page 3658) is read in. The default name of this file is `sdtmt.btn`.

The Main Window

The main window provides a text area (which displays output from the monitor system), an input line (used for entering and displaying textual command line input to the monitor system) and a button area (with buttons for execution of monitor commands).

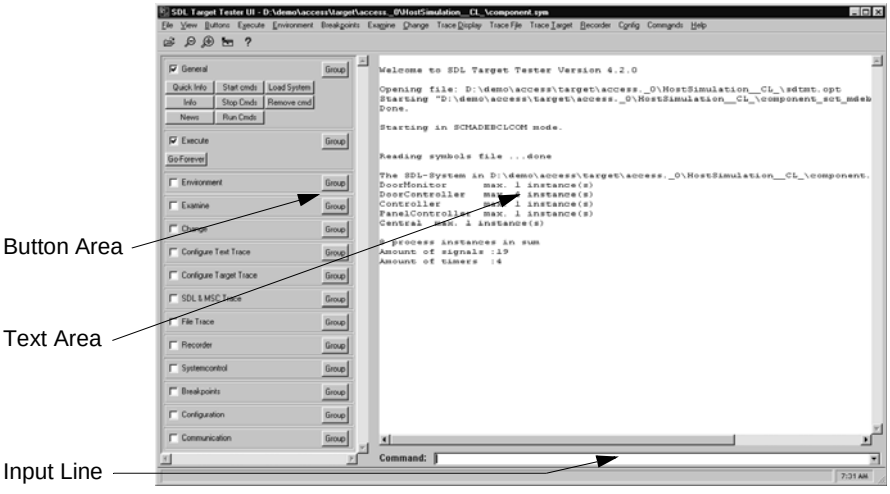

Figure 606: The Main window

The Text Area

The *text area* displays all text output from the monitor system, including user prompts, error messages and command results.

Commands cannot be entered in this area, but a command given on the input line or through the use of the command buttons is echoed after the displayed prompt:

```
Command>
```

The Input Line

The *input line* is used for entering and editing monitor commands from the keyboard. For information on available monitor commands, see "Syntax of SDL Target Tester Commands" on page 3629.

The last commands entered on the input line are saved in a history list. This list can be traversed by using the `<Up>` and `<Down>` keys on the input line.

When `<Return>` is pressed anywhere on the input line, the complete string is saved in the history list and is moved to the text area. The command is then executed.

Parameter Dialogs

If a command entered on the input line requires additional user input (i.e. parameter values), the information will automatically be prompted for in a dialog:

- Parameter values of enumeration type are presented in lists, from which the value can be selected (see Figure 607).

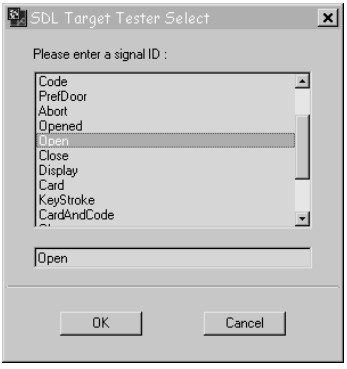

Figure 607: A typical selection dialog

The value can also be entered or edited on the text input line below the list in the dialog. For those commands that take an optional variable component, the component must be entered on the text input line after the selected variable name. It will not be asked for in a dialog.

- Other parameter values are asked for in simple text input dialogs.

Each parameter dialog has an *OK* button for confirming the value and a *Cancel* button for cancelling the command.

The Button Area

The *button area* is used for entering monitor commands by clicking the left mouse button on a command button. Each button corresponds to a specific monitor command. The buttons are divided into groups, roughly corresponding to the different types of commands listed in "SDL Target Tester Commands" on page 3629. Each group is shown as a *module* in the button area. Any number of button modules may reside in the button area. If the modules do not fit in the button area, a vertical scroll bar is added.

The definition of the buttons and button groups are stored in a *button definition file* (see "Button and Menu Definition File" on page 3673). New buttons can be added and existing ones deleted or redefined by using the *Group* menu in a button module.

If a button's definition contains parameters, the parameter values are prompted for in dialog boxes before the command is executed, in the same way as described for commands entered from the input line. See "Parameter Dialogs" on page 3657.

When no more parameter values are requested, the string shown on the input line is saved in the history list and moved to the text area. The command is then executed.

A Button Module

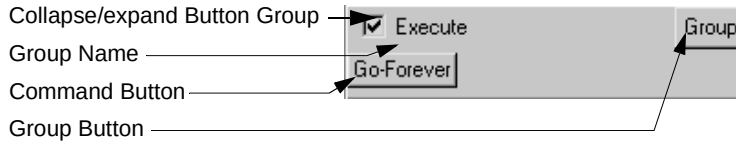

Figure 608: A button module

Each *button module* consists of a title bar and a number of command buttons arranged in rows and columns. The title bar displays:

- A *collapse/expand* toggle button. Click this to collapse (so that only the title bar is visible) and expand the module.
- The *group name* of the button module.
- A *Group* button, providing a menu with commands affecting the buttons in the module.

The *Group* button contains the following menu choices:

Add

This menu choice opens a dialog where you may add one or several new buttons to the button module. You should specify a label of the new button and a command that is to be executed when the button is clicked. Click *OK* or *Apply*, to add the button to the end of the module. For the syntax of a button definition, see "Button and Menu Definitions" on page 3674.

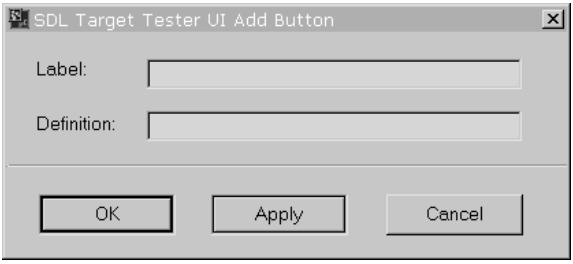

Figure 609: Adding a new button

> **Note:**
> Several buttons are allowed to have the same name within the same module. When you edit the button definition or delete the button, it is always the first occurrence that will be deleted or modified.

Edit

This menu choice opens a dialog where you can select a button to edit, that is, its label and definition. You edit the button in a similar way as described in "Add" on page 3659.

> **Note:**
> If several buttons have **the same button label**, it is always **the first button** found that will be edited, regardless of the selection.

Delete

This menu choice opens a dialog where you can select one or several buttons to be deleted.

> **Note:**
> If several buttons have **the same button label**, it is always **the first button** found that will be deleted, regardless of the selection.

Rename Group

This menu choice opens a dialog where you can edit the name of the current button module.

Delete Group

Select this menu choice deletes to delete the current module from the button area. You will be asked to confirm the operation.

The Default Button Modules

The following tables list the default buttons in the button modules and the corresponding monitor command. See "SDL Target Tester Commands" on page 3629 for more information.

> **Note:**
> The buttons in the button modules are specified in the button definition file. If the default button file is not used, the button modules may differ from those described here. See "Button and Menu Definitions" on page 3674 for more information.

The *Environment* Module

Button	SDL Target Tester command
Send without params	Output-NPAR
Send with params	Output-PAR

The *Execute* Module

Button	SDL Target Tester command
Go-Forever	Go-Forever

The *Examine* Module

Button	SDL Target Tester command
Queue	?Queue
Process	?Process-State
Last Error	?Errors
Timers	?Timer-Table
Process List	?All-Processes

Button	SDL Target Tester command
Active	Active-Timer
Profile	?Process-Profile

The *Change* Module

Button	SDL Target Tester command
Set Timer	Set-Timer
Reset Timer	Reset-Timer
Create	Create
Stop	Stop
Nextstate	Nextstate
Remove Q	Remove-Queue
Remove S	Remove-Signal
Remove all S	Remove-All-Signals
Scale Timers	Scale-Timers

The *Configure Text Trace* Module

Button	SDL Target Tester command
ON	Display-On
OFF	Display-Off
Detail Level	Tr-Detail
Show Params	Tr-Params 1
Hide Params	Tr-Params 0

The *Configure Target Trace* Module

Button	SDL Target Tester command
ON	Tr-On

Button	SDL Target Tester command
OFF	Tr-Off
Signal	Tr-Signal
Process	Tr-Process
NO Symbols	Tr-Process * B'00000000000000000000000000000000'
ALL Symbols	Tr-Process * B'11111111111111111111111111111111'

The *SDL & MSC Trace* Module

Button	SDL Target Tester command
Start MSC	Start-MSC-Log
Stop MSC	Stop-MSC-Log
Start SDL	Start-SDLE-Trace
Stop SDL	Stop-SDLE-Trace

The *File Trace* Module

Button	SDL Target Tester command
Binary Infile	Input-File
Binary Outfile	Output-File
Close binaries	Close-File
ASCII Outfile	Start-Trace-Log
Close ASCII	Stop-Trace-Log
Page File	Page-File
Convert File	Convert-File

The *Recorder* Module

Note:

The SDL Target Tester's Record and Play functions are only available if a Cmicro Recorder license is available.

Button	SDL Target Tester command
Recorder off	Recorder-Off
Record	Recorder-On
Play	Recorder-Play
Delay	Recorder-Delay
Real-time	Recorder-Realtime
Input recfile	Input-File recfile.trc
Output recfile	Output-File recfile.trc
Close recfile	Close-File recfile.trc

The *Systemcontrol* Module

Button	SDL Target Tester command
Single-Step	Single-Step
Next-Step	Next-Step
Exit-Single-Step	Exit-Single-Step
Reinit	Reinitialize
Shutdown	Shutdown
Resume	Resume
Disable Timer	Disable-Timer
Enable Timer	Enable-Timer
Suspend	Suspend

The *Breakpoint* Module

Button	SDL Target Tester command
Break input	BPI
Break nextstate	BPS
Break all	BP
View Breakpoints	?Breaklist
Clear all	BA
Continue	Continue

The *Configuration* Module

Button	SDL Target Tester command
Unit scale	Unit-Scale 1.0
Unit name	Unit-Name “milliseconds”
Target	Get-Configuration

The *Communication* Module

Button	SDL Target Tester command
Start Gateway	Start-Gateway
Coder Config	?Coder
Interface State	Line

The Menu Bar

This section describes the menu bar of the SDL Target Tester main window and all the available menu choices in the default configuration.

The menu bar contains the following fixed menus:

- *File Menu*
- *View Menu*
- *Buttons Menu*

- *Help Menu*
  (See "Help Menu" on page 15 in chapter 1, *User Interface and Basic Operations*.)

The menu bar can also contain additional menus listed in a menu definition file (see "Button and Menu Definition File" on page 3673). The following menus are defined in the delivered version of this file:

- *Execute Menu*
- *Environment Menu*
- *Breakpoint Menu*
- *Examine Menu*
- *Change Menu*
- *Trace Display Menu*
- *Trace File Menu*
- *Trace Target Menu*
- *Recorder Menu*
- *Config Menu*
- *Commands Menu*

File Menu

The *File* menu contains the following menu choices

- *Open*
  (See "Open" on page 9 in chapter 1, *User Interface and Basic Operations*.)
- *Set Directory*
- *Exit*
  (See "Exit" on page 15 in chapter 1, *User Interface and Basic Operations*.)

Set Directory

This menu choice opens a dialog where you can enter the path to your current project directory.

View Menu

The *View* menu contains the following menu choices:

- *Find*
- *Find Next (F3)*

- *Find Selection*
- *Copy from Text Area*
- *Paste into Command Line*
- *Line Numbering*
- *Clear Text Area*

Find

This menu choice opens a dialog where you can search for text.

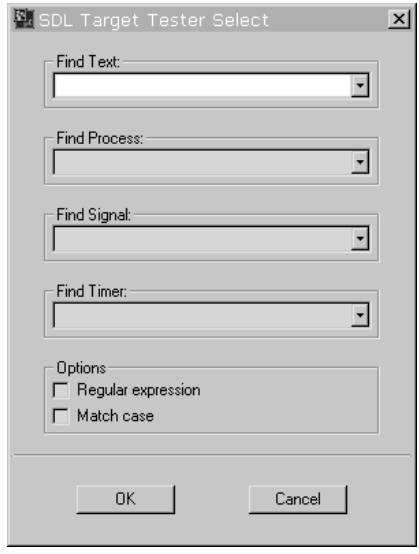

Figure 610: The Find dialog

It is possible to use regular expressions for finding text or to select to find a process, signal or timer belonging to the SDL system.

Find Next

This menu choice will search again for text already found.

Find Selection

This menu choice will search for text currently selected in the SDL Target Tester's text area.

Copy from Text Area

This menu choice will copy the text selected in the SDL Target Tester's text area.

Paste into Command Line

The menu choice will paste the content of the clipboard to the command line.

Line Numbering

This menu choice toggles line numbering in the SDL Target Tester's text area. Line numbering allows a better overview.

Clear Text Area

This menu choice will clear the complete text area of the SDL Target Tester.

Buttons Menu

The *Buttons* menu contains the following menu choices:

- *Load*
- *Append*
- *Save*
- *Save As*
- *Expand Groups*
- *Collapse Groups*
- *Add Group*

For more information on the UI's button definition file, mentioned in the menu commands below, see "Button and Menu Definition File" on page 3673.

Load

This menu choice opens a dialog where you can specify a new button definition file. This will override the current button definitions. All buttons and modules currently in the button area are deleted and replaced by the buttons and modules defined in the new file.

Append

This menu choice opens a dialog where you can specify to append the contents of a new button definition file into the current button definitions. Buttons with new labels are added to the button area, while buttons with already existing labels in the same module will be duplicated (possibly with different definitions).

Save

This menu choice saves the current button and module definitions in the button definition file under its current file name.

Save As

This menu choice opens a dialog where you can save the current button and module definitions in a new button definition file.

Expand Groups

This menu choice expands all modules in the button area.

Collapse Groups

This menu choice collapses all modules in the button area.

Add Group

This menu choice opens a dialog where you can specify the of a new button module to add. The new module will be added after the last module in the button area. It is also possible to add several modules.

Execute Menu

Item	SDL Target Tester command
Start Gateway	Start-Gateway
Go-Forever	Go-Forever
Single-Step	Single-Step
Reinit	Reinitialize
Disable-Timer	Disable-Timer
Next-Step	Next-Step

Button and Menu Definition File

In the SDL Target Tester UI, the button definition information is stored on file (per default this file is named `sdtmt.btn`), i.e. definitions of button groups and button commands in the main window's button area. Furthermore it is possible to define menu entries.

At start-up of the UI, the file is determined in the following way. If the file name does not contain a directory path, the files are searched for in the following directories:

- The current directory
- The SDL Suite installation directory

Once the file has been found, it is read and the contents of the corresponding window is set up. If the file cannot be found, the corresponding window area becomes empty and a file selection dialog is opened to enter the required file name.

The text file can contain comment lines starting with the `'#'` character. Empty lines are discarded.

Note:

When a file is read, no checks are made upon the relevance or correctness of the definitions contained in the file.

Button and Menu Definitions

The *button and menu definitions* are stored in a definition file with the default extension `.btn`. The definitions are divided into groups where each group defines a button module in the main window's button area or a menu in the menu bar.

Syntax

In the file, a button group has the following syntax:

```
:[DISPLAY_AS] <entry name>
<item label>
<definition>
<button label>
<definition>
  . . .
```

The [DISPLAY_AS] prefixes the button group's or menu's name <entry name> and can take three different keywords:

- `COLLAPSED`
  A button group is created, initially collapsed.
- No keyword
  A button group is created, initially expanded.
- `MENU`
  A new menu is created.

The <item label> is either the label of the button in a button module or the label of an menu item.

The <definition> is the SDL Target Tester command that will be executed when the button is pressed/the menu item is selected. The syntax of a button definition is the same as when entering a command textually to the monitor.

Missing parameters at the end of the command will open dialogs for those parameters.

After all there is no limit in the amount of buttons in a button group or the amount of items in a menu entry except the visibility and usability of the buttons/items.

Comparing with the Simulator there is a simple rule of ordering the buttons shown in Figure 611. A new button row is added only if the previous row has got 3 buttons.

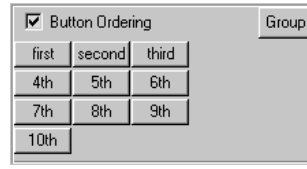

Figure 611: Ordering of the buttons in a button group

The Target Library

General

The target library is a mandatory part of the SDL Target Tester. The SDL Target Tester is of no use without the functions and definitions contained within.

In order to use the options of SDL Target Tester's host site, the target library must be configured accordingly.

A lot of defines make it possible to reduce the SDL Target Tester's functions within the target, so that memory requirements can be reduced when necessary.

In the following sections are explanations of the file structure and the application program interface (API) within the target.

File Structure

The following picture explains the file structure for the SDL Target Testers target library.

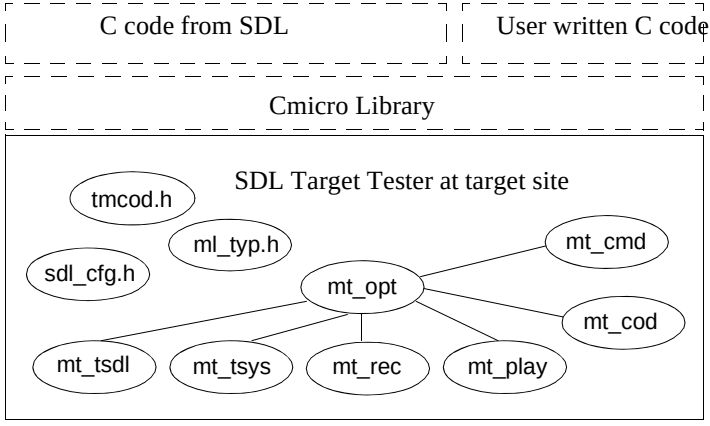

Figure 612: Files of the Cmicro Library

Description of Files

sdl_cfg.h

This file is generated automatically by the Cmicro SDL to C Compiler into the directory which is currently active. It contains compilation flags used for the automatic scaling of the Cmicro Library and the generated C code. The file must not be edited by the user.

> **Caution!**
>
> This file always carries the same name for each SDL system generated and is stored into the currently active directory. A conflict will occur if the user tries to generate several systems into the same directory.
>
> Therefore be sure to use different working directories for each SDL system. Otherwise, unpredictable results during run-time of the generated code will occur, as some automatic scalable features may not re-compiled.

ml_typ.h

This file is the central header file in the Cmicro Package. It contains

- more #includes
- defines which are of global interest and Cmicro Library internal defines
- typedefs which are of global interest and Cmicro Library internal typedefs
- extern-declarations which are of global interest and Cmicro Library internal extern declarations

tmcod.h

`tmcod.h` is an automatically generated file of the Target Message Coder Generator (TMCOD). All the SDL Target Tester command tags and the corresponding parameter structures are defined here. It is strongly recommended not to modify this file.

mt_cmd.c

This file is part of the command interface on the target site. The commands received via the communications link will be performed by this file.

mt_cod.c

This is the module which exports the functions to encode / decode any message from the Cmicro Protocol.

mt_opt.c

This module exports the functions which allow the user to define options regarding the tracer, recorder and player components.

Options may be specified to reduce the traffic load of the system, This is important when a slow communications interface is involved and the user wants to test in real-time.

mt_play.c

This file is part of the Cmicro Recorder and it contains all the functions for the play mode.

mt_rec.c

This file is part of the Cmicro Recorder and it contains all the functions for the record mode.

mt_tsdl.c

This module exports functions to trace SDL actions. These functions are mainly for the use of the Cmicro Kernel and Tester.

Functions to trace either into RAM, into a file or via a V.24 interface are delivered.

The module is common for all these trace methods. The functions exported are called directly by the Cmicro Kernel if the SDL Target Tester or part of the SDL Target Tester is involved when executing the SDL system.

mt_tsys.c

This module contains the functions which handle the trace of system events such as scheduler events or the trace of system errors.

mt_*.h

These header files contain the external definitions of the corresponding `.c` files.

The API on Target

General

The C application program interface (API) can be used both by SDL processes and / or by any other C function on the target.

The simplest method, however, is to set some options before initializing the SDL system and hold these options during the whole run-time. A more comfortable method is to set some options before initializing the SDL system and then change the options in an SDL process, when a specific situation is detected. By using this method it is possible to reduce the amount of information and to make it easier to find unwanted behavior or an erroneous situation in a trace. This can be achieved, for example, by writing the necessary C function call(s) into an SDL task symbol using the #CODE directive.

The following pages introduce the C function interface, which is used in the target to set the trace options.

> **Caution!**
>
> It is important to take care with function parameters. Any function return value should also be checked.

Initialization

```
void xmk_InitOptions ( void )
```

Initialization of the SDL Target Tester is absolutely necessary. It must be done before any other initialization, directly before the C function call `xmk_InitSDL`. The user should not remove this function call in the template `main()` function if one wants to use the SDL Target Tester.

Nothing happens before the C function `xmk_OptionsSymbol` is called, and `xmk_TracerActive` is set to `XMK_TRUE`.

Switch the Cmicro Tracer on / off

In order to get an execution trace it is first necessary to switch it on by assigning

```
xmk_TracerActive = XMK_TRUE
```

This should normally be done after the C function `xmk_InitOptions`.

The settings of functions whose names begin with `xmk_Options*` remains unaffected when changing the above flag.

The flag is **not** set by default.

Selecting SDL Symbols That are to Be Traced

```
xmk_OPT_INT xmk_OptionsSymbol ( unsigned char process-type-id,
                                long bitmask )
```

This function must be called in order to begin the trace. By default, no symbol is selected.

Select the trace for process-type-id and then set or un-set different symbols with the bit mask. If anything goes wrong the function will return `XMK_ERROR`, else `XMK_OKAY`.

It is possible to specify bit mask values for a specific SDL process, for all SDL processes, for the environment and for the kernel part of the Cmicro Library. The last possibility is necessary to allow the optional trace for system events like error trace and trace of scheduling events.

Allowed values for process-type-id:

0	First process-type-id, XPTID_ from `sdl_cfg.h`
1	Second.....
N-1	Last... (N is the maximum number of process types)
xNULLTYPE	specify trace for all processes
any other value	The environment
MICROKERNEL	specify trace for Cmicro Kernel
ENV	Indicates the SDL environment

Allowed values for bit mask:

SDL symbols	System events
TSDL_STATE	TSYS_SCHEDULE
TSDL_INPUT	TSYS_ERROR
TSDL_SAVE	TSYS_SHOWPRIO
TSDL_OUTPUT	
TSDL_CREATE	
TSDL_STOP	
TSDL_STATIC_CREATE	
TSDL_DYNAMIC_CREATE	
TSDL_DECISION	
TSDL_TASK	
TSDL_PROCEDURE	
TSDL_RESULT	
TSDL_TIMER	
TSDL_SET	
TSDL_RESET	
TSDL_ACTUAL_RESET	
TSDL_SIGNALPARAMS	
TSDL_DISCARD	
TSDL_IMPLICIT_CONSUMPTION	

Selecting SDL Signals to Be Traced

```
xmk_OPT_INT  xmk_OptionsSignal ( xmk_T_SIGNAL signal id,
                                 unsigned char bitmask )
```

This function is optionally called because the trace of all SDL signals is switched on per default.

Select the trace for signal id. Then set or un-set different symbols with bit mask. If anything went wrong, the function will return `XMK_ERROR`, else `XMK_OKAY`.

It is possible to specify either “off” for all signals, “on” for all signals, “off” for a specific signal or “on” for a specific signal.

Allowed values for signal-id:

0	First signal-id, #define from generated C code and `<systemname>.ifc`
1	Second.....
N-1	Last.....
XMK_ALLOW_NO	Specify trace for all processes
XMK_ALLOW_ALL	Specify trace for Cmicro Kernel

Allowed values for bitmask:

- Any value in the range of `0x00` to `0xff`.
- A value != `0x00` switches the trace for the signal on.
- A value == `0x00` causes the trace for the given signal(s) to be switched off.

Example to Set Trace Options

A simple method to set the trace options is to set them directly within the C function `main`, before the Cmicro Kernel is initialized. The user will find this example as a template in the file `bare_ex.c` delivered with the Cmicro Package, below the directory `<sdtdir>/cmicro/template`.

Example 623 ----------

```
#include "sdl_cfg.h"
#include "ml_typ.h"
    ... main ( ... )    {
  extern int xmk_TracerActive ;
  long       bitmask = 0      ;
  int        result  = XMK_OKAY ;

/* Initialize SDL Target Tester */
xmk_InitOptions ( );

/* Set all options ON */
result = xmk_OptionsSymbol (xNULLPID, 0xffffffff);
if (result != XMK_OKAY) ErrorInUsage ();

/* Set some options ON */
bitmask = TSDL_INPUT  ;
bitmask = TSDL_STATE  ;
bitmask = TSDL_OUTPUT ;

                /*          +---- Proces-Type - Id (see automatically */
                /*          |     generated file *.ifc)               */
                /*          V                                         */
 result = xmk_OptionsSymbol (0, bitmask );
 if (result != XMK_OKAY) ErrorInUsage ();
 result = xmk_OptionsSymbol (1, 0x00000000 );
 if (result != XMK_OKAY) ErrorInUsage ();

/* S w i t c h   o n   t h e   t r a c e */
xmk_TracerActive                = XMK_TRUE ;
/* Template to set options to filter signals */
                   /*                                              */
                   /* +---- Allow all Signals to be traced       */
                   /* V                                           */
 xmk_OptionsSignal (XMK_ALLOW_NO, 0);
                /* +---- Signal id is to be set correctly !    */
                /* |     according to the automatically       */
                /* |     generated *.ifc - file               */
                /* V                                          */
 xmk_OptionsSignal (1, 0xff);
 xmk_OptionsSignal (2, 0xff);
 xmk_OptionsSignal (3, 0xff);
/* I n i t i a l i z e   C m i c r o   K e r n e l */
xmk_InitSDL ()

/* R u n   C m i c r o   K e r n e l */
if (xmk_RunSDL (0xff) != XMK_STOP);
exit (0);
}
```

Getting a Trace in SDL Tasks with C Code

The Cmicro SDL to C Compiler generates usable traces for SDL tasks only if it is a task containing at least one SDL assignment. Whenever C code is specified within a task symbol (by using the #CODE directive), the Cmicro SDL to C Compiler is not able to generate good trace information.

There are two C functions which enable a work-around:

- `xmk_PrintString (const char *)` or
- `xmk_TSDL_Task (const char *)`

in order to get a trace from C code. The trace output of a call like

```
xmk_PrintString ('Hello SDL world')
```

looks like:

```
USER:   Hello SDL world
```

The strings have to be unique, in order to distinguish a trace of one process from another. Another difference between the above function is that the C function `xmk_PrintString` does not check if a trace is wanted or not. The trace will be done unconditionally via the SDL Target Tester's communications link.

Of course, the function may also be applied in non SDL program parts.

Using Record or Play Mode of the Cmicro Recorder

```
xmk_OPT_INT xmk_SetRecorderMode ( int mode )
```

This function must be called by the user in order to:

- switch the record mode of the Cmicro Recorder on, or
- switch the play mode of the Cmicro Recorder on, or
- switch any function of the Cmicro Recorder off.

Allowed values for mode:

- `XMK_RECORDER_RECORD`
- `XMK_RECORDER_PLAY`
- `XMK_RECORDER_OFF`

Environment Functions

xInEnv ()

```
void  xInEnv ( void )
```

This function is called each time the Cmicro Kernel's main loop is entered. A more detailed description of the C function `xInEnv()` can be found in "xInEnv()" on page 3533 in chapter 66, *The Cmicro Library*.

xOutEnv ()

```
int  xOutEnv ( xmk_T_SIGNAL sig,
               xmk_T_PRIO prio,
               xmk_T_MESS_LENGTH data_len,
               void *p_data,
               xPID Receiver
```

This function is called each time the SDL system wants to output a signal to the environment. If the environment should be another system (e.g., an MS DOS PC), the signal can be sent directly by calling the C function `xmk_Cod_Encode` (which is described in the following section). A more detailed description of the C function `xOutEnv` can be found in "xOutEnv()" on page 3536 in chapter 66, *The Cmicro Library*.

xmk_Cod_Decode ()

```
int  xmk_Cod_Decode ( char *p_RAWBuffer,      In
                      int *p_MessageClass,    Out
                      int *p_MessageTag,      Out
                      int *p_MessageLength,   Out
                      char *p_dest,           In/Out
                      int dest_len )          In
```

This function is free to be used on the target site. It decodes a given data link frame in the Cmicro Protocol format into the different pieces of data. `MessageClass` may be in the range from `F3h` to `FFh`. The value `Fh` in the higher nibble is used to synchronize the data stream if synchronization fails and `0h` to `2h` in the lower nibble is used by the SDL Target Tester itself. `MessageTag` may be of any value. `p_struct` is a pointer to a C structure which is to be transferred via the communications link. `Struct_length` is the result of the sizeof operator being applied to this structure.

The function is the counterpart to the C function `xmk_Cod_Encode`.

xmk_Cod_Encode ()

```
int  xmk_Cod_Encode ( int MessageClass,
                      int MessageTag,
                      char *p_data,
                      int length )
```

This function is free to be used on the target site: It encodes the given information into a data link frame of the Cmicro Protocol format and sends it via the communications interface. `MessageClass` may be in the range from `F3h` to `FFh`, the value `Fh` in the higher nibble is used to synchronize the data stream if synchronization fails and `0h` to `2h` in the low-

er nibble is used by the SDL Target Tester itself. `MessageTag` may be of any value. `p_struct` is a pointer to a C structure which is to be transferred via the communications link. `Struct_length` is the result of the sizeof operator being applied to this structure.

The function is the counterpart to the C function `xmk_Cod_Decode`.

> **Note:**
> The maximum amount of characters which can be transferred is restricted to 255 per default in this Cmicro Package version.

Compiling and Linking the Target Library

Some defines are to be set in order to compile and link the parts of the SDL Target Tester correctly. These defines can be set either on the command line when invoking make or in the header file `ml_mcf.h`. Be sure that for each configuration possibility all the defines are set appropriately.

The best way to select the compiler options for the SDL Target Tester is to use the Targeting Expert. Please view the section "Configure the SDL Target Tester (Cmicro only)" on page 2947 in chapter 59, *The Targeting Expert*.

Here is a first idea of what has to be to set in the configuration file `ml_mcf.h`:

```
#define XMK_ADD_MICRO_TESTER
#define XMK_ADD_MICRO_TRACER
#define XMK_USE_V24
#define XMK_USE_COMMLINK
```

Scaling of SDL Target Tester Functionality

In order to reduce the amount of memory - e.g. if memory gets scarce within a progressing project - it is possible to reduce the SDL Target Tester's functionality on target site.

Removing the whole SDL Target Tester

It is quite simple to remove any functionality used by the SDL Target Tester by specifying:

```
#undef XMK_ADD_MICRO_TESTER
```

Removing the Cmicro Tracer

This is possible by specifying

```
#define  XMK_ADD_MICRO_TESTER
#undef   XMK_ADD_MICRO_TRACER
```

Removing the Cmicro Recorder (Inclusive Play Mode)

This is possible by specifying

```
#define  XMK_ADD_MICRO_TESTER
#undef   XMK_ADD_MICRO_RECORDER
```

Removing the Command and Debug Interface

This is possible by specifying

```
#define  XMK_ADD_MICRO_TESTER
#undef   XMK_ADD_MICRO_COMMAND
```

Partial functionality may be left out by un-defining one of the defines described under "Message Transfer and Presentation of Messages" on page 3689.

Configuration of Buffers

Users must configure buffers used by the SDL Target Tester.

The reason behind this is that the SDL Target Tester uses an efficient way to handle those buffers. This is of great importance especially for micro controllers.

Additionally, these buffers must be consistently dimensioned. For instance, the message buffer of the communications link must be able to handle the largest parameter list of a signal from SDL. The same situation arises in the trace of SDL tasks and procedure names.

Caution!

If any buffer is dimensioned too small a run-time error may result.

The following defines are used to dimension buffers.

XMK_MAX_PRINT_STRING

This define restricts the amount of characters transferred via the communications link when using the C function `xmk_PrintString`. This function is used only by the user.

XMK_MAX_LEN_SYMBOL_NAME

This define is used to restrict the amount of characters transferred via the communications link for the SDL tasks and SDL procedure names.

The transmit and receive buffers of the default communications link software must be configured in the data link (`dl`) module using the following defines:

Transmitter buffer:

```
#define XMK_MAX_SEND_ONE_ENTRY          1000
#define XMK_MAX_SEND_ENTRIES            20
```

Receiver buffer:

```
#define XMK_MAX_RECEIVE_ONE_ENTRY       1000
#define XMK_MAX_RECEIVE_ENTRIES         20
```

where `*_ONE_ENTRY` is the dimensioning of one message, and `*_ENTRIES` is the maximum amount of entries in the message FIFO of the data link module. Note, that `*_ONE_ENTRY` must be greater than the greatest of the `XMK_MAX_*` defines above, plus a reserve of 6 bytes.

Connection of Host and Target

General

The following sections will detail the technical requirements and the technical implementation of the connection between host and target. The following items will be outlined:

- "Structure of Communications Link Software" on page 3689
- "Default Implementation of Communications Link Software" on page 3689 as delivered.
- How to implement user host executables, which are able to communicate with the SDL Target Tester's target library. This is described in the subsection "Open Interface" on page 3726.

Structure of Communications Link Software

This is the structure for the communications link software, which is - in principle - applicable for host, as well as for target site:

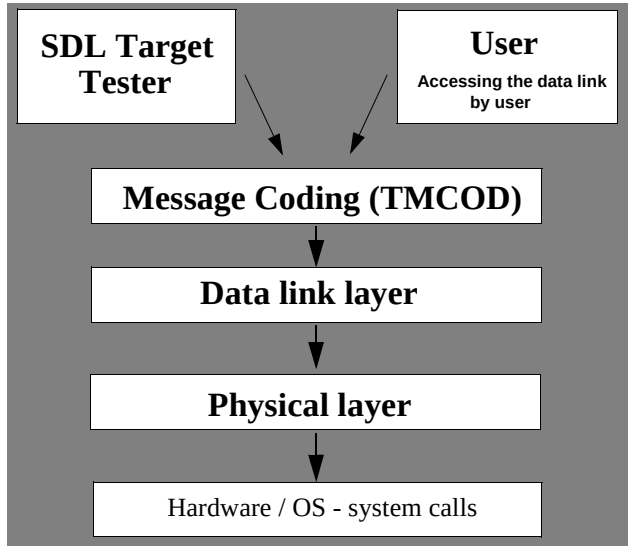

Figure 613: Structure of the communications link software

The following subsections describe the current implementation and how to implement a new communications link software.

Default Implementation of Communications Link Software

Message Transfer and Presentation of Messages

State Machine and Handshake

For all the commands and messages, there is a small state machine to handle the correct transfer of information. All messages, which have the suffix `_REQ` (request) in their name (message tag) are to be confirmed from the target with one of the `_CNF` (confirmation) messages. (See the file `tmcod.h`, where all message tags are defined).

For messages which take parameters, there is always (no exception) a special _CNF message which carries the response parameters back to the requestor. The requestor is usually the host.

For the messages, which do not carry parameters, a positive confirmation is done via the message CMD_OKAY_CNF.

If a message cannot be recognized or processed within the target, a negative confirmation CMD_ERROR_CNF is used in all cases.

Each _REQ message must be confirmed before the next one can be sent.

Messages with an _IND (indication) suffix are mostly sent from target to host in order to indicate a specific situation. For these messages, the sender is always the originator.

Message Formats

The following subsections give a complete list of messages which can be sent to and received from the target.

Each typedef shown below is packed into a data link frame in its target representation.

That means a memcpy (destbuffer,struct,sizeof(struct)) is performed to copy a structure to/from the data link frame.

On host site, it is therefore necessary to perform message encoding and message decoding.

Formats Concerning the Cmicro Tracer

All messages belonging to the Cmicro Tracer are part of the message class XMK_MICRO_TRACER (F1h).

- Message tag: CMD_TTASK

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Task
Sent when          :Execution of that SDL symbol
Direction          :T->H
Typedefinition     :xmk_T_CMD_TTASK
Conditional compile:XMK_ADD_TTASK
```

  Message description: The message is sent when a task symbol is entered in generated C Code and when the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TSET

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Set
Sent when          :Execution of that SDL symbol
Direction          :T->H
Typedefinition     :xmk_T_CMD_TSET
Conditional compile:XMK_ADD_TSET
```

Message description: The message is sent when a timer set is performed in generated C Code and when the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TRESET

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Reset
Sent when          :Execution of that SDL symbol
Direction          :T->H
Typedefinition     :xmk_T_CMD_TRESET
Conditional compile:XMK_ADD_TRESET
```

Message description: The message is sent when a timer reset is performed in generated C Code and when the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TSTOP

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Stop
Sent when          :Execution of that SDL symbol
Direction          :T->H
Typedefinition     :xmk_T_CMD_TSTOP
Conditional compile:XMK_ADD_TSTOP
```

Message description: The message is sent when an SDL process stop is performed and when the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TSTATE

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL State
Sent when          :Execution of that SDL symbol
Direction          :T->H
Typedefinition     :xmk_T_CMD_TSTATE
Conditional compile:XMK_ADD_TSTATE
```

Message description: The message is sent when an SDL nextstate is performed and when the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TSTATIC_CREATE

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Static create
Sent when          :Execution of that SDL symbol
Direction          :T->H
Typedefinition     :xmk_T_CMD_TSTATIC_CREATE
Conditional compile:XMK_ADD_TSTATICCREATE
```

Message description: The message is sent for each statically created SDL process for which the start transition is executed and for which the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TCREATE

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Create
Sent when          :Execution of that SDL symbol
Direction          :T->H
Typedefinition     :xmk_T_CMD_TCREATE
Conditional compile:XMK_ADD_TCREATE
```

Message description: The message is sent when the SDL action create is performed and when the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TDYNAMIC_CREATE

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Dynamic create
Sent when          :Execution of that SDL symbol
Direction          :T->H
Typedefinition     :xmk_T_CMD_TDYNAMIC_CREATE
Conditional compile:XMK_ADD_TDYNAMICCREATE
```

Message description: The message is sent for each dynamically created SDL process, when its start transition is executed, and when the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TDECISION

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Decision
Sent when          :Execution of that SDL symbol
Direction          :T->H
Typedefinition     :xmk_T_CMD_TDECISION
Conditional compile:XMK_ADD_TDecisionValue
```

Message description: The message is sent when an SDL decision is executed and the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TSAVE

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Save
Sent when          :Execution of that SDL symbol
Direction          :T->H
Typedefinition     :xmk_T_CMD_TSAVE
Conditional compile:XMK_ADD_TSAVE
```

Message description: The message is sent when a signal save is performed and when the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TTIMER

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Timer
Sent when          :Execution of that SDL symbol
Direction          :T->H
Typedefinition     :xmk_T_CMD_TTIMER
Conditional compile:XMK_ADD_TTIMER
```

  Message description: The message is sent when an SDL timer has expired and is input into the owner process and the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TINPUT

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Input
Sent when          :Execution of that SDL symbol
Direction          :T->H
Typedefinition     :xmk_T_CMD_TINPUT
Conditional compile:XMK_ADD_TINPUT
```

  Message description: The message is sent when an SDL input is performed and when the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TPROCEDURE

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Procedure
Sent when          :Execution of that SDL symbol
Direction          :T->H
Typedefinition     :xmk_T_CMD_TPROCEDURE
Conditional compile:XMK_ADD_TNAME
```

  Message description: The message is sent when an SDL procedure is entered and when the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TOUTPUT

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Output
Sent when          :Execution of that SDL symbol
Direction          :T->H
Typedefinition     :xmk_T_CMD_TOUTPUT
Conditional compile:XMK_ADD_TOUTPUT
```

  Message description: The message is sent when an SDL output is performed and the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TDISCARD

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Discard
Sent when          :Execution of that SDL symbol
Direction          :T->H
```

```
Typdefinition      :xmk_T_CMD_TDISCARD
Conditional compile:XMK_ADD_TDISCARD
```

Message description: The message is sent when an SDL discard has been detected and when the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_PRINT_STRING

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :User command Print string
Sent when          :Execution of fct.xmk_PrintString()
Direction          :T->H
Typedefinition     :xmk_T_CMD_PRINT_STRING
Conditional compile:XMK_ADD_CPRINT_STRING
```

Message description: The message is sent unconditionally, when the C function `xmk_PrintString` is called by the user.

- Message tag: CMD_TIMPLICIT_CONSUMPTION

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Implicit consumption
Sent when          :Implicit consumption occurs
Direction          :T->H
Typdefinition      :xmk_T_CMD_TIMPLICIT_CONSUMTION
Conditional compile:XMK_ADD_TIMPLICIT_CONSUMPTION
```

Message description: The message is sent when an SDL implicit consumption is performed and when the trace is set for this symbol. Furthermore, the trace must be active.

- Message tag: CMD_TACTUAL_RESET

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of SDL Actual reset
Sent when          :SDL timer is actually reset
Direction          :T->H
Typedefinition     :xmk_T_CMD_TACTUAL_RESET
Conditional compile:XMK_ADD_TACTUAL_RESET
```

Message description: The message is sent when an SDL timer is actually reset and the trace is set for this symbol. Furthermore, the trace must be active. An actual reset applies only if a timer was previously set and has not expired.

- Message tag: CMD_TSYS_ERROR

```
Messageclass       :XMK_MICRO_TRACER
Meaning            :Trace of system error
Sent when          :Any kind of systemerror was detected
Direction          :T->H
Typedefinition     :xmk_T_CMD_TSYS_ERROR
Conditional compile:XMK_ADD_TERROR
```

Message description: The message is sent when a system error of any type has been detected and the trace is set for this event. Furthermore, the trace must be active.

- Message tag: CMD_TSYS_SCHEDULE

```
Messageclass        :XMK_MICRO_TRACER
Meaning             :Trace of system schedule event
Sent when           :When scheduling is performed
Direction           :T->H
Typedefinition      :xmk_T_CMD_TSYS_SCHEDULE
Conditional compile:XMK_ADD_TSCHEDULE
```

Message description: The message is sent when the Cmicro Kernel begins scheduling and the trace is set for this event. Furthermore, the trace must be active.

- Message tag: CMD_TSYS_SHOWPRIO

```
Messageclass        :XMK_MICRO_TRACER
Meaning               :Trace of system event : change priority
level
Sent when           :When changing to another prioritylevel
Direction           :T->H
Typedefinition      :xmk_T_CMD_TSYS_SHOWPRIO
Conditional compile:XMK_ADD_TSHOWPRIO
```

Message description: The message is sent when the Cmicro Kernel schedules from one priority level to another and the trace is set for this event. Furthermore, the trace must be active.

- Message tag: CMD_TBETWEEN_SYMBOL

```
Messageclass        :XMK_MICRO_TRACER
Meaning             :Another symbol than input is executed
Sent when           :Another symbol than input is executed
Direction           :T->H
Typedefinition      :xmk_T_CMD_TBETWEEN_SYMBOL
Conditional compile:XMK_ADD_SDLE_TRACE
```

Message description: With this command the process ID of the current executed process is sent and a system wide unique identifier. The SDL Target Tester can force the SDL Editor to highlight the current SDL symbol.

- Message tag: CMD_TAT_FIRST_SYMBOL

```
Messageclass        :XMK_MICRO_TRACER
Meaning             :An Input symbol has bee executed
Sent when           :An Input symbol is executed
Direction           :T->H
Typedefinition      :xmk_T_CMD_TAT_FIRST_SYMBOL
Conditional compile:XMK_ADD_SDLE_TRACE
```

Message description: Similar like CMD_TBETWEEN_SYMBOLS the currently executed SDL input symbol will be highlighted in the SDL Editor.

Formats Concerning the Cmicro Recorder

All messages belonging to the Cmicro Recorder are part of the message class XMK_MICRO_RECORDER (F2h).

- Message tag: CMD_RECORD_COUNT_IND

```
Messageclass        :XMK_MICRO_RECORDER
Meaning             :Show recorded event counter to host
Sent when           :When ENV->SDL stimuli detected
Direction           :T->H
Typedefinition      :xmk_CMD_RECORD_COUNT_IND
Conditional compile:XMK_ADD_MICRO_RECORDER
```

Message description: The message is sent when the Cmicro Recorder is active and is in record mode. It is sent together with, but always before CMD_RECORD_OUTPUT_ENV2SDL.

- Message tag: CMD_RECORD_OUTPUT_ENV2SDL

```
Messageclass        :XMK_MICRO_RECORDER
Meaning             :Indicate stimuli ENV->SDL to host
Sent when           :When ENV->SDL stimuli detected
Direction           :T->H
Typedefinition      :xmk_T_CMD_RECORD_OUTPUT_ENV2SDL
Conditional compile:XMK_ADD_MICRO_RECORDER
```

Message description: The message is sent when the Cmicro Recorder is active and is in record mode. It is sent after CMD_RECORD_COUNT_IND.

- Message tag: CMD_RECORD_OUTPUT_SDL2ENV

```
Messageclass        :XMK_MICRO_RECORDER
Meaning             :unused
Sent when           :-
Direction           :T->H
Typedefinition      :-
Conditional compile:XMK_ADD_MICRO_RECORDER
```

Message description: This message is currently unused and is never sent.

- Message tag: CMD_PLAY_SECTION_REQ

```
Messageclass        :XMK_MICRO_RECORDER
Meaning             :Request next sections from host
Sent when           :When current cnt reaches debit cnt
Direction           :H->T
Typedefinition      :-
Conditional compile:XMK_ADD_MICRO_RECORDER
```

Message description: The message is sent when the Cmicro Recorder is active and is in play mode. It is sent if the target has to put in the next stimuli (an environment signal).

- Message tag: CMD_PLAY_COUNT

```
Messageclass       :XMK_MICRO_RECORDER
Meaning            :Transfer Debitcounter to target
Sent when          :When target requests next sections
Direction          :H->T
Typedefinition     :xmk_T_CMD_PLAY_COUNT
Conditional compile:XMK_ADD_MICRO_RECORDER
```

Message description: The message is sent when the Cmicro Recorder is active and is in play mode. It is sent if the target requests the next stimuli (an environment signal). It is also sent in the initialization phase of the play mode. Outside the initialization phase, it is always sent together with, but after `CMD_PLAY_OUTPUT_ENV2SDL`.

- Message tag: CMD_PLAY_OUTPUT_ENV2SDL

```
Messageclass       :XMK_MICRO_RECORDER
Meaning            :Transfer stimuli ENV->SDL to target
Sent when          :When target requests next sections
Direction          :H->T
Typedefinition     :xmk_T_CMD_PLAY_OUTPUT_ENV2SDL
Conditional compile:XMK_ADD_MICRO_RECORDER
```

Message description: The message is sent when the Cmicro Recorder is active and is in play mode. It is sent together with `CMD_PLAY_COUNT` but always before `CMD_PLAY_COUNT` if the target request the next stimuli (an environment signal).

- Message tag: CMD_PLAY_OUTPUT_SDL2ENV

```
Messageclass       :XMK_MICRO_RECORDER
Meaning            :unused
Sent when          :-
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_MICRO_RECORDER
```

Message description: This message is currently unused and is never sent.

- Message tag: CMD_RECORDER_OFF

```
Messageclass       :XMK_MICRO_RECORDER
Meaning            :Switch off recorder
Sent when          :When at end of replay session detected
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_MICRO_RECORDER
```

Message description: This message is sent if the host detected an end of file after the target has requested the next stimuli (an environ-

ment signal). It switches the Cmicro Recorder within the target off and execution returns from simulation to real-time.

Formats Concerning the Command and Debug Interface

All messages belonging to the Cmicro Commands are part of the message class `XMK_MICRO_COMMAND (F0h)`.

- Message tag: CMD_SUSPEND_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Suspend Cmicro Kernel
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CSUSPEND
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_RESUME_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Resume  Cmicro Kernel
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CRESUME
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_SYSTEM_REINIT_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Reinitialize SDL system
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CREINIT
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_SYSTEM_SHUTDOWN_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Shutdown SDL system
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CSHUTDOWN
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_SINGLE_STEP_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Go into single step
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CSINGLE_STEP
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_DISABLE_TIMER_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Disable processing of timers
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CDISABLE_TIMER
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_ENABLE_TIMER_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Enable processing of timers
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CENABLE_TIMER
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_NEXT_STEP_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Execute next step
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CNEXT_STEP
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_SYSTEM_CONTINUE_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Continue system, if halted
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CCONTINUE
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_SET_BREAKPOINT_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Set breakpoint
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T__CMD_SET_BREAKPOINT_REQ
Conditional compile:XMK_ADD_CBREAK_LOGIC
```

Message description: This message is send if the user typed in the appropriate command.

- Message tag: CMD_BREAK_INPUT_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Set breakpoint on SDL input
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_BREAK_INPUT_REQ
Conditional compile:XMK_ADD_CBREAK_LOGIC
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_BREAK_STATE_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Set breakpoint on nextstate
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_BREAK_STATE_REQ
Conditional compile:XMK_ADD_CBREAK_STATE
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_CLEAR_BREAKPOINT_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Clear specified breakpoint from list
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_CLEAR_BREAKPOINT_REQ
Conditional compile:XMK_ADD_CBREAK_LOGIC
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_CLEAR_ALL_BREAKPOINT_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Clear all breakpoints
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CBREAK_LOGIC
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_QUERY_BREAKPOINT_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Query the breakpoint list
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CBREAK_LOGIC
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_QUERY_ERROR_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Query last error occured in system
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CQUERY_ERROR
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_NEXT_STATE_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Modify processstate to value
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_NEXT_STATE_REQ
Conditional compile:XMK_ADD_CNEXTSTATE
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_CREATE_PROCESS_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Create SDL process
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_CREATE_PROCESS_REQ
Conditional compile:XMK_ADD_CCREATE_PROCESS
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_TBUF_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Query Tracebuffer
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CTBUF
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_KILL_PROCESS_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Kill process
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_KILL_PROCESS_REQ
Conditional compile:XMK_USE_CMD_KILL&XMK_ADD_CKILL_PROCESS
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_PCO_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Define PCO
Sent when          :unused
Direction          :H->T
Typedefinition     :-
Conditional compile:-
```

  Message description: This message is currently not implemented and is never sent.

- Message tag: CMD_QUERY_PROCESS_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Query process state
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_QUERY_PROCESS_REQ
Conditional compile:XMK_ADD_CQUERY_PROCESS
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_QUERY_QUEUE_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Query all queues
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CQUERY_QUEUE
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_RMQUEUE_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Flush all queues
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CRM_QUEUE
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_SET_TIMER_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Set SDL timer
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_SET_TIMER_REQ
Conditional compile:XMK_ADD_CSET_TIMER
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_RESET_TIMER_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Reset SDL timer
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_RESET_TIMER_REQ
Conditional compile:XMK_ADD_CRESET_TIMER
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_QUERY_TIMER_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Query timertables
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:XMK_ADD_CQUERY_TIMER
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_ACTIVE_TIMER_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Query, if timer active
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_ACTIVE_TIMER_REQ
Conditional compile:XMK_ADD_CACTIVE_TIMER
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_FLUSH_SIGNAL_BY_SID_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Flush signals with given ID
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_FLUSH_SIGNAL_BY_SID_REQ
Conditional compile:XMK_ADD_CFLUSH_SIGNAL_BY_SID
```

  Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_FLUSH_SIGNALS_BY_PID_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Flush signals of process
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_FLUSH_SIGNALS_BY_PID_REQ
Conditional compile:XMK_ADD_CFLUSH_SIGNALS_BY_PID
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_RESET_ALL_TIMERS_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Reset all timers
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_RESET_ALL_TIMERS_REQ
Conditional compile:XMK_ADD_CRESET_ALL_TIMERS
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_SCALE_TIMER_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Scale timers
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_SCALE_TIMER_REQ
Conditional compile:XMK_ADD_CSCALE_TIMER
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_START_SDL_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Starts the SDL system
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_START_SDL_REQ
Conditional compile:-
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_OUTPUT_TO_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Sends a signal from the environment
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_OUTPUT_TO_REQ
Conditional compile:-
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_OUTPUT_INTERNAL_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Sends an internal signal
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:-
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_GET_CONFIG_REQ

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Gets the target's configuration
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:-
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_REC_OFF

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Switch recorder off
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:-
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_REC_PLAY

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Switch recorder to play mode
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:-
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_REC_RECORD

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Switch recorder to record mode
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:-
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_TRACE_ON

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Switch trace on in general
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:-
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_TRACE_OFF

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Switch trace off in general
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :-
Conditional compile:-
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_TRACE_PROCESS

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Modify traceoptions for process
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_TRACE_PROCESS
Conditional compile:-
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_TRACE_SIGNAL

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Modify traceoptions for signal
Sent when          :User typed in command
Direction          :H->T
Typedefinition     :xmk_T_CMD_TRACE_SIGNAL
Conditional compile:-
```

Message description: This message is sent if the user typed in the appropriate command.

- Message tag: CMD_BREAK_HIT_IND

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Indicate breakpoint hit to host
Sent when          :Breakpoint hit in target
Direction          :T->H
Typedefinition     :xmk_T_CMD_BREAK_HIT_IND
Conditional compile:XMK_ADD_CBREAK_LOGIC
```

  Message description: This message is sent if one of the breakpoints defined in the breaklist has been hit. The SDL system is halted and waits on the next commands from that point on.

- Message tag: CMD_ERROR_CNF

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Negative acknowledge on command
Sent when          :A command couldn't be executed
Direction          :T->H
Typedefinition     :-
Conditional compile:-
```

  Message description: This message is sent if the target was not able to respond to a command from the user.

- Message tag: CMD_TBUF_CNF

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Indicate Tracebuffercontents
Sent when          :Response to user command
Direction          :T->H
Typedefinition     :-
Conditional compile:-
```

  Message description: This message is currently not implemented and will never be sent.

- Message tag: CMD_OKAY_CNF

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Command acknowledge
Sent when          :Command correctly executed
Direction          :T->H
Typedefinition     :-
Conditional compile:unconditional
```

  Message description: This message is sent from target to host as a response for all commands which do not carry parameters of any kind. It is used within the host library as a general confirmation of most messages.

- Message tag: CMD_QUERY_PROCESS_CNF

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Indicate process state
Sent when          :Response to user command
Direction          :T->H
Typedefinition     :xmk_T_CMD_QUERY_PROCESS_CNF
Conditional compile:XMK_ADD_CQUERY_PROCESS
```

  Message description: This message is sent as a reaction to the message CMD_QUERY_PROCESS_REQ. It carries information about the process state.

- Message tag: CMD_QUERY_QUEUE_CNF

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Indicate queue states
Sent when          :Response to user command
Direction          :T->H
Typedefinition     :xmk_T_CMD_QUERY_QUEUE_CNF
Conditional compile:XMK_ADD_CQUERY_QUEUE
```

  Message description: This message is sent as a reaction to the message CMD_QUERY_QUEUE_REQ. It carries information about the queue state.

- Message tag: CMD_QUERY_TIMER_CNF

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Indicate timer table
Sent when          :Response to user command
Direction          :T->H
Typedefinition     :xmk_T_CMD_QUERY_TIMER_CNF
Conditional compile:XMK_ADD_CQUERY_TIMER
```

  Message description: This message is sent as a reaction to the message CMD_QUERY_TIMER_REQ. It carries information about the timer tables.

- Message tag: CMD_ACTIVE_TIMER_CNF

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Indicate, if timer is active
Sent when          :Response to user command
Direction          :T->H
Typedefinition     :xmk_T_CMD_ACTIVE_TIMER_CNF
Conditional compile:XMK_ADD_CACTIVE_TIMER
```

  Message description: This message is sent as a reaction to the message CMD_ACTIVE_PROCESS_REQ. It carries information about the state of a timer according to SDL semantics.

- Message tag: CMD_QUERY_BREAKPOINT_CNF

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Indicate breaklist to host
Sent when          :Response to user command
Direction          :T->H
Typedefinition     :xmk_T_CMD_QUERY_BREAKPOINT_CNF
Conditional compile:-
```

  Message description: This message is sent as a reaction to the command CMD_QUERY_BREAKPOINT_REQ. It carries the breaklist from target to host.

- Message tag: CMD_QUERY_ERROR_CNF

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Indicate last error occured
Sent when          :Response to user command
Direction          :T->H
Typedefinition     :xmk_T_CMD_QUERY_ERROR_CNF
Conditional compile:-
```

  Message description: This message is sent as a reaction to the message CMD_QUERY_ERROR_REQ. It carries information about the last error which has occurred in the target.

- Message tag: CMD_START_SDL_IND

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Indicate ready for configuration
Sent when          :Response to user command
Direction          :T->H
Typedefinition     :-
Conditional compile:-
```

  Message description: This message is sent when the target is ready for configuration from the host. In this state the target's SDL system is not initialized.

- Message tag: CMD_START_SDL_CNF

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Confirm SDL system start
Sent when          :Response to user command
Direction          :T->H
Typedefinition     :-
Conditional compile:-
```

  Message description: This message is sent as a reaction to the message CMD_START_SDL_REQ.

- Message tag: CMD_GET_CONFIG_IND

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :Send target's configuration
Sent when          :Automatic at startup
Direction          :T->H
Typedefinition     :xmk_GET_CONFIG_IND
Conditional compile:-
```

Message description: This is the second message which shows the target configuration. This means the scaling configuration (`ml_mcf.h`) as well as run-time configuration.

- Message tag: CMD_GET_DATA_CONFIG_IND

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :see description below
Sent when          :Automatic at startup
Direction          :T->H
Typedefinition     :xmk_GET_DATA_CONFIG_IND
Conditional compile:XMK_USE_AUTO_MCOD
```

Message description: This is the first message which indicates the target's length, alignment and endians of the basic c-data types.

- Message tag: CMD_GET_CONFIG_CNF

```
Messageclass       :XMK_MICRO_COMMAND
Meaning            :
Sent when          :Response to user command
Direction          :T->H
Typedefinition     :xmk_T_CMD_GET_CONFIG_CNF
Conditional compile:-
```

Message description: This message is the reply message to the host's `CMD_GET_CONFIG_REQ`. It sends the same information as `CMD_GET_CONFIG_IND`.

Used Default Protocol

The data link part of the communications link is represented by the data link module and the coder module. The coder module ensures that each data link frame is encoded / decoded according to definitions of the default protocol.

- The protocol delivered with the Cmicro Package is easy to modify.
- It allows transfer of all the data necessary for each part of the SDL Target Tester
- It allows the transfer of user defined data to be integrated.
- No handshake procedure or retransmission request is implemented

Each frame of the Cmicro Protocol is seen from the physical layer as binary data.

Each frame consists of the following items:

- **`Message Class`**
  Used to classify the information (is it SDL Target Tester or User de-

fined data?). The codes F3h to FFh are free to use by the user, the other ones are reserved for the SDL Target Tester.

- **Message Tag**
  Used to differentiate the different information either of the SDL Target Tester or the user defined data. For user defined data, the message tag is free to use. If more than 255 bytes are to be transferred, the most significant bit of the message tag is set, otherwise it is cleared. This means there are up to 128 free values for the message tag.

- **SYNC**
  Fixed marker 0xaa is used to check if the receiver is synchronized with the sender. This is to detect problems in the start-up phase of host and target. This field of the message header is used in combination with the message class (>= F0h) to re-synchronize the data stream in the host's data link layer (sdtgate).

- **Message Length**
  Used to store the information about how many bytes are to follow after the length information, excluding the CRC information. The message length is normally encoded in one octet, which means the following data has a maximum length of 255 octets. If there is more data the most significant bit of the message tag is used to indicate that the message length exceeds 255 octets. In that case the message length is encoded in 2 octets which makes it possible to transfer 65536 octets of data.

- **Data**
  Free formatted data (user data or data for the SDL Target Tester).

- **Checksum**
  Used to check if the frame is OK on the receiving site. The checksum is built beginning from tag1 to the last data byte by a modulo-8 operation. The sync byte is included in the CRC.

The following is an example of a coded Cmicro Protocol frame for a MS DOS PC, where the message tag is coded as `CMD_TSTATIC_CREATE`. Note this is only an example and the real coding may be different.

Example 624: Coding for MS-DOS PC ----------

Message-class	Message-tag	SYNC	Message-length	-any kind of data-	Checksum
0xF1	0x06	0xAA	0x02		0x??

The functions described in "The API on Target" on page 3679 can be used to encode / decode these frames.

The Communications Link's Target Site

The Data Link Layer

General

The data link of the communications link usually handles the separately message transfer of information from host and to host.

The data link uses the services and functions of the physical layer in order to transmit and receive information.

The data link offers functionality that makes it possible to send and to receive messages via the physical layer assigned to the data link. This functionality can be used by all programs (if implemented so). Mainly it is the SDL Target Tester which uses the data link layer services in order to send and to receive messages. But the users may want to send and receive messages, too. This is possible by using the data link layer functions and by regarding the defined protocol used for each message.

The data link layer offers the following functionality:

- Receive a message from any part of the system like kernel SDL processes or user defined C functions.
- Store messages in a buffer.
- If the physical layer is ready with the transfer of the last message, send the next message to the physical layer.
- If the physical layer indicates a complete message, store it into the receiving buffer.

- Deliver the messages, which have been stored within the receiving buffer to the requesting program parts.
- Poll the physical layer.
- Handle both directions in parallel.
- CRC procedures (if necessary).

The data link layer is represented by the following functions, which are exported by the data link (`mg_dl`) module.

Data Link Functions Used by SDL Target Tester

The SDL Target Tester's target library uses the following C functions of the link and buffering file `mg_dl.c`. The body of each C function may be rewritten according to the users needs.

`xmk_DLInit`	Initialization of data link
`xmk_DLQuery`	Polling the receiver of data link
`xmk_DLRead`	Reading a message from data link
`xmk_DLWrite`	Writing a message to data link
`xmk_DLDeinit`	Deinitialization of data link

These functions are fixed into the SDL Target Tester's data link layer and they handle the mapping and the access to the physical layer.

The Physical Layer

General

Any type of physical communications link can be used to connect host and target, e.g. it could be a V.24, a TCP/IP or a IEEE 488 interface or it could be any other serial or parallel interface.

The physical layer of the communications link normally handles the byte-wise transfer of messages from host to target and the other way around.

It uses the services of the underlaying hardware like interrupts, CPU registers or memory mapped I/O.

The physical layer offers functionality to the data link layer in order to make it possible to transfer any kind of information, including SDL Target Tester data and / or user data.

The physical layer offers the following functionality:

- Receive a buffer which is to be transferred from the data link layer.
- Send this buffer byte-wise via special hardware (or OS - system call) to the receiving system (either host or target).
- If all characters of this buffer have been transmitted, request next buffer.
- Receive characters from the sending system via special hardware (or OS - system call).
- Collect characters until a message is complete; characters are stored within a temporary buffer.
- If message is complete in temporary buffer, transfer it to the data link layer.
- Handle both directions simultaneously.
- CRC procedures (if necessary).

Physical Layer Functions Used by the Data Link Layer (Default)

As described above the data link layer of the SDL Target Tester's target library is shown in the files `mt_cod.c` and `mg_dl.c`. Please note that `mg_dl.c` is only a template with a default implementation for the connection between data link and physical layer.

Distributed with the SDL Target Tester's target library, there are several template files for the physical layer (TCP/IP and V.24 interfaces) contained in the `cmicro/template/commlink` directory in the installation directory. These template files are tested only for the specific hardware in the Cmicro Package test environments. An error free compilation or execution cannot be guaranteed for the user's target hardware.

There are physical layer templates for the following target hardware:

- Intel 8051 derivatives -> 8051_v24.[ch]
  Franklin/Keil C51 and IAR C51 compilers

- Siemens 80C166 -> 80166v24.[ch]
  BSO/Tasking 80C166 compiler
- MS Windows NT/95 -> win32v24.[ch]
  Microsoft VC++ 6.00
- MS Windows NT/95 -> win_sock.[ch]
  Microsoft VC++ 6.00
- SunOS 5.x -> ux_sock.[ch]
  GNU gcc, Sun WorkShop compilers CC and cc

For use in the target executable, one of the modules listed above is automatically included in `mg_dl.c`. Which physical layer module is included depends on the compiler selected and the flags set in `ml_mcf.h` (e.g. `XMK_USE_V24 or XMK_USE_SOCKETS`).

The template module `mg_dl.c` works as follows:

The function `xmk_DLInit` initializes the buffers used for the data link and calls the initialization of the physical layer (by default this is `xmk_V24Init`).

`xmk_DLDeinit` is the counterpart of `xmk_DLInit` and frees the interface device. This function is normally empty in microcontroller applications but has to be used on PCs, under Microsoft Windows or UNIX.

`xmk_DLWrite` is called when a complete frame should be sent to the host. There are two ways the connection to the physical layer can be handled.

1. Blocked

   If a frame is to be sent it is necessary that the previous frame has already been completely sent. If not, the data link has to wait until the previous frame is sent. See the module `mg_dl.c` (for the compilers KEIL_C51 and IARC51) to get an idea of this connection.

2. Unblocked

   If the frame should be sent, it is handed over to a ring buffer. Although the previous frame has not been sent completely, SDL can execute because the data link does not have to wait.

   One exception must be mentioned: If the transmitter's ring buffer (used for V.24 communication) is full (macro

XMK_MAX_SEND_ENTRIES) the data link will still have to wait here. Also the size allowed for the ring buffer's entries must be great enough (to verify this see the macro XMK_MAX_SEND_ONE_ENTRY.

xmk_DLRead will be polled with each cycle of the SDL loop xmk_RunSDL (see module mk_main.c). If the transmitter and the receiver of the physical layer are not implemented as interrupt service routines (which is strongly recommended) the transmit and receive functions have to be called here (xmk_V24Receive and xmk_V24Send for the distributed V.24 templates). In addition for the V.24 interface the XON handshake has to be called here doing xmk_V24Handshake.

As in xmk_DLWrite there are two ways the receiver buffers can be handled in xmk_DLRead. It is also possible to use a ring buffer for the receiver's side. Similar as in xmk_DLWrite it is necessary to fill the macros XMK_MAX_RECEIVE_ONE_ENTRY and XMK_MAX_RECEIVE_ENTRIES with useful values.

Steps to Implement a Communications Link

Extension to the Template Makefile

In the distribution of the Cmicro Package there are several template makefiles.

On UNIX the existing makefile templates are called makeoptions.no_tester and makeoptions.with_tester.

In Windows the existing makefile templates are called makeno_t.opt and makew_t.opt.

The intention is to give one template makefile where the SDL Target Tester is not included (which means that there is no compilation of any SDL Target Tester C code), and to give one template makefile including the SDL Target Tester.

In the template makefiles that include the SDL Target Tester, it is necessary to define the communications link software by adding the name of the C module(s) that contain(s) this. This can be achieved by changing the list of the object files given in sctLINKTARGET_WITH_TESTER (e.g. 8051_v24.suffix). In addition, the compilation rules for this/these additional module(s) must be specified as well in the makefile.

Finally, the makefile name must be changed into `makeoptions` on **UNIX**, and into `make.opt` in **Windows**.

> **Note:**
>
> The `makeoptions` and `make.opt` files below the predefined kernel directories in `<sdtdir>/SCMA*` are not intended to be used for target or target debug applications.

Adapting the Data Link Layer

The data link layer for the SDL Target Tester on target site is represented by the module `dl.c` with the functions

- `xmk_DLInit()`
- `xmk_DLRead()`
- `xmk_DLWrite()`
- `xmk_DLQuery()`
- `xmk_DLDeinit()`

Several ways to fill these functions are already given in `mg_dl.c`.

The data link layer can be build using a ring buffer for all the trace message or writing each message directly to the physical layer.

Furthermore the data link layer must be build to work together with the physical layers (E.g. ISR driven or not).

It is recommended to have a look into the distributed template `mg_dl.c` which shows different ways.

- For using the ring buffer, please follow the flag `TCC80166`.
- For using no ring buffer, please follow the flags `IARC51` or `KEIL_C51`.
- For using an ISR driven physical layer, please follow the flags `IARC51` and `KEIL_C51`.
- For using a not ISR driven physical layer, please follow the flag `TCC80166`.

Adapting the Physical Layer

There are given tested physical layers for the micro controllers 8051 and 80166.

The structure of these physical layers should be taken and filled with the functions for the needed communications link. E.g. the function to write to a serial interface must be replaced by a function to write to an Ethernet interface.

The Communications Link's Host Site

The sdtgate is one executable of the SDL Target Tester's tool chain on host site. It is built to simplify the communication between the host and the target.

In this release of the SDL Target Tester, the sdtgate is built using a V.24 interface and the sockgate is build using a TCP/IP interface. But as you can see in this subsection, it will be very simple to implement any other communication interface as a new executable.

Communication between the SDL Target Tester Executables

The SDL Target Tester executables `sdtmtui`, `sdtmt` and `sdtgate` communicate with the help of the Cmicro Postmaster. The Cmicro Postmaster handles all the communication between the SDL Target Tester tool chain and is started automatically when the SDL Target Tester is invoked.

The Default V.24 Connection: Sdtgate

Fork Parameters for the Sdtgate

There are two groups of fork parameters handed over to the sdtgate.

The Sdtgate Device Specifications

Inside the SDL Target Tester configuration file `sdtmt.opt` there are 7 entries for the gateway executable.

Example 625: On UNIX

```
USE_GATE              <pathname>/sdtgate
GATE_CHAR_PARAM_1     /dev/ttya
GATE_CHAR_PARAM_2     0
GATE_CHAR_PARAM_3     0
GATE_INT_PARAM_1      9600
GATE_INT_PARAM_2      0
GATE_INT_PARAM_3      0
```

On UNIX, it muse be ensured that the device (`/dev/ttya` above) is accessible. Ask the system administrator if there are problems to open this device.

Example 626: In Windows

```
USE_GATE              <pathname>/sdtgate.exe
GATE_CHAR_PARAM_1     COM2
GATE_CHAR_PARAM_2     0
GATE_CHAR_PARAM_3     0
GATE_INT_PARAM_1      9600
GATE_INT_PARAM_2      0
GATE_INT_PARAM_3      0
```

USE_GATE gives the name of the used gate only.

Inside the delivered sdtgate for V.24 interface only the GATE_CHAR_PARAM_1 (a string) and the GATE_INT_PARAM_1 (an integer) are used. For future developments there are 2 further string parameters and two further integer parameters which are handed over when forking the gate.

The delivered version of the sdtgate uses fixed values for parity, start bits, stop bits...

These are: databits = 8, startbits = 1, stopbits = 1, parity = none

Coding Rules

There are two coding rule pieces of information the gate needs to work.

These are the length of a character on the target in octets (normally 1) and the position of the character. This value is necessary for special micro controller memory layouts e.g. the MSP58C80 gets the character length of 2 octets but the used character is the lower octet only. In this case the character position is 1. Normally if the character size is 1 the character position is 0.

The TCP/IP Connection: Sockgate

The Sockgate Device Specifications

Like the sdtgate, the sockgate is using only 3 of the 7 entries for the gateway executable inside the SDL Target Tester configuration file `sdtmt.opt`.

Example 627: ----------

```
USE_GATE              <pathname>/sockgate
GATE_CHAR_PARAM_1     207.46.138.0
GATE_CHAR_PARAM_2     0
GATE_CHAR_PARAM_3     0
GATE_INT_PARAM_1      9000
GATE_INT_PARAM_2      0
GATE_INT_PARAM_3      0
```

USE_GATE gives the name of the used gate only.

It must be ensured that the IP-address (`207.46.138.0` above) is accessible.

Inside the delivered sockgate only the `GATE_CHAR_PARAM_1` (a string) and the `GATE_INT_PARAM_1` (an integer) are used. The delivered version of the sockgate uses an address string (a valid IP-address) and a port number (valid between 1 and 65535).

Building an Custom Made Communications Link

All the C files and libraries necessary to re-build the default gateway sdtgate are delivered with the SDL Target Tester. The files for a custom built gateway are named usergate to distinguish between the custom and the delivered sdt- and sockgate.

The Modules Building a Usergate

The following files are part of the usergate:

```
cmicro
   + sdtmpm
   |    + sunos5
   |    |    + sdtmlib.a (SunOS 5 version)
   |    + wini386
   |         + sdtmpmcl.lib (Microsoft C++ 6.0 version)
   |         + sdtmpmcl5.lib (Microsoft C++ 5.0 version)
   + mcod
   |    + mcodfnc.[ch]pp
   |    + mcodlib.[ch]pp
   |    + mcod.h
   + sdtgate
   |    + mg_ctrl.[ch]
   |    + usergate.rc (Windows only)
   |    + sunos5
   |    |    + usergate.[ch] (SunOS 5 version)
   |    + wini386
   |         + usergate.[ch] (Windows version)
   + template
        + mg_dl.[ch]
        + commlink
             + <interface>.[ch]
```

Files with suffix `.h` and `.hpp` are not listed but are still being used.

<interface> stands for the selected interface type.

On UNIX the module `ux_v24.c` is used (`ux_sock.c` for sockets).

In Windows the module `win32v24.c` is used (`win_sock.c` for sockets).

The purpose of each module is as follows:

- `mcodfnc.cpp`

  This module delivers all functions to decode and encode the messages sent between the different executables of the SDL Target Tester tool chain. All functions are contained within a C++ class called ClassHostMessage.

  As these functions have to be suitable for the executables sdtmt and sdtmtui, no changes need be made by the user.

- mcodlib.cpp

  This module is automatically generated by the Message Coding Generator (MCOD) and delivers a decode or encode strategy for each message that can be exchanged between the parts of the SDL Target Tester tool chain.

  No modifications can be done inside this module.

- mcod.h

Like `mcodlib.cpp` this file is generated by MCOD too. It contains all MessageTags for the communication between sdtmtui, sdtmt and sdtgate and no modifications are to be done here.

- mg_ctrl.c

  In this module the reactions of the messages exchanged between the SDL Target Tester tool chain are invoked. Like `mcodlib.cpp` and `mcodfnc.cpp` there is no need to make any modification inside this module because the communication between the different parts of the tool chain depends on it.

- usergate.rc **(Windows only)**

  This resource file is for use in MS Windows executables only. It just needs to be compiled and to be linked together with the other object files.

- usergate.c

  This file handles all the initialization and communication of the sdtgate with the Cmicro Postmaster.

  This file is platform specific and needs to be modified in some cases, e.g. when using the V.24 or socket interface on MS Windows a Windows Message is generated when a character is received or completely sent. The reaction on the WM_COMMNOTIFY message can be removed here if another interface is used.

- sdtmlib.a/sdtmpmbc.lib/sdtmpmcl.lib

  This library presents the connection to the Cmicro Postmaster.

- <Interface>.c

  The last of the listed files needs some modifications if the communication interface is to be changed.

  There are eight functions inside this module

  – `xmk_V24Init`() and `xmk_SocketInit()`
  These functions are called only once after the sdtgate has been forked. All initialization of the communication device have to be done here.

Errors should be given as plain text and will be sent to the user interface.

- `xmk_V24Deinit()` and `xmk_SocketDeinit()`
  These functions may not need to be filled for the wanted communication interface. If it has to, all deinitialization can be done here. This function is called directly before exiting the gate.

- `xmk_V24Handshake()`
  The V.24 RS-232 protocol describes the use of the XON - XOFF communication. In the SDL Target Tester's host - target communication XON characters sent only every second. If using another communication protocol (like RS-422/RS-485) this function must be left empty.

- **`xmk_V24Receive()`** and `xmk_SocketReceive()`
  This function does several things.
  At first the communication interface is polled and all available characters are taken from the interface. Then the gate checks the received character stream for the correct sync field position, the length field is read and the amount of characters used to build one complete target message is sent to sdtmt, unless there are no complete messages left.
  The re-synchronization of the data stream is also done in this function if the sync field is not in the correct position.

- **`xmk_V24Send()`** and `xmk_SocketSend()`
  If the gate gets a message from sdtmt which is to be transmitted to the target, this function is called.
  There are several ways to transmit the whole message. For instance, on Windows NT it is possible to hand over a character buffer to the serial interface. The rest of the transmission is being done by the interface itself.

- `xmk_ExtractControl()` / `xmk_MaskControl()`
  These two functions are for use with an XON-XOFF protocol. If a message contains an XON or XOFF character, in front of this XON or XOFF an ESC is inserted in `xmk_MaskControl()` to differ this (XON/XOFF-) character from the control XON/XOFF.
  On the other hand if a message containing XON/XOFF characters is received, the function `xmk_ExtractControl()` removes all ESC from the data stream.

These functions are called from `xmk_V24Send()` and `xmk_V24Receive()` only and the function calls should be removed if the new communication interface does not support the XON-XOFF protocol.

Compiler Settings

- **On UNIX:**

  The following defines have to be made. The user can use the makefile `makefile.template` in the directory `$sdtdir/cmicro/sdtgate` as a template to compile and link his own gateway.

  - `_GCC_`
  - `XMK_UNIX`
  - `SDTGATE`
  - `XMK_USE_V24` (for the default gateway sdtgate)
  - `XMK_USE_SOCKETS` (for the socket gateway)

- **In Windows:**

  The source code for the sdtgate is tested only in combination with the Microsoft C++ compiler 6.x on a Microsoft Windows installation.

  The following defines have to be made.

  - `MICROSOFT_C`
  - `XMK_WINDOWS`
  - `SDTGATE`
  - `XMK_USE_V24` (for the default gateway sdtgate)
  - `XMK_USE_SOCKETS` (for the socket gateway)

Current Restrictions for Communications Link Software

SDL Restrictions

It is impossible to transfer pointer values via the communications link. An example may be the SDL predefined sort charstring which is by default implemented as a pointer in C.

To avoid problems, users must not use SDL sorts that are implemented as pointers (like charstring), whenever it is required to send / receive them via the communications link (e.g. Cmicro Tracer or Cmicro Re-

corder functionality). This means, that this kind of sorts should only be used in signals inside the SDL system but not at it's environment.

Message Length

The maximum length of the message length is restricted.

An explanation follows:

Each message is transferred as:

```
Header + Data + CRC
```

The length field contained in the header may represent the values from 0 to 255. If the MSB in the message tag is set to "1", then the length field is expected to be a 2 octet values, which makes it possible to represent the value from 256 to 65535.

However, the length field consisting of 2 octets is currently not implemented.

In fact, no message may be greater than 4 + 255 + 1 = 260 characters in total (1 character normally is equal to 1 Byte, which consists of 8 Bits).

Connection of a Newly Implemented Communications Link

The SDL Target Tester uses only a few C function calls in order to send and receive information via the communications link. From the C syntax point of view, users only have to implement the body of these functions and to link them together with the SDL Target Tester's target library into one executable program.

However, when considering timing constraints, critical paths, interrupts and similar things, users have to note the following.

Critical Paths

Critical paths occur in any type of software which uses interrupts. Especially the transfer of information between ordinary C code and interrupt service routines must be considered, e.g. for the communication from the physical layer (which may be implemented as an ISR) to the data link layer (which may be implemented as ordinary C functions).

Critical paths may occur at any place in the software which accesses global C variables.

The beginning of each critical path must be blocked with something like “disable interrupts” (see `XMK_BEGIN_CRITICAL_PATH` in the compiler section of `ml_typ.h`). The end of a critical path must be released with something like “enable interrupts” (see `XMK_END_CRITICAL_PATH`).

Timing Constraints

Often there are timing constraints to be considered within the target system. Timing problems must be prevented. Each ISR must be implemented with a few statements only, in order to make the execution time as short as possible.

Interrupts

C functions which should be compiled as ISRs by the C compiler in use are mostly

marked by a preprocessor directive or by a special C compiler keyword. The C compilers reference manual must be consulted in order to implement ISRs.

Open Interface

The open interface can be used to implement user host executables which are able to communicate with the SDL Target Tester at the target site. The SDL Target Tester at the target site is represented by the target library.

Using the Open Interface

In order to use the open interface in this way, the following are of interest:

- Which messages can be sent to the target. This is described within the earlier subsection “Message Formats” on page 3690.
- Which messages are to be expected from the target. This is also described within “Message Formats” on page 3690.
- The format of these messages. Also described within the earlier subsection “Message Formats” on page 3690.

- The situations in which the messages may be sent. Please refer to the subsection "State Machine and Handshake" on page 3689.
- The situations in which a particular message may be received. Again, please refer to "State Machine and Handshake" on page 3689.

It is not of great interest what the format of the data link frames is because it is possible either to use the existing protocol or to re-implement the protocol (e.g. it may be necessary in order to integrate the SDL Target Tester into an existing communication link's software).

The host site must send each message in target representation.

For instance, if the target system uses integers as 2 octet values with the ordering higher octet first, then the host must send an integer value with higher octet and then lower octet, irrespective of its own layout.

For the other direction (reception of messages at host site), the host must also map the information according to the relation between the target memory layout and its own internal representation.

Accessing the Data Link by User

The user can send information via the communication link by calling the C function `xmk_DLWrite` with appropriate parameters. The following example shows one possibility.

Example 628 ----------

```
#define HelloWorldTag <AnyValueAllowed>

char buffer     [20];
char helloworld [15];
int  length     = 0;
int  write_result ;
strcpy (helloworld, 'Hello World');

buffer [0] = 0x11;
length ++;
/* any value for Messageclass, except      */
/* reserved values for SDL Target Teste    */
/* reserved values begin from 250 to 255   */

buffer [1] = HelloWorldTag;
length ++;
/* any value for Messagetag                */
/* Messagetag is made unique together      */
/* with Messageclass, so that no           */
/* conflict occurs.                        */

buffer [2] = strlen (helloworld);
length ++;
/* length of data for this message         */
/* length is given without calculating     */
/* the CRC field                           */

memcpy (buffer [3], helloworld, strlen (helloworld);
length += strlen (helloworld);
/* It is assumed, that no stringterminator */
/* is included in the message (the length  */
/* can be calculated from Messagelength)   */

buffer [length] = xmk_EvalChkSum (buffer, length);
/* Evaluate the checksum of current buffer */

write_result = xmk_DLWrite (buffer, 5 + strlen (helloworld));
/* transmit buffer via communications link */
```

The user can receive information from the communication link by calling the C function `xmk_DLRead` with appropriate parameters.

Example 629: `xmk_RunSDL ()` ----------

The following section is partially implemented within the module `mk_main.c`

```
p_data = xmk_DLRead () ;
if (p_data != (char *) NULL)
{
  /* if anything received, decode it    */
  /* according to Cmicro Protocol       */
  result = xmk_Cod_Decode (p_data,
                           &MessageClass,
                           &Messagetag,
                           &MessageLength,
                           buffer,
                           sizeof (buffer));
if (MessageClass == XMK_MICRO_COMMAND)
{
  result = xmk_HandleCmd ( Messagetag, (xmk_U_CMDS*) buffer );
  return;
}

/*
** Received user message
*/
if (MessageClass != 0xF8)
{
  ErrorHandler (-7777);
  return ;
}

if (HelloWorldTag == Messagetag)
{
  /* HelloWorldTag is used in this example to */
  /* identify the hello world message         */
  /* The user can choose any value for the    */
  /* Message tag                               */
  char helloworld [15];

  memset (helloworld, 0, sizeof (helloworld));
  memcpy (helloworld, buffer, MessageLength);
  printf ('%s', helloworld);
}
```

The above examples assume that the Cmicro protocol (which is described in "Used Default Protocol" on page 3710) is used.

More Technical Descriptions

The File Formats of Sdtmt

General

This section deals with the general file format of the different files which are written to or read by the SDL Target Tester's tool chain. The section is not of general interest, and need be read only when implementing and connecting other tools to the host. The format of the file containing symbols is described in the subsection "The Symbol Tables" on page 3730.

<infile> and <outfile>

Physically, there is the same file format behind the input files and output files written by sdtmt. These files store the information as received via the communications interface in a 1:1 format. The trace of the SDL execution flow and the information from the record mode is simply copied into the file on the hard disk. The same header information is used as on the communications link. This has some advantages.

Without exception the format of the information stored in <infile> or <outfile> is exactly the same as the format of the Cmicro Protocol. Therefore these files are using the memory layout of the target system.

The reason for this is that binary files are always more compact than readable ASCII files.

The message decoder of the host must be active only when information is to be converted, for example if they are to be displayed. This can decrease the performance a little.

The Symbol Tables

The symbol tables which are used by the SDL Target Tester are automatically generated by the Cmicro SDL to C Compiler. Most of the intelligence to interpret SDL traces and recorded events is implemented on the host system. Normally, the host system has enough memory and performance to do the interpretation, whereas the target has not. This is the reason, why the symbol tables used by the Cmicro Package mainly reside on the host. However, some parts of the symbol table reside

where the Cmicro Kernel physically is executed, i.e. within the target system.

The Target Symbol Table

The following table is generated by the Cmicro SDL to C Compiler. For each SDL process, there is one entry in the table representing a pointer to the different trace options for that process.

```
/*****************************************************
**  Symbol trace table
*****************************************************/
#ifdef XMK_ADD_TEST_OPTIONS
XSYMTRACETBL *xSYMTRACETBL[MAX_SDL_PROCESS_TYPES+1] =
{
  (XSYMTRACETBL_ENTRY *)  NULL,
...........
...........
  (XSYMTRACETBL_ENTRY *)  NULL,
  X_END_SYMTRACE_TABLE
};
#endif
```

The Host Symbol Table

Generated File <systemname>.sym

The host symbol table is generated by the Cmicro SDL to C Compiler into a file called `<systemname>.sym`. This file is to be specified when the host site is invoked (see subsection "Invoking the SDL Target Tester's Host" on page 3619).

In the following, the file format is described with EBNF like syntax:

```
SymbolFile          ::= Header SymbolDescriptions
Header              ::= HeaderComment Timestamp
HeaderComment       ::= "Cmicro .sym file, version x.y"
Timestamp           ::= "TIMESTAMP <GenerationTime>"
SymbolDescriptions  ::= ( DescriptionLine ) ...
DescriptionLine     ::= Depth Subject SDTReference
Depth               ::= [0-9]+
Subject             ::=  SYSTEM IDs
                       | BLOCK IDs
                       | SIGNAL IDs
                       | PROCESS IDs
                       | START IDs
                       | INPUT IDs
                       | OUTPUT IDs
                       | NEXTSTATE IDs
                       | <to be continued>
SDTReference        ::= "#SDTREF(<sdt-reference>)" LF
LF                  ::= "\n"
```

In the following an example is given that was produced with a simple "ping pong" SDL system:

Example 630 ----------

```
Cmicro .sym file, version 2.0
TIMESTAMP <GenerationTime>

1 SYSTEM <SystemName>  #SDTREF(sdtref)
2 BLOCK <BlockName>  #SDTREF(sdtref)
3 PROCESS <ProcessName> 0 1  #SDTREF(sdtref)
4 START 0  #SDTREF(sdtref)
4 INPUT 1  #SDTREF(sdtref)
4 INPUT 2  #SDTREF(sdtref)
4 OUTPUT 3  #SDTREF(sdtref)
4 NEXTSTATE State1 1 4  #SDTREF(sdtref)
4 OUTPUT 5  #SDTREF(sdtref)
4 NEXTSTATE - 0 6  #SDTREF(sdtref)
4 TASK 7  #SDTREF(sdtref)
4 STOP 8  #SDTREF(sdtref)
3 PROCESS <ProcessName> 1 1  #SDTREF(sdtref)
4 START 9  #SDTREF(sdtref)
4 INPUT 10  #SDTREF(sdtref)
4 ASSIGNMENT 11  #SDTREF(sdtref)
4 NEXTSTATE State1 1 12  #SDTREF(sdtref)
4 ASSIGNMENT 13  #SDTREF(sdtref)
4 DECISION 14  #SDTREF(sdtref)
4 OUTPUT 15  #SDTREF(sdtref)
4 STOP 16  #SDTREF(sdtref)
4 OUTPUT 17  #SDTREF(sdtref)
4 NEXTSTATE - 0 18  #SDTREF(sdtref)
4 DCL counter Integer  #SDTREF(sdtref)
3 SIGNAL PING 1  #SDTREF(sdtref)
3 SIGNAL PONG 2  #SDTREF(sdtref)
3 SIGNAL PONG_SAY_BYE_BYE 3  #SDTREF(sdtref)
3 SIGNALROUTE SR1  #SDTREF(sdtref)
3 SIGNALROUTE SR2  #SDTREF(sdtref)
```

The first line, `Cmicro .sym file, version x.y`, gives some comment about the Cmicro symbol file version.

The `TIMESTAMP <GenerationTime>` value is used internally for consistency checks with the SDL Target Tester. With this time-stamp, a rough consistency check for the generated files is performed and warning messages are printed out in the case of an inconsistency.

The lines following the time-stamp information, contain in the first position an integer value indicating the depth of the structuring level in which the information is found in SDL. For example, the SDL system is in level 1, a block in the SDL system level is in level 2, and so on.

The next column in these lines describe the subject, e.g. if it is a system, block, channel, signal route, process, procedure, signal, start, input or output, or whatever.

For each subject there are IDs generated, these are used in the target executable program for generating trace information. The IDs begin with

0 (in the case above it is the start symbol of the first process) and end with the number of the last SDL symbol in the system.

The last column in the lines contains a `#SDTREF` reference, which points to the location of the subject in either SDL/GR or SDL/PR.

Internal Symbol Table Structure

The symbols of a trace can be found during the conversion of internal information into a displayable format.

The following three SDL objects are treated:

- Processes
- Signals/Timers
- States

They are handled in the same way. Namely by building a linked list of symbols for processes, a linked list for signals and a linked list for states.

Cmicro Recorder

The information given in the following sections are valid both for host and target and there is no differentiation made between these.

> **Note:**
>
> The SDL Target Tester's Record and Play functions are only available if a Cmicro Recorder license is available.

Type and Amount of Stored Information

As already mentioned in earlier sections, using the Cmicro Recorder makes more sense in those cases where an SDL system is executed in real-time in the target.

That's why the amount of stored information is to be kept very small. Of course, this leads to the problem that not all types of errors can be found with the Cmicro Recorder but there is a good chance to find most of them. The information which the Cmicro Recorder produces at target site and which the Cmicro Recorder uses at host site cannot be configured in their dimension. The packets which are to be transmitted via the communications link are always the same. A technical description follows in the next section.

Record Mode

First, the SDL system executes the start transitions of all statically created processes. At the occurrence of a “counted” symbol, an internal counter variable is incremented (which was set to zero before going into the SDL start-up phase). The counter will simply be incremented until the first environment signal is sent from the environment to a process in the SDL system, or until the first timer expires within the SDL system.

These are special events for the Cmicro Recorder.

In that case, the Cmicro Recorder on the target site sends the following messages to the host:

```
Host <-------- <Counter value> ------------ Target
Host <-------- <Event> --------------------- Target
```

Both messages are stored in the <outfile> on the host.

The counter is reset to zero again and the procedure restarts by counting the “counted” symbols and sending the above messages to the host, either when an environment signal is sent from the environment to a process in the SDL system, or when the first timer expires within the SDL system.

The <outfile> is closed when the user terminates the record mode on the host site, i.e. it is not possible to close the file by ending the record mode on the target site. The record mode can be finished at any time.

After the record mode has been switched off, it is not allowed to switch the record mode or the play mode on again.

The <outfile> on the host now contains messages like this:

```
<trace event 1>
....
<trace event N>
<Counter value>
<Event>
<trace event N+1>
....
<trace event N+1+M>
<Counter value>
<Event>
```

As can be seen, the following sections are stored in the file whereas each section is optional:

```
For all events in the target
            [Store trace section]
            [Store Counter value section]
            [Store Event section]
```

Counted Symbols

The occurrence of the following SDL symbols will be “counted” by an internal counter (a C integer variable):

STATE	The SDL nextstate operation
INPUT	The SDL input operation
SAVE	The SDL save operation
CREATE	The SDL create operation
STOP	The SDL stop operation
STATIC CREATE	Used at system start, appears for each statically created process
DYNAMIC CREATE	Used at start of a dynamically created process
DECISION	SDL decision
TASK	SDL task (not C Code)
OUTPUT	The SDL output operation (see remarks below)
PROCEDURE	SDL procedure call
SET	SDL action: Set timer
RESET	SDL action: Reset timer
DISCARD	SDL Discard
IMPLICIT CONSUMPTION -	SDL implicit transition

A special case is the SDL output operation:

If the output is from one process in the SDL system to another process in the SDL system or if the output is from one SDL process in the SDL system to the environment, the occurrence of this symbol is counted.

Otherwise if the output is from the environment to a process within the SDL system, the event is relevant for the Cmicro Recorder (as the timer expiry is).

C code in an SDL task is normally not counted when recording. The users are free to count C code by calling:

`xmk_Record (CMD_TTASK)` for the record mode and

C code written into an SDL Task (i.e. by using the #CODE directive)

`xmk_Play (CMD_TTASK)` for the play mode.

Play Mode

In play mode, the target accepts signals coming from the SDL environment only from the Cmicro Recorder. These signals are read from the file which was previously written to in record mode.

Caution!

No environment signals may be handled by the user in the C function `xInEnv`! At the beginning of `xInEnv`, there should be a statement like

```
if (xmk_RecorderMode == XMK_RECORDER_PLAY)
   return (XMK_OKAY));
```

In addition, no signal may be sent by any other environment function (like ISRs) to the SDL system.

At the beginning of the play mode, the host reads the first <counter value> from the <infile> and sends it to the target.

```
Host -------- <Counter value> ---------------> Target
```

The meaning of this is: Please execute the amount of “counted” symbols as indicated in the <counter value>. The target executes the start transitions of all statically created processes (start-up-phase). When preemption is used, it is possible that a transition which is not a start transition

is executed. Each “counted” symbol increments a counter value which is compared against the debit, which was indicated by <counter value>.

If the current counter value reaches the debit counter value, then an environment signal (or timer expiry) plus the next <counter value> is requested by the Cmicro Recorder.

```
Host <------- <Request> --------------------- Target
Host ---------------- <Event> --------------> Target
Host -------- <Counter value> --------------> Target
```

If the target has requested the next <Event> and <Counter value>, the target is waiting for these messages only and is not able to handle other messages. This is not a restriction because the environment is disabled in play mode in the target.

If the end of file of <infile> has been reached, the host indicates the end of the play mode to the target. <Counter value> and <event> are always stored together in record mode. Therefore the end of file can only be reached after reading an EnvSig or Timer expiry.

```
Host -------- <Play mode off> --------------> Target
```

Note:

After the play mode has been switched off, it is not allowed to switch the record mode or the play mode on again.

General Restrictions on Record and Play

Of course, there are restrictions in the use of the Cmicro Recorder, especially for the play mode. However, there may be situations where the Cmicro Recorder does not help in finding the source of the problem. The user must decide when the Cmicro Recorder can be properly utilized.

Firstly, the user has to ensure the same configurations are used for hardware and software, in order to allow comparison between the results of a recorded session with the ones of the replayed session. This is only a general recommendation. It is possible that he even would like to compare two different hardware configurations, and the Cmicro Recorder should help him finding the differences between these. As a more general recommendation we would say: Compare only those configurations that are definitely comparable.

Secondly, starting and ending the record and the play mode must be as follows. Host and target are to be synchronized.

Restrictions when Starting Record

The target may not transfer information to the host until the host has become active.

Therefore, the SDL Target Tester's host site should be started first and the file to write in should be opened.

If the target is started (e.g. reset-button), it has to wait on sdtmt before transmitting information (see "XMK_WAIT_ON_HOST" on page 3505).

Restrictions when Ending Record

Ending the record session is to be done from the GUI (sdtmtui) by closing the <outfile>. The user can enter any exit commands at any time. He should pay attention to the exact time when he exits. If exit is performed in the middle of a running SDL transition in the target, then the traces following will not be stored! The last information may then be unpredictable.

Restrictions when Starting Replay

The target may not transfer information to the host, until the host has become active. The host may not transfer information to the target, before the target has become active.

Therefore the SDL Target Tester's host site should be started first and the file containing the recorded session should be opened.

If the target is started (e.g. reset-button) it has to wait for the host before transmitting information.

Restrictions when Terminating Replay

In principle, the play mode reaches the end when the last stimuli stored in the recorded file was read and sent to the target. Actually, the play mode should end when all the transitions which follow that stimuli have ended. This is a discrepancy which is solved as follows:

When the target has received the last stimuli from the recorded session, it enters the "recorder off" mode. The problem with this is, that timers are simulated during the play mode but are no longer simulated if changing to "recorder off" mode. Timers will expire as they have been set and it is the real-time that will be used to allow them expire instead of the simulated timer expiry in the Cmicro Recorder.

Real-time Play Mode

The host tries to replay the SDL environment events at the same absolute time values as they occurred during the record session, if so required by the user (real-time-play is switched on).

Internally, a time stamp is stored for each environment signal, which is compared within the target with the current value of SDL now. SDL now and the time stamps in the signals are calculated with the value 0 from system reset on. The target generates the SDL now values in any case.

Of course, the processing power of host and target together must be large enough to handle this. As a rule of thumb, the recorded environment signals may not be sent to the SDL system more often than one every few hundred microseconds. But that - of course - also depends on the communications link in use.

Restrictions when Using Preemption

There are some restrictions when the Cmicro Recorder is used in combination with preemption. The problem is that in a real-time execution, signals coming from the environment (this may be a hardware interface) can cause a preemption of a running SDL process by a new process with a higher priority. The preemption may occur at any time, which means at any machine instruction (see notes below). On the other hand, only SDL symbols are registered by the Cmicro Recorder.

This means that the play mode may produce a different system behavior other than the recorded one.

The only alternative to implement an exact reproduction of the recorded session would be the use of special debugger hardware (not a general solution).

Some Additional Comments

Real-time behavior cannot be expected in play mode. When considering the other direction, from SDL to the environment, it is not absolutely necessary to cut this connection off (C function `xOutEnv`). It may be a good idea to let this connection be as it is in record mode. For example, if there is a display driver in the environment, which is controlled by SDL, it would then be possible to see the reactions on the display in the same way as they have been observed in record mode.

Utility Functions

File Structure

Description of Files

The modules and functions described in this subsection are used to handle first in-first out buffering, ring buffering, message coding and other possibilities.

ml_buf.c

This module contains functions to handle first-in first-out buffers and ring buffers.

It is mainly used internally by the SDL Target Tester to write and read trace information into/from a first-in first-out buffer within the RAM.

These functions are also free for users.

Three functions are implemented representing the low level functions. Each entry has to be of the same size, because the handling is in principle similar to an array. The type of each entry is not relevant. In addition, the caller of the functions contained in this module defines the memory for the trace buffer as well as a control structure representing all the internal data and variables necessary to administrate the trace buffer.

As a result, users are free to have more than 1 instance of this buffer type.

ml_buf.h

This is the header file containing the external definitions of `ml_buf.c`.

Trouble-Shooting

What to Do if the SDL Editor Trace Does Not Work?

The SDL Target Tester gets the SDL Editor references from the generated file `<systemname>.sym` in the known form `#SDTREF( ... )`.

As it is possible to generate an SDL system and to test it on another platform it is possible that the paths contained in each `#SDTREF()` are not up to date if using the SDL Target Tester.

All the paths in `<systemname>.sym` must simply be updated.

What to Do if There Is a Warning of the Information/Message Decoder?

If the message decoder detects an error there will be a warning like the one shown in Example 631.

Example 631: warning of the message decoder ––––––––––––––––––––––––––––––

```
**WARNING: There is an inconsitency in the information decoder.
This message will be suppressed form now on.
Message Class: 241,d
Message Tag  : 5,d
Number of data bytes received=6
Number od data bytes decoded =5

  ***Received buffer (32 octets):
  ***f1 05 aa 06 00 00 00 00 - 01 04 ab ee ee ee ee ee
  ***ee ee ee ee ee ee ee ee - ee ee ee ee ee ee ee ee
```

––

This warning must be interpreted as follows:

- In the Cmicro Package there are the following message classes:
  - Cmicro Tester commands = 0xf0 = 240
  - Cmicro Tester trace = 0xf1 = 241 (see Example 631)
  - Cmicro Recorder = 0xf2 = 242

- The message tag can be found in the file "tmcod.h" on page 3677

  In Example 631 the message tag 5 (decimal) is the message `CMD_TSTATE`. Furthermore there is a structure called `xmk_T_CMD_TSTATE`. This structure looks like

```
typedef struct
{
  xPID        process;
  xmk_T_STATE state;
}
```

- The shown buffer from above can be interpreted as:
  f1 -> Cmicro Tester trace
  05 -> `CMD_TSTATE`
  aa -> sync byte
  06 -> message data length 6 octets.

- The message data contains the values `xPID` and `xmk_T_STATE`. In the Example 631 the `xPID` value is an `unsigned int` and the `xmk_T_STATE` is an `unsigned char`.

Note:

The kind of C basic type the `xPID` value is represented by, depends on the SDL system in use (single instance processes only or multiple instance processes). Please view the typedef of `xPID` in the file `ml_typ.h`.

The size of the C basic type depends on the microcontroller and compiler that is used.

By having a look to the C struct (`xmk_T_CMD_TSTATE`) which is represented by the 6 data octets received a value for `xPID` is found like `0x00000000` as an integer is given with the length 4 octets in this example.

Note:

The kind of C basic type the `xmk_T_STATE` value is represented by, depends on the SDL system in use, please view the flag "XMK_USE_HUGE_TRANSITIONTABLES" on page 3489.

The size of the C basic type depends on the microcontroller and compiler in use.

Having a look to the fifth octet of the message data the value for `xmk_T_STATE` is `0x01`, as the length of character is 1 and the alignment of character is 8. Please view "Preparing the Host to Target Communication" on page 3614.

After all in this example there are 5 bytes (octets) decoded (4+1) and 6 received which leads to the inconsistency in the information decoder.

The user is asked to correct the settings in the file `sdtmt.opt` to support the SDL Target Tester's host site with the correct information about the target's memory layout.

Caution!

The Example 631 is an exception concerning the inconsistency in the information decoder.

The compiler used for this example only knows C structures with a size dividable by two which leads to a message data length of 6.

The value 0x04 in the example only represents a filler octet which does not need to be noticed.

Chapter 67 The SDL Target Tester

Chapter

68

Cextreme Code Generator Reference

The Cextreme Code Generator is a SDL to C compiler with many advanced features. It generates code with a small memory footprint, which often can be made even smaller by applying some of the many optimizations available.

The Cextreme Code Generator is inteded to be used to develop applications on embedded systems. It is of course possible to use it for other types of applications as well, but its features are designed to be used when developing embedded systems.

The Cextreme Code Generator can generate applications in two modes, Light and Threaded. The Light integration creates a single-threaded application to be executed on a standard environment, while the Threaded integration gives the user control over how many threads that should be created, what they should execute and more.

Finally, the Cextreme Code Generator generates code that has few macros and is easy to read and understand.

File Structure

An application generated by the Cextreme Code Generator consists and depends on a number of files.

The generated code reflects the contents and behavior of the system described by the SDL model. This code consists of a number of `.c` and `.h` files that are put in the target directory (or, in some circumstances, in a subdirectory to the target directory).

In addition to the generated code, there is a number of files that supports the building of an application. These files, and how they should be managed is discussed in this section.

Essential files

Files found in target directory

Depending on the code generation options, files with the following suffixes and extensions might be found in the same directory as the generated C files.

- `.m`

  This is the makefile for compiling the set of files generated from the SDL model.

- `_env.tpm`

  This is a template makefile to be used to include other `.c` files that should be compiled and become part of the executable. The Cextreme Code Generator generates this template at the same time it generates a file with the environment functions. You can then modify the template and store it under a new name, so it does not get overwritten, and then specify that the modified file should be used during compilation.

- `.ifc` files

  These files contain all important declarations on the outermost system level. It is used to access objects in the generated C code from external code, for example in the file implementing the environment functions.

- `_env.c`

This file contains templates for the environment functions. The environment functions are used to connect the SDL model to its environment. In many cases the details in the environment functions are filled in by adding a user specified file containing a number of macro definitions. If that is the case, the `_env.c` file can be regenerated and still be valid. In more difficult cases the structure of the generated environment template does not fit and then the template should be copied to a new name and modified. In this case the `_env.tpm` file needs to be modified as well to compile the correct environment file.

- `auto_cfg.h`

  This is a scaling and configuration file generated by the Cextreme Code Generator. It contains information about sizes and about what SDL constructs are used. This information is used to determine the size of some data structures and to exclude data and code not needed for the application.

- `extreme_user_cfg.h`

  This is a configuration file generated by the Targeting Expert. It contains information about the build options used when building the application and generating code.

- `.o` / `.obj`

  After compilation the target directory will also contain object files (`.o` or `.obj` in most cases) and an executable (`.sct` normally).

Files found in kernel directory

A number of files are found in the kernel directory, usually located at: `<installation_dir>/sdlkernels/cextreme/kernel`

- `extreme_kern.c` and `extreme_kern.h`

  These files are the basic implementation of the run-time kernel. The file `extreme_kern.h` is included by all `.c` files.

- `sctpred.c` and `sctpred.h`

  These files implement the support for predefined data types.

Files found in RTOS directory

In a subdirectory named RTOS to the kernel directory, all the supported RTOS (real-time operating system) integrations can be found, each integration in a subdirectory of its own.

- `rtapidef.h` and `rtapidef.c`

Each integration contains two files, `rtapidef.h` and `rtapidef.c`. As of today, the following integrations are supported:

- POSIX pthreads integration in subdirectory POSIX
- Win32 integration in subdirectory Win32
- VxWorks integration in the subdirectory VxWorks

Include structure for C files

extreme_kern.h

The top level for definitions is the `extreme_kern.h` file. This file is included by all `.c` files and includes in turn a number of other `.h` files according to the list below.

This file includes:

- standard C header files like `string.h`, `stdlib.h`, `limits.h` etc.
- `extreme_user_cfg.h`
- `auto_cfg.h`
- `comphdef.h` (compiler/hardware integration)
- `rtapidef.h` (run-time API integration)
- `sctpred.h`

extreme_kern.c

Include is also used for `.c` files. In this way the complete kernel will be compiled when the top element, `extreme_kern.c`, is compiled.

- `extreme_kern.h`
- `rtapidef.c` (run-time API integration) if you select this

- `sctpred.c`

Environment Functions

General

Virtually all real applications have some physical environment, let it be software or hardware. The SDL model describes on a high abstraction level the interaction the environment (sending or receiving signals or remote procedure calls), but not what should really happen. A signal sent from the SDL system should for example cause a hardware register to be set or a TCP/IP packet to be sent over a network. The implementation of the interaction is provided in the environment functions.

Separating the decision that an interaction should occur from its implementation simplifies the understanding of the overall behavior of the model. It is also easier to simulate or validate the model, as in such a situation it is necessary to have full control over the environment. For example, it is usually not suitable to simulate on the target platform, which makes hardware unable to access.

The following environment functions are available for use:

```
extern void xInitEnv (void);
extern void xCloseEnv (void);
extern void xOutEnv (xSignal *);
extern void xInEnv (void);
```

- `xInitEnv` and `xCloseEnv` are used to initialize and close down the environment in a controlled way
- `xOutEnv` is called by the run-time kernel when a signal is sent from the system to the environment and should implement the actions needed when signals are sent from the system.
- `xInEnv` provides the reverse support, i.e. to send a signal into the system due to events in the environment. The details depend somewhat on the situation and will be described below.

The usage of the environment functions is controlled in the Targeting Expert by specifying which environment function should be used. This results in the possible inclusion of the macro defines

```
#define USER_CFG_USE_xInitEnv
#define USER_CFG_USE_xCloseEnv
#define USER_CFG_USE_xOutEnv
#define USER_CFG_USE_xInEnv
```

in the file extreme_user_cfg.h generated by the targeting expert.

xInitEnv

This function is to be used to initialize the environment. The function is called once during the initialization of the application (in function xInit in uml_kern.c).

xCloseEnv

This function can be used to close down the environment. The function is called once in the main function in extreme_kern.c.

Note: In an RTOS integration this might not be a suitable way to perform the closing of RTOS tasks – refer to the technical documentation of the RTOS how to properly close down OS threads.

xOutEnv

The xOutEnv function passes a pointer to a signal that is sent to the environment. It is called from the signal sending functions in extreme_kern.c (xOutput and xOutputSimple). The function should perform whatever action that is necessary when the signal passed as parameter is sent to the environment.

The function should free the memory of any signal parameters that is implemented using pointers. The handling of the signal itself is, however, performed by the calling functions. In the generated template for the xOutEnv function that is discussed below, the proper code for memory management is automatically inserted. An example of an xOutEnv is also shown in the section on the template environment functions.

xInEnv

The xInEnv function is a way to handle signals that are sent from the environment to the application. If it is a suitable way, or not, depends on the actual application and the integration mode. Independent of how and where signals to be sent into the system are handled, there are two functions in extreme_kern.c that should be used:

```
extern xSignal*
  xGetSignal (xSignalId, int, xSignal **);
extern void
  xENVOutput (xSignal *, xuint8, SDL_Pid);
```

First, xGetSignal is used to get a pointer to a signal data area. Then the signal parameters should be assigned their values and last the signal is sent using the xENVOutput function.

xGetSignal parameters:

- first parameter to xGetSignal: The signal identity (a number).
- second parameter to xGetSignal: The size of the data area for parameters. If the system contains no signal, no timer, and no part with parameters, then this parameter is not used at all.
- third parameter to xGetSignal: This is an optimization parameter that should always be 0.

xENVOutput parameters:

- first parameter to xENVOutput: Reference to the signal obtained by xGetSignal
- second parameter to xENVOutput: Signal priority for the signal. If signal priorities are not enabled, then this parameter is excluded.
- third parameter to xENVOutput: The receiver of the signal.

More details on how to give these parameters can be found in the sections below.

Implementing signal sending to the application

There are three typical cases of how to implement signal sending into the application.

Sending without use of xInEnv

In the first case the xInEnv function is not used. Consider the situation of a bare integration (no underlying RTOS). In that case it is possible to send signals directly in interrupt routines into the system, using the functions described above. To protect the data structure for signals and signal queues it is then necessary to implement functions or macros to disable and enable interrupts.

Sending using xInEnv in bare integration

Case two is also a bare integration (no underlying RTOS). However the signals are not sent directly in the interrupt routines. Instead the inter-

rupt routines are just used to set up some global data structure to remember information about external events. The `xInEnv` function is then used to actually send the signal. `xInEnv` will be repeatedly called from the scheduler (function `xMainLoop` in `extreme_kern.c`) between each transition executed by the system. In each call the `xInEnv` function should check for external events and send the appropriate signal(s) into the system. `xInEnv` should the return as fast as possible to the scheduler. It is up to you to protect the data structure used to remember external event. The data structures in the Cextreme Code Generator kernel need not to be protected in this case.

Send signals with xInEnv in a RTOS integration

Case three handles the situation of an RTOS integration. In that case it is suitable to run `xInEnv` in a thread of its own. In the predefined integrations the main thread runs `xInEnv` after it has created the other threads. The `xInEnv` function should in this case look something like:

```
while (1) {
  wait for an event;
  if (event corresponding to signal 1) {
    send signal 1;
  }
  if (event corresponding to signal 2) {
    send signal 2;
  }
  and so on;
}
```

The “wait for an event” should hang this thread when there is nothing to do. Otherwise this thread might run all the time. When something happens that should cause a signal to be sent to the environment, the code where this has been detected should store information in some global data area (protected!) and execute code to restart the `xInEnv` function. In simple cases just a semaphore can be used to handle `xInEnv`.

A polling solution can be obtained in the structure above by just implementing “wait for an event” as a sleep for an appropriate amount of time. During each turn the `xInEnv` will then check if some external event has occurred and send the corresponding signal.

Note: If a polling solution for xInEnv is choosen it is important that the thread is suspended for a long enough time. The minimal time to wait depends on the pace in which injected signals can be consumed by the application. This in turn can depend on various things, such as the design

of the model, which thread deployment that is used, or even on how threads are allocated on different hardware artifacts. In general you must make sure that signals are not injected in the application at a faster pace than they can be consumed. Otherwise the application will eventually run out of resources.

Interface header file (.ifc)

The `.ifc` file is a system interface header file containing information about entities defined inside the system. For such entities code is generated. Some of these definitions can be useful in external code, like for example the envi-ronment functions. In the generated code for the system, except the `.ifc` file, all SDL name are prefixed or suffixed to make the names unique in C. In the `.ifc` file the SDL names have a predefined prefix.

In the `.ifc` file names for the parts in the system can be found. These names can be used as receiver, when sending signals in the `xInEnv` function.

Generated environment functions

In the beginning of the `systemname_env.c` file the following statements can be found.

```
#include "extreme_kern.h"
#ifdef XENV_INC
#include XENV_INC
#endif
#include "exenv.ifc"
```

By defining `XENV_INC` to a file name it is possible to include a user defined file. This macro is suitable to define in the `extreme_user_cfg.h` file generated by The Targeting Expert. Use the possibility to include your own defines and insert something like:

```
#define XENV_INC "my_defines.h"
```

In this way the skeletons for the generated environment functions can be filled in using macro definitions from the included file. The environment functions can then be regenerated without the risk of overwriting manually inserted or modified code.

xInitEnv and xCloseEnv structure

The `xInitEnv` and the `xCloseEnv` functions have the following structure:

```
extern void xInitEnv(void)
{
    /* Code to initialize the environment
       may be inserted here */
    XENV_INIT
}
extern void xCloseEnv(void)
{
    /* Code to bring down the environment in a
controlled
       manner may be inserted here. */
    XENV_CLOSE
}
```

where `XENV_INIT` and `XENV_CLOSE` are empty macros if you have not defined them earlier. These macros should be the sequence of statements and function calls needed at the initialization and termination.

The function `xInitEnv` is surrounded by:

```
#ifdef USER_CFG_USE_xInitEnv
#endif
```

(similar for `xCloseEnv` as for `xInEnv` and `xOutEnv` discussed below) to compile the function only if you have specified that the function should be used. This is set in the `extreme_user_cfg.h` file by the Targeting Expert.

xOutEnv structure

The generated `xOutEnv` function will have the following structure.

```
extern void xOutEnv(xSignal *SignalOut)
{
  OUT_START_CODE
  /* Signal s1 */
  #ifndef OUT_SIGNAL_sig_s1
    #define OUT_SIGNAL_sig_s1
  #endif
  if (SignalOut->Sid == sig_s1) {
    OUT_SIGNAL_sig_s1
    return;
  }
  /* Signal s2 */
  #ifndef OUT_SIGNAL_sig_s2
    #define OUT_SIGNAL_sig_s2(P1, P2)
  #endif
  if (SignalOut->Sid == sig_s2) {
```

```
      OUT_SIGNAL_sig_s2(
          ((ySignalPar_sig_s2 *)SignalOut)->Param1,
          ((ySignalPar_sig_s2 *)SignalOut)->Param2)
      xFreeSignalPara(SignalOut);
      return;
    }
  }
```

where `OUT_START_CODE` is an empty macro if you have not defined it. The code consists of a sequence of if statements, each handling one of the signal types that can be sent to the environment. For each signal the if expression tests the signal identity.

When the correct if statement is found the statements defined by the macro `OUT_SIGNAL_signalname` is executed. This macro has one parameter for each signal parameter and is empty if you have not defined it. This means that the code will compile, but do nothing if the `OUT_SIGNAL` macros are not defined. The structure makes incremental development possible, that is to say that you can implement the treatment of a few signals and then start testing, without bothering about the code for all the other signals.

The code in the example above assumes that the name for signals used in the `.ifc` file is `sig_%n`, where %n is the signal name in SDL. The `xFreeSignalPara` function call in the s2 section is necessary when any of the signal parameters is implemented using dynamic memory and a `free` operation is needed for the parameter value. The data area for the signal itself is handled in `extreme_kern.c` at the places where `xOutEnv` is called.

xInEnv structure

The generated `xInEnv` function has the following structure. The example below shows an example suitable in a bare integration.

```
extern void xInEnv (void)
{
  xSignal *SignalIn;
  IN_START_CODE
  /* Signal s1 */
  #ifdef IN_SIGNAL_sig_s1
  if (IN_SIGNAL_sig_s1) {
    SignalIn = xGetSignal(sig_s1, 0, 0);
    xENVOutput(SignalIn, IN_RECEIVER_s1);
  }
  #endif
  /* Signal s2 */
  #ifdef IN_SIGNAL_sig_s2
  if (IN_SIGNAL_sig_s2) {
```

```
    SignalIn = xGetSignal(sig_s2,
        sizeof(ySignalPar_sig_s2), 0);
    ((ySignalPar_sig_s2 *)SignalOut)->Param1 =
        IN_PARA1_sig_s2;
    yAssF_s_7(
        ((ySignalPar_sig_s2 *)SignalOut)->Param2,
        IN_PARA2_sig_s2,
        XASS_MR_ASS_NF);
    xENVOutput(SignalIn, IN_RECEIVER_s2);
  }
  #endif
  IN_END_CODE
}
```

where the macros `IN_START_CODE` and `IN_END_CODE` are empty if you have not defined them.

Each signal is treated in four steps.

- The enabling macro `IN_SIGNAL_signalname`. This is used in an if statement to determine if an external event has occurred that should cause the signal to be sent into the system.
- The `SignalIn` variable is assigned a new signal data area.
- The signal parameters are filled in, if any. The value for each parameter should be defined using the appropriate macro `IN_PARA1_signalname`, `IN_PARA2_signalname` and so on.
- The signal is sent by calling `xENVOutput`. Here the receiver of the signal must be given by the macro `IN_RECEIVER_signalname`. The appropriate values can be found in the `.ifc` file looking for defines of type:

```
#define xPartNo_Partname  <integer number>
```

The structure above also enables incremental development as the complete section for a certain signal is removed if the enabling macro is not defined.

For a threaded application the structure is very similar. A loop is included in the function according to the following.

```
extern void xInEnv (void) {
  xSignal *SignalIn;
  IN_START_CODE
  while (1) {
    IN_WAIT_FOR_ACTION
    /* To avoid that the thread running xInEnv takes
       all resources it should wait on for example a
       semaphore until something occurs that should
```

```
            cause a signal to be sent into the system */

          /* Here the code for the signals is placed
             in the same way as in the previous example.
          */
        }
        IN_END_CODE
      }
```

Note: IN_WAIT_FOR_ACTION must be implemented according to the previous discussion.

Compile and Link an Application

Integration types

Cextreme comes with two different kind of integrations, Light and Threaded.

- Light Integration

  The Light Integration is a single threaded integration that requires very little interaction with the underlying OS. The SDL system runs as a single OS task, scheduling is handled by the standard kernel running a complete state transition at a time. The worst case scheduling latency is that of the longest transition.

- Threaded Integration

  The threaded integration can use multiple threads where the scheduling and communication in each thread is controlled by the SDL kernel, but scheduling and synchronization of data (such as input queues) between different threads make use of the underlying OS primitives. Worst case latency can be made as small as the underlying OS permits by carefully distributing OS threads in the system and setting different priorities for them. To be able to use the threaded integration a deployment diagram has to be created, see The Deployment Editor.

For a more in depth discussion of the different integration types, please refer to the Cadvanced documentation on the matter, Different Integration Models, since they are very similar.

Essential files

The essential files used for compilation and linking of an Cextreme Code Generator application are

- `comp.opt`: Defines commands for compiling, linking etc.
- `make.opt` or `makeoptions`: Contains compiler flags and compilation of the kernel.
- `<compiler and integration dependant name>.m`: This is the generated makefile for the application. The name depends on the

choice of compiler and integration type, e.g. `cl_appl_ce.m` for light integration using Microsofts cl compiler.

- `systemname_env.tpm`: This is the generated template makefile for files that are not under full control of the code generator. This file is generated if template environment functions are generated.

comp.opt

The `comp.opt` file can be used to control the complete build process from a custom build script. The `comp.opt` file consists of five important lines (plus lines counted as comments). The syntax for the file is described in "Creating a New Library" on page 3139, where a more detailed description of the complete make process can also be found. Below an overview for Cextreme Code Generator can be found.

- **Line 1:** The syntax for including `make.opt` in the generated makefile for the application.
- **Line 2:** Template for a compilation command.
- **Line 3:** Template for link command.
- **Line 4:** The command to be executed to start the make process. This should be a shell command that the build script will execute after it has finished the code generation.
- **Line 5:** Template for building a library.

systemname.m

When the code generator has finished the process of generating code it will execute the command defined in `compt.opt` at line 4. This usually is some-thing like:

```
make -f systemname.m sctdir=<a directory>
```

This will invoke the make facility with the generated makefile.

makeoptions (make.opt)

In the beginning of the generated makefile is an include statement, including the file `makeoptions` (`make.opt`) can be found. The variable `sctdir`, passed to make at the command line, is used to point out the directory where to find `makeoptions`.

The make program will process the `makeoptions` file, where it finds a number of settings for compiler, linker, and options for the compilation com-mands for the kernel files. In the generated makefile it will then find the com-pilation commands for the generated files and a command to link the object file to an executable.

system name_env.tpm

The template makefile mentioned above, is used to compile the files that are not directly under the control of the code generator. Such a file is generated if a file with template environment functions is generated. This file will have the name `system name_env.tpm` and handles compilation of the file with template environment functions. Targeting Expert lets you specify what template makefile to use. This can either be the generated one (use the file name *), or a user defined file. The contents of the specified template makefile is copied last into the generated makefile.

Adopting a compiler

If you need to adopt e.g. a cross compiler, you should do that by creating a new directory where a `comp.opt` and a `makeoptions` (or `make.opt`) file are placed. The easiest way is usually to copy existing `comp.opt` and `makeoptions` (or `make.opt`) files to a new directory and modify them.

Integration with Compiler and Operating System

This section describes how to set up a compiler and target platform in order to get an application running.

Integration with a new compiler

There are mainly two aspects when a new compiler should be used. Compiler name and switches, and what include files are needed.

Compiler name and switches

Specifying compiler name and suitable compiler switches are part of the build process. These topics are discussed in the previous section – see Compile and Link an Application.

Include files

The other major aspect is the include files needed for the kernel code and for the generated code, but also include files used for user specific code. If no integration is specified a default section including the `.h` file needed by the kernel and the generated code is used. This follows ISO C specifications on system include files. In this case the following is included (compare with the kernel file `extreme_kern.h`):

```
#if defined(USER_CFG_COMPHDEF)
  #include "comphdef.h"
#else
  /* Use default (ISO-C) */
  #include <string.h>
  #include <stdlib.h>
  #include <limits.h>
  #include <stdarg.h>
  #ifdef CFG_ADD_STDIO
    #include <stdio.h>
  #endif

  #if defined(__cplusplus) && defined(_MSC_VER)
    #include <cstddef> /* C++ and Microsoft compiler
*/
  #else
    #include <stddef.h>
  #endif
#endif
```

That is if `USER_CFG_COMPHDEF` is not defined the include files given above is included.

Note: stdio.h is only needed if printing is used.

If the compiler/run-time library with the compiler does not provide the functions defined in `string.h`, the kernel (`extreme_kern.c`) includes implementations of the function that is used from this file. The functions are:

`memset`, `memcpy`, `strlen`, `strcpy`, `strncpy`, and `strcmp`

By inserting defines from the list below to the `extreme_user_cfg.h` file generated by the Targeting Expert, it is possible to use the kernel implementations of these functions:

```
#define USER_CFG_USE_memset
#define USER_CFG_USE_memcpy
#define USER_CFG_USE_strlen
#define USER_CFG_USE_strcpy
#define USER_CFG_USE_strncpy
#define USER_CFG_USE_strcmp
```

To customize the list of included system files (and possibly other `.h` files needed in your application), the macro `USER_CFG_COMPHDEF` should be defined. This can be done in the Targeting Expert.

Another option, used in the predefined kernels, is to include this definition on the command line to the compiler using a -D option or something similar.

In this case the file `comphdef.h` will be included. It is then also necessary to adopt the build process, specifically the list of directories where the compiler looks for include file, so the compiler finds the correct `comphdef.h`. Usually this is performed by -I options to the compiler.

Integration with the run-time system

There are a number of aspects that is important in the integration with the run-time system provided by the underlying hardware and software:

- Clock function
- Memory management for dynamic memory
- Protecting data by disabling/enabling interrupts (non threaded integration)
- Threaded integration with an RTOS.

Just as for the compiler integration you can enable your own integration by including a define of the macro `USER_CFG_RTAPIDEF` in `extreme_user_cfg.h` (or as a compiler option):

```
#define USER_CFG_RTAPIDEF
```

In that case the file `rtapidef.h` will be included in `extreme_kern.h` and `rtapidef.c` will be included in `extreme_kern.c`. Appropriate options must be given to the compiler so it finds the correct `rtapidef.*` files.

If `USER_CFG_RTAPIDEF` is not defined then a standard integration is used. The algorithm used for this selection is:

```
if (threading is used)
  if (Microsoft or Borland compiler is used)
    Use a Win32 threaded integration
  else
    Use a POSIX pthreads integration
  endif
else
  Use a non-threaded integration
endif
```

Note: POSIX pthreads integration and non-threaded integrations will likely work on most UNIX systems/compilers. This is however tested only on supported systems/compilers.

Clock function

To support the SDL concept of timers, a clock function is necessary. The generated code and the kernel assumes that there is a clock function called `xNow` that returns the current time. Time values are represented by values of type `SDL_Time`.

There are two standard implementations of the clock function, one for UNIX like systems and one for Windows. In Windows the standard function `_ftime` is used to read the system clock, while on UNIX like systems the standard function `clock_gettime` is used.

To implement a clock function you should include your own `rtapidef.h` and `rtapidef.c` files according to the details below.

If timers are not used and the clock is not explicitly accessed in SDL or C, there is no need for a clock implementation. Just include the macro definition:

```
#define xInitSystime()
```

in `rtapidef.h`.

If a clock implementation is needed then include the following prototypes in `rtapidef.h`:

```
extern void xInitSystime(void);

extern SDL_Time xNow (void);
```

If no initialization function is needed then the `xInitSystime` function can be replaced by the macro.

```
#define xInitSystime()
```

In the file `rtapidef.c` the implementation of these functions should be provided. The implementations will depend a lot on the support in software and hardware for the underlying architecture.

Memory management

In some cases dynamic memory is needed by a generated application. To support this an `alloc` and a `free` function must be provided. You have three possibilities:

- The first alternative is to use the built-in memory package. This option can be specified in the Targeting Expert. In this case an array of bytes is defined and the memory in this array is used as dynamic memory. The algorithm used for the memory management is implemented in the kernel and is basically a best fit algorithm. The size of the array can, of course, be set by you. It is also possible to specify a minimum block size. In that case only blocks of `size 2^n * min_block_size` will be allocated. This may reduce the risk for memory fragmentation.
- The second alternative is to rely on a `calloc` and a `free` function provided by the underlying layer. This is the default behavior. If calloc is not available a combination of malloc and memset can be used instead, by defining `CFG_NO_CALLOC_AVAILABLE`.
- The third alternative is to implement the memory management yourself. In that case the macro `USER_CFG_USE_USER_MEMFUNC` should be defined. It is assumed that you implement the functions:

```
extern void *xAlloc (unsigned int);
extern void xFree (void **);
```

in the file `rtapidef.c`. The prototypes are present in `extreme_kern.h` so it is not necessary to insert them into `rtapidef.h`.

Note: If the application does not use dynamic memory, there is no need to implement these functions.

The `xAlloc` function should allocate memory of the size given as parameter and return a reference to the memory. It is assumed that the memory is set to 0 by the `xAlloc` function. Example:

```
void *xAlloc (unsigned int Size)  {
  void * Ptr;
  Ptr = (void *)malloc(Size);
  if (Ptr)
    (void)memset(Ptr, 0, Size);
  return Ptr;
}
```

The `xFree` function takes a pointer to a pointer to some memory to be returned to the pool of free memory. The function should free the memory and set the pointer to 0. Example:

```
void xFree (void ** Ptr)
{
  if (*Ptr) {
    free(*Ptr);
    *Ptr = (void *)0;
  }
}
```

The `xAlloc` and `xFree` functions must be thread safe. The functions in the built-in memory package are protected by a semaphore or by turning off and on interrupts. In case two, when using the OS `calloc` and `free` it is assumed that these functions are thread safe.

Disable and enable interrupts

In a non-threaded application where you want to be able to send signals into the system in interrupt routines, some important data structures for signals must be protected from simultaneous access. To achieve this it is necessary to disable interrupts while executing certain operations in the kernel.

To implement disabling and enabling of interrupts, you should in define two macros in `rtapidef.h` with the structure given below.

```
#define XBEGIN_CRITICAL_PATH \
        UserCodeToDisableInterrupts;
#define XEND_CRITICAL_PATH \
```

```
UserCodeToEnableInterrupts;
```

where `UserCodeToDisableInterrupts` and `UserCodeToEnableInterrupts` should be replaced by code performing these actions for the hardware and software platform that is used.

Threaded integrations

To implement a new integration it is recommended to use this manual together with the code for some existing integration(s). There are some major aspects that have to be handled to implement an integration with real-time operating system.

- It is necessary to implement a clock function.
- There is need for a number of mutexes or binary semaphores to protect some shared data.
- Some startup code, for creating threads with relevant properties and synchronizing them are needed.
- A thread must be able to suspend its execution when it is idle. It must then be possible to wake it up again when a signal is sent to a part in the thread.

To explain the details in these integration aspects the POSIX integration will be used as an example. Apart from the code mentioned below the `rtapidef.h` should include the necessary system include files to be able to access the concepts needed.

Example 632: Includes in rtapidef.h for POSIX

```
#include <pthread.h>
#include <sched.h>
#include <semaphore.h>
#include <time.h>
#include <sys/time.h>
```

If the RTOS has any requirements on the `main()` function, which might be the case, it is possible to rename the `main()` function included in `extreme_kern.c` by defining `XMAIN_NAME` to for example:

```
#define XMAIN_NAME cextreme_main
```

Then the user has to implement a proper main function that calls the `cextreme_main` function.

The clock function

The clock function should be implemented according to the description found in a previous section.

Protection of shared data

It is necessary to protect the list of available signals, the list of available timers, the list of free parts (for create actions), and, if the memory package is used, the memory used by the package.

For this four global mutexes or binary semaphores are needed. These variables should be defined extern in `rtapidef.h` and declared in rtapidef.c. The names of the variables should be the same as in the example given below.

Example 633: In rtapidef.h:

```
extern pthread_mutex_t xFreeSignalMutex;
extern pthread_mutex_t xFreeTimerMutex;
extern pthread_mutex_t xCreateMutex;
#ifdef USER_CFG_USE_MEMORY_PACK
  extern pthread_mutex_t xMemoryMutex;
#endif
```

Example 634: In rtapidef.c:

```
pthread_mutex_t xFreeSignalMutex;
pthread_mutex_t xFreeTimerMutex;
pthread_mutex_t xCreateMutex;
#ifdef USER_CFG_USE_MEMORY_PACK
  pthread_mutex_t xMemoryMutex;
#endif
```

These four variables should be initialized during the startup of the application to an unlocked state. The function `xThreadInit` is a proper place for this initialization.

Example 635: xThreadInit

```
void xThreadInit (void) {
  (void)pthread_mutex_init(&xFreeSignalMutex, 0);
  (void)pthread_mutex_init(&xFreeTimerMutex, 0);
  (void)pthread_mutex_init(&xCreateMutex, 0);
  #ifdef USER_CFG_USE_MEMORY_PACK
    (void)pthread_mutex_init(&xMemoryMutex, 0);
  #endif
  ....
}
```

The lock and unlock operation must also be implemented for mutexes or binary semaphores. The following two functions should be implemented.

Example 636: Functions for lock and unlock

In `rtapidef.h`:

```
extern void xThreadLock (pthread_mutex_t *);
extern void xThreadUnlock (pthread_mutex_t *);
```

In `rtapidef.c`:

```
void xThreadLock (pthread_mutex_t *M)
{
  (void)pthread_mutex_lock(M);
}
void xThreadUnlock (pthread_mutex_t *M)
{
  (void)pthread_mutex_unlock(M);
}
```

Startup phase - creating the threads

After some basic initialization the Cextreme Code Generator kernel will start the specified threads in the `main()` function.

For each thread the functions `xThreadInitOneThread` and `xThreadStartThread` will be called, where `xThreadInitOneThread` should perform some thread specific initialization and `xThreadStartThread` should start the thread. Each thread should run the function `xMainLoop` declared in the kernel. This is performed by using a wrapper function, `xThreadEntryFunc`, which is defined in the integration and is the function that is actually started in the thread.

After all the threads have been started the function `xThreadGo` is called in the function `main()`. Some more information on these functions are given below.

It is important that the started threads do not execute any SDL transitions before all threads are created. Therefore the `xThreadEntryFunc` will as first action wait on a semaphore. The `xThreadGo` function will when all threads are created release this semaphore.

The global data structure `xSysD` is an array with components of type `xSystemData`, with one component per thread. `xSysD` contains global information about what is going on just now in the threads. Details about the information in `xSysD` can be found in the section Overview of

Important Data Structures. In the context of RTOS integrations two aspects are important. Each thread (the `xMainLoop` function) must know the address for the component in `xSysD` representing the thread. Each `xSysD` component contains a field of type `xThreadVars`, which should be defined in the RTOS integration.

Example 637: xThreadVars type in rtapidef.h

```
typedef struct {
  pthread_mutex_t SignalQueueMutex;
  pthread_cond_t  SignalQueueCond;
  pthread_t       ThreadId;
} xThreadVars;
```

where the two first fields will be discussed in the next section, and the `ThreadId` will be used during the startup phase to store the identity of the threads.

The code for the behavior described in this section should look something like the following example.

Example 638:

In rtapidef.h:

```
extern sem_t xInitSem;
#if !defined(USER_CFG_USE_xInEnv) && !defined(XENV)
  extern sem_t xMainThreadSem;
#endif
extern void xThreadInitOneThread (
      struct _xSystemData *);
extern void xThreadStartThread (
      struct _xSystemData *,
      unsigned int, unsigned int,
      unsigned int, unsigned int);
```

In rtapidef.c:

```
sem_t xInitSem;
#if !defined(USER_CFG_USE_xInEnv) && !defined(XENV)
  sem_t xMainThreadSem;
#endif

void xThreadInit (void)
{
  ....
  (void)sem_init(&xInitSem, 0, 0);
}

void xThreadInitOneThread(struct _xSystemData
```

```
*xSysDP)
{
  (void)pthread_mutex_init(
      &xSysDP->ThreadVars.SignalQueueMutex, 0);
  (void)pthread_cond_init(
      &xSysDP->ThreadVars.SignalQueueCond, 0);
}

static void *xThreadEntryFunc (void *xSysDP)
{
  (void)sem_wait(&xInitSem);
  (void)sem_post(&xInitSem);
  xMainLoop((xSystemData *)xSysDP);
}

void xThreadStartThread(struct _xSystemData *xSysDP,
      unsigned int StackSize, unsigned int Prio,
      unsigned int User1, unsigned int User2)
{
  pthread_attr_t Attributes;
  ....
  (void)pthread_create(&xSysDP->ThreadVars.ThreadId,
        &Attributes, xThreadEntryFunc, (void
*)xSysDP);
  ....
}

void xThreadGo(void)
{
  (void)sem_post(&xInitSem);
  #if defined(USER_CFG_USE_xInEnv)
    xInEnv();       /* Cextreme  */
  #elif defined(XENV)
    xInEnv(xNow()); /* Cadvanced */
  #else
    (void)sem_init(&xMainThreadSem, 0, 0);
    (void)sem_wait(&xMainThreadSem);
  #endif
}
```

The `xInitSem` semaphore is used for synchronization of the threads. It is initialized in the beginning of `xThreadInit` to 0, i.e. to a blocking state. After that the `xThreadStartThread` once for each thread that is to be started. The function `pthread_create` will call the function given as third parameter (`xThreadEntryFunc`) with the `void *` parameter given as fourth parameter (the `xSysD` pointer) as parameter. `pthread_create` will also store the identity of the thread in the variable passed as first parameter. The second parameter is the properties of the thread. This will be discussed later in this section.

If any of the threads get a chance to execute before all the threads are created, these threads will hang on the `sem_wait` call in `xThreadEntryFunc`, until the main thread calls `xThreadGo` that will post the semaphore `xInitSem` once. One of the threads waiting on this semaphore will then be able to execute and will immediately post the semaphore again. This will continue until all threads are free to execute.

After that all threads are running and depending on the OS and the application properties, the main thread can perform different things. The recommendation is to call the `xInEnv` function and let that function run in this thread. Another alternative is to hang the main thread on a semaphore, as shown above using the semaphore `xMainThreadSem` (if `xInEnv` is not used). In this case you can post the `xMainThreadSem` semaphore anywhere to restart the execution of the main thread.

When the main thread returns from the function `xThreadStart`, the program will continue to execute in the `main()` function and will perform a call to `exit`. The behavior of a threaded program when the main thread performs exit is OS dependent. In POSIX pthreads all threads are stopped at such an action. That is the reason why it is important to hang the main thread at the end of the `xThreadStart` function.

Now to the properties of the threads. In most RTOS, properties like stack size and priority can be set for individual threads.

- The first value is interpreted as the stack size.
- The second value is interpreted as the priority.
- The third and fourth values can be used for other properties, defined by the RTOS integration or defined by you.

The currently predefined integrations only makes use of the first and second values. These values are passed as parameters to the `xTreadStartThread` function.

How the properties are set up in detail depend on the RTOS. Compare with the available integrations, in the function `xThreadStartThread`, for examples.

In `rtapidef.h` proper default values for the four `xThreadData` fields should be set up. These default values are used if no value is specified in the thread definition.

Example 639:

```
#define DEFAULT_STACKSIZE     1024
#define DEFAULT_PRIO             0
#define DEFAULT_USER1            0
#define DEFAULT_USER2            0
```

Suspending and waking up threads

When a thread finds out that it has nothing more to do, at least just for the moment, it should suspend itself to make the processor available for other threads. The thread should then wake up again either when a timer has expired and needs to be handled, or when some other thread (including `xInEnv`) sends a signal that should be treated by the suspended thread.

To implement these features one mutex (binary semaphore) is used together with some sort of conditional variable. You need the possibility to perform a condition wait, with or without a time-out. You also need a way to signal to a thread to wake up again. These two entities are needed for each thread and is therefore included in the `xThreadVars` struct mentioned earlier:

```
typedef struct {
  pthread_mutex_t SignalQueueMutex;
  pthread_cond_t  SignalQueueCond;
  pthread_t       ThreadId;
} xThreadVars;
```

The purpose of the `SignalQueueMutex` is to protect the signal queue where signals from the outside of the thread are inserted (`ExternSignalQueue` in the `xSysD` array). The `SignalQueueCond` should facilitate the conditional wait.

The `SignalQueueMutex` should be initialized in `xThreadInitOneThread`. If `SignalQueueCond` needs to be initialized it could be performed at the same place.

Example 640:

```
void xThreadInitOneThread(struct _xSystemData
*xSysDP)
{
  (void)pthread_mutex_init(
             &xSysDP->ThreadVars.SignalQueueMutex,
             0);
  (void)pthread_cond_init(
             &xSysDP->ThreadVars.SignalQueueCond,
             0);
```

```
}
```

The `SignalQueueMutex` is locked by using the function `xThreadLock`, discussed above. It is then unlocked in three different ways:

- `xThreadUnlock` (discussed above)
- `xThreadWaitUnlock`
- `xThreadSignalUnlock`

The `xThreadWaitUnlock` is called by the thread itself when it has come to the conclusion that it should suspend itself, while `xThread-SignalUnlock` is called by another thread that wants to wake up the current thread. Both functions are passed the `xSysD` pointer for the thread that the operation should be performed on.

Example 641:

In `rtapidef.h`

```
extern void xThreadWaitUnlock (
               struct _xSystemData *);
extern void xThreadSignalUnlock (
               struct _xSystemData *);
```

In `rtapidef.c`:

```
void xThreadWaitUnlock (struct _xSystemData *xSysDP)
{
  #if defined(CFG_USED_TIMER) || defined(THREADED)
    #ifdef THREADED
      /* Cadvanced */
      if (xSysDP->xTimerQueue->Suc ==
          xSysDP->xTimerQueue) {
    #else
      /* Cextreme */
      if (! xSysDP->TimerQueue) {
    #endif
        (void)pthread_cond_wait(
            &xSysDP->ThreadVars.SignalQueueCond,
            &xSysDP->ThreadVars.SignalQueueMutex);
      } else {
        struct timespec timeout;
        #ifdef THREADED
          /* Cadvanced */
          timeout.tv_sec =
            ((xTimerNode)xSysDP->xTimerQueue->Suc)->
          TimerTime.s;
          timeout.tv_nsec =
            ((xTimerNode)xSysDP->xTimerQueue->Suc)->
            TimerTime.ns;
        #else
          /* Cextreme */
```

```
            timeout.tv_sec = xSysDP->TimerQueue->
              Time.s;
            timeout.tv_nsec = xSysDP->TimerQueue->
              Time.ns;
          #endif
          (void)pthread_cond_timedwait(
            &xSysDP->ThreadVars.SignalQueueCond,
            &xSysDP->ThreadVars.SignalQueueMutex,
            &timeout);
        }
    #else
        (void)pthread_cond_wait(
          &xSysDP->ThreadVars.SignalQueueCond,
          &xSysDP->ThreadVars.SignalQueueMutex);
    #endif
    (void)pthread_mutex_unlock(
      &xSysDP->ThreadVars.SignalQueueMutex);
}

void xThreadSignalUnlock (struct _xSystemData
                            *xSysDP)
{
  (void)pthread_cond_signal(
    &xSysDP->ThreadVars.SignalQueueCond);
  (void)pthread_mutex_unlock(
    &xSysDP->ThreadVars.SignalQueueMutex);
}
```

At the time when `xThreadWaitUnlock` or `xThreadSignalUnlock` is called the `SignalQueueMutex` will be locked and must therefore be unlocked at the end of both functions.

In `xThreadWaitUnlock` the thread wants to suspend itself. If timers are used and there is a timer active in the timer queue, it should wait until the timer expires or until some other thread tells it to wake up. In POSIX pthreads the function `pthread_cond_wait` performs exactly this. If timers are not used or there is no timer active, the thread should be suspended until someone else wakes it up. In POSIX pthreads this can be achieved with the function `pthread_cond_wait`.

In `xThreadSignalUnlock` the thread given by the parameter should be waken up. Here the pthread function `pthread_cond_signal` can be used.

The integrations described here are also used when the C Code Generator is used to generate threaded applications. This adds a few requirements in the implementation of a threaded integration. First a function that can stop a thread is needed.

In rtapidef.h:

```
#if defined(THREADED) || \
    defined(CFG_USED_DYNAMIC_THREADS)
  extern void xThreadStopThread(struct _xSystemData
*);
#endif
```

In rtapidef.c:

```
#if defined(THREADED) || \
    defined(CFG_USED_DYNAMIC_THREADS)
void xThreadStopThread(struct _xSystemData *xSysDP)
{
  pthread_mutex_destroy(
      &xSysDP->ThreadVars.SignalQueueMutex);
  pthread_cond_destroy(
      &xSysDP->ThreadVars.SignalQueueCond);
  pthread_exit(0);
}
#endif
```

`THREADED` is defined when using the C Code Generator but not when using the Cextreme Code Generator. The `xThreadStopThread` function should clean up the thread specific semaphores and stop the thread. It is always the thread that should be stopped that will call this function to stop itself.

Another difference is the way timers are accessed for the two code generators. This affects the details in the `xThreadWaitUnlock` function.

In the case of the C Code Generator the RTOS integrations are accessed through a macro layer. The macros in this layer is used in the C Code Generator kernel files and in the generated code.

Example 642: Defines in scttypes.h

The following defines are relevant (from `scttypes.h`):

```
#define THREADED_GLOBAL_VARS
#define THREADED_GLOBAL_INIT \
      xThreadInit();
#define THREADED_THREAD_VARS \
      xThreadVars ThreadVars;
#define THREADED_THREAD_INIT(SYSD) \
      xThreadInitOneThread(SYSD);
#define THREADED_THREAD_BEGINNING(SYSD)
#define THREADED_AFTER_THREAD_START \
      xThreadGo();
#define THREADED_START_THREAD(F, SYSD, \
                              STACKSIZE, PRIO, \
                              USER1, USER2) \
      xThreadStartThread(SYSD, STACKSIZE, \
                         PRIO, USER1, USER2);
#define THREADED_STOP_THREAD(SYSD) \
```

```
      xThreadStopThread(SYSD);
#define THREADED_LOCK_INPUTPORT(SYSD) \
      xThreadLock( \
            &SYSD->ThreadVars.SignalQueueMutex);
#define THREADED_UNLOCK_INPUTPORT(SYSD) \
      xThreadUnlock( \
            &SYSD->ThreadVars.SignalQueueMutex);
#define THREADED_WAIT_AND_UNLOCK_INPUTPORT(SYSD) \
      xThreadWaitUnlock(SYSD);
#define THREADED_SIGNAL_AND_UNLOCK_INPUTPORT(SYSD) \
      xThreadSignalUnlock(SYSD);
#define THREADED_LISTREAD_START \
      xThreadLock(&xFreeSignalMutex);
#define THREADED_LISTWRITE_START \
      xThreadLock(&xFreeSignalMutex);
#define THREADED_LISTACCESS_END \
      xThreadUnlock(&xFreeSignalMutex);
#define THREADED_EXPORT_START \
      xThreadLock(&xCreateMutex);
#define THREADED_EXPORT_END \
      xThreadUnlock(&xCreateMutex);
```

Optimization and Configuration

Optimization and configuration is mainly performed in two `.h` files. These are `auto_cfg.h` and `extreme_user_cfg.h`. The file `auto_cfg.h` is generated by the Cextreme Code Generator, and contains the optimization and configuration that can be automatically computed given the system that code is generated for. The `extreme_user_cfg.h` file is generated by The Targeting Expert from configuration information provided by the user.

auto_cfg.h

The `auto_cfg.h` has the contents discussed below. The first section in the file is used to configure mainly the size of some arrays and the size (8, 16, or 32 bits) needed to represent certain entities.

```
#define CFG_NUMBER_PROCESS_TYPES 2
#define CFG_MAX_INSTANCES 1
#define CFG_NUMBER_TIMERS 0
#define CFG_MAX_TIMER_INSTS 0
#define CFG_NUMBER_SIGNALS 4
#define CFG_NUMBER_THREADS 0
#define CFG_MAX_ACTIONS 2
#define CFG_MAX_STATES 1
#define CFG_MAX_STATE_INDEX_ENTRY 2
```

In the second section information is given about what concepts that are used in the system that code is generated for. For concepts that are used a `#define` is generated, while for concepts not used, a comment, saying the corresponding macro is not defined, is generated. The information in this section is used to scale the code, to remove code and fields in data structures that is not needed.

```
#define CFG_USED_DYNAMIC_THREADS
#define CFG_USED_UNLIMITED_INSTANCES
#define CFG_USED_TIMER
#define CFG_USED_CREATE
#define CFG_USED_STOP
#define CFG_USED_SAVE
#define CFG_USED_STATE_STAR
#define CFG_USED_INPUT_SAVE_STAR
#define CFG_USED_GUARD
#define CFG_USED_SIGNAL_WITH_PARAMS
#define CFG_USED_TIMER_WITH_PARAMS
#define CFG_USED_SIGNAL_WITH_DYN_PARAMS
#define CFG_USED_SENDER
#define CFG_USED_OFFSPRING
#define CFG_USED_PARENT
#define CFG_USED_SELF
```

```
#define CFG_USED_PROCEDURE
#define CFG_USED_RPC
#define CFG_USED_INITFUNC
```

The third section contains information about items in connection with data types, used to remove code in the file `sctpred.c` not needed by the generated application. The section contains a sequence of defines looking like the example below.

```
#define XNOUSE_"at-lot-of-things-about-data-types"
```

In rare cases the `auto_cfg.h` file might contain information that does not fit the application to be built. One such case is if the third section contains information that a certain function is not used, and therefore removed with ifdefs. The function is, however, used in user provided C code, in for example the environment functions. In such cases it is possible to override the information in `auto_cfg.h` by including macro definitions last in `extreme_user_cfg.h`.

Example 643: Assume the `auto_cfg.h` contains

```
#define XNOUSE_LENGTH_CHARSTRING
```

which shows that the length function for character strings are not used. To override this the following code should be included in `uml_cfg.h`:

```
#ifdef XNOUSE_LENGTH_CHARSTRING
  #undef XNOUSE_LENGTH_CHARSTRING
#endif
```

extreme_user_cfg.h

This file is generated by the Targeting Expert and contains information about the options that you have selected.

`extreme_user_cfg.h` is, just as `auto_cfg.h`, a file that should contain defines that are used to build the Cextreme Code Generator application with specified options. The file `extreme_user_cfg.h` will include `auto_cfg.h`.

Some of the features discussed below can be selected in the Targeting Expert and will affect the contents of the `extreme_user_cfg.h` file. The options not included in the UI can be inserted in the file directly, just make sure that your modifications won't be overwritten by the Targeting Expert.

Process properties

- `#define USER_CFG_USE_NUMBER_FREE_INST <Integer>`

  In case there are parts with no maximum number of instances, then memory will be dynamically allocated at startup for the number of initial instances plus the value given here. The value must be > 0. Default value is 5.

Signal properties

- `#define USER_CFG_MAX_SIGNAL_INSTS <Integer>`

  This defines the length of the static signal queue. If dynamic signals are not used (compare with `USER_CFG_NOUSE_DYNAMIC_SIGNALS`), an error occurs if the signal queue is full at the same time as an attempt to send a signal is made.

- `#define USER_CFG_NOUSE_DYNAMIC_SIGNALS`

  Turn off usage of dynamic memory for signals. This feature should normally be turned off in smaller systems, where dynamic memory is not to be used. In that case it is important to set `USER_CFG_MAX_SIGNAL_INSTS` to an appropriate value.

- `#define USER_CFG_SIGNALS_NEVER_DISCARDED`

  Define to remove the code for freeing signal parameters in case a signal is discarded. Only applicable if signals with dynamic parameters are used. If `XMK_USED_SIGNAL_WITH_DYN_PARAMS` is defined in `auto_cfg.h`. If `USER_CFG_SIGNALS_NEVER_DISCARDED` is defined and a signal with dynamic parameters is discarded there will be a memory leak.

- `#define USER_CFG_USE_SIGNAL_PRIORITIES`

  Use priorities on signals. This means that the signal queue is sorted first in priority order and then in arrival order (when same priority).

- `#define USER_CFG_TIMER_PRIO <Integer>`

  The priority assigned to all timer signals. Default is 50.

- `#define USER_CFG_CREATE_PRIO <Integer>`

  The priority assigned to all startup/create signals. Default is 50.

- `#define USER_CFG_DEFAULT_PRIO <Integer>`

The priority assigned to all signals not having an explicit priority. Default is 50.

- `#define USER_CFG_MSG_BORDER_LEN <Integer>`

  This defines the length of the data field for parameters within the signal. If the signal parameters do not fit into this memory dynamic memory allocation is used. Default is 4 if signals with parameters is used (`XMK_USED_SIGNAL_WITH_PARAMS` is defined) and 0 if no signals have parameters.

Timer properties

- `#define USER_CFG_MAX_TIMER_INSTS <Integer>`

  Length of static timer queue. The default length is the computed value `CFG_MAX_TIMER_INSTS` from `auto_cfg.h`, which in case of timers without parameters is the maximum amount of possible active timers. In case of timers with parameters this value can, in extreme cases, be to small. Normally a value smaller than `CFG_MAX_TIMER_INSTS` might be used. If dynamic timers are not used (compare with `USER_CFG_NOUSE_DYNAMIC_TIMERS`), an error occurs if the timer queue is full at the same time as an attempt to set a timer is made.

- `#define USER_CFG_NOUSE_DYNAMIC_TIMERS`

  Turn off usage of dynamic memory for timers. This feature should normally be turned off in smaller systems, where dynamic memory is not to be used. In that case it is important to set `USER_CFG_MAX_TIMER_INSTS` to an appropriate value.

- `#define USER_CFG_TIMER_SCALE <Integer>`

  Scale all time-outs in set actions with this value. This can for example be used during early testing to delay short time-outs to become visible (making for example a 1 millisecond time-out take 1 s). The feature should not be used in a finalized application, as it will cause some speed overhead.

Dynamic memory allocation

- `#define USER_CFG_USE_MEMORY_PACK`

Define to use the memory management package provided in the library, instead of OS functions malloc, free. If this package is used `USER_CFG_MEMORY_SIZE` should also be set (if the default is not appropriate). Default is undefined.

- `#define USER_CFG_USE_MEMORY_PACK <Integer>`

  Define the number of bytes to be used by the memory package. To avoid unnecessary problems define this value as a multiple of 16. Default is 8192 bytes.

- `#define USER_CFG_MEMORY_MIN_BLOCKSIZE <Integer>`

  Define the minimum size of the memory block. If defined only blocks of size:

  2^N * USER_CFG_MEMORY_MIN_BLOCKSIZE, N>=0, are used. This value should be a multiple of 16. Default is undefined.

Error detection

- `#define USER_CFG_ERR_CHECK_BASIC`
  - Turn on checking of basic state machine properties:
  - No more memory for signal sending or create
  - No more memory to allocate the parameters of a signal
  - No more memory for timer instance
  - `xOutEnv()` is not present and signal is sent to the environment
  - Signal is discarded
  - Cannot create more instances as maximum limit reached
  - Public attribute access error

  Default is undefined.

- `#define USER_CFG_ERR_CHECK_INDEX`

  Test that array index is in range. Default is undefined.

- `#define USER_CFG_ERR_CHECK_RANGE`

  Test that syntype values are in range. Default is undefined.

- `#define USER_CFG_ERR_CHECK_PREDEF_O`

  Test error situations in predefined operators. Default is undefined.

- `#define USER_CFG_ERR_CHECK_DECISION`

  Test that there is a path for the current decision value. Default is undefined.

- `#define USER_CFG_ERR_CHECK_NULL_PTR`

  Test that pointers are not NULL before de-referencing. Default is undefined.

- `#define USER_CFG_ERR_CHECK_MEMORY_PACK`

  Test for error situations in the memory package. Default is undefined.

- `#define USER_CFG_ERROR_MESS_STDOUT`

  Define if error messages should be printed on sdtout. Default is undefined.

- `#define USER_CFG_ERROR_MESS_STDERR`

  Define if error messages should be printed on stderr. Default is undefined.

- `#define USER_CFG_USE_ERR_MESS`

  Define if error messages, not only error numbers, should be printed. Default is undefined.

- `#define USER_CFG_WARN_ACTION`

  If defined the user provided function:

  ```
  void xUserWarnAction (unsigned char WarningNumber);
  ```

  is called in case of a warning. Default is undefined.

- `#define USER_CFG_ERR_ACTION`

  If defined the user provided function:

  ```
  void xUserErrAction (unsigned char WarningNumber);
  ```

  is called in case of an error. Default is undefined.

Miscellaneous

- `#define USER_CFG_USE_xInitEnv`
- `#define USER_CFG_USE_xCloseEnv`
- `#define USER_CFG_USE_xInEnv`
- `#define USER_CFG_USE_xOutEnv`

  Define the above to include calls of the corresponding environment function. Default is undefined.

- `#define USER_CFG_ADD_STDIO`

  Define if `stdio.h` should be included. This is automatically performed if any of `USER_CFG_UML_TRACE_STDOUT`, `USER_CFG_ERROR_MESS_STDOUT`, `USER_CFG_ERROR_MESS_STDERR` is defined. Default is undefined.

- `#define USER_CFG_UML_TRACE_STDOUT`

  Define if trace on SDL level should be printed on stdout. Default is undefined.

- `#define XUSE_TYPEINFONODE_CFG`

  Enables the removal of unused type info nodes. Type info nodes are data structures that are used during run-time by the functions providing generic implementations of SDL operators. By removing unnecessary type info nodes the memory footprint of the system can be greatly reduced.

Code generation commands

There are some options in the Targeting Expert that is passed to the code generator, sdtsan, and does not affect the `extreme_user_cfg.h` file. The purpose is to be able to generate as readable code as possible, which is also the default. If certain features are needed, that will affect the readability, these features can be selected individually. These options can be found in the “SDL to C compiler”-tab, in the group “Code generation options”.

- Amount of comments (`Set-Extreme-C-Comments`)

In the code generated for state machines it is possible to select the amount of comments added to the code. The available choices are:

- **1. Off**: Only some comments used to identify transitions are included.
- **2. Structure**: As 1 plus a comment for each translated SDL symbol.
- **3. Full**: As 2 plus comments giving some explanations to the code.

- Generate Run Time Tests (`Set-Extreme-C-Run-Time-Test`)

  This feature must be selected if any of the run-time tests `USER_CFG_ERR_CHECK_INDEX`, `USER_CFG_ERR_CHECK_RANGE`, `USER_CFG_ERR_CHECK_DECISION`, or `USER_CFG_ERR_CHECK_NULL_PTR` is selected.

- Generate Sdt references (`Set-Extreme-C-Sdt-Ref`)

  Include references to SDL source in generated code as C comments. Such references can be used to navigate back to the SDL source.

- Generate trace code (`Set-Extreme-C-Trace`)

  Selecting this feature will tell the code generator to include calls to trace functions (`xTrace` functions) in the generated code. This must be enabled if `USER_CFG_UML_TRACE_STDOUT` is enabled.

- Use Signal Priorities (`Set-Extreme-C-Signal-Prio`)

  This will generate signals with priorities. The priority is an integer value where a lower number means a higher priority.

Overview of Important Data Structures

All the important types discussed in this section are defined in `extreme_kern.h`. Please have that file ready at hand while reading this section.

In generated code there is information about each part in the system. For each part a struct variable of type `xPartTable` is generated. Example:

```
xPartTable xPartData_p_01 = {
  (xInstanceData *)xInstData_p_01,
  sizeof(yVDef_p_01),
  1,
  1,
  (xIniFunc)yIni_p_01,
  (xTransFunc)yPAD_p_01,
  xTransitionData_p_01,
  xStateIndexData_p_01
#ifdef CFG_USED_GUARD
  , 0
#endif
};
```

There is also in generated code an array containing the addresses to the `xPartTable` structs for all parts in the system. This global variable is used at many places to access information about parts. Example:

```
xPartTable *xPartData[] = {
  &xPartData_p_01,
  &xPartData_q_02
};
```

Looking through the contents of the xPartTable struct, it contains the following components:

Component	Description
`InstanceData`	A pointer to an array with one element for each instance of the part. These components are used to store instance specific values of different kinds, like state and local variable values.
`DataLength`	The size of each array element mentioned for the previous component.
`MaxInstances`	The maximum number of concurrent instances of this part.
`InitialInstances`	The number of instances at system start up.

Component	Description
yIni_Function	A reference to a function that initializes the at–tributes of the active class.
yPAD_Function	A reference to the function that implements the state machine for the part.
TransitionTable and StateIndexTable	Tables (arrays) used to determine how to handle a certain signal in a certain state.
GuardFunc	A reference to a function that can compute guard expressions used in the state machine.
ThreadNumber	The thread that this part belongs to. Only used in threaded integrations.

Other important global data structures are the array of available signals and timers. These are

```
/* Signal array */
static xSignal
    xSignalArray[CFG_STATIC_SIGNAL_INSTS];

/* Pointer to first element in list
   of free signals */
static xSignal *xFreeSignalList;

/* Timer array */
static xTimer
    xTimerArray[CFG_STATIC_TIMER_INSTS];

/* Pointer to first element in list
   of free timers */
static xTimer *xFreeTimerList;
```

These variables can be found in `extreme_kern.c` and define one array of signals and array of timers, together with starting pointers for the lists of available signals and timers.

The last important global data structure is the `xSystemData` variable called `xSysD`. In a non-threaded application `xSysD` is a variable of type `xSystemData`, while in a threaded application `xSysD` is an array with components of type `xSystemData`, with one component per thread.

xSysD contains global information about what is going on just now in the application or thread. The following components can be found in xSysD:

Component	Description
CurrentPid	This is the Pid value for the currently executing instance in the application or thread.
CurrentSymbol-Nr	This is the symbol number where the execution should start in the function implementing the state machine. The selection is performed by a switch in the beginning of the function.
CurrentData	This is a pointer to the local variables for the executing instance. This reference goes to the appropriate element in the InstanceData component in the xPartTable for the part.
CurrentSignal	This is a pointer to the signal that caused the currently execution transition.
SignalQueue	This is a reference to the first signal in the global signal queue (global for application or thread). The signals in this queue are linked together in a linked list.
ExternSignal-Queue	This is a signal queue where signals coming from other threads or from the environment first are stored. At well defined points (between transitions) signals are moved to the SignalQueue.
OutputSignal	Variable used as temporary variable while sending a signal in generated code.
TimerQueue	This is a reference to the first timer in the global timer queue (global for application or thread).
ThreadVars	In a threaded application this is a struct containing data about the thread itself. The contents depend on the integration.

Some other data structures that are worth discussing in more detail are Pid values, and contents of signals and timers.

A Pid value is a reference to an executing instance. The Pid value consists of two parts, the part number (parts are numbered 0, 1..., which is used to index the global `xPartData` array) and the instance number (which is used to index the `InstanceData` array in the `xPartTable` for the part). The Pid type is an unsigned type of suitable size to contain these two values.

A signal is defined by the type `xSignal` and contains the following components.

Component	Description
`Next`	Pointer used to link signals in lists.
`Sid`	The identity of the signal (signal type)
`Receiver`	The Pid value of the receiver.
`Sender`	The Pid value of the sender.
`SaveState`	Used to speed up handling of saved signals.
`Prio`	The signal priority, if you have set up to use signal priorities.
`ParPtr`	A pointer to the parameters of the signal. Refers either to ParArea or to allocated memory.
`ParArea`	This is the inline area for signal parameters used if the parameters fit into this area.

A timer is defined by the type `xTimer` and contains the following components:

Component	Description
`Next`	Pointer used to link timers in lists.
`Sid`	The identity of the timer (timer type)
`Owner`	Pid value for the owner of the timer
`Time`	The time set for the timer.
`TimerParValue`	Optional integer parameter for timers.

Chapter

69 *SOMT Introduction*

This chapter describes the techniques that the SOMT method is based on. It also gives a first brief description of the method and the activities it consists of.

Last in the chapter is a list of references, which are referred to throughout this volume.

Background

Object-oriented analysis is a well-known and popular technique for understanding a problem and analyzing a system. There are many different versions of object-oriented analysis published as different methods in various books. The Object Management Group (OMG) has agreed upon a standard language for object-oriented methods and tools - the *Unified Modeling Language* (UML) and its notation ([37], [38]).

SDL [24] and MSC [26], on the other hand, are standardized notations used for specification and design of systems. They have a solid foundation in terms of support for design, formal verification and code generation. Especially for distributed, reactive, real-time applications SDL and MSC has a successful track record.

The scope of this volume is to present a method that integrates object-oriented analysis and SDL design with a special focus on application areas where SDL is known to be suitable. The intention is of course to provide developers with the best of both worlds: The strength of the object oriented analysis in the early phases together with the strong back-end provided by SDL and SDL tools.

The method has been given the name SOMT (short for *SDL-oriented Object Modeling Technique).* As the name indicates the method is essentially an adaptation of OMT to the requirements given by the special application area of distributed, reactive, real-time systems together with the usage of SDL for the design.

Another object-oriented analysis method that has provided input to SOMT is the Objectory method by Jacobsson [19]. In particular, the idea of use cases that originated from this method has been incorporated into SOMT.

A special focus of SOMT is to provide solutions that can be directly applied in a development project. For instance, it provides guidelines about how to apply OMT in a way that enables a smooth transition between analysis and design.

The volume is focused on how to use the different notations and concepts of object-oriented analysis and SDL and does not provide a detailed description on the specific notations. It is therefore recommended that you are at least reasonably familiar with both the general concepts of object-oriented analysis, the OMT notation and SDL before reading this report. [21] is a good introduction to the OMT notation and there exist several text books on SDL, for example [27].

The rest of this document is structured as follows:

- This chapter, *SOMT Introduction*, gives an overview of the SOMT method and introduces the different activities
- chapter 70, *SOMT Concepts and Notations* describes briefly the different concepts and notations that SOMT uses
- chapter 71, *Requirements Analysis* covers the requirements analysis activity
- chapter 72, *System Analysis* presents the system analysis activity
- chapter 73, *From Analysis to Design* discusses the steps and considerations when moving from analysis to design
- chapter 74, *System Design* moves on to system design
- chapter 75, *Object Design* deals with object design
- chapter 76, *SOMT Implementation* ends the SOMT activities with a description of the implementation activity
- chapter 77, *SOMT Projects* focuses on how to organize a SOMT project

Overview of the SOMT Method

The SOMT method provides a framework that shows how to use object-oriented analysis and SDL-based design together in a coherent way. The framework is based on describing the analysis and design of a system as a number of activities. Each activity deals with some specific aspects of the development process. The work done in the activities is centered around a number of models, that document the result of the activities. As an integral part of the SOMT method, guidelines are given for the transition between the different models. The activities and the main models used in SOMT are illustrated in Figure 614.

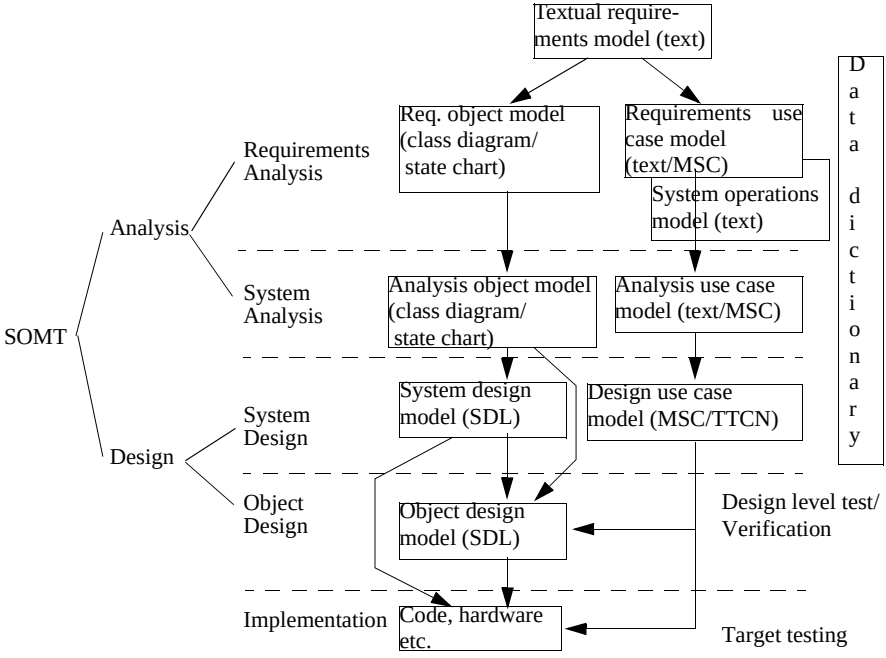

Figure 614: SOMT activities and main models

As can be seen in Figure 614, SOMT consists of five major activities:

- *Requirements analysis.* The purpose of the requirements analysis is to analyze the problem domain and the requirements on the system to be built, essentially by analyzing the system as a black-box in its intended environment.
- *System analysis.* The purpose of the system analysis is to identify the architecture and most important objects that must be represented in the system to achieve the required functionality.
- *System design.* The purpose of the system design phase is to precisely define the architecture of the system including the detailed interfaces between different parts. In the system design the architecture of the system is also analyzed in terms of implementation strategies and decomposition into work packages for different development teams
- *Object design.* The purpose of the object design is to define in detail the functionality including the behavior of all objects.
- *Implementation.* The purpose of this phase is to create the executing application that implements the requirements.

As seen above, SOMT uses a number of different models to describe different aspects of the system. In many cases there are relations between objects in the different models. One especially important relation is that in some cases one object can be seen as an implementation of another object. In SOMT this type of relation is called *implink* (short for implementation link) and corresponds to a design decision taken during the development. The creation and maintenance of implinks forms an important part of the SOMT method. Two points can be made:

- Since the transition between different models is a creative process involving a number of engineering decisions, this is a manual, but tool supported, activity.
- The major tool support is a *Paste As* functionality that will allow you to copy an object in one model and paste it into another model while automatically creating an implink. For example: an object model class from the analysis object model may be pasted as an SDL process type in the system design model.

Note that the *Paste As* functionality can be seen as an implementation of transformation rules between the different models, e.g. from object models to SDL design models.

Another important aspect of implinks is that they facilitate consistency checks between the different models.

It is important to note that even though the description in SOMT of the different activities is a sequential description, this does not mean that in practice these activities can or should be carried out in sequential order. On the contrary, depending on the size and complexity of the application, the different activities can be organized in a number of different ways. This is the topic of the chapter 77, *SOMT Projects*.

Scope of the SOMT Method

The primary focus of the SOMT method is on system development using object oriented analysis and SDL design, with extra support for interface definitions in other notations like ASN.1 [23]. Nevertheless, an important issue in SOMT is the possibility to use the analysis part of SOMT together with design using other notations. Some examples:

- The system to be built is composed of several different parts, where some parts are not suitable to design using SDL. A simple example might be where the system includes a window based user interface that is easier to design using a special purpose tool.
- Another example is when the system includes a data base component. The analysis of the data is suitable to perform using object oriented analysis, but the data base component is preferably designed and implemented using a commercial data base tool.
- Different parts of the system may be designed in different parts of the world and for some reason there has been a choice to use SDL-based development for some parts and other methods for other parts.

The scope of the support given by SOMT when using a design notation other than SDL is, as can be seen in Figure 615, basically:

- The requirements and system analysis of the system are still valid.
- Parts of the system design activity are still supported by SOMT.
- The SDL-based design of components is of course supported.

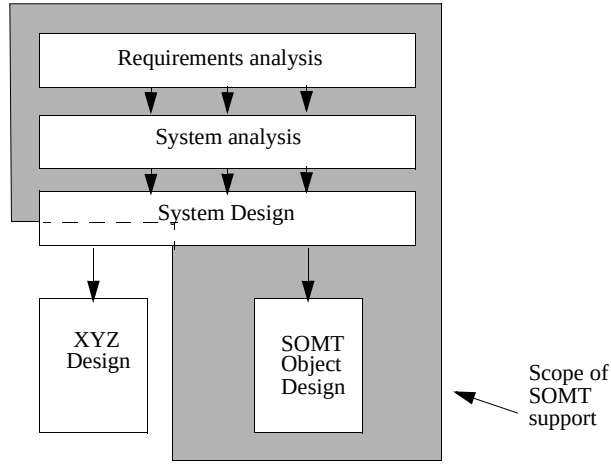

Figure 615: Using SOMT analysis and design together with design using other methods/notations

How much of the system design part that is supported by SOMT is of course very much depending on the “XYZ” method used (see Figure 615). However, the support given by SOMT when using “external” components is at least the definition of the interface of the “external” components. This includes definitions of both static and dynamic aspects as will be seen in chapter 74, *System Design*.

Requirements Analysis

The requirements analysis is the first activity in the SOMT method. The purpose of the activity is, as stated above, to capture and analyze the problem domain and the user requirements on the system to be built. For this purpose the system is viewed as a black-box and only the objects and concepts visible on the system boundary and outside the system are modeled.

There are five major models used in this phase:

- A textual requirements model
- A use case model
- A requirements object model
- A data dictionary

- A system operation model

The textual requirement model is a conventional textual requirements specification. This may come from the customers as input to the development project or it may be created as part of the requirements analysis as a complement to the other models.

The use case model consists of a set of use cases, each described using structured text and/or using MSCs and HMSCs. The purpose of this model is to capture and validate requirements from a user's point of view to make sure that the system will solve the right problem.

The requirements object model is a conventional object model, i.e. one or more diagrams illustrating a number of objects and their relations (including inheritance and aggregation relations). State charts may also be included in the object model to provide high level descriptions of the behavior of important objects. The purpose of the model is two-fold:

- To use context diagrams to describe the system and the external actors that interact with the system
- To document all the concepts found during the requirements analysis and the relations between them in order to ensure that developers and users have a common understanding of the problem domain

The system operation model is a description of the atomic transactions the system must be able to perform. The system operations can be viewed as more detailed specifications of the events that are part of the use cases.

During the requirements phase a data dictionary is also created. The data dictionary is a list of the concepts identified in this phase together with brief explanations of the concepts. It is used and refined throughout all the development phases.

System Analysis

In the system analysis phase the system to be built is analyzed using an object-oriented method. The purpose of the phase is to describe the architecture of the system and identify the objects that are needed to implement the required functionality. The models used in this phase are:

- An analysis object model, to describe the architecture of the system and represent the objects in the system

- An analysis use case model where the interaction between some of the objects is described
- Textual analysis documents to document decisions and architecture related requirements not suitable to be expressed in the object models and use cases

The analysis object model is a conventional object model, consisting of class diagrams and possibly state charts, that forms the input to the object design phase. The analysts should in this model be concerned with identifying the objects that must be present in the system. These objects may come from the requirements object model produced in the requirements analysis, or they may be added in this phase for different reasons. For example, objects may be needed to represent the control logic described by the use cases from the requirements analysis. The differences between the object model in the system analysis phase and the object model in the requirements analysis phase are:

- The requirements analysis object model consists of objects visible on the border of the system and outside the system, e.g. users of the system, while the system analysis object model is focused on the internal object structure of the system.
- The purpose of the object model in the requirements analysis is different from the purpose in the system analysis. The purpose in the requirements analysis is to describe the problem that the system is to solve, while the purpose in the system analysis is to describe the system itself.

System Design

The purpose of the system design is to define the implementation structure of the system and to identify overall design strategies. The models used in this activity are mainly:

- A design module structure, describing the source modules of the design

- An architecture definition, containing
  - SDL system/block diagrams that define the architecture of the resulting application
  - SDL interface definitions of the components of the system using signals or remote procedures
- A design use case model, described by MSC and HMSC diagrams, to define the dynamic interfaces between the different components in the system
- Textual design specifications, describing aspects of the components not suitable for formalization like user interface definitions and other non-functional requirements

The designer of the system will have several different aspects to cover within the system design activity:

- The decomposition of the system into work items, maybe to be implemented by different development teams
- Reuse aspects of the design

Object Design

The purpose of the object design is to create a complete and formally verified description of the behavior of the system. The models used in this phase are essentially SDL diagrams, in particular SDL process graphs that are used to define the behavior of active objects.

One very important aspect of this phase is usage of the *Paste As* concept that will take a user from object models to SDL diagrams. Essentially the designer of the system will in this phase have to consider two major aspects when creating the design model:

- The representation of the analysis object model concepts in the design

  This involves issues like to decide for each object if it is an active or passive object.

- The dynamic behavior of the design objects

The object design also includes a testing/verification task. The purpose of this is to verify that the requirements on the system, expressed e.g. in the design use cases from system design, are correctly implemented in the design.

Implementation

The implementation and testing activities are aimed at producing the final application, i.e. executable software and hardware. The activities in this phase are very much depending on the execution environment of the application but may include:

- Using an automatic code generation tool to produce the code from the SDL design
- Adapting the generated code (the running SDL system) to its environment i.e. regarding signal handling
- Integrating the code to the hardware requirements by means of using real-time operating systems and cross-compilers to generate the executable for the hardware
- Implementing and executing test cases in the target environment based on the design use cases from the system design activity

Summary

SOMT is a method specially designed to suit the development of distributed, reactive, real-time systems. It is based on well-established and industrial-strength techniques:

- object models for analysis
- SDL for design

SOMT recognizes not only a number of models to be made, but also the importance of having a glue between these models. Therefore, SOMT introduces the *Paste As* concept to provide a smooth and well-defined transition between the different models, e.g. between the analysis and design, enabling traceability using *implinks.*

The benefit for a development project is that the analysts and developers all can use the notations best suited for each phase of a development project. The object oriented analysis strength when analyzing requirements and creating conceptual analysis models is combined with the strong back-end given by SDL tools for design, verification and code generation.

Chapter 69 SOMT Introduction

Chapter

70

SOMT Concepts and Notations

This chapter describes the major concepts and notations used in the SOMT method. The notations treated includes object models, state charts, SDL diagrams and Message Sequence Charts (MSCs). Note that the descriptions in this section only briefly describes the different notations. For a more thorough treatment, please consult a textbook on the specific notation.

Activities, Models and Modules

As seen in the previous chapter, the SOMT method describes object oriented analysis and design as a number of activities that produce one or more models. A *model* is here used in an abstract fashion to denote a collection of diagrams, text documents or whatever is needed in the particular model. The concept of a model is used to be able to discuss the results of an activity without going into detail of how the actual diagrams/documents are organized.

A *module*, on the other hand, is the concept used in SOMT to define how the diagrams/documents are organized. The major purpose of the modules is that they form units that should be fairly self-contained and that can be developed by themselves, maybe by different teams. A module is a container of e.g. diagrams and textual documents that has no semantics by itself but that forms a scope unit for names (if this is not given by the notation used). For example, if the Analysis Object Model is described in two modules that both contain a class called “Person”, then these definitions do not refer to the same class. There will be two different “Person” classes, one in each module.

In practice it is beneficial to have a simple mapping between models and modules, either a one-to-one or, if a model is too large, a one-to many mapping where a model is decomposed into several modules.

The actual documentation produced according to SOMT is thus a collection of modules containing diagrams/documents that together form this particular projects representation of the SOMT models.

Implinks and the Paste As Concept

The SOMT method introduces a number of different models that are used to describe different aspects of the system. In particular there are three levels formed by:

- The requirements that describe the problem and external requirements on a system
- The system analysis describing the concepts used in the system
- The system and object design that defines the structure and behavior of the system

One very common relation between objects in different models is that one object can be seen as an implementation of an object in another model. For example, an object in the object model created in the system analysis phase may be reintroduced in the design model as a process type or an ADT (abstract data type). Another example may be an object that was identified in the requirements analysis as something visible on the system boundary, and that later is reintroduced in the analysis object model and finally ends up as a signal in the SDL design. To represent this type of relations among objects the concept of implementation links (*implinks*) is used. An implink is a directed relation between two objects, usually (but not necessarily) in different models. Conceptually we get a picture as in Figure 616.

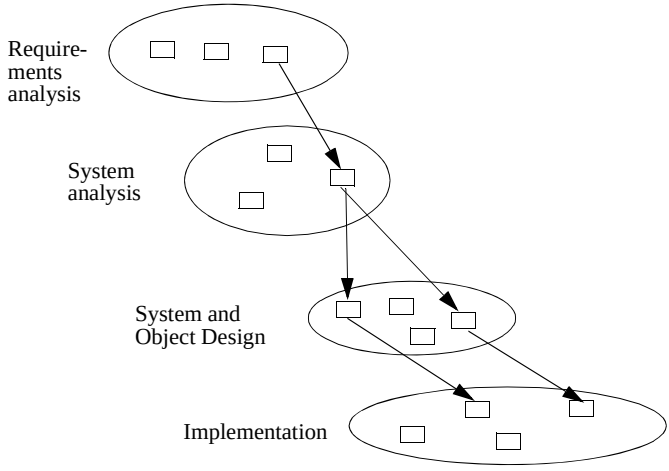

Figure 616: Implinks between objects in different models

If used carefully, the implinks give a possibility to trace requirements all the way down into code. There are several situations where the implinks are very useful:

- *What if* analysis. What are the consequences if a particular requirement is changed?
- Consistency checking. Are all concepts in e.g. the system analysis model implemented?

- Understanding design by following the links backwards from implementation to requirements. What is the purpose of a particular design object? What happens if we change it?

It is important to see that the act of creating an implink is a creative design action that encapsulates a design decision. The *Paste As* mechanism is a special concept used in SOMT to support the task of creating implinks. The idea is that an object in one model can be copied and then *pasted as* a new object in another model, see Figure 617. This action serves both to create the new object and to document the design step using an implink.

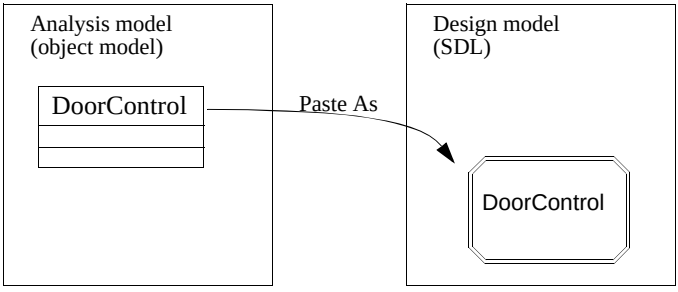

Figure 617: Using Paste As to capture a design step from the system analysis model to SDL

Consistency Checking

The SOMT method uses a number of models and notations and the checking of various aspects of the models is an important part of a development project. This checking can be formulated as a question of identifying “entities” or “concepts” in different models (or in one model), to identify some rules of how these entities should relate to each other, and finally to check that the models are consistent with respect to these rules. This type of checking is in this document called *consistency checking*. Three different types of consistency checking can be identified:

- Checking the internal consistency within one model, e.g. checking that an SDL system is correct with respect to the syntactical rules for SDL

- Checking that two models are consistent with respect to each other and some consistency requirement, e.g. checking that all classes in an object model are described in the data dictionary
- Checking traceability aspects, i.e. checking that the entities in two models are correctly linked (using implinks) to each other. For example, checking that all objects in an analysis model are implemented in the design model

In some sense the checking of traceability aspects is a special case of the checking of the consistency between two models, but it is an important special case and it is given a special treatment in SOMT.

One general observation that can be made is that the identification of concepts/entities is very much depending on the particular notation used. Each separate notation will have to be treated separately following the particular rules that apply to this language. For formal languages like SDL, the concepts and procedures how to find the entities are well defined, while for other languages the rules are different, and for plain, informal text the entity identification will have to be explicitly done by the user. In SOMT there is a special possibility to “mark” words or phrases in text documents. The intention is that this marking means “this concept is important” or “this is a concept that I would like to for consistency checks”.

In the rest of this volume, each activity of the SOMT method together with its associated models will be described in different chapters. Each of these chapters will also include a discussion on consistency rules that are relevant for this particular model.

Object Model Notation

The object model notation from Object Modeling Technique (OMT) and Unified Modeling Language (UML) is a commonly accepted graphical notation used for drawing diagrams that describe objects and the relations between them. The notation that is used in examples in this volume is shown in Figure 618 through Figure 623. For more details about other, more advanced OMT object model concepts, please consult [21], and for details about the UML notation see [37] and [38].

Class

The most important concept in an object model is the class definition. A *class* is a description of a group of similar objects that share the properties defined by the class. The object model notation for a class is exemplified in Figure 618, where the second class definition also shows how to define attributes and operations.

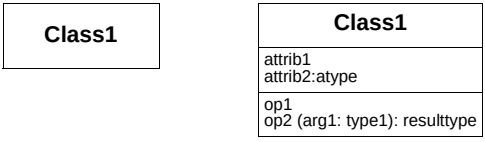

Figure 618: A collapsed class symbol and a class symbol with attributes and operations

In some cases it is necessary to reference classes from an external module. The notation used for this purpose is *ExternalModule::Class*.

Classes may *inherit* attributes and operations from other classes. The object model notation for this is shown in Figure 619.

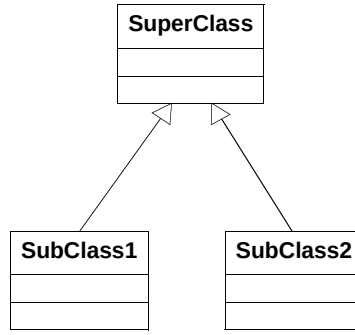

Figure 619: Inheritance between classes

Relations and Multiplicity

Classes may be physically or logically related to each other. This is shown in the object model by means of *associations* as shown in Figure 620. An association may have a name and/or the endpoints of the association may be labeled by the role of this endpoint.

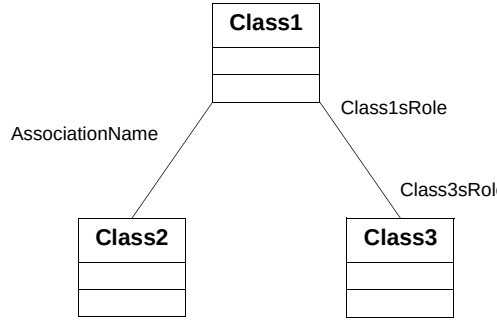

Figure 620: Associations between classes

Aggregation is special kind of association that has its own notation as shown in Figure 621.

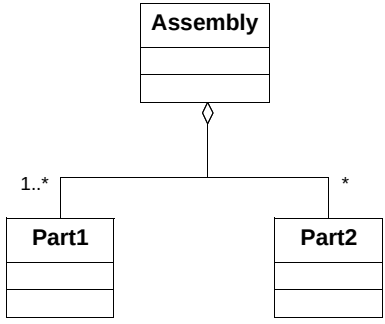

Figure 621: Aggregation

The endpoints of associations and aggregations may have a multiplicity as shown in Figure 622.

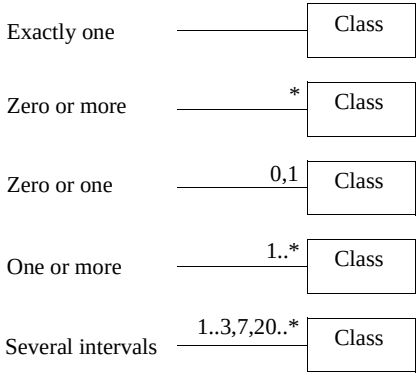

Figure 622: Multiplicity of associations and aggregations

Module

In practise the complete requirements object model is often too big to fit into one diagram. To solve this problem it is possible to use multiple object model diagrams that can be organized into a module, which simply is a list of diagrams. It is important to notice that a class may be present in more than one diagram and still only represent one logical class.

Objects

Besides class definitions, object models may of course also contain objects and their relations. The relation that exists between objects are links, which corresponds to the associations for classes. The object symbol has one field containing the name of the object together with a reference to the class, and an attribute field where constant or default values can be assigned to the object attributes. See Figure 623.

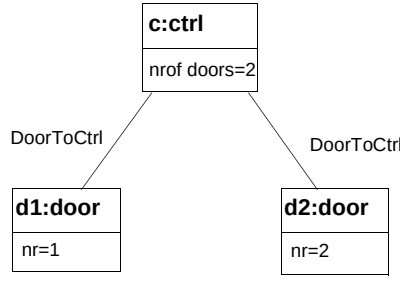

Figure 623: Objects related by links

State Chart Notation

The notation presented in this section is a subset of the notation for state charts presented by David Harel [36] which is used in the Unified Modeling Language (UML) [37] as well as in the Object Modeling Technique (OMT) [21].

A state chart model is suitable to use together with class and object models. The descriptions of the behavior of a class in a class diagram is collected into a state chart which describes the dynamic view of the model by means of states and transitions. The notation to use is presented below.

Notation

State

To describe state charts a state symbol is needed. The state symbol is divided into three compartments, State Name, State Variable and Internal Activity, which are all optional. The top compartment contains the optional name of the state. State symbols with the same name within the same context are considered to be the same. It is not necessary to name states and if several anonymous states exists; each anonymous state symbol is considered to be an individual state. Figure 624 shows a collapsed state and a state with events.

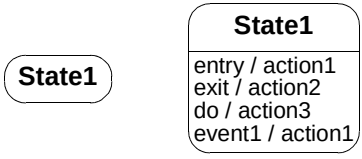

Figure 624: A collapsed state symbol and a state symbol with events

A state symbol may contain an Internal Activity compartment which describes the activities of the current state, activities that are done upon entering the state, activities taking place while in the state and activities executed when exiting the state. Each activity is described in the format:

event-name argument-list '/' action expression

Each event name may appear only once within a state symbol. The event names "entry", "exit" and "do" are reserved and they describe the following actions:

'entry' '/' action expression
An atomic action performed upon entering the state

'exit' '/' action expression
An atomic action performed upon exiting the state

'do' '/' action expression
An action performed during the state

Transition

The second necessary symbol for drawing state charts is the transition. The transition symbol is an arrow which connects two symbols of either type of state, start and termination, see Figure 625.

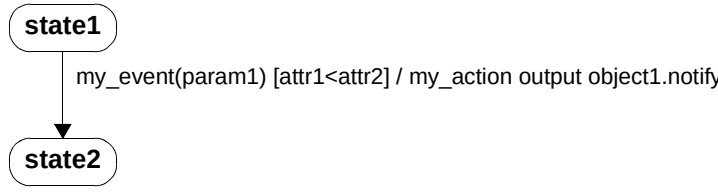

Figure 625: The transition from state1 to state2 is triggered by the event my_event and the condition that attr1 is less than attr2

The syntax for the transition symbol follows the format:

event-signature '[' guard-condition']' '/' action-expression 'output' send-clause

The event-signature consists of the parts:

event-name '(' parameter ',' ... ')'

The guard-condition is a Boolean expression formed by the parameters of the triggering event together with possible attributes and links of the object described by the state chart.

The action-expression describes the action that is executed during the transition. The action may be described by procedures, affected attributes and links.

The send-clause has the format:

destination-expression '.' Destination-event-name '(' argument '.' ...')'

The destination-expression identifies the receiving object or a set of receiving objects.

The Destination-event-name is the name of an event that may be received by the receiving object(s).

Start and Termination Symbol

The start symbol denotes the starting point of a state machine described by a state chart and the termination symbol denotes the point of termination of a state machine. Figure 626 shows a simple state machine, describing the behavior of a door, including a start symbol and a termination symbol.

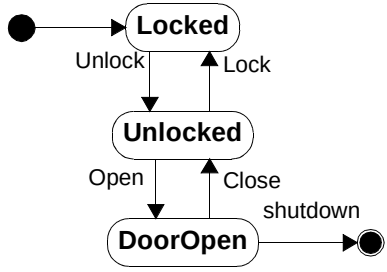

Figure 626: A simple state chart with a start symbol and a termination symbol

Substates

States may be refined into nested diagrams of sub-states, or hierarchical states. The state represents a simplification of more complex behavior expressed in the nested diagram.

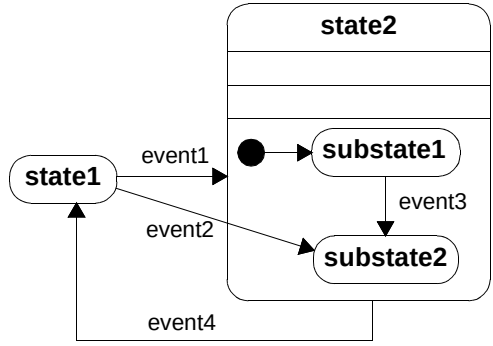

Figure 627: A state chart with states and substates.

State Charts in SOMT

State Charts and SDL

Both State Charts and SDL process graphs are two notations used to express state machines. The two notations have both their advantages. State Charts are good for expressing high level functionality typically used in early activities like analysis. SDL is good for expressing detailed functionality as in design activities. SDL is also a formal notation, with well defined semantics, from which it is possible to generate code.

State Charts in Requirements Analysis

State charts might be used to express high level functionality of a system by focusing on the behavior of the system rather than the behavior of the system's parts. It might also be useful to express the behavior of complex actors that are interacting with the system.

State Charts in System Analysis

In the context of system analysis, state charts are useful to express the behavior of the system parts and how these parts interact dynamically. The architecture of the system is described in a class diagram named Logical Architecture. Using state charts in addition to the class diagram makes it possible to describe the dynamic properties and the behavior of the system or parts of the system. The behavior descriptions should be included in a set of documents called the Object Behavior Diagram which together with the Logical Architecture is part if the Analysis Object Model.

State Charts in System and Object Design

During the activities of System and Object Design, SDL process diagram is the preferred notation for describing the behavior of the system. The product of the Object Design activity should be a complete description of the system which enables code generation. State Charts, due to their weak semantics, may be useful to express a less detailed overview of rather complex behavior expressed in SDL.

Message Sequence Charts

A message sequence chart (MSC) is a high-level description of the message interaction between system components and their environment. A major advantage of the MSC language is its clear and unambiguous graphical layout which immediately gives an intuitive understanding of the described system behavior. The syntax and semantics of MSCs are standardized by ITU-T, as recommendation Z.120 [26].

There are various application areas for MSCs and within the system development process MSCs play a role in nearly all stages, complementing SDL on many respects. MSCs can e.g. be used:

- To define the requirements of a system
- For object oriented analysis and design (object interaction)
- As an overview specification of process communication
- For simulation and consistency check of SDL specifications
- As a basis for automatic generation of SDL skeleton specifications
- As a basis for specification of TTCN test cases
- For documentation

Plain MSC

The most fundamental language constructs of MSCs are *instances* (e.g., entities of SDL systems, blocks, processes and services) and *messages* describing the communication events, see Figure 628.

Another basic language construct is the *condition* symbol which is drawn as a hexagon. A condition describes either a global system state referring to all instances contained in the MSC, or a state referring to a subset of instances (a non-global condition). The minimum subset is a single instance.

An MSC can reference another MSC using an *MSC reference* symbol. (Such a symbol can also reference a High-level MSC, explained later.) This symbol is drawn as a rectangle with rounded corners and has the name of the associated MSC stated inside it. MSC references can for example be used to have one MSC describing an initialization sequence and then reference this MSC from a number of other MSCs.

The reference symbol may not only refer to an MSC but can also contain MSC reference expressions that reference more than one MSC. This construct gives us a very compact MSC representation and it also provides an excellent means for reusability of certain MSCs.

The textual MSC expressions are constructed from the operators alt, par, loop, opt and exc:

- An MSC reference with the keyword **alt** denotes alternative executions of MSC sections. Only one of the alternatives is applicable in an instantiation of the actual sequence.
- The **par** operation defines parallel executions for MSC sections. All events within the parallel MSC sections will be executed (free merge) with the only restriction that the event order within each section must be preserved.
- An MSC reference with a **loop** construct is used for iterations and can have several forms. The most general construct, `loop<n,m>`, where n and m are natural numbers, denotes iteration at least n and most m times. The operands may be replaced by the keyword inf, like in `loop<n,inf>`. This means that the loop will be executed at least n times. If the second operand is omitted, like in `loop<n>`, this will be interpreted as `loop<n,n>`. If both operands are omitted the interpretation will be `loop<1,inf>`.
- The **opt** operation is an operator with one operand only. It is interpreted in the same way as an alt operation where the second operand is an empty MSC.
- An MSC reference where the text starts with **exc** followed by the name of an MSC indicates that the MSC can be aborted at the position of the MSC reference symbol and instead continued with the referenced MSC. If the exception does not occur the events following the exc expression are executed. The exc operator can thus be viewed as an alternative where the second operand is the entire rest of the MSC. MSC references with exceptions are frequently used to indicate exceptional cases when using MSCs to formalize use cases.

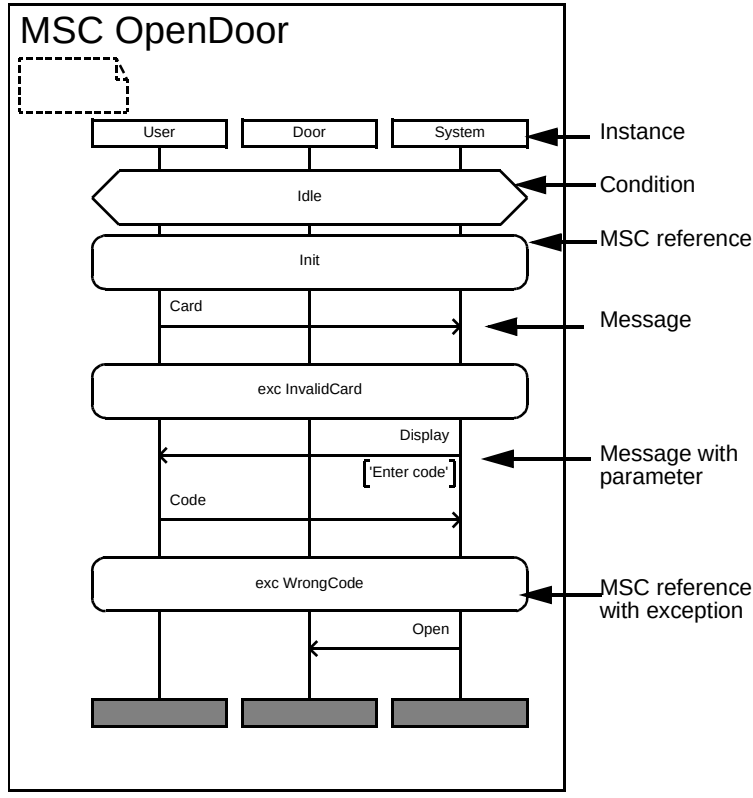

Figure 628: Example of a plain MSC

By means of *inline operator expressions* composition of event structures may be defined inside an MSC. Graphically, the inline expression is described by a rectangle with dashed horizontal lines as separators. The operator keyword **alt**, **loop**, **opt**, **par** or **exc**, placed in the upper left corner, are used with the same meaning as when used together with the MSC reference symbol.

Whether to use inline operator expressions or MSC reference symbols with an operator is a matter of taste. The same things can be expressed with both notations. Using inline expression several scenarios can be expressed in one single diagram, i.e. we just have one single file to handle. If we use MSC reference symbols to express e.g. exceptions and alternatives there is a need for us to handle several files. On the other

hand, the diagram becomes less cluttered if we refer to other MSCs instead of trying to express all possible scenarios in it.

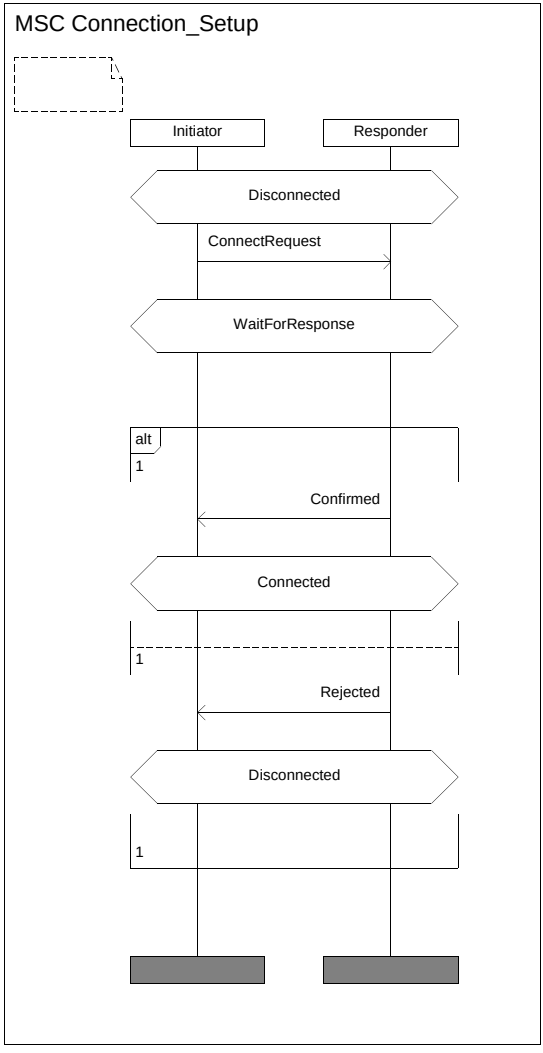

Figure 629: A plain MSC with inline operator expression

For information about more plain MSC concepts, like e.g. timers, please consult the MSC standard Z.120.

HMSC

A high-level MSC (HMSC) provides a means to graphically define how a set of MSCs can be combined. Contrary to plain MSCs, instances and messages are not shown within an HMSC, but it focus completely on the composition aspects. You can get a picture of how an HMSC works in practice by comparing it with a road map. HMSCs, like normal road maps, may easily become quite complex if they are not structured in any way. Fortunately, HMSCs can be hierarchically structured, i.e. it is possible to refine HMSCs by other HMSCs. The power of the MSC language is considerably improved with the new concepts introduced with HMSCs. It is e.g. much easier to specify a main scenario together with all accompanying exceptions.

An HMSC is a directed graph where each node is either (see Figure 630):

- A start symbol which denotes the start of an HMSC (there is exactly one start symbol in each HMSC).
- A stop symbol which denotes the end of an HMSC.
- An MSC reference used to point out another (H)MSC diagram which defines the meaning of the reference. The reference construct in HMSC can thus be seen as a placeholder for an MSC diagram or another HMSC diagram. Like a reference symbol in a plain MSC, an MSC reference symbol in an HMSC can contain references to several (H)MSCs through using MSC reference expressions and the operators alt, par, loop, opt and exc.
- A condition symbol is used to set restrictions on how adjacent referenced MSCs can be constructed. An HMSC condition immediately preceding an MSC reference has to agree with the (global) initial condition of the referenced MSC according to name identification. All conditions on HMSC level are considered to be global, they refer to all instances contained in the MSC. They can be used to guard the composition of MSCs described by HMSCs.
- A connection point which denotes that two crossing lines are actually connected. This symbol has no semantic meaning but is introduced only to simplify the layout of the HMSC.

Flow lines connect the nodes in the HMSC and they indicate the sequencing that is possible among the nodes in the HMSC. If there is more than one outgoing flow line from a node this indicates an alternative.

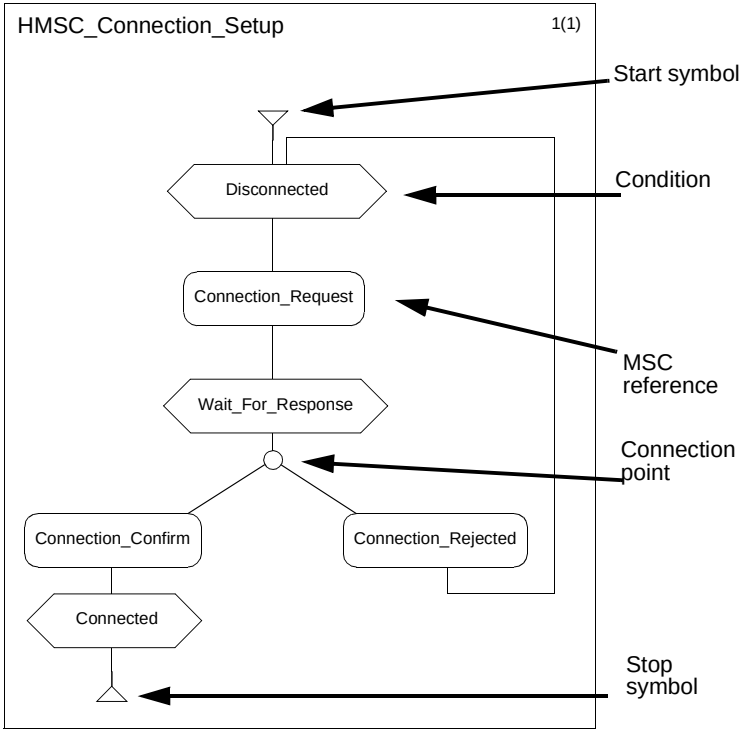

Figure 630: Example of an HMSC

SDL

SDL (Specification and Description Language) is mainly used for specifying behavior of real-time systems. This section provides a small overview of the language. For further reading, we recommend [27], [28] and [29] as useful textbooks about SDL. The SDL language is standardized by ITU-T, as recommendation Z.100 [24].

An SDL system consists of the following components:

- Structure
  - Hierarchical decomposition with *system*, *block*, and *process* as the main building blocks
  - Type hierarchies: inheritance, generalization and specialization are supported for hierarchical building blocks
- Communication
  - Asynchronous *signals* with optional signal parameters
  - *Remote procedure* calls for synchronous communication
- Behavior
  - *Processes*
- Data
  - *Abstract data types* that can be inherited, generalized and specialized
  - ASN.1 data types according to Z.105 [25]. See "ASN.1" on page 3836
- Modularization
  - Components like *block/process types*, *data types*, and *signals* can be placed into *packages* that can be imported into a *system*, enabling separate development.

Structure

Figure 631 shows the hierarchical levels in SDL: *system*, *block*, *process*, *procedure* and *service*.

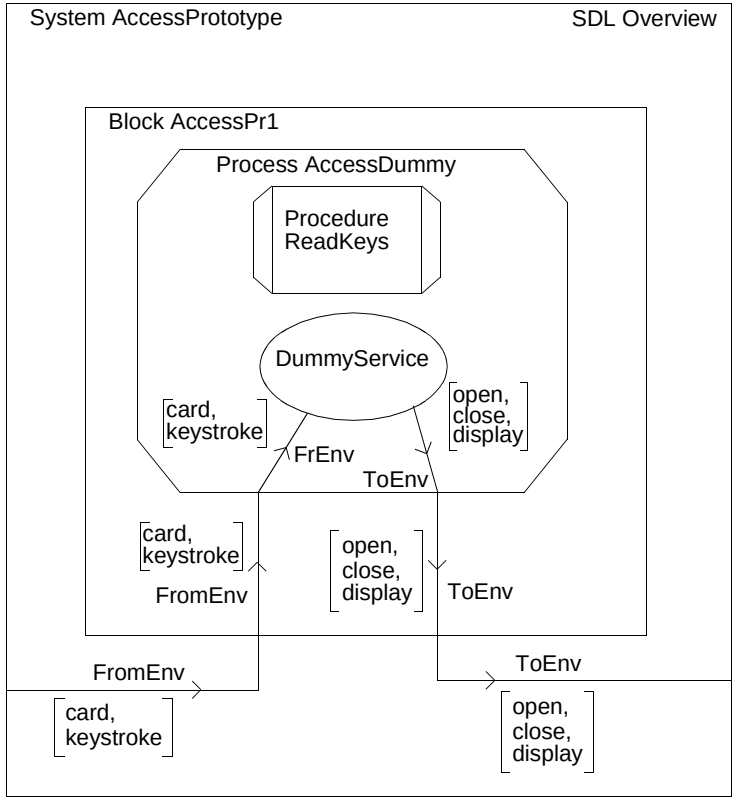

Figure 631: The hierarchical decomposition of an SDL specification

A *system* must contain at least one *block* and a *block* must contain at least one *process*. *Services* can exist within a process, being executed one at a time, controlled by the received signals. Thus the incoming signal sets of services in one process must be disjoint. Using *procedures* is a way to structure the information within processes and services. Processes, services and procedures are described by a flow chart-alike notation, see "Behavior" on page 3827.

The static structure of a *system* is defined in terms of *blocks*. Blocks communicate by means of *channels*.

The dynamic structure of an SDL *system* consists of a set of *processes* that run in parallel. A *process* is a finite state machine extended with data. *Processes* are independent of each other and communicate with discrete *signals* by means of *signal routes*.

Communication

Since SDL does not allow any use of global data, all information that has to be exchanged must be sent along with *signals* between processes, or between processes and environment. Signals are sent asynchronously, i.e. the sending process continues executing without waiting for an acknowledgment from the receiving process.

Signals travel through *channels* between blocks, and from one process to another via *signal routes*. See Figure 631.

Synchronous communication is possible via a shorthand, *remote procedure call*. This shorthand is transformed to signal sending with an extra signal for the acknowledgment. Remote procedures are often used when a process wants to offer services to other processes.

Behavior

The dynamic behavior in an SDL system is described in the processes. Processes in SDL can be created at system start or created and terminated dynamically at run time. More than one instance of a process can exist. Each instance has a unique *process identifier* (PId). This makes it possible to send signals to individual instances of a process. The concept of processes and process instances that work autonomously and concurrently makes SDL appropriate for distributed applications.

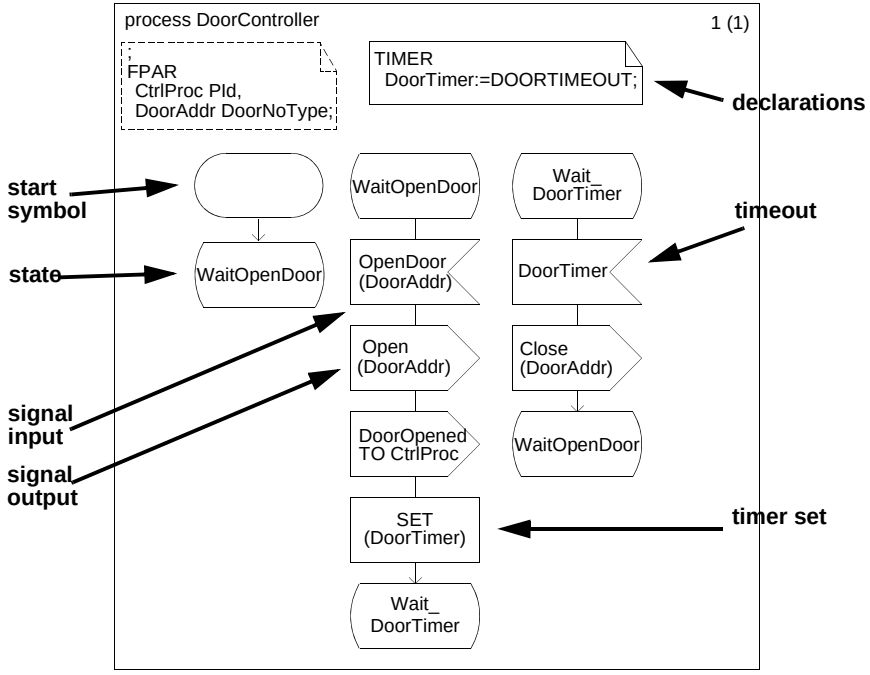

Figure 632: Behavior described by an SDL process

A process must have one start symbol. Since a process is a state machine, a transition between two states is made only after a signal has been received. If there are no incoming signals the process is inactive in a state. In SDL a transition takes no time. To be able to model time, and to set time restrictions, there is a timer concept. Each process has its own set of timers that can be set to expire on different durations.

Data

The set of predefined sorts in SDL makes it possible to work with data in SDL in a traditional way:

- Integer
- Real
- Natural
- Boolean
- Character
- Duration
- Time
- Charstring
- PId

More complex data sorts can be created by using *arrays*, *strings* and *structs*.

Abstract Data Types in SDL can be used for more than representing data, e.g:

- Hide data manipulation
- Hide algorithmic parts of a specification
- Create an interface to external routines

Data manipulation is hidden in *operators*. For a more thorough description on how to use complex data structures with operators in practice, please see [32].

Structural Typing Concepts

The object-oriented concepts of SDL give you powerful tools for structuring and reuse. The concept is based on type definitions. All structural building blocks can be typed: *system type*, *block type*, *process type* and *service type*. An exception is the *procedure* that is a type in its original form.

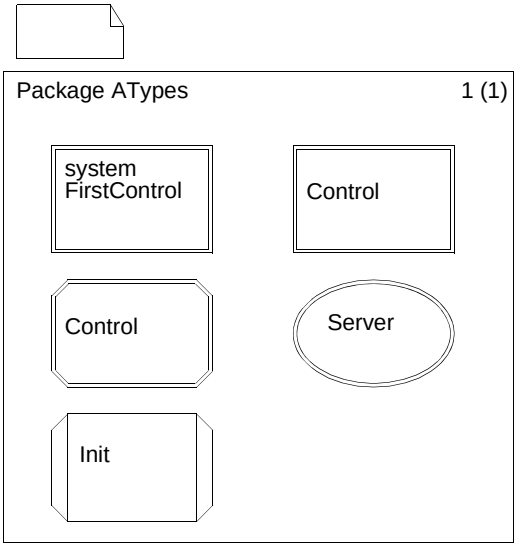

Figure 633: Package with type definitions

Type definitions may be placed outside the system in *packages*. *Packages* can be seen as libraries of frequently used functions. The structural typing concepts are shown in Figure 633. All types can inherit from other types of the same kind.

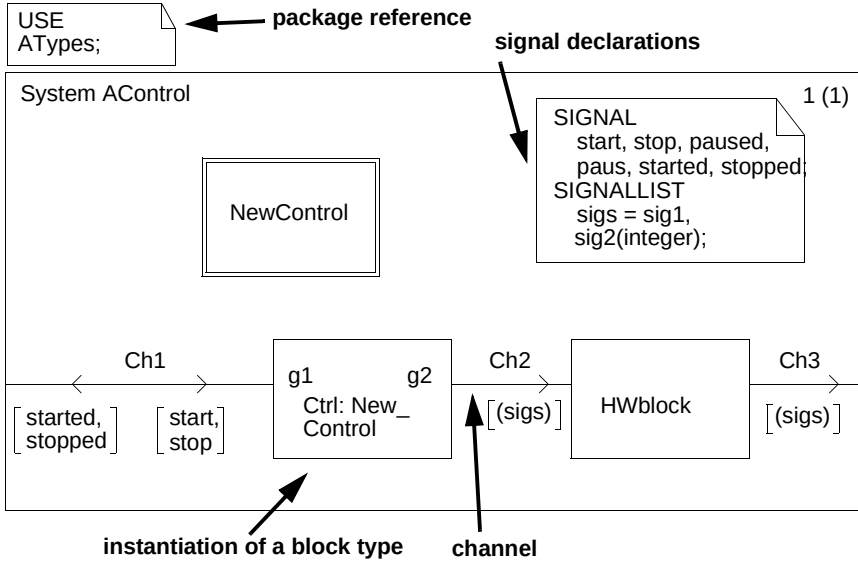

Figure 634: A system diagram with block instantiation and communication

One of the major benefits of using an object oriented language is the possibility to create new objects by adding new properties to existing objects, or to redefine properties of existing objects. This is what is commonly referred to as *specialization*.

In SDL-92, specialization of types can be accomplished in two ways:

- A subtype may add properties not defined in the supertype. One may, for example, add new transitions to a process type, add new processes to a block type, etc.
- A subtype may redefine virtual types and virtual transitions defined in the supertype. It is possible to redefine the contents of a transition in a process type, to redefine the contents/structure of a block type, etc.

Figure 634 and Figure 635 describe adding and redefining properties in a system and in a block type while Figure 636 describes the same features in a process type diagram.

To be able to instantiate a type regardless the context (by means of channels), a special concept is needed: *gates*.

Since a channel always has to be connected to a signal route and the connection mechanism lies inside the process, a gate is necessary since it is a way to specify the connection in a transparent manner.

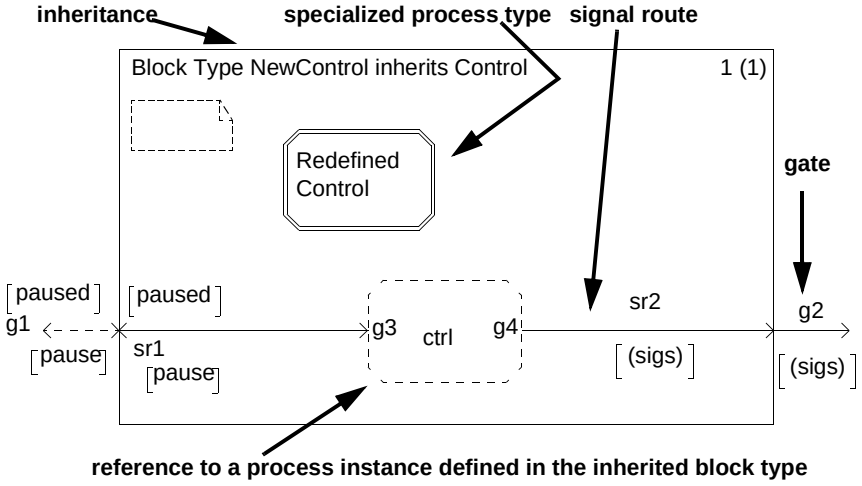

Figure 635: An inherited block type diagram with process specialization, instantiation and communication

In the inherited block type Control, the process ctrl is an instance of the process type Control.

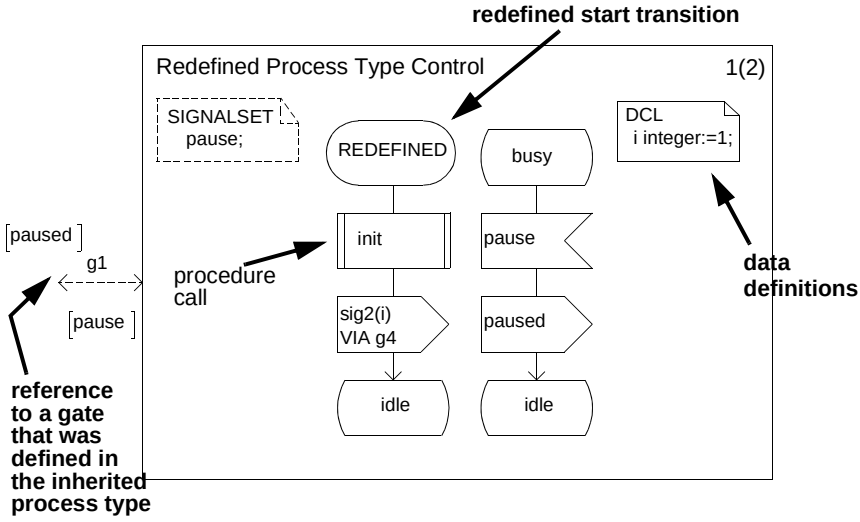

Figure 636: A specialized process type with added signals, a new transition and a redefined transition

Graphical and Textual Notation

The SDL language supports two notations that are equivalent. Beside the graphical representation (SDL/GR), a textual phrase representation (SDL/PR) is standardized.

TTCN

TTCN (Tree and Tabular Combined Notation) is a special purpose notation to describe test suites [34]. TTCN is a language standardized by ISO for the specification of tests for communicating systems. TTCN has been developed within the framework of standardized conformance testing (ISO/IEC 9646).

With TTCN a test suite is specified. This is a collection of various test cases together with all the declarations and components it needs.

Each test case is described as an event tree. The tree is represented as an indented list in a table. The indentation represents progression with respect to time. See Example 644.

Example 644: A TTCN test case ----------

```
     Behavior Description                Constraint        Verdict
1    DuToEnv? Display                    Enter_Card
2     EnvToDu! Card                      Card1
3      DuToEnv? Display                  Enter_Code
4       EnvToDu! Digit                   digit1
5        EnvToDu! Digit                  digit3
6         EnvToDu! Digit                 digit5
7          EnvToDu! Digit                digit7
8           DuToEnv? Unlock              nopar
9            EnvToDu! Open               nopar
10            DuToEnv? Display           Please_Enter
11             EnvToDu! Close            nopar
12              DuToEnv? Lock            nopar
13               DuToEnv? Display        Enter_Card        PASS
14         EnvToDu! Digit                digit1
15          DuToEnv? Display             WrongCode
16           DuToEnv? Display            Enter_Card        PASS
```

Each line consists of a line number, a statement, a constraint reference and a mandatory verdict. A statement can be:

- An event
- An action
- A qualifier

The event statements are statements that can be successful dependent on the occurrence of a certain event, either:

- Receive (represented by a “?”)
- Otherwise
- Timeout

The action statements will always execute and will therefore always be successful:

- send (represented by a “!”)
- implicit_send
- assignment_list
- timer_operation
- goto

A qualifier is simply an expression that must be true if an event should match or an action should be performed.

In TTCN, the communication is asynchronous. The *implementation under test*, IUT, communicates with the environment via *points of control and observation*, PCOs. The interaction occurs at PCOs and are described by *protocol data units*, PDUs, embedded in *abstract service primitives*, ASPs.

At line 1 in s above, the ASP `Display` occurs at the PCO `DuToEnv`. The constraint `Enter_Card` determines exactly which ASP value is to be received.

The leaves in the tree are usually assigned a verdict.

ASN.1

ASN.1, described in [23], stands for Abstract Syntax Notation One. ASN.1 is a language for the specification of data types and values. ASN.1 is very popular for the specification of data in telecommunication protocols and services, especially in higher (i.e. application oriented) layers. Many telecommunication standards are based on ASN.1. Also TTCN is based on ASN.1. An example of an ASN.1 module is shown below.

Example 645: An example of an ASN.1 module

```
ProtocolData DEFINITIONS ::=
BEGIN
- - contains data definitions for an example
protocol

CheckSum ::= INTEGER (0..65535)

DataField ::= OCTET STRING (SIZE (0..56))

PDU ::= SEQUENCE {
        sequenceNr INTEGER (0..255),
        dataField DataField,
        checksum CheckSum OPTIONAL }

END
```

A strong point of ASN.1 is that there are encoding rules that define how an ASN.1 data value is encoded to bits, the most well-known being the Basic Encoding Rules. From an ASN.1 data type definition, functions can be automatically generated that take care of the coding and decoding.

An ASN.1 definition can be imported into SDL as if it was a package. When an ASN.1 data type is imported into SDL, automatically a set of operators that is defined in Z.105 [25] is available for that type.

It is recommended to use ASN.1 for the specification of parameters of signals to/from the environment of the SDL system, especially when encoding rules are to be applied on such signals, or when a TTCN test suite is to be developed. In the latter case the ASN.1 definitions can be directly reused in the TTCN test suite.

Chapter

71 *Requirements Analysis*

This chapter gives a thorough description of the different models in the requirements analysis activity as well as some guidelines on how to create these models. A recommendation on consistency rules that are relevant for the models in this activity is also included.

The chapter requires that you are at least reasonable familiar with the concepts concerning object models as well as the concepts concerning MSC diagrams.

Requirements Analysis Overview

The purpose of the requirements analysis is to establish an understanding of the application domain and to capture, formalize, analyze and validate the user requirements on the system to be built. For this purpose the system is viewed as a black-box and only the objects and concepts visible on the system boundary and outside the system are modeled.

The input to this activity can of course be very different depending on the application, from an extensive requirements specification provided by a customer to some more or less vague ideas not documented on paper. In any case the result of the activity should be the same: An understanding of the problem domain that the system is to be operating within and an understanding of the role the system is to fulfill in this environment, i.e. the requirements on the system to be built.

In many cases the requirements analysis can be divided into two activities:

- A problem analysis
- A system requirements analysis

The problem analysis concentrates on understanding the problem domain the system is going to operate in, without any reference to the system itself. The system requirements analysis focuses directly on the functional requirements on the system, viewed as a black box.

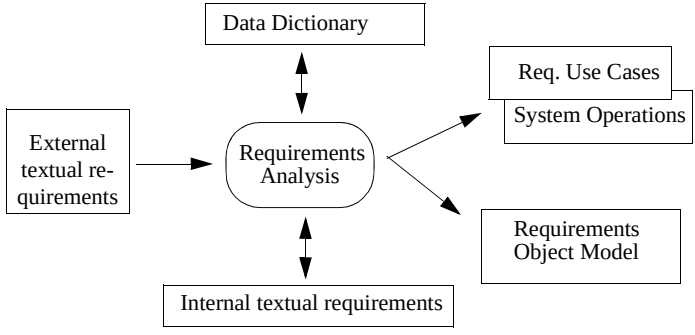

Figure 637: Overview of the requirements analysis activity

An overview of the requirements analysis activity is depicted in Figure 637. As can be seen a number of models are used:

- Textual requirements model as described in "Textual Requirements" on page 3840. Some requirements are supplied as input to the activity, others may be produced within the activity.
- Data dictionary, further described in "Data Dictionary" on page 3841.
- Use case model, described by text, plain MSCs, or plain MSCs in combination with HMSCs. The use case model shows the system and the actors interacting with the system. It is described in "Use Cases" on page 3843.
- Requirements object model using object model notation. This model includes both a problem domain model and context diagrams showing the system and the external actors that interact with the system. The requirements object model is described in "Requirements Object Model" on page 3851.
- System operations model, see "System Operations" on page 3856.

The requirements analysis is a highly iterative process where the different tasks creating the different models are iterated over and over again but the following outline can give some guideline on how to structure the work:

1. Study any textual requirements that are provided as input and other sources of information that are available, e.g. read text books about the problem domain and talk to potential users of the system. This may also include rewriting (or creating from scratch) the textual requirements to make them more complete or structured.
2. While performing 1 above create a first version of the data dictionary, including lists of actors, use cases and important problem domain concepts.
3. Create a first version of the requirements object model:
   - Use context diagrams to give an overview of the actors and the system.
   - Use an information model to describe the problem domain.

4. Create a first version of the use case model.
   - Review and optimize the list of use cases found so far.
   - Describe the details of the most important use cases as text and/or MSCs. If the use cases are complex, HMSCs can be used in combination with plain MSCs. Start with the normal cases and leave the exceptional cases for the moment.
5. Refine and extend the requirements object model and use case model until the use cases and their exceptions cover a sufficient part of the requirements. Add state charts to the requirements object model if the behavior of an object needs to be considered. When needed use system operations to define the details of the interactions between the actors and the system.

Textual Requirements

Conventional textual requirements are in most development projects an important input and result of the requirements analysis. In SOMT, the textual requirements model is simply one or more text documents. It is however important to include them within the scope of SOMT to get a possibility to create implinks from them to the other models in SOMT, and thus make it possible to trace the implementation of the requirements.

The source of the requirements may in some cases be the customers in which case the textual requirements form one of the inputs to the requirements analysis. In other cases the textual requirements are created by the development team as part of the requirements analysis.

Non-functional requirements are an example of a type of requirements that are important to capture, but may be difficult to formulate using the other models in the requirements analysis. The non-functional requirements may express properties about for example:

- Performance issues like response time or number of transactions per second.
- Reliability like the mean time between failure.

This type of requirements are most easily expressed in natural language and entered into the textual requirements model.

It is important to not only write down the requirements but also to analyze them. One aspect of this analysis is to mark all important concepts in the requirements that can be useful later when identifying objects and use cases.

Data Dictionary

The data dictionary is a textual list of all concepts that are defined during the analysis. The purpose of the data dictionary is to define a vocabulary that is common to all the members of the development team and to the customers and users of the system.

It is important to notice that the data dictionary is not a separate list of entities that is unrelated to the other models in the requirements analysis. Rather it can be seen as a different viewpoint on the same set of basic concepts that are used and defined in the use cases and in the requirements object model. For example all domain objects should be added to the data dictionary as soon as they are defined in the object model.

For each entity defined in the data dictionary at least the name of the entity and a brief explanation of the entity must be supplied.

Note that although the data dictionary is created in the requirements analysis it can be used during the entire development process and be updated when new concepts are found also in the other activities. The following Example 646 shows a part of a data dictionary for the access control system.

Example 646: A part of a data dictionary description

```
NOUNS

Access control system - A system to control the
access rights to an office. Unauthorized persons
should not be able to enter without permission.

Card - Each employee working in the office has a
card and a corresponding personal code.

Card reader - The hardware into which the employee
enters the card. The cardreader reads the cardId.

Code - Each employee has a four digit personal code
connected to the card. To enter the office the
employee must type the code on the keypad.
```

Display - The hardware unit by which the system tells the employee what to do.

Door - Employees enter and exit the office by opening a door. The door is always kept locked and unlocks only when the employee enters the office with a valid card and code or when the employee is leaving the office by pressing the exit button. Each door provides a cardreader, keypad and display on the outside of the office and an exit button on the inside.

Keypad - The hardware unit used to type personal codes. The keypad has keys for the digits 0-9.

Employee - The holder of a position in the office. Every employee has a registered card with a personal code to get access to the office.

RELATION PHRASES

Card with code - Each employee in the office has a card with a a personal code.

Code consists of four digits - The personal code that every employee has got, consists of four digits.

Door provides local panel - Each door has a localpanel on the outside of the office. This localpanel is made up of a card reader, a display and a keypad.

Door provides exit button - Each door has an exit button on the inside of the office.

Registerfile contains employee identifications, cardnumbers and codes - The registerfile contains the data relevant to the access control system.

VERB PHRASES

Connection is lost - The connection between a door and the central controller can sometimes fail. In case of broken connection nobody can enter the office. It is, however, possible to leave the office.

Inform employee - The system gives the employee instructions by means of the display.

```
Enter office - A use case which describes the
interaction between an employee and the access
control system when the employee wants to enter the
office.

Exit office - A use case which describes the
interaction between an employee and the access
control system when the employee wants to exit the
office.
Validate card - The central controller validates a
card with respect to info in the registerfile.

Validate code - The central controller validates the
correctness of a code with respect to info in the
registerfile.
-------------------------------------------------------
```

In Example 646, the items in data dictionary are categorized into nouns, relation phrases and verb phrases. By categorizing the items, it may be easier to find the objects, attributes, operators, actors and use cases and also the relations between these entities in each model.

Use Cases

The most important problem to tackle when designing a new system is not to verify the correctness of the system or to get an optimized implementation. None of this matters if the system *does not solve the right problem*. User-centered requirements analysis using use cases is an approach to capture requirements from the user's point of view. The intention is of course that the users will be able to understand and validate the use cases, and thus confirm that they indeed define the right system to be built.

Consider a system that controls the access to a building, allowing users to enter the building through doors that can be opened by entering a card and a code into a card reader. Some typical use cases for this system may be:

- "Register a new user"
- "Open door"

An important term when discussing use cases is the notion of an "actor". An actor is an outside entity that interacts with the system. An actor can be a human being, a hardware unit, a computer program or anything else that can communicate with the system. Usually there is also made a distinction between the individual users of a system and the actors. An actor is not supposed to be an individual user, but rather represents one of

the different “roles” individual users can play when interacting with the system.

Each use case describes essentially the possible sequences of events that take place when one or more actors interact with the system in order to fulfill the purpose of the use case. Note that the use case does not define one specific sequence of events, but rather a set of possible sequences.

A use case is thus simply a description, in one format or another, of a certain way to use the system. It has been found to be a very efficient way to capture a user’s view of the system and the concept of use cases is now used in a number of object-oriented methods. The version used in SOMT is mainly a combination of the original use cases as described in [19] and the OMT version [20]. A difference is that, as will be seen below, SOMT puts some more effort in the formalization of the use cases to be able to use them for verification purposes during the object design.

In SOMT the use case model is in practise composed of three parts:

- A list of actors
- A list of use cases
- The collection of use case descriptions

The list of actors should describe all actors that have been identified, why they use the system (or which service they provide to the system) and what their responsibilities are.

The list of use cases just gives a one-sentence description of each use case.

The lists of actors and use cases can either be separate documents or be a part of the data dictionary. The lists are particularly useful in the beginning of the requirements analysis when trying to identify the most important use cases and actors.

Two different formats are used to describe use cases in SOMT. One purely textual format and one format that uses MSC diagrams to define the use cases. Depending on the application (and the users) one or both of the notations can be used in a specific project. If the chosen approach is to describe the use cases by means of MSCs and they turn out to be very complex, it is possible to use a combination of plain MSCs and HMSCs to describe them. Most of the things that can be expressed with

HMSCs can also be expressed by plain MSCs, so it is a matter of taste if you want to use HMSCs or not. HMSCs have certain advantages, especially if the system is complex:

- They give a good overview of what is happening in the system and thereby facilitate understanding of the system behavior.
- They make it easier to maintain the use case model.

The choice of notation for use cases is a matter of personal taste and the application at hand. There are four different possibilities:

- Use only textual use cases.
- Use only MSC use cases.
- Give a brief textual description of the use case. Then give a complete formal MSC definition of the use case.
- Give a complete detailed textual description of the use case, covering all exceptions etc. Then use MSCs to exemplify some of the more important cases.

Textual Use Cases

The textual format consists essentially of natural language text structured into a number of fields and is easiest introduced with an example. Consider the *Enter building* use case for the access control system that controls the doors of a building. This use case is depicted in Example 647.

Example 647: Textual description of the *Enter building* use case––––

```
Use case name: Enter building
Actors: Regular user, Door
Preconditions: 'Enter card' is displayed and doors
are closed and locked
Postconditions: Same as preconditions
Description: A user enters a card into the
cardreader. 'Enter code' is displayed on the
display. The user enters his code (4 digits) using
the keyboard. The door is unlocked and 'Door
unlocked. Please enter.' is displayed. The user
opens the door, enters the building and closes the
door again. the door is locked again and 'enter
card' is displayed.
```

```
Exceptions: - If the user enters the wrong code then
'Wrong code' is flashed for 3 seconds and then
'enter card' is displayed.
- If the user does not open the door after it has
been unlocked, then the door is locked again after
30 seconds and 'Enter card' is displayed
------------------------------------------------------------
```

As can be seen in the example, a use case has the following fields:

- Name: The name of the use case.
- Actors: A list of the actors involved in the use case.
- Preconditions: A list of properties that must be true for this use case to take place.
- Postconditions: A list of properties that are true when the use case is finished.
- Description: A textual description of the "normal" sequence of events that describe the interaction between the actors and the system.
- Exceptions: A list of exceptional interactions that complement the "normal" flow of events described in the *Description* field. If an exception leads to different postcondition properties compared to the "normal" sequence, this should be noted.

As with the textual requirements, it is important to analyze the textual use cases and clearly mark all important concepts in order to be able to use them when identifying classes and when performing consistency checks between the different models.

Message Sequence Charts

The second notation for use cases used in SOMT is Message Sequence Charts (MSCs). An MSC is a diagram that shows a number of communicating entities (called instances) and the messages that they exchange. Two MSCs that correspond to the "Enter building" use case are shown in Figure 638 and Figure 639. Figure 638 describes the normal case and Figure 639 describes one of the exceptions.

A comment to this use case: There is always a choice of how much to show in a use case. In this particular example there is of course a choice whether to show the interaction between the *User* and the *Door* that

does not involve the system. There is of course such an interaction where the user opens and closes the door. What to do depends on the purpose of the use case. Is the purpose mainly to describe and understand the problem domain or is the purpose to define the precise requirements on the system? In this use case we have assumed that the purpose is to define the requirements so the interaction that does not directly involve the system is left out of the MSC.

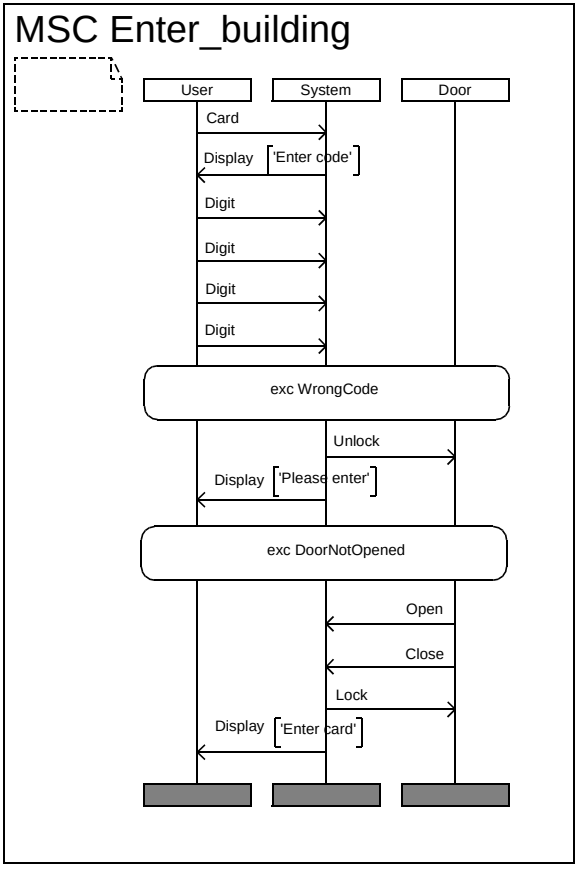

Figure 638: The “Enter_building” use case

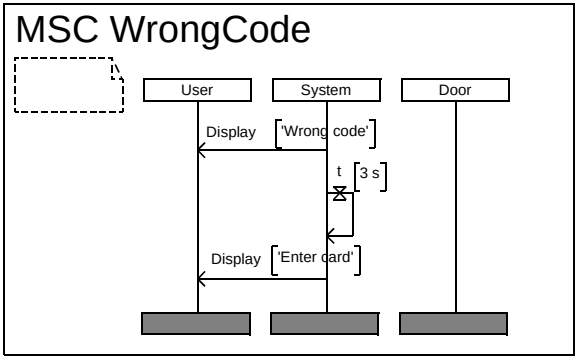

Figure 639: The exception "WrongCode" for the "Enter_building" use case

Identifying Use Cases

Often some use cases are found very easily from the purpose of the system, but in some cases it is more difficult. One strategy that works well, both as a means to find use cases and as a means to check that all important use cases have been found, is:

1. Identify the actors.
2. Identify the use cases needed by each actor.

These two tasks are discussed in the following sections.

Finding Actors

By reading the textual requirements model or discussing with customers, candidates for actors can be found through the answers to the following questions:

- Which user groups need help from the system to perform a task?
- Which user groups are needed by the system in order to perform its functions? These functions can be both:
  - Main functions
  - Secondary functions, such as system maintenance and administration

- Which are the external hardware or other systems (if any) that use the system or are being used by the system in order to perform a task?

Now, we have a set of possible actors. From this, we have to decide if these candidates really are actors or if they are parts of the (software) system. By doing this, we identify the *boundaries* of the system. This step does not provide any final solutions and decisions taken here might be modified later.

If the actor represents a user, perhaps one, single user, try to keep the level of abstraction that comes with the actor concept. It might be the case that this specific user can perform some tasks that can be performed by other users and some unique tasks. Therefore, try to distinguish between the roles that the users can play, i.e. the actors, and the users themselves. See Figure 640.

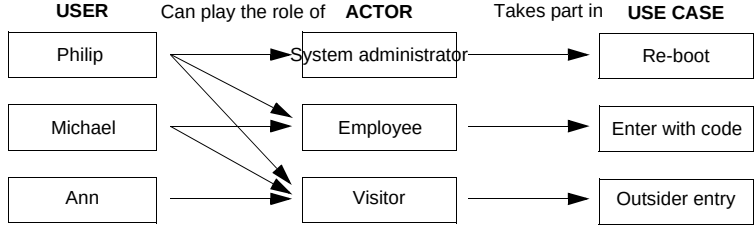

Figure 640: Example of difference between users and actors

Document all actors in a list, describe each actor by a name and describe briefly its role when interacting with the system. The description should contain the actors' responsibilities and the way the actor uses the system. During the process of identifying the actors these descriptions are most conveniently kept in the textual document that lists all actors. This can either be a separate document or a part of the data dictionary.

The set of actors may be due to changes after having started to describe the use cases. Especially the MSC diagrams are useful to pinpoint the problem of determining the actors. In practice this means that the activity of identifying use cases by defining actors and use cases should be performed iteratively.

Finding Use Cases

When you have defined a set of actors, it is time to describe the way they interact with the system.

Steps:

1. For each actor, find the tasks and functions that he should be able to perform or tasks which the system needs the actor to perform. Search the textual requirements for verb phrases, these are possible candidates for use cases.
   - If possible, make the use cases as complete as possible, i.e. make *one* use case of a complex function rather than splitting it up into several use cases for each sub-function.
   - To begin with, concentrate on the normal cases. Leave the exceptional cases until a later stage.
2. Name the use cases and enter them in a textual list of use cases.
   - The names should be informative and be accompanied with general descriptions of the use case functionality.
   - The naming should be done with care, the description of the use case should be descriptive and consistent. Example: the use case that describes when a person leaves deposit items to a recycling machine could either be named *Receive deposit items* or *Returning deposit items*, but the latter is preferable since it is usually better to give names that reflect the users point of view rather than the systems.
   - From the list of use cases, try to discard unnecessary use cases. A use case should represent a set of events that leads to a clear goal (or in some cases several distinct goals that could be alternative) for the actor or for the system.
3. Describe the use cases using the textual use case format and/or give a formal description of the use cases using MSCs (combined with HMSCs if necessary). Use the terms in the requirements object model and data dictionary as much as possible. Focus to begin with on the normal cases.
4. Refine the use cases by examining the exceptional cases that are possible for each use case.

Now, we have got a view of possible candidates for use cases. It is not sure that all of these need to be described in separate use cases; some of them may be modeled as exceptions to other use cases. Consider what the actor *wants* to do!

While finding (or specifying) the use cases, it might be the case that you have to make changes to your set of actors. All actor changes should be updated in the textual list of actors and use cases. The changes should be carried out with care, since changes to the set of actors affect the use cases as well.

Requirements Object Model

The purpose of the requirements object model is to document all the concepts found during the requirements analysis and the relations between these concepts. The benefits of establishing this type of model are obvious:

- The developer and users get a common medium that can be used to check that they have a common understanding of the problem.
- It can to a large extent be reused in the system analysis as a foundation of the system object model.
- It is invaluable when new members of the development team are introduced into the problem domain.

As we have already seen there are different categories of concepts that can be described in the requirements object model. The two major types of requirements object model diagrams show either:

- The logical structure of the data and information
- The environment and context of the system, including the actors that use the system.

Finding the Objects

The classical question when discussing object models is: How do we find the objects?

The final answer to this question is yet to be found, but some obvious sources of information are:

- The use cases
- Textual requirements

The use cases are helpful in more than one way. They directly define the actors that interact with the system and these are of course obvious object candidates. They also describe what is to be entered into the system and what will come out of the system. This may be physical entities like the card in the access control system or abstract data like a data unit in a telecommunication protocol. In either case the entities that are transported in to or out from the system are likely candidates for the requirements object model.

If there exist textual requirements specifications a classical way to find the objects that may be useful is to study the requirements and note all nouns that are used. If a particular substantive is used in many places it may represent a concept that is worth including in the requirements object model.

Other possible sources of information that can be helpful in finding the objects include:

- General domain knowledge from text books or experts
- The physical environment the system will operate in

Finding Relations

After we think that we have found a sufficient number of objects, we want to relate these objects, or more generally, the classes. There are three different kinds of relations:

- Aggregation – describing a “consists of” relation
- Generalization or inheritance – describing a relation where one of the classes are generalized from the other class(es)
- Association – describing how different classes (that are not closely related by aggregation or generalization) are related by means of information exchange

Relations can be found by

- Searching the textual requirements for “relation phrases”, for example: “card with code”, “the central controller has access to the register file” and “each local panel consists of a display, a keypad, and a card reader”
- Looking in the textual use case description

In order to increase to readability of the model, name the associations. If needed, you can also attach role names to each class in an association. Generalization and aggregation relations can also be named.

Finding Attributes and Operations

Closely related to the associations are the *attributes*. Attributes are entities (that could be classes of their own) that are considered to be individual for a class.For example: name, address and phone number could be three different attributes of the class person. This information can be found in:

- The textual requirements
- The use cases

Sometimes it is not easy to decide if an entity should be an attribute of a class or if it should be a class of its own and have an association to the other class. If the independent existence of a property is important, then it should be a class. Consider also possible future changes and extensions, this might also give a reason for making the entity a class of its own. Example: A card in the access control system could change owner after a reorganization.

Operations describe functionality of a class. Operations are often used to modify the attributes of a class. If an operator has features of its own (attributes that do not have to be known for the whole class), then it could be modeled as an individual class.

Operations can be found

- By looking at the system operations and distributing the responsibilities to several classes
- In the textual requirements
- In the textual use cases

Information Modeling

The requirements object model forms a description of the problem domain in a graphical way using object model diagrams. The purpose of the requirements object model is to give an overview of the concepts used by experts in the problem domain when discussing various aspects of the problem. Notice that the object models give the overview of the concepts, more details should be defined in the data dictionary. In the

requirements object model the focus is on classes and associations between classes.

Another way to view the requirements object model is that it at least should describe all concepts that are visible on the “outside” of a system. Note that this does not only include physical entities that a user can see but also the knowledge the user must have to be able to use the system.

As an example of a small requirements object model consider Figure 641 that shows a requirements object model for an access control system that describe the different kinds of persons that are of interest for the application area, how they relate to cards and codes and the structure of an office building.

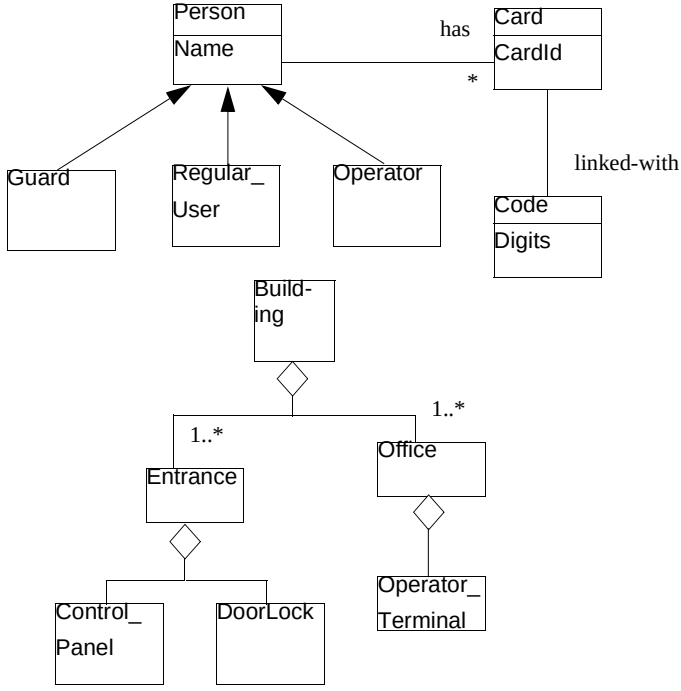

Figure 641: A requirements object model for an access control system

Context Diagrams

Context diagrams are intended to give a static overview of how the system will interact with its environment. This is accomplished by showing in a class diagram (if needed exemplified in instance diagrams) what external actors exist that will interact with the system. The context diagrams are obviously very closely linked with the use cases since they show all types of actors that are defined in the use cases. Actually, one of the major benefits with the context diagrams is thus that they in one (or a few) diagrams capture the static information that otherwise is hidden in the use cases. As an example, consider Figure 642 that shows a simple context diagram for the access control system.

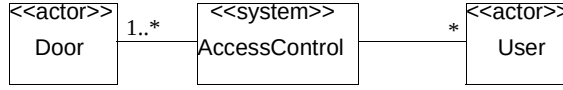

Figure 642: A context diagram for an access control system

Instance diagrams can be used to show specific configurations or examples as in Figure 643 which show a situation where there are three doors and two users.

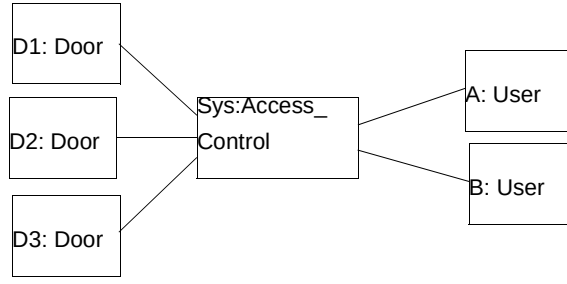

Figure 643: A context diagram using object instances instead of classes to show an application example

An important aspect of the context diagrams is that they show where the borderline between the system and the environment is, event though it is shown in an abstract fashion.

Modeling Behavior

In some cases it is useful to give a description of the internal behavior of the most important objects that appear in the object model. Due to the simplicity of the notation State Charts is the preferred notation in the analysis activities. As an example consider the DoorLock object in Figure 641. A description of the behavior of this object is shown in Figure 644.

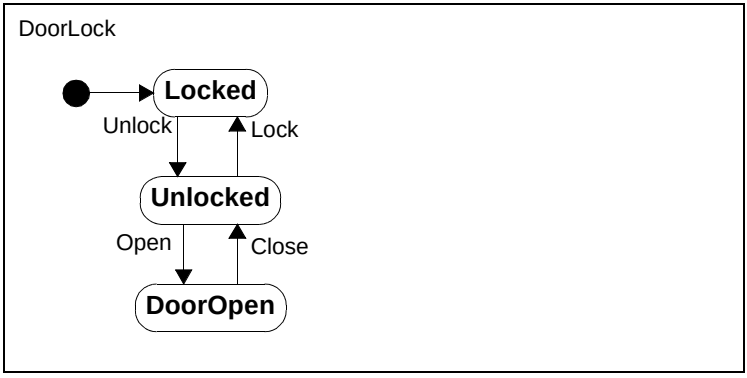

Figure 644: An SDL state machine describing the behavior of the DoorLock object

System Operations

In the use cases a number of events can be found that form the elementary communication means that is used when the system and the actors interact. For example in the “Enter building” use case in Figure 638 there are several events, e.g. “enter card” and “enter digit”. It is important to understand and document the events that are used in the use cases, since they define the interface between the system and its environment. This can be done in the requirements object model and in the data dictionary, but sometimes a more detailed definition is useful. This is the purpose of the *system operations*, a concept that originates from the Fusion method [30].

A system operation is a definition of what that system must do to handle an event. It defines declaratively the behavior of the system as a response to an event in terms of the changes of state and events that are output or returned. System operations are in SOMT defined using sche-

mata containing structured text. As an example consider the system operation in Example 648 that defines the *Enter card* operation.

Example 648: A system operation schemata for the enter card operation ----------

```
Operation: EnterCard
Responsibilites: Informs the system of the fact that
a card has been entered into one of the card readers
Inputs: Card identificatio Card reader
identification
Returns: Enter code' is displayed
Modified objects: A 'card' object,a 'card reader'
object
Preconditions: The door must be closed
Postconditions: The card identification is stored in
a 'card' object associated with the 'cardReader'
object with an id equal to the card reader
identification that was an input to the operation
```

The different rows in the schemata has the following meaning:

- Operation: The name of the system operation (equal to the name of the event that it handles).
- Responsibilities: A short description of the operation.
- Inputs: The data that is supplied as parameters.
- Returns: The events that are returned to the outside of the system as a result of the operation.
- Modified objects: The internal objects that are changed by the operation.
- Preconditions: Predicates that define when definition of the operation given in this schemata is valid.
- Postconditions: The postconditions for the operation define how the state of the system has changed due to the execution of the operation.

Note that in general more than one schemata is needed for each system operation: one schemata is needed for each possible variant of the preconditions.

The criteria for choosing to use the system operations in addition to the use cases are based on the estimated complexity of the opera-

tions/events in the use cases. If the events are simple there is no need for a more detailed description of them. If the events are complex, e.g. when they are parametrized with complex data structures or involve some complex algorithm, then system operations are useful as a means to define the details.

Consistency Checks

This section contains some consistency checks applicable to the models in the requirements analysis. The following list should be viewed as suggestions and must be adapted to the way the requirements analysis is performed in a particular project:

- Check the use cases and requirements object model with actual users.
- Reread the textual requirements and check that all important concepts are clearly marked as such.
- Reread the textual use cases and check that all important concepts, like actors, are marked as such.
- Check that all important concepts in the textual requirements model and in the use cases, and all entities in the requirements object model are added to the data dictionary.
- Check that all important concepts in the textual requirements are modeled by the requirements object model.
- Check that all actors in the use cases are modeled in the context diagram(s) and vice versa.
- Check that all functional requirements in the textual requirements model are modeled by the use cases.
- Check that all complex events in the use cases are described by system operations.
- Check that the requirements object model follows the syntactic/semantic rules for object models.
- Check that the MSC use cases follow the syntactic/semantic rules for MSCs.

Summary

The requirements analysis is an activity that is focused on understanding and documenting the problem domain and the requirements on the system. The major models produced are:

- A textual requirements model
- A use case model, where the different ways a system is to be used are defined
- A requirements object model, i.e. a description of the objects needed to understand the problem domain and external requirements
- System operations
- The data dictionary, which is a list of concepts used in the problem domain and requirements

Chapter 71 Requirements Analysis

Chapter

72 *System Analysis*

This chapter gives a thorough description of the different models in the system analysis activity as well as some guidelines on how to create these models. A recommendation on consistency rules that are relevant for the models in this activity and for the consistency between the models from the previous activity and this activity, is also included.

System Analysis Overview

While the purpose of the requirements analysis is to understand the problem to be solved and the requirements this puts on the system, the purpose of the system analysis is to understand the architecture of the system itself. Essentially the issue of the system analysis is to find out what objects are needed to implement the requirements on the system. This means that the system analysis to a large extent is an analysis of the information that is needed to be represented in the system and the structure of the system itself. Information is here used in a broad sense which includes not only the data to be manipulated in the system but also the containers for algorithms and interfaces.

The system analysis in SOMT is very similar to corresponding activities in other object-oriented analysis methods and the major input and outputs of this activity are illustrated in Figure 645.

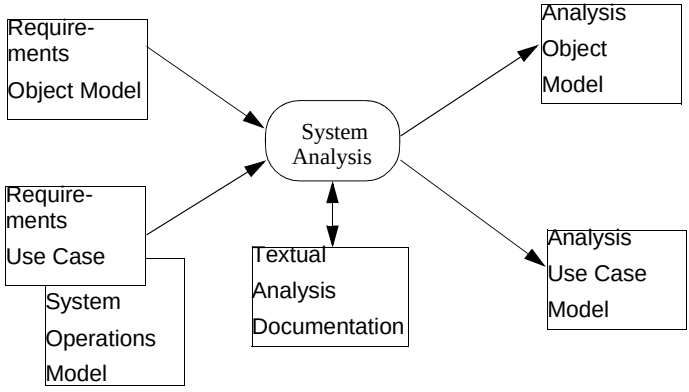

Figure 645: The major inputs and outputs of the system analysis activity

The main input to the system analysis is the requirements object model and use cases developed during the requirements analysis and the main output is another object model, the analysis object model that describes the logical architecture of the system. In addition to this model a use case model is also created in the system analysis to describe the dynamic aspects of the architecture and textual analysis documentation is used to document analysis results not suitable to be express as use cases or object models. The different models will be discussed in detail in the following sections, the analysis object model in "Analysis Object Mod-

el" on page 3863 and the use cases in "Analysis Use Case Model" on page 3875.

The tasks to perform in the system analysis activity are thus essentially the following:

1. Start defining an initial version of the analysis object model, in particular concentrating on creating an overall architecture of the application.
2. Then start refining some of the most important requirements use cases to check that the architecture defined in the analysis object model will work.
3. Continue by iterating between modifying/refining the analysis object model and creating more analysis use cases, either by refining requirements use cases or by describing particular mechanisms in the application.

In parallel with the tasks above it may also be necessary to study various aspects of the chosen architecture, e.g. with respect to non-functional requirements. These results can be documented in the textual analysis documentation.

Analysis Object Model

The intention with the analysis object model is that it is a means to describe the architecture, i.e. the main objects that need to be implemented in the completed system. The notations used are the same as for the requirements object model in the requirements analysis. An overview of the notations is given in "Object Model Notation" on page 3810 and in "State Chart Notation" on page 3814.

At a first glance the requirements object model in the requirements analysis and the analysis object model in the system analysis seem similar but there are several reasons to distinguish between them. The major motivation is that the purpose of the models are different: The purpose of the requirements object model is to investigate and describe the problem that the system is to solve and the environment that the system is to operate in, while the purpose of the system analysis model is to analyze and define the architecture of the system itself. Another more pragmatic difference is that the requirements object model consists of objects visible on the border of the system and outside the system, e.g. users of the

system, while the system analysis object model is focused on the internal object structure of the system.

In the same way as the requirements object model can be structured into a number of different diagrams, the analysis object model can naturally also be decomposed into more than one diagram. This is even more important than it was for the requirements object model since the analysis object model tends to be much larger than the requirements object model.

The Logical Architecture of the System

The major purpose of the analysis object model is to describe an object structure that defines the logical architecture of the application. It describes how the application at a certain level of abstraction can be considered to be divided into a number of subsystems or objects that together fulfil the requirements posed on the application.

For each class that is identified in the logical architecture the most important issue is to note the responsibilities of this class. Why is the class included into the architecture? What is it supposed to do? The responsibilities of an object of a specific class are described by answers to a set of questions:

- What information or knowledge is the object responsible for maintaining?
  - This is described by the attributes of the class.
- What should the object be able to do?
  - Described by the operations of the class.
- What other objects does the object need to know to fulfill its responsibilities?
  - Defines associations and aggregations to other classes.
- Are the responsibilities of objects of this class similar to that of other classes? Is it “the same as class ... except that...”?
  - Defines inheritance relations.

The result when identifying different objects and answering the questions above is one (or more) class diagrams that describe the architecture of the system. The responsibilities are described by the operations

and attributes. The associations between the classes in the model represent needs for objects to be aware of other objects to be able to fulfil its task. As an example, consider Figure 646 that describes the architecture of the access control system.

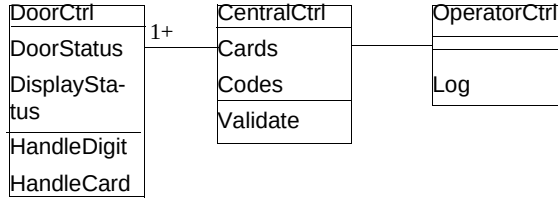

Figure 646: Object model diagram describing the system architecture

Note that object analysis model can be viewed as a refinement of the context diagrams in the requirements object model.

Finding the Objects

The objects in the analysis object model can come from several different sources. Some useful examples are:

- objects from the requirements object model
- objects from interfaces
- objects from use cases

These different sources are described in the following sections.

Requirements Object Model as Source of Objects

The requirements object model is of course one of the major sources of objects for the analysis object model, in particular for the information modeling part. Since the requirements object model should contain most of the objects in the problem domain a lot of them will probably have to be represented in the system and should thus be part of the analysis object model. Note however, that in this case it is not the same object that is found in the requirements object model and the analysis object model. The object in the analysis object model is in this case a container of information about the “real” object that is modeled in the requirements object model. In many cases of course entire inheritance and/or aggregation hierarchies can be reused in the analysis object model as illustrated in Figure 647. Notice that the *Guard* object is not need-

ed to be represented in the system and thus is not introduced in the analysis Object Model.

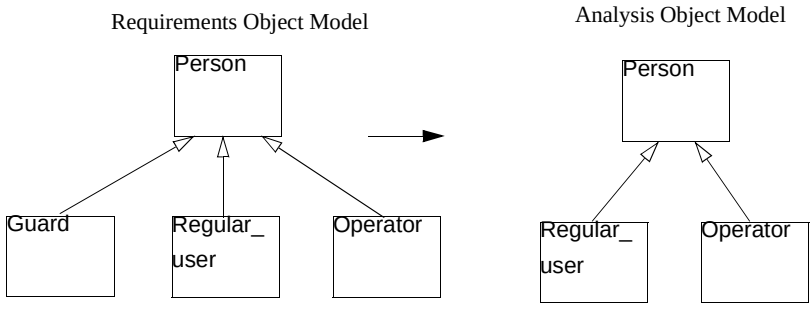

Figure 647: Reuse of requirements object model in the analysis object model

The objects found in the requirements object model usually have one thing in common, they represent entities in the real world that the system needs to store information about.

An algorithm to find the information objects needed by the system based on the requirements object model can thus be phrased as follows.

- For all objects in the requirements object model:
  - Decide if the system needs information about this object to fulfil its task.
  - If the answer is “yes” then add it to the analysis object model using *Paste as* to get the implinks and thus provide traceability back to the requirements object model.

Objects from Interfaces

Another useful way to find objects is to consider the interfaces that the system will have to the environment. It is often very useful to introduce a special kind of object that hides the specific features about how to access the interface from the rest of the system. In [19] these kind of objects are called *interface objects*. Where do we get the interface objects from? There are several different sources to search:

- The application area itself, which in some cases make it obvious what interfaces must exist in the system.

- The use cases from the requirements analysis can be searched for interface objects:
  - They may explicitly identify some interface, e.g. “The user enters a card into the card reader”.
  - Since they define actors that communicate with the system, each actor must use some kind of interface when interacting with the system, even if it is not stated explicitly which interface that is used. So by starting with the actor we may analyze what interfaces he/she will need. If nothing else the actor itself may introduce an interface object.

One important motivation for introducing interface objects is to make modification of the system easier. If the hardware of an interface is changed, e.g. the card readers of an access control system, then the logic of how to handle them is encapsulated in one object. This makes it likely that this object is the only thing that needs to be changed in the software.

Performance requirements are another motivation to introduce interface objects. Very often the interfaces can be a bottleneck with respect to performance. By encapsulating the interface in one object providing high-level operations to the rest of the system it is possible to make an optimized implementation of this object, e.g. making special purpose hardware or enhance the performance.

As an example consider the access control system and specifically the *Enter building* use case described in text in Example 647 on page 3845. From this text we can directly find a number of interfaces: a card reader, a display, a door lock, etc. All of these are likely candidates to result in interface objects in the analysis object model. When describing the interface objects it is usually fruitful to use a communication style class diagram to show how they interact with the external actor and the relevant objects in the analysis object model. If the interaction is non-trivial it might also be a good idea to show the interaction pattern using one or more MSC use cases that describe the different ways this particular object interacts with its environment.

Objects from Use Cases

The use cases can be used as a tool to find the objects that are needed. The strategy is to take a use case and investigate how the functionality that is implied by the use case is distributed among the objects in the analysis object model. One way to do this is to produce an MSC that describes the interaction as described in "Analysis Use Case Model" on page 3875. Check which interface objects are involved, which internal objects are modified or accessed and consider the question of introducing a special controller object to encapsulate the sequencing of the use case. Is there already a control object that might take on the responsibility, or is there a need to create a new control object to handle the logic of the use case?

Consider for example the *Enter building* use case described textually in Example 647 on page 3845 and using an MSC in Figure 638 on page 3847. Since this use case contains a sequence of steps the system needs to represent that essentially has to do with the state of one of the doors and the associated lock and other devices, a special control object *DoorControl* seems natural to introduce. This could give an object model diagram as in Figure 648.

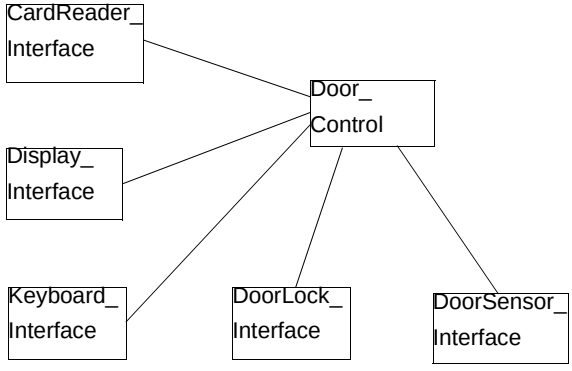

Figure 648: An object model diagram that introduces the DoorControl object

Notice that the objects in this object model correspond to the interface objects that more or less directly could be extracted from the use case text together with the new control object. It may in this context be useful to name the objects according to their function. The interface objects are

in this example called “XXInterface” and the control objects “XXControl” or something similar.

Notice that this model also introduces associations between the interface objects and the control object. These associations represent the communication paths that are needed among the objects. In one way or another information will flow following these associations.

Another type of object that might be found when analyzing the use cases are DataServer objects. These objects define the access possibilities to (complex) data structures. There are several possible sources to search for these type of objects:

- The object structures that come from the requirements object model represent information that has to be stored in the system. In many cases there is a need for a DataServer object that “owns” this information and that provides an access to it. So, investigating the objects from the requirements object model and how they are to be used is a way to identify DataServer objects.
- A second source of information is given by the use cases, since they often express the need for some kind of computation that involves several, related objects. When there is a need for a more complex algorithm that operates on an object structure a DataServer object might be useful.

By once more analyzing the *Enter building* use case described in Example 647 on page 3845 we can see that there is a need for a checking mechanism that determines if the code a user enters is the correct code associated with the card he previously has entered. This indicates the need for a *CardAndCodeDataServer* object that is responsible for maintaining the information about cards and code. Furthermore we can see that a likely operation on this object is a *Validate* operation that tells if one particular combination of card and code is correct. This may give an object model as in Figure 649.

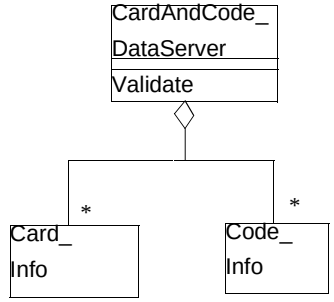

Figure 649: An object model diagram introducing the CardAndCodeDataServer object

Finding Attributes and Operations

As discussed above the attributes and operations are used as a means to describe the responsibilities of objects. They describe the purpose of introducing an object into the model by answering the questions:

- What should the object be able to do?
- What information or knowledge is the object responsible for maintaining?

In practise, the attributes can be found for example:

- In the use cases
- In the requirements object model (by keeping already described attributes)
- In the textual requirements

Some useful sources of operations are:

- The requirements object model (keeping the existing operations)
- The analysis use case model (the messages in the MSC diagrams)

The MSC messages in the analysis use case model can often be considered for operations in the analysis object model. Consider the behavior patterns in the use case model as well, since they often describe the functionality on a more detailed level.

Finding Associations

As discussed above the associations are used to show how object of one class need to know other objects. Usually the associations are found when analyzing the responsibilities of the classes since the motivation for introducing an association is that it is needed by a particular object.

However, some other sources where it is useful to look for the associations are:

- The requirements object model (preserving or modifying existing relations)
- The textual requirements
- The analysis use case model

In particular the last source, the use cases are important. The activity of finding associations in the analysis object model and the activity of constructing the analysis use case model are closely related.

Describing Object Behavior

Sometimes it is useful to describe the behavior of the objects presented in the Logical Architecture. The Analysis Use Case Model describes how objects of the Logical Architecture interact. State Charts describe how these objects reacts internally as a result of the interaction presented in the Analysis Use Case Model.

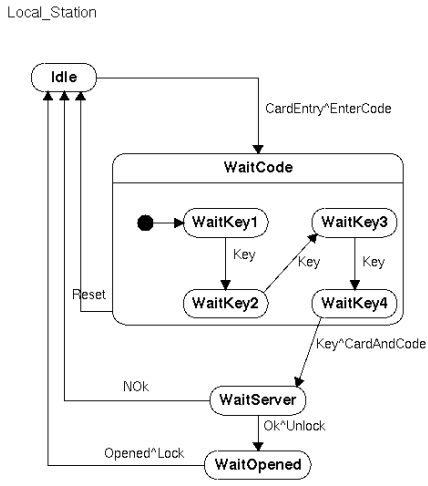

Figure 650: A state chart describing the behavior of an object

It is not necessary to describe the behavior of every object in the Logical Architecture. The focus should be on objects with complex behavior and where complex data structures are dependent of the state of their object. Modeling the behavior of an object will lead to a better knowledge of how the object will function internally. “Which are the actions of the object?”, and “what data structures are needed?” are some questions that may be answered. If an object is too complicated it might be necessary to divide its class into several smaller classes which should be reflected in the corresponding class diagram. In other words: the relationship between the Logical Architecture diagram and the Object Behavior diagram is bidirectional.

When creating a state chart, the Logical structure is the obvious source of information. It is necessary to consider the object’s class specification when specifying its behavior. An operation on a class will lead to transitions in the behavior model. A transition may lead to an internal action or a sending of an event to an external object. A transition may also lead to value changes of the object’s attributes. If these attribute changes are important they should be reflected in the state chart. The operations on the class may also be found in the Analysis Use Case Model together with the possible sending of events.

Architecture of Large Systems

For large applications it is also often necessary to divide the analysis model into more than one module, e.g. to facilitate an analysis by more than one team. One possible strategy for doing this is a recursive approach where we first make an architecture on a high level, where each class represents a subsystem. Then each subsystem is refined by a separate team. It is important to be vary careful about the responsibilities of the classes in the top-level architecture, as described by their attributes and operations, since they will form the input to the different analysis teams.

In this context it is useful to use aggregations to describe a “subsystem” or “is-composed-of” relation, i.e. to describe how the system is decomposed into parts that recursively are decomposed into smaller parts. As an example, consider Figure 651 that describes the structure of the access control system. In this example the system is composed of one or more DoorCtrls, one CentralCtrl and one OperatorCtrl. The OperatorCtrl is itself composed of a component handling remote communication (RemoteCom) and a UserInterface.

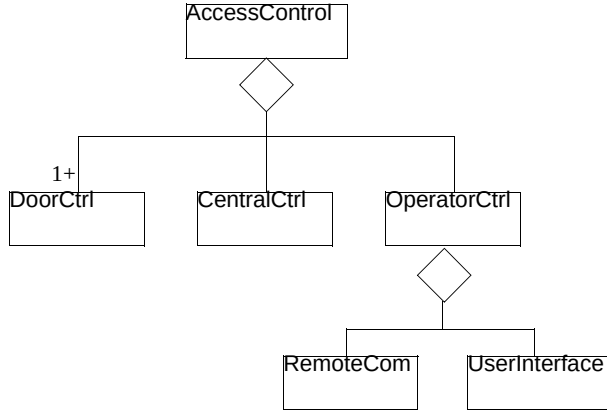

Figure 651: Using aggregations to describe the access control system

Note that the usage of aggregation as a means to describe subsystem relations has an impact on the object structure. Since the assembly classes are used to represent aggregation of classes and not single objects, they should in general not have any “intelligence” by themselves. This implies that the operations provided by the aggregate classes in practise

should be implemented by one or more of the parts classes that the aggregate class contain.

It is a good practise to make the decomposition into modules aligned with the top-level architecture. One top level module architecture of the upper level of the application, identifying the responsibilities of the subsystems. The leaf classes of this top level architecture are then defined in separate modules possible by different analysis teams. The top level module then forms an interface or contract between the analysis teams.

It is impossible to give any rules for how to find the best way to divide a system into subsystems, but most authors agree on some measures to tell if a certain decomposition is a good one. The following two rules are from [5] describing OMT guidelines for decomposition interpreted in the SOMT context:

- The structure must be designed so that most interactions are within the subsystems and not across the boundaries.
- A system should not be divided into too many subsystems, 20 is probably too many. It is better to use a hierarchy of subsystems instead.

The subsystems may be chosen based on several different approaches, but the major idea is to group together objects, that together provide a certain function to the rest of the system, into a subsystem which then can be used as an abstraction of the entire group of objects.

Analysis Use Case Model

The purpose of the analysis use case model is to show the dynamic view of how the functionality of the system is decomposed in the same way as the analysis object model describes the static view of the decomposition. This implies that the internal communication between the various parts of the system is the major concern for this activity. Two different types of use cases can be distinguished in the analysis use case model:

- Refined requirements
- Behavior pattern use cases

Refined Requirements

The analysis use cases that are refined requirements are simply the use cases from the requirements analysis refined to the analysis object model level. Each requirements use case is distributed among the objects from the analysis object model. The purpose of these use cases is mainly to document how the logical architecture as described in the analysis object model is capable of implementing the requirements that are expressed by the use cases. In practice this is done by taking each of the use cases defined in the requirements analysis and reformulate it in terms of the objects that are defined in the analysis object model. It is possible to use both the textual use case notation and the MSC notation to represent the use cases, but since the purpose of the analysis use case model is to show how the functionality is distributed among the objects the MSC notation is especially useful. As in the requirements analysis, HMSCs can be used to simplify the use case model.

Consider again the access control system with a logical architecture according to Figure 646 on page 3865 where the system is divided into a DoorCtrl, a CentralCtrl and an OperatorCtrl components. If we take the *Enter building* use case as defined by an MSC in Figure 638 on page 3847 and replace the system with the three components we get an MSC as shown in Figure 652.

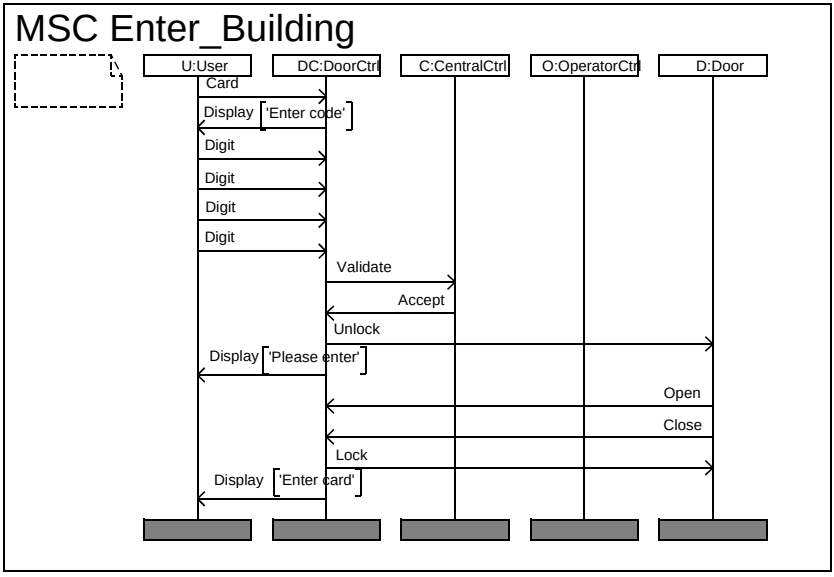

Figure 652: The Enter Building use case distributed over a logical architecture

In this MSC we can see that the original system instance is replaced by instances of DoorCtrl, CentralCtrl and OperatorCtrl. This use case deals mainly with the handling of user interaction at the door and since this is the responsibility of the DoorCtrl most of the action is performed by this component. Only the validation of the card and code is performed centrally.

It is easy to see that the strategy outlined above is extendable to allow a decomposition of a system into not only one level of components, but into a hierarchy of components. For each new level of decomposition all use cases that involve the decomposed components are taken as input to the validation of the new decomposition. The component that was decomposed is replaced by the new components and new versions of the use cases are created.

Behavior Patterns

When designing the object structure for a system there is often a need to document behavior patterns that involve one or more objects that participate to fulfill a common objective. Sometimes this can be described in the refined requirements use cases, but there are two advantages of creating special use cases for specific mechanisms and behavior patterns:

- By describing detailed communication patterns in special use cases, the refined requirements use cases can be on a higher level of abstraction and are not made unnecessary complex.
- By focusing special use cases on specific parts of the system, it is easier to understand and maintain the requirements of the involved object than if these where distributed among all the refined requirements use cases.

As an example consider the keyboard interface of the access control application. The purpose of the keyboard is to allow the user to enter a code consisting of four digits. In a refined requirements use case showing a user entering an office by pushing the digits on a keyboard this can be shown using an MSC reference symbol, as in Figure 653.

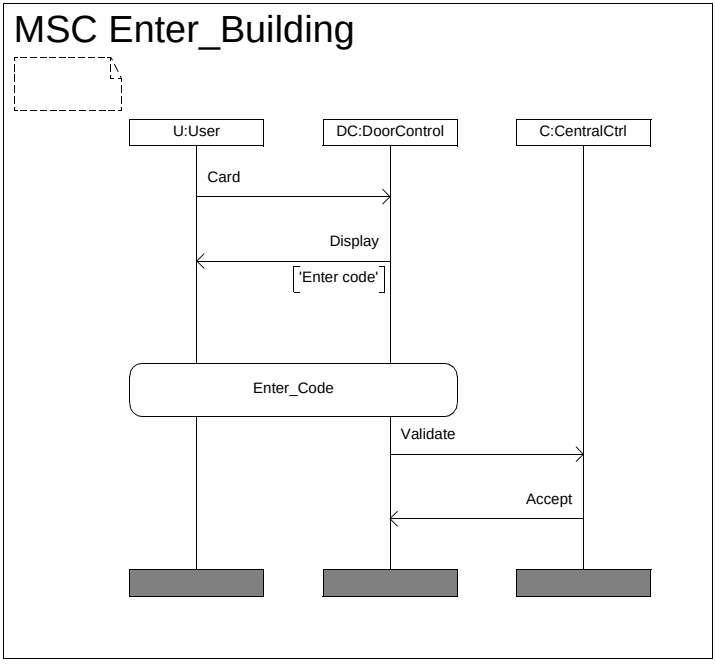

Figure 653: Part of a refined requirements use case

What happens when the user enters a code is thus described in the MSC Enter_Code. We see that it is the user and the DoorControl object that are involved in this interaction.

However, there is of course a specific protocol for Keyboard objects that defines how they interact with the user and the DoorCtrl that is not shown on the abstraction level of the refined requirements use case. This may for example look like in Figure 654, which shows the behavior pattern use case Enter_Code.

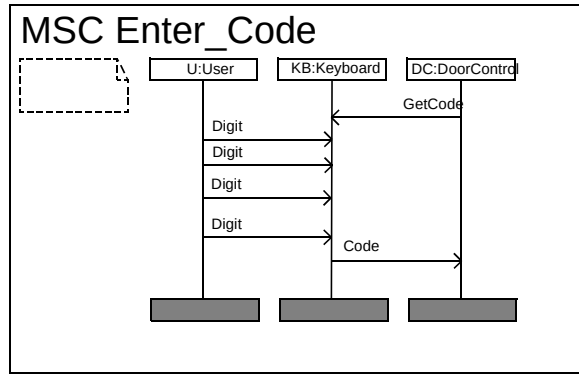

Figure 654: A behavior pattern use case showing the protocol for Keyboard interface objects

Other examples of behavior patterns that may need special use cases are internal communication between different parts of a system using proxies (i.e. local dummy objects that are used instead of a remote object and hides the communication aspect from the user of the proxy), initialization protocols that describe how various objects are created and exchange information, and in general all other tactical solutions to problems that need a special explanation in the system analysis.

Textual Analysis Documentation

In many cases there is a need to express aspects of the architecture or architecture related requirements in a textual format as a complement to the more structured object models and use cases. This may for example be to record experiments performed to check performance aspects of the architecture or other non-functional requirements. Other examples may include documentation of risk assessments performed in the system analysis phase.

To satisfy this need SOMT allows different textual documents to be included among the analysis documentation.

Requirements Traceability

One important aspect in the system analysis is the relation between the models that are created in this activity and the requirements, both external requirements specifications and the models from the requirements analysis. Important questions are:

- Have all requirements been implemented?
- Which are the system analysis objects that implement one particular requirement?
- Which are the requirements that are implemented by one specific object in the analysis object model?

To be able to answer this type of questions it is important to create and maintain descriptions of the dependencies between concepts among the requirements and system analysis concepts. As discussed in "Implinks and the Paste As Concept" on page 3806 the means to do this in SOMT is given by what is called implementation links (or implinks for short). An implink is an association between two concepts where one of the concepts implements the other. One example is the implinks that exist between objects in the requirements object model and the corresponding object in the analysis object model. Consider for example Figure 647 on page 3866 that illustrates how domain objects are modeled in the analysis object model. In this case there should for example be an implink between the *Operator* object in the requirements object model and the *Operator* object in the analysis object model.

Another example is the links between use cases on different levels. Links between the requirements use cases and the analysis use cases show that the requirements are handled on the system analysis level.

In particular when doing "what if..." analysis of the consequences a modification or extension of the system has, these type of links are invaluable. For example consider the case where we would like to specialize the concept of an *Operator* into *RegularOperator* and *ChiefOperator* where the chief operator has some special privileges that a regular operator does not have. We then look at the requirements object model and try to understand what consequences this modification will have. With an implink we immediately see that the analysis object OperatorInfo will have to be changed and with further links from this object we can get a good idea of the consequences caused by the modification.

Consistency Checks

This section provides a list of consistency checks that can be made on the models produced by the system analysis.

- Check that all use cases from the requirements analysis have been refined to analysis use cases.
- Check that all entities in the requirements object model are either represented in the analysis object model or not really needed by the application.
- Check that the object model diagrams and MSCs conform to the static rules for each notation.
- Check that the instances in the MSCs correspond to classes in the object model or to actors that interact with the system.
- Check that the messages received by the instances in the MSCs correspond to operations on the corresponding classes. Note that for remote procedures there may be two messages in an MSC for one operation, one message for the request and one for the reply. In this case the reply message should not have any corresponding operation.

Summary

The system analysis is an activity that is focused on understanding the system to be built. The major tools to facilitate and document the understanding of the system are the analysis object model and the analysis use case model. The analysis object model is intended to capture the objects that are needed in order to describe a solution of the problem.

The analysis use case model describes how the objects in the analysis object model cooperate to fulfill the requirements posed on the system by the use cases from the requirements analysis.

Chapter 72 System Analysis

Chapter

73 *From Analysis to Design*

This chapter describes the differences between analysis and design activities. The aspects to cover when you are moving from object models to SDL, are also described.

From Analysis to Design – Overview

The task of moving from the analysis model of a system to a design of the system is a creative step that involves many design decisions to be taken. The reason is that the purpose of the analysis model is to give an abstract understanding of the system to be built, and an understanding of the concepts that are needed in order to describe a solution of the problem the system is to solve. The purpose of the analysis model is not to give a precise definition of **how** the problem is to be solved or to decide how the architecture and reuse issues are taken care of. These aspects are the purpose of the design activities. Both the system design and the object design are focussed on these type of questions that are necessary to solve in an efficient way in a development project.

The SOMT method introduces a specific concept to emphasize the task of moving from one model to another. It is particularly useful when moving from the analysis model, with its abstract view of the problem, to the design model, with its constructive precise definition of the system that solves the problem. This is the *Paste As* concept that was introduced in "Implinks and the Paste As Concept" on page 3806.

During design the idea is to encapsulate the creative design action taken when moving from the analysis model to the design model into one visible action. From a pragmatic point of view the designer just takes an analysis object and pastes it as a design object. However by doing this simple action the designer documents a number of the design decisions that are involved in the design activity.

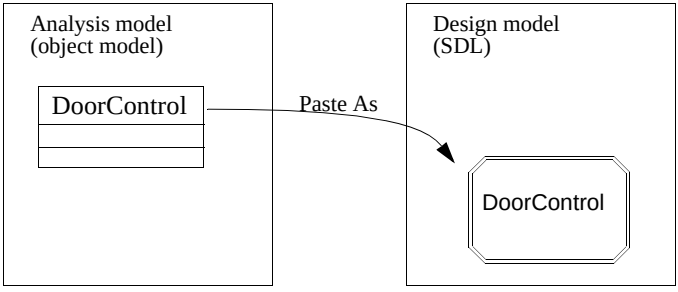

Figure 655: The Paste As concept

One important aspect of the paste-as concept is the relation to traceability links between different models. When performing the paste-as ac-

tion the designer not only creates design objects. He also creates a link between the analysis object and the design objects. This link defines in a precise and compact way the design decisions taken. The links are a vital part of the project documentation that is automatically created by the tools. The links can be inspected when understanding the system and can be used for a number of purposes, e.g.:

- Verification that all analysis concepts are implemented
- "What if" analysis, what happens if one analysis object is changed because of changed requirements

Analysis vs. Design

When comparing analysis to design there is always a question of where the borderline between the activities are. In practise the distinction between analysis and design is somewhat arbitrary. From a practical point of view the important decision is not to define exactly what to call a specific activity, but rather to decide where to document a decision: in the analysis documentation or in the design model. The most important input to guide this decision is to consider the purpose of the different models. The analysis model has a focus on the architecture and most important concepts in the system, abstracting away from implementation details. It is used to provide a means to understand the application as efficiently as possible. The SDL design, on the other hand, is a complete definition of all necessary details.

In the context of mapping object models to SDL in SOMT the trade-off between analysis and design, essentially is a matter of where to document a decision:

- In the object model
- In the SDL model

As an example of this type of question that either can be described in the analysis model or in the design model, consider the issue of the traversal direction of an association, i.e. is the association a one-way or two-way association.

If the choice is to be made in the object model a notation or convention is needed to make it possible to add the extra information. For the one-way/two-way associations a possible notation could be to use an arrow head to denote the direction of the association. Note that this is only an example. SOMT does not recommend this convention.

If the choice is to be documented in the SDL model there is a choice of how the designer expresses his/her choice:, either

- During the Paste-As
- Directly in the SDL model

The result is in both cases the same: The design choice is documented in the combination of the implink (that defines the relation to the analysis model) and in the SDL model (that defines the details of the design choice).

For the one-way/two-way association the Paste-As alternative would imply that the designer interactively entered information as a parameter to the Paste-As of a class to a SDL data type that defined weather an association would be visible in the SDL data type. The association would only be visible if the direction was *from* the given class (or it was a two-way association).

If the one-way/two-way design choice was to be expressed directly in SDL the designer would manually either include or not include the association in the SDL data type corresponding to the class.

SOMT makes a trade-off between the different alternatives to accomplish an as smooth as possible transition from the analysis model to the design model. The SOMT mechanism is based on the following:

- The information that is naturally found in an analysis model is used as far as possible to deduce the mapping to SDL.
- The Paste-As functionality is defined to encapsulate the major design choices, like if an object will be mapped to a process type, struct data type or to some other concept. Paste-As also provides a predefined default choice for all other, minor design choices that have to be made. The intention is that the default settings should be useful in many cases, but in general some of the default choices will have to be modified during the design process.
- The designer will make the final design decisions directly in SDL. This implies that the SDL model is the artifact that documents most of the design choices.

The rationale behind this mechanism is mainly to be able to fulfil the objective of the analysis and design models as good as possible. The analysis model should define the high-level architecture and provide a sound basis for understanding the application as efficiently as possible.

To facilitate this the analysis model should be as abstract as possible while still containing all relevant information. The implication is that design decisions that are not needed to understand the application as far as possible should be kept in the design model and that abstractions should be used as much as possible in the analysis.

Active vs. Passive Objects

One choice to be made when moving from analysis to design is to decide whether an analysis object is to be implemented as an active object or a passive object. An active object is one that has its own thread of control and that can exhibit an autonomous behavior without any other object acting upon it. An active object can be viewed as executing in parallel with other active objects. In a distributed system the active objects may execute on different hardware. In other cases the scheduling mechanisms and operating system creates an abstract interface on which the active objects are executing. One important implication of this is that when two different active objects interact, e.g. when invoking operations, this interaction is a communication between two parallel possibly distributed applications over some communication medium. The communication may be synchronous, e.g. in a client-server relation between objects; the client requests a service from the server and waits for a response from the server before continuing, or asynchronous, e.g. when peer entities are performing a common task using a specific protocol.

A passive object on the other hand does not have its own thread of control. It changes state only when it is being operated upon by another object. Typically a passive object is mainly an information container used in the system to store information about the outside world and the internal state. If the information handled by a system is complex then an entire structure of passive objects may be needed to model it. Often, particularly in distributed applications, there is a relation between the active objects and the passive objects in the sense that an active object "owns" a passive object. The passive object is part of the same thread of control as the active object and it is localized in the same place in the system structure. An example of this might be an active data base server object that handles the control of the access and operations on a data base defined by a number of passive objects. This is very similar to the notion of "container classes" that are used as abstractions of the classes that they contain.

Reuse Issues in the Design Models

Another aspect of objects is if a particular object class is subject to reuse or not. The reuse may be on different levels of ambition. The lowest level of reuse is when an object is reused within one subsystem in an application. This has no major implication on how to package the object definition. Since one subsystem is most often developed by a small group of individuals there are no special requirements on the packaging of the object. The next level is when an object class is found to be useful in different subsystems implemented by different development teams. This situation makes things a bit more complex, since the object definition now probably should be grouped together with other similar objects and put in a special package. This package is used by many of the development groups and there may even be a special team devoted to the development of this support package. In any case it needs its own version control, interface definitions etc.

The third level of reuse is when an object is found so general and useful that it can be used in more than one project for more than one application. In this case there is obviously an even stronger need for a packaging mechanism, since the object together with other related objects now must be seen as a separate product.

Designing an object that is suitable for reuse requires special care: already early in the design it is necessary to identify that an object might be suitable for future reuse. Then the object needs to be specially designed to make it as general (and reusable) as possible. Careful thinking is also required to identify the parts of the object that later might have to be redefined when reused. These parts have to be marked “virtual” in SDL. A rule of thumb is that it is worthwhile to design a reusable object when it is expected that the object can be reused at least three times.

Mapping Object Models to SDL

When moving from an analysis view of an application to a design of the application, one of the major tasks is to define the relation between analysis concepts and design concepts. There are two different ways to view this: either the design is seen as an elaboration and refinement of the analysis model or the design can be seen as a transformation of the analysis model. In practice both viewpoints are useful. When creating the design a transformation is performed from the object model developed in the analysis activity to the SDL design models. The concepts in the object model are mapped to suitable concepts in the SDL domain. However, when this mapping has been done the analysis model is used as an abstract view of the application where only the details relevant from an analysis perspective is present and the design is viewed as an elaboration and refinement of the analysis model.

When mapping object models to SDL there are several aspects to cover:

- Mapping the structure of object models to the structure of SDL
- Mapping the interfaces of objects to interface definitions in SDL
- Mapping the classes in the object model to SDL definitions
- Mapping existing state charts to SDL process definitions

The structure of an object model of interest for the mapping to SDL are of two kinds:

- The aggregation structure in the class diagrams
- The module structure that defines how the complete object model is divided into different modules

The aggregation structure in the object model is in general in SDL represented by the block hierarchy as described in "Architecture Definition" on page 3895. The actual mapping between the object model and SDL involves creating the block structure based on the aggregation structure and is further discussed in "Mapping Aggregations of Active Objects" on page 3917.

The module structure of the analysis model is one of the inputs to the definition of the design module structure. In SDL the major code structuring concept is the package and in general it is recommended to keep a simple mapping from the module structure of the analysis model to the packages in the SDL design. This is further discussed in "Design Module Structure" on page 3897.

In SDL the interfaces of processes, blocks etc. are separated from the description of behavior or implementation of the block/process. This implies that in general there are two different mappings from classes in the object model to SDL, one to the interface definition and one to the process/block definition. Interfaces in SDL are defined using signals or remote procedure calls as described in "Static Interface Definitions Using SDL" on page 3901 and the mapping to these concepts is outlined in "Mapping Object Models to SDL Interface Definitions" on page 3902.

The mapping of the classes in the object model to the corresponding SDL behavior definition is an issue of object design and is depending on if the object is an active or passive object. Active objects are mapped to SDL processes (or process types) and passive objects to data types. These different mappings are discussed in "Mapping Object Models to SDL Design Models" on page 3914.

Summary

When moving from analysis to design, several decisions has to be made. These decisions should be documented and it should be possible to view the impact of such decisions. A way to achieve this is the Paste As functionality that produces links that could be traversed in order to do "what if" analysis or to do consistency checks between requirements and design.

When we start to design from our analysis models, several possible SDL mappings exist for entities in the object model and the use cases. The important decisions that have to be made concern issues like reuse and determining if objects should have autonomous behavior or not (active/passive objects).

Chapter

74 *System Design*

This chapter gives a thorough description of the different models in the system design activity and some guidelines on how to create these models. A recommendation on consistency rules that are relevant for the models in this activity as well as for the consistency between models from previous activities and this activity, is also included.

The chapter requires that you are at least reasonable familiar with SDL.

System Design Overview

One of the most important issues of software development, if not the most important of all, is to define the architecture of the system. Define how the system is built up of smaller parts that in turn may be composed of even smaller parts until each part is manageable by itself. The architecture is proposed in the system analysis architecture but the precise definition of this structure is the major task of the system design activity.

The components of a system may have several different important functions to fulfill:

- They act as a unit for work division. Different development teams can be responsible for different components.
- They form a decomposition of the functionality. Each component may be responsible for one aspect of the total functionality of the system.
- They act as distribution units. The components can define how the system is distributed in the physical world.
- They may act as technology units. The design of the different components may use different notations and tools and, although SOMT has its main focus on SDL, the system design activity also takes other possibilities into account.

The major inputs to the system design activity are the analysis object model and the analysis use case model produced in the system analysis activity. The system design is the process that based on these inputs define in detail how the system is decomposed into components and to define the interfaces between the different parts. This is illustrated in Figure 656 that also shows the three major artifacts developed in the system design; the design module structure, the architecture definition and the design use case model. In addition to these formalized descriptions there is often a need to specify non-functional aspects of the components in a textual design documentation.

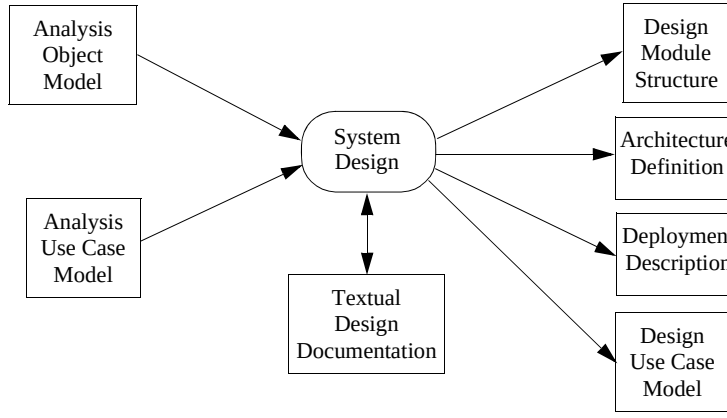

Figure 656: Inputs and outputs of the System Design activity

The architecture is in the system design formalized primarily using SDL. In SDL the major structuring concept is the *block* and the notation is the block diagram. Seen from an object-oriented point of view a block is a container of objects. The block can either be directly described by the objects that it contains or it is decomposed into lower level blocks. The block structuring mechanism is discussed more in "Architecture Definition" on page 3895.

Where the logical architecture defines the decomposition of logical functionality the *design module structure* defines the decomposition into work items. It defines the different modules the design teams can start working on and also provides a mapping from the logical architecture to design modules. In SDL the design modules are usually SDL *packages*. The design module structure also takes a slightly broader perspective of the system to be built and describes how existing frameworks, tools and components are incorporated into the development structure.

The *deployment description* is a way to describe the physical distribution structure of the SDL system. It is also the place where the implementation strategy for different parts of the system can be described.

There should be a simple (if possible one-to-one) mapping between the top levels of the architecture definition and some of the modules in the design module structure. The benefit gained from a simple mapping is

that the design modules define the possibilities to divide the work on different development teams and the logical blocks comprise well-defined sets of functionality and responsibilities. If they do not map to each other there is an obvious risk for complex interfaces between the development teams.

As always when a system is decomposed into smaller parts one very important issue is how the interface between the parts are defined. In particular if the components are used as division of work load and designed by different development teams the interface definition is the means to communicate between the different groups and a common understanding of the interface is crucial. There are two aspects of the interface:

- A static aspect, defining the operations or services that a block offers
- A dynamic aspect, that defines how the different blocks cooperate to solve a common task

Both aspects are important and the definition of them is a vital part of the system design activity.

In SOMT the major concepts used to define the static interface are the SDL concepts *signals* and *remote procedures*, and the dynamic aspect is a continued usage of use cases. However, since there very often is a need to design parts of a system using other techniques than SDL or to use existing modules, other interface definitions techniques are also used in SOMT.

The major tasks to be performed in system design in an SDL based project can thus essentially be summarized as the following:

1. Create an (incomplete) SDL system that is a starting point for the formalization of the architecture of the application. This is further discussed in “Architecture Definition” on page 3895.
2. Define the design module structure. Draw a diagram that illustrates the structure and create the necessary packages etc. as described in “Design Module Structure” on page 3897.
3. Define the physical distribution strategy for the SDL system, see “Deployment Description” on page 3900.
4. Define the static interfaces as discussed further in “Static Interface Definitions Using SDL” on page 3901.
5. Define the dynamic aspects of the interfaces by a continued use of use cases. See section “Design Use Case Model” on page 3904.

There is, as we will see in “Object Design” on page 3911, a close relation between the system design activity and the object design activity in the sense that the object design activity is concerned with the representation and behavior of the objects and the system design deals with the distribution of the objects into blocks and defining the communication paths between the objects.

The rest of this chapter will discuss the system design activity. SDL will frequently be used to define the architecture and interfaces and examples of SDL diagrams will be used throughout the chapter. A complete presentation of the SDL language is however outside the scope of this document. For more information, please consult either the Z.100 standard itself [24], or a text book about SDL like [28].

Architecture Definition

When using SDL to design a system the architecture of the system is defined by the block diagrams. They define how the system is decomposed into blocks and how these blocks either form the leaves of the block hierarchy or are further decomposed into smaller blocks. Essentially this block structure is a formalization of the logical architecture from the system analysis.

As an example, consider once again the access control system. The system controls the doors of a building to unlock the doors when an authorized user wants to enter or exit the building. The task in system design is to define how to structure this system. One natural choice is a distributed structure where the control of each door is localized close to the door and a central controller keeps all common information about authorized users, cards and codes. Furthermore one special block is responsible for the handling of an operator panel. A logical architecture that described this was illustrated in Figure 651 on page 3873 in chapter 72, *System Analysis*. The SDL diagram that shows a beginning of a formalization of this architecture is depicted in Figure 657.

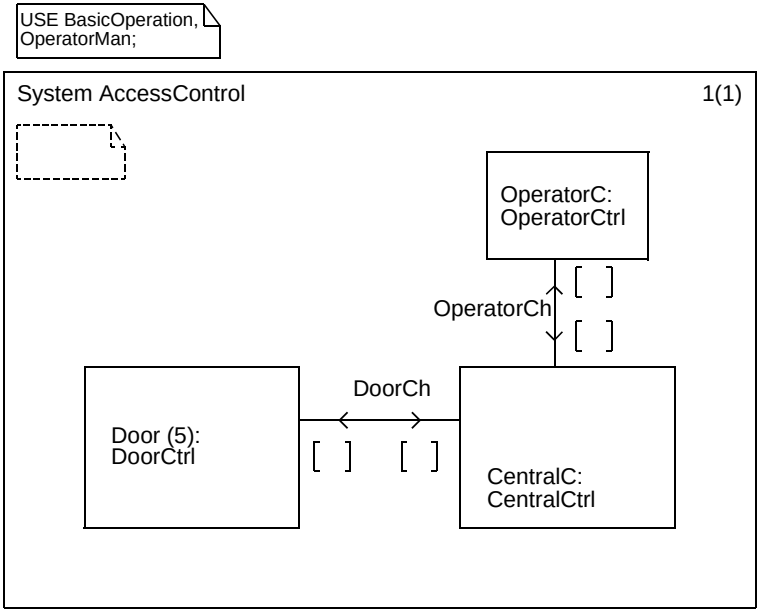

Figure 657: The architecture of the Access Control system defined by an (incomplete) SDL system diagram

In this diagram we can see the blocks *CentralC*, *Door* and *OperatorC* that are instances of the block types *CentralCtrl*, *DoorCtrl* and *OperatorCtrl*. *CentralC* contains the common information base about cards, codes etc. that are registered in the system. *Door* is the block responsible for the control of each door and *OperatorC* handles the operator communication. The diagram also shows how the blocks communicate using the channels *DoorCh* and *OperatorCh*. Note that there are five doors in the building in this case and that this is shown by defining *Door* to be a block instance set. The types *DoorCtrl*, *CentralCtrl* and *OperatorCtrl* are assumed to be defined in the packages *BasicOperation* and *OperatorMan* that are referenced in the *USE* clause in the top of the diagram.

Design Module Structure

The purpose of the design module structure is to show the actual components the application will be built from. The module structure should depict the actual source code modules etc. that the application will contain. A number of different aspects must be taken into account when defining the module structure:

- The implementation strategy for each module: Some modules may be designed in SDL with automatic C code generation. Other modules may be manually designed and implemented in a programming language and yet other modules may need a hardware implementation.
- Existing utility modules that can be reused in the new application
- Existing architectural frameworks that can be reused in the application
- Of-the-shelf utility modules that can be purchased and used in the application

Especially the reuse of existing architectural frameworks is very common and very beneficial. Most applications are not built from scratch, they are rather extensions/modifications of old applications and the design module structure is the place to show how this is done.

One notation that can be used in SOMT to describe the design module structure is object model instance diagrams, where the instances represent the different modules. Where relevant, the attribute field can be used to show what components of the logical architecture are contained in the modules. As an example consider a typical SDL application running on a small microprocessor where a proprietary real-time operating system is used. A possible module structure is shown in Figure 658.

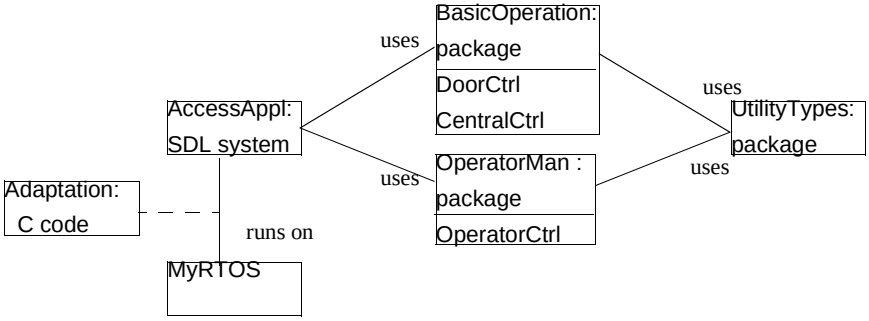

Figure 658: The module structure of the Access Control system using an in-house real time operating system

In this example the top-level of the application is described in the SDL system AccessAppl which is defined using the types defined in the packages BasicOperation and OperatorMan, both of which uses common types defined in the UtilityTypes package. The application will run on the already existing real time operating system MyRTOS. To make the C code generated from the SDL system run on MyRTOS a C code module Adaptation is used that defines the necessary interfaces.

In this example it is very likely that some of the modules will be developed within the project (the AccessAppl and the modules it uses) while others are already existing (like the real time operating system) and some can be taken from previous projects and be modified to fit the current project (like the Adaptation module).

The most important aspect of the module structure is that it forms the basis for dividing the work load on different development teams. This is in many cases the major reason to decompose the system into design modules. However, another reason may be the issue of reuse.

The design for reuse can in this context be viewed as an activity that defines the design module structure based on other premises than the architecture as discussed so far in this chapter. Consider for example the access control system decomposed as in Figure 657 on page 3896, where the system is divided into three different parts according to essentially the physical distribution that is needed in the application. There may in this example exist concepts that can be used in more than one of the subsystems. Examples may include knowledge about some passive

data structure, like the concept of a card, but also entire functionalities like the concept of time seen as a clock functionality.

The identification of these type of components is also a task of the system design. It is particularly important if the different subsystems are to be designed by different design teams. It is also important to identify common components to avoid duplicate work and lower the complexity of the individual subsystems.

The concept that is used to describe the different modules is the *package*. A package is essentially a container of SDL types, this may range from system types and block types over process types down to signals and data types. When a package is used by an SDL system the types defined in the package can be referenced from within the SDL system. For example, in the access control system we may decide that we need a package UtilityTypes (as in Figure 658) that defines the common data types needed in the different subsystems.

Another issue that needs to be handled in the system design is to analyze the consequences of the requirements on different configurations of the system. Are there any optional parts or functionality? In many cases the optional parts are captured by different modules in the system structure, but sometimes, like if there would be an optional requirements on a synchronized clock in all parts of the access control system, it is distributed over the different blocks in the system. If this is the case a package is the most useful concept to use to encapsulate the optional feature.

The discussion so far has been about reuse within one development project focused on one specific application. There is however also the issue of reuse outside the local project. When using an object-oriented approach to the analysis and design the objects tend to be fairly general and applicable in more than one project. If the objects in a particular part of the system are defined as types in a package this will form a good foundation for reusing the objects in future projects. This implies that there may be a reason to use a package structure that is different from the block structure of the system. The package structure reflects the decomposition into packages as defined by the possibility for reuse while the block structure defines the current system structure.

Deployment Description

The purpose of the deployment description is to define the physical distribution of the application and also define the practical details on how to build the different parts.

The specific objectives for a deployment description might vary during different activities: during design we are more concerned on describing on how to verify or validate the design, i.e. how to simulate the design in different ways, while in later activities it is desired to specify the final application build process for the application structure. It is therefor possible to have several deployment descriptions for one system.

There is a textual format for defining a deployment description – for more information, see *"Build Scripts" on page 2642 in chapter 56, The Cadvanced/Cbasic SDL to C Compiler, in the User´s Manual*.

Example of a textual deployment description, i.e. build script:

```
set-kernel SCTAAPPLCLENV
set-env-header on
program UserPart
component system AccessControl / block LocalStation
make-template-file UserMake.tpm
generate-micro-c
program CentralPart
component system AccessControl / block CentralUnit
make-template-file CentralMake.tpm
generate-advanced-c
```

Static Interface Definitions Using SDL

SDL offers two major means to define the interfaces of a block:

- Signals (for asynchronous communication)
- Remote procedure (for synchronous communication)

When signals are used to define the interface to a block they define the communication items that can be sent to and from the block. A signal can represent a service to be carried and it contains all relevant data that is associated with the request. A useful way to structure the signals if one particular interface contains many signals is to define signal lists that group together related signals. Consider the CentralCtrl block above. This block has two interfaces, one to the Door blocks and one to the OperatorCtrl block. The interface to the Door blocks can in SDL be defined as in Figure 659.

```
/* CentralCtrl door interface definition */
signal
  Validate(Card, Code), /* Check card and code authorization */
  Accept,               /* Card and code accepted */
  Reject;               /* Card and code rejected */
signallist CCService = Validate;
signallist CCServiceReply = Accept, Reject;
```

Figure 659: An interface definition using signals

When using signals to define the interface of a block we do not put any constraints on the execution strategies in the respective blocks, we only define the data that is transported. However, in some cases, especially when using a client-server based architecture, it is more convenient to define the interface using remote procedures instead of signals. As an example consider once more the CentralCtrl block. The major responsibility of this block is to store the cards with their associated code. Some possible operations on this data is to check weather a particular card is registered and what the code for a particular card is. A remote procedure definition of these operations is depicted in Figure 660.

```
/* CentralCtrl interface definition */
remote procedure CardRegistered; fpar Card; returns Boolean;
remote procedure GetCode; fpar Card; returns Code;
```

Figure 660: An interface definition using remote procedures

In addition to the signals/remote procedures that are used to define the interfaces in SDL there is of course also a need to define the data types that are visible in the interface. This issue is to a large extent the same as the issue of mapping passive objects to SDL data types. This is treated in more detail in section "Mapping a Passive Object" on page 3921.

Mapping Object Models to SDL Interface Definitions

When mapping object model concepts to SDL there are two aspects that need to be taken care of:

- The design of the interface
- The design of the object itself

In SOMT this implies that an analysis object is seen to have two different descriptions in the design model, one description of the interface and one description of the object itself. In the system design the focus is on the interface definition so we will save the mapping from object models to SDL object definitions until the next chapter ("Object Design" on page 3911). However, defining the relation between the object model concepts and the interfaces between the components of the system is a very relevant issue for this section.

Since the basic mechanism in SOMT to go from analysis to design is using the *Paste-As* mechanism (see "Implinks and the Paste As Concept" on page 3806) this is of course also used when defining the interfaces. As seen in the previous section interface definitions in SDL are defined using signals and/or remote procedure calls. Consequently this is what is produced when mapping a class to an *SDL Interface*.

As an example consider the DisplayInterface objects in Figure 661 that has one operation each.

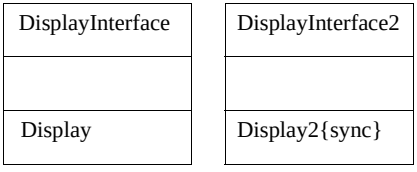

Figure 661: The DisplayInterface objects

When mapping these objects to SDL interface definitions we get in the first case the signal interface definition in Figure 662 (with the signal *Display*) and in the second case the remote procedure definition in Figure 663 (with a definition of the remote procedure *Display2*).

In SDL the natural way is to express interfaces by asynchronous signals, therefore this mapping has been chosen to be the default. (It can also be explicitly denoted with the word *async* within brackets, after the operation name.) If synchronous interface is preferred, this can be denoted by the word *sync*. This is an extension of the original class diagram notation.

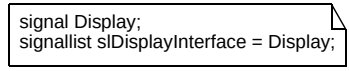

Figure 662: The signal interface from the DisplayInterface object in Figure 661

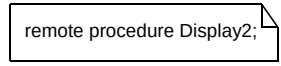

Figure 663: The remote procedure interface given by the DisplayInterface2 object in Figure 661

It is of course also possible to have a mixed signal/remote procedure interface. In this case some of the operations are asynchronous and thus mapped to signals while other are synchronous and thus mapped to remote procedure definitions.

Design Use Case Model

The static interface definition alone is not enough to define how the blocks are supposed to cooperate to meet the requirements on the system. In the requirements and system analysis, use cases were used to describe the requirements on the system. This is continued in the system design to define the dynamic interface between the blocks in the system. Essentially the idea is to take each one of the use cases found in the system analysis and formalize this to a sufficient degree of detail that is consistent with the level of detail that is found in the static interface definitions. The degree of detail must be precise enough to make the design use cases act as detailed test specifications.

A benefit with the design use cases is the structured way in which they are constructed. It is easy to verify that all requirements as expressed by the requirements use cases and refined in the analysis use cases are handled by the design use cases and this gives a formal link between the requirements and the structure of the system that implements it.

In a development environment where the different blocks are developed by different teams they also form a necessary common definition of the responsibilities of their respective blocks and how their blocks are to together fulfill the requirements on the system.

From a practical perspective this puts some requirements on the notation used to describe the design use cases:

- It must be precise and formal enough to allow an specification of test cases on a detailed level of abstraction.
- It should be possible to automatically check the design use cases against the SDL design model.
- There must be a well-defined way to transform the design use cases to executable test programs that can be executed in the target environment against the application.

There are two levels of testing of interest for the design use case model:

- Module testing
- System testing

Module testing is intended to test one specific part of the system and should check that this particular part of the system fulfills its requirements. The system testing is intended to test the integration of the different parts and check that they together fulfil the requirements on the total system.

The design use case models should form the basis for both kinds of testing.

Another aspect of testing is when in the development project it is performed. One of the benefits of SDL is that it is possible to test already on the design model, essentially testing against a simulation of the SDL system. In addition there is of course also a need to test the implementation in the target environment, but if the logics of the application already has been tested during design then the focus of the target testing can be on target integration issues and the risk for logical errors in the design is reasonably small. The design level testing is further discussed in "Design Testing" on page 3950.

In SOMT two different alternative notations are used:

- MSC
- TTCN

Usage of MSC

MSCs can be used in a way that is precise and formal enough and can automatically be checked against SDL design models. A benefit is that it is used also in requirements analysis and system analysis and is intuitive and easy to understand also for non-experts. Notice however that there is a difference between the analysis use cases and the design use cases. The fairly abstract messages exchanged between the instances in the analysis use cases must in the design use cases be refined to the level of the static interface definitions, this may include specifying parameter values that where left out and even replacing one message with a sequence of message exchanges. It may also often be necessary to have more than one design use case for each analysis use case, for example to handle a situation where the analysis use case has left out a parameter and there is a need to test more than one combination of parameters.

Consider again the access control system with a decomposition according to Figure 657 where the system is divided into a DoorCtrl, a CentralCtrl and an OperatorCtrl block. If we take the *Enter building* use case as defined on requirements level by an MSC in Figure 638 on page 3847 and refined to the analysis use case in Figure 645 on page 3862 in chapter 72, *System Analysis*. When further refining this to a design use case we get an MSC as shown in Figure 664 where some of the messages have been refined.

Note that an MSC describes both the requirements on the separate parts of the system and the requirements on the whole system. This implies that the same MSC can be used to define both module and system tests.

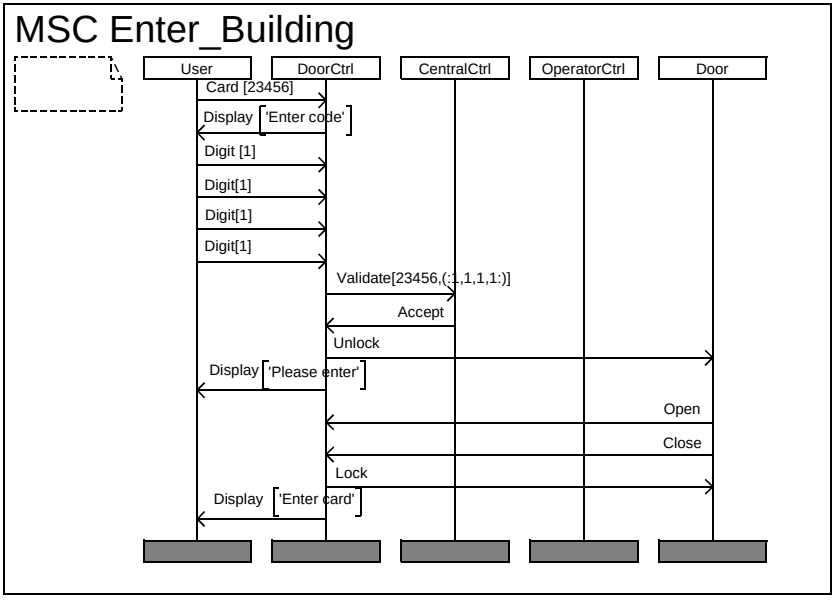

Figure 664: The Enter building use case distributed over an architecture

It is easy to see that the strategy outlined above is extendable to allow a decomposition of a system into not only one level of blocks, but into a hierarchy of blocks. For each new level of decomposition all use cases that involve the decomposed block are taken as input to the validation of the new decomposition. The block that was decomposed is replaced by the new blocks and new versions of the use cases are created.

Usage of TTCN

TTCN is another notation that is suitable for formalizing use cases on the design level. The benefit of TTCN is that it is a special purpose language for test description including:

- Facilities for describing constraints on complex data values
- Preambles and postambles to show how to compose test cases

- Possibilities to handle alternative outcomes of a test case
- A special “verdict” construct to define the outcome of a test case

TTCN is also an established notation for test description so there is good tool support for executing TTCN test cases on target platforms.

The drawback is that it has not a particularly intuitive syntax, making it more difficult for non-experts to maintain, create and review TTCN test suites.

If TTCN is used to define both system and module testing each analysis use case will result in several TTCN test cases, one for each part of the system and then one for the entire system. As an example consider Example 649, that shows a test case testing the requirements from the Enter_Building use case on a DoorCtrl, and Example 650, that shows a test case testing the requirements from the Enter_Building use case on the entire AccessControl system.

Example 649: A TTCN test case testing a DoorCtrl ----------

```
1  UsrPCO?Card                                  Card1
2    UsrPCO?Display                             Enter_Code
3      UsrPCO!Digit                             Digit1
4        UsrPCO!Digit                           Digit1
5          UsrPCO!Digit                         Digit1
6            UsrPCO!Digit                       Digit1
7              CentralPCO!Validate              Validate_1
8                CentralPCO?Accept              AcceptOK
9                  DoorPCO!Unlock               Unlock!
10                   UserPCO!Display            Please_Enter
11                     DoorPCO?Open             Open1
12                       DoorPCO?Close          Close1
13                         DoorPCO!Lock         Lock1
14                           UserPCO!Display    Enter_Card P
```

Example 650: A TTCN test case testing the AccessControl system----------

```
1  UsrPCO?Card                                  Card1
2    UsrPCO?Display                             Enter_Code
3      UsrPCO!Digit                             Digit1
4        UsrPCO!Digit                           Digit1
5          UsrPCO!Digit                         Digit1
6            UsrPCO!Digit                       Digit1
7              DoorPCO!Unlock                   Unlock!
8                UserPCO!Display                Please_Enter
9                  DoorPCO?Open                 Open1
10                   DoorPCO?Close              Close1
11                     DoorPCO!Lock             Lock1
12                       UserPCO!Display        Enter_Card P
```

The choice between MSC and TTCN as design use case notation is very much influenced by application and development organization aspects:

- It is more efficient if the same test definitions can be used both for design level testing and target testing, so the plans for how to perform the target level testing may have an implication for the choice of notation. If the target testing should be done using a TTCN environment then at least the system tests should be defined in TTCN also for the design level testing.
- On the other hand, if the target tests are performed using an in-house test script notation implying that the same notation can not be used both in design and target testing, then MSC has the advantage of being a simpler notation and is already known and used in the previous activities.

Textual Design Documentation

The SDL architecture definition and the design use cases form a specification of the static and dynamic aspect of the components from a functional viewpoint. In many cases there is a need to extend this with more information that is not suitable to express in SDL or as use cases. An example may be a system that requires a user interface with windows, menus etc. or a system with specific requirements on reliability or response times for some or all of the components.

To give the possibility to express this type of specifications and also to allow other types of design or project documentation in an environment that is mainly SOMT and SDL oriented, the SOMT method gives a possibility to include textual documents in the system design documentation.

Consistency Checks

This section gives a number of examples of consistency checks that can be made on the models produced in the system design.

- Check that there is a simple (preferably one-to-one) mapping between all the top-level subsystems in the architecture definition and some of the design modules as defined in the design module structure.
- Check that the actual modules (SDL packages etc.) used in the design are consistent with the design module structure.
- Check that the subsystems in the logical architecture in the analysis object model are mapped to the architecture definition in the design.
- Check that all use cases from the requirements analysis and system analysis are refined to design use cases.
- Check that the instances in the design use cases correspond to the blocks/processes in the architecture definition.
- Check that all objects in the analysis object model either has been mapped to some interface definition or really are internal to their module.
- Check that the different models conform to the rules for their respective notation (like SDL and MSC).

Summary

The system design is an activity in which the architecture of the system to be built is defined in SDL. Use cases from the analysis are refined to a granularity that will be sufficient for describing the behavior of the subsystems in the architecture. These use cases should be a source for module and system testing in later activities.

Chapter 74 System Design

Chapter

75 *Object Design*

This chapter gives you the rules for how to transform object models to SDL design models. Mappings for active and passive objects and associations are described and exemplified. How to define the behavior of an object is also discussed as well as a section on how to test the design.

The chapter requires that you are at least reasonably familiar with SDL.

Object Design Overview

The object design is the activity that completes the definition of the system. It carries on where the system design finished and fills in the details about object behavior and system structure. The object design is a creative activity that refines the object definitions and system structure taking at least three aspects into account:

- The system structure: where in the system is an object localized
- The reuse structure: is the object a subject for reuse internally within the system or externally
- The precise definition of internal object structure, the behavior and data aspects

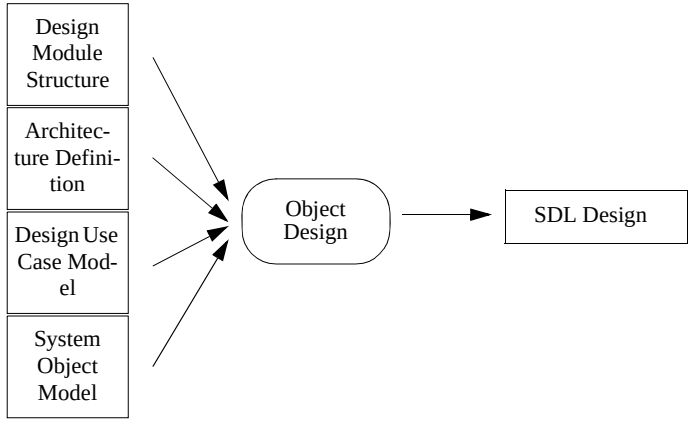

Figure 665: Overview of the object design activity

There is a close relation between the system design and the object design, in the sense that both activities are dealing with the structure of the system. The difference between the activities is mainly a difference in the point of view. The system design takes a top-down look at the system to identify subsystems and overall structures. The object design on the other hand focuses on the objects and uses them as a starting point for the refinement and structuring.

In practice one of the major tasks of the object design is to define the behavior of the objects. Essentially the object design can be viewed as three sequential tasks that must be performed.

1. Map all the classes in the relevant part of the analysis object model to suitable SDL concepts.
   - Active classes are mapped to processes or process types and passive classes are mapped to data types. This mapping is described in "Mapping Object Models to SDL Design Models" on page 3914.
   - The localization of the process (type) or data type in terms of the SDL package/system structure should be done according to the design module structure and architecture definition from the system design.
2. Choose a set of essential use cases and define the behavior of the SDL processes and data types that implements these use cases. Concentrate on the normal behaviors and leave the exceptions for a later step. The design of SDL processes is further discussed in "Describing Object Behavior" on page 3943.
   - Note that this also includes a testing activity that verifies that the SDL design implements the requirements from the use cases. This is further described in "Design Testing" on page 3950.
3. Elaborate the design by introducing more use cases and refine the SDL design to handle also these cases. Take care of exceptional situations like error handling etc.
   - This elaboration is an iterative process where the design is incrementally developed until all requirements are implemented.
   - Each iteration also includes a testing step where both newly implemented and old functionality is checked.
   - The elaboration can include both refining existing processes/ data types and introducing new process/types.

In a project where the design is split on several development teams the iterations in the design will often have to be synchronized. This is further discussed in chapter 77, *SOMT Projects*.

Mapping Object Models to SDL Design Models

In SOMT object design, an important step is the transformation of (parts of) the analysis object model to an SDL system. This section describes this transformation.

There are several aspects important in the transformation:

- How to map objects to SDL, taking into consideration e.g. whether the object is active or passive
- How to represent associations in SDL
- How to preserve the inheritance/aggregation relations in SDL

The mapping to ASN.1 will also be discussed briefly.

Mapping an Active Object

Consider an object in the analysis model that has been found to be an active object. How should this be mapped into the design model? The default choice is to map this object as an SDL process type. The attributes of the object will then be mapped to variables and the operations will correspond either to remote procedures defined in the type or signals handled by the process type. As an example consider the DisplayInterface object in the Access control system. This object is responsible for interfacing a display that is capable of showing a line of text to a user. In the analysis object model this object may look like Figure 666. It has one attribute, *Text*, and one operation, *Display*.

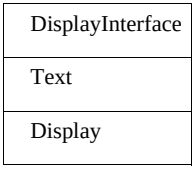

Figure 666: The DisplayInterface object

When mapped to an SDL diagram as a process type the result will be a process type reference, as shown in Figure 667.

Figure 667: The DisplayInterface process type

Now consider the case where the *Display* operation was defined to be an asynchronous operation which is the default. If we now take a look at the DisplayInterface process type definition we can see that it has a variable called *Text* and a gate with the signal *Display*. This process type definition is shown in Figure 668.

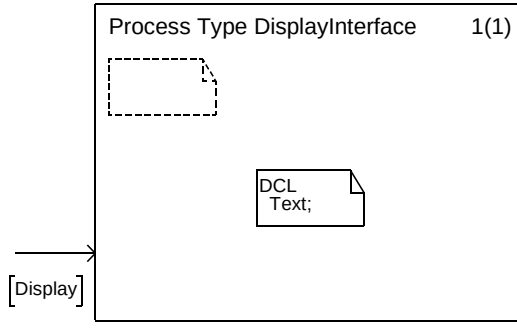

Figure 668: The DisplayInterface process type definition

If, on the other hand, the *Display* operation was defined to be synchronous (by giving the keyword *sync* after the operation name), then the definition of the DisplayInterface process type would now also be different. It would contain a definition of the Display remote procedure instead of a gate with a signal. See Figure 669.

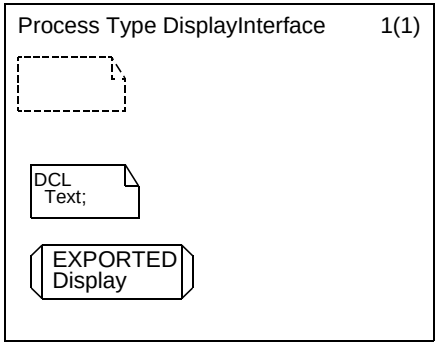

Figure 669: The DisplayInterface process type when mapped to a process type with RPCs

When mapping an object like the DisplayInterface, the design issue of reuse shows up as a question of *where* to define the SDL object. If the DisplayInterface class is considered to be a general class that is to be reused in different projects or by different development teams, the most natural choice is to put the process type in a package that includes this type definition and other related types that are to be reused in different contexts. The design choice of what packages to use in a project was one of the issues of system design.

If the DisplayInterface only is intended to be used in this project but it is used in several of the blocks representing subsystems then there is also a possibility to put the process type on the system level. This would allow the type to be used in the entire system but it would not be convenient to use it in other projects.

If the DisplayInterface is only to be used within the local block it can be defined anywhere in the scope in question, even if it probably is a good idea to keep all process type references on one page in the block diagram.

Finally, if the DisplayInterface object is only to be used in one particular place in the system, it is possible to define it as a process directly where it will be used instead of as a process type. This would be done the same way that it was mapped to a process type except that a process would be generated instead of a process type. Sometimes this strategy is a good idea since it slightly reduces the complexity of the system, however it is only possible if the object is only used in one place in the system.

Mapping Active Objects with Inheritance

Inheritance among active objects is common in object models and is mapped directly to inheritance between the corresponding process types. For example, when mapping the EnglishDisplay object from Figure 670 to a process type, the result is as shown in Figure 671.

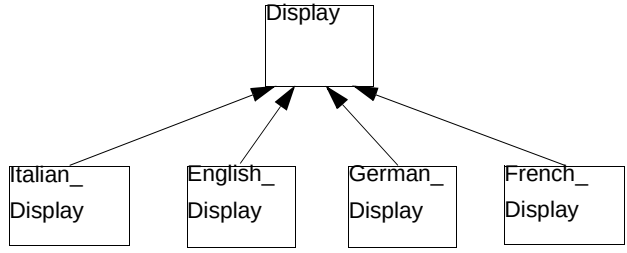

Figure 670: Object model with inheritance

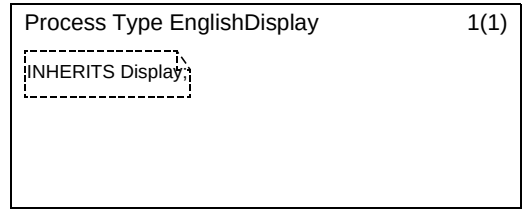

Figure 671: Process type with inheritance

Mapping Aggregations of Active Objects

A fairly common structure is an aggregation with one assembly class that contains a number of other object classes, the part classes[1]. This is common for example when using container classes as abstract interfaces to a certain functionality. One example is given in a description of the software in one part of the access control system: the part that controls the access to one particular door in the building.

1. Terminology (assembly and parts classes) after [21] the “Object Model Notation Basic Concepts”

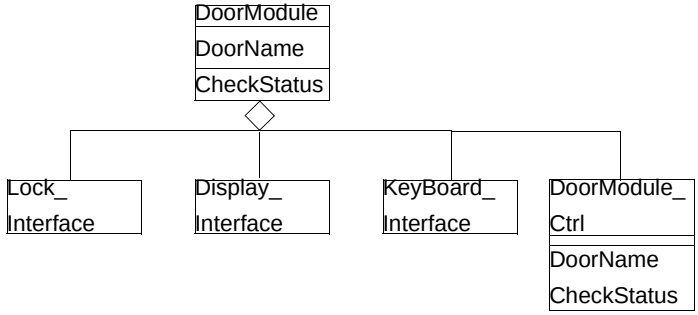

Figure 672: An example of an aggregation of active objects

The most common mapping for this type of structure is to map the assembly class to a block or a block type, depending on the strategy for reuse that has been decided upon for the object.

One special, but fairly common, case is when the assembly object class contains attributes. In this case there are two possibilities: either the aggregation is considered as a “subsystem”, in which case the attributes should be implemented by one of the parts classes, or the object should in addition to the mapping to a block (type) also be mapped to a process within the block that acts as a data server. This mapping follows the same principles as was discussed in section “Mapping an Active Object” on page 3914.

Another possibility is that the assembly object class contains operations. This implies that these operations should be included in the interface of the block/block type. In the same way as when pasting as process types there is a design choice involved here. Are the operations intended to be synchronous remote procedures or are they asynchronous signals? In this case it is also important to define where the operations are to be implemented. Also in this case there are two choices: either the operations are implemented in one of the parts classes or a process is introduced in the block that handles the operations the same way a data server process handles the attributes.

As an example consider the analysis model in Figure 672. The block type DoorModule has both an attribute and an operation. A design counterpart for this is shown in Figure 673 and Figure 674. The process DoorModuleCtrl is the server process that handles the data and operations defined in the DoorModule analysis object.

The choice where to implement the operations and the attributes of the aggregate class is depending on the intended meaning with the aggregation. In SOMT the recommended practise is to use aggregation in object model that describes the architecture of a system as a “subsystem” or “parts vs. whole” relation, meaning the aggregate class is completely determined by its parts classes. In this case the operators and attributes of the aggregate class should be implemented by the parts classes.

Note that this is an example where the attributes and operations of the aggregate class DoorModule have been implemented by one of the part classes, the DoorModuleCtrl class.

Figure 673: A block type reference for the DoorModule object

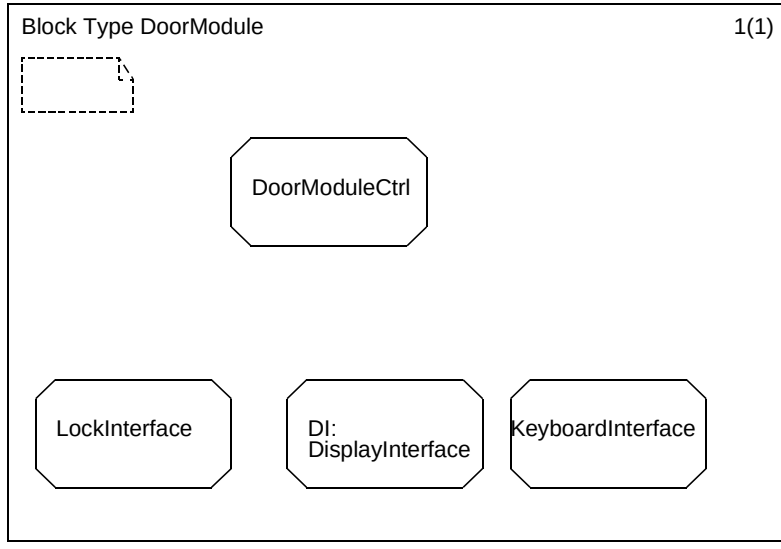

Figure 674: A block type with a data/operations server process

If the object that is mapped to a block type is a subtype of another object in the object model, then the resulting block type will be defined as a

subtype that inherits a block type that corresponds to the supertype in the object model.

Mapping State Charts to SDL Process Graphs

The principle of reusing as much information as possible of the information gained during the analysis activities when working in the design activities implies that an effort should be made to translate state chart descriptions into SDL process graphs. For a thorough description of the mapping rules please refer to: *"Converting State Charts to SDL" on page 1702 in chapter 39, Using Diagram Editors, in the User´s Manual*.

State charts may be converted into SDL. Converting state charts without any hierarchical states is very straight forward, but converting a state chart containing hierarchical states requires flattening since the concept of hierarchical states does not exist in SDL.

The state chart LocalStation Figure 675 contain a hierarchical state with sub states and need to be flattened when converted to SDL.

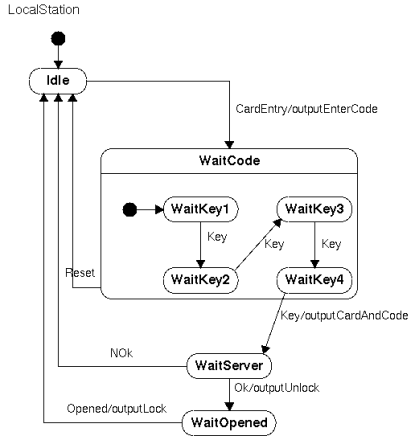

Figure 675: The State Chart Local Station

The behavior of the SDL process LocalStation Figure 676 is the behavior defined in the state chart LocalStation. The process is flattened and gives a straight forward view of the behavior. To increase traceability

between the state chart and the SDL process the converter functionality provides comments on states and transitions which are related to any hierarchical state.

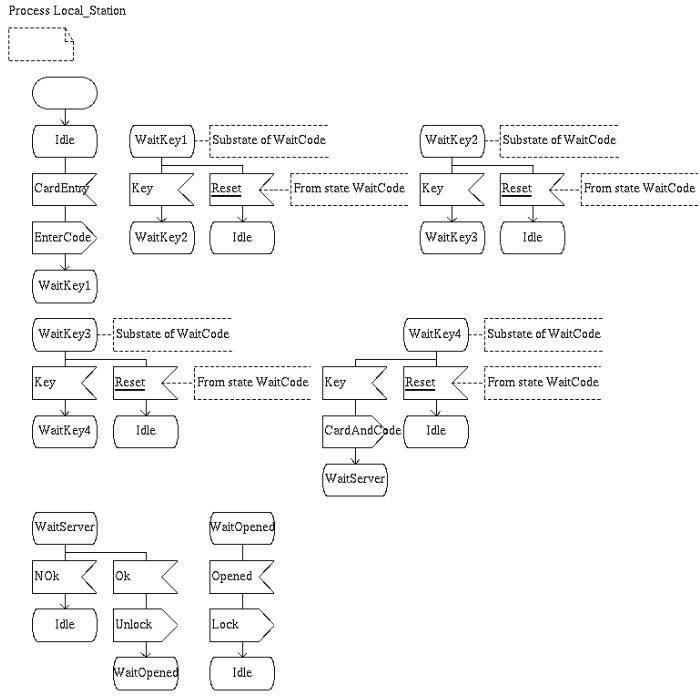

Figure 676: The SDL process LocalStation

Mapping a Passive Object

A passive object is an object that does not have any thread of control or spontaneous behavior of its own. A passive object is often used to encapsulate a certain amount of information that is needed in the system. In the context of distributed systems it is often useful to classify the passive data descriptions into two broad classes depending on the way the data is used: *external* data and *internal* data

- The external data is focused on describing the data units that will be transported across the system when that application executes. In an application where the different components execute in different

memory spaces, and maybe even on different hardware, there is a need to consider transportation format and maybe even coding/decoding of the data. Often the description of external data is focused on the information contents of the data units and not very much on the operations that can be performed on the data units. Typical example applications where external data is very common includes protocols in telecom applications. A common property of this kind of data is that they are usually structured in trees, in an object model often in aggregation hierarchies, and not in graph structures.

- The internal data is characterized by the fact that it is used to describe information that the application needs to do its work. Typically the data is localized to one concurrent execution unit. The internal data units are thus used to store rather than to transport data. Some typical examples are data bases and complex data structures in conventional program units. A local data unit is typically not copied from one component to the other. Instead operators are used to access the data unit.

As will be seen in the next sections the mapping of passive objects to SDL data types is slightly biased towards the external data view of passive objects, the mapping to ASN.1 data types is very biased to external data view, and the mapping to C data types is slightly biased towards the internal data view of passive objects.

Mapping Objects to SDL Structs

In general, the SDL construct that can be used as the design representation for a class is an SDL STRUCT. This is exemplified in Figure 677 below.

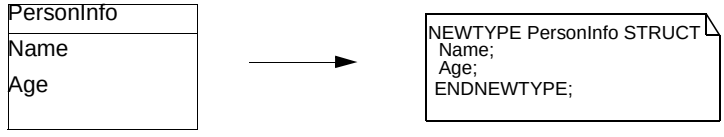

Figure 677: Mapping a passive object to a STRUCT type

In this mapping all attributes of the class are mapped to fields of the STRUCT.

Attribute Data Types

The attributes of a class may have data types associated with them. In general there are three ways to handle these data types:

- Defining the data type in the analysis model.
- Giving an abstract definition in the analysis model and making a final decision in the design model.
- Consider it to be a design issue and give no definition of the data type in the analysis model.

As usual the choice is a matter of personal taste but should be directed by the general idea that the analysis model must be complete enough to be understandable by itself, but as small as possible to facilitate overview and ease of use.

The default mapping in SOMT is a simple literal mapping of whatever exists in the analysis model to the design model in SDL. See Figure 678.

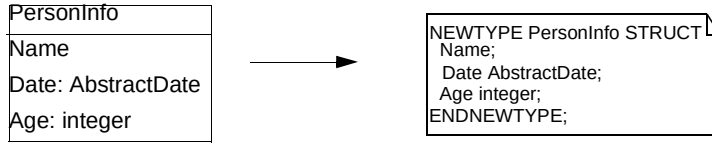

Figure 678: A data type mapping example

A special case which might be of interest in the analysis is when more complex data types like lists or sets are used. SOMT treats this type of data in the same way as elementary types are treated.

Mapping Operations

When a class is mapped to a data type in SDL there exists several ways to map the operations of the class. Operations could be mapped to:

- Operators described by (textual) operator definitions
- Operators described by operator diagrams
- Operators described using C code
- Procedures described in SDL
- External procedures

The default mapping used by SOMT is to map operations to SDL operators with operator diagrams.

Operators Described by Operator Definitions

Operators described by operator definitions is the simplest choice. Consider the PersonInfo class as defined in Figure 679.

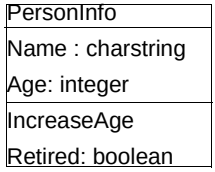

Figure 679: A class with operations

This object has two operations: IncreaseAge and Retired which are intended to increase the age of the person with one, and to check if the person has reached the age where he/she has retired from his job.

Figure 680 shows how a mapping of operations to operator definitions can be done.

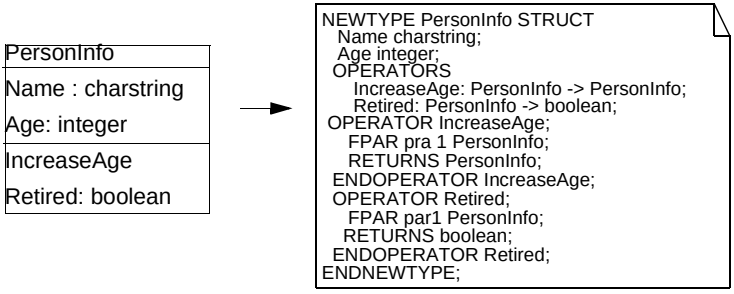

Figure 680: Data type with operator diagrams implementing the class operations

Operators Described by Operator Diagrams

Operators described by operator diagrams is another alternative.

If a mapping to SDL is done using operators with operator diagrams, the SDL will look like in Figure 681.

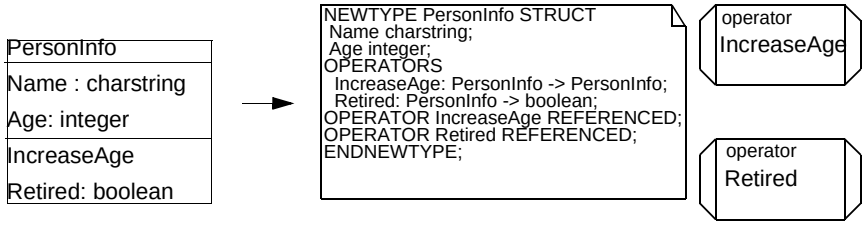

Figure 681: Data type with operator diagrams implementing the class operations

SDL Operators in General

Some things worth noting about SDL operators are:

- An SDL operator can only be used within an expression, e.g. “var:= oper(1) + 1”.
- All operators must return a result.
- Operators can not have IN/OUT parameters. All parameters are IN parameters.

A consequence of this is that an operator cannot both modify an object and return a result. The operators can thus be divided into two classes:

- Modifiers, that modify the object
- Extractors, that extract information from the object but does not modify it

The modifiers are defined as:

```
ModOp: ObjType, P1type, P2type -> ObjType;
```

and used as

```
MyObj := ModOp( MyObj, p1, p2 )
```

An extractor would be defined as:

```
ExtrOp: ObjType, P1type, P2type -> ResultType;
```

and used as

```
Result := ExtrOp( MyObj, p1, p2 )
```

However, SOMT allows a way to overcome the third aspect above. If a C implementation is used as discussed below, the restriction that operators cannot modify the parameters is somewhat relaxed, since the data type itself can be defined using a pointer and then whatever is pointed at can of course be modified by the operator.

Operators Described Using C Code

The second mapping possibility for object model operations is to map them to SDL operators with C implementation. See Figure 682.

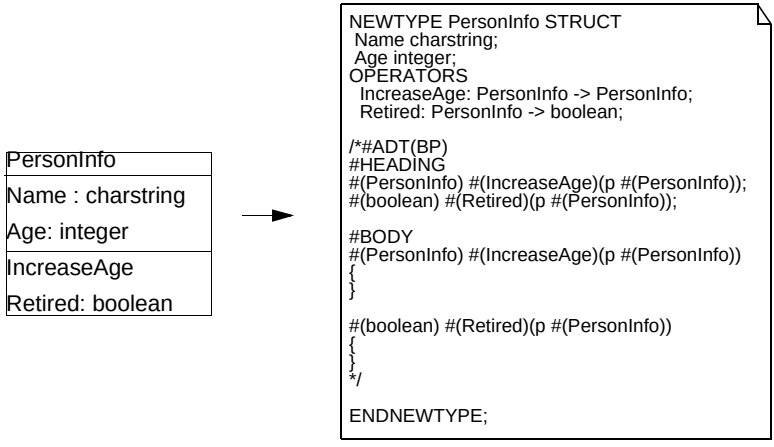

Figure 682: Data type with C implemented operators

Procedures Described in SDL

The third way to implement operations of a class is to use SDL procedures. In this case the definition of the PersonInfo class would be like in Figure 683.

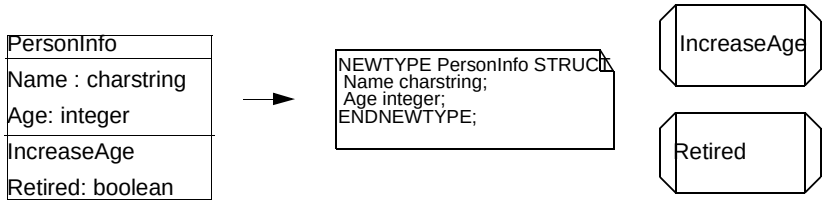

Figure 683: Data type with procedure implementation of operations

Some differences when procedures are used compared to when operators are used:

- Procedures can use both IN parameters, IN/OUT parameters and a return value.
- There is no syntactic relationship between the procedure and the data type definition.
- Procedures can be used in two different ways:
  - using special procedure call symbols (like in Figure 684).

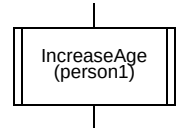

Figure 684: Procedure call symbol

  - in expressions with a syntax as the following example:

```
ret:= CALL retired(p1)
```

External Procedures

The fourth way is to implement the operations as normal C functions. These functions correspond in SDL to *external procedures*. For example, to implement the `IncreaseAge` operation, one could have the following C function (the PersonInfo data type would have to be specified as a C type):

```
void IncreaseAge (PersonInfo *p)
{
  (p->age)++;
}
```

External procedures can be declared in text symbols, and they are called as if they were normal SDL procedures, as shown in Figure 685. "Mapping Passive Objects to C" on page 3935 gives more details about mapping operations to C.

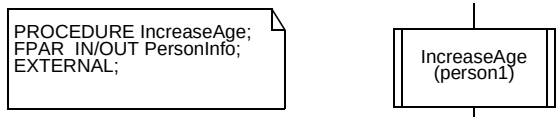

Figure 685: External procedures in SDL

Mapping Aggregations

A common situation is that the information used by a system has to be structured into some kind of tree structure. In the analysis this will appear as an aggregation hierarchy of passive objects. An example is shown in Figure 686.

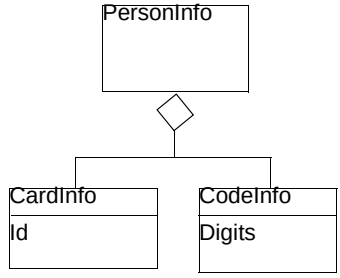

Figure 686: An aggregation of passive objects

If the PersonInfo object is mapped to a struct the aggregation would be visible in the design model as fields in the struct the same way attributes would be mapped. The mapping of the PersonInfo object from Figure 686 into an SDL diagram is shown in Figure 687.

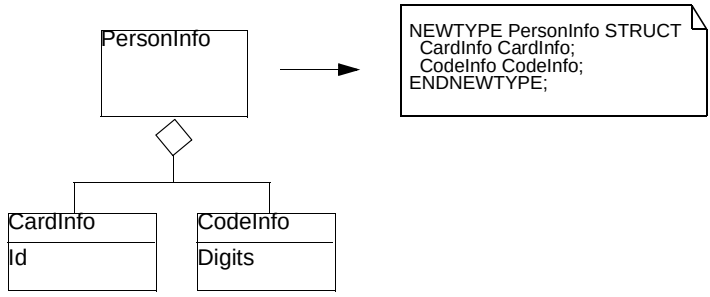

Figure 687: The SDL mapping of a passive object with aggregation

A common special case is when there is a multiplicity associated with the aggregation as in where one person can have more than one card.

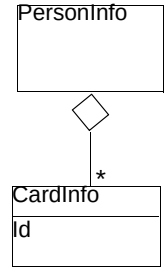

Figure 688: An aggregation with associated multiplicity

In general the multiplicity implies that there is a list or set of elements associated with the aggregation. There are several mappings to SDL possible, for example based on:

- Standard SDL generators like:
  - *Array*
  - *String*
  - Other data types as described in chapter 2, *Data Types*
- A user-defined C implementation of lists

The default mapping in SOMT is a mapping to a type called “xxxList”, where “xxx” is the name of the class. In Figure 689 the mapping of the PersonInfo type is illustrated.

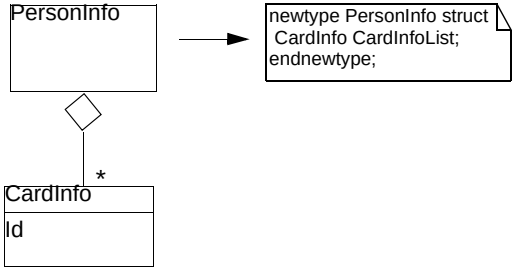

Figure 689: An SDL mapping an aggregation with multiplicity other than one

The “xxxList” type will then have to be designed separately. One simple way is to use an SDL *string* as in Figure 690 for the CardInfoList type.

```
newtype CardInfoList
 string( CardInfo, EmptyCardInfoL )
endnewtype;
```

Figure 690: An SDL implementation of a list using the string generator

Another special case is given by recursive data structures that are used to describe tree structures. In Figure 691 a simple recursive tree is illustrated. In general this type of tree can of course also include a multiplicity other than one.

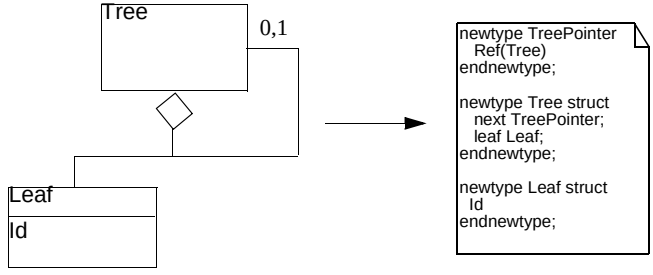

Figure 691: A recursive object model

Due to the lack of pointers in SDL, this type of structure can normally not be defined in standard SDL-92. However, SDL tools may offer tool-specific pointer generators that can be used to represent the above tree. Figure 691 shows how the recursive data structure can be represented with help of the `Ref` pointer generator of the SDL Suite.

Inheritance

Inheritance in an object model is used to model “is-a” relationships. In practise the inheritance shows how attributes, operations and associations are inherited from a superclass to the subclasses. An example is shown in Figure 692 which models the fact that both the users and operators are persons.

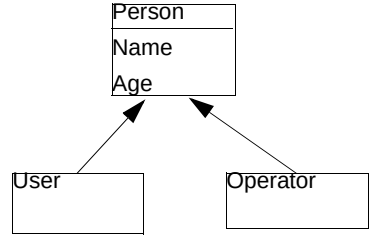

Figure 692: Inheritance relations

When mapping classes that inherit other classes to SDL data types there are three mechanisms that can be used:

- Flattening
- Delegation
- The SDL inheritance concept

Flattening means essentially that all operators, attributes and associations are copied from the superclass to the subclasses. In the example above this strategy would imply that the SDL representation of the User class might look like in Figure 693.

```
newtype User struct
 Name charstring;
 Age integer;
endnewtype;
```

Figure 693: Representing inheritance using flattening

Using delegation to represent inheritance is essentially to replace the inheritance hierarchy with aggregation hierarchies. When using this strategy the SDL representation of the classes in Figure 692 will be as illustrated in Figure 694.

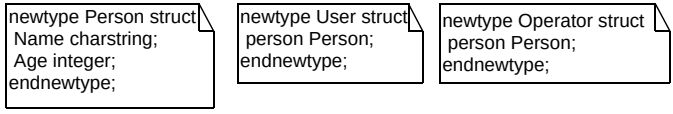

Figure 694: Using delegation to represent inheritance

When using the data types defined as in Figure 694, note that the syntax for accessing the attributes will of course show the delegation strategy used. For example, in order to access the name attribute of a User a construction like “uservar!person!name”” will have to be used.

SDL includes an inheritance concept for inheritance between data types. Unfortunately the inheritance between data types is an inheritance of operators only which limits the usefulness of the SDL inheritance. For more information about inheritance between SDL data types see “Inherits” on page 69 in chapter 2, *Data Types*.

Multiple inheritance implies that attributes, operations and association are inherited from more than one superclass as illustrated in Figure 695, that models the fact that a user is both a person and a card holder.

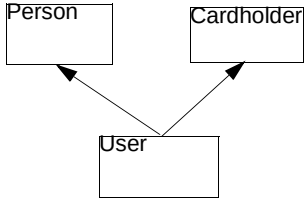

Figure 695: Multiple inheritance example

When mapping classes with multiple inheritance to SDL both the flattening and delegation strategy works fine (except for name clashes when using the flattening strategy) but the SDL inheritance does not include multiple inheritance so it can not be used. In Figure 696 the delegation strategy is used to map the User class from the previous example to SDL.

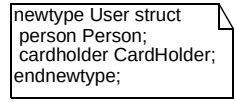

Figure 696: Mapping multiple inheritance using delegation

Delegation is the default mapping of inheritance used in SOMT.

Mapping Passive Objects to Signals

A special kind of passive objects in the analysis object model are the objects that are used only for communication, either between the system and its environment or between modules within the system. For example, when defining the use cases it is useful to show the relations among the events using an object model. It is especially useful if there are inheritance relations among the events as shown in Figure 697. The corresponding SDL signal definitions are shown in Figure 698.

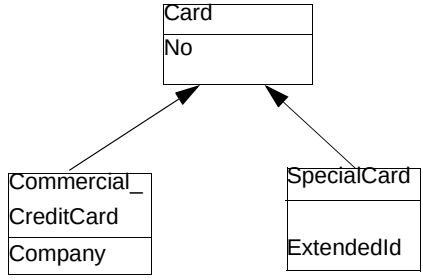

Figure 697: Object model describing communication events

There is often a choice of whether to map a passive object used for communication to a struct data type or to a signal. This is one of the design decisions that has to be taken during the object design.

```
signal Card( No );
signal CommercialCard inherits Card adding (Company);
signal SpecialCard inherits Card adding (ExtendedId);
```

Figure 698: SDL signal definitions corresponding to the object model in Figure 697

Mapping Passive Objects to C

Passive objects can also be mapped to C data types and functions. In C, classes correspond to types, attributes of a class to fields in struct types, and operations to functions.

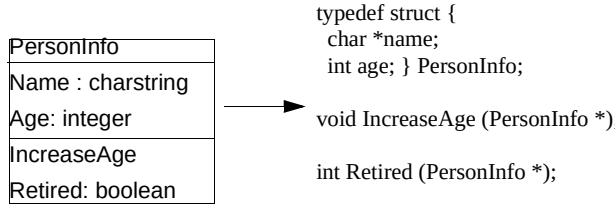

Figure 699 Mapping a passive object to C

Figure 699 shows a possible mapping of class PersonInfo to C. Note that in the mapping of the operations, a parameter is present to identify the PersonInfo object.

To represent aggregations in C, the same mechanisms as described in "Mapping Aggregations" on page 3928 can be used. When mapping inheritance to C, the flattening and delegation mechanisms described in "Inheritance" on page 3931 can be used.

When mapping associations to C, pointers are very powerful. Figure 700 shows an example of a one-to many association that is mapped to a linked list in C. Note how the role name has been used in the mapping.

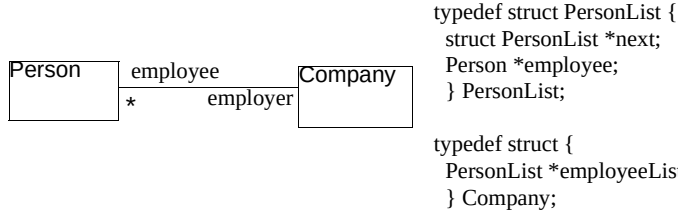

Figure 700 Mapping an association to C

The SDL Suite has facilities to instantiate classes that have been mapped to C, and access their attributes and operations from SDL. This is described more detailed in chapter 2, *Data Types*.

Note:

Try to avoid pointers to data in other SDL processes! Data inconsistency will occur if the same data can be read/written by more than one SDL process at the same time. This can be achieved by avoiding pointers in parameters of signals and remote procedures.

Figure 701 shows an SDL fragment that uses the C types for PersonInfo of Figure 699. The `CString2CStar` operator converts an SDL `Charstring` to C's `char *`. Operations are called by means of SDL procedure calls. Note also the address operator '`&`' in the call to `IncreaseAge`.

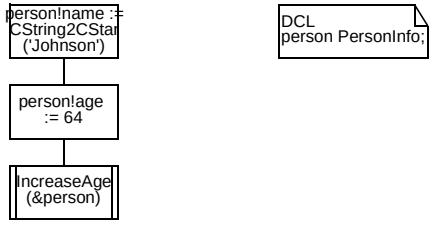

Figure 701 Using C type PersonInfo in SDL

The choice between the SDL struct representation of classes and the C code representation is to some extent a matter of taste. There is a trade-off between simplicity and expressiveness. The SDL struct definition is very simple and all SDL based tools can completely analyze and manipulate this type of data. When using a C implementation, you take over some of the responsibilities from the tools. This means more work for you, but also a possibility to define in detail what you want.

Mapping Passive Objects to ASN.1 Data Types

An analysis object can also be mapped to an ASN.1 data type. The ASN.1 SEQUENCE construct corresponds best to a passive object with attributes. The most basic example is illustrated in Figure 702 below.

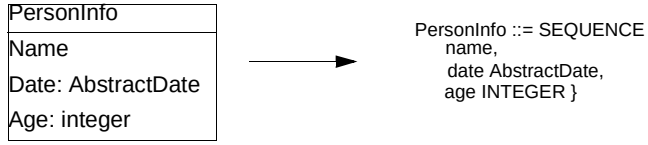

Figure 702: Passive object mapped to ASN.1

The ASN.1 SEQUENCE can be compared with the SDL STRUCT, so most of chapter "Mapping a Passive Object" on page 3921 on mapping classes to STRUCTs is also valid for ASN.1. The few differences are treated here.

The largest difference is that ASN.1 has no possibility to specify operators. Therefore the operations of a passive object should be inserted in some dummy SDL type, while the attributes are mapped to a different ASN.1 type, as illustrated below.

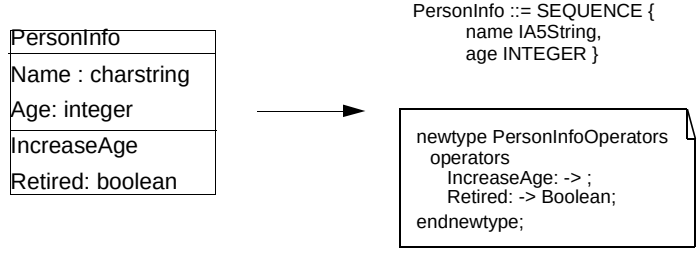

Figure 703: Passive object with operators mapped to ASN.1

The second difference is that ASN.1 has no concepts for inheritance. Therefore only flattening and delegation can be used to represent inheritance. ASN.1 has a special construct, COMPONENTS OF, that is useful to represent flattening. An example of this is given in Figure 704 below.

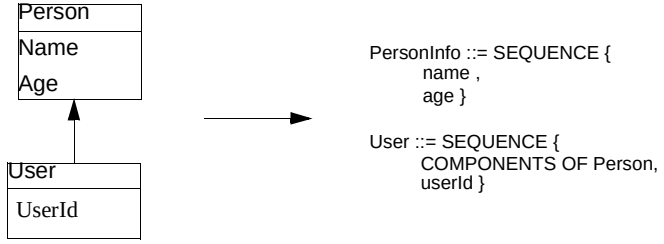

Figure 704: The use of COMPONENTS OF to represent inheritance

The SDL Suite only allows use of ASN.1 in separate ASN.1 modules, that have to be included into SDL with the IMPORTS construct.

Mapping Associations

Associations are in object models used to represent relationships between objects of different classes. The instances of associations are called *links*. An example is given in Figure 705. In this example the association is a relationship between Cards and Codes that describes that a card must have exactly one valid code. In the object model this is represented by an association called Valid between the classes Card and Code.

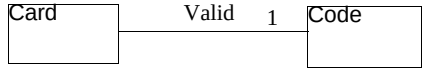

Figure 705: An example of an object model with associations

In the mapping to SDL, the information about the association is kept in one or both of the involved classes, in the example in Card, in Code, or in both.

There are several aspects of associations that are important to consider when mapping an association to SDL:

- Whether involved objects are active or passive
- The structure of the associations: graph vs. tree
- Intrusive vs. non-intrusive representation
- The traversal direction, one-way vs. two-way
- The multiplicity of the association
- Role names vs. association names

- Association attributes/association class

The rest of this section will discuss these issues and how they influence the mapping to SDL.

In general, associations form a graph structure among the objects where each object may have associations to a number of the other objects. Mapping associations to SDL implies in most cases that some kind of object references or pointers must be used.

In general, associations between active objects indicates that there is a possibility for the objects to communicate. In SDL this means that there must exist a communication path (signal routes and channels) between the corresponding SDL concepts (usually processes). In addition, an association between two active objects may also need to be represented by a PId variable in one (or both) of the processes.

There are however cases when PIds should not be used: as PId is a concept that only exists in the SDL world, associations with objects outside the SDL system cannot be represented with PIds. Instead, data types defined in protocols define how to refer to external objects. For example in the TCP/IP protocol, TCP services are addressed by a host address (for example 3.1.29.1) and a local port number. In an SDL implementation of a TCP service it would be impossible to refer to a service outside the SDL system by means of a PId; the host number and the port number must be used instead.

Since strict SDL does not include a pointer concept, associations with passive objects must be represented by other data types. Alternatively a C representation can be used when mapping the objects to SDL as discussed in "Mapping Objects to SDL Structs" on page 3922.

There is one special case where there is no need for special data types. This is the case when the associations form a pure tree structure and furthermore all associations are one-way one-to-one associations with a traversal direction from the root to the leaves. In this case a strategy based on mapping classes to SDL structs can be used, i.e. a reference to an object is in SDL represented by the object itself.

Sometimes an association is implicitly represented in the class definitions themselves, which is called an intrusive representation. In this case the association does not have a representation of its own in the SDL model. For example, if the classes are represented by SDL structs then the association can be represented by a field in one (or both) of the

structs. As an example the Valid association from Figure 705 is mapped in Figure 706 to a field in the struct that represents the Card.

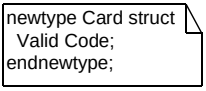

Figure 706: Mapping an association to a field in a struct

A non-intrusive representation of the association, on the other hand, does not rely on fields in structs that represent classes or any similar strategy. Instead the association is explicitly represented in SDL. A convenient way to accomplish this is to use the SDL array generator as exemplified in Figure 707.

Figure 707: A non-intrusive mapping of an association using an SDL array

The design choice to make when choosing a mapping to SDL depends on the way it will be traversed in the application: is the traversal of the association always in one direction or is it traversed in both directions. This is usually not relevant in the analysis model but influences the SDL representation. For example if the Valid association in Figure 705 is a one-way association only traversed from the Card to the Code then the SDL representation in Figure 706 is all that is needed. If, on the other hand, the association is also traversed from the Code to the Card then the Code representation will also have to contain an element corresponding to the association (note that this requires a C implementation due to the lack of pointers in SDL) or alternatively a non-intrusive representation can be used.

The multiplicity of the association defines how many instances of one class can be associated with an instance of the other class. A one-to many association requires a list or set representation. This is essentially the same as an aggregation with a multiplicity greater than one, which is described in "Mapping Aggregations" on page 3928.

Role names are an alternative that can be used instead of or in combination with association names. A role is one end of an association, and the role name uniquely identifies the object from the perspective of the ob-

ject at the other end. An example is given in Figure 708 where the association is identified using role names instead of an association name.

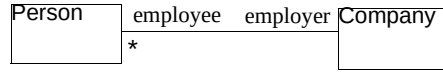

Figure 708: An association that uses role names instead of an association name

In many cases the role names are more convenient and less confusing than an association name. In a mapping to SDL it is preferred to use the role name as e.g. the name of a field in a struct rather than the association name. As an example consider Figure 709 where the Person object from Figure 708 is mapped to a struct in SDL and the role name is used as the field name.

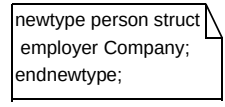

Figure 709: SDL mapping of a an association using the role name instead of the association name

An association may have an associated class as illustrated in Figure 710.

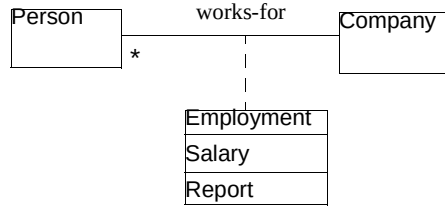

Figure 710: An example of an association class

The implication of this is that there are some attribute values and/or operations associated with each link of this association class that exists between the two objects. When mapping this construct to SDL there are two strategies: an intrusive representation and an explicit representation of the association class. If an intrusive strategy is used there is no explicit representation of the association so the attributes/operations must

instead be associated to one of the objects involved in the relation. This strategy is possible only if at least one of the end points involved has the multiplicity “1”. In the example in Figure 710 it would be possible to incorporate the association class into the Person object since there is only one company for each person in this model. A structured way to represent this in SDL is illustrated in Figure 711.

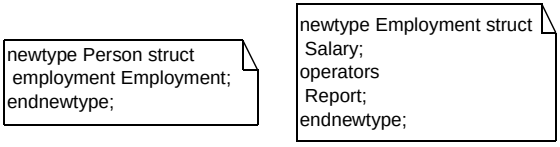

Figure 711: The association class from Figure 710 mapped into the Person object with an intrusive strategy

The second alternative is essentially to view the association class as a regular class and map it to SDL using any of the strategies that can be used to map regular classes to SDL. This is necessary for many-to-many associations.

The default mapping of associations between passive objects in SOMT is to use the intrusive strategy where classes are mapped to SDL structs and thus associations are mapped to fields in these structs. The name of the field in the struct is the corresponding role name if a role name exists, otherwise it is the association name. If there is no name specified for one of the roles and furthermore no name for the association, then no field is generated in the corresponding struct, and the association is considered to be a one-way association.

Summary of Mappings from Object Models to SDL

There are a number of possible SDL target concepts that an analysis object can be mapped to. The choice of target depends mainly on properties of the object:

- Active objects are mapped to processes or process types
- Aggregations of active objects are mapped to blocks or block types
- Passive objects are mapped to struct data types (or to signals if they are used for communication only)

- Associations between passive objects are mapped to fields in struct data types, or to new data types that explicitly represent the association
- Associations between active objects are mapped to communication paths (and possibly to variables within processes)

Describing Object Behavior

Once the type of SDL target concept has been chosen, the behavior of the object can be defined. Processes and process types are defined by creating the process graphs and ADTs are preferably defined by giving operator diagrams for the operators.

In practise, the major task of the object design activity is the definition of the behavior of SDL processes since they are the SDL representation of active objects that tend to have a more complex behavior than the passive objects. SDL process graphs provide a graphical notation for extended finite state machines, i.e. finite state machines with variables. In Figure 712 an example of a small process graph that illustrates some of the constructs possible in an SDL process is shown. More details about SDL and SDL process graphs are provided in section "SDL" on page 3825.

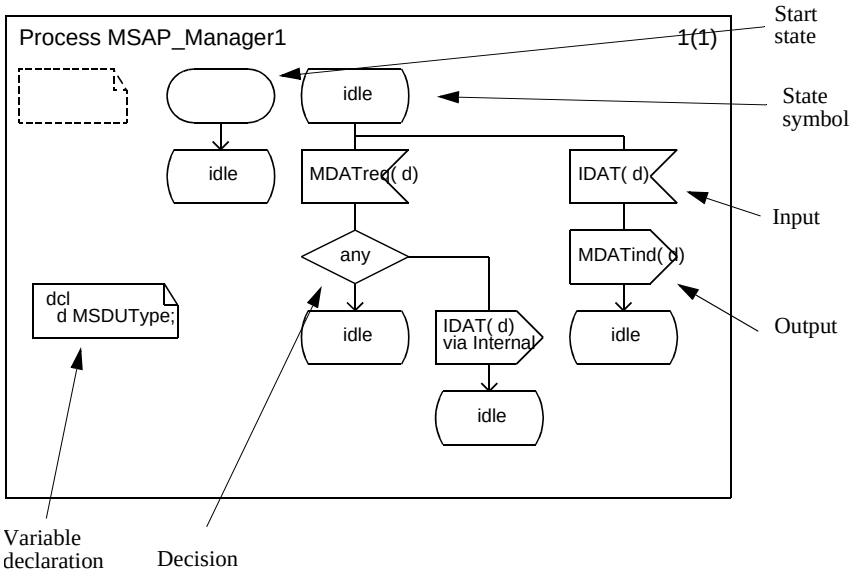

Figure 712: An SDL process graph

The possible inputs to the process design task are illustrated in Figure 713. The possible inputs directly from the system analysis/design are:

- MSC use cases from the design use case model or analysis use case model
- Possibly a state machine, described by a state chart, giving an overview of the behavior if this was defined in the system analysis

The inputs resulting from the mapping of object models to SDL are:

- The signal and/or remote procedure call interface of the process
- Some process variables defined by the attributes of the object model class

Based on these inputs the goal of the process design is to create a process diagram that defines the behavior of the process.

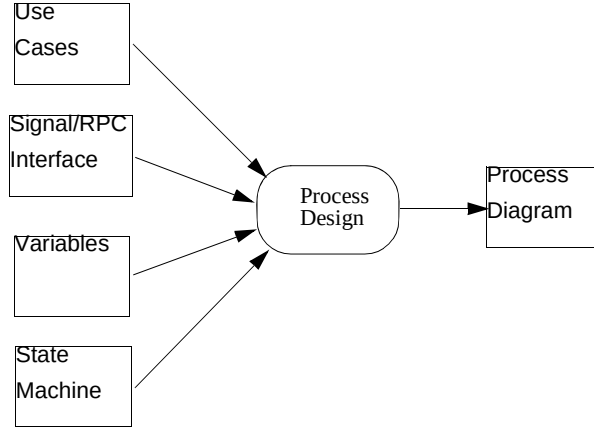

Figure 713: Inputs and output of the process design task

A useful way to structure the tasks that are needed to create a complete process are:

1. Create a first version of the process that defines the control structure in terms of states and transitions. There are two subtasks that in practise are performed more or less in parallel:
   - Defining the control structure
   - Defining data aspects.
2. Elaborate the process by e.g. considering secondary use cases and exceptional cases.

The First Version – Defining the Control Structure

The control structure of an SDL process is defined by the states and the transitions of the process. Ideally the states of a process represent what the environment might expect of the process. Different states represent different stable phases in the life-time of a process and depending on what state a process is in it will respond differently to requests and inputs from the environment.

One straight-forward way to find the states of a process is to analyze the use cases. Since the use cases show an external view of the processes

they reflect the expectations the environment can have on the behavior of the process. Both directly in terms of sequences of inputs and outputs the process has to conform to but also indirectly in terms of states since each input of a process must be preceded by a state.

So, the task of designing the control structure of the process starts with selecting a set of typical and essential use cases. If the use cases are in MSC format and on an appropriate abstraction level that includes the process to be defined, the use cases can be analyzed directly. If not they should be rewritten to clearly show the responsibilities of the process in question.

Analyze each use case in terms of states and transitions for the process. Incrementally build up the process graph by adding states and transitions. Start in the beginning of the use case and figure out what state the process must be in. Manually walk through the use case, checking the process defined so far and incrementally adding states and transitions to the process graph. Check for each transition in the use case (i.e. input followed by one or more outputs by the process in question) that the transition exists in the process graph. If it does not exist, add it. Take a look in the use case to see if there is an external need for a state change in the process: has the expectations on the process changed after this transition in the use case? If no: go back to the same state again. If yes: is there an already defined state that may fit these expectations? If there is one, use it. If there is no such state, create a new one and give it a name that describes the expectations. Continue until all use cases has been analyzed.

When adding transitions do not forget to check with the mapping from the object model if it is a regular transition with input and outputs or a remote procedure that is to be added. Also check if state lists (and “*” states) can be used as the starting state of the transition.

During the design of the process also consider what part of the control to put in the process graph states and what to put in variable values. In general it is recommended to define the control flow using the process graph states, but there are cases when it is better to put parts of the control in data values instead of as explicit process states. One example is loop variables that count the number of occurrences of something and is used to exit the loop after a certain number.

One problem that might occur during the use case analysis is that two of the use cases seem to be very difficult to combine in the same process

since they require different states of the process. This is an indication that some restructuring is needed and that maybe the process should be divided into different processes or into a set of services.

When finished with the analysis of the selected use cases the result should be a skeleton process graph that contains states and transitions with mainly inputs, outputs, remote procedures, timer actions and a few tasks and decisions that deal with control variables. Make sure that the state/transition structure makes sense. The states should represent external expectations on the behavior and their names should reflect it. This is an important issue, in particular for the possibilities to maintain the process.

The next step is now to consider the data aspects of the transitions.

The First Version – Data Aspects

Often there will be three kinds of variables in an SDL process: temporary variables used to handle the parameters of signals, control variables like loop counters as discussed above, and "real" variables that store information about some entity that will be accessed later during the execution. Most of the "real" variables should have been identified during the analysis are given by the mapping from the object model to SDL. The task now is to define how the "real" variables are affected by the transitions. Add temporary variables handling the parameters of the signals when needed and tasks with expressions that define the needed computations. If complex computations are needed it is good practise to hide them in procedures or operators. The transitions should preferably stay fairly simple.

The first version of the process is considered to be finished when it is possible to verify that the process fulfills the selected use cases, e.g. by running a simulator or verifying MSC use cases (compare with "Design Testing" on page 3950). Both the control and the data aspects should be dealt with.

Now it is time to start with the elaboration of the process.

Elaboration of the Process

The purpose of the first version of the process was to define the control structure of the process and make sure that this is able to cope with the requirements from the most typical and important use cases. The pur-

pose of the elaboration is to complete and refine this structure to make the process definition reliable and facilitate the maintenance. There are several aspects to cover in this elaboration:

- Secondary use case and exceptional cases in primary use cases
- Simplification e.g. using state lists and procedures
- Robustness and completeness of the process
- Restructuring for inheritance and reuse

The major topic for the elaboration task is to consider the secondary use case that was not treated in the first version and also the exceptional cases of the already treated use cases. This is done essentially the same way as when creating the first version as described in "The First Version – Defining the Control Structure" on page 3945. The use cases are walked through by hand and the process graph is checked and possibly extended to cope with the new cases.

To enable the understanding of the process and thus also to make it possible to maintain it, it is important that the definition is as simple as possible. This is a topic that is dealt with in the elaboration task. Procedures can be used to simplify process definitions considerably by defining a particular piece of code in one place and using it in several. Procedures can also be used on a higher level to indicate different phases in the lifetime of the process. Using state lists and "*" states it is also possible to simplify the definition of a process by defining transitions that are common to many states in one place.

The robustness and completeness of the process must also be handled in the elaboration. The strategy is essentially to make sure that the appropriate action is taken by the process, not only for the expected cases but also for unexpected cases. So, for each state in the process and each input signal/ remote procedure call possible; check that the action taken makes sense. Also check the treatment of unexpected parameter values.

Another topic to be treated in the elaboration is to consider how to facilitate reuse of the created process. Is it possible to create a more general process type by factoring out some parts of the definition and defining a more general process type that can be specialized in other situations?

The elaboration is in practise an iterative process where all the aspects above are treated more or less in parallel. When the elaboration is fin-

ished, the process definition is completed and is ready for integration test. The module test should preferably already have been done at this stage.

Operator Diagrams

When defining the behavior of passive data types defined in SDL the preferred way to define the operator is using operator diagrams. An operator diagram is essentially a flow graph with a start symbol, symbols defining the actions performed by the operation and one or more return symbols. The symbols may for example be tasks with assignments or decisions. An example is given in Figure 714 that shows the operator diagram for an operator *BirthDay* that increases the age of a person by 1.

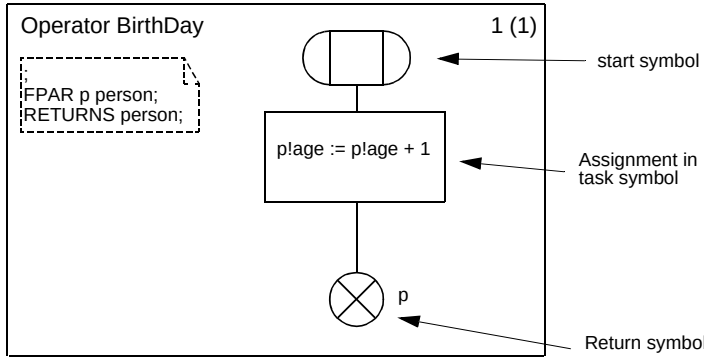

Figure 714: An operator diagram

Design Testing

One of the major benefits with a design notation like SDL that has a well-defined and complete semantics, is the possibility to test the application already in the design activity. This is feasible since the completeness of an SDL design makes it possible to simulate the design taking distribution and concurrence into account.

It is important to emphasis that the output of the object design activity is not only an SDL design but it is a *tested* SDL design that has been shown to fulfil its requirements. This implies that the design testing is an important task in the object design activity.

Testing Strategy

A traditional development/test strategy can be described by a “V” as in Figure 715. The design is performed top down, starting with a system design where the major components and their interfaces are defined, followed by a module design and an implementation phase where the application is implemented. The implementation of each module is then tested separately in a module test and finally the entire system is tested. The system test can also sometimes be divided into two parts, one focusing on the integration of the different modules and the other focusing on testing the functionality of the complete system.

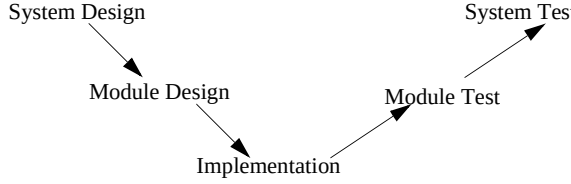

Figure 715: The “V” model of a traditional design/test strategy

This model works in practise fairly good but it has one problem: the complete functionality is not tested until the system tests are performed in the end of the development/testing process. To some extent this problem can be overcome by an iterative process that includes more than one “V” in a development project. Using techniques like SDL this can be even more improved by introducing one more line of testing in the model as in Figure 716.

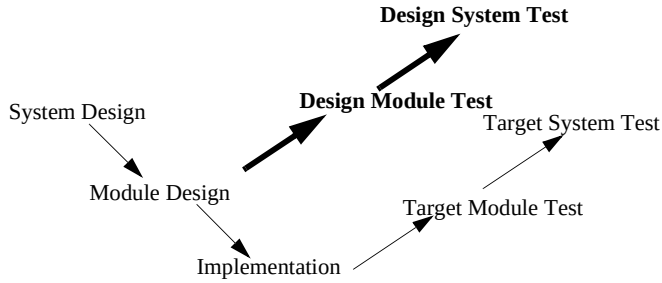

Figure 716: The improved “V” design/test strategy

The extra line of testing represents the design level testing that is the focus of this section. There are two practical aspects that differentiates the design testing from the traditional target testing:

- It is performed using a simulation of the design instead of on the real application in its target environment:
- It is performed as part of the design activity instead of as a separate testing activity performed after the implementation.

The second aspect is very important. Problems that otherwise would not show up until system test time is now found and solved during design at a much lower cost.

In the figure it may look like the testing effort has doubled in the improved “V” strategy since there are now two lines of testing instead of one. This is fortunately not the case. What has happened is that the effort of testing has switched from the target testing to the design testing, making the total amount of testing more or less the same. There are several reasons for this:

- The cost of testing is smaller for design testing than for target testing: the design testing on SDL level is very easy to perform. Since a large portion of the testing is performed at the SDL level this reduces the total testing cost.
- The target testing can focus on the integration and targeting aspects since the logic of the design has already been tested in the design tests. In practice the target module testing can even be skipped if automatic code generation is used when producing the implementation.

Test Case Sources

There are several sources from where the test cases may come:

- From Design Use Cases
- Internally developed during design
- From external sources.

The most important input, both to module and system test, is the design use case model from the system design. This model should capture most of the requirements on the system and using the implinks it is also possible to trace the dependencies from the original requirements all the way to the design use cases. Furthermore, the design use case should be in a format that is possible to test more or less automatically against the SDL system, like MSC or TTCN.

However, during the object design there are usually more test cases developed that tests other aspects of the design, and these form also an important part of the module testing tests.

The third source of tests is external sources. For example, in the telecommunication area it is common to have standardized tests suited for certain types of applications or interfaces. In other cases the customer may have specified acceptance tests that the system must comply to before it is approved. These type of tests should of course also be part of the design tests, in particular for system testing the external sources are important.

It is convenient, but not necessary, if the same notation is used for the design use cases, the tests developed during object design and the external test suites.

Tools for Testing

To perform the testing there is a need for tools, and fortunately there are several tools available that make a number of testing strategies possible:

- Manual or batch simulation of an SDL system using a standard SDL simulator
- MSC verification and automatic testing using a state space exploration tool
- Integrated-simulation of SDL and TTCN, using standard SDL and TTCN simulators

Using a standard SDL simulation tool it is of course possible to manually simulate the test cases and check that the system performs as expected, but it requires quite a lot of manual work. A better way is to produce test scripts that contain the simulator commands that are needed and then execute them automatically in a batch mode and log the results on a log file. To check the outcome of the test either the log files are manually inspected or checked by a post processing tool that e.g. compares the new log files with old, manually inspected log files.

Another approach to testing is to use a state space exploration tool that can automatically check if an MSC is consistent with the SDL system. The benefit with this method is that MSCs can be directly input to the tool and checked and furthermore there is no need for a manual inspection of the results: a verdict can be automatically generated by the tool. The drawback is that some features like the combination of user-written and automatically generated code can not always be handled by state space exploration tools.

A third approach that is useful if the tests are defined using TTCN is to use an integrated-simulation of an SDL system and a TTCN test suite as the means to perform design testing. Essentially this is similar to using an SDL simulator alone, but instead of specifying the input as simulator commands a TTCN simulator specifies the input to the SDL simulator and checks the outcome of the test.

Test Practices

A common situation in particular when performing module tests is that there is a need to test one part of an SDL system in isolation from the rest of the system. In an SDL system the part may be for example a block, a process or a data type definition. The simplest way to accomplish this in SDL is to use a package as a container of e.g. the block (which in this case will have be a block type) or data type and then use a special test system to specify the test environment.

As an example consider the DoorCtrl part of the access control system. Assume that this part is designed as a block type “DoorCtrlT” in a package DoorCtrlPack. To perform a module test on this block the simplest way is to create a special test system DoorCtrlTest that instantiates the DoorCtrlT and connects all its gates to the environment.

Consistency Checks

This sections describes some consistency checks that are useful to perform on the models produced in the object design.

- Check that all objects from the analysis object model has been implemented in the design.
- Check that the design model is complete according to the SDL rules, e.g. that all processes have a defined behavior.
- Check that the design model correctly implements the requirements from the design use cases using design level testing.

Summary

The object design activity should produce a complete and tested design of the system. The precise system and internal object structure as well as the reuse structure are defined in this activity. Relevant parts of the object models are mapped to SDL concept and then completed in an SDL process design activity with design use cases as the main input. This is done iteratively by starting with a initial set of essential use cases, making that part of the design complete and then testing the design (verifying it against the use cases). The activity is finished when all use cases have been implemented and the final design has been tested against all the use cases.

Chapter

76 *SOMT Implementation*

This chapter describes the different ways to implement an SDL design and the tasks that have to be done in connection with this. The focus is on automatic implementation relying on automatic code generation and using C as the target language.

Implementation

The implementation activity results in a tested and running application in the target environment.

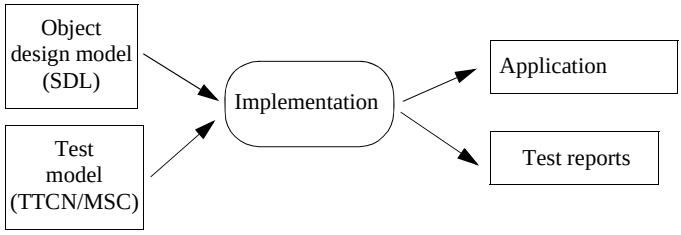

Figure 717: Overview of the implementation activity

The activities during implementation are highly dependent upon the application and target and there are several possible ways to implement an SDL design. It can be manually implemented in software or hardware or a more automatic implementation can be used relying on automatic code generation. The discussion in this section is mainly intended to give an overview of different aspects on the latter approach using C as the target language. There are several tasks to be done in the implementation activity:

- Partitioning the SDL system into different software (and/or hardware) run-time modules.
- Implementing the adaptation code that is needed for this specific SDL system to operate in its environment.
- Selecting and implementing a general integration strategy for the target hardware and run-time environment.
- The generation of C code and the customizing of it for different application areas.
- Testing to ensure that the application works in the target environment.

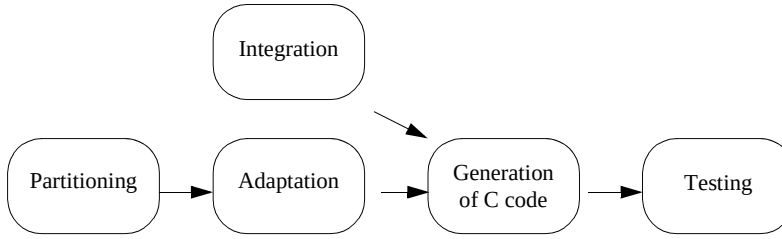

Figure 718: Example of activities during the implementation

Partitioning an SDL System

The purpose of the partitioning task is to partition the SDL system into separate parts that will form stand-alone executables by themselves, either to run as separate programs on one computer or distributed on several computers in a network.

There are two different possible strategies for how to do the partitioning in practise:

- Use directives to the C code generator to define what parts of the system that will form separate run-time executables.
- Create different SDL systems for the different partitions and generate code for them separately.

Adaptation

An application generated from an SDL description can be viewed as having three parts:

- The SDL system
- The physical environment of the system
- The environment functions, where the SDL system is connected with the environment

When adapting the application, the environment functions may have to be specified depending on the integration mechanism used. The environment functions are the place where the two worlds, the SDL system and the physical environment, meet. Signals sent from the SDL system

to the environment can be specified to perform any event in the physical environment, and events in the environment are specified to cause signals to be sent into the SDL system.

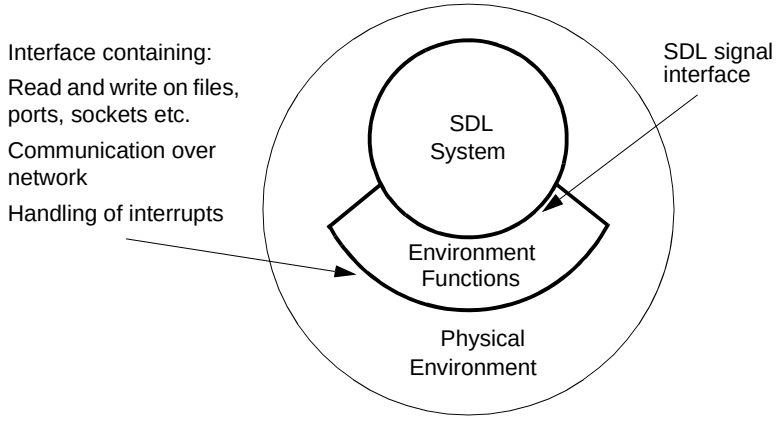

Figure 719: The structure of an application

In a distributed system an application might consist of several communicating SDL systems. Each SDL system will become one executable program. The environment functions that has to be written for each SDL system are:

- `xInitEnv` – handles the initialization of the environment and will be called during the start-up of the application (before the SDL system is initialized).
- `xCloseEnv` – is called when the SDL system terminates.
- `xOutEnv` – will be called each time a signal is sent out of the SDL system.
- `xInEnv` – This function is repeatedly called during the execution of the system. During this call, the environment could be scanned for events which should result in a signal sending into the SDL system.
- `xGlobalNodeNumber` – returns a number that is unique for each communicating SDL system that constitutes an application.

Integration

The purpose of the integration task is to select (and implement if no predefined integration exists) a generic integration mechanism that makes it possible to execute a generated application in a target hardware/software environment. There are three different strategies available for this integration:

- Making an integration using the SDL run-time system, where the SDL application directly runs on a micro processor without any additional operating system support.
- Making a light integration to an operating system, where an SDL system (together with a run-time system) is treated as one task in the operating system.
- Making a tight integration to a real-time operating system, where each SDL process instance (or set of instances of a specific type) results in a task in the operating system.

Both the integration using the SDL run-time system and the light integration use a supplied run-time system to execute the SDL system that takes care of the SDL semantics including scheduling of processes etc.

A tight OS integration consists of a set of files that define how the SDL semantics is mapped to the operating system in question. The main categories are:

- Macro definitions that define the macros in the generated code
- Functions that handle constructs that cannot be used directly in the operating system (i.e. saving of signals)
- Functions that are dependent on the specific operating system (i.e. allocate/free memory)
- Definitions and handling of SDL predefined data types
- Identifiers for signals, timers and remote procedure calls
- Post processing utilities to enumerate signal and process types

An existing integration for an operating system is highly reusable and several predefined integrations are available.

C Code Generation

Although the C code generation is a highly automated activity, there are several ways of customizing the generated code. Some examples are:

- Generating separate C files for different SDL structural entities
- Assigning priorities to processes to enable scheduling (which is undefined in SDL)
- Making a user-defined implementation for the handling of certain signals
- Making a user-defined main-loop (run-time system) in the generated application

Separation of the C files is recommended for large systems, since a minor, local change in for example a block diagram only requires a regeneration and recompilation of the code for that unit. The object files (the compiled versions of the C files) for the other unchanged units can then be used in the link operation to form a new executable program. Thus, the turn-around time from a change in the design to an executable application is minimized.

When doing a customization of the code, it is important that this is done in a way that keeps maintenance of the design easy.

Testing

The purpose of the testing task in the implementation activity is to verify that the application works in its target environment. The input is the test cases specified in the system design and the output is a test report and a tested application. The details of the testing task is very much depending on the target environment and the possibilities to run tests against the application in this environment. Essentially the tasks involved in the testing are:

- Creating a test environment that can communicate with the application and where the tests can be executed
- Transforming the test cases to a format that can be used in the test environment
- Run the tests
- Analyze the results of the tests

Summary

The final SOMT activity, the implementation, completes the development activities by creating an application that runs on the target environment. From the SDL object design, C code is created, the code is adapted to handle the environment of the SDL system and then integrated to the hardware by means of generic interfaces to real-time operating systems. Finally, the application is tested in its target environment.

Chapter 76 SOMT Implementation

Chapter

77 *SOMT Projects*

This chapter describes how to organize the activities and models of SOMT into a project. The description is intended to be suitable for a medium size project.

SOMT Projects

A development project that uses an object oriented approach like the SOMT method is not very different from any other development project. The project has a starting point, the project members work hard and finally the project is finished, hopefully successfully accomplishing the goals of the project in terms of quality, functionality and delivery time. The skill of planning, managing and executing a successful development effort has been studied and described in many books and it is outside of the scope of this document to give a complete treatment of this topic. A recent book that treats management and planning issues for object oriented projects is “Object Solutions” [33] which is recommended for further reading.

Nevertheless, this section is intended to give some indications on how to organize the activities and models of the SOMT method into a project. The description is intended to be suitable for a medium sized project where the effort is big enough to force the development to be divided into several development teams. A smaller project would most likely need less formalism in the development process and a bigger one more control.

Project Phases

From an external point of view (like a manager’s point of view) it is useful to organize a project into a number of *phases*, where each phase represents work performed during a limited period of time resulting in a set of artifacts, deliverables that summarizes the state of the work after the phase is finished. There is a fundamental difference between the phases of a project and the activities as used in this document to describe the SOMT method:

- The phases are used to organize the calendar time of a project.
- The activities represent a categorization of different kinds of tasks by their nature, not by their relative time in a project.

Nevertheless there is a strong relation between the phases of a project and the activities that has to be performed. There is a dependency between the activities of the SOMT method that indicates an ordering in time between the activities. There is no reason to start the system/object design before a substantial amount of work has been done on the system analysis. Likewise there is no reason to start the system analysis before

there is a common understanding of the requirements elaborated in the requirements analysis. On the other hand it would be a waste of time and even dangerous for the project to get bogged down with the details of the requirements for a substantial amount of time without considering their consequences in terms of architecture and design.

The dependency between the activities indicates that a fruitful way to organize a SOMT project is to consider it as a sequence of iterations of the activities. The phases are introduced as a means to get a visibility of important milestones and deliverables from the project. One way to define the phases of a SOMT project is as follows:

- Prestudy/conceptualization phase
- First iteration
  - Requirements analysis phase
  - System analysis phase
  - System design phase
  - Design/implementation phase
- Elaboration phase
  - Planned consecutive iterations

Each of these phases has a section of its own in this chapter.

Multi-User Support

There is often a need to facilitate multi-user support when working with an SDL system managed by SDL Suite. That is, we want to have a development environment capable of handling parallel development. One way to get support for the development process is through using Configuration Management (CM). With CM is usually meant the check in and check out control of sources and binaries, and the ability to perform builds of these entities.

If CM is to be used within a project it has to be planned for. This planning is not something that is carried out in isolation. It is a part of the overall project planning process and is implemented throughout the life cycle of the project. The plan should cover activities to be performed, the schedule for the activities, the assigned responsibilities and the resources needed (including staff, tools and computer facilities). A key

task is to decide exactly which items that are to be controlled and define the engineers responsible for these items. During the development process the code is usually stored in a database based on a revision control system. The developers checkout a copy of it to their own personal workspace. Changes are then made locally and checked in when completed and tested. The developer is responsible for making sure that the module works before he checks in the changed files.

When several users work on an SDL system, the management of the system file may be difficult to synchronize. This problem is solved if every user or group has control over their own part of the system file. The multi-user support in SDL Suite is based on letting the users split the system file into several files, called *control unit files*. Where to split the system is an active action taken by the user, but the idea is to partition the system according to work responsibilities and to assign a control unit to each partition. Apart from supporting parallel development, the control unit files also facilitate merging of the individual results to one common system file. An example is a large SDL system where there are several blocks on system level developed in parallel by different developers. Each block could then be associated with a control unit file. Now, the blocks can be updated independently and the changes are shaping the local control unit files. Also, there is no need to manually merge changes into the system file when the work has been done. This is because the management of control unit files, performed by the Organizer, includes the merge.

Another way to get support for parallel development is through using the object oriented concepts of SDL, i.e. types and packages. Instead of introducing a block reference symbol for every subsystem we introduce a block type. The block types are placed in packages together with the signal and data type definitions that are needed within that particular block. If two blocks need the same signals and data types then these definitions are placed in a package of their own. Other packages can then use this package. In the same way as we define block types we can also define process types instead of process reference symbols. The different packages containing the types can be analyzed independently. We can also create instances of the types to simulate, verify and validate the behavior of a particular part of the system. When all parts of the system have been designed and tested we put them together, i.e. we create instances of the types and test and verify the overall system behavior.

Prestudy/Conceptualization Phase

The prestudy/conceptualization is the initial activity needed to establish the core requirements that satisfy a well-defined user need and to identify the risks involved in the project by establishing a proof of concept for the project. It is not in the scope of the prestudy/conceptualization to completely analyze all aspects of the requirements, it should rather establish a vision of the underlying idea. It should also validate the assumptions on user needs and implementation technology. One way to do this can be to build an early prototype that illustrates the goals of the project. The prototype may also be an aid in the identification of risks, e.g. related to technical aspects or to the functionality of the system.

In many cases the prestudy/conceptualization can be viewed as a project by itself, following essentially the same steps and phases as any other project, with the exception that the time scale is shorter and that the result is not a finished system. The tangible results from the prestudy/conceptualization should be:

- A clear vision of the requirements (possibly illustrated by an early prototype)
- A risk assessment that identifies the major obstacles ahead

Requirements Analysis Phase

After the prestudy/conceptualization phase it is time for the first iteration through the activities in the SOMT method. This will go through the requirements analysis, system analysis and system/object design and sometimes also the implementation activity. This first iteration is in some sense the most important part of the project since it involves both an analysis of the requirements on the system and the development of an architecture that will meet these (and future) requirements. If this first iteration is successful the further elaboration and refinement of the system will work without any catastrophes. If the first iteration is not successful, e.g. an insufficient understanding of the requirements leading to an inappropriate system architecture, there are loads of problems ahead.

The requirements analysis phase starts the first iteration. The activities of this phase are of course centered around the analysis of the requirements as detailed in chapter 71, *Requirements Analysis*. When this phase is finished the analysis team must have established a common vo-

cabulary and a common understanding of the system's desired behavior. The deliverables are first versions of the models associated with the requirements analysis:

- The textual requirements
- The data dictionary
- The requirements object model, including both information models of the problem and context diagrams
- The use case model
- The system operations model

The most important of these are the use case model, the requirements object model, including the context diagrams, and the data dictionary. Together these describe the major behavior of the system and define a vocabulary describing the application and its environment. The textual requirements are hopefully part of the input to the requirements phase and it is often useful to elaborate these further mainly in the case where the original requirements are too unstructured or incomplete. The system operations are useful if the level of abstraction in the use cases are not found to be detailed enough.

In practise most of the time during the requirements analysis is usually spent designing the use cases, using these as a means to investigate the intended behavior of the system. It is impossible to completely cover the entire set of behaviors in the requirements analysis. Finding the right trade-off between the completeness of the use cases and the time and effort spent in requirements analysis is an important aspect of this phase. A recommended practise from [33] is that the use cases should cover 'approximately 80% of the primary scenarios along with a representative selection of the secondary ones'. The use case model (as well as the other models) will be further extended and refined during the elaboration phase so it is important to force the requirements analysis phase to a completion when a sufficient level of understanding has been reached.

System Analysis Phase

The system analysis phase takes over where the requirements analysis stopped. Where the requirements analysis focussed on *external requirements* the system analysis focuses on the *internal architecture* of the system. The analysis object model is the major medium used to describe the architecture. The architecture is defined in terms of the objects and object structures defined in this model. To establish the responsibilities of the different classes and verify that the proposed architecture is sufficient the use cases from the requirements analysis are in this phase refined in the analysis use case model.

It is not uncommon in practise that there is an overlap in time between the different phases and this is also true for the requirements analysis phase and the system analyses phase. It makes sense to start sketching the architecture of the system before the requirements analysis is brought to completion to capture ideas about the architecture whenever they emerge. It is however important to view this as a side activity and not forget to force the requirements analysis to a completion before digging into the details of the architecture.

The system analysis is finished when there is a consistent and well understood definition of the major objects needed in the system, including a clear definition of the responsibilities for the different objects, and the architecture is validated using the analysis use cases. It is beneficial if the system analysis can be performed by a small team consisting of the best people available including an experienced architect and some more developers.

System Design Phase

For many projects there is a need to divide the design work on more than one design team. In this situation the system design phase is a crucial phase since this is when the interfaces between the different parts of the system are defined. A good interface definition is essential to give the different development teams a possibility to progress with their work without confusion. In the system design the logical architecture from the system analysis is used to decompose the system into subsystems to be implemented by different teams and the interfaces between the subsystems are defined. The static interface is defined in terms of signals and/or remote procedure calls. The dynamic aspects of the interface are

defined in the design use cases that should be precise enough to be used as test cases by the design teams.

For practical reasons it is best if the same team that performed the system analysis phase also is involved in the system design phase, but extended with more designers and test engineers from the teams that will continue the design work to ensure that an understanding of the architecture is spread also into the different design teams.

The system design also includes planning the design module structure to be used in the design of the system to facilitate a smooth integration between the different subsystems. The design module structure is in essence a definition of the structure of the work to be performed by the different teams and it must be designed in order to facilitate reuse of common components and existing frameworks.

A third aspect to be considered in the system design phase, which is more of a project management nature, is to plan the following design and elaboration phases. The planning should be based on the achieved knowledge of the architecture and behavioral requirements and is intended to define the order in which the different features of the application is designed. The major criteria for defining this order is to minimize the risks involved in the project by validating the assumptions about the architecture as soon as possible and by designing the difficult and uncertain parts as early as possible. This implies that the design phase following the system analysis should concentrate on designing a first version of the application that covers an ‘interesting’ subset of the behavioral requirements (as defined in the use cases) and create a skeleton structure where all major components are in place but where their complete functionality is not yet realized.

When the system design is completed the tangible results are thus:

- A detailed architecture described using SDL block structures, including:
  - Static interface definitions with signals, remote procedures and the necessary data definitions, possible described using ASN.1
  - Design use cases describing the dynamic aspects of the interfaces
- A design module structure describing the structure that is to be used in the design phase

- A plan for the design process, that identifies key concepts to be designed and key use cases to use as a focus of the design phase and the elaboration phase

Design/Implementation Phase

The design/implementation phase, which as discussed above in general, is performed in parallel by several different development teams is in an SDL based SOMT project aimed at producing an executable SDL model of the application. Executable may here mean that it is possible to verify the design use cases against the SDL-model by executing the SDL model in e.g. a simulator or state space exploration based tool, but it may also imply an implementation activity that creates a first version of the application running in the target environment.

The choice of when to start the implementation activity is mainly risk-driven. If performance or memory requirements are crucial and seen as a risk in the project, e.g. if the hardware architecture is new and untested, then at least parts of the system should be implemented on the target to minimize these risks. If this is not the case, the integration with the target hardware can be planned to be part of some of the iterations in the elaboration phase.

Depending on the circumstances for the specific project the target platform can of course be very different, from the simplest case being that the target platform is the same type of computer as the development platform to the more complex situation where an embedded system is to be built and the target platform is a small micro processor. In the latter case, the implementation activity for an SDL-based project does in general consist of using a code generator to generate the code from the SDL system, write adaptation code to interface to the target hardware and the run-time environment to be used on this platform, and to use a cross compiler to produce code that is executable on the target machine.

In any case the deliverable from the design/implementation phase is an executable system that implements some of the requirements posed on the application and that is internally released as the first version of the application. The system should also have been through a testing process that verifies that the selected design use cases that where implemented indeed works as they should. This testing will of course consist of both a module testing performed on the different parts by themselves as well

as a system/integration test that verifies that the system as a whole works as it should.

The Elaboration Phase

The rest of the project, the elaboration phase, consists of a number of iterations through all the activities, from requirements analysis to implementation. Each iteration produces a new internal release of the application and refines and extends the architecture and system until it finally is finished. A typical iteration starts with a requirements analysis activity that includes a review and refinement of the use cases to be implemented in the current iteration. This is followed by system analysis and design activities that checks that the use cases are correctly distributed over the architecture and that the interface definitions are updated if needed. These activities should preferably be performed by an architecture group containing representatives both from the original architecture group who worked in the system analysis/design phase and from the different design teams.

The design and implementation activities that are part of an iteration are of course as before performed by the different design teams, each one refining and extending their part of the system to implement the use cases that are the goal of this particular iteration. The result of the design and implementation activity should be a new internal release of the application that has been through the appropriate module and system tests to verify its functionality.

In addition to extending the functionality of the system each iteration should also be focussed on minimizing the risks in the project. Crucial and difficult aspects should be tackled as early as possible in the elaboration phase to avoid unpleasant surprises at the end of the project.

Summary

A SOMT project can be described in terms of a number of phases, that describe the calendar time of the project. The phases are introduced as a means to get a visibility of important milestones and deliverables from the project. The various phases of a SOMT project are:

- Prestudy/conceptualization phase
- First iteration
  - Requirements analysis phase
  - System analysis phase
  - System design phase
  - Design/implementation phase
- Elaboration phase
  - Planned consecutive iterations

A graphical view of a possible SOMT project is illustrated in Figure 720.

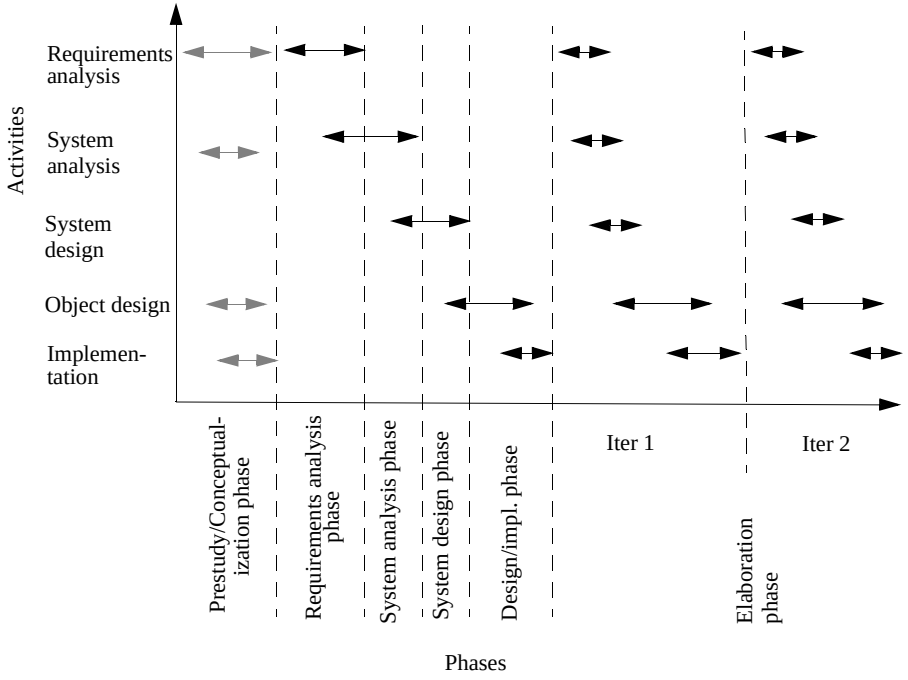

Figure 720: The different phases in a SOMT project

In this figure the various activities (as show on the vertical axis) are divided into a number of phases (as shown in the horizontal axis). The dashed lines indicate the deadlines for the different phases. Note that the activities associated with a specific phase may often start before the deadline of the previous phase is reached. This is common and useful. The purpose of the organization of the activities into phases is not to control when an activity starts, but to be able to focus on when an activity should be finished. This is what indicates the progress of the project.

Chapter

78 *SOMT Tutorial*

This tutorial is intended to present how to combine object-oriented analysis and SDL design in practise in a development process. This is a method developed by IBM Rational, known as the SOMT method, *SDL-oriented Object Modeling Technique*.

We will demonstrate, using an Access Control system as example, the various activities and models in SOMT together with the provided tool support for SOMT in SDL Suite.

Through the tutorial you will practise on various exercises that will get you familiar with the SDL Suite tools as well as the SOMT method.

Introduction

Purpose of This Tutorial

This tutorial presents how to use the SOMT method and the SDL Suite in practise in a design process.

The working example is an Access Control system. The system shall control the entrances to an office. Each employee working in the office has a card and a personal code. To enter the office, the employee enters a card into a card reader and types a personal code on a keypad. To exit the office the employee presses an exit button.

You will perform the development process for the Access Control system applying the SOMT method. The tutorial will guide you through the development process step by step presenting a number of hands on exercises for you to perform. The tutorial is expected to be read sequentially.

After reading the tutorial, you should have gained knowledge about how to apply the SOMT method on a development process.

Note: Platform differences

This tutorial, and the others that are possible to run on both the UNIX and Windows platform, are described in a way common to both platforms. In case there are differences between the platforms, this is indicated by texts like “on UNIX”, “Windows only”, etc. When such platform indicators are found, please pay attention only to the instructions for the platform you are running on.

Normally, screen shots will only be shown for one of the platforms, provided they contain the same information for both platforms. This means that **the layout and appearance of screen shots may differ** slightly from what you see when running SDL Suite on your platform. Only if a screen shot differ in an important aspect between the platforms, two separate screen shots will be shown.

Required Skills

It is assumed that you have a basic knowledge about UML and SDL. We also recommend newcomers to acquaint themselves with the basic features of the SDL Suite tools. You can do this by practising on the exercises in the tutorials provided for the different tools. Please see the previous chapters in this volume.

It is recommended that you have read the SOMT Methodology Guidelines starting in chapter 69 in the User's Manual.

Preparations

1. Make a new empty directory of your own for the purpose of this tutorial, e.g. `~/somttutorial` **(on UNIX)** or `C:\IBM\Rational\SDL_TTCN_Suite6.3\work\somttutorial` **(in Windows)**.

2. Copy the SOMT tutorial directory and its subdirectories in `$telelogic/sdt/examples/somttutorial` **(on UNIX)**, or `C:\IBM\Rational\SDL_TTCN_Suite6.3\sdt\examples\somttutorial` **(in Windows)**, into this new directory (contact if necessary your system manager).

> **Note: Installation directory**
>
> **On UNIX, the installation directory is pointed out by the environment variable** `$telelogic`. If this variable is not set in your UNIX environment, you should ask your system manager or the person responsible for the SDL Suite environment at your site for instructions on how to set this variable correctly.
>
> **In Windows, the installation directory is assumed to be** `C:\IBM\Rational\SDL_TTCN_Suite6.3` **throughout this tutorial.** If you cannot find this directory on your PC, you should ask your system manager or the person responsible for the SDL Suite environment at your site for the correct path to the installation directory.

3. **On UNIX**, `cd` to your own subdirectory `somttutorial`

4. Start SDL Suite.

5. Specify the source directory for the system by double clicking on the *Source directory* symbol located second uppermost in the Organizer window. The source directory specifies where new documents that you have created are saved by default, and from where to read when opening and converting documents. Since there are multiple versions of the Access Control system, each version with diagrams stored on files with identical names (but in different directories), omitting to specify the source directory may cause the wrong version of a file to be opened.

6. In the Set Directories dialog that is opened, select the third radio button associated with *Source directory*. In the text field, enter the complete path and name of your own `somttutorial` directory, if it is not there already. Press *OK* to close the dialog. (You do not have to change any of the other options in this dialog.)

Preparing the Documentation Structure

What You Will Learn

- To prepare a SOMT project by making preparations in the Organizer

Introduction to the Exercise

Your task is to modify the *basic view* of the Organizer to get the desired document structure.

The result of the exercise will be an Organizer structure containing a number of *chapters* and *modules*, see Figure 723 on page 3982. The chapters will correspond to the different activities in SOMT and the modules will correspond to the models in each activity.

Deleting Unwanted Chapters

When you start a new project in SDL Suite you will get the default *basic Organizer view*, see Figure 721. (This view could be different if you do not have the default preferences set). The Organizer contains a few black lines with attached names, the *chapters*. The purpose of these chapters is to group together collections of documents.

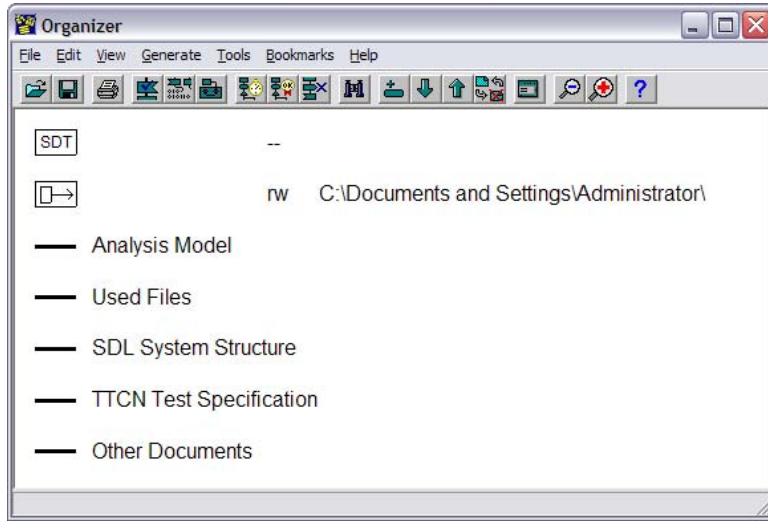

Figure 721: The basic Organizer view

We want each chapter in the Organizer view to represent an activity in SOMT. The current chapters in the Organizer will not fit into our future documentation structure so they should be removed.

Delete the unwanted chapters by following the steps below:

1. Make sure you have the basic view in the Organizer.
2. Select the chapter named `Analysis Model`.
3. Select the *Remove* command in the *Edit* menu or press the `<Delete>` button. You also find the *Remove* command in the pop up menu. The Remove dialog is issued asking you to *Remove* or to *Cancel* the action.
4. Press the *Remove* button. The dialog disappears and the chapter is deleted.
5. Repeat the steps above and remove all of the remaining chapters.

Adding New Chapters

You should now organize the Organizer view into chapters corresponding to the different activities in the SOMT method, i.e. each chapter should contain documents and diagrams from one particular activity.

You will have to add four chapters and they will be named `Requirements Documents`, `System Analysis Documents`, `System Design Documents` and `Object Design Documents`, respectively.

First, add the `Requirements Documents` chapter:

1. Select the *Add New* command in the *Edit* menu. The Add New dialog arises with the *Organizer* radio button set.
2. Select the *Chapter* option in the option menu connected to the Organizer radio button.
3. Change the document name `Untitled` to **`Requirements Documents`**.
4. Press the *OK* button or <Return>. A chapter named `Requirements Documents` will appear as the uppermost chapter object.
5. Now repeat the steps above and add the three remaining chapters and name them **`System Analysis Documents`**, **`System Design Documents`** and **`Object Design Documents`**, respectively.

If the chapters show up in another order than the one you want in the Organizer window, you may move a selected chapter by using the arrow quick buttons in the tool bar.

6. If needed, move the chapters in the Organizer to get a structure corresponding to the one in Figure 722.

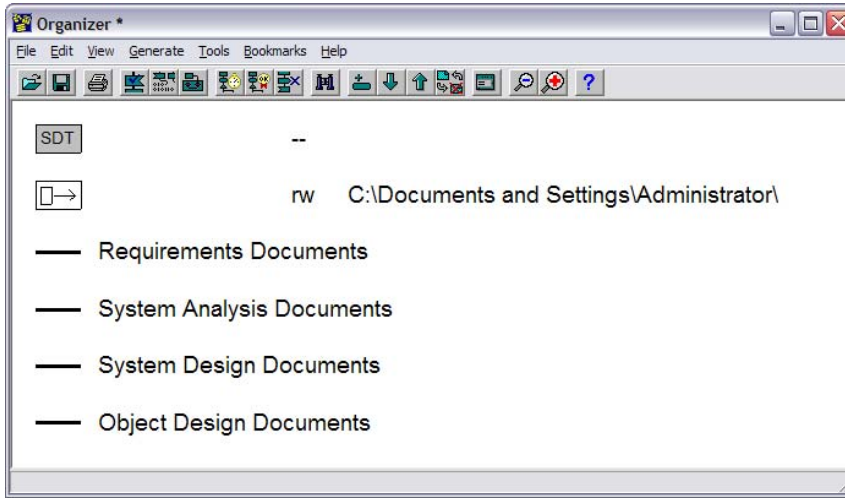

Figure 722: The Chapter structure

Adding the Organizer Modules

The next step to take when preparing the document structure is to add the Organizer *modules*. A module in the Organizer forms a naming scope around the documents it contains. It may contain any kind of documents.

As each activity in SOMT consists of a number of models, it seems natural to let a model correspond to a module in the corresponding chapter. You should now add the modules to the chapters in the Organizer structure.

1. Select the chapter named `Requirements Documents`.
2. Select the *Add New* command in the *Edit* menu.
3. In the Add New dialog, make sure that the Organizer radio button is set. Select the *Module* option in the Organizer option menu.
4. Change the name `Untitled` to **`RequirementsUseCaseModel`**

> **Note:**
>
> You are not allowed to have any space characters in the name of a module.

5. Press the *OK* button. A module named `RequirementsUseCaseModel` appears in the `Requirements Documents` chapter.

6. Now add the other modules to their respective chapter in the Organizer view. Let each model in a SOMT activity have its own module. The document structure in the Organizer should look like Figure 723 when you are finished.

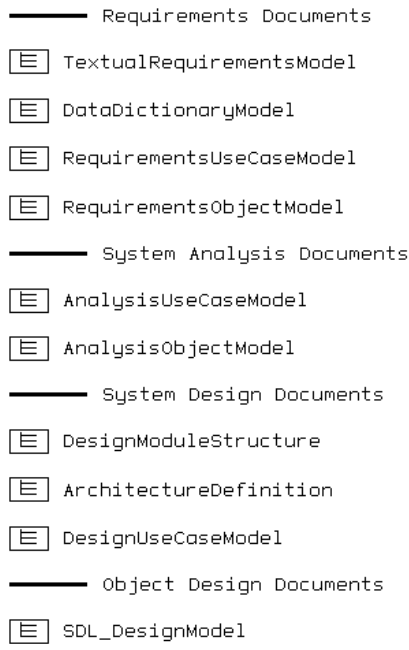

Figure 723: The complete document structure

This structure will form the framework to organize the forthcoming documents around.

7. *Save* the Organizer structure and name the file **`accesscontrol.sdt`**.

Now you have finished the preparations and you can start to develop the Access Control system using the SOMT method.

Identifying the Requirements

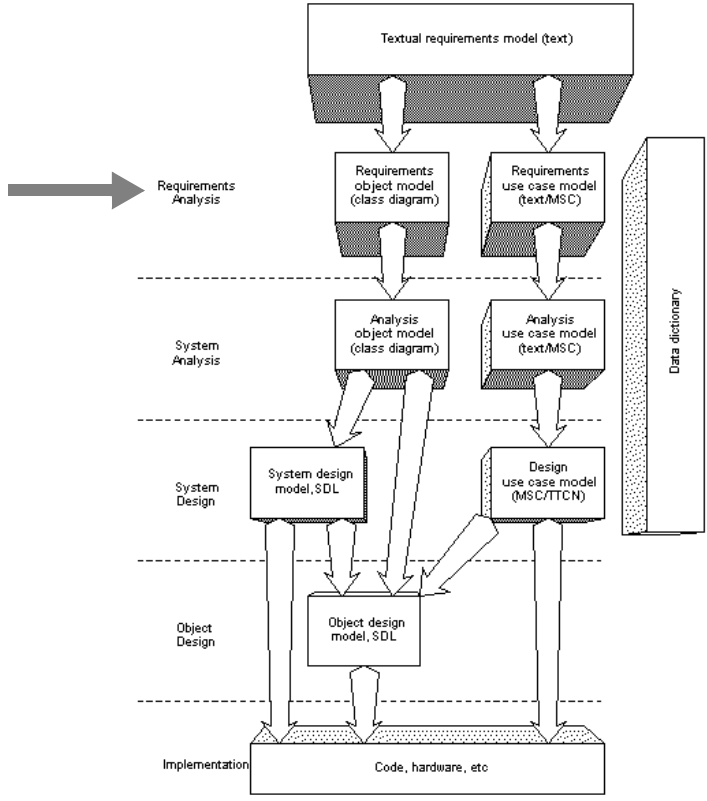

Figure 724: Overview of the SOMT process

What You Will Learn

- To bring in external (requirements) documents into the Organizer
- To identify important concepts
- To use a data dictionary
- To identify actors and use cases and to compile the information gained into textual documents

- To create a textual use case
- To create an MSC use case out of a textual use case
- To make a requirements object model
- To connect important concepts in the different documents with *implinks*
- To perform consistency checks

Introduction to the Exercise

In this exercise you will perform the tasks associated with the requirements analysis activity. The purpose of the requirements analysis is to:

- Gain understanding of the problem domain - the Access Control system and the environment in which it is going to exist.
- Find and understand all requirements imposed on the Access Control system.

Producing a complete requirements analysis would take too much time in this tutorial. Therefore, you will only perform parts of every required step of the process.

The result will not be a complete requirements structure, but you will have acquired knowledge of how to use the SOMT method in the process of identifying requirements.

Preparing the Exercise

You can use your own document structure from the previous exercise (just move your `accesscontrol.sdt` file to the `ReqA` directory), or use a provided solution.

1. Open the system file `somttutorial/ReqA/accesscontrol.sdt` **(on UNIX)**, or `somttutorial\reqa\accesscontrol.sdt` **(in Windows)**.
2. Check that the Source directory is set to `somttutorial/ReqA/` **(on UNIX)**, or `somttutorial\reqa\` **(in Windows)**, in the same way as you did in the preparation to this tutorial (see "Preparations" on page 3977).

Studying the Textual Requirements

Including External Textual Requirements

A textual document with requirements is the input to the Access Control system development project and it will form the base from which the Access Control system is developed. You will later on create implementation links (so called *implinks*) between the textual requirements document and other models. This is done to make it possible to follow a requirement through a number of models all the way down to code.

The textual requirements document of the Access Control system is contained in a text file. This file should now be included in the Organizer work area.

1. Select the module named `TextualRequirementsModel` in the `Requirements Documents` chapter.
2. Select the *Add Existing* command in the *Edit* menu.
3. In the Add Existing dialog, change the filter to **`*.txt`** and press the *Filter* button. Select the file `TextualRequirements.txt` and press *OK* to add it.
4. The `TextualRequirements` document is now added to the module `TextualRequirementsModel` in the Organizer and the *Text Editor* showing the document is opened. The document looks like Example 651.

Example 651: The textual requirements ––––––––––––––––––––––––

The task is to design the software to support a computerized Access Control system. The purpose of the system is to control the accesses to an office.

An entrance leading to an office can have four different security levels:

1. Always unlocked
2. Requires a card to unlock
3. Requires a card as well as a code to unlock
4. Always locked

The security levels of an office entrance can be altered during the day.

Each employee working in the office has a card with a personal code consisting of four digits. To open a door with security level three, the

employee enters her card into a card reader and types her personal code on a keypad. The time between consecutive keystrokes when typing the code is not allowed to exceed three seconds. To enter through a door with security level two, the employee just enters her card into a card reader.

Each entrance leading into the office consists of a door with an electric lock as well as a card reader, a keypad and a display on the outside, and an exit button on the inside. The employee needs a card and a code to *enter* the office. To exit, the employee just presses the exit button and the door is unlocked for ten seconds.

All entrances communicate directly with a central controller which makes sure that a validation of the correctness of cards and codes is performed. The controller has access to a database consisting of all card numbers and their corresponding personal codes. If the card is valid and, in case of security level three, the corresponding code correct, the door is unlocked for ten seconds and the employee may enter. In case of an invalid or unregistered card, access to the office is not allowed. In case of an incorrect code, the employee is informed of this and must try again by entering the card into the card reader and retyping the personal code.

The Access Control system must read its data, consisting of card numbers with their corresponding personal code, from a database. The database is managed by using a separate management system that is not developed within the project. The system operator, who is running the management system, is authorized to register new employees, cards and codes, to change a code if the employee wishes so, to delete employees from the database and to change the security level of an entrance. The system operator is also responsible for initializing the Access Control system. All the actions mentioned above are done using the management system.

The system must be able to recover from computer and connection failures. If a connection between an entrance and the central controller is lost, the door is locked from the outside not permitting anyone to enter (i.e. security level four is set). It is, however, possible to open the door from the inside by means of the exit button.

The system must be extensible to include new functions and be easily maintained.

Creating Textual Endpoints

Now you should study the textual requirements document and mark all concepts (nouns) that you find essential for the problem domain as *link endpoints*. These marks will be very useful in later stages of the project. In this tutorial most of the endpoints in the textual requirements document have already been created. You task is to add the two missing ones:

1. In the second sentence of the textual requirements document locate the word “office” and mark it with the mouse.

   When you mark an endpoint see to it that you only mark the word itself and not any additional characters, like a space or a dot after the word.

2. In the *Link* submenu in the *Tools* menu, choose *Create Endpoint*.

3. The text will be underlined indicating that the text fragment now is a link endpoint.

4. Now, locate the word “entrance” in the third sentence and create an endpoint out of it by repeating the procedure above.

5. If you go through the rest of the document you can see that the rest of the important concepts already have been marked as endpoints.

6. *Save* the document.

7. Open the *Link Manager*. This is done by choosing *Link Manager* in the *Link* submenu in the *Tools* menu. You can do this either in the Organizer window or in the Text Editor window; the result will be the same.

   The Link Manager window will pop up showing all the endpoints of the textual requirements document. The endpoint background color is used to show the endpoint status. As the endpoints are newly created, and the link file has not been saved yet, the background of the endpoints is painted gray.

8. *Save* the link file from the *File* menu, giving it the name `Links.sli`.

9. Close the Link Manager window.

Creating the Data Dictionary

A data dictionary is a textual document which should define all important concepts found during the whole development process. It forms a common vocabulary for the members of the project. It is a good idea to:

- Provide each item included in the data dictionary with a name and a brief explanation.
- Categorize the concepts in nouns, verb phrases and relation phrases.
- Sort the concepts alphabetically.
- Have a section in the data dictionary for each activity. This might be a good idea because a certain concept often has different meanings in different activities. For example, a concept can be described by a class in one activity and in the next activity it might be described by a block with a corresponding process.

All the important objects, relations and verbs that you find in the textual requirements should be included in the data dictionary. This has already been done in an existing `DataDictionary` file, so you do not have to do anything. Just add the existing file:

1. Add the existing `DataDictionary.txt` file to the `DataDictionaryModel` module in the Organizer. The Text Editor will show the `DataDictionary`.
2. Read through the document to get yourself acquainted with the problem domain vocabulary.

All nouns, relation phrases and verb phrases in the data dictionary are marked as link endpoints. This has been done to make it possible to do *entity matches* between any model and the data dictionary. An entity match checks that all entities in one model have matching entities in another model. That is, we can check that all entities in a model really are described in the data dictionary. This will be performed in "Entity Match" on page 4005.

The example below shows a part of the requirements analysis data dictionary.

Example 652: A data dictionary

Nouns/Objects

Access control system - A system to control the access rights to an office so that no unauthorized persons can enter without permission.

Card - Each employee working in the office gets a card and a corresponding personal code. By means of this card and code, the employee can get access to the office.

Cardnumber - The number that uniquely defines a card.

...

Relation Phrases

Card with code - Each employee in the office has a card with a personal code.

Connection between central controller and entrance - There is a connection between every entrance and the central controller.

...

Verb Phrases

Change code - An operation done by the system operator to change the code of a card.

Change Security Level - An operation done by the system operator to alter the security level of an entrance.

Connection is lost - The connection between an entrance and the central controller can sometimes fail. In case of broken connection nobody can enter the office. It is, however, possible to leave the office.

...

Creating the Use Case Model

The purpose of a *use case model* is to capture the requirements and present them from the users point of view, thus, making it easier for the intended users to validate the correctness of the requirements analysis.

The use case model consists of:

- A list of actors
- A list of use cases
- A number of MSCs (message sequence charts) and/or textual use cases

The use case model is also a useful source of information when developing the *requirements object model*, see "Creating the Requirements Object Model" on page 4001.

A use case is a sequence of actions showing a possible usage of a system. Use cases developed during the requirements analysis activity should mainly concern the interaction between the system and the users of the system. No message exchanges within the system should be shown.

Users of a system may be people, other systems or objects outside the system border which interact with the system.

An *actor* is a user taking part in a use case. An actor is not supposed to be an individual user, but rather represents one of the different roles a user can play when interacting with the system.

There are different ways to describe a use case:

- A textual description of the use case
- A description of the use case using an MSC
- A combination of both a textual description and an MSC

Describing use cases using textual descriptions will make it easier to model exceptions and alternative paths of action sequences. Describing use cases using MSCs will make the use cases more formal and easier to verify. Also, as MSCs will be used in the coming activities, it might be a good idea to start using them already in the requirements analysis. The tutorial will use both textual descriptions and MSCs in the requirements analysis activity, and only MSCs in the later activities.

Creating a List of Actors

Now it is time to create a list of actors. The list of actors should list the actors by name, together with their respective responsibility.

1. In the Organizer, select the `RequirementsUseCaseModel` module and choose *Add New*. In the Add New dialog, set the *Text* radio button and choose *Plain* in the corresponding option menu. Name the new document **`ActorsList`** and set the toggle button *Show in Editor*. This will give you a new text document in the Organizer window and an empty Text Editor window will pop up.
2. Try to find the actors of the Access Control system by studying the textual requirements in Example 651 on page 3985. For information on how to find actors, see "Finding Actors" on page 3991 below.
3. List the actors by name in the newly created textual document together with a brief description of the actor's role when interacting with the system.
4. Mark the actors in the `ActorsList` as endpoints in the same way as you did in "Creating Textual Endpoints" on page 3987.
5. *Save* the document giving it the name **`ActorsList.txt`**.

Finding Actors

You will find actors by studying the textual requirements. Useful questions to ask are:

- Which users will need services from the system to perform their tasks?
- Which users are needed by the system to perform its tasks?
- Are there any external systems that use or are being used by our system?

In practise, the activity of defining actors should be performed iteratively. Try to find as many of the actors as possible now. If you do not believe you found them all, start creating some MSC use cases (as having done some MSCs often makes it easier to determine the actors). Then go back and complete the list of actors.

In our case with the Access Control system we find that an employee, who daily interacts with the system, is an obvious candidate for the list

of actors. Also, considering the third question above, it is obvious that the management system is being used by our system and therefore should be added to the list. The third actor, the door, may not be so easy to find at a first glance, but when you have created the MSCs it will become more evident that the door is an actor as well. The door's interaction with the system consists of notifying the system every time it is opened or closed.

The example below shows a part of the list of actors.

Example 653: Part of a list of Actors

Employee - Someone who needs to enter and exit the office. To enter the office, an employee must have a registered card and (depending on the current security level) a corresponding personal code. To exit, the employee must press an exit button to unlock the door.

ManagementSystem - The management system starts and maintains the Access Control system. All changes to the database are handled by the management system. The management system is run by a system operator.

...

Creating a List of Use Cases

When you have defined the set of actors it is time to describe the way they interact with the system, which is done in use cases. The first step is to create a list of all use cases. The list of use cases should list the use cases by name together with a short description.

1. *Add* a *new* plain text document in the `RequirementsUseCaseModel` module. Name it **`UseCaseList`** and set the toggle button *Show in Editor*. Press *OK*.

2. Try to find the normal use cases and list them in the newly created textual document. For information on how to find use cases, see "Finding Use Cases" on page 3993.

3. To each use case, add a general one-sentence description of its functionality.

4. For each normal use case, examine which exceptions that can occur and state these exceptions as well in the list.
5. Mark the use case names in the `UseCaseList` as endpoints.
6. Save the document giving it the name **`UseCaseList.txt`**.

Finding Use Cases

It is often quite easy to identify use cases by looking at the purpose of the system. To verify that you have identified most of the important use cases you should:

- look at the list of actors, and, for each actor,
- identify the tasks that the actor should be able to perform and the tasks which the system needs the actor to perform. Each such task is a candidate for a new use case. It is often very useful to check the textual requirements document for verb phrases (or you could look directly in the DataDictionary to see which verb phrases that have been stated as important); these are possible candidates for use cases.

Start with the employee actor and try to determine which actions he or she needs to perform. There are different ways to enter an office, either using a card or using both a card and a code. Both ways are obvious candidates for the use case list. Also, the employee must be able to exit the office, this will be yet another use case.

The Management system must inform the Access Control system when there has been a change in security level. This will be our fourth use case.

As for the door actor, the task of notifying the system when a door is opened and closed can be included in the enter/exit office use cases. You should always try to make the use cases as complete as possible, that is, make **one** complete use case instead of several minor ones.

When you have found the normal use cases, refine them by examining the exceptions that are possible for each use case. Look in the textual requirements document and try to find the exceptions that can occur.

In the case where an employee enters the office, the first thing that can go wrong is that there is a connection failure between the entrance and the central controller. Other possible things that can fail are that the card

is invalid, the code is wrong, the time between consequent keystrokes when typing the code is too long, and, finally, the door is never opened even though it was unlocked. All these exceptional cases can be found by studying the textual requirements thoroughly.

The example below shows a part of the use case list.

Example 654: Part of a Use Case List ––––––––––––––––––––––––––

Normal Cases:

Enter_Office_With_Card - Describes the interaction between an employee and the Access Control system when the employee wants to enter the office through a door with security level two.

Enter_Office_With_Card_And_Code - Describes the interaction between an employee and the Access Control system when the employee wants to enter the office through a door with security level three.

Exit_Office - Describes the interaction between an employee and the Access Control system when the employee wants to exit the office.

...

Exceptional Cases:

Exc_No_Connection

Exc_Invalid_Card

...

––

Creating a Textual Use Case

Now that we have a list of the actors to the system as well as a list of use cases, we can start to create a more detailed description of the use cases. A textual use case consists essentially of natural text structured into a number of text fields, see "Describing a Textual Use Case" on page 3995. In this exercise we will only create one textual use case, as creating them all takes too much time. The use case we will focus on

throughout the rest of the tutorial is the one where an employee enters an office with both a card and a code.

1. Add a new textual document in the `RequirementsUseCaseModel` module and name it **`Enter_Office_With_Card_And_Code`**.
2. Try to create the textual use case consisting of the fields described in "Describing a Textual Use Case" on page 3995.
3. Create endpoints of the textual use case name (for consistency use exactly the same name as you used in the list of use cases) and of the actors involved in the use case.
4. Save the document giving it the name **`Enter_Office_With_Card_And_Code.txt`**.

Describing a Textual Use Case

A textual use case should consists of the following fields:

- **Name**: The name of the use case.
- **Actors**: A list of the actors involved in the use case.
- **Preconditions**: A list of properties that must be true for this use case to take place.
- **Postconditions**: A list of properties that are true when the use case is finished.
- **Description**: A textual description of the normal sequence of events that describe the interaction between the actors and the system.
- **Exceptions**: A list of exceptional interactions that complement the normal flow of events described in the `Description` field. If an exception leads to different postcondition properties compared to the normal sequence this should be noted.

The description field should thus describe what happens when everything is going as expected. No exceptions should be considered here. They are not described until the exceptions field.

The example below shows a textual description of the use case "Enter office with card and code."

Example 655: A Textual Use Case

Use case name: Enter_Office_With_Card_And_Code

Actor: Employee, door

Preconditions: System is initialized, security level three is set, and the door is closed and locked. The display displays “Enter card”.

Postconditions: The door is closed and locked again.

Description: An employee enters a card into the card reader. The display displays “Enter code”. The employee enters a code consisting of four digits using the keypad. The door is unlocked and “Please enter” is displayed. The employee opens the door, enters the office and closes the door again. The door is locked and “Enter card” is displayed.

Exceptions:

- If the employee enters an invalid or unregistered card, “Invalid card” is displayed for three seconds and then “Enter card” is displayed.

- If the time between consequent keystrokes when typing the code exceeds three seconds, everything is interrupted and “Enter card” is displayed.

- If the employee types the wrong code, “Wrong code” is displayed for three seconds and then “Enter card” is displayed.

- If the employee does not open the door within ten seconds after it has been unlocked the door is locked again and “Enter card” is displayed.

- If there is no connection between the entrance and the central controller and a card is entered, then the text “Connection failure” is displayed for three seconds and then “Enter card” is displayed again.

Creating an MSC Use Case

The second notation for use cases used in SOMT is MSCs. Creating MSCs for all the use cases and their exceptions takes too much time in this tutorial. Therefore you will concentrate on the use case corresponding to the textual description you just created,

`Enter_Office_With_Card_And_Code`, and one of its exceptions, when an employee enters an invalid card.

1. Select the module `RequirementsUseCaseModel` and choose *Add New*. In the Add New dialog, set the *MSC* radio button. Name the document **`Enter_Office_With_Card_And_Code`** and set the *Show in Editor* toggle button.

2. In the MSC Editor, try to create the MSC. Look at the textual description of the use case and describe it by means of the notations defined for MSCs. Also, make references to exceptions at the points where these can occur. Figure 725 shows an example of the complete MSC.

   – Each actor should be represented by a separate instance. The Access Control system itself should also be represented by a separate instance.

   – Actions, displayed messages, etc. should be drawn as MSC messages between the instances.

   – An exception is drawn by adding an *MSC reference* symbol, located last in the MSC Editor's symbol menu. An MSC reference symbol is a reference to another MSC, described in a separate MSC diagram. The symbol is added to one of the instance axes. By convention, MSC exceptions are named "exc" followed by the name of the exception. To connect the symbol to all three axes, select *Connect* from the *Edit* menu. Press the *Global* button to connect the reference symbol to all axes.

3. Save the MSC diagram giving it the name **`Enter_Office_With_Card_And_Code.msc`**.

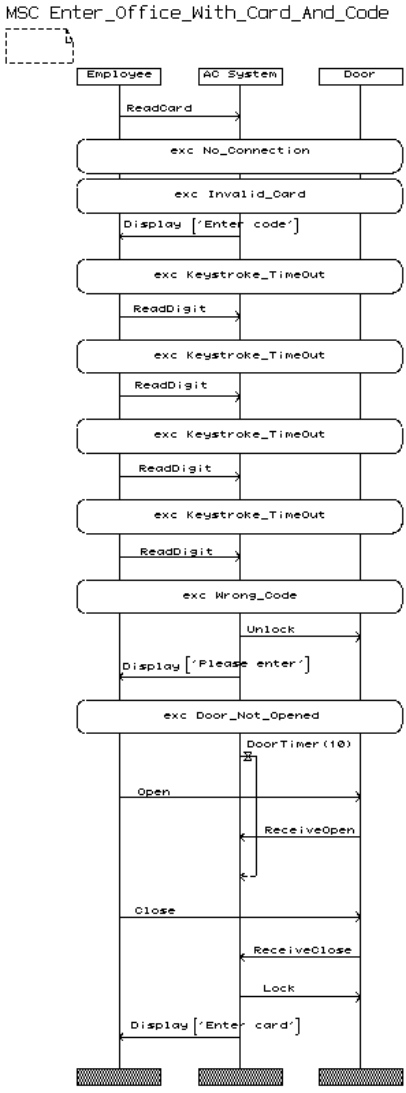

Figure 725: An MSC example

4. Create a new module in the `Requirements Documents` chapter in the Organizer. Name the module **`MSC_Exceptions_ReqA`**.
5. Add a new MSC document to the newly created module in the Organizer and name the document **`Exc_Invalid_Card`**.
6. In the MSC Editor, try to create the exception, i.e. describe what happens when an employee has entered an invalid card.
7. Save the diagram giving it the name **`Exc_Invalid_Card.msc`**.

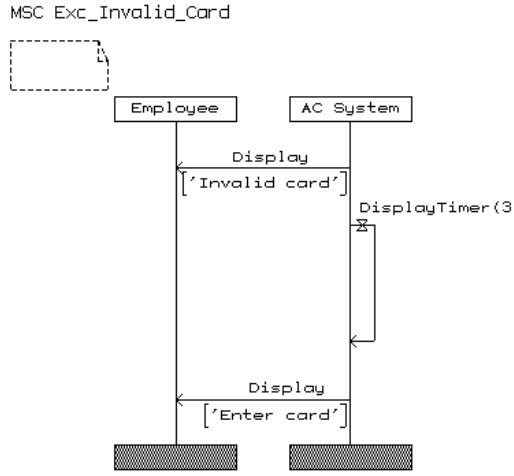

Figure 726: An MSC exception example

8. In the Organizer view, select the MSC `Exc_Invalid_Card` and then choose *Associate* in the *Edit* menu. The Associate dialog appears.
9. Choose to associate the `Exc_Invalid_Card` MSC with the `Enter_Office_With_Card_And_Code` MSC as it is an exception to this use case.

The `Requirements Documents` chapter should now look like in Figure 727.

In reality you repeat the steps above for all the use cases found and associate each one of them with its exceptions. In this tutorial, however,

we will not create the entire use case model as that would take too much time.

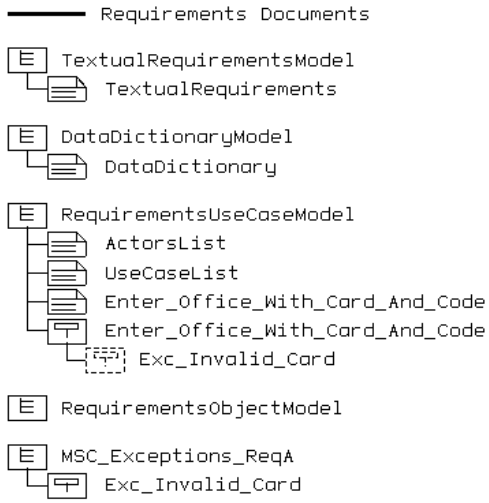

Figure 727: The Requirements Documents chapter

Now, when we have our use cases and a data dictionary we will continue the activity with producing a requirements object model. In practise, you should work with all the models in parallel. The activities in SOMT are **not** supposed to be performed in a sequential order, rather, producing the models is a highly iterative process.

Creating the Requirements Object Model

The requirements object model is intended to capture the objects, the relations between these objects and other concepts of the real world that are of importance for the application we intend to build. There are different types of concepts that can be described in this model. The two major diagram types show the logical structure of the data and information and the context of the system.

Relations between objects in the model will be expressed through associations, aggregations and inheritance.

Creating a Requirements Object Model

Now you should create the requirements object model.

1. In the Organizer, select the `RequirementsObjectModel` module and choose *Add New*. In the Add New dialog, set the *UML* radio button and make sure the *Object Model* option in the UML option menu is set. Name the new document **`LogicalStructure`** and set the toggle button *Show in Editor*. This will pop up an empty OM Editor window.
2. Try to find the objects, see "Identifying the Objects" on page 4003.
3. Enter the classes found into the object model diagram in the OM Editor and give them a suitable name. As you can see, every class is automatically marked as an endpoint.
4. Relate the classes by means of associations, aggregations and inheritance, see "Identifying the Relations" on page 4004.
5. Consider if multiplicity is needed on any of the associations and if so, add it. (Double-click a line to bring up the Line Details dialog.)
6. To increase the readability of the model, name the associations or attach role names to the classes. The diagram should look something like in Figure 728 when you are finished.

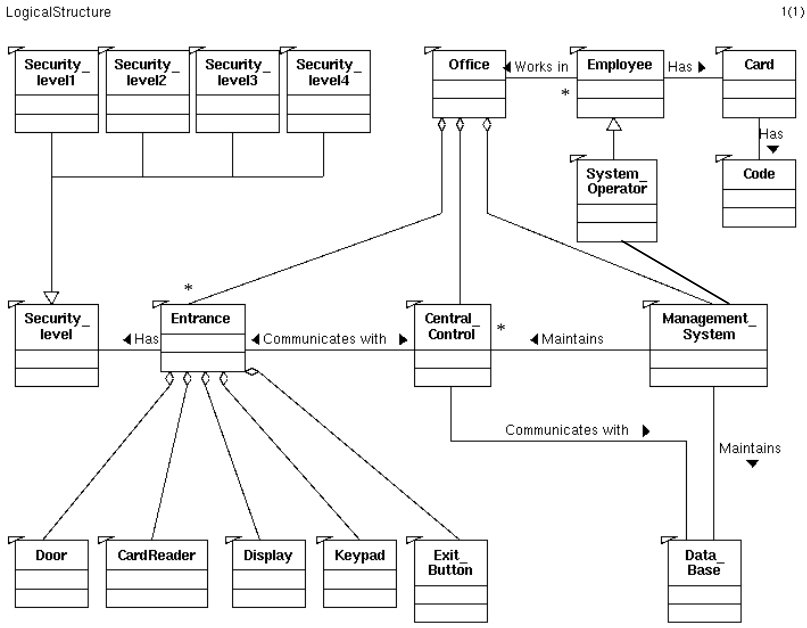

Figure 728: The logical structure

7. Save the diagram giving it the name **`logicalstructure.som`**.

8. Add yet another object model to the `RequirementsObjectModel` module in the Organizer. Name it **`ContextDiagram`**.

9. In the diagram, show the system and the external actors interacting with it. Use collapsed class symbols (select *Collapse* from the *Edit* menu). The classes are automatically marked as endpoints.

10. *Clear* the endpoint on the `Access_Control_System` class as we will not need this. (Select *Clear Endpoint* from the *Link* submenu in the *Tools* menu.)

11. *Save* the diagram giving it the name **`contextdiagram.som`**.

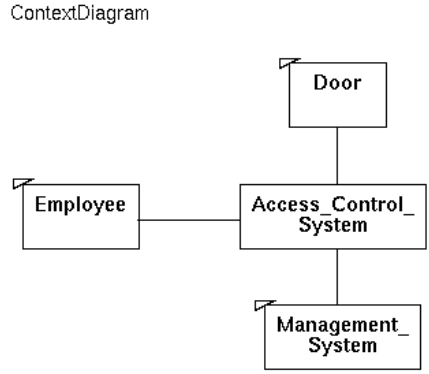

Figure 729: The Context diagram

Identifying the Objects

The main input sources to the requirements object model are the textual requirements, the use case model and the data dictionary. Other sources of information are domain experts, textbooks etc.

A classical way to find the objects is to study the textual requirements and note all nouns (or look directly in the nouns section in the data dictionary). If a particular noun appears in many places, the concept is probably important for the problem domain and should be modeled in the requirements object model.

The use cases are also helpful for finding the objects. They define the actors that interact with the system and these are obvious object candidates. Other likely object candidates are the entities that are transported in to or out of the system. The use cases are helpful in identifying these concepts as well.

The requirements object model should at least describe all concepts that are visible on the outside of the system. This includes all physical entities that a user can see as well as the knowledge a user must have to use the system. It is, however, not only concepts **outside** the system that should be modeled in the requirements object model. Concepts **inside** the system that are so obvious that we know of them already at this stage should be dealt with as well. In our Access Control system, for instance, it is quite easy to see that the system itself is built up of a central control and a number of entrances, each having its own local control. Therefore,

in the requirements object model, we do not model the heart of the system as one class, but as two communicating classes.

Identifying the Relations

The information sources when identifying relations between objects are the same as when identifying the objects. Look for relation phrases in the textual requirements (or use the data dictionary as an information source). You may also take a look at each object and ask the questions:

1. What services does the object provide?
2. Does the object need services from other objects to complete its services?

If the object needs services from other objects, identify these objects and model the relations in the object model.

There are three different types of relations, described below.

The Association Relation

The association relation describes how different classes relate to each other by means of information exchange.

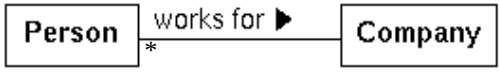

Figure 730: An Association relation

The Aggregation Relation

The aggregation relation is a special case of the association relation and it describes a “consists of” relation. For example: a document **consists of** paragraphs.

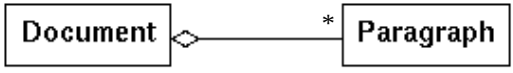

Figure 731: An Aggregation relation

The Inheritance Relation

The inheritance relation describes an “is a” relation. For example: a car **is a** vehicle.

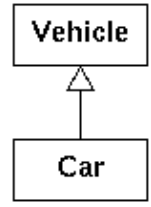

Figure 732: An Inheritance relation

Entity Match

Now it is time to do some consistency checks between the created models. When you do an entity match you check that all entities in one model have matching entities in another model.

1. *Open* the Link Manager. The window popping up shows all endpoints from the models you have created during the requirements analysis activity.

2. To be able to perform an entity match you must be in entity mode (i.e. **not** in endpoint mode). Press the *Show endpoints or entities* button in the Tool bar to change to entity mode. (The view in the Link Manager window will look just the same, since one entity corresponds to exactly one endpoint in all our models.)

The first thing we will check is that all important concepts in the textual requirements model are described in the data dictionary.

3. Choose *Consistency Check* in the *Tools* menu. The Consistency Check dialog appears and you are asked to choose between a link check and an entity match. Set the *entity match* radio button and press *Continue*.

4. A new dialog appears and you are asked to select the documents representing the **from** group. Select the `TextualRequirementsModel` module and press *Continue*. (As you can see, the text document in the module is also selected when you select the module.)

5. Yet another dialog appears asking you to select the documents representing the **to** group. Select the `DataDictionaryModel` module and press *Check*.

6. The Link Manager window will show the result of the entity match in a new *consistency view*. Entities from the **from** group are shown as normal endpoints and entities from the **to** group are shown as dashed endpoints. The links shown are temporary links created by the Link Manager to indicate matching entities, see Figure 733.

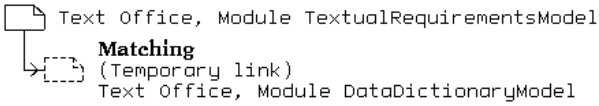

Figure 733: Matching entities

7. As you can see, if you scroll through the Link Manager window, all the concepts from the textual requirements have a matching entity in the data dictionary. (An endpoint from the **to** group without a matching link from it would have indicated that no corresponding entity could be found in the **to** group.)

There are a few more consistency checks which you can perform at this point:

- Check that all entities in the requirements object model are described in the data dictionary.
  - Let the `RequirementsObjectModel` module form the **from** group and the `DataDictionary` module the **to** group.
  - As you can see from the result all concepts but the four different security levels have been described in the data dictionary.
- Check that all important concepts in the textual use cases are described in the data dictionary and in the use case list. Important concepts in a textual use case are the actors and the use case name. The actors should be described in the data dictionary and in the actors list. The use case name should be described in the use case list.
  - In this case the **from** group will be the textual use case, `Enter_Office_With_Card_And_Code`, and the **to** group will be the `DataDictionary`, the `ActorsList` and the

`UseCaseList`. (You can select any number of individual documents in the list, not only modules.)

– The result shows that the use case name was found in the `UseCaseList` and that the actors were described both in the data dictionary and in the list of actors.

- Check that all actors in the use cases are modeled in the context diagram and vice versa.

  – First, the `Actorslist` will form the **from** group and the `Context Diagram` will form the **to** group, then we will do another entity match with the groups vice versa.

Creating Implinks

Now that we know that all our models are consistent, it is time to add the *implinks*. Implinks are used to enable traceability between the models.

We will start with creating implinks from the concepts in the textual requirements to the requirements object model, in particular the logical structure diagram.

1. Open the Link Manager by selecting it in the submenu *Link* in the *Tools* menu if it is not already open.
2. Make sure the window shows endpoint view, not entity view or consistency view. If necessary, press the *Show endpoint or entities* quick button.

   In the Link Manager window you see all the endpoints from the different models in the requirements analysis activity. If you scroll to the very end of the window you can see how many endpoints and links you have in your system. There should be no links at this point.
3. To check that all endpoints are present in the Link Manager window, choose *Check Endpoints* in the *Tools* menu.
4. The Check Endpoints window will pop up showing if any previously unknown endpoints were found. If so, select these and press *Add*. Then press *Continue*.
5. Another version of the Check Endpoints window pops up showing if any invalid endpoints were found. In such case you can choose to

delete these by pressing *Delete*. Press *OK* when you are done and want to close the dialog.

6. To be able to create the implinks between the textual requirements and the classes in the logical structure you only need to see the endpoints from these diagrams in the Link Manager window. You do not have to see all the other endpoints. Therefore, choose *Filter* in the *View* menu.

   The Filter dialog pops up and you can choose to set filter settings for links, endpoint or documents, by selecting from the option menus.

7. Choose to set the filter for *documents* and select that the only documents to be *shown* should be the textual requirements and the logical structure documents.

8. Press *Apply* and then *Done*.

9. In the Link Manager window, highlight the endpoint `Text Office` by first selecting the endpoint and then clicking the *Highlight quick* button in the tool bar. The endpoint is highlighted with a frame around it.

10. Create an implink to the `Class Office` by first selecting the class and then pressing the *Create Link* quick button in the tool bar. The Create Link dialog will open.

11. Name the link **`Implementation Link`** and press the *Create* button. A link from the text “office” to the class Office is created.

The rest of the links between the textual requirements and the object model diagram are created in a similar way. You can do this if you want, or go to the next exercise, where this has been done, and check out the result.

Links from the `UseCaseList` to the different MSCs and their exceptions should also be created. You cannot do this here however, as you have not created all the use cases.

What we aim at here is to create links from the textual requirements, through the object models of the different activities, to the SDL design. Simultaneously we want to create links from the list of use cases, through the use case models in the different activities, to the SDL design. The result of this will be that we can trace a design decision backwards to requirements through either object models or use case models.

Summary

After having completed an entire requirements analysis, the `Requirements Document` chapter the Organizer view should look like in Figure 734.

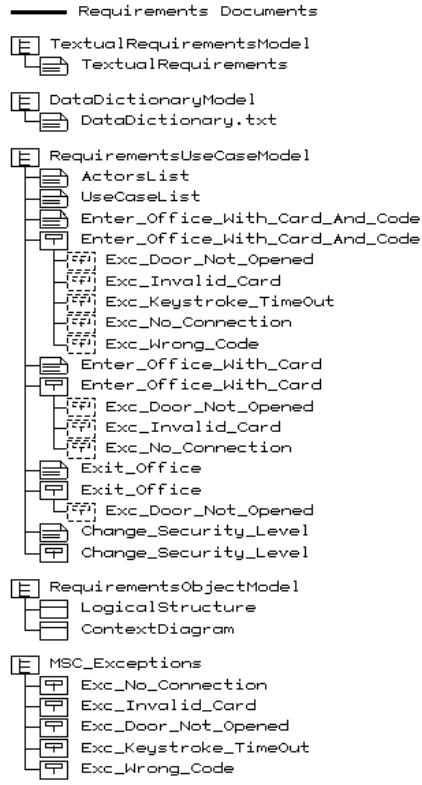

Figure 734: The entire requirements analysis document structure

Performing the System Analysis

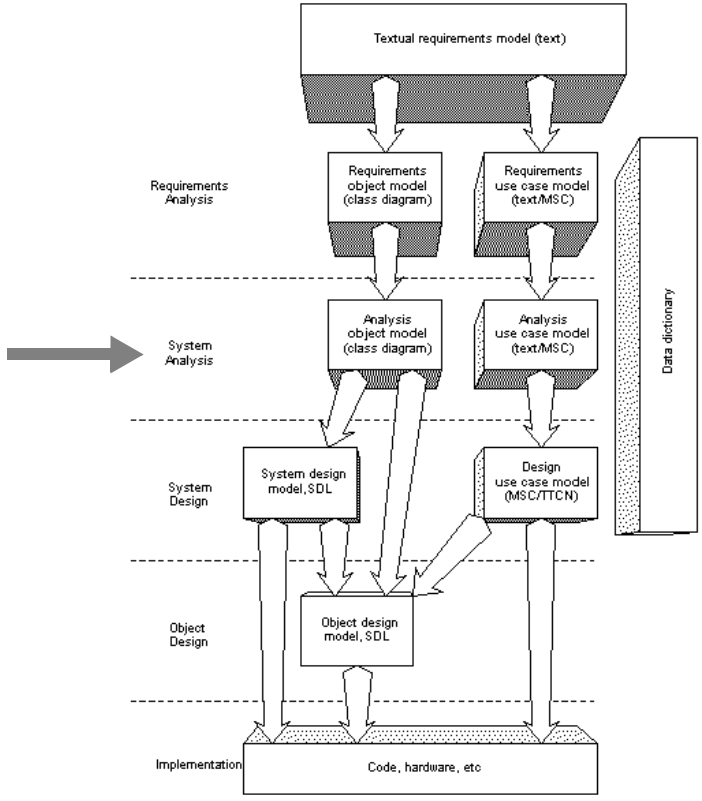

Figure 735: Overview of the SOMT process

What You Will Learn

- To identify and present the logical architecture of a system which includes refining the object model from the previous phase
- To refine use cases from the previous phase
- To use the *Paste As* mechanism

Introduction to the Exercise

In this exercise you will perform the system analysis activity. The purpose of the exercise is to outline a logical model of the Access Control system. This model will fulfil the requirements that were identified in the requirements analysis. In other words, the purpose of this activity is to identify the objects that are needed in the Access Control system and the services these objects should provide.

Producing a complete system analysis structure takes too much time. Thus, you will only perform parts of every step necessary to produce the complete structure.

The input to the system analysis activity is a complete requirements structure with the two main models:

- requirements object model
- requirements use case model

The output from the system analysis activity are the two models:

- analysis object model
- analysis use case model

These two models should be created in parallel through a number of iterations.

Preparing the Exercise

1. Open the system file `somttutorial/SysA/accesscontrol.sdt` **(on UNIX)**, or `somttutorial\sysa\accesscontrol.sdt` **(in Windows)**.
2. Check that the Source directory is set to `somttutorial/SysA/` **(on UNIX)**, or `somttutorial\sysa\` **(in Windows)**.

What you see in the Organizer window is a complete requirements analysis structure with all implinks made.

Creating the Analysis Object Model

The analysis object model is a refinement of the requirements object model. However, when transferring from the requirements analysis to the system analysis you change the focus.

During the requirements analysis the focus is on understanding the problem and the problem domain. In the system analysis the focus is to model a solution and to understand the logical structure of the system that will be the solution to the stated problem. This change of focus should be reflected by the analysis object model.

Little emphasis should be put on implementation aspects during the system analysis activity. Questions regarding the implementation of the solution will very likely hide our actual problem.

A glance at the headlines may give you the impression that the activity of creating the analysis object model is a sequential activity, but it is not. You will probably not first add all the necessary classes, then the relations, and finally specify the attributes and operations. This is, however, the way the text is structured here to make it readable and to highlight the important tasks of the activity.

Creating a Logical Architecture

Now it is time to create the logical architecture diagram.

1. Select the `AnalysisObjectModel` module in the `System Analysis Documents` chapter in the Organizer.
2. Add a new object model diagram and name it **`LogicalArchitecture`**.
3. Open the `LogicalStructure` diagram from the previous activity as well as the new `LogicalArchitecture` diagram in the OM Editor.

Adding Classes to the Logical Architecture

Now you should start adding classes to the logical architecture diagram. For information on how to find the classes, see "Finding Classes" on page 4014.

Several of the classes in the requirements object model can be transferred as-is to the analysis object model. The provided *Paste As* mechanism lets you transfer objects from one model to another while auto-

matically creating implinks between the objects in the two separate models. This mechanism should be used here, see below.

4. *Select* the class `CentralControl` in the `LogicalStructure` diagram and choose *Copy* in the *Edit* menu.
5. Go to the `LogicalArchitecture` diagram by selecting it in the *Diagrams* menu.
6. Choose *Paste As* in the *Edit* menu. The Paste As dialog is opened.
7. Set the option menu to *Class* and see to it that the *Create link* toggle button is **set**. Press the *Paste As* button.
8. Select where in the `LogicalArchitecture` diagram you want to place the `CentralControl` object.

Now you have created a class named `CentralControl` in your `LogicalArchitecture` diagram. The class is connected with an implink to the `CentralControl` class in the `LogicalStructure` diagram. The link is indicated by the filled triangle on the class symbol.

9. Repeat the procedure above with the class `Entrance` but name the new class **`EntranceUnit`** as this is a more descriptive name.
10. The classes `Cardreader`, `Keypad`, `Display` and `ExitButton` are obvious interfaces to our system and, also, parts of an `EntranceUnit`. Repeat the procedure above with these classes. As it is often useful to name objects according to their function, give the new classes names of the form **`xxxInterface`**.

One class in the requirements object model may result in several classes in the analysis object model. One reason may be that the class provides so much functionality that splitting the class into several smaller may be convenient. Another reason may be that a class identified in the requirements object model needs services from other, not yet introduced classes. Consequently these classes should be introduced at this point of the development process.

In practice, the actions in the two cases above are the same. The newly introduced classes should be linked to the original class in the requirements object model. In our example this is the case with the class Door. In the requirements object model we have one single class representing the door. Further analysis, however, shows that the door object includes both a door lock as well as a door sensor. This aggregation structure

should be shown in the analysis object model. See section "Finding Relations" on page 4016.

11. *Copy* the class `Door` in the `LogicalStructure` diagram.
12. *Paste* it three times *as* a class in the `LogicalArchitecture` diagram and see to it that the implinks are created at the same time. *Name* the new classes `DoorUnit`, `DoorLockInterface` and `DoorSensorInterface` respectively.

Now look at the classes you have so far in the `LogicalArchitecture` diagram. Think about the tasks of the different objects. As you can see there is no class that can handle the logic, that is, an object that is responsible for what happens at an entrance. Therefore, you should add such an object and name it **`EntranceCtrl`**, see below. The `EntranceCtrl` will be a part of the `EntranceUnit`.

13. *Copy* the class `Entrance` from the `LogicalStructure` diagram.
14. *Paste* it *as* a class in the `LogicalArchitecture` and rename the class, giving it the name `EntranceCtrl`.
15. Also, *copy* and *paste* the `SecurityLevel` class and its subclasses.

Classes in the requirements object model that only exist outside the system border or classes that do not provide any necessary services should not be transferred at all to the analysis object model.

Finding Classes

Useful sources where you can find objects that may be included in the analysis object model are:

- the requirements object model
- interfaces that the system will have to the environment
- use cases

When you intend to transfer objects from the requirements object model to the analysis object model, consider the following to validate each requirements object:

- Decide if the system needs information about the object to fulfill its task.
- If the answer is "yes" then add the class to the analysis object model.

Another useful way to find the objects is to examine which interfaces the system needs. Often the application area itself makes it obvious what interfaces must exist. To find the interface objects, go through the list of actors and, for each actor, decide which interfaces that are needed to the system.

The use cases from the system analysis activity are also a useful source for finding the objects. The problem is that we have not created these use cases yet. As stated before, the work done in each activity is often done iteratively. This is a typical situation where an iteration is needed as some objects in the analysis object model may not be found until we have created and inspected the analysis use case model.

When you have created the MSCs you should examine them to check which interface objects that are involved and which internal objects that are modified. Also, check if there is a control object that might handle the logic of the use case or if there is a need to introduce such an object in the analysis object model.

Adding Relations to the Logical Architecture

When you have identified all classes it is time to add the relations. For information about how to add relations, see "Finding Relations" on page 4016.

In our Access Control system example, most of the relations from the requirements object model can be preserved.

1. Connect the `CentralControl` to the `EntranceUnit` with an association. Add multiplicity to the association. The `CentralControl` may be connected to several `EntranceUnits` but the Access Control system has only one `CentralControl`.
2. Connect the `EntranceUnit` to the `DoorUnit` with an aggregation. One `EntranceUnit` consists of only one `DoorUnit`.
3. The `DoorUnit` consists of a `DoorLockInterface` and a `DoorSensorInterface`. Add aggregations from the `DoorUnit` to the `DoorLockInterface` and to the `DoorSensorInterface`.
4. Connect the rest of the classes you have added with necessary associations, aggregations and generalizations. Also consider if multiplicity is needed or not.

Finding Relations

Useful sources that may assist the process of finding relations are:

- the requirements object model (preserving and modifying existing relations)
- analysis use case model
- textual requirements

The process of finding new relations and verifying old ones are closely related to the process of creating the analysis use case model. It is mainly a question about which other objects the object needs to know about to be able to provide its services. Also generalizations and aggregational dependencies have to be considered, see "Identifying the Relations" on page 4004.

Adding Attributes to the Logical Architecture

Now we have come to the point where it is time to add the attributes. For information on how to find the attributes, see "Identifying Attributes" on page 4016.

There are not many classes in our `LogicalArchitecture` diagram that need any attributes. In fact there is only one, the class `Display`. This class must be able to display different text messages depending on the situation at hand. Therefore:

1. Define `Text` to be an attribute of the class `DisplayInterface`.

Identifying Attributes

Attributes can be found in:

- the requirements model (keeping existing attributes)
- the textual use cases
- the textual requirements

Attributes describe a property of an object and often correspond to nouns. For example, possible attributes of an object "Person" may be eye color, weight, shoe size, and so on. Attributes that may describe a vehicle are owner, color, current speed, current gear, and direction.

Adding Operations to the Logical Architecture

The last thing to add to the logical structure object model are the operations. For information on how to find the operations, see "Identifying Operations" on page 4018.

Add the operations `Open`, `Close`, `Lock` and `Unlock` to the assembly class `DoorUnit`. This implies that you also must add the operations `Open` and `Close` to the class `DoorSensorInterface` and `Unlock` and `Lock` to the class `DoorLockInterface`.

1. Select the class `DoorUnit`.
2. Click on the operations section in the class.
3. Add the operations `Open`, `Close`, `Lock` and `Unlock`.
4. Repeat the procedure for the classes `DoorLockInterface` and `DoorSensorInterface` adding their respective operations.
5. Continue to add the missing operations of the other classes in the diagram. When you are finished, your diagram should look something like in Figure 736.
6. Save the diagram.

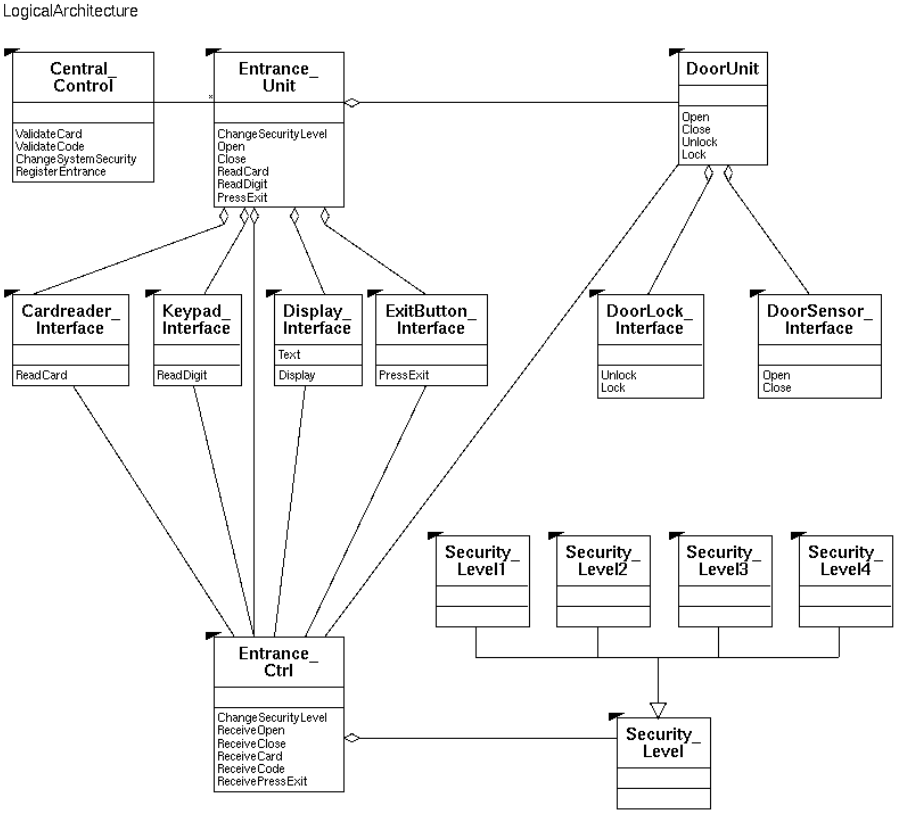

Figure 736: The logical architecture

Identifying Operations

Sources that may support the identification of operations are:

- the requirements object model
- the analysis use case model (the messages in the MSC diagrams)
- the data dictionary (the description of the objects)

By studying the responsibilities of each object is it possible to identify a set of operations that will provide the services assigned to the object.

Let one operation perform only one task. However, the class should not contain too many public operations. A large public interface of a class may indicate that the object is assigned too many responsibilities. Instead the object should probably be split and the responsibilities of the object should be distributed between several objects.

The easiest way to find the operations is probably to look at the MSC messages in the system analysis use cases. The messages can often be considered as operations in the analysis object model. A message received by an instance in an MSC corresponds to an operation on the corresponding class. Note that the operations on the classes representing subsystems define the interface of this subsystem and should often also exist as operations on some of the objects within the subsystem.

Creating an Information Diagram

Now it is time to create an information diagram. This diagram describes the concepts outside the system that the system must know of to fulfill its task. In our Access Control system example, `Card` and `Code` are two such concepts.

1. *Add* a *new* object model diagram to the Organizer in the module `AnalysisObjectModel`. Name the diagram **`InformationDiagram`**.
2. *Open* the `LogicalStructure` diagram from the previous activity and the new `InformationDiagram` in the OM Editor.
3. *Select* and *copy* the classes `Card` and `Code` in the `LogicalStructure` diagram and *paste* them *as* classes in the `InformationDiagram`, while automatically creating the implinks.
4. Consider if any or both of the classes should have any attributes.
5. Associate the classes with each other.
6. Save the diagram.

Your diagram should look like in Figure 737 when you are finished.

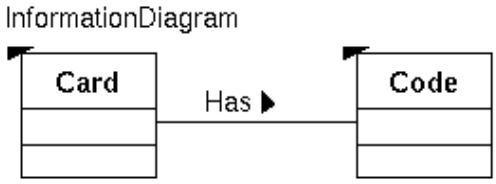

Figure 737: The Information diagram

Creating the Analysis Use Case Model

The design of the two models in the system analysis activity, the object model and the use case model, is usually going on in parallel. The models view the Access Control system from two different perspectives, a dynamic perspective and a static perspective.

The analysis use case model shows the dynamic aspects and consists of a set of MSC diagrams. These diagrams may be categorized into two types:

- Refined requirements use cases
- Behavior pattern use cases

Refined Requirements Use Case

A refined requirement use case is what it reads like. Each valid use case from the requirements use case model is transferred to the analysis use case model and redesigned and refined to the analysis object model.

The purpose of the refined use cases is to validate whether the analysis object model really implements the requirements. At the same time the analysis use case model is an important source of information for identifying operations on the classes in the object model.

In the analysis use case model, the use cases are documented preferably using MSCs. MSC diagrams are more formal and correspond better to the object model than textual use cases.

Each instance in the MSC diagram corresponds to an object or subsystem in the analysis object model. The level of abstraction you choose is a trade-off between detail and clarity.

An object which encapsulates interfaces and just transfers the calls to other objects without adding much functionality may be omitted, but objects providing crucial functionality should be part of the MSC.

Creating a Refined Requirements Use Case

Now you should create an analysis use case of the `Enter_Office_With_Card_And_Code` use case from the requirements analysis activity.

1. Create a new MSC diagram in the `AnalysisUseCaseModel` module and name it **`Enter_Office_With_Card_And_Code_SysA`**.
2. Open the requirements use case `Enter_Office_With_Card_And_Code`. The system analysis use case is based on the requirements use case and it is therefore useful to use the latter as a reference (using copy and paste).
3. Create the MSC on subsystem level, that is, replace the original system instance with instances of `EntranceUnit` and `CentralControl`.
4. Create endpoints of the three instances in the MSC diagram. (Select *Create Endpoint* from the *Link* submenu in the *Tools* menu.)
5. For each message in the requirements use case decide which instances that exchange that particular message in the analysis use case. Also consider which additional messages you need to add. All message exchanges **inside** the system that we did not consider in the requirements use cases have to be added at this point. Also, make references to exceptions at the points where these can occur.
6. Replace the four `ReadDigit` signals with an MSC reference symbol referring to the MSC ReadCode. ReadCode is a behavior pattern which you will create later, see "Behavior Pattern Use Cases" on page 4023.
7. Save the diagram.
8. In the Organizer, create an endpoint out of the newly created MSC diagram. (This is done in the same way as in the editors.)
9. Open the Link Manager and connect this endpoint to the `Enter_Office_With_Card_And_Code` MSC from the requirements use case model. Name the link **`Implementation Link`**.

The created MSC should look like in Figure 738.

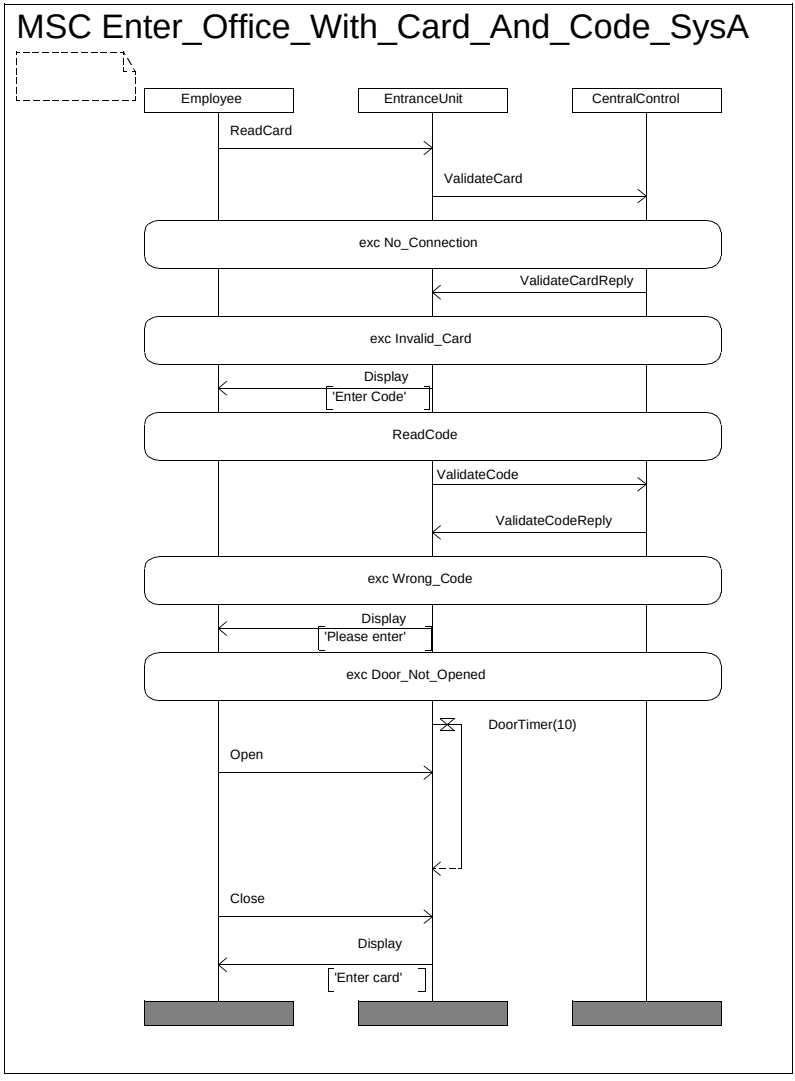

Figure 738: A system analysis MSC use case

The rest of the requirements use cases and their respective exceptions are refined in a similar way. This will not be done in this tutorial because that would take too much time.

Behavior Pattern Use Cases

A behavior pattern is a detailed use case that may be used to examine special communication patterns in detail. A behavior pattern is part of an ordinary use case and most often several use cases share a behavior pattern. A use case may include none or several behavior patterns.

Behavior patterns let refined requirements use cases be presented in a higher abstraction level, making these less complex and easier to understand. By focusing use cases on special parts of the system it is easier to understand and maintain the requirements on the involved objects.

Creating a Behavior Pattern

The refined use case that you just created was created on subsystem level. With the help of behavior patterns we can describe what really happens at a certain point in the use case, i.e. which objects that interact and the messages that they exchange. In our case, where we will create a behavior pattern for the task of reading a code, we have to replace the MSC instance `EntranceUnit` with the MSC instances `KeypadInterface` and `EntranceCtrl`.

1. Create a new Organizer module in the `System Analysis Documents` chapter. Name it **`BehaviorPatterns`**.
2. In the MSC Editor, create the behavior pattern `ReadCode`, see Figure 739.
3. Save the diagram using the name **`Behavior_Pattern_ReadCode`**.
4. In the Organizer, associate the behavior pattern MSC with the use case MSC which it really is a part of. That is, associate it with `Enter_Office_With_Card_And_Code_SysA`.

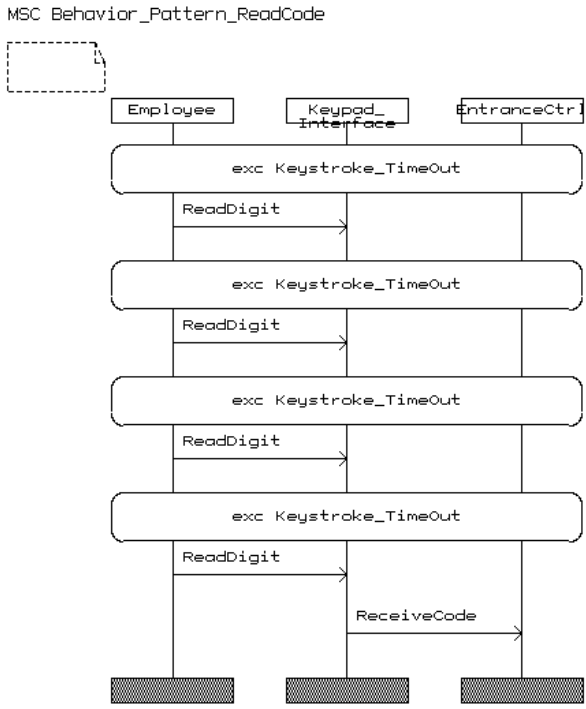

Figure 739: A behavior pattern example

The `System Analysis Documents` chapter should now look like in Figure 740.

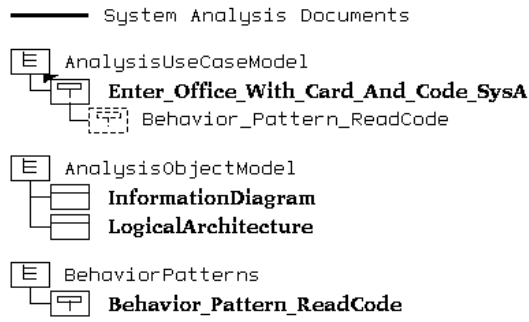

Figure 740: The System Analysis Documents chapter

Requirements Traceability

One important aspect in this activity is the relation between the models created here and the models created in the requirements analysis activity. We want to be able to check:

- That all requirements have been implemented
- Which system analysis object that implements a certain requirement
- Which requirement that is implemented by a certain object in the analysis object model

The means to check the issues above is through consistency checks. There are two types of consistency checks:

- Entity matches
- Link checks

We will start with a link check and then we will perform an entity match.

Link Check

The first thing to check is that all entities described in the logical structure in the requirements object model are either represented in the analysis object model or not really needed by the application.

1. *Open* the Link Manager. A link check can be performed in both entity and endpoint view, so it does not matter which view you have in the window.
2. Choose *Consistency Check* in the *Tools* menu to perform a link check.
3. The Consistency Check dialog pops up asking you to select the documents representing the **from** group. Select the `LogicalStructure` object model and press *Continue*.
4. Yet another Consistency Check dialog appears, now asking you to select the documents representing the **to** group. Select the `AnalysisObjectModel` module (this will also highlight the documents in the module) and press *Check.*
5. The Link Manager will show the result of the link check. You can see that all entities from the requirements, except the system operator, employee, database, management system and office, are represented in the analysis object model. These are concepts on the outside of the system and, thus, not really needed by the application.

To follow links from one model to another we use the *Traverse* command. To see how this works follow the steps below:

6. Go to the `LogicalArchitecture` diagram in the OM Editor and select the class `CentralControl`.
7. In the *Link* submenu in the *Tools* menu, choose *Traverse*.
8. The OM Editor will open the `LogicalStructure` diagram and the `CentralControl` class will be selected. Go yet another step backwards by choosing *Traverse* in this diagram.
9. The Traverse Link dialog pops up asking you to select a link to traverse. The class is the one we just came from so you should choose the text fragment and press *Traverse Link.*
10. The Text Editor opens and the endpoint `centralcontrol` is selected.

In the same way we traversed from system analysis to requirements here, you can also traverse from the requirements to system analysis. Try this!

Entity Match

Now it is time for another consistency check. This time you should check that the instances in the MSC diagram correspond to classes in the object model or to actors that interact with the system.

1. See to it that you have entity view in the Link Manager window. If not, press the *Show endpoint or entities* button in the tool bar.
2. Choose *Consistency Check* in the *Tools* menu. Set the *entity match* radio button in the Consistency Check dialog and press *Continue*.
3. As a document representing the from group, select the MSC `Enter_Office_With_Card_And_Code_SysA`.
4. As documents representing the to group, select the `AnalysisObjectModel` module and the `ActorsList`.
5. The result shows that all MSC instances really are described in the analysis object model or in the list of actors.

Summary

After having completed an entire system analysis, the `System Analysis Document` chapter would look like in Figure 741.

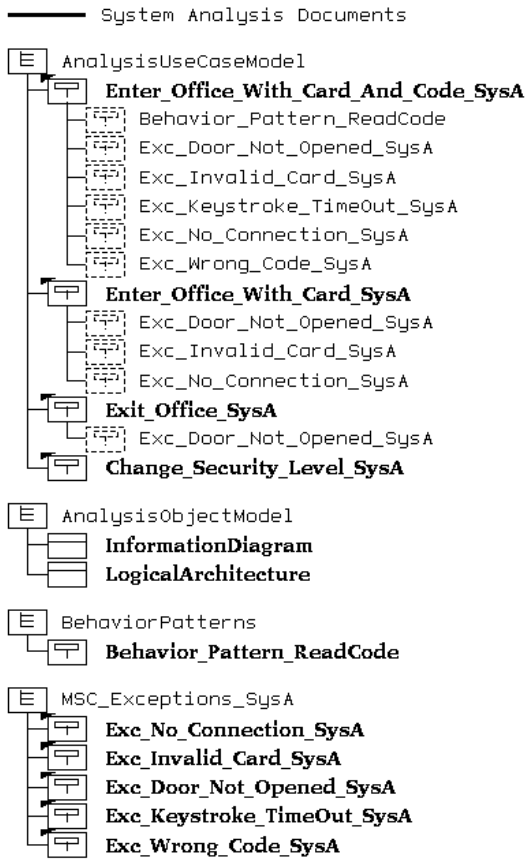

Figure 741: The entire system analysis document structure

Performing the System Design

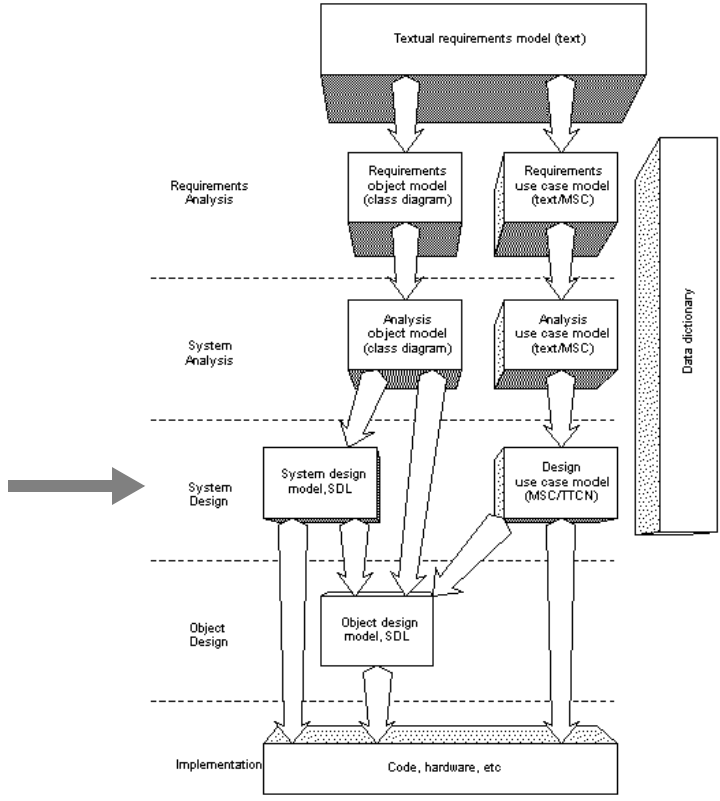

Figure 742: Overview of the SOMT process

What You Will Learn

- To create a design module structure
- To define the static interfaces in packages
- To make an architecture definition of the system
- To make formalized testable use cases
- To use the *Paste As* mechanism when transferring from the system analysis activity to the system design activity

Introduction to the Exercise

This is an exercise on system design. In this activity we no longer make use of object models; from now on SDL will be used. You will learn how to map concepts from the analysis object model from the previous activity into an SDL model. Mapping object-oriented concepts to SDL concepts forces you to make several design decisions. Support for these design decisions is provided through the *Paste As* mechanism. This exercise will teach you to make use of this support.

Useful sources for information in the system design activity are the analysis object model and the analysis use case model. The first provides information about the static structure and is useful when structuring the system into units. The latter provides information about the dynamic structure and is useful for the definition of the interfaces between the units.

Major tasks to perform in the system design are:

- Define the design module structure.
- Define the static interfaces.
- Create an SDL system structure as a starting point for the formalization of the architecture.
- Define the dynamic aspects of the interfaces by a continued use of use cases.

Producing a complete system design structure in the tutorial takes too much time. Thus, you will only perform parts of every step necessary to produce a system design structure.

Preparing the Exercise

1. Open the system file `somttutorial/SysD/accesscontrol.sdt` **(on UNIX)**, or `somttutorial\sysd\accesscontrol.sdt` **(in Windows)**.
2. Check that the Source directory is set to `somttutorial/SysD/` **(on UNIX)**, or `somttutorial\sysd\` **(in Windows)**.

What you now see in the Organizer window is a complete requirements analysis and system analysis structure.

Design Module Structure

An important part of the system design is to divide the system into units considering division of work, distribution of functionality and physical distribution.

The purpose of the design module structure is to show the actual source code modules the application will be built from. The most important aspect of the module structure is that it forms the basis for dividing the work load on different development teams.

In our Access Control system example we have two different subsystems, EntranceUnit and CentralControl. It might be the case that these subsystems are implemented by two different teams. Therefore, it seems natural to introduce two different modules, each module being described by the concept of a package. The contents of the packages will not be defined until the architecture definition, the task here is only to identify the modules needed.

The notation that will be used in this tutorial to describe the design module structure is the object model instance diagram where the instances represent the different modules.

Creating a Design Module Structure

1. Add a new object model diagram to the Organizer in the module `DesignModuleStructure` and name the document **`DesignModuleStructure`**.

2. In the OM Editor, create a first object instance symbol representing the whole SDL system. Name it using the name **`SDL_System_Access_Control`**.

3. Decide which modules, i.e. packages, the SDL system is to make use of. In this example it might be suitable to introduce two different modules, one for each subsystem. Therefore, create two more object instances and name them **`CentralControlPackage`** and **`EntranceUnitPackage`** respectively.

4. Draw associations from the SDL system module to the two new modules. The associations describe that the SDL system uses these two packages.

5. Create yet another module which will consist of all common types and signals. This package is used by the other two packages and thus

also by the SDL system itself. Name the module **`UtilityTypesPackage`** and draw the associations. Your diagram should now look like in Figure 743.

6. *Create endpoints* out of the three packages. (Endpoints are not created automatically for object instance symbols.)
7. Save the diagram giving it the name **`designmodulestructure.som`**.

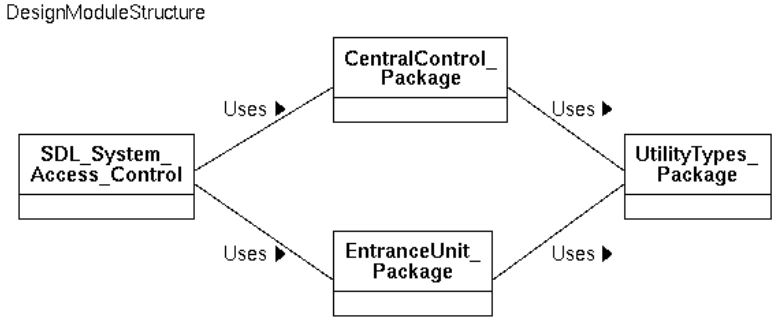

Figure 743: The Design Module Structure

Creating the Architecture Definition

When using SDL to design a system, the architecture is defined by block diagrams which define how the system is decomposed into blocks. The block diagrams are more or less a formalization of the analysis object model.

The first thing we will do when defining the architecture is to define the contents of the packages introduced in the design module structure, see "Defining the Packages" on page 4033. The `UtilityTypesPackage` will contain data type declarations that are common to the subsystems of the system. Signals/remote procedures that make up the interface between the subsystems will also be defined in the `UtilityTypesPackage`. The other two packages, `CentralControlPackage` and `EntranceUnitPackage`, will contain block types and the signals/remote procedures that make up the interface to the particular block. If you have many signals it is often useful to structure these into signal lists.

The basic mechanism used in SOMT when going from analysis to design is the *Paste As* mechanism. This is used here when defining the signal interfaces, the blocks and block types, and, to some extent, the data type declarations.

The second task to do when creating the architecture definition is to define the system by means of SDL block diagrams, see "Creating the SDL System Diagram" on page 4038.

Defining the Packages

Mapping Object Models to SDL Block Types

You should now define the two block types, `CentralControl` and `EntranceUnit` in their respective package using the *Paste As* mechanism.

1. *Add* three *new* SDL packages to the `ArchitectureDefinition` module in the Organizer and name them according to the modules in the design module structure.
2. *Open* the `LogicalArchitecture` diagram in the `AnalysisObjectModel` module.
3. Select the class `CentralControl` and *copy* it.
4. Go to the SDL Editor and the `CentralControlPackage` diagram and choose *Paste As*. The Paste As dialog is opened.
5. *Paste* the class `CentralControl` *as* a *Block Type* (use the option menu) and create an implementation link from the copied object to the pasted object at the same time. The link is automatically created by default.
6. *Copy* and *paste* the class `EntranceUnit` *as* a block type in the `EntranceUnitPackage` in a similar way.

Mapping Object Models to SDL Interface Definitions

Now it is time to design the interfaces of the newly pasted blocks. Interface definitions in SDL are defined using signals and/or remote procedure calls. Consequently, this is what is produced when mapping a class to an SDL interface.

Note that the signals that constitute the interface between our subsystems should be described in the `UtilityTypesPackage`. The rest of the signals, i.e. signals that are **not** exchanged between the subsystems should be described now. Signals from the environment to the subsystem and signals inside the subsystem are such signals.

1. Once again, go to the `LogicalArchitecture` diagram in the `AnalysisObjectModel` and *copy* the class `EntranceUnit`.
2. Go to the SDL Editor and the `EntranceUnitPackage` diagram and *paste* the class *as* a *Text symbol with SDL interface*. See to it that an implementation link is created at the same time.

   If you look at the signal definition you see that the `ChangeSecurityLevel` signal is present. This is a signal exchanged between our two subsystems and, thus, should not be declared here.
3. Delete the `ChangeSecurityLevel` signal.
4. Add the signal parameters. The signals `ReadCard` and `ReadDigit` are the only ones that need parameters. See Figure 744.
5. Save the diagram, giving it the name **`entranceunitpackage.sun`**.

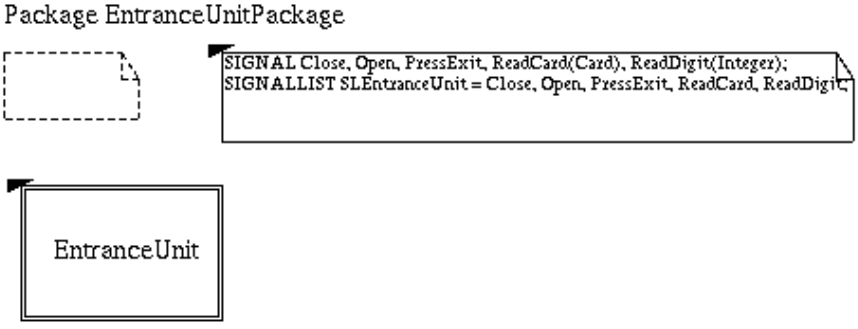

Figure 744: The EntranceUnitPackage

6. Go back to the `LogicalArchitecture` diagram and *copy* the class `CentralControl`.
7. *Paste* it *as* a text symbol with SDL interface in the `CentralControlPackage`.

8. If you look at the signal definition you realize that the `ValidateCard`, `ValidateCode` and `RegisterEntrance` signals are signals exchanged between our subsystems and, thus, should not be defined here. Therefore, delete these signals from the signal definition.
9. Add a signal parameter of the type integer to the `ChangeSystemSecurity` signal, see Figure 745.
10. Save the diagram, giving it the name **`centralcontrolpackage.sun`**.

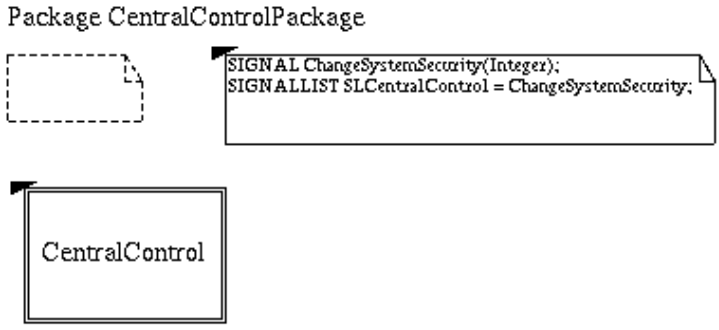

Figure 745: The CentralControlPackage

It is now time to define the last package, the `UtilityTypesPackage`. It will define the common data types needed in the subsystems as well as the interface between the subsystems. To define the package you should use the same procedure as above.

1. *Copy* the class `CentralControl` from the `LogicalArchitecture` diagram.
2. *Paste* it *as* a text symbol with SDL interface in the `UtilityTypesPackage` diagram.
3. Delete the signal `ChangeSystemSecurity` as this has already been defined in the `CentralControlPackage` (because it is a signal from the environment).
4. Add signal parameters to the three remaining signals.

5. Continue with copying the class `EntranceUnit` and *paste* it *as* a text symbol with SDL interface in the `UtilityTypesPackage`.

6. Remove all signals that have already been defined, i.e., all but the `ChangeSecurityLevel` signal.

Note that the Validate commands (`ValidateCard` and `ValidateCode`) have to be implemented with signals and not remote procedure calls. This is due to the fact that we must be able to keep track of how long it takes before we get the answer of a validation (to find out if there is a connection failure or not). As a consequence of this, the reply signals to the Validate commands have to be defined here.

7. Add the two signals `ValidateCardReply` and `ValidateCodeReply` to the latest pasted signal definition.

8. Add signal parameters to the three signals in the definition.

Mapping Object Models to SDL NewTypes

Now it is time to declare the common data types. In our Access Control system example the concepts of card and code are data types common to all parts of the system.

The data type `Card` is best declared as a SYNTYPE. You will have to do this declaration manually as there is no support in the *Paste As* mechanism for pasting something as a SYNTYPE. In declaring the data type `Code`, however, the *Paste As* mechanism can be used.

1. Declare the `Card` concept as a SYNTYPE in the `UtilityTypespackage`, see Figure 746.

2. *Open* the `InformationDiagram` in the `AnalysisObjectModel` and *copy* the class `Code`.

3. Go to the SDL Editor and the `UtilityTypesPackage` and choose *Paste As*. The Paste As dialog is opened.

4. *Paste* the class `Code` *as* a *NEWTYPE with graphical operator* or as *NEWTYPE with textual operator* (it does not matter which one you choose as the class Code has no operator) and see to it that an implementation link is created at the same time. This will only give you the structure, you have to fill in all relevant information yourself.

5. As it is a type we are declaring, change the name `Code` to **`CodeType`**. Define the `CodeType` concept to be an array consisting of four integers (you will have to delete the word STRUCT). The index type of the array should be integer and you will have to define this type too, see Figure 746.

6. Declare a SYNONYM **`NbrOfEntrances`** that will be used to alter the number of entrances we are to control in our system. For now, you can set the value of the variable to **`1`**, see Figure 746.

Before you save and close the diagram you should create an implementation link between the class `Card` from the InformationDiagram to the definition of `Card` in this diagram. You have earlier used the Link Manager to manually create links. We will now show how to use the *entity dictionary* for this.

The entity dictionary is available in all editors and lists all entities in the system, i.e. all modules, diagrams, and endpoints. The main usage of the entity dictionary is to reuse names of entities, but it can also be used to create links.

1. In the `UtilityTypesPackage` diagram, select the text symbol containing the `Card` definition.

2. From the *Window* menu, choose *Entity Dictionary*. The Entity Dictionary window is opened. You will recognize the structure and icons of chapters, modules and diagrams from the Organizer window. In addition, all endpoints are listed beneath the corresponding diagram.

3. Scroll the Entity Dictionary window until you find the class `Card` in the `InformationDiagram` in the `AnalysisObjectModel` module. Select the icon representing the class `Card`. (Make sure not to double-click an icon, since that will copy the name of the icon into the current diagram!)

4. In the Entity dictionary, press the *Create Link* quick button.

5. The Create Link dialog pops up. (This is the same dialog as when you created links in the Link Manager.) Set the *from* radio button, name the link **`Implementation Link`** and press *Create*.

6. *Close* the Entity dictionary by using the *Close* quick button.

7. *Save* the diagram, giving it the name **`utilitytypespackage.sun`**.

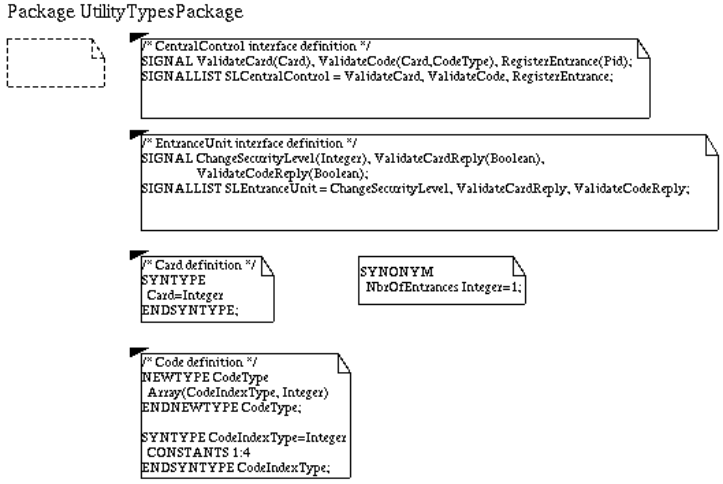

Figure 746: The UtilityTypespackage

8. In the Organizer, *create endpoints* out of the three packages.

Creating the SDL System Diagram

Now you should define the system structure, something which is to be done by means of SDL blocks in a system diagram.

1. *Add* an SDL system diagram to the `ArchitectureDefinition` module in the Organizer and name it **`AccessControl`**.

2. *Copy* the class `CentralControl` in the `LogicalArchitecture` diagram and *paste* it *as* a *Block* in the system diagram. See to it that an implementation link is created at the same time.

3. Also, *copy* and *paste* the class `EntranceUnit` as a *block.*

4. Change the name of the block instances, from `CentralControl` to **`theCentralControl`** and from `EntranceUnit` to **`theEntranceUnit`**. Also, define which block type the blocks are an instance of, see Figure 747.

5. There will often be more than one entrance in a building and therefore you should define the block `theEntranceUnit` as a *block instance set*. (Use the variable `NbrOfEntrances` defined in the `UtilityTypesPackage`.)

The two blocks `theCentralControl` and `theEntranceUnit` must be able to communicate with each other as well as with the environment. The next step is to create all necessary channels in the system diagram.

6. Draw the channels through which the blocks communicate and name them and the gates with suitable names. Also, draw the channels to/from the environment. State which signals that run on a certain channel. To identify the signals consult the `AnalysisObjectModel` made in the system analysis.

7. At this point we see the need to introduce a new signal, the `EnvDisplay` signal which goes from the `EntranceUnit` to the environment (i.e, to the display hardware). This signal contains information that is to be read by persons in the system environment. The parameter of this signal is `Charstring`. Define it in the `EntranceUnitPackage`.

8. Reference the packages the SDL system makes use of in a USE clause in the top of the diagram. Your system diagram should now look like in Figure 747.

9. Save the diagram, giving it the name **`accesscontrol.ssy`**.

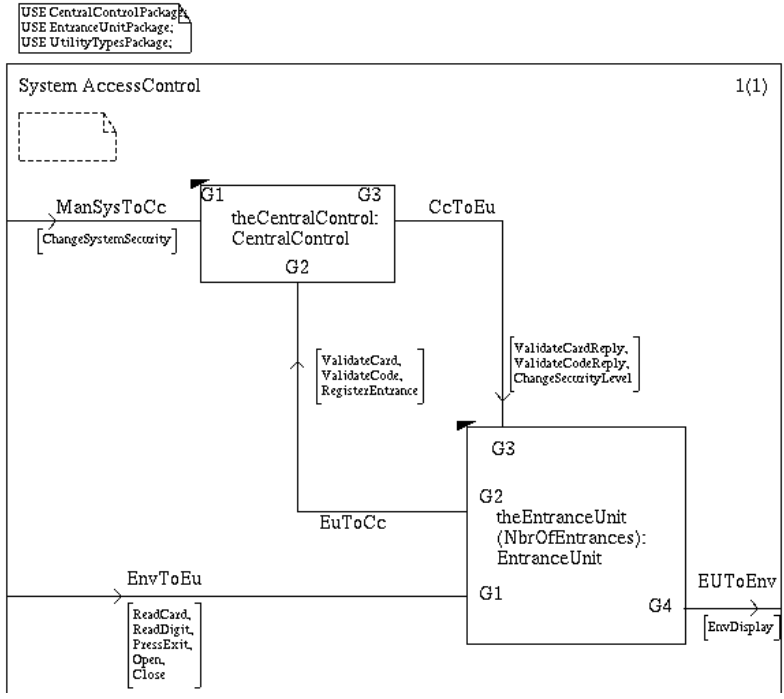

Figure 747: The Access Control system diagram

Refining the EntranceUnit – Mapping Aggregations

Considering the aggregation structure in the `LogicalArchitecture` diagram, the block `EntranceUnit` may be divided into several sub-blocks.

When mapping an aggregation structure from the analysis object model to an SDL diagram, the most common choice is to map the assembly class to a block type. Classes which are part of the assembly class will be mapped to process types, or, if the part class itself is an assembly class, to block types.

The block type corresponding to an assembly class will thus contain processes or blocks.

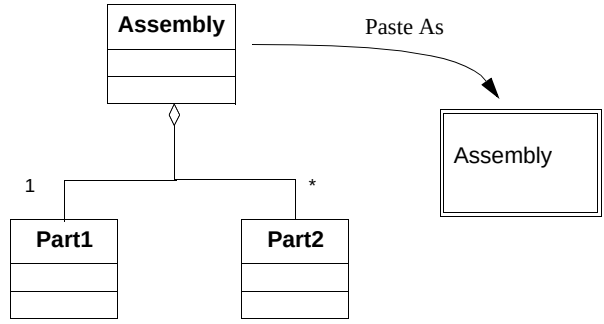

Figure 748: Mapping aggregation to a block type

The process types and block types should be placed in a suitable package to enable reuse. The instances of the types should then be placed in the appropriate system or block diagram to form the system.

Mapping Classes to Block Types and Signal Interfaces

1. Select the class `DoorUnit` in the `LogicalArchitecture` diagram. *Copy* it and *paste* it *as* a block type in the `EntranceUnitPackage`.
2. Call the *Paste As* command again. This time, choose to paste the class as a text symbol with SDL interface in the `EntranceUnitPackage`.
3. The resulting signal definition contains two signals that already have been defined in the package, namely `Open` and `Close`. Therefore, delete these signals in the newly pasted signal definition.

Mapping Classes to Blocks

Now it is time to place a block instance of the `DoorUnit` block type in the `EntranceUnit` block type.

1. Double-click on the `EntranceUnit` block type in the `EntranceUnitPackage` diagram. The Edit dialog pops up, press *OK*. The Add Page dialog pops up. Create a *block interaction page*.
2. For the third time, choose *Paste As* and paste the class `DoorUnit` as a block in the `EntranceUnit` block diagram. The block will be named *DoorUnit*.

3. Change the block name so it is marked as an instance of the block type according to the SDL syntax. Change the name to **`theDoorUnit:DoorUnit`**.

Introducing new Block Types

Since SDL does not allow processes and blocks at the same level you have to create two more block types to be placed in the `EntranceUnitPackage`. These block types will be used as containers to the remaining classes that will be mapped to processes and process types. Give the first block type the name **`EntranceInterface.`** We introduce this block as a generic term for all those classes that represent an interface to the system, i.e. the cardreader, the keypad, the display and the exitbutton. The second block type to be placed in the `EntranceUnitPackage` is **`EntranceCtrl`**.

1. *Copy* the class `DisplayInterface` in the `LogicalArchitecture` diagram.
2. *Paste* it *as* a block type and *as* a text symbol with SDL interface in the `EntranceUnitPackage`.
3. Rename the block type and give it the name `EntranceInterface`.
4. Add a signal parameter called `MessageType` to the `Display` signal definition. By using this type for messages the `EntranceCtrl` does not have to handle strings. This solution makes the system independent of the language used, see "Performing an Iteration" on page 4068 for an example on how this works.
5. Define the NEWTYPE `MessageType`, see Figure 749.
6. Also, *paste* the class `DisplayInterface` *as* a block in the `EntranceUnit` block diagram. Rename the block and give it the name **`theEntranceInterface:EntranceInterface`**.
7. Using the Entity Dictionary, create implementation links between the CardReaderInterface, KeypadInterface and ExitButtonInterface classes in the `LogicalArchitecture` diagram and the `EntranceInterface` block type **and** block.

   Note that you do not have to paste these three classes as SDL interfaces as their operations have already been defined as signals in the `EntranceUnitPackage`.

8. *Now*, *copy* and *paste* the class `EntranceCtrl` as a block type and as a text symbol with SDL interface in the `EntranceUnitPackage`.
9. Delete the signal `ChangeSecurityLevel` as this already has been defined in the `UtilityTypesPackage`.
10. Add signal parameters where they are needed i.e. to the signals `ReceiveCard` and `ReceiveCode`.
11. Also, *paste* the class *a*s a block in the block type `EntranceUnit` diagram. Give the block the name **`theEntranceCtrl:EntranceCtrl`**.

The `EntranceUnitPackage` will look like in Figure 749.

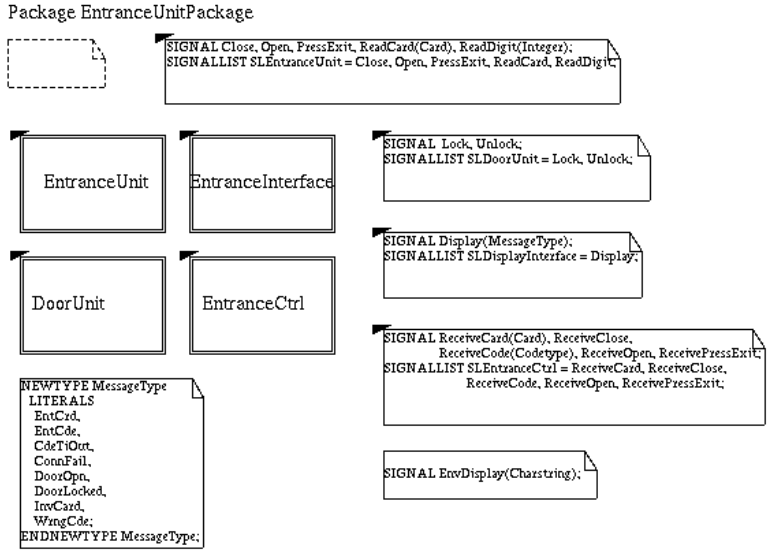

Figure 749: The EntranceUnitPackage

The block type `EntranceUnit` diagram should now contain three blocks: `theDoorUnit`, `theEntranceInterface` and `theEntranceCtrl`.

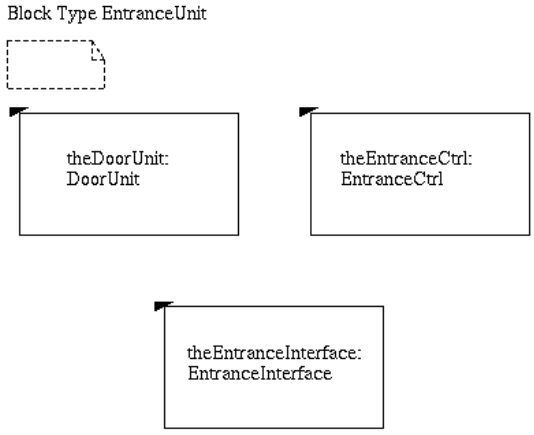

Figure 750: The block Type EntranceUnit

Defining the Communication Structure

Now you should define the communication structures within the block type `EntranceUnit`. Define the channels needed for the three blocks `theEntranceCtrl`, `theEntranceInterface` and `theDoorUnit` to communicate.

To define the channels in the block type `EntranceUnit`, follow the steps described below.

1. Identify necessary channels.
2. Identify the signals that should be carried by the channels. You get a lot of information from the `AnalysisObjectModel` here.
3. Name the channels and the gates.
4. The complete block diagram for `EntranceUnit` should look something like in Figure 751.

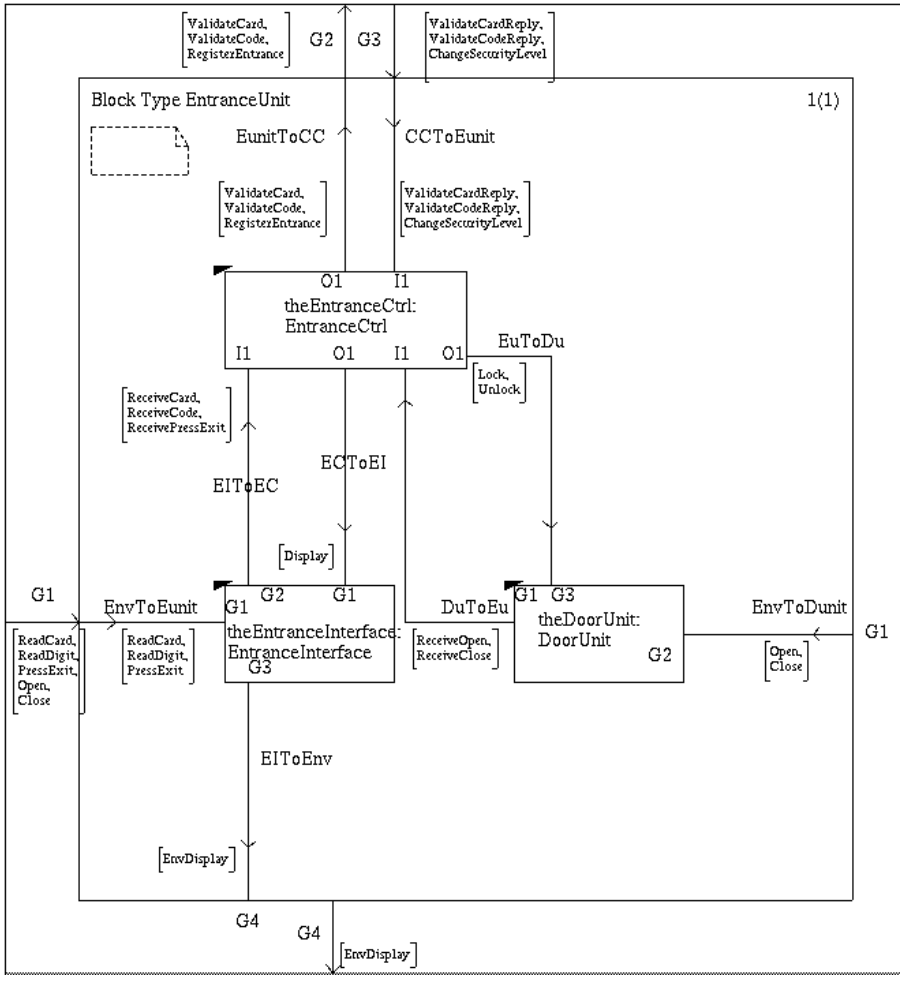

Figure 751: The complete structure of the block Type EntranceUnit

When you have completed the architecture definition, the `System Design Documents` chapter should look like in Figure 752.

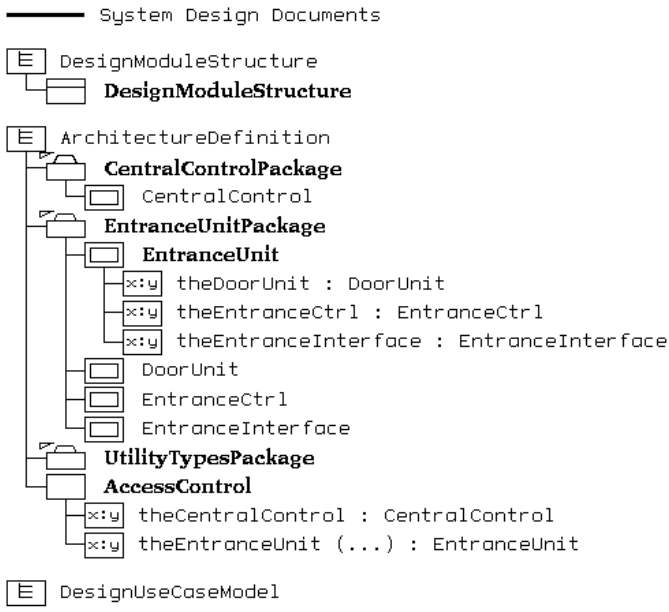

Figure 752: The System Design Documents chapter

Creating the Design Use Case Model

In system design we continue with the use of use cases, this time to define the dynamic interfaces between the blocks in the system.

In our example, the block theEntranceUnit in the system diagram is split into the three blocks, theEntranceCtrl, theEntranceInterface and theDoorUnit. The use cases will consist of the block instances theCentralControl, theEntranceCtrl, theEntranceInterface and theDoorUnit as well as an instance representing the environment.

The use cases must be formalized to a sufficient degree of detail, a level that is consistent with the level of detail found in the static interface definition. Also, the level of detail must be precise enough to make the design use cases act as detailed test specifications.

Formalizing Use Cases

A number of things have to be done when formalizing and refining analysis use cases to design use cases.

- Check that each MSC instance head has a corresponding block in the architecture definition. The use cases define the dynamic interface between the blocks in the system and thus all blocks have to be represented.
- The MSC instances corresponding to actors in the system environment should have **`env_`** stated in their instance head before the actual name, e.g. **`env_Employee`**.
- The MSC instances must have names corresponding to block instances as it is the instances that communicate. That is, the name of those instances that have been defined as block types in the SDL package structure must be changed to the corresponding block instance name. E.g. the MSC instance `CentralControl` can no longer have this name; the name has to be changed to `theCentralControl` according to the architecture definition.
- The messages often have to be replaced with a sequence of message exchanges.
- The MSC messages have to be complemented with parameters according to the definition of signals and remote procedures in the architecture definition. It should not be the **name** of the parameter that should be added but a **value** that the parameter can take. Alternatively the parameters can be skipped entirely.

Creating a Formalized Use Case

Now you should begin to formalize and refine one of the use cases from the system analysis.

1. *Add* a *new* MSC diagram to the `DesignUseCaseModel` module in the Organizer.
2. In the *Add New* dialog, set the toggle button *Copy existing fil*e. As the file to be copied, select the MSC `Enter_Office_With_Card_And_Code_SysA` from the system analysis activity. This file can be found in the `somttutorial/sysanalysis` directory.

3. In the MSC Editor, rename the instance head `Employee` to **`env_Employee`** and change/add the other instance head names. They should conform to the names used on the block instances in the SDL system diagram and the blocks in the `EntranceUnit` block diagram in the architecture definition.

4. For each message, decide if it has to be exchanged with a sequence of messages. If so, add these new messages to the MSC.

5. Add parameters to the messages. Look at the definition of the signals in the architecture definition and add parameters to those messages that are defined to have parameters. E.g. the message `ReadCard` should have a parameter consisting of the card. Note that it is not the parameter name `Card` that is to be used here but an example of a value that the parameter can take, e.g. **`123`**.

6. Rename the use case and save it under its new name, `Enter_Office_With_Card_And_Code_SysD` (use *Save As*).

The exceptions and behavior patterns to this use case must also be formalized.

The other design use cases are created in a similar way. All design use cases should also be connected with implementation links to the corresponding analysis use case and exception. This is done in order to make it possible to check that all use cases from the requirements analysis and system analysis have been refined to design use cases.

Consistency Checks

Now the time has come to performing consistency checks on the models created in system design.

Entity Match

The first thing to check is that the actual modules (SDL packages) used in the design are consistent with the design module structure.

1. In the Link Manager, choose *Consistency Check* in the *Tools* menu and set the *entity match* radio button. Note that you have to be in **entity mode** to be able to perform an entity match.

2. Let the packages in the `ArchitectureDefinition` form the **from** group and the `DesignModuleStructure` module the **to** group.

The result shows that all packages in the `ArchitectureDefinition` really are described in the `DesignModuleStructure`. The consistency view (i.e. the resulting Link Manager window) also shows the contents of the packages. As you can see there are no matching entities to the block references, block types, etc. in the `DesignModuleStructure`. There should not be any, so just ignore this.

Link Check

By doing a link check we will first check that all objects in the analysis object model are mapped to the architecture definition.

1. Once more, choose *Consistency Check* in the *Tools* menu and perform a link check. It does not matter which view you have in the link Manager window, a link check can be performed in either view.

2. Let the `AnalysisObjectModel` form the **from** group and the `ArchitectureDefinition` module form the **to** group.

The result shows that most of the objects from the analysis object model are described as block types and block references in the architecture definition. Many of the objects have also been mapped to an interface definition. The fact that some classes have no corresponding mapping indicates that these classes probably should reside as processes inside some of the mapped blocks. This holds e.g. for the `DoorSensorInterface` and the `DoorLockInterface` as well as for the `SecurityLevel` classes.

At this point you can also select any block or block type in the architecture definition and choose *Traverse link*. The corresponding class in the analysis object model will then be selected. By choosing *Traverse link* again you can follow a link all the way back to the textual requirements. It is also possible to follow a link in the other direction, i.e. from the textual requirements via the object models, to the design. Try this!

Summary

After having completed an entire system design the corresponding document structure in the Organizer would look like in Figure 753.

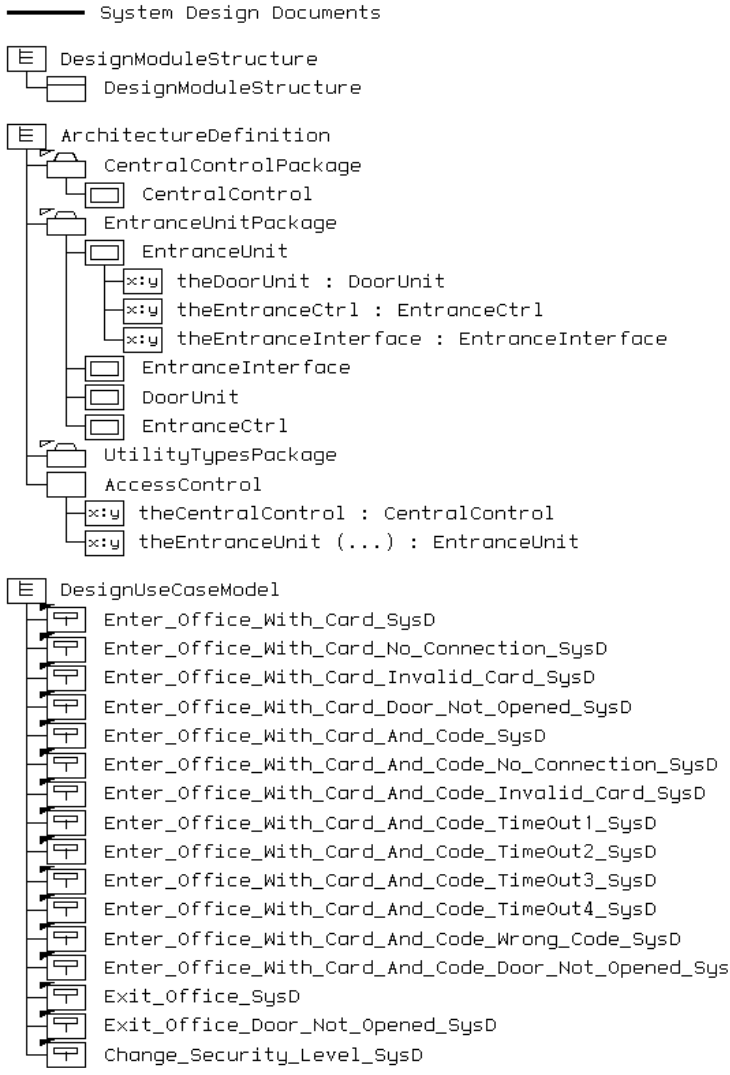

Figure 753: The entire System Design Documents structure

Performing the Object Design

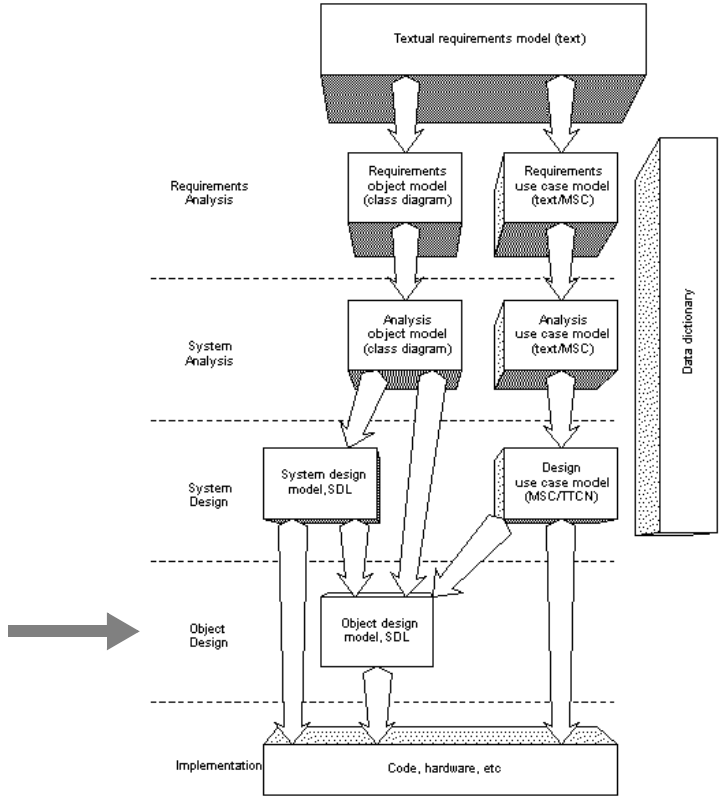

Figure 754: Overview of the SOMT process

What You Will Learn

- To transfer the analysis object model into a consistent object design model in SDL
- To use the *Paste As* functionality to assist the task
- To perform design level testing

Introduction to the Exercise

In this exercise you will perform the object design activity. This activity is, like the system design activity, focused on SDL. However, while the system design is focused on how to structure the architecture and how to decompose the system into blocks, the object design is focused on decomposing the blocks into processes and defining the behavior of the single processes.

The object design activity may be divided into three separate tasks:

1. Map the classes and associations in the analysis object model to suitable SDL concepts.
2. Choose a set of essential use cases and define the behavior of the SDL processes and data types that implement these use cases.
3. Elaborate the design by introducing more use cases and refine the SDL design to handle also these use cases.

Preparing the Exercise

The input to this activity should be a complete requirements analysis, system analysis and system design structure.

1. Open the system file `somttutorial/ObjD/accesscontrol.sdt` **(on UNIX)**, or `somttutorial\objd\accesscontrol.sdt` **(in Windows)**.
2. Check that the Source directory is set to `somttutorial/ObjD/` **(on UNIX)**, or `somttutorial\objd\` **(in Windows)**.

Mapping Active Objects to SDL

An object with its own behavior is called active object. The opposite is an object which acts as an information container - a passive object. Active objects are, most often, mapped to SDL process types. Active objects may also sometimes, as was the case in the system design activity, be mapped to block types.

The default choice in the *Paste As* mechanism is to paste a class copied from an object model diagram as a process type in an SDL diagram.

The attributes of the copied object will be pasted as variables. The operations will be pasted either as signals or as remote procedures of the

process type. This depends on whether the operations are synchronous or asynchronous.

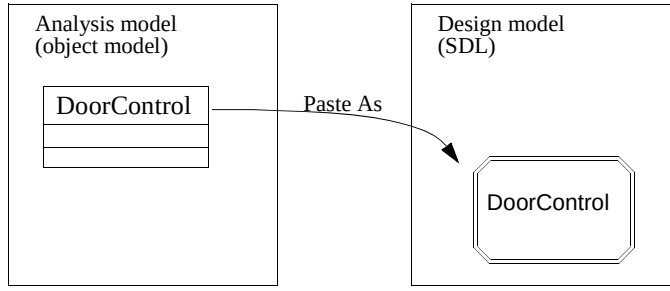

Figure 755: Mapping a class to a process type

Mapping to Process Types

Now it is time to map the classes in the analysis object model that should be mapped to SDL process types. In this example you should map the processes which will reside within the block type EntranceInterface.

The classes which should reside as processes in the block `EntranceInterface` are: the `CardreaderInterface`, the `KeypadInterface`, the `DisplayInterface` and the `ExitButtonInterface`.

1. *Copy* and *paste* each class from the `LogicalArchitecture` diagram as a *Process Type* in the `EntranceUnitPackage`.
2. *Open* the block type `EntranceInterface` diagram in the SDL Editor by double-clicking on the corresponding block type symbol in the `EntranceUnitPackage`. Press *OK* in the Edit dialog. In the Add Page dialog choose to create a *process interaction* page.
3. *Copy* each class once again and *paste* it as a *Process* in the block type `EntranceInterface` diagram.

When pasting e.g. the class `KeypadInterface` as a process, the process will get the same name as the class. This name should be changed since the syntax for process instances requires both an instance name and the name of the corresponding process type. The number of statically and dynamically created instances must also be stated.

4. Name the process **`theKeypadInterface`**. The process `theKeyPadInterface` should have one statically created instance and it should not be possible to create any instances dynamically. The following text should thus be written in the process name area: **`theKeyPadInterface(1,1):KeyPadInterface`**.

   (If the *Remove Reference Symbol* dialog appears, just click *OK*.)

5. Change the other three process names too, according to the above.

Now the block type `EntranceInterface` should contain four processes named: `theCardreaderInterface`, `theKeyPadInterface`, `theExitButtonInterface` and `theDisplayInterface`.

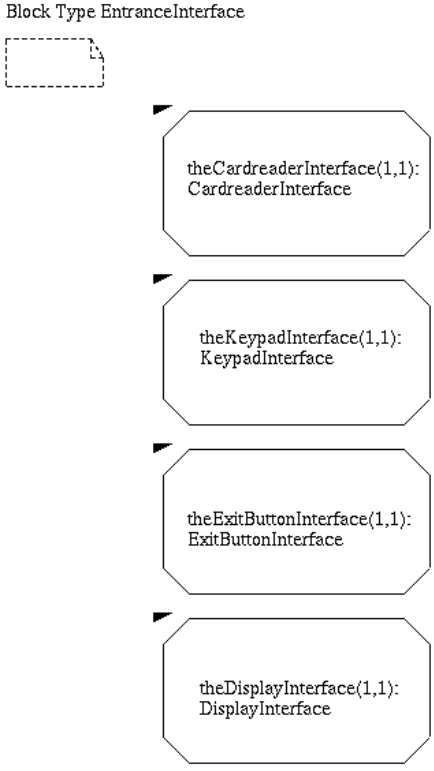

Figure 756: The block type EntranceInterface

Defining the Communication Structure

You have already specified the channels to and from the block `theEntranceInterface` (this was done in the block type `EntranceUnit`). Now you have to connect the processes within this block with the outside.

Creating a communication structure between processes and the border of the block is made in the same way as creating communication structures between blocks, with one difference. The terminology specifies *signal routes* instead of channels as the name for the communication structures at this level. However, there is no practical difference between signal routes and channels.

Now, edit the block type `EntranceInterface` diagram:

1. Connect each process with the border of the block with a signal route in each direction.
2. Give the gate of the input signal to each process the name *Entry* and the other gate the name *Exit*.
3. Specify the signals that are transported on each signal route. Consult the system analysis object model and the specification of the block `theEntranceUnit` to find all signals you should specify.
4. Connect the signal routes with the channels by specifying the appropriate gate for each signal route.

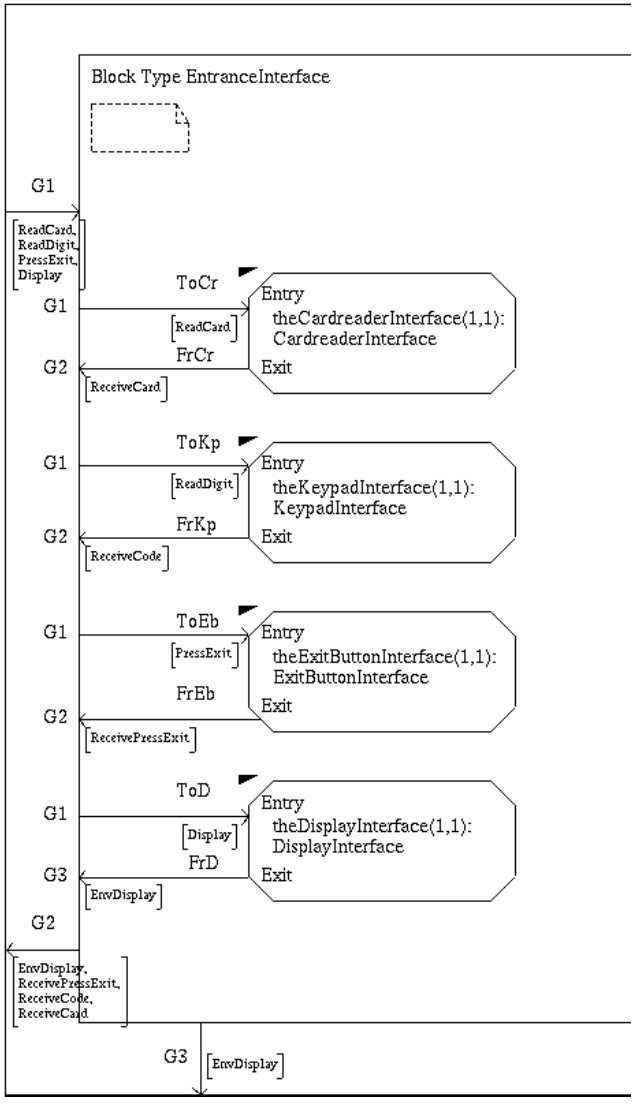

Figure 757: The complete structure of the block type EntranceInterface

Defining the Object Behavior

The activity of describing object behavior is a pure SDL design activity. This section is intended to describe how to structure this activity. It will not focus on specific SDL details.

The most important source of information in this activity are the use cases which specify the signal calls and responses to and from the blocks and processes in the system.

The design of the processes is best made iteratively:

- Select a subset of use cases which describe the most common interaction sequences. Create a basic version of the processes that correspond to these use cases.
- Second, you should introduce a couple of more use cases. Edit the behavior of the processes making them correspond to the extended subset of use cases.
- Continue with introducing more use cases. Edit the processes to cover these, until the behavior of the objects correspond to the complete set of use cases.

Using MSCs to describe the use cases makes it fairly simple to identify the states and transitions of the processes. A transition in a process graph is an input signal, often followed by one or more output signals from the actual process in a use case.

If the situation occurs that two use cases are difficult to combine, you should consider to split the process in question into two separate processes, one process for each use case.

An example is the block type `EntranceInterface` which have a quite complex structure of input and output signals. However, by dividing the block type into four separate processes, each one of these processes becomes fairly simple.

Defining the Basic Behavior of a Process

1. Take a look at the process type `KeypadInterface`. You will see that the process has a signal set of only two signals: the input signal `ReadDigit` and the output signal `ReceiveCode`.

2. If you study the MSC diagram `Enter_Office_With_Card_And_Code_SysD` and the behavior pattern ReadCode you see that four `ReadDigit` signals generate the output signal `ReceiveCode`.

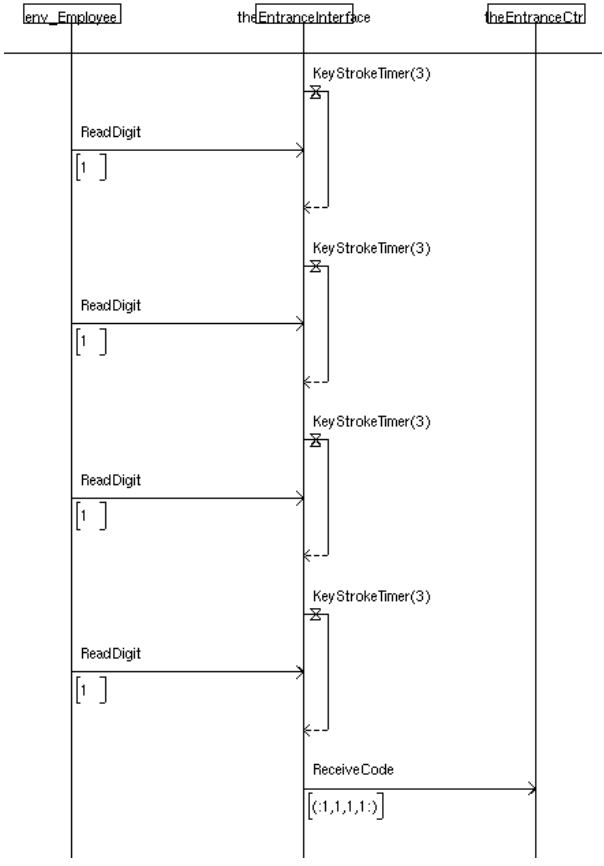

Figure 758: The signal sequence of the process theKeyPadInterface

Creating the behavior of the process out of this information is a quite easy task. Adding the timer, which provides the time-out functionality, will make the first version of the behavior specification of the process complete.

3. In the `EntranceUnitPackage`, double-click on the `KeypadInterface` process type symbol.
4. In the process type diagram, define the basic behavior of the process.

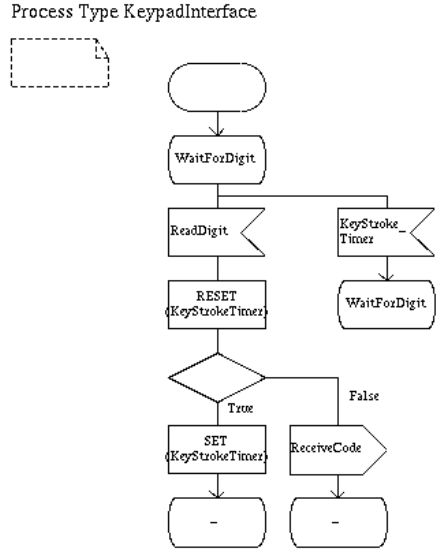

Figure 759: Basic behavior of the KeypadInterface process type

Defining the Data of a Process

The processes will of course also need some data containers, entity variables and control variables. The control variables, such as loop counters and flags, are identified during the object design. Entity variables are most often identified during the system analysis and they may be mapped to the process diagrams from the analysis diagrams.

If we take a look at the process `theKeyPadInterface` again we will notice that we need to introduce a counter to control the number of times a digit will be read before the signal `ReceiveCode` will be sent. We will

also need an index to place the read digit in the correct position of the `Code` array.

1. Place a text symbol in the diagram and declare a `CodeIndexType` named `i` in the process.
2. The parameter of the `ReadDigit` signal is of type integer. Declare a variable named `Digit` of type integer.
3. The parameter of the `ReceiveCode` signal is of type `CodeType`. Therefore, declare a variable `Code` of this type.
4. Change the name of the gate `GKeypadInterface` to `Entry`.
5. Also, add an `Exit` gate and the signal `ReceiveCode` going out of the process type.
6. Declare a timer `KeyStrokeTimer` with duration 3.
7. Refine the behavior of the process.
8. Save the diagram.

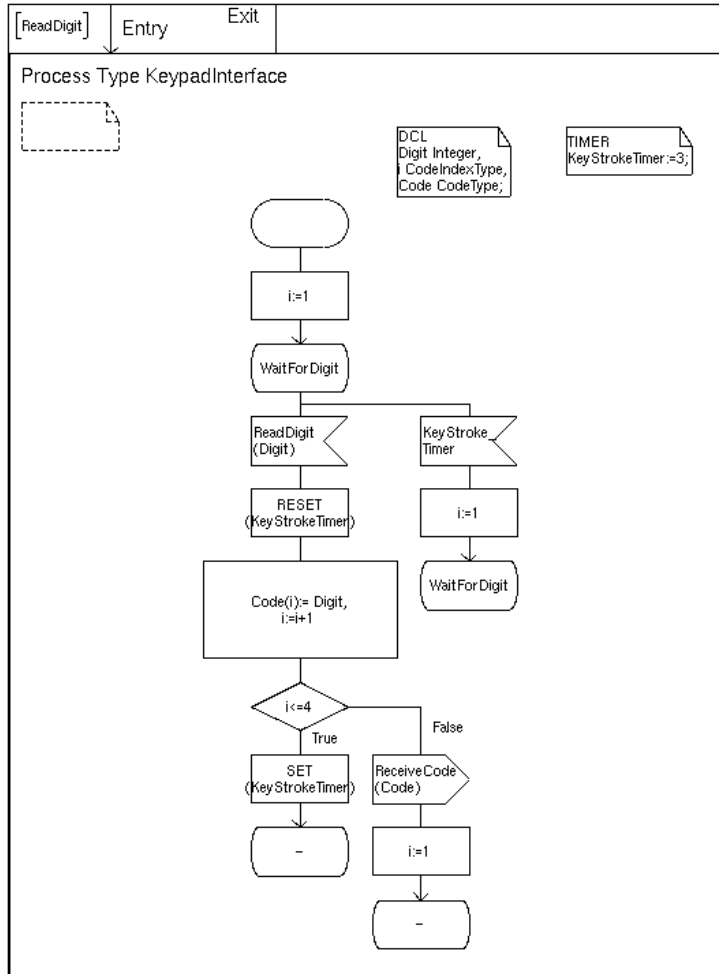

Figure 760: The complete process type KeypadInterface

The rest of the processes in the system are created in a similar way. However, this will not be done in this tutorial.

Design Testing

SDL makes it possible to test the system already during the design. It is possible to simulate an SDL system taking both concurrency and distribution into account. It is also possible to verify requirements specified in MSCs using the Explorer.

The MSC diagrams may, with no or little effort, be used directly as input to the Explorer. This makes the requirements verification simple and efficient.

Preparing the Design Testing

To be able to test your design you must have a complete system.

1. Open the system file
   `somttutorial/objdesign/accesscontrol.sdt` **(on UNIX)**, or
   `somttutorial\objdesign\accesscontrol.sdt` **(in Windows)**.
   What you see in the Organizer now is a complete system structure. All four documentation chapters representing activities from the SOMT method are complete.
2. Check that the Source directory is set to
   `somttutorial/objdesign/` **(on UNIX)**, or
   `somttutorial\objdesign\` **(in Windows)**.

Simulating the System

Simulating the system gives information about how different parts respond to certain inputs and how different parts of the system interacts with other parts. Simulating is often done during the object design to test different parts of the system.

The complete system should also be tested using the simulator to verify that the whole system works as it is intended to.

Try to simulate the system AccessControl. Follow the steps below to make a simulator version of the system AccessControl.

1. Select the system AccessControl in the Organizer.
2. Choose the *Make* option in the *Generate* menu.
3. In the Make dialog, choose the code generator to be *Cbasic*.
4. Choose the standard kernel to be *Simulation*.

5. Press *Full Make*. The system will be automatically analyzed. If there are any warnings you can ignore them. These warnings show up because we have not used all our declared signal lists. As they are just warnings, not errors, you can ignore them.

6. When the make process is finished, start the Simulator by choosing Simulator UI in the *SDL* submenu in the *Tools* menu.

7. In the SDL Simulator UI window, open the file `accesscontrol1_smb.sct` **(on UNIX)**, or `accesscontrol1_smb.exe` **(in Windows)**. Now you can simulate the system, as you have learned in previous tutorials.

Validating the System

When the design of the system is finished you want to verify that the system meets the requirements. This is quite easily done in the SDL Suite by using the SDL Explorer.

MSCs from the system design are used as input to the Explorer.

The requirements use case model is the essential part of the requirements and is often the specification of the system which the customer and the contractor agree upon. Thus, by verifying the system with the MSCs from the system design you are verifying that the system meets the customers requirements.

By making it possible to verify the customers requirements already in the object design and not in a special system design test phase, as in an ordinary design process, you save a lot of effort and time.

Now you should validate some of the MSCs from the system design activity.

1. Select the system AccessControl in the Organizer.

2. Choose the *Make* option in the *Generate* menu.

3. In the Make dialog, choose the code generator to be *Cbasic*.

4. Choose the standard kernel to be *Validation.*

5. When the Make process is finished, start the *Explorer UI* and open the file `accesscontrol1_vlb.val` **(on UNIX)**, or `accesscontrol1_vlb.exe` **(in Windows)**. Now the system is ready to be validated.

6. Press the *Verify MSC* button and choose the system design MSC diagram `enter_office_with_card_sysd.msc` which you can find in the directory `somttutorial/sysdesign`.

7. If the verification succeeds, you will get the message "** MSC <Diagram name> verified **".

It is perhaps too much work to verify all the MSC diagrams of the system design activity during this tutorial and you may quit when you feel that you have understood the principle of how to verify an SDL system.

If all diagrams can be verified against the system, then it is verified that the system also meets the requirements specified in the beginning of this tutorial.

Consistency Checks

There are mainly two consistency checks that should be performed in the object design activity:

- Check that all objects from the analysis object model have been implemented in the design.
- Check that the design model correctly implements the requirements from the design use cases.

The second consistency check is done through design level testing, see "Design Testing" on page 4062. The first one will be performed through a link check, see below.

Link Check

In our complete Access Control system there are implementation links from the system analysis models to both the system design models and the object design models. This implies that we must check our analysis object model against both these design models to see if all the classes have been implemented in the design.

- Perform a link check. Let the analysis object model form the from group. The architecture definition and the SDL design model will form the to groups.

The result shows that all classes but the class `SecurityLevel` have corresponding processes, blocks, signal interfaces or procedures in the design. The `SecurityLevel` does not have any behavior of its own, it is

implemented through its subclasses, and, therefore, the result is just as we want it.

We have now completed the design of the system. It is possible to pick an endpoint in the textual requirements and follow the implink from it, through the object models, to SDL. It is also possible to traverse links the other way, i.e. from design to requirements. Try this!

The use cases are also connected to each other, from requirements to design, as can be seen in the view of the link file in the Link Manager window.

Summary

After having completed an entire object design the corresponding document structure in the Organizer would look like in Figure 761.

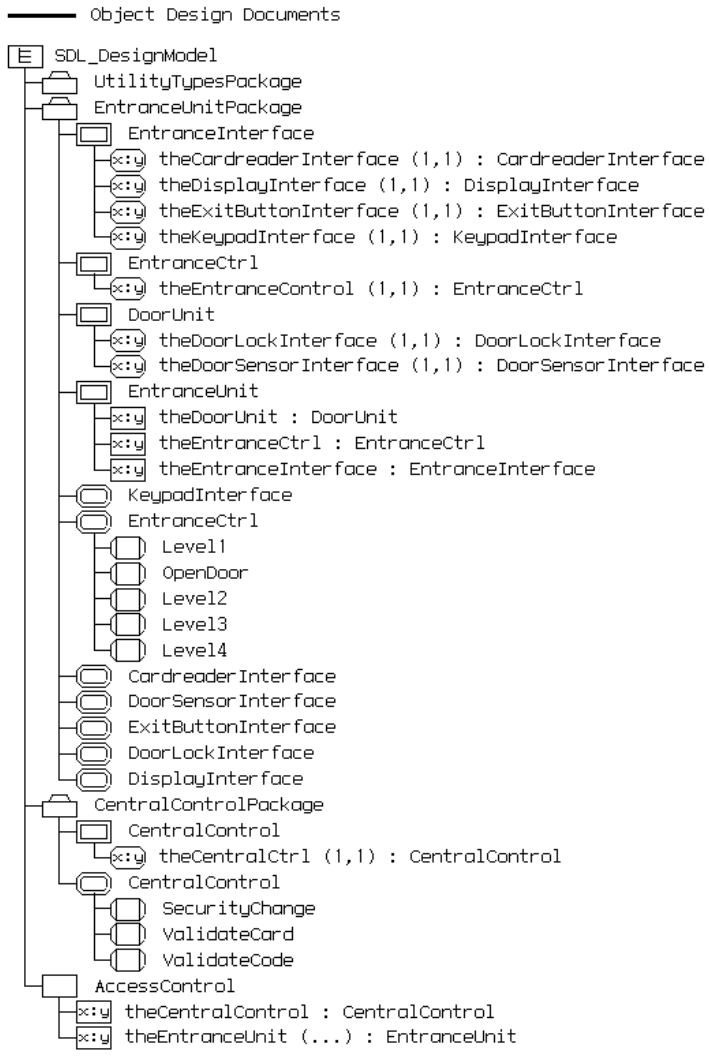

Figure 761: The entire Object Design Documents structure

Implementation

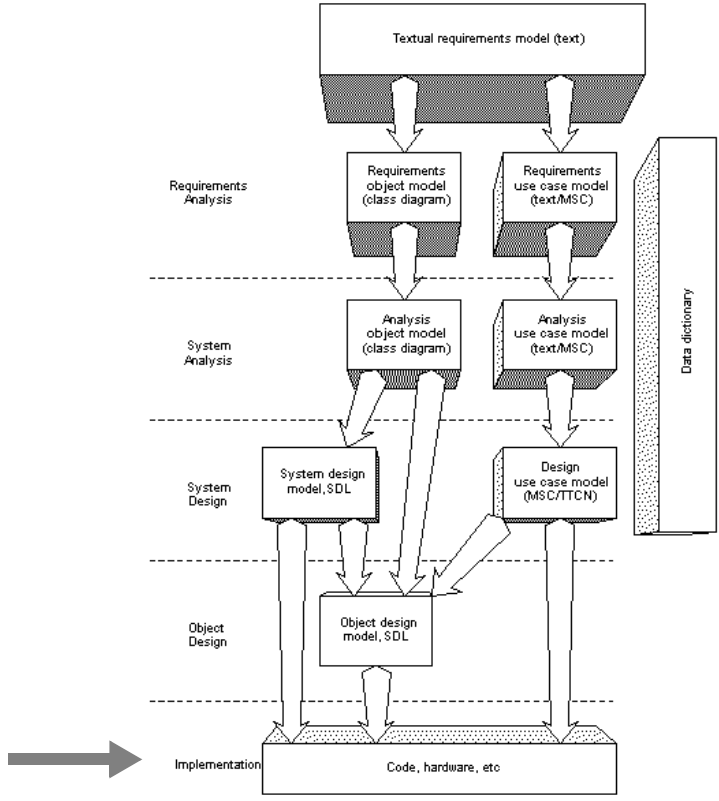

Figure 762: Overview of the SOMT process

The implementation of the system lies outside the scope of this tutorial. For information about the implementation activity, see the SOMT Methodology Guidelines starting in chapter 69 in the User's Manual.

Performing an Iteration

What You Will Learn

- To introduce changes to a system in a controlled way
- To use the *implementation links* to assist you in the activity

Introduction to the Exercise

During the life time of a system new requirements and changes in existing requirements are almost always introduced. We have to be able to handle these requirement changes and adapt the system to the new situation in a controlled way. We call this process iteration. An iteration may also be planned in advance in, for example, incremental development.

This section will describe the scenario of an iteration caused by the introduction of an additional requirement.

Preparing the Exercise

As input to this exercise we will use the complete Access Control system.

1. Open the system file `somttutorial/Iter/accesscontrol.sdt` **(on UNIX)**, or `somttutorial\iter\accesscontrol.sdt` **(in Windows)**.
2. Check that the Source directory is set to `somttutorial/Iter/` **(on UNIX)**, or `somttutorial\iter\` **(in Windows)**.
3. Create a new chapter and name it **`Iteration Documents`**.
4. Add a new module called **`AdditionalTextualRequirements`** to the new chapter.
5. Add the existing file `AdditionalTextualRequirements.txt` to the new module.

Studying the Additional Requirements

- *Open* the additional textual requirements document if it is not already open. The example below shows the document.

Example 656: Additional requirements ––––––––––––––––––––––––

The system should be able handle the languages English, German and French. One version of the system should handle a specific language and the system should be easily configured to handle a new language.

––

As stated in the example above, the task is to redesign the system so it can handle different languages. The design should be made in a way that makes it easy to configure the system to new languages.

The words English, German and French are marked as endpoints in the document.

Examining the Consequences

Now it is time to validate what consequences the new requirement has on the system. The new requirement identify one object that may be affected, the `Display` object.

1. Study the requirements regarding the `Display` in the original textual requirements document. You should find that the new requirement does not contradict with the original requirements.
2. *Traverse* the implementation link from the text fragment `Display` in the original textual requirements. The logical structure diagram in the requirements object model will pop up with the class Display selected.
3. With the class still selected, choose *Traverse Link* once more and follow the link to the logical architecture diagram in the analysis object model. The class `DisplayInterface`, with operation `Display` and attribute `Text` will be selected. The class is a part of the class `EntranceUnit`. It also has a connection to the class `EntranceCtrl`, see Figure 763.

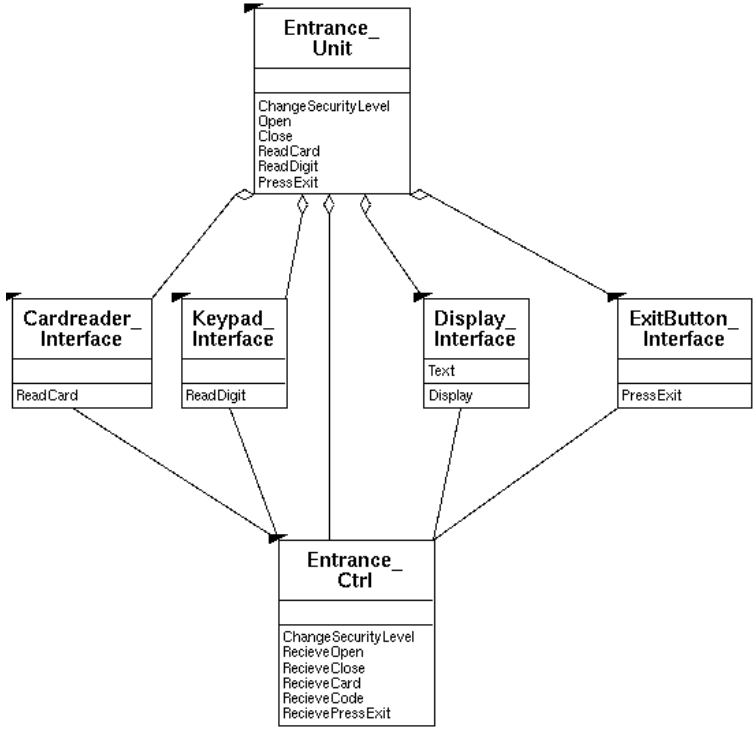

Figure 763: Part of the Logical Architecture diagram

4. Continue to follow the link of the class `DisplayInterface`, from the logical architecture to the package `EntranceUnitPackage`. The class is connected with the block type `EntranceInterface` and the process type `DisplayInterface` as well as with the signal interface defining the signal `Display`.

5. You can also follow the implementation links from the class `DisplayInterface` to the block `theEntranceInterface` (within the block type `EntranceUnit`) and to the process `theDisplayInterface` (within the block type `EntranceInterface`).

6. *Open* the block type `EntranceInterface` in the `Object Design Documents` structure. Study the signal routes leading to and from the process `theDisplayInterface`. You will notice two signals:

`Display` and `EnvDisplay`. Examining the two signals with help of the Signal Dictionary will give you information about the signals. `EnvDisplay` has the parameter `Charstring` and the signal `Display` has the parameter `MessageType`.

7. *Open* the process type `DisplayInterface`. Study the behavior. You will notice that it is possible to change the content of the `EnvDisplay` signal without affecting the behavior of the process type. It also seems like the required changes to the system are limited to the process type `DisplayInterface`.

Introducing Changes in Documents

Now you should introduce the necessary changes to the system to get the desired behavior. Changes should be made in a controlled way. All documents affected of the changes should be edited, to keep the consistency.

Updating the Data Dictionary

1. *Open* the data dictionary. Include information presented in the additional requirements to the data dictionary.

2. *Save* the file as `DataDictionary.txt` in the current directory.

Updating the Requirements Object Model

As we saw earlier, the change we have to introduce to the system is focused on the process type `DisplayInterface`. The new requirement specify that one version of the system should handle a specific language and the only language dependent part of the system is the process type DisplayInterface.

It seems natural to introduce a class for each one of the languages English, German and French in the logical structure diagram. These classes should be subclasses to the class `Display`, i.e. an inheritance structure is needed.

1. *Add* the three new classes to the logical structure diagram in the requirements object model. Name the classes **`FrenchDisplay`**, **`EnglishDisplay`** and **`GermanDisplay`** respectively.

2. *Link* the classes with the corresponding text in the additional textual requirements document.

3. *Save* the diagram *as* `logicalstructure.som` in the current directory.

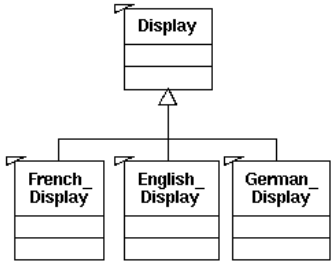

Figure 764: The class Display and its subclasses

4. Make a link from the class `Display` to the class `DisplayInterface` in the logical architecture diagram in the analysis object model.

Updating the Analysis Object Model

In the logical architecture diagram we have to create an inheritance hierarchy corresponding to the inheritance hierarchy in the logical structure.

1. Create the three subclasses to the class `DisplayInterface`. Name the classes **`EnglishDisplayInterface`**, **`GermanDisplayInterface`** and **`FrenchDisplayInterface`**.

2. *Create* implementation *links* to the corresponding classes in the logical structure diagram. (An alternative here would have been to *copy* the classes from the logical structure diagram and *paste* them *as* classes in the logical architecture diagram. The implementation links would then have been created automatically.)

3. *Traverse* the *link* from the class `DisplayInterface` to the process type `DisplayInterface` in the `EntranceUnitPackage`.

Updating the SDL Design

Now it is time to make some changes to the SDL design, making it correspond to the logical architecture. The inheritance hierarchy of the `DisplayInterface` classes should be mapped to an inheritance hierarchy of process types.

1. Create two new process types in the `EntranceUnitPackage`. Name the process types **`GermanDisplayInterface`** and **`FrenchDisplayInterface`**. The already existing `DisplayInterface` process type will function as the `EnglishDisplayInterface`.

2. Mark these process types as endpoints and create links between them and the corresponding classes in the logical architecture. (Alternatively, use the Copy-Paste As mechanism.)

   Now, edit the `DisplayInterface` process type to make it more general and suitable for reuse.

3. Double-click on the `DisplayInterface` process type in the `EntranceUnitPackage`.

4. Create a variable of type `charstring` for each possible message that can be sent to the environment. You will need eight such variables.

5. Put the text **`Virtual`** in the start symbol.

6. Insert a task symbol just after the start symbol.

7. In the task symbol you should initialize the message variables to the corresponding message.

8. Edit each output symbol making it use the corresponding message variable as a parameter instead of a text string. The process type `DisplayInterface` will use English language.

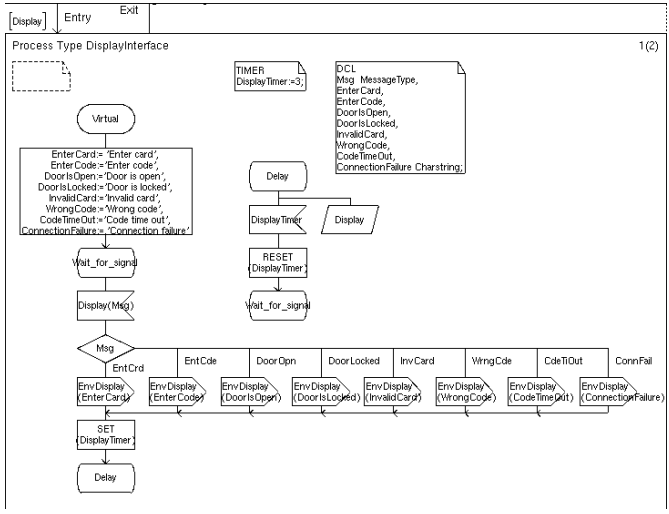

Figure 765: The process type DisplayInterface

9. *Save* the diagram in the current working directory.

After editing the `DisplayInterface` process type it is time to create the process types `GermanDisplayInterface` and the `FrenchDisplayInterface`. For each process follow the steps below:

10. Open a graph page for each process type by double-clicking on the corresponding process type symbol in the `EntranceUnitPackage`. Press *OK* in the edit dialog.

11. In the additional heading you should enter the text:
    `INHERITS DisplayInterface ADDING;`

12. Place a start symbol in the diagram and enter the text **`REDEFINED`** in the symbol.

13. Connect a task symbol to the start symbol. The task is to initialize the message variables to the appropriate messages. Do not use national characters.

14. Connect a state symbol with the task symbol and name it **`Wait_for_signal`**.

15. Save the diagrams.

Now the necessary behavior is described and it is time to show how to configure the system to make use of the new design.

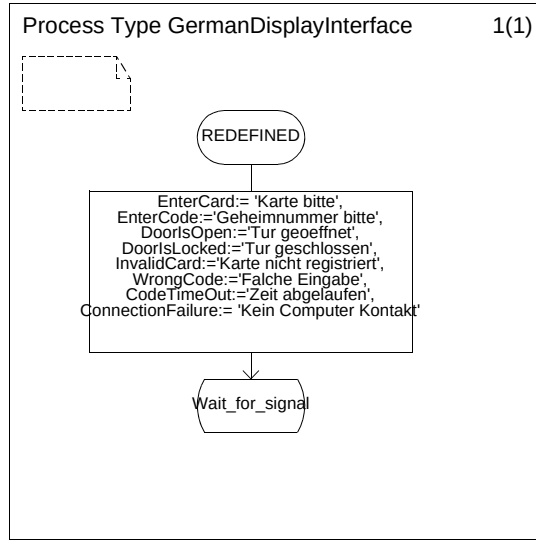

Figure 766: The process type GermanDisplayInterface

Configuring the System

The necessary design is done and we want to configure our system to make use of the new design. Following the steps below will configure the system to a German version.

1. Open the block type `EntranceInterface`.
2. Select the process `theDisplayInterface` and change the text `theDisplayInterface(1,1):DisplayInterface` to **`theDisplayInterface(1,1):GermanDisplayInterface`**
3. Now you can analyze the system. Perhaps you want to simulate the new version of the system; if so, follow the steps described in "Simulating the System" on page 4062.

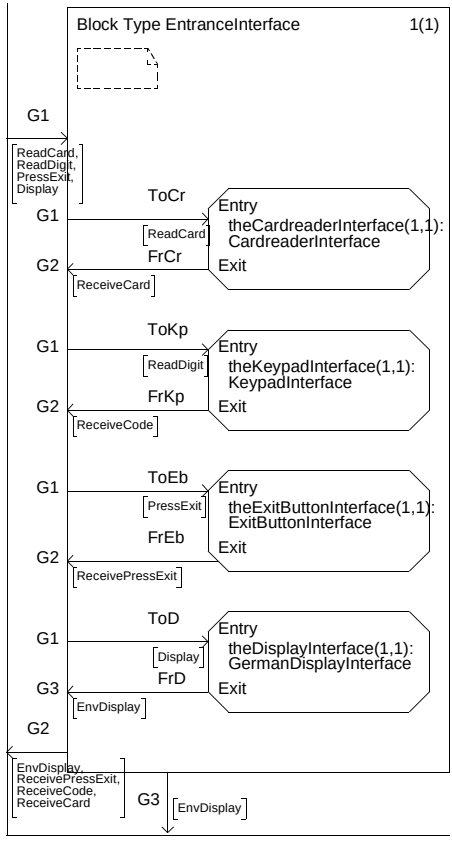

Figure 767: The block type EntranceInterface

Now you have completed the iteration exercise.

To Conclude...

You have now learned the steps of the SOMT method, and we hope you have enjoyed the tour.

Once again we would like to point out that the activities are presented in a sequential order in this tutorial just to simplify the reading. In practise, the task of developing a system using SOMT is a highly iterative process. One activity may start before the preceding activity is completed and the models inside an activity are usually created in parallel.

The SOMT method is intended to support the development process, not to control it. In other words, it is a **proposed** way of working. For your own work, you should not feel that you are locked by SOMT, but pick the parts that suit you best.
